The purpose of this research project is to explore how people's perception of the perpetrator's gender identity affects perceptions of an incident of interpersonal violence (IPV). This is one of the first studies to explore specific gender identities and their relationship with perceptions of IPV. Previous research has shown that people perceive IPV situations differently depending on the gender of the people involved. For example, Harris and Cook (1994) found that when participants read a vignette about IPV, the abuser was held more responsible when it was a man abusing his wife rather than a wife abusing her husband. Additionally, Bates, Pennington, and Hamil (2019) found that male abusers were seen as strong while female abusers are seen as weak. It is important to further explore these findings in order to see if situations of IPV are being overlooked due to a person's gender identity. Similar to other research Hypothesis 1 is that cisgendered men perpetrators will be rated the most severe, violent, and responsible for IPV compared to the other gender identities. Hypothesis 2 is that scenarios involving people assigned male at birth (cisgendered men and transgender women) will be perceived similarly due to people's perceptions of transgender women being viewed as still "male." Finally, hypothesis 3 is that genderfluid people will be rated the most intermediately to the transgender and cisgender identities. Participants will be presented with a randomly assigned vignette depicting IPV in which the gender of the perpetrator will vary from cisgendered man, cisgendered woman, transgender man, transgender woman, and genderfluid person. Participants will rate the severity, violence of the incident, responsibility of the perpetrator and victim, and perceived victim's fear of the perpetrator. Mean ratings of the survey items will be compared across groups using a one-way ANOVA in SPSS, followed by post-hoc tests.

Abstract Name: Appropriation vs. Appreciation: Beyoncé and Madonna

This research examines the appropriation and exploitation of Harlem ballroom culture by non-community members, focusing on the works of Jennie Livingston and Madonna. Through a review of their projects, the documentary "Paris Is Burning" and the song "Vogue," this study explores the ways these artists have been critiqued for their voyeuristic and exploitative approaches. The research extends to evaluate Beyoncé's

"Renaissance" tour and album, assessing whether it represents a reclamation of Black culture by a Black artist or an exploitation of queer culture by a non-queer artist. The analysis is grounded in the historical context of Black media and spaces, addressing internal issues such as the rejection of queerness and the monolithic representation of Black culture. It further explores the responsibility of community representation, highlighting how Madonna and Livingston's lack of accountability contrasts with Beyoncé's more inclusive and accountable engagement with ballroom culture. The findings suggest that while Beyoncé's work signifies progress in the intersection of Blackness and queerness, it also raises questions about commodification and responsibility in artistic representation. This study underscores the need for artists to engage thoughtfully and ethically with the cultures they draw from, ensuring equitable representation and compensation.

Abstract Name: Comparative Analysis of Deep Learning Models for Structural Defect Segmentation in Bridges

Automated structural defect detection is crucial for ensuring the safety and maintenance of civil infrastructure, particularly in bridges, where defects such as cracks, spalling, and corrosion can compromise structural integrity and pose safety risks. This research presents a comparative study of three semantic segmentation models—U-Net, Feature Pyramid Network (FPN), and DeepLabv3+—for detecting and classifying structural defects in bridge imagery. Each model was evaluated using two different encoder architectures, EfficientNet B3 and MobileOne S4, to assess the impact of varying feature extraction strategies on segmentation accuracy. The experiments were conducted using the DACL benchmark dataset, which includes a diverse range of defect categories, providing a comprehensive testing ground for evaluating model performance. Among the tested combinations, FPN paired with EfficientNet B3 demonstrated the highest mean accuracy across most defect categories, including common defects such as cracks and graffiti, making it the most effective approach overall. However, challenges were encountered in detecting certain more complex defect types, such as hollow areas and cavities, where all models showed decreased performance. The results of this study emphasize the potential of deep learning models in automating defect detection for infrastructure monitoring while also identifying key areas for improvement. Specifically, further refinements in feature extraction techniques and model tuning are needed to enhance detection accuracy in more complex defect scenarios. This research contributes to the ongoing development of AI-powered solutions for infrastructure inspection and provides insights for future improvements in automated structural health monitoring.

Abstract Name: Sit Still and Have Humility: Women's Writing and Religion in the Late Middle Ages

"Sit Still and Have Humility: Women's Writing and Religion in the Late Middle Ages" dissects early

women's writing through the lens of conduct literature. Conduct literature is a form of didactic literature that depicts how people, oftentimes women, are expected to behave as upstanding members of society. These texts served equally as advice and warning, damning those who refused to heed their teachings. While women in the Late Middle Ages were often not allowed to write and share their works, many found ways to subvert that expectation by channeling their passions through religion and mysticism. Notable female mystics include Julian of Norwich, Margery Kempe, and Christine de Pizan. The works of these women withstood the scrutiny of society not only because they showed literary promise, but because they additionally conformed to the standards expected of women as written in conduct literature. By utilizing texts such as "How the Good Wife Taught Her Daughter" as a lens for appropriate female conduct and "The Lament of Mary" as a lens for affective piety, this paper posits that the main reason that the works of female mystics are studied today is due to their meticulously selected subject material and careful word choice that allowed these authors to express their desires and thoughts under the guise of religious musings.

Abstract Name: Sleep Quality in School-Aged Children

Background: Sleep is a crucial component of growth and development in school-aged children, yet many fail to achieve the recommended nine–11 hours of sleep per night. Factors such as increased screen time, reduced physical activity, poor dietary habits, and inconsistent bedtime routines contribute to inadequate sleep, leading to significant consequences, including poor academic performance, behavioral issues, and an increased risk of chronic health conditions like obesity and cardiovascular disease. Purpose: This study aims to explore the effectiveness of specific sleep-promoting behaviors and assess how educating parents about these behaviors can improve their children's sleep quality and duration. By addressing gaps in parental knowledge and identifying barriers to implementation, this research will provide evidence-based strategies to improve sleep health in school-aged children. Method: Using a quantitative design, the study will employ the Children's Sleep Habits Questionnaire (CSHQ) to assess baseline sleep behaviors. Parents will receive tailored educational resources that emphasize reducing screen time, increasing physical activity, and establishing consistent bedtime routines. These interventions will be implemented over a four-week period. Post-intervention data will be collected via the CSHQ after four weeks to measure the impact of education and behavioral changes on sleep habits. Conclusion: By implementing sleep-promoting behaviors, physical activity, and screen time reduction, this project hopes to improve sleep quality and overall health outcomes in children. These findings will also implement sleep-promoting behaviors and physical activity and underscore the importance of targeted parental education and collaboration between nurses and families to address sleep deficiencies in school-aged children and promote healthier lifestyles. Keywords: sleep in school-aged children, bedtime routines, screen time, sleep quality, digital devices.

Abstract Name: Bell Pepper Strips as a Healthy Snack: Development and Evaluation of Physicochemical Properties, Consumer Acceptance, and Purchase Intent

Justification: This research investigated air-frying as a method to enhance the physicochemical properties of blanched, seasoned red bell peppers, addressing the gap in the existing literature. The goal was to upcycle excess bell peppers into a plant-based snack, aligning with consumer demands for alternatives to energy-dense foods. **Methods:** Red bell peppers were washed with warm water, cored, and cut into rectangular pieces (1 cm x 6 cm). Samples were microwave-blanching for 90 seconds, seasoned with onion salt, and then air-fried at 140°F for 5 or 6 hours. Control samples were plain without seasoning. The samples were deemed microbially safe and served to 103 consumers (n=103) to assess acceptance for different attributes on a 9-point hedonic scale, culinary applications by check-all-that-apply (CATA), and purchase intent (PI) on a yes/no scale. Data was analyzed using ANOVA and the Tukey test. **Results:** Moisture content ranged from 46.9% to 79.2%, and water activity showed significant ($p < 0.001$) differences among samples: plain-5h (0.9677), seasoned-5h (0.9685), plain-6h (0.8945), and seasoned-6h (0.8605). For sensory attributes, plain-5h had the highest scores in appearance (6.74), color (7.33), and flavor (5.83). Seasoned-5h scored highest in aroma (6.28) and overall liking (6.19). The top five culinary applications selected by consumers were pizza topping (67%), salad topping (56%), garnish with meals (50%), soup/stews (45%), and sandwiches (40%) while a single-serving healthy snack was selected by (27%) of the consumers. Positive PI responses were 45.6% (plain-5h), 34% (plain-6h), 52.4% (seasoned-5h), 47.8% (seasoned-6h), and 60.2% (proposed a single-serving packaging). **Significance:** An estimated 350 million pounds of bell peppers are wasted annually in U.S. supermarkets. This study demonstrated one way bell peppers can be upcycled prior to spoilage. **Summary:** Red bell pepper can be upcycled into a healthy snack through air-frying and may also be used for other culinary applications.

Abstract Name: Self-Advocacy Experiences of Adolescents and Young Adults with an Invasive Cancer Diagnosis

Background: Adolescent and Young Adult (AYA) cancer researchers and clinicians aim to improve patient-centered care, but a lack of knowledge about how AYAs self-advocate makes this challenging. This qualitative, cross-sectional study aimed to describe self-advocacy experiences among of AYA patients with a history of cancer. **Methods:** Adolescent and Young Adult (AYA) patients (ages 12-29) with an invasive cancer diagnosis were recruited in person in clinic through UPMC Children's Hospital of Pittsburgh or through the Pitt+Me registry. Study participants described experiences of self-advocacy through an online survey and one-on-one semi-structured qualitative interviews in person or virtually. Interviews consisted of several questions surrounding challenges faced by participants, how they self-advocated for themselves, and factors that made it harder or easier to self-advocate. All interviews were audio-recorded and transcribed verbatim. Participants were compensated \$25 following participation. **Results:** 12 participants enrolled, with a mean age of 17.7 ± 1.1 years old. Most participants were female (75%), students (67%), with only few working

(33%), and half having a hematological cancer. Participants reported varying self-advocacy experiences, and with the challenges of diagnosis and treatment made feasible through positive support of friends and family. The adolescent population utilized parental guidance to communicate with physicians, while the young adult population communicated independently. Most participants experienced side effects including allergic reactions and varying hormone levels to treatment that were often dismissed by the healthcare team. Participants struggled with lack of physician understanding of personal values and needs. Conclusion: Self-advocacy experiences of AYA vary but demonstrate distinct themes. Results indicate a transition from reliance on parents to independently managing their cancer, though difficulties communicating with healthcare providers occurred across age groups. This pilot study demonstrates novel information that can be used to improve communication between AYAs with cancer and their healthcare teams.

Abstract Name: Experimental Efficiency: How Machine Learning Estimations Streamline Catalytic Density-Functional Theory Calculations

Density-Functional Theory (DFT) is a system of quantum calculations that provide information on the ground state of many forms of atomic systems, particularly with compounds and crystals. Despite the decades of refinement of these formulas, strictly mathematical DFT calculations cannot be effectively used for larger and more complicated structures due to outside factors that cannot be easily computed using the formula. In this case, use of machine learning (ML) can minimize experimentation and analyze similar structure behavior, such as electron affinity (EA), ionization energy (IE) and radius (r), along with the potential reactants of an experiment to output the most optimized set of those reactants. Using previously conducted research, I will explain how ML is used to predict optimized DFT calculations, and how ML can be used positively in the experimental space to save time and funding to create the most optimal experiment to then conduct testing on. DFT and ML methods and algorithms and their error metrics are also used to determine which of these metrics produce the most consistently accurate results without losing efficiency.

Abstract Name: Caspar David Friedrich: Spiritual, Theological, and Emotional Concepts in 19 c. Romanticism

Caspar David Friedrich's landscapes played an integral role in the innovation of the Romantic movement through the incorporation of spiritual, emotional and theological themes throughout his works. Through in depth research of Friedrich's works, Robert Rosenblum's studies, Ralph Waldo Emerson's writings on nature, and individual studies of solitude's connectivity to spirituality, this essay aims to prove just how much Friedrich portrays emotional and spiritual depth through his personal experiences in life. Friedrich, being capable of cultivating awareness and connection with life and nature through personal narratives, was able to

proficiently portray melancholic attributes of wistful remembrance and self contemplation, and gothic themes on life and death as well as the connection to the universe through adversity. Additionally, he successfully depicted serene joyous themes of life after death, spiritual tranquility, and personal serenity into landscape paintings encouraging the inclusion of emotional, spiritual, and theological subject matter, furthermore prompting viewers to connect to nature more profoundly.

Abstract Name: The Possibility for Crayfish to Exhibit Food Preferences and Compounded Decision Making

Crayfish may exhibit food preferences and compounded decision-making processes during food selection. Crayfish are the primary benthic biomass feeders in many areas and while their stomach contents have previously been analyzed, their active food preference choices and the accompanied behavior have not. This study aimed to provide quantitative data on the food-choice preferences of three different crayfish species found in the Lake Erie Basin water shed. Ten individuals from each species were introduced to behavioral arenas with two food choices separated by a divider. These choices included tilapia (*Oreochromis niloticus*), Jungle Val (*Vallisneria americana*) and Japanese mystery snails (*Heterogen japonica*). Crayfish were allowed to move freely in these tanks while being monitored using EthoVision Software over a 55-minute period. Additionally, crayfish preference for deceased invasive Japanese mystery snails with and without operculums was determined using repeated, triplicate exposures with individual crayfish. These repeated trials were conducted to determine the ability of crayfish to make compounded decisions through learned behavior. Results indicated a preference for fish tissue when available and for Jungle Val over Japanese mystery snails with intact opercula. Over successive trials, crayfish spent less time with Japanese mystery snails possessing opercula, suggesting a potential compounded decision-making process. These findings provide insight into crayfish food preferences and decision-making behaviors.

Abstract Name: Comparison of Assessing High Versus Low Effort Sampling Protocols for Benthic Macroinvertebrates

Numerous stream ecosystem studies have demonstrated that benthic macroinvertebrates serve as important indicators for determining stream quality. This is because these organisms are highly sensitive to environmental changes, their presence, diversity, and abundance can provide insights into the overall health of aquatic ecosystems. While various methods of stream sampling exist, researchers strive to determine which protocol is the most effective for collecting macroinvertebrates while maintaining high-quality data and efficiency. In this study, high-effort whole site and low-effort targeted site sampling techniques were conducted within a 61 m reach to collect macroinvertebrates, comparing taxa collected and stream quality

metrics in Lily Cache Creek, Plainfield, Illinois. The reach was sectioned off into four 15.2 m quadrants for a high-effort technique that focused on sampling using a dip net to collect specimens from riffles, runs, macrophytes, sediment, and/or snags within each quadrant. For the lower-effort targeted site, two riffles and one snag were sampled using a similar dip net collecting technique. Both methods were assessed for ecological stream quality indicators such as the Macroinvertebrate Biotic Index (MBI), Shannon Diversity Index (SDI), %EPT / %nonEPT (insect orders Ephemeroptera, Plecoptera, Trichoptera) individuals, %pollution tolerant / pollution intolerant individuals. Both methods produced mostly similar results. Taxa richness was higher for high-effort sampling but both techniques resulted in a rating of “Excellent” according to Illinois Riverwatch standards (14 and 18 respectively). There were no significant differences in EPT/non-EPT and pollution intolerant/tolerant comparisons, but high effort resulted in higher SDI (2.00 / 1.72) but lower stream quality (fair/good) than low effort sampling. Overall, the findings suggest that low-effort techniques can yield roughly similar results to high-effort techniques for stream quality metrics and can serve as an adequate alternative to high-effort sampling to save time and money for future conservation research.

Abstract Name: Machine Learning for Diagnosis of Traumatic Brain injury and Developing tools for Educating the General Public

Identifying brain injuries in the preliminary stages through machine learning is crucial to prevent further complications, including long-term conditions like Alzheimer's disease and chronic traumatic encephalopathy. Recent advances in machine learning have shown promise in improving the early detection of traumatic brain injuries (TBIs), enhancing diagnostic accuracy, and reducing the need for multiple diagnostic scans. Studies in 2023 have demonstrated that advanced deep learning models can outperform traditional radiological assessments in identifying subtle patterns indicative of TBIs from MRI data, helping to reduce patient exposure to unnecessary radiation. In this research, we aim to utilize machine learning techniques to detect traumatic brain injuries using MRI datasets through classification and clustering approaches. The process begins by importing labeled datasets using Python, followed by visualizing the topographical brain images. Subsequently, the MRI image data will be converted into numerical form suitable for machine learning algorithms. We will then develop models to classify images as either normal or abnormal, indicating the presence of a traumatic brain injury. Our approach incorporates recent advancements in convolutional neural networks (CNNs) for improved feature extraction and classification accuracy. Finally, we will evaluate the model's performance using metrics like accuracy, precision, recall, and F1 score. Preliminary results indicate promising outcomes with models achieving accuracies exceeding 90% in distinguishing between normal and TBI-affected brains. This research demonstrates the potential of machine learning to significantly enhance early-stage diagnosis of brain injuries, reducing the risk of delayed intervention and long-term neurological complications.

Abstract Name: Investigating Behavioral Effects of Conventional and Organic Pesticides in *Bombus impatiens*

Bees are vital pollinators for both agriculture and ecosystems. While there is plenty of evidence of sublethal behavioral effects caused by synthetic pesticides, there is a lack of research comparing the behavioral effects of synthetic pesticides to natural pesticides. The project aims to identify any differences in behavior caused by acephate (synthetic organophosphate) and neem oil (natural pesticide). The behaviors investigated include olfactory association, color association, and memory. Both pesticides are expected to negatively impact these behaviors. MethodsThe study used two treatments of one control and two experimental groups, which were fed acephate or neem oil at field specific doses. Bees were trained to positively associate blue color. Bees foraged for 15 minutes in the foraging chamber, containing a set of blue and yellow flowers with reservoirs. Yellow flowers contained water while blue flowers contained sucrose. Trials repeated every five days for a total of four trials, and activity was recorded. Recordings were analyzed and results were averaged over the number of bees in each group. Data were analyzed using ANOVA in R. Bees were trained to positively associate orange scent, by exposure to orange essential oil with each feeding. After 21 days, bees were placed in a choice maze and chose between orange oil or lavender oil. ResultsFlower color and date were significantly correlated with number of visits, and bees preferred blue flowers over yellow. Bees unanimously preferred the scent of orange oil. There was no significant difference between the control group and the experimental groups. ConclusionAlthough it is known that synthetic pesticides negatively impact behavior in bees, data did not support a significant handicap in visual or olfactory associations for bees exposed to the pesticides. There was strong evidence of the bees' abilities to learn and associate colors and smells with rewards.

Abstract Name: Stimulus-Response Uncertainty Impacts Cross-Cerebral Connectivity in Youth with Obsessive Compulsive Disorder and comorbid Anxiety

Various psychiatric disorders are comorbid with obsessive compulsive disorder (OCD). An understanding of comorbidities in OCD is immensely important for treatment planning and long-term management of the condition. Despite generalized anxiety disorder being one of the most prevalent comorbidities in obsessive-compulsive disorder (30% of OCD patients), few studies have researched its impact on the OCD phenotype. In this context, understanding mechanisms of brain network dysfunction may be useful in providing salient biological signatures of the impact of such co-morbidity, particularly in the context of uncertainty, a stressor that provokes the experience of anxiety. In this study, we will examine whether the presence of comorbid anxiety in OCD patients will be associated with differences in cross-cerebral functional connectivity in previously acquired fMRI data. Brain network interactions were evoked using a Perception – Action task where the relationship between percepts varied from certain (“always respond to the stimulus regardless of its color”) to uncertain (“only respond to a the green stimulus”). Data were acquired in healthy controls (HC), and OCD patients with or without comorbid anxiety (OCD, OCD+Anxiety). Image processing and connectivity analyses will rely on established methods. We expect uncertainty to disproportionately impact

functional connectivity in OCD+Anxiety patients (relative to OCD) because comorbid anxiety will make these participants more susceptible to interference of this condition on brain network function. Our results may contribute much needed information on the underlying mechanisms of comorbid anxiety in OCD.

Abstract Name: Her Stories: The Unseen Journeys of Southeast Asian Refugee Women in Milwaukee

This research investigates the lived experiences of Southeast Asian refugee women in Milwaukee through oral history, focusing on their food memories, food practices, and the ways they create a sense of home in a new country. Central to this study is the exploration of women's journeys, a narrative often overlooked in migration stories. Unlike the research on immigrant households, which centers on men who immigrate in search of work to support their families financially through labor, these women's stories highlight their resilience and contributions to domesticity and community. Many women left their parents' homes as teenagers, taking on significant responsibilities to provide for their families, despite enormous obstacles. Using oral history methodology, this research engages directly with Southeast Asian refugee women in Milwaukee, documenting their stories to understand the cultural and practical roles that food plays in these women's narratives. Food not only plays as a link to the past but also as a way to preserve culture and build community. By situating these personal narratives within broader frameworks of migration, gender studies, and foodways, the study aims to challenge the existing narratives that marginalize women's contributions in migration contexts. Preliminary findings reveal the transformative power of food in creating a sense of belonging and identity while showcasing these women's strength and adaptability. This work contributes to the broader discussion on migration by amplifying the voices of refugee women and acknowledging their vital roles in shaping their families and communities. It highlights the need for more inclusive narratives that recognize the complexity and diversity of migration experiences, ultimately offering a richer understanding of resilience and cultural preservation.

Abstract Name: Water Transport and Kidney Stones Using a *Drosophila* Malpighian Tubule model

Kidney stones represent a significant clinical issue affecting approximately 10% of the global population, with no available treatment. Drinking more water is effective in reducing kidney stone occurrence by increasing urinary flow and decreasing ion supersaturation. In this study, we investigated Ca-oxalate (CaOx) crystal formation in *Drosophila* Malpighian tubules (MT) to determine whether genetic manipulation of water channels (Drip, Prip) and a salt transporter (NDAE1) in stellate cells could influence crystal formation. F1-knockdowns were generated by crossing 724-GAL4 flies with UAS-RNAi lines targeting Drip, Prip, and NDAE1. The resulting F1 flies were fed food supplemented with 10 mM NaOx for 4 days. MTs were then

dissected, and fixed on slides, and CaOx crystals were quantified using birefringence via polarizing microscopy. Previous studies have demonstrated that MTs secrete fluid at a faster rate on a per-cell basis than any other epithelium. Drip and Prip exhibit significant water permeability when expressed in *Xenopus* oocytes, and knockdowns of Drip and Prip lead to decreased fluid secretion and increased crystal formation. Our updated findings indicate that knockdowns of Drip, Prip, and NDAE1 result in statistically significant increases in both the number and surface area of CaOx crystals compared to control. This suggests that NDAE1-mediated ion transport supports transepithelial water movement and helps maintain dilute MT secretions, preventing crystal formation. Together, these results highlight that both AQP-mediated water transport and salt-driven water transport mechanisms are crucial in maintaining the dilutive capacity of MT secretions to avoid crystal formation. These findings also suggest that developing therapeutics to enhance urine flow, such as aquaretics, may offer new options for preventing kidney stone disease, especially when increased water intake alone is insufficient.

Abstract Name: The Eagle and the Dragon: US and Chinese Foreign Direct Investment in Latin America

Since enduring colonization by the Spanish and Portuguese and neocolonialism under United States capitalism-hungry policies, Latin American countries have been objectified for their material resources for centuries. The 21st century has seen a shift in investment and attention to another global superpower as China has stepped in to implement numerous foreign direct investment (FDI) infrastructure projects. As US government agencies and think tanks express concern regarding China's investment trends, Latin American countries now face the unique situation of being the point of political and economic competition between the eagle and the dragon. So that Latin American countries can best understand how investment strategies affect them, they must first recognize the potential relationships that the US and China display in their investment strategies. This matter of FDI relationship gives rise to the question: does US FDI reactively follow Chinese FDI in Latin American countries? This article compiles data from the US Bureau of Economic Analysis, the Inter-American Dialogue and Boston University Global Development Policy Center, and other sources in an analysis of Chinese and US government FDI in Latin America as a region and in individual countries from 2007 to 2023. Through statistical analysis of US direct investment positions abroad and loans from China's development finance institutions, I test the data for correlation between US changes in FDI levels in relation to previous Chinese FDI trends. While research is ongoing as I conclude the statistical analysis process, I hypothesize that US FDI trends will follow Chinese FDI increases and decreases in the region due to US-China political tensions and the question of future hegemonic power in Latin America. With this data, Latin American countries could exploit FDI patterns to negotiate improved FDI deals and gain traction on the world stage.

Abstract Name: Searching for the Remains of the Jaundole Castle Near Riga, Latvia Using Ground Penetrating Radar (GPR)

This study explores the potential location of the subsurface remains of Jaundole Castle on Dole Island, Latvia, using ground-penetrating radar (GPR) to detect and interpret anomalies associated with the castle's ruins. Historical records show that Jaundole Castle, constructed in the 14th century by the Dome Chapter as a defensive and administrative structure, played a key role in regional governance and trade. In 1416, the Livonian Order assumed control of the castle. It then returned to the Dome Chapter, serving various functions, including a refuge for the Archbishop of Riga's servants. By the mid-16th century, it had become a crown estate under Polish rule. During the Polish-Swedish War in 1628, the retreating Poles deliberately destroyed the castle to prevent its use by Swedish forces. Over time, the ruins were buried, with little visible evidence remaining by the 18th century. In the summer of 2024, researchers from Duquesne University and the University of Wisconsin-Eau Claire conducted GPR surveys where historical maps and written accounts indicated the location of the castle near the mouth of the now-defunct Lebjava River, at the point where it enters the Daugava River. GPR data was collected using a Sensors and Software GPR system and a 500 MHz antenna. Visual interpretation of both slice view and cross-section data plots revealed linear features that are remnants of castle walls and circular patterns indicative of towers or other structural elements, which match historical depictions of the castle's layout and positioning. Based on GPR data, historical maps, and documents, the detected anomalies are likely remnants of the Jaundole Castle. Recommendations for future research include targeted test excavations to validate these findings, and a possible full-scale excavation to facilitate the conservation of the Jaundole Castle ruins, thus aiding in the preservation of Latvia's medieval heritage.

Abstract Name: Academic Burnout as Existential Crisis: Heidegger's Anxiety and Authenticity in Student Life

This paper argues that Martin Heidegger's ideas of anxiety and authenticity, presented in *Being and Time*, provide an understanding of academic burnout in students. Heidegger's analysis of anxiety as a mood that discloses an individual's confrontation with their potential for authentic existence offers a way to reinterpret burnout. Often reduced to psychological terms like exhaustion or inefficacy, burnout is reframed here as an existential crisis, where students are caught in inauthentic modes of being shaped by institutional and social pressure. The central thesis of this paper is that academic burnout reflects not just a psychological challenge but an existential one, involving a failure to confront or embrace one's authentic potential. The paper first introduces the phenomenological method and Heidegger's concepts of anxiety and authenticity, situating these within contemporary discussions on mental health in education. It contrasts Heidegger's existential anxiety with conventional understandings of anxiety, highlighting how the former offers more into the nature of burnout. The paper then analyzes burnout through Heidegger's framework, using ideas like temporality and intersubjectivity to show how academic expectations drive students into inauthenticity. Examples from student life are used to illustrate burnout as a confrontation with existential limits, one that goes beyond just academic stress. Finally, the paper examines resoluteness in reclaiming authenticity. It argues that while Heidegger provides no methodical steps for reaching authenticity, his idea of resoluteness points to a way of being that could help students transcend burnout. Treating burnout as an existential phenomenon challenges educators and institutions to rethink their approaches to education, emphasizing the need for learning environments that support authentic engagement and well-being.

Abstract Name: skandiver: a divergence-based analysis tool for identifying intercellular mobile genetic elements

Motivation: Mobile genetic elements (MGEs) are as ubiquitous in nature as they are varied in type, ranging from viral insertions to transposons to incorporated plasmids. Horizontal transfer of MGEs across bacterial species may also pose a significant threat to global health due to their capability to harbor antibiotic resistance genes. However, despite cheap and rapid whole-genome sequencing, the varied nature of MGEs makes it difficult to fully characterize them, and existing methods for detecting MGEs often do not agree on what should count. In this manuscript, we first define and argue in favor of a divergence-based characterization of mobile-genetic elements. Results: Using that paradigm, we present skandiver, a tool designed to efficiently detect MGEs from whole-genome assemblies without the need for gene annotation or markers. skandiver determines mobile elements via genome fragmentation, average nucleotide identity (ANI), and divergence time. By building on the scalable skani software for ANI computation, skandiver can query hundreds of complete assemblies against >65 000 representative genomes in a few minutes and 19 GB memory, providing scalable and efficient method for elucidating mobile element profiles in incomplete, uncharacterized genomic sequences. For isolated and integrated large plasmids (>10 kb), skandiver's recall was 48% and 47%, MobileElementFinder was 59% and 17%, and geNomad was 86% and 32%, respectively. For isolated large plasmids, skandiver's recall (48%) is lower than state-of-the-art reference-based methods geNomad (86%) and MobileElementFinder (59%). However, skandiver achieves higher recall on integrated plasmids and, unlike other methods, without comparing against a curated database, making skandiver suitable for discovery of novel MGEs.

Abstract Name: Real-Time Fluid Simulations by a GPU-based Lattice Boltzmann Method

The purpose of this project is to demonstrate the capabilities of the lattice Boltzmann method, via a real time fluid simulation that replicates a partially fluid-filled box that can be manipulated in real time. LBM has been shown to outperform conventional computational fluid dynamics (CFD) methods in solving the Navier-Stokes equation in terms of computational efficiency. This is particularly true for complex problems involving multi-phase and multi-component flow. LBM models can be computed in parallel using OpenCL, which allows for significant speed improvements. When paired with a powerful graphics processing unit (GPU), the work can be distributed across thousands of cores, enabling real-time simulations of complex fluid dynamics. By combining this real-time capability with user-controlled fluid acceleration, via an Arduino

equipped with an Inertial measurement unit (IMU), the sloshing process in a partially fluid-filled box can be simulated and visually demonstrated.

Abstract Name: A Case Study Analysis of Area Deprivation and Sleep Health: Results from the All of Us Research Program

Quality sleep underpins countless physiological and psychological processes, from regulating hormones to boosting cognitive function. Despite its importance, millions suffer from sleep disturbances, experiencing negative consequences ranging from cardiovascular disease and diabetes to anxiety and depression. Recent studies suggest that socioeconomic factors, impacting access to resources and living conditions, might contribute to these disparities. In this case study, we look to explore the potential link between sleep quality and socioeconomic status, using predetermined deprivation indexes for different zip codes as a proxy. By exploring this potential connection, we aim to elucidate the systemic factors influencing sleep health and address sleep inequities, enhancing the overall well-being across diverse communities. We ran a cross-sectional study in the All of Us database and after stratifying and cleaning our dataset for null values, we arrived at a cohort size of about $n = 9,600$. We ascertained sleep quality by the percentage of deep sleep the individual had and sleep efficiency by the ratio of time spent asleep against time spent in bed. We ran a regression analysis and visualized these variables against median income and neighborhood deprivation using the deprivation index, an aggregate derived from six American Community Survey (ACS) metrics. The correlation coefficient between the sleep quality and deprivation index was approximately 0 ($r = 0.0087$) and insignificant. The same was the case for the correlation between sleep efficiency and deprivation index with a value of $r = 0.05$. Among the study participants enrolled in All of Us, there are no significant relationships between neighborhood deprivation and sleep health. It is possible that the biggest effects on sleep health lie in genetics and other non-socioeconomic risk factors such as age, family history, and drug use.

Abstract Name: Automating congenital heart disease patient-specific mesh creation from cardiovascular images

Congenital Heart Disease (CHD) is one of the most common types of birth defects and deaths worldwide, with nearly 40,000 babies born with CHD annually in the United States. As these conditions are remedied by high-risk open-heart surgeries, there is a need for personalized treatment and patient-specific interventions in the operating room. Computational modeling for CHD patients can facilitate treatment and surgery planning, with analysis done on patient-specific anatomical heart models generated from cardiovascular images (CT, MRI, etc.). However, the process of generating accurate heart models is time-consuming and painstaking, highlighting the need for automation. In this study, ground truth segmentations of 43 CHD patients' cardiac CT images were created using 3D Slicer, indicating the ventricles, atria, and great vessels, to form a training dataset (n = 165) for a previously developed UNet-based segmentation convolutional neural network. This dataset contained different CHD conditions and combinations such as ventricular septal defect (VSD), double outlet right ventricle (DORV), pulmonary atresia, Tetralogy of Fallot, atrioventricular septal defect (AVSD), d-transposition of great arteries, etc. Algorithm performance was assessed by manually scoring each segmentation in line with the patient's diagnosis and corresponding cardiac anatomical features. After training, an improvement of 28% ($p < 0.01$) was observed in the accuracy of heart model generation from the testing CT images (n = 30). In the future, these ground truth segmentations can be used to further improve machine learning methods to generate patient-specific heart anatomical models at high throughput with minimal user interaction and aid clinicians when planning and administering treatments for CHD patients.

Abstract Name: Activation of Intrinsic Glioblastoma GABAA Receptors Impairs Cancer Viability

Glioblastoma (GBM) is a highly aggressive brain cancer with a 2-year survival rate of ~25%. GBMs are challenging to treat due in part to their molecular heterogeneity and the physical roadblock presented by the blood-brain barrier, which acts to limit therapeutic effectiveness. There is an urgent need for therapeutic approaches that can overcome this cancers' heterogeneity and the blood-brain barrier. Interestingly, brain and systemic cancers, including lung and melanoma, possess functional Type-A GABA receptors (GABAARs), which are the major inhibitor neurotransmitter receptors in the adult human brain. Furthermore, GABAARs in cancer cells functionally resemble embryonic GABAARs and move chloride ions out of the cell. In contrast, GABAARs in mature neurons move chloride ions into the cell. My laboratory discovered a new class of small molecules that bind to and activate GABAARs in cancer cells, eliciting a significant outward flow of chloride ions and ultimately cell death. My research is investigating if we can leverage the presence of GABAARs in GBM cells to impair their viability using this new class of small molecules and if so, their mode-of-action. We report that these small molecules can impair GBM viability by triggering autophagy, the cells 'self-eating' phenomena.

Abstract Name: Morphological changes with foraging strategy in *Euonymus fortunei*

Euonymus fortunei, or wintercreeper, is a non-native evergreen liana that forms a dense groundcover as a juvenile and ascends trees when mature. Wintercreeper is considered an invasive species in the U.S. due to its ability to grow in a range of conditions, aggressiveness in colonizing new environments, and tendency to outcompete native species. While lianas tend to colonize disturbed areas, my research takes place in a relatively undisturbed, old-growth forest, an ecosystem which is increasingly rare and represents a significant conservation concern. The closed canopy conditions of old-growth forests transmit less light to the understory, which may impact the growth and foraging strategy of *Euonymus fortunei*. *Euonymus fortunei* has two distinct phases in its development, with potentially different morphological strategies. The juvenile form extends horizontally along the ground and forms a dense layer that can exclude native species. Once the liana encounters a suitable host tree, it ascends the trunk and may become reproductively mature, reaching up to 60 feet into the forest canopy. The goal of my work is to examine the morphological differences regarding foraging strategies of each phase. I investigate the morphological changes between juvenile, mature, and fruiting forms of *Euonymus fortunei* collected from Beall Woods State Park, an old-growth riparian forest. The samples were analyzed for internode length, branch length, petiole length, LAI, leaf water content, and stem density. If *E. fortunei* alters its strategy in seeking out host trees, I expect juvenile forms to exhibit a searching strategy, with longer internodes, more branching, and less dense stems and mature forms to allocate more resources to leaves and stems and to grow straight up a tree with less branching. Increasing knowledge about *Euonymus fortunei*'s ecological strategies may be crucial to effectively manage this invasive species.

Abstract Name: A Machine Learning Approach to Predicting Student Dropouts on the ELS:2002 Study

Academic dropout concerns all levels of education, and a vast body of research attempts to interpret and minimize the issue. Machine learning models have become a topic of interest regarding the latter objective as a means of statistical prediction. This research delved into using machine learning models to predict student dropouts using data from the Education Longitudinal Study 2002 (ELS:2002), over 4000 variables, and 16,000 observations, comparatively utilizing various models and determining which makes the most accurate predictions on academic dropout. The dataset, which nationally represents the educational progress of the student body from high school to postsecondary years, contains a wide array of academic and non-academic characteristics of students, including academic performance, socioeconomic status, school engagement, and family background. We aimed to develop predictive models by using these attributes to identify students at risk of dropping out of high school. We made use of a variety of supervised, machine learning models appropriate for classification-focused prediction. The data first undergoes feature selection based on the number of missing values in each feature column to ensure that only high-quality attributes contribute to the prediction. Subsequently, various preprocessing methods, such as imputation, feature encoding, and oversampling, are applied to further format and clean the dataset. Precision, recall, and F1-score metrics were utilized to assess the model's classification performance. Ultimately, we found that applying XGBoost to the ELS:2002 dataset, which was preprocessed with SMOTE (Synthetic Minority Oversampling Technique) oversampling and data imputation, yielded the most favorable balance between these metrics. This research agrees with previous studies that confirm XGBoost's effectiveness in predicting student dropout while contributing findings with the ELS:2002 dataset, which, to our knowledge, has yet to be utilized for dropout prediction via machine learning methods.

Abstract Name: The Self in Sport and Exercise: A Scoping Review

The purpose of this research study was to find all of the pertinent information available regarding the self as it pertains to sport psychology. The research team gathered work published on the topic of self and sports and summarized the key findings and ideas. The study examined what has been found regarding a numerous selection of self-related terms and their relationship to the world of sport. Through a specific search protocol, the research team conducted a scoping review of the literature. This research is important because it aims to give a strong conclusion on the role the self plays in sport, which can ultimately help to shape sport psychology consulting techniques. Though not yet concluded, the key findings will likely be that there was a substantial amount of research already conducted on the self in sport psychology, and the research team anticipates that the culmination of research will agree that the self plays a monumental role in sport and exercise, in many more aspects than would be readily apparent. Further, knowledge gaps in the literature will also be identified to help guide future research in this area.

Abstract Name: Effect of Diclofenac on Cardiomyocyte Cells

Nonsteroidal anti-inflammatory drugs (NSAIDs), such as aspirin and ibuprofen, are commonly used to manage pain, decrease inflammation & fevers, and prevent blood clots. NSAIDs have also been linked with increased risk of gastrointestinal bleeding, myocardial infarction, and stroke. Diclofenac is an NSAID used around the world associated with the highest risk of stroke & heart attacks in clinical studies and recently became available over-the-counter in a topical form in the United States. However, the mechanisms of damage by diclofenac to cardiomyocyte cells are not well understood. The goal of my investigation is to determine if physiologically relevant doses of diclofenac increase oxidative stress and cause cardiomyocyte cell damage by conducting cell culture experiments using C2C12 mouse myoblast cells. These experiments include mitochondrial membrane potential experiments, cell survival assays, western blotting, superoxide ion detection, and proteasome biochemical assays. Preliminary results show that there were significant differences in mitochondrial membrane potential assays between control & diclofenac treatment showing that the mitochondria of cells treated with diclofenac will not be able to produce ATP as efficiently and were more likely to experience mitochondrial dysfunction. Mitochondrial membrane health is associated with oxidative stress and damage, which is supported by increased levels of reactive oxygen species in diclofenac-treated cells, and this damage is associated with higher risks of stroke & heart attack.

Abstract Name: Adsorption of Anionic and Cationic Dyes with Pumpkin Peels

Removal of cationic and anionic dyes from water using waste biomass is a growing area of bioremediation research. This research focused on the use of sugar and knucklehead pumpkin peels to remove hazardous dyes from water. Dye adsorption studies were conducted with crystal violet and acid green 5 at varying pH levels. The pumpkin biomasses were not effective in removing the crystal violet dye from the solution in neutral conditions but showed promising results in basic solution: 80% removal in 60 minutes with both sugar and knucklehead pumpkin peels. The biomasses showed little effectiveness in the removal of acid green 5 dye in neutral conditions, but could not be tested in acidic or basic solutions due to its role as a pH indicator. The sugar pumpkin appeared to have released a secondary pollutant (β -carotene) into the solution, making it a less ideal bioadsorbent. The use of a different anionic dye that does not change color with pH could potentially provide a more clear study of the adsorption of anionic dyes by pumpkin peels in acidic and basic conditions.

Abstract Name: Automating Atoll Resilience: AI-Driven Geospatial Analysis at Lalo in the Face of Climate Change

The increasing vulnerability of atoll island communities to climate change, particularly due to sea-level rise (SLR) and intensified hurricanes, raises significant concerns globally. It is predicted that low-lying atolls, such as those within the Papahānaumokuākea Marine National Monument (PMNM), may face submersion within the next 100-200 years. Lalo, an open atoll within PMNM, plays a critical ecological role, as a nesting rookery for 90% of the threatened Hawaiian green sea turtle population. In 2018 a category 3 hurricane known as Walaka, struck Lalo, causing significant shoreline erosion and reef loss, which underscored the importance of understanding the recovery and resilience of these islands. This research aims to improve the geospatial analysis of shoreline change at Lalo, with a particular focus on East Island, through the newly developed Segment Island and Atoll Model (SIAM). SIAM automates the labor-intensive task of manually digitizing atoll shorelines, providing a more efficient and accurate solution. Currently, SIAM utilizes Python programming to process satellite imagery and generate metadata files compatible with GIS platforms, while also allowing future integration with machine-learning applications. Its user-friendly interface and batch processing capabilities significantly reduce analysis time by... The ultimate goal is to integrate SIAM with the

open-source program QGIS, enabling fully automated shoreline change detection for atoll and island communities. This study aims to assess SIAM's ability to monitor and quantify shoreline changes at Lalo. Expected results include faster, more accurate detection of coastal changes, significantly enhancing our understanding of atoll resilience in the face of climate-induced impacts. These insights are essential for supporting conservation efforts within the PMNM and ensuring the protection of biocultural ecosystems.

Abstract Name: Barriers to Healthcare Access for Refugees in Pittsburgh

In search of better living conditions, refugees often undertake migration journeys that are long, arduous, and detrimental to their health. Thus, it is a priority for refugees to receive high quality healthcare upon resettlement, but in the United States – despite having one of the largest refugee resettlement programs in the world – this is not certain. Pittsburgh, Pennsylvania, a major city in one of the top 10 states that resettle refugees in the country, is home to a significant number of refugees, but there is a lack of information about their healthcare experiences. This study aimed to fill these gaps by exploring the different barriers to healthcare access encountered by refugees resettled in Pittsburgh. Three refugees from Swahili-speaking nations and with an average of six years of residence in Pittsburgh were interviewed. In general, three major barriers to healthcare access were reported: (1) transportation, (2) language barriers, and (3) cost of treatment. Notably, participants indicated that they faced fewer of these barriers when assisted by a refugee agency in their first few months after resettlement. The lack of diversity in participants' countries of origin and the small sample size of this study limits its generalizability, revealing the necessity for larger, more diverse studies in the future. Despite the limitations, this study serves as an exploration into the barriers faced by refugees in Pittsburgh and emphasizes the need for improved access to high quality healthcare services for this population.

Abstract Name: One Man's Trash: Influences of Urbanization and Land Connectivity on Scavenger Behavior
Data collection in progress

Scavengers are vital, yet often neglected, parts of the ecosystem. Urbanization creates complex gradients in landscape and food availability for scavenging species. While much research has focused on urbanization's impact on behavior, little has specifically addressed scavengers. Our study investigated scavenger behaviors

along a rural-to-urban gradient in Mobile County, Alabama, and Central Georgia (CG) using trail cameras at bait stations. Data from Mobile County, collected from 2015 to 2017, served as pilot and comparison data for CG, defined as areas south of Interstate 20 and north of Highway 280, including Baldwin, Washington, Hancock, Putnam, Jones, and Bibb Counties. We also examined the impact of land connectivity to resources like bodies of water, greenspaces, and stormwater handling systems. We hypothesized that urbanization would affect scavenger behavior in three ways: 1) Increasing species diversity from rural to urban areas; 2) Altering the succession of species at bait sites between urban, suburban, and rural areas; and 3) Influencing species composition based on land connectivity within levels of urbanization. Preliminary analyses from Mobile County indicated that while species diversity was not significantly impacted, the succession of species at bait stations was. Avian scavengers (e.g., turkey vultures) arrived first in rural areas, while small mammals (e.g., opossums, raccoons, domestic cats) arrived first in urban locations. Further investigation across more diverse sites is necessary. Geographical Information Systems (GIS) analyses will be conducted to confirm urbanization levels and examine land connectivity aspects. This study aims to enhance our understanding of ecosystem health and inform future research on animal behavior and cognition.

Abstract Name: Predators in Paradise: The Impact of Non-native Barn Owls on Kauai's Seabirds and Waterbirds

Invasive species are one of the leading causes of extinction, worldwide. They are particularly devastating on isolated archipelagos, such as the Hawaiian Islands where 67% of endemic birds have already been lost to human-induced extinction. Here, we study the diet and likely impact of invasive Barn Owls (*Tyto alba*) on the island of Kauai, Hawaii. Building on several previous semesters of class research, the Fall 2024 General Zoology class quantified the diet of Barn Owls using stable carbon and nitrogen isotope analysis of partially grown owl feathers and potential prey items. We found that waterbirds are isotopically distinct from other prey, including seabirds, rodents, and insects. However, waterbirds composed a small minority of Barn Owl diet, which was dominated by rodents and insects, followed by seabirds. To infer the dietary preferences of invasive Barn Owls, we also worked to generate a body condition index (BCI) using body mass and the length of cleaned tibiotarsi. We found a marginally significant effect of diet on BCI, wherein owls consuming >10% seabirds had a poorer body condition than remaining owls (who typically consumed >90% rodents and insects). Similarly, we found that owls with lower body masses were more likely to consume seabirds. Our results substantiate the concern conservation managers have about Barn Owls – a unique invasive predator in Kauai, given its ability to fly over predator-proof fences to kill critically endangered seabirds. However, our data also imply that seabirds are not high quality or preferred prey for Barn Owls. We suggest that owl control efforts keep pace with rodent control. Otherwise, loss of Barn Owls' primary prey (rodents) might further increase their depredation of seabirds.

Abstract Name: A Comparative Analysis of Sonic Hedgehog Activation and WNT Pathway Inhibition in Human Cochlear Organoids

The human auditory system detects sound waves and converts the vibrations into neural signals. This mechanism relies on inner ear hair cells—mechanosensory neurons found within the cochlea. These cells lack regenerative capacity, therefore strong or prolonged insults ultimately result in permanent hearing loss. Rodent models are used to study various aspects of auditory mechanisms, however, limitations persist due to anatomical and developmental differences between species. To address this limitation, we introduce human cochlear organoids. Cochlear organoids are 3D cell culture models designed to recapitulate the human auditory system. During inner ear development, vestibular structures arise dorsally, whereas cochlear structures originate ventrally. Activation of the Sonic Hedgehog pathway and inhibition of the WNT pathway, using Purmorphamine and IWP2, promote ventralization, potentially leading to the formation of functional cochlear hair cells. By day 18 of cochlear organoid development, otic placodes—precursors to the inner ear structure—should begin formation, eventually evolving into otic vesicles. After 60 days, these vesicles are expected to contain both hair cells and supporting cells. Otic placode formation marks the initial step of inner ear induction and plays a critical role in establishing necessary structures for hair cell generation. Currently, we are investigating which time point during placode formation exhibits the highest expression of PAX8, a

key marker of posterior otic placodes. This information is crucial for optimizing differentiation protocols and ensuring accurate development of cochlear structures. To validate the effectiveness of the PUR + IWP2 protocol, we will compare treated organoids to untreated controls. Assessments will include analysis of gross organoid morphology and marker expression patterns. Immunohistochemistry assays will be used to quantify the expression of PAX8 (an otic placode marker), SOX2 (a marker for supporting cells), and MYO7A (a hair cell marker). This approach will allow us to validate the protocol's ability to generate functional cochlear structures.

Abstract Name: Effects of Low-Level Light Therapy (LLLT) on Differentiated Vascular Smooth Muscle Cell (dVSMC) Wound Recovery

Previous research in skeletal muscle has indicated that low-level light therapy (LLLT) can accelerate wound recovery under certain circumstances. The purpose of this study was to discover if LLLT had similar effects on differentiated vascular smooth muscle cell (dVSMC) wound recovery. One theory on the mechanism for LLLT suggests that red LED photons absorbed into the mitochondria cause increased ATP production for cellular processes, including the rate of cell division. If so, then dVSM could benefit from similar treatment. To test this, rat aorta cells (A7r5) were cultured in vented flasks and subcultured in six-well plates where they underwent a scratch wound assay. The scratch width was measured before and after ten, twenty, or thirty minutes of LLLT, where some treatment groups received constant LED light exposure and others received pulsing. Although there was no significant difference in wound recovery after the pulsed LED light treatment, this experiment showed for the first time a significant increase in dVSM wound recovery after constant LED light treatment, with the best results after thirty minutes of treatment.

Abstract Name: Phenological changes in Wisconsin deciduous forests

Phenology is the study of plant and animal life in relation to seasonal climatic changes. Historically, plant phenology studies were done using field data that, although valuable, were limited in extent. Remote sensing overcomes this limitation by utilizing satellites to acquire images of the Earth's surface at regular intervals. We are combining NASA's Harmonized Landsat Sentinel-2 (HLS) product and the Normalized Difference Vegetation Index (NDVI) to characterize phenological changes in deciduous forests from 2016 to 2024. We chose two locations in Wisconsin based on their relatively high density of deciduous forests. The first area is

located southwest, in a portion of Devil's Lake State Park in Sauk County. The second location is northeast of Antigo, surrounding Baker Lake in Langlade County. The HLS data offers high spatial and temporal resolutions, which is ideal for tracking rapid changes on the ground. The NDVI, an indicator of greenness, is widely used to produce temporal curves to identify the stages vegetation goes through. We removed pixels contaminated with clouds, cloud shadows, water, ice, or high aerosol from the imagery and extracted NDVI values for areas designated as deciduous forests according to the Annual National Land Cover Database maps. Through a time series analysis of the seasonal changes in NDVI, we will identify the length of the growing season (DUR), the start of the growing season (SOS), and the end of the growing season (EOS). Studying these phenological metrics will be crucial to understanding whether Wisconsin is experiencing a lengthening of the growing season.

Abstract Name: Modeling the Force-Extension Response of Binary Copolymers With Molecular Dynamics Simulations

The mechanical properties of elastomers are governed by the force-extension response of individual polymer chains that make up their network structures. For many polymer chemistries, the force-extension response of a chain can be accurately captured by the freely-jointed chain (FJC) model. However, the FJC model assumes that the polymer is composed of 1 monomer species, but many natural polymers, like proteins, are copolymers composed of many different amino acids. Currently, there is no comprehensive theoretical model for the force-extension response of copolymers with chemically distinct units. We apply molecular dynamics simulations to study force-extension response in copolymers containing hydrophobic and hydrophilic monomers. We simulate copolymers at varying temperatures and externally applied tensions and measure the resulting chain extension $R(T,f)$. Consistent with experiments, we find copolymers display a coil-to-globule transition below a sequence-specific critical temperature. This transition produces abrupt jumps in force-extension response as chains partially unravel.

Abstract Name: Analysis of Automated Theorem Proving through Abstraction of Logical Expressions

Propositional logic, or first-order logic, defines the fundamental rules for modeling Boolean relationships. It is used extensively within the field of computer science to model logical scenarios and represent situations that evaluate to a value of true or false. Automated Theorem Proving (ATP) is the process of proving any mathematical theorem. In most cases, these theorems can be reduced to first-order logical expressions, and consequently, there are extensive tools to evaluate first-order logic. One method of ATP in logical expressions

is modeled in the Boolean satisfiability (SAT) problem. The SAT problem asks whether a set of propositional formulas under Conjunctive Normal Form (CNF) is satisfiable. The SAT problem can be solved algorithmically, with optimizations to SAT-solving still being studied today. The advancement of machine learning in natural language processing capabilities has led to a heightened interest in a machine's ability to understand and model natural language as propositional logic, independent of human intermission. If a machine could model natural language in such a way, then proving facts and consistencies in articles could be highly automated. Further, the capability to model natural language as propositional logic could have further applications in software development to assist with debugging, finding loop invariants, or adhering to specifications. This research bridges the gap between natural language and propositional logic by building and evaluating a novel end-to-end solution that takes English sentences modeled as logical scenarios and converts these into propositional logic expressions. From there, these expressions are converted to CNF and solved for satisfiability. This approach utilizes existing libraries and models to build this pipeline to evaluate methods of understanding English language as logical expressions.

Abstract Name: Evaluating the Inhibitory Potential of Xylitol on Oral Biofilm Formation in Cariogenic Conditions

Streptococcus mutans is a known key contributor in dental caries development and flourishes in the presence of common dietary sugars such as sucrose. *S. mutans* forms biofilms on tooth surfaces, facilitating enamel demineralization and promoting dental caries development. This study examines the inhibitory effects of xylitol, a non-fermentable sugar alcohol, on biofilm formation. While xylitol is known to impede biofilm formation due to *S. mutans*' inability to metabolize it, this study aims to focus particularly on its potential inhibitory effects on *S. mutans* biofilm growth even in sucrose-rich conditions. Using extracted human teeth immersed in mucin-enriched artificial saliva as an artificial oral environment, biofilm formation was assessed using a crystal violet plaque assay, with quantification performed via spectrophotometric methods. The experimental conditions included 1% sucrose, 1% xylitol, and a 1% sucrose-1% xylitol mixture. The results reveal statistically significant differences in biofilm accumulation between treatments, with pronounced biofilm accumulation observed in sucrose conditions and minimal biofilm accumulation in xylitol conditions. Most notably, the sucrose-xylitol mixture treatment exhibited lower levels of biofilm accumulation with significantly attenuated growth compared to sucrose alone, implying a potential antagonistic interaction between the two sugars. These findings highlight the potential of xylitol as a preventative agent for dental caries, even under cariogenic conditions. Furthermore, this study contributes to the growing amount of evidence supporting the use of xylitol in oral health strategies, suggesting its potential to be integrated into dental care regimens aimed at reducing caries risk and promoting oral health. Future research should focus on exploring the biochemical mechanisms underlying xylitol's inhibitory effects and its potential antagonistic interactions with other common sugars and cariogenic bacteria.

Abstract Name: Investigating the effects of noise exposure on endoplasmic reticulum stress-linked molecules and their contributions to the pathogenesis of noise-induced hearing loss

Noise-induced hearing loss (NIHL) is a highly common form of acquired hearing loss with no preventative biological therapies. Pathological noise exposure (NE) causes damage and/or death to cochlear hair cells, causing NIHL. However, the underlying molecular mechanisms by which noise-induced hair cell damage leads to hearing loss is not well understood. One potential mechanism by which NE causes NIHL is elevated or prolonged endoplasmic reticulum (ER) stress, triggered by a buildup of misfolded proteins in the ER and high levels of reactive oxygen species. Cells attempt to resolve ER stress by initiating the unfolded protein response (UPR), which can be beneficial or detrimental, and includes gene expression changes, signaling cascades, and cell survival/death pathways. To investigate the role of ER stress in NIHL, we utilized a mouse model of pathological NE. Adult mice were exposed to 105 decibels (dB) of 8-16 kilohertz (kHz) noise for 2 hours. Auditory brainstem response (ABR) testing conducted one day post NE confirmed that our NE model causes significant hearing loss. To assess dynamics in ER stress in response to NE, we examined cochlea-wide expression patterns of critical ER stress genes (Hspa5, Ddit3, Atf6, Atf4, and Atf3) using quantitative PCR. Results revealed upregulation of Hspa5, Ddit3, and Atf4 mRNA one day post NE, consistent with elevated ER stress. We are performing immunohistochemistry and will present our results on potential cochlear hair cell protein expression dynamics in ER stress-linked molecules. To validate and contextualize our findings, we are comparing our results to mice subjected to Tunicamycin-induced ER stress, a well-established model of ER stress. In summary, our results implicate ER stress molecules in the pathogenesis of noise-induced hearing loss. Future research will contribute towards a continued understanding of the ER stress response in cochlear hair cells and the underlying pathophysiology of NIHL.

Abstract Name: Turbo-Flag-MYBPC3 normally localizes to the sarcomere, enabling proximity labeling experiments to evaluate the effect of pathogenic missense variants within the sarcomere.

MYBPC3 is the gene most commonly mutated in hypertrophic cardiomyopathy (HCM) located within the A-band of the sarcomere. It has been previously demonstrated that N-terminally flag-tagged MyBP-C, the protein encoded by MYBPC3, normally localizes to the sarcomere within neonatal rat cardiomyocytes. Proximity labeling is a technique that involves using a mutated form of biotin ligase (TurboID) to rapidly label proteins with biotin in proximity to the protein of interest. The proximity proteins of MyBP-C within cardiomyocytes have not previously been identified. We hypothesized that TurboID could be attached to the N-terminus of our Flag-MyBP-C construct while still maintaining its ability to localize to the sarcomere. If our hypothesis is correct, this would enable us to label proximity proteins within the sarcomere with biotin. This hypothesis was tested by transfecting TurboID-Flag-MYBPC3 into induced pluripotent stem cell derived cardiomyocytes that have been genetically modified not to express MyBP-C. This study answered questions about the localization of TurboID-Flag-MyBP-C using immunofluorescence staining with antibodies for MyBP-C and Flag. To evaluate the localization of biotin-labeled proximity proteins, fluorescently labeled streptavidin protein was used that tightly binds to biotin. This study reveals that TurboID-Flag-MyBP-C localizes to the sarcomere and labels proteins in the A-band for both wild-type MyBP-C and mutant forms of MyBP-C that carry pathogenic missense variants causing hypertrophic cardiomyopathy (R495Q, R502W, W792R, R810H). This work validated essential protein constructs which will enable proximity labeling mass spectroscopy to be performed. We hope this future work will identify changes in proximity proteins caused by pathogenic missense variants.

Abstract Name: Breaking Barriers: Researching the Underrepresentation of Female Pilots in Aviation, Education and Training

Although most professional fields have evolved, aviation still remains male-dominated, with women making up only 5% of the total airline pilots in the world. This disparity is rooted in cultural, educational, and systemic challenges. This study investigates how specialized training, and education can help bridge this gap and incorporate more women into aviation. Using statistical analysis, we analyzed student Psychological Capital survey results. Our preliminary results indicate that there is a significant difference between male and female efficacy. These findings suggest that addressing educational and systemic barriers can enhance the persistence of female pilots in aviation. Building on these findings, our current work examines additional variables, such as motivations, barriers to entry, and perceptions of the aviation profession. We are also

developing strategies to address systemic barriers: mentorship programs, inclusive education curricula, and closer partnerships between academia and aviation companies. These will create an even more enabling environment that should see more women participate in aviation and see them sustain careers in this industry. By exploring these factors, we aim to identify actionable solutions to increase female participation in aviation.

Abstract Name: Air Quality and Environmental Justice in the Lehigh Valley, PA: A Comparative Analysis of Disparities

PURPOSE: Air pollution disproportionately affects marginalized communities, yet little empirical research has focused on the Lehigh Valley region. This study addresses the following objectives: (1) to analyze air quality data across different towns in the Lehigh Valley and correlate it with demographic data (race, socioeconomic status, immigration status) and (2) to assess the role of economic activities, such as warehouse traffic, in exacerbating air pollution levels in marginalized communities. **METHODOLOGY:** This study employs a cross-sectional, correlational design using geographic information systems (GIS) and statistical modeling to analyze air quality and demographic data from U.S. Census Tract data over multiple years. The analysis uses multiple regression and ANCOVA models to assess correlations between air quality and demographic characteristics. Additionally, qualitative data is incorporated to explore the role of local economic activities, particularly warehouse and transportation hubs, in air quality disparities. Environmental policy effectiveness is evaluated by reviewing local air quality standards and enforcement practices.

RESULTS: Preliminary results indicate that towns with higher proportions of people of color, low SES populations, and immigrants show elevated levels of particulate matter and other pollutants. Economic activities, especially those related to warehouses and truck traffic, appear to contribute to higher pollution levels in these communities. Current environmental policies show limited effectiveness in addressing these disparities, as pollution levels remain higher in marginalized communities despite existing regulations.

CONCLUSIONS: This study highlights significant disparities in air quality across the Lehigh Valley, disproportionately affecting marginalized groups. The findings suggest a need for stronger environmental policies and targeted interventions to address both the pollution sources and their effects on vulnerable populations. **Keywords:** air pollution, people of color, low SES, immigration status, environmental justice

Abstract Name: The Effects of COVID-19 on Educators in South Mississippi

This study was focused on discovering what may have caused educators in kindergarten through 8th grade classrooms in mid-south Mississippi to leave or consider leaving the profession as it relates to the COVID-19 pandemic within different content areas. Participants identified issues within the system that diminished their abilities to educate their students effectively and that related directly to the pandemic. Research from “Mississippi Teachers Are Eyeing the Exit” (Ballard, 2023) and “Teachers’ Dissatisfaction during the COVID-19 Pandemic: Factors Contributing to a Desire to Leave the Profession” (Gillani, 2022) showed that teachers were having strong difficulties during the pandemic which led to many leaving the profession. Research also proved that, throughout all areas of Mississippi, teacher retention was reaching an all-time low. Administration neglected their educators during some of the most challenging times of their careers, and, as a result, the teacher shortage is now at critical levels (Wright & Betz, 2019). A lack of support by administration could have caused an uptick in the number of educators considering leaving their jobs or leaving the profession all together. Participants conveyed feelings of being overworked, with limited resources and support from their administrators or district. The study demonstrated how varying content areas struggled more than others. A survey was given, and through the use of descriptive statistics, t-tests, and ANOVAs, statistics showed that more educators now, more than ever, are struggling to find a purpose in the classroom and they feel as though they no longer have a healthy balance of home and work life (Brouwers, 2020).

Abstract Name: Optimization and Assessment of CD45 and CD3 Protein Expression in Chronic Constriction Injury of Male and Female Rat Sciatic Nerve

Even though females and males develop hypersensitivity within the same time frame and to the same quantitative degree with equivalent nerve injury, they have distinct neuroinflammatory responses. Past research has suggested that T cells play an important role in peripheral nerve injury in females, not males, and IL-18 is a central mediator of neuropathic pain. Based on these observations, it is now important to look at the various proteins that work with T cells and the role they might play in these types of injuries. Glycoprotein CD45 appears to be required for the function of T cells, as the CD45 receptor activates the T cell antigen receptor complex. Protein CD3 has been shown to promote pro-inflammatory CD4–IL16 signaling in T cells. Using sciatic nerve tissue from a female rat that underwent chronic constriction injury, an immunohistochemical double primary antibody experiment was performed to optimize visualization of these proteins. Immune cells with expression of both these proteins demonstrated infiltration into the injured nerve epineurium, as well as the fasciculated nerve bundle. Further analysis will explore the neuroinflammatory accumulation of CD45 and CD3 positive cells in both injured females and injured males.

Abstract Name: Optimizing Brain Control Interfaces Performance through EEG- Based Critical Feedback: A Time and Frequency Domain Analysis Approach

Brain-computer interfaces (BCIs) enable individuals to control external devices through brain-generated electrical signals, typically captured via electroencephalography (EEG). While these systems hold significant potential, their prolonged use can lead to cognitive fatigue, necessitating the development of shared autonomy models to alleviate user strain. A novel strategy in this domain involves leveraging participants' EEG-based feedback, allowing users to act as critics of the system's performance. This feedback aids in distinguishing correct from erroneous decisions, thereby enhancing system efficiency. This study employs a publicly available dataset from BNCI Horizon 2020 to advance collaborative innovation within the BCI community. By applying time and frequency domain feature extraction methods, the research develops a classification model aimed at accurately interpreting user intentions with minimal trials, paving the way for more efficient and user-friendly BCIs.

Abstract Name: Evaluating Travel Time Accuracy in Navigation Systems

GPS-based navigation applications, such as Google Maps, Waze, BingMaps, and MapQuest, have become part of our daily travel, offering users real-time traffic information and ETAs to help construct the best routes possible. Yet, the accuracy of such ETAs in relation to observed ground truth data is under-explored, raising questions about the reliability of these systems in making route decisions. This study aims to determine the quality of traffic information provided by major navigation services by comparing ETAs with observed travel times from physical sensors and traffic data systems. The methodology used in this work has two major components. First, we design a Python-based web mining system to collect real-time traffic data, including estimated time of arrivals (ETAs) from four well-known navigation platforms: Google Maps, Waze, MapQuest, and BingMaps. Second, we collect ground truth traffic data from publicly available sources, including electronic toll tag readers and loop detectors provided by the New York Department of Transportation (NY DOT). The datasets are classified based on specific time frames, which include rush hours, non-rush hours, and weekends. We conduct a case study of densely populated urban areas, using New York City as the experimental setting. Using statistical methods, we compare differences between predicted and actual travel times. Descriptive statistics are also used to identify trends and anomalies across different navigation systems. Our results aim to improve the knowledge of ETA reliability, helping users make better-informed route decisions, while also enabling navigation providers to enhance their systems. These insights can be integrated into a user-friendly dashboard, bridging the gap between raw traffic data and actionable route recommendations. This work contributes to advancing technology in intelligent transportation systems and interdisciplinary research in data science, computer science, and smart cities.

Abstract Name: The AIDS Epidemic: Dance as a Platform for Social Commentary and Reflection

First recognized in the United States in 1981, Acquired Immunodeficiency Syndrome (AIDS) was an epidemic that affected the lives of many. As early cases were most common in young gay men and intravenous drug users, people were quick to blame patients' lifestyles. Popular theories focused on lifestyle created fear and prejudice directed at those affected by this epidemic. Among the gay men affected by AIDS were dance artists. Artists involved in dance performance and choreography often develop a strong sense of community and connection. As members of this dance community witnessed close friends and family members lose their lives to AIDS, dance works were created in reaction to this crisis. Two specific works created in response to the tragedies of the AIDS epidemic were Garth Fagan's *The Disenfranchised* and Bill T. Jones' *Still/Here*. These pieces express different perspectives of those experiencing the AIDS epidemic. Fagan focused on the suffering of the people in disenfranchised groups while Jones took inspiration from working with individuals living with terminal illness. In examining *The Disenfranchised*, I had the opportunity to interview Natalie Rogers-Cropper, the current executive director of Garth Fagan Dance, to discuss her experience during this creative process. During a time of crisis, creative works serve as platforms for social commentary and reflection.

Abstract Name: Intertissue Double-Stranded RNA Signaling as a Driver of Age-Related Inflammation in *C. elegans*

Age is the primary risk factor for various diseases including cardiovascular disease, cancers, and multiple neurodegenerative diseases. Because of this, understanding age-associated processes that contribute to disease is an important research priority. Chronic inflammation is a central hallmark of aging that has been repeatedly shown to contribute to disease progression, but the drivers of age-related inflammation remain incomplete. Although the origins are currently unknown, double-stranded RNA (dsRNA) accumulation has emerged as a potential driver of chronic inflammation in aging and age-related diseases. Our lab and others have shown that endogenously-originated dsRNA accumulates with age and instigates inflammation that negatively impacts cellular health and longevity. More recently, intercellular and intertissue dsRNA signaling was found to regulate the lifespan of the model organism *Caenorhabditis elegans*. This intertissue dsRNA signaling requires the dsRNA transporter encoded by the *sid-1* gene. Others recently showed that overexpression of *sid-1* decreases *C. elegans* lifespan, thus, we tested whether *sid-1* overexpression negatively impacts longevity by allowing for accelerated dsRNA accumulation with aging. To do this, we analyzed dsRNA accumulation, immune activation, healthspan (maximum crawling velocity), and lifespan in *sid-1* overexpression and null strain at different ages. Then, to understand if excessive intertissue dsRNA signaling causes inflammation and reductions in lifespan, we treated the *sid-1* overexpression strain with the autophagy activator, Urolithin A, to increase cytoplasmic clearance of dsRNAs. These experiments will provide insight into whether intercellular and intertissue dsRNA signaling and accumulation contribute to the aging process, and may unveil novel targets (e.g., dsRNA transporters) for anti-aging interventions.

Abstract Name: Benefits of NCUR Participation: Analyzing Mentored versus Non-Mentored Research in the Context of Active Learning and Intersectionality

This study explores the differential benefits of attending the National Conference on Undergraduate Research (NCUR) for students engaged in mentored research compared to students without research faculty mentorship. By implementing a structured approach that includes testimonial data collection from students at a R1 institution, we aim to assess how Principal Investigator mentorship influences student experiences and outcomes at NCUR. Our previous experience over the past two years revealed two distinct groups: those engaged in faculty-mentored research who demonstrated higher levels of engagement and confidence, and students who were able to follow through and achieve successes but faced challenges when navigating the research landscape independently. Additionally, this research seeks to illuminate the varied experiences of diverse student populations by incorporating intersectional factors such as first-generation status and socioeconomic background. We will present qualitative data measuring engagement, satisfaction, and research self-efficacy, that provide deeper insights into individual journeys. We will illustrate specific instances of success among mentored students, highlighting how structured support enhances their academic and professional trajectories. By analyzing these approaches, we intent to contribute valuable insights to the existing literature on undergraduate research and active learning, particularly in the context of NCUR. Our findings will inform educators and institutions on best practices to foster inclusive environments that support all students in their pursuit of research and scholarship.

Abstract Name: The Ethical Considerations of Utilizing Artificial Intelligence in Public Relations

The rapid integration of artificial intelligence (AI) into the public relations (PR) industry has fundamentally reshaped professional practices and methodologies. PR practitioners have had mixed emotions regarding the utilization of AI technology in PR, acknowledging both opportunities and ethical concerns. To discover the ethical barriers of AI in PR, a secondary content analysis study was conducted using scholarly articles and supplementary industry reports from credible entities. These sources provided insights into the capabilities of AI when harnessed for PR, along with relevant ethical dilemmas. This study also examined James Grunig's Excellence Theory and how one may apply the theory in context to implementing AI in the PR industry. Findings reveal that AI tools, such as generative AI programs, can innovate the PR industry by quickly generating high-quality content, managing PR campaigns and crises, and aiding practitioners with redundant tasks. However, risks such as misinformation, data privacy violations, biases, and the diminishment of the human touch emphasize the importance of balancing AI's capabilities with the industry's fundamental values. Mixed opinions regarding the integration of AI highlight the need for universally observed ethical guidelines. This study contributes to the ongoing dialogue surrounding ethical AI integration, offering

recommendations for PR practitioners on responsibly utilizing AI technology. By addressing both the opportunities and risks associated with AI, this study guides PR practitioners in leveraging AI to enhance their work while maintaining credibility, authenticity, and public trust. These characteristics are crucial as AI becomes commonplace in modern PR practices.

Abstract Name: Understanding Vermeer's Intention through Art Conservation

Art conservation changed the previously perceived art history of Johannes Vermeer's 1657 painting "Girl Reading a Letter at an Open Window." In 1979, art historians took an X-ray of the Vermeer painting, and a framed painting of a nude Cupid appeared in the background. After the 1979 scholars rejected suspicion of tampering, modern historians reevaluated the X-rays in 2017, and several evaluation tests were run. The tests resulted in the criminal discovery that the nude Cupid was covered forty years after Vermeer's death. After the painting of Cupid was revealed, the iconography and symbolism of the prominent factors in the painting, the girl and the letter, changed from reflecting unusual independence to domestic femininity. With the Cupid found to be criminally covered, a microscopic cross-section was done to evaluate the layers further. The 2021 investigation found that the layer of paint to cover the cupid was painted to match the already-aged Varnish used by Vermeer approximately sixty years before the repainting. The difference in the material caused a yellow stain to blemish Vermeer's original varnish layer. Since Vermeer intended the varnish to add muted tones to create a melancholy and calming effect, when the conservators ultimately removed the varnish layer, they also removed the impact of the muted tones. The conservation team claims they regret the unfortunate decision they had to make as they recognize that future viewers will never experience the full intensity of the painting. A scientific study was conducted in November 2023 on the viewer's visual opinion of the painting "Girl Reading a Letter at an Open Window." The conclusion was that viewers preferred the before version when they saw the side-by-side comparison of the painting before and after the conservation. Concluding that art conservation can change the previously perceived and the assumed future art history.

Abstract Name: Predicting 3D protein structure of gene fusions in AMKL patients using AlphaFold

The organization of DNA in 3D space is important for gene regulation. Changes in DNA organization and resulting gene expression can have effects on cellular development and function, and have been linked with numerous diseases such as cancer. One way DNA organization may be altered is through binding of fusion proteins containing an intrinsically disordered region (IDR) and DNA binding domain. Fusion proteins form when two portions of independent genes fuse together – which occurs via structural rearrangements

(predominantly translocations). This project aims to help fill the gap that recent literature has highlighted regarding the structure of fusion proteins. This will be done using AlphaFold: an artificial intelligence program that uses amino acid sequences to predict 3D protein structure. This research project aims to predict the 3D structure of two gene fusions which were previously predicted by the Perreault lab to be found in Acute Megakaryoblastic Leukemia (AMKL) patients. ColabFold, a software within Google Colaboratory that makes use of AlphaFold, will allow the prediction of numerous proteins simultaneously. A program called ChimeraX will then be used to visualize and analyze the protein structures. Uncovering the protein structure of genes linked with cancer is key for obtaining a clearer picture of tumorigenesis. Thorough analysis of predicted protein structure may illuminate features that may be useful for future drug development for AMKL. Preliminary results have shown that both fusions likely contain intrinsically disordered regions as well as DNA binding domains – possibly suggesting that these combined features play a role in AMKL development.

Abstract Name: Effects of Adolescent Social Isolation on Serotonin Responsiveness and Anxiety-Related Behaviors in Rats

Early-life stressors, such as post-weaning social isolation, profoundly influence mental health outcomes, as demonstrated by rodent models. This study investigates the impact of social isolation on serotonin receptor 2A (5-HT_{2A}) expression and anxiety-related behaviors, and whether these differ by sex. Rats were housed individually or in pairs from postnatal day 21 to day 42, followed by pair-housing until young adulthood (approximately postnatal day 70), when behaviors were assessed or brains collected for analysis. Behavioral assessments included two maze tests to evaluate anxiety-like behaviors: open field testing, where wall-oriented movement indicated anxiety, and social interaction, where anxiety should decrease rats' sociability. Following behavioral testing, brains were coronally sectioned, with analyses of differential serotonin receptor levels focused on the medial prefrontal cortex and basolateral amygdala. Specifically, fluorescent immunohistochemistry was performed to assess 5-HT_{2A} receptor expression and its presence in parvalbumin interneurons vs. principal projection neurons. Preliminary findings suggest that post-weaning isolation may alter serotonin system responsiveness and anxiety-related behaviors.

Abstract Name: Analyzing Media Narratives with Machine Learning: Topic Alignment and Sentiment in Trump's Rally Speeches and News Media Coverage

Considering pivotal democratic elections like those of 2020 and 2024, understanding the role of news media in shaping political polarization is critical: media influence profoundly impacts democratic processes. Using agenda-setting theory and ingroup/outgroup dynamics from social identity theory as frameworks, this study examines the framing of Trump's rally speeches and their coverage by liberal and conservative news sources. Study 1 uses a BERT-based LLM and the probabilistic LDA model to analyze the relationship between topics in liberal versus conservative media coverage, examining how media outlets' political alignments influence the alignment and selective emphasis of topics in relation to the topics present in Trump's rally speeches. This led to further inductive analysis of topics using a neural-network based topic modeling pipeline. In Study 2, the political alignment of media outlets in connection to the sentiment of news articles was examined using another BERT-based LLM, while also considering the sentiment expressed in Trump's rally speeches. Our findings revealed that despite significant differences in topic alignment throughout sources, both liberal and conservative sources exhibited predominantly negative sentiments. Further analysis revealed that each outlet selectively criticizes the other to express ideological bias, rather than merely advocating its own views. This conclusion exemplifies a pervasive issue in contemporary media: the emphasis on adversarial coverage over constructive discourse. Such coverage inundates the public with divisive narratives, heightening political polarization and weakening trust in media institutions, thus impairing informed decision-making. Our research demonstrates the need for increased media literacy to safeguard against a misinformed electorate, reduce polarization, and strengthen democratic processes. Keywords: topic modeling, sentiment analysis, agenda-setting theory, ingroup-favoritism, outgroup-discrimination, social identity theory, media literacy, polarization

Abstract Name: The Identification of a Safer Alternative to BPA Using a Zebrafish Model

The prevalence of Bisphenol compounds, such as Bisphenol-A (BPA) found in plastics, may pose health risks and have been linked to diabetes, obesity, infertility, and hormone-dependent cancers. BPA, an endocrine disruptor, exerts its effect by binding to and activating estrogen receptors. BPA and BPA (Bisphenol-B (BPB) and Bisphenol-C (BPC)) replacements are found in many products, such as thermal receipts, linings of food cans, and other food packaging. Previous studies have identified Bisguaiacol-F (BGF) as a potential replacement for BPA. BGF is derived from paper pulp and has been shown to lack estrogenic activity. Our present research uses a zebrafish model to determine the effects BPA, BPB, BPC, and BGF have on development and determine if BGF is a safer alternative. Our current work has determined that BPC is the most toxic of the compounds tested, followed by BPB and BPA, with BGF being the least toxic. Our present studies include examining the expression levels of known estrogen-responsive genes such as *vtg1*, *vtg3*, and *cyp19a1b*. We will also look at the effects of the estrogen receptors $ER\alpha$, $ER\beta1$, and $ER\beta2$. RNA-seq analysis (at 24, 48, and 72 hpf) is used to generate a genetic profile for each compound. Genes identified from RNAseq whose expression levels appeared to be altered would be confirmed and quantified using real time quantitative polymerase chain reaction (PCR). Once genes of interest are identified, they will be classified according to their function. Our studies using a zebrafish model will help further understanding of the health risks posed by potential environmental toxins.

Abstract Name: Enriching Communities through Impactful Service-Learning Projects

Service-learning combines community service with academic learning for practical application. Often, service-learning is overlooked as a method of conducting research. However, it can be highly beneficial in enabling students to develop effective problem-solving skills, foster personal growth, and make a positive impact on the community. Through various fundraising methods, volunteering, and providing emotional support, we aim to eliminate disparities in the Birmingham community while empowering freshmen students in this crucial year of their college experience. This study consists of seven different freshmen groups (e.g., Blazer League, Fire Starters, and One For All) who partnered with various community partners such as First Light, Leukemia and Lymphoma Society, and Magic Moments. Remarkably, The Alphas have raised over \$700 for Light the Night hosted by the Leukemia and Lymphoma Society. Through mentorship with freshmen students, they gained guidance, developed critical thinking skills, and fostered a sense of community within the campus, ultimately improving their college experience. In the near future, we plan on assessing the impact each individual freshman group has on the Birmingham community. The assessment will be conducted through ongoing communication and collaboration with the community partners. Challenges such as a lack of communication between mentees and mentors, lack of awareness of project timelines, and time constraints for the freshman groups are hindrances that we will address for future success.

Abstract Name: Decoding the Sunspot Lifespan: The Influence of Solar Cycles and Zurich Classified Sunspots

This study investigates data analyzed from the Debrecen Heliophysical Observatory Fenyi and Specola Solare Ticinese databases. Our study was to investigate the factors influencing a sunspot's lifespan. We also address potential discrepancies with sunspot analysis due to different sunspot counting methods. The data in our study is based on the timeframe for solar cycles 19 to 24. Our analysis focused on the lifespan of sunspots through various solar cycle activity levels. We defined our parameters as sunspot decay and growth states (Zurich classification method) and solar activity (solar minimum and maximum cycles) to find factors that influence the lifespan of a sunspot. When comparing solar maximum and minimum periods we noticed an average difference of 2.47 days between activity levels, showing a relationship between solar cycles and sunspot lifespan. Our study also shows the Zurich classification plays a role in determining the lifespan of the sunspot. However, undeveloped sunspots remain largely independent of the solar cycle's activity level.

Conversely, we noticed an increased sensitivity regarding developed sunspots and from sunspots that transitioned between undeveloped and developed sunspots based on solar activity. This behaviour may indicate a relationship between the individual magnetic fields of sunspot groups and solar cycles. Additional factors like whole spot area and umbra area, can be used to further investigate the relationship between sunspot types and the sunspot lifespan.

Abstract Name: Timing of energy intake and associations with adiposity among postpartum women: A pilot study

Approximately 60-75% of postpartum women fail to return to their pre-pregnancy weight (i.e., postpartum weight retention, PPWR) and many women gain weight postpartum. Interpregnancy weight gain and PPWR negatively impact women's cardiometabolic health and increase the risk for complications in future pregnancies. Conventional postpartum weight management interventions (i.e., modifying caloric intake and diet quality, increasing physical activity) have limited success. Therefore, novel strategies to manage PPWR are needed. Eating late into the day/overnight has adverse effects on weight and metabolism. Postpartum women may be more likely to eat overnight due to infant-related sleep disruptions. Yet, data characterizing eating patterns postpartum are scarce and no studies have considered the timing of food intake as an intervention target for managing PPWR. Therefore, this study aims to characterize postpartum women's eating schedules, assess associations between meal timing and body composition, and explore factors impacting meal timing postpartum. Women (N=55) who are 5-24 weeks postpartum will be recruited and complete three 24-hr diet recalls and a qualitative interview to understand factors influencing eating patterns and barriers/facilitators to reducing late-night eating. Weight/height will be measured and body composition will be assessed using dual-energy x-ray absorptiometry. Histograms will be used to determine the distribution of energy intake over the 24-hr period. Associations between night-time (8pm-5:59am) caloric intake and total body fat will be examined using multiple linear regression modeling. Findings will inform the development of a novel postpartum diet intervention focused on meal timing.

Abstract Name: Nourishing Communities: Food Security and Sustainability in North Wake and Durham

Food security and sustainability are critical challenges requiring community-driven solutions to combat hunger and ensure equitable access to resources. In North Wake County, a population of 1.18 million faces economic inequality and high housing costs, despite a median household income of \$102,918. In Durham County, with 295,845 residents and a 13.6% poverty rate, economic disparities exacerbate food insecurity for

low-income families and seniors. Local organizations address these challenges while fostering sustainable practices for long-term community resilience. In North Wake, Wake Forest Community Table provides free meals and fosters community connections, while Hope House supports underserved families with food pantries, mentorship programs, and senior services. The Food Shuttle Farm integrates food distribution with chemical-free farming and composting, promoting eco-friendly practices and reducing waste. In Durham, Meals on Wheels delivers meals and wellness checks for seniors, Farmer Foodshare links marginalized farmers with food-insecure communities, and Durham Farmers' Market supports local vendors and improves food access with initiatives like SNAP/EBT and Double Bucks. These organizations use innovative approaches such as chemical-free farming, composting, and partnerships with local businesses to address root causes of food insecurity, including economic inequality and limited access to fresh food. Programs like The Food Hub and Mini-Grants empower small and BIPOC-owned farms, creating a sustainable food system while supporting local economies. By fostering collaboration and addressing systemic challenges, these efforts provide essential resources to vulnerable populations, strengthen resilience, and raise awareness of equitable food access. This study underscores the transformative potential of community-driven initiatives in aligning food security and sustainability. By addressing hunger, supporting vulnerable populations, and promoting environmental stewardship, these organizations offer a scalable model for building resilient, inclusive communities.

Abstract Name: Effects of Ventral Pallidum-Nucleus Accumbens Shell Neural Pathway Modulation on Sucrose Consumption and Motivation in Female Rats: a Chemogenetic Manipulation Study

Background: The neural control of food intake involves interactions between homeostatic and non-homeostatic systems. The shell of the nucleus accumbens (AcbSh) and the ventral pallidum (VP) play key roles in regulating ingestive behavior and project to each other. Previous studies have shown that these projections influence food consumption, with sex differences reported in modulation of sucrose intake by VP projections. Objective: This study aimed to investigate the effects of chemogenetic activation or inhibition of projections from the VP to the AcbSh on sucrose consumption and the motivation to work for sucrose in female rats. Methods: Female rats were used for the study. Chemogenetic tools (DREADDs) were employed to selectively activate or inhibit VP projections to the AcbSh. Rats were trained on a progressive ratio (PR) operant task to assess motivation to work for a food reward. Additionally, sucrose consumption tests were conducted using a 20% sucrose solution. Results: Chemogenetic manipulation of VP projections to the AcbSh did not significantly affect the motivation to work for sucrose in the PR task. However, a significant interaction between DREADD type and drug administration was observed in the sucrose consumption test. Activation of the VP-AcbSh projection (using excitatory DREADD) decreased sucrose intake, while inhibition (using inhibitory DREADD) increased sucrose intake. Conclusions: The study shows that projections from the VP to the AcbSh modulate sucrose intake but do not affect the motivation to work for food. Chemogenetic activation reduced sucrose consumption, while inhibition increased it, suggesting that distinct neural circuits within the VP-AcbSh pathway may differentially regulate feeding behaviors. These findings highlight the role of this pathway in the consumption of palatable foods and indicate that future research should consider factors such as sex, food type, and specific neural subpopulations to better understand its role in feeding behavior.

Abstract Name: Potassium Sensing using Ionophore-based Optical Sensors

Physiologic monitoring systems are critical in acute and ICU settings, but existing devices lack the ability to monitor chemical and biochemical parameters, such as electrolytes and blood gases, essential for managing critically ill patients. Blood-contacting sensors for continuous monitoring face challenges like biofouling, component leaching, and risks of thrombosis and infection. To overcome these issues, this research proposes an innovative droplet microfluidics-based platform that uses immiscible oil with sensing agents to detect analytes like sodium, potassium, calcium, chloride, and oxygen through fluorescence or absorbance changes. This project focuses on developing ionophore-based optical sensors (IBOS) for cations, designing sensors for anions and neutral molecules, and fabricating IBOS for real-time critical care monitoring and bioimaging.

Abstract Name: Determining the location of interaction between the Hippo signaling pathway and *C. trachomatis* Tarp N-terminal region using *Drosophila melanogaster* as an in-vivo model

Chlamydia trachomatis is the most prevalent bacterial sexually transmitted infection in the United States, yet its secreted effectors remain largely unexplored. Effectors are proteins that aid in infection of *Chlamydia*. One effector is the translocated actin-recruiting protein (Tarp). Tarp's C-terminus bundles and polymerizes actin subunits into filaments and is well understood, but its N-terminus's (N-Tarp) function remains unknown. Tarp is present across *Chlamydia* species, indicating its importance to *Chlamydia* infection. Using *Drosophila melanogaster* as an in-vivo model, we are able to observe phenotypic changes induced by N-Tarp expression and trace them back to the perturbed pathway, a unique strength of the model. When Tarp's N-terminus is transgenically expressed in *Drosophila*, we observe overgrowth of tissue in the wings, resulting in crumpled wing phenotypes, consistent with altered host Hippo pathway signaling. The Hippo signaling pathway controls cell proliferation and apoptosis. Yorkie, a co-activator of the Hippo pathway, causes these phenotypes due to its over-expression. We confirmed that N-Tarp interacts with the Hippo pathway when a Yorkie mutants demonstrated a genetic rescue from the N-Tarp induced crumpled phenotype back to normal straight wings. I aim to discover where N-Tarp and the Hippo pathway interact through a series of genetic experiments. Because N-Tarp interacts with the Hippo signaling pathway and *Chlamydia trachomatis* delays host apoptosis, a potential impact of this research may be establishing a link between N-Tarp expression and the anti-apoptotic effects observed in *Chlamydia* infection.

Abstract Name: Identifying risk factors in adolescence that contribute to metabolic syndrome in Asian Americans using the National Longitudinal Study of Adolescent to Adult Health

Metabolic syndrome (MetS) is a cluster of risk factors that significantly increases the likelihood of type 2 diabetes and cardiovascular disease. The consensus definition of MetS incorporates criteria from the International Diabetes Foundation, the American Heart Association, and the National Heart, Lung, and Blood Institute and consists of elevated waist circumference, elevated triglycerides, low HDL cholesterol, high blood pressure, and high fasting blood glucose levels. Three of five criteria are needed to establish MetS. Despite having lower average BMIs, Asian Americans exhibit a disproportionately higher prevalence of MetS compared to other ethnic groups. This study utilizes data from Waves I (1994-95, ages 11-18), III (2001-02, ages 18-26), IV (2008-09, ages 24-32), and V (2016-18, ages 33-43) of the National Longitudinal Study of Adolescent to Adult Health, to explore early-life and adulthood dietary and lifestyle risk factors associated with MetS. We will identify participants who meet consensus MetS criteria, based on biomarker and anthropometric data during Waves IV and V. We will identify potential MetS risk factors using survey data measured in Waves I and III and use multivariable logistic regression to estimate associations between risk factors and MetS to identify common and unique risk factors across racial and ethnic groups[JS1] [MOU2] . We expect to uncover specific dietary and lifestyle risk factors that contribute to the high prevalence of MetS in Asian Americans. These findings will provide a foundation for public health strategies aimed at reducing metabolic health disparities among Asian Americans. [JS1]Not sure what we decided for the groups - White and Asian Americans only, or do you want to include Black and Hispanic participants too? I think either way is fine, just specify what the groups will

Abstract Name: Enhancing Recovery: The Efficacy of Encephalomyosynangiosis in Promoting Angiogenesis Post-Ischemic Stroke

Ischemic stroke represents a sudden neurovascular injury with enduring long-term consequences. Each year, approximately 650,000 stroke survivors in the US face permanent functional disabilities. There are many existing treatment options for post ischemic strokes like transient plasminogen activators (TPAs) and stent placement, but they do not provide neuroprotection or support functional recovery beyond the acute phase of ischemic stroke. This makes the discovery of a novel treatment imperative for ischemic stroke imperative as there is no effective treatment for stroke patients. The diminished blood supply, both directly and collaterally, following an acute ischemic stroke results in dysfunction of brain cells and networks, leading to sudden neurological deficits which limits the brain's ability to recover and self-heal. The primary objective of stroke therapy remains the restoration of blood supply to the affected region. Enhancing angiogenesis to improve blood flow in ischemic areas presents a promising therapeutic strategy. However, previous attempts using erythropoietin, statins, and growth factors have been hampered by significant toxicity or limited

translatability. Encephalomyosynangiosis (EMS), a surgical technique originally developed for moyamoya disease, involves partially detaching a section of the temporalis muscle, performing craniotomy, and grafting the muscle onto the affected cortex. EMS stands out from other treatment options due to its relatively straightforward grafting procedure using the nearby temporalis muscle, which does not require complete excision or disconnection from its blood supply. The resulting angiogenesis supports neurovascular protection and recovery following ischemic stroke, suggesting a preventive role in stroke management. We hypothesize that EMS promotes angiogenesis around the infarcted area and create an enriching environment that allows the brain to quickly recover from an ischemic stroke. The results come from a histological assessment using immunofluorescent techniques to identify if EMS promotes angiogenesis after an ischemic stroke.

Abstract Name: IlluminATE1

Protein arginylation is important for the removal of damaged proteins and has implications for human disease. Arginylation is catalyzed by the enzyme, Arginyltransferase 1 (ATE1). The loss of ATE1 in mice was shown to cause defects in fat metabolism as well as neurodegeneration. However, in these studies ATE1 loss occurred in all tissues throughout the body. Therefore, it is unclear in which tissues ATE1 is important. We have observed differences in ATE1 activity between tissues with similar ATE1 protein levels. This predicts the existence of tissue- or cell type-specific regulators of arginylation. As a means to survey the spatial and temporal regulation of ATE1 in a comprehensive manner, we recently generated transgenic ATE1-reporter mice which express a dual-fluorescent reporter sensitive to its activity. Here, we are validating transgenic founder mice and confirming propagation of the ATE1 reporter through genotyping of genomic DNA isolated from tails.

Abstract Name: Cost Benefit Analysis of the Sustainability of EV Bikes in Lehigh Valley Region of PA-Community Partnership Project Through Common Intellectual Experience

One of the aims of SDG 11 (Sustainable Development Goals) of the United Nations by 2030 is the establishment of sustainable communities. The main aim of such sustainable communities is to create cities and human settlements safe, resilient, inclusive and sustainable. Our research focuses on the application of microeconomic theory of externalities and calculating costs and benefits of the EV bikes production business in the Lehigh Valley of PA. The project was developed in consultation with local business as part of Common

Intellectual Experience project in a university, for undergraduate students. This project studies the impact of EV bikes in the Lehigh Valley (LV) region vis- a- vis the use of a gas driven car or motor bike through data on improvement of public health, reduction of pollution and economic growth. The negative externalities associated with infrastructure development and costs of the production of EV bikes along with forecasted increase in costs of production through potential higher tariffs on raw materials and parts imported from outside the USA will also be calculated. The potential benefits of the business for the LV region along with potential growth of ancillary businesses will be forecasted. The research will calculate the costs and benefits to society with emphasis on those costs which are otherwise neglected and excluded in private benefit and cost calculation. The results of the research will be shared with the local business which will enable the local business to seek funding or investments for future growth and expansion.

Abstract Name: Investigating Targeted and Epigenetic Therapies for EGFR Mutated Non-Small Cell Lung Cancer

Lung cancer is one of the most diagnosed cancers globally and remains the primary cause of cancer-related fatalities, accounting for around 1.76 million deaths annually. Notably, Kentucky experiences an age-adjusted lung cancer incidence of 84.4, significantly surpassing the national average of 54. Over the past two decades, advancements in treatment approaches have made remarkable strides toward progress in patient outcomes, but improvements can still be made. Non-Small Cell Lung Cancer (NSCLC) is the prevailing type of lung cancer, with EGFR (Epidermal Growth Reception Factor) emerging as a critical component. EGFR mutations can trigger aberrant cell signaling and growth activation, leading to uncontrolled cell proliferation and tumor growth. Targeting EGFR with Tyrosine Kinase Inhibitors, specifically Osimertinib, has shown promise, but therapeutic resistance is common. Within tumor epigenetics, the enzyme EZH2, part of the Polycomb Repressive Complex 2 (PRC2), is instrumental in adding methyl groups to histone H3, leading to repressive histone modifications and gene silencing. EPZ6438 (Tazemetostat), an FDA-approved EZH2 inhibitor, has shown potential in targeting this process. In this study, we sought to investigate the mechanisms in which resistance arises through apoptosis, cell cycle, immunofluorescence imaging, and synergy experiments and to see whether targeting EZH2 could enhance the response to EGFR-targeting drugs in both the parental and resistant H1650 cell lines. The results so far have shown that we can produce an Osimertinib-resistant H1650 cell line, although the parental cells show some intrinsic resistance. Combination of Osimertinib with EPZ6438 is predominately additive, with some synergy at highest doses in the parental and resistant H1650 lines. EPZ6438 treatment drives strong de-repression of the PI3K negative regulator PI3KIP1, suggesting a mechanism for synergism. Our findings shed light on the complex interplay between EGFR-targeted therapies, tumor resistance, and epigenetic regulators in NSCLC that may help researchers find combination therapies to improve treatment outcomes.

Abstract Name: Optimizing Carbon Dioxide Hydrate Formation for Carbon Capture and Storage: The Key to Climate Change Mitigation

Currently, carbon capture, storage, and utilization (CCSU) promises a great role in climate change mitigation as the global greenhouse gas (GHG) emission has been rapidly increasing over the last 50 years. The COP29, headed by UN Secretary-General Celeste Saulo, highlighted the urgency of drastic reductions in GHG emissions to net-zero in 2050 so that global warming could be controlled below 2oC. Carbon dioxide (CO₂) hydrates stand out among many potential solutions for CCSU because of the low energy consumption and low cost. Specifically, CO₂ hydrates are crystalline compounds that form as a lattice structure of water ice trapping CO₂ molecules within, containing the CO₂ in a solid stable form. Hence, understanding the thermodynamic properties driving this phase-change reaction is essential to developing an efficient method of capturing and storing CO₂. This investigation aims to elucidate the parameters influencing formation hydrates and maximize the quantity of gas contained within with nanoscale additives for an improvement in efficiency. In this study, we utilized an over-pressurized system to enable a high solubility of CO₂ in water, leading to high quantities of CO₂ trapped within the water ice lattice as the hydrate nucleates and forms. In doing so, we have determined that higher pressure yielded greater solubility in water and more efficient hydrate formation. This was because more CO₂ was available to dissolve into the water, and the high pressure encouraged greater nucleation. Hence, using the conditions found from the experimental results, we can begin to explore additives including carbon nanoparticles (CNPs) to offer more nucleation sites and further enhance the quantity of CO₂ trapped within the hydrate. It has been hypothesized that the high surface area to volume ratio of the nanoparticles in conjunction with the high pressure of CO₂ will allow for the formation of a more efficient and stable hydrate.

Abstract Name: Race and a History of Preeclampsia Influence Circulating Neuroinflammatory Biomarker Levels in Women

Introduction: Preeclampsia (PE) is a multisystem, pregnancy-specific hypertensive disorder linked to systemic inflammation, posing significant cerebrovascular risks and increasing susceptibility to long-term cognitive decline. Black women are at increased risk for both preeclampsia and dementia. This study investigates the association between race, history of PE, and neuroinflammatory biomarker profiles, shedding light on mechanisms underlying cognitive and neurodegenerative vulnerabilities. Methods: In a cohort of 144 Black and White women approximately 15 years postpartum, we analyzed 37 biomarkers spanning vascular injury, angiogenesis, chemokines, and proinflammatory cytokines in plasma (Meso Scale Discovery, Neuroinflammation Panel 1). Results: Significant demographic differences were observed, with Black women having a significantly lower age and higher BMI compared to White women. After controlling for these variables, 11 biomarkers demonstrated significant racial differences. Most of these biomarkers, including IL-15, IL-17A, MIP-1 α , MCP-1, CRP, and IL-8, showed higher concentrations in Black women. IL-12/IL-23p40 and VCAM-1 were the exceptions, with elevated levels in White women. Although fewer biomarkers showed significance based on preeclampsia status alone, the combined effects of race and PE revealed intricate interactions shaping biomarker variability. These findings align with prior research indicating that Black women with PE experience disproportionately higher rates of cognitive decline, potentially due to the

heightened neuroinflammatory responses observed in this population. Discussion: These findings highlight race as a critical factor in neuroinflammatory responses, independent of age and BMI, and underscore the disproportionate burden of cognitive decline among Black women, particularly those with a history of PE. This research emphasizes the need for further investigation into inflammatory pathways contributing to health disparities. Future work will explore correlations between these biomarkers and cognitive and cardiovascular health, advancing efforts to mitigate risks associated with systemic inflammation and vascular dysfunction.

Abstract Name: MobiScout: A Comprehensive Mobile System for Driver Monitoring Through Multi-Modal Sensing

Driver monitoring systems have become increasingly important for improving road safety and understanding driving behavior. However, existing solutions often require expensive specialized hardware or lack comprehensive data collection capabilities. This paper presents MobiScout, a cost-effective iOS mobile application that leverages smartphone sensors and video analytics to monitor and analyze driver behavior in real-time. The application integrates multiple data streams including video footage, vehicle sensor data through OBD connectivity, and physiological measurements to provide a comprehensive assessment of driving patterns and potential safety risks. MobiScout captures and processes video data of the driver's face and road conditions while simultaneously collecting speed, acceleration, and engine performance metrics through Bluetooth-connected OBD devices. The system implements real-time analysis of these multimodal inputs to detect signs of fatigue, distraction, or unsafe driving practices. A key innovation is the application's ability to synchronize and correlate different data streams, enabling deeper insights into the relationships between physiological states, driving conditions, and vehicle handling. The collected data is stored securely and can be reviewed through an intuitive interface that presents both historical trends and instant feedback. The application includes features for video playback of recorded trips, speed monitoring, location tracking, and detailed trip statistics. MobiScout's architecture emphasizes data privacy and efficient storage management while maintaining real-time processing capabilities. Future work will focus on conducting comprehensive user studies to validate the system's effectiveness in real-world driving conditions and expanding the analytical capabilities to include predictive safety features. This research contributes to the field of intelligent transportation systems by providing an accessible, smartphone-based solution for comprehensive driver monitoring that can be widely deployed without significant infrastructure investment. The proposed system could serve as a valuable tool for both individual drivers seeking to improve their driving habits and organizations managing vehicle fleets.

Abstract Name: Bridging Perception and Recovery: Synesthesia Neural Connections as a Pathway for Traumatic Brain Injury Rehabilitation

Traumatic Brain Injury (TBI) often results in diffuse axonal injury (DAI), disrupting connectivity within and between intrinsic neural networks, which can occur in 40% - 50% of TBI patients. Synesthesia, a condition where one sensory experience involuntarily triggers another, provides unique insights into heightened sensory connectivity and multisensory integration. This research looks at brain connections in synesthesia, specifically grapheme-color, sound-color, and color-hearing, for potential as a model for developing neurorehabilitation techniques for patients with TBI. Examining studies on synesthetic brain connectivity, highlights functional and structural network differences in synesthetes, particularly in regions like the parietal and temporal cortices and the V4 color-processing area. Synesthetic brains exhibit distinctive cross-modal connectivity patterns, characterized by stable and atypical neural connections. These connections could be harnessed to develop innovative therapies and enhance rehabilitation for TBI patients. Current neurorehabilitation methods—such as Constraint-Induced Movement Therapy (CIMT), Robotic Therapy Training (RTT), and sensory relearning therapies—might be enhanced by adopting principles of synesthetic neuroplasticity, including cross-modal facilitation, consistency, and sensory binding. By analyzing synesthetic connectivity—such as increased integration in visual, auditory, and parietal networks—this study aims to map these unique patterns to guide rehabilitation strategies. Methods include a comprehensive review of neuroimaging and behavioral studies, examining the intrinsic connectivity networks of synesthetes and individuals with TBI, alongside comparative analyses of neural integration. Synesthetic training studies show how stable neural pathways can be induced, suggesting a framework for improving sensory integration, motor recovery, and cognitive resilience in clinical populations. The findings underscore the transformative power of synesthetic networks as a promising avenue for advancing personalized neurorehabilitation protocols, curating the need for deeper exploration into how these neural patterns might unlock unexpected pathways toward recovery. Keywords: traumatic brain injury (TBI), diffuse axonal injury (DAI), synesthesia, neurorehabilitation, cognitive, function, cross-modal connectivity, neuroplasticity, networks

Abstract Name: From Earth to Algorithm: Enhancing Soil Quality with AI

Agriculture significantly impacts the economy. The population is increasing rapidly, and with this increase, the demand for food and employment is also rising. Traditional farming methods, once used by farmers, are no longer sufficient to meet these demands. According to the research, one of the major reasons for less production of food on huge land is the lack of proper management of soil. Here Soil Management comes into play; AI in soil management could be a solution to these problems. It's very hard to predict the quality of soil and what minerals are required for it, but we can use AI to analyze this, with the help of an electrochemical sensor combined with the auto feature of AI, which can analyze the data and read the PH value of soils finally provides us details about the soil. Although various methods are used in collecting sample data, Precision Farming and AI revolutionize soil management by analyzing data to optimize nutrient levels. Algorithms process information from sensors, historical data, and soil samples. Machine learning algorithms process the collected data to generate detailed soil maps, identifying areas with nutrient deficiencies, excessive moisture and other important factors. Based on the AI analysis, farmers can receive targeted recommendations on where and when to apply fertilizers, irrigation, or other soil amendments. These recommendations only work where the farmers are aware of Artificial Intelligence paradigms and understands the applications of it. Spiio method can be used to non-tech savvy farmers. Spiio is a sensor-based device, which is capable of sensing ground soil temperatures, moisture, salinity, and even light. This device is not sufficient to eliminate the current limitations, but we can further develop a better sensing device with the current knowledge to create it more capable of detecting the level of nutrients present in soil.

Abstract Name: Will The World Weep When We Are Gone? Ariel Francisco's Guide to the End of the World

The first step to fixing a problem is often recognizing that there is one in the first place. Francisco's book is a portent written to cure people of their ignorance and prepare them for the inevitable. In *A Sinking Ship is Still a Ship*, Ariel Francisco warns that there is not enough room on this small Earth for everything, and due to rising water and the rapacious lifestyle of tourists, residents of Miami, Florida may not be left with a space they can call home. Ariel Francisco depicts water as the main threat in *A Sinking Ship is Still a Ship*. In his poems, "Spring Break Forever," and "305 Till I Die," Francisco cautions that the inhabitants of Miami cannot survive the water that will eventually drown the city. The speaker of the poems suggests that everyone will die, and all things that humans created will be lost. In "Poem Written in the Parking Lot of a Tattoo Shop While Waiting For My Appointment," he argues against the permanence of human presence on the Earth; he instead admits that the end is inevitable. Francisco's poems suggest that most people remain purposefully ignorant to their own end by pushing the idea away, pretending it does not exist, or making it a future generation's problem. Francisco calls them out for their ignorance. In "Don't Ever Come to Florida," he points out what is being ignored and displays it in a way the readers cannot ignore in hopes that they will stop escalating the problem.

Abstract Name: Effects of RECQL Overexpression on Herpes Simplex Virus Type 1 Infection

Herpes Simplex Virus 1 (HSV-1) affects 50-80% of the general population in the United States. Symptoms typically present as cold sores or fever blisters but can also cause genital herpes and more severe effects such as keratitis leading to blindness or encephalitis. Multiple viral and cellular proteins act on the viral genome during viral infection. Previous studies found that human RECQ Like Helicase (RECQL) associates with the HSV-1 genome during viral DNA replication. RECQL is a DNA helicase enzyme that helps repair DNA damage and maintain a stable genome. The function of RECQL during viral replication has yet to be defined. Prior research in the lab found that RECQL knockdown resulted in a slight increase in viral yield. Therefore, it is hypothesized that RECQL is inhibitory during HSV-1 replication and that overexpression of RECQL will result in less efficient HSV-1 DNA replication. To test this, RECQL was successfully cloned into the pLEX305-c-dTAG vector and transfected into HEK293 cells. Proteins were collected, and a western blot was run, indicating that RECQL was successfully overexpressed in the cells. The HEK293 cells were also infected with the HSV-1 laboratory strain KOS to determine how RECQL expression affects viral yield. Virus was collected from infected cells, and a plaque assay will be completed. Fewer plaque-forming units are expected to be present with the overexpression of RECQL, indicating less viral replication. If the expected results

occur, the hypothesis will be accepted that RECQL acts as an inhibitory protein during HSV-1 replication, and further research must be done to define the pathways or mechanisms of the inhibitory effects.

Abstract Name: Invisible Scholars

In the United States, every year there are approximately 1.3 million students who are homeless, an individual who lacks a fixed, regular, and adequate nighttime residence. Homelessness among students has a significant impact on their academic performance, mental health, and behavior. Factors like higher absenteeism, constant movement, and lack of support can all contribute to decreased academic achievement. Ultimately, this leads to students having to repeat grades or not graduating high school, compromising their abilities to succeed in the future. In addition to the decrease in academic achievement, behavioral and mental challenges exacerbated by the stress of housing instability also affect the student's development. In Macon, Georgia, there are currently five hundred students aged six to seventeen, who lack stable housing. These students have access to assistance through programs like the McKinney Vento Homeless Assistance Act and Rapid Rehousing. McKinney Vento Homeless Assistance Act helps students to have access to school and stay in school, while Rapid Rehousing aims to provide housing resources for students and their families. However, these programs have differing definitions of homelessness that lead to gaps in how many students are able to receive housing support. In downtown Macon, there is an urban renewal occurring aimed at bringing more life downtown. This, along with social and community services, influenced the decision to create a space for homeless students right in the heart of Macon. The aim of my thesis is to connect these students with resources and the community, as well as provide them with stability in their most developmental years.

Abstract Name: Probing the Interactions Between Dematin's Headpiece and the IDR via solution NMR

We aim to understand an internal, non-covalent interaction between an N-terminal intrinsically disordered region (IDR) and C-terminal HP domain in human protein dematin, central for the regulation of shape and function of mature red blood cells through binding/bundling actin filaments (F-actin). Headpiece (HP) domain phosphorylation triggers a functional change in dematin: from an F-actin bundling to F-actin binding protein (regulatory effect). We hypothesize that the interactions between dematin's N-terminus of the IDR (d160N) and headpiece can be modulated by HP phosphorylation. 2D NMR spectra can help decipher the

interaction but are complex and hard to analyze: segmental isotopic labeling may help (REU 2023 work). By introducing sortase as a catalyst, we aim to create two ligation products: wild type dematin headpiece (DHP) ligated to a ¹⁵N labeled d160N and dematin phosphomimetic (Ser381Glu) headpiece (DPHP) ligated to a ¹⁵N labeled d160N. We aim to use NMR spectroscopy to scan for any differences in peak intensities or positions between d160N and the two ligation products. By understanding these intermolecular interactions, we may be able to modulate dematin's ability to bind and bundle F-actin in red blood cells.

Abstract Name: Spring-Variable Mass System: Study With Different Fluids

The present work describes the oscillations of an inexpensive and easily built-up physical oscillatory spring-mass system with mass varying in time. We used different fluids in this study, including both liquids and granular media: freshwater, acetone, clean and dirty sand, and a sugar-salt mixture. Instead of the most reported classical oscillating pendulum, this spring-mass system allows us to inquire about the deposition of mass and the effect of mass loss on the variables that describe the system's oscillation of a granular media. In this case (granular media), we studied avalanche occurrence during the deposition of the grains and the possible effect of downward-upward motion during the losing mass as the fluid column length varies with each oscillation. A description of the apparatus is given.

Abstract Name: Lower Jaw Shape Rather than a Unique Cartilaginous Margin Likely Facilitates Periphyton Scraping in Stoneroller Minnows (Genus *Campostoma*).

Stoneroller minnows in the genus *Campostoma* are common and abundant inhabitants of eastern North American streams, known for rolling rocks during the construction of their nests as well as for a diet usually including stream periphyton scraped off of surfaces. Like all minnows, stonerollers lack jaw teeth, and previous literature described the lower jaw in stonerollers as having a prominent and distinguishing cartilaginous edge. After general gross examination of jaws in *Campostoma* wherein we did not observe distinctive cartilage anatomy, we hypothesized that obvious cartilaginous structures may not comprise the primary specialization for scraping of periphyton in stonerollers. We used clearing and staining and paraffin histology using Masson's trichrome and toluidine blue staining of multiple *Campostoma*, *Nocomis*, and other

related minnow species to explore differences in jaw structures. In *Campostoma* we found marginal hyaline-cell cartilage (not hyaline cartilage) at the anterior edge of bony shelves on the dentary bone with an overlaying thickened keratinized epithelium. However, in the closely related, non-periphyton-scraping genus *Nocomis* we found a similar anatomy except without bony shelves. Other minnow species examined had less hyaline-cell cartilage and a less extensively keratinized epithelium. This suggests that the shelf-like extension of the dentary likely is a specialization for scraping but that the keratinization and extensive hyaline-cell cartilage may not be uniquely associated with periphyton scraping, and may be associated with the rock moving during nest building observed in *Campostoma* and *Nocomis*. Future work will include greater species sampling and more specific analysis in the context of phylogeny.

Abstract Name: Language Development and Stuttering

Research on bilingualism has been important for understanding language and cognitive processes. The research has resulted in debates about whether speaking more than one language increases cognitive capacities such as flexibility, ability to learn languages, and executive function or potentially limits these capacities. Therefore, efforts to identify language behaviors that reflect cognitive capacities in bilinguals have been at the forefront of this area of research. One behavior that has been examined as a reflection of decreased executive functioning is stuttering, which has been studied as far back as 1937. While some studies show no difference in stuttering rates between bilinguals and monolinguals, others suggest a correlation. This study used an online survey to explore bilingualism and stuttering experiences. Most previous studies reported whether participants who stuttered had been diagnosed by a speech therapist/doctor. That could overlook people who stutter but do not have the resources to get an official diagnosis. The present study asked participants whether or not they felt they stutter often. Bilinguals may stutter more in a secondary-language, indicating emotional influences often overlooked in stuttering research. In an online survey, 71 participants were asked how many languages they spoke and whether or not they stuttered: 33-identified as multilingual, 37-as monolingual, and one did not specify. Only 5 had a formal stuttering diagnosis, but 28 reported experiencing stuttering. 2 did not report on stuttering, while 41 reported no issues. Among multilinguals, 51.5% (N=17) felt they stuttered, versus 48.5% (N=16) who did not. In monolinguals, 30.6% (N=11) reported stuttering, and 69.4% (N=25) did not. This multilinguals vs. monolingual difference approached statistical significance, $\chi^2(1, N = 69) = 3.14, p = .077$. Participants reported stuttering equally in their first and second-languages, with no relationship to second-language fluency or age of acquisition. Findings suggest multilingual individuals may be more likely to stutter than monolinguals.

Abstract Name: Hybrid Microfluidic Devices Using Photolithography and 3D printing

Microfluidic devices have transformed numerous fields, including chromatography and DNA sequencing, due to their ability to manipulate fluids at the microscale. These devices are pivotal in creating compact, efficient systems for applications ranging from point-of-care diagnostic tests to high-throughput drug screening. Devices are often made by photolithography, which allows for high resolution but leads to significant challenges like integrated nozzles or intricate routing, since the channel pattern must be two-dimensional. 3D printing has emerged as a potential approach to overcome these limitations, but its current resolution of 50µm holds back the fabrication of features at the scale required for precise microfluidic operations. Therefore, our group has proposed that a hybrid device that combines a 3D-printed part and a microfabricated part would offer favorable results for processing single cells at a high throughput. We fabricated a device that consists of a complex microfluidic channel system with an onboard 3D-printed reservoir and two external nozzles. Preliminary parts were modeled on OnShape's CAD software, printed through Formlabs with Tough1500 resin, then iteratively optimized to meet the required volume capacity and nozzle dimensions. Separately, photolithographically-patterned microfluidic chips were fabricated from transparent epoxy - to allow for visibility of cells within the device. Finally, the micropatterned part was bonded to the aforementioned printed parts and finalized devices were tested against a predetermined quality control checklist. Altogether, these devices demonstrate successful integration of high-resolution channels with 3D-printed routing and nozzle systems. Our approach resolves the limitations of planar fabrication and enhances the functionality of the device by enabling multi-layer and complex geometries. This innovation is significant because it paves the way for complex microfluidic devices with enhanced capabilities, fostering advancements in fields such as personalized medicine and synthetic biology. Furthermore, it underscores the importance of combining technologies to meet the evolving demands of microfluidics.

Abstract Name: Fruits of My Labor: Writing, Illustrating, and Designing a Picture Book About Creativity and Burnout

Picture books are a powerful tool for displaying both visual and verbal storytelling techniques. At a time where breaking into the creative industry seems like a daunting task, a picture book serving as a reminder to believe in one's artistic voice can offer a feeling of comfort to a young maker. Expressing the bumpy yet exhilarating experience of creative work through whimsical allegory, *Ada and the Lemon Tree* tells the struggles of Ada, a mythical being born of a lemon seed with a single task: to care for and aid in the growth of her lemon tree. Being the only lemon tree in the orchard she resides in, she embarks on a journey of finding confidence in her abilities, her work, and sense of self, reflecting the growth of an artist. The illustrations for the picture book were made on illustration board using paint markers and colored pencils. Rendered with expressive lines and layered markmaking, the characters and environments contrast traditional Western fairytale imagery with contemporary color and design. After completion, the drawings were scanned and digitally edited using Adobe Photoshop software, and later formatted with the story text using Adobe InDesign software. The final product resulted in a ready-to-print picture book able to be distributed both physically in print, and in a digital format. Using visual and verbal storytelling tools, *Ada and the Lemon Tree* is a picture book focused on portraying the ups and downs of creative work in a world of spectators and makers alike, and seeks to encourage young adult artists to have faith in who they are and what they can create.

Abstract Name: Anticipating and Acting: Exploring the link between Race-Related vigilance and Superwoman Schema

Objective: Superwoman Schema (SWS) reflects multiple dimensions of coping with life stressors (i.e. depression) among African American (AA) women. Similarly, race-related vigilance (RRV), a pattern of anticipatory coping behaviors linked to prior exposures to discrimination, has been linked to increased depression risk directly, and indirectly through rumination. Currently, no studies have examined the association between SWS and RRV. In the present study, we examined the relation between SWS and its associated subscales; the obligation to present strength, the obligation to suppress emotions, the intense motivation to succeed, a resistance to vulnerability, and the obligation to care for others, and race-related vigilance. Method: We ran a correlational analysis to examine the relationships between SWS and RRV in a sample of (n=53) Black women (100% female, Mage =19.77 SD=1.67). Our sample had a mean SWStotal score of 67.64 (14.26), which is in the moderate range for SWS endorsement (36-70). Our sample also had a mean score of 2.48 (.84) for RRV and 49.3 (13.88) for rumination. The mean score for depression was 2.14 (.35). Results: RRV was positively correlated with SWStotal, $r(51) = .319, p = .02$, and the subscales, SWSstrength, $r(51) = .479, p < .001$, and SWShelp, $r(51) = .276, p = .046$. In follow up regression analysis, controlling for rumination and depression, RRV reliably predicted SWShelp and SWSstrength, but the effect for SWStotal was diminished. Conclusion: SWS and RRV are correlated independently and indirectly through depression. This means that RRV and SWS may represent distinct but similar methods of coping, both of which have been linked to greater risk for depression amongst African American women. Future research should examine whether women who utilize RRV to cope are also more likely to feel the need to present strength and help others despite one's own needs.

Abstract Name: A Franciscan Friar's Defiant Journey: The Extent of Individual Power in Colonial Mexico, 1782

During Spanish occupation of Mexico from 1521 to 1821, religion was used as an extension of the Spanish Empire as Mexico's indigenous populations were forcibly converted to Catholicism. Religious orders, including Franciscan friars, a group of men who wandered and preached to help the poor and sick, were used in the systematic conversion of indigenous populations. Utilizing a 1782 diary written by an unidentified Franciscan friar held at the University of Kentucky Libraries Special Collections Research Center, this research will explore the work and experiences of one friar within the institution of Catholicism and the Spanish Empire itself. The diary is handwritten in 18th century Spanish, which is significantly different from contemporary Spanish. Research will create a transcription of the full 62 page diary in order to better analyze its content. Critical discourse analysis will be employed to uncover hidden meaning in the original diary text to view how the Franciscan friar's use of language reinforces his power relationship and place in the social

hierarchy within Spanish Catholicism as his actions become increasingly defiant. To supplement the diary, existing literature on Franciscan friars will be put into conversation to gauge previous interpretations of Franciscan friars's power. Ultimately, the research will uncover the power of an individual in the face of institutional power, a power struggle that is immortal in its relevance.

Abstract Name: Accurate Assessment of Social Skills for Differential Diagnosis in Young School-Age Children

Social communication disorder (SCD), autism spectrum disorder (ASD), and developmental language disorder (DLD) often have overlapping symptomology in young, school-age children, with a core feature related to difficulty adequately using language to be social. The current study aimed to determine whether children in first through third grade with language-based goals (e.g., morphosyntactic, semantic) on their Individualized Education Programs (IEPs) use qualitatively and quantitatively different social responses from their typically developing peers. Skills were elicited through targeted social conversation language samples using three standardized prompts. Through individual video and transcript analysis and Systematic Analysis of Language Transcripts (SALT) programming, qualitative and quantitative data were collected. Qualitative analysis examined the quality of social responses using a Likert scale that reflected the appropriateness and specificity of the response by context. Quantitative data examined the number of social bids given by the examiner compared to the number of responses by the child. Additional quantitative data gathered from SALT programming examined Mean Length of Utterance (MLU) and Number of Different Words (NDW). Data has been collected and is currently being analyzed. Group differences and trends will be discussed. Challenges to eliciting verbal social skills during authentic assessment and finding measurement tools for this purpose will also be shared. Adequately and accurately assessing social communication skills to discover trends in characteristics will help increase efficiency in differential diagnosis, leading to increased evidence-based practice for intervention.

Abstract Name: Navigating Pediatric Hematology/Oncology Care Before and After the COVID-19 Era: Understanding the Influence of Social Determinants on Telehealth Visits

Telehealth has emerged as a vital tool for healthcare delivery, particularly during the COVID-19 pandemic, offering the potential to address many social determinants of health (SDOH) for pediatric patients, particularly those in hematology and oncology. These patients often encounter significant barriers to care, such as transportation challenges, financial strain, and disruptions to their education and social networks. By reducing the need for frequent in-person visits, telehealth has the potential to alleviate some of these burdens

while maintaining access to specialized care. However, the extent to which telehealth impacts these social factors equitably remains uncertain. This study investigates how SDOHs, including race, insurance status, language, location, and socioeconomic factors, influence access to telehealth and health outcomes for pediatric patients at Riley Children's Hospital's division of hematology/oncology. The research specifically examines trends in telehealth usage across three distinct periods: pre-COVID-19, during COVID-19, and post-COVID-19. By evaluating these trends, the study aims to assess the impact of telehealth on care access, health outcomes, and equity within this patient population. The hypothesis guiding this research is that, with the widespread adoption of telehealth, healthcare providers may exhibit a preference for certain patient populations, particularly favoring those with lower social determinants of health for virtual visits. To explore this hypothesis, the study seeks to identify barriers to telehealth adoption and assess whether these barriers disproportionately affect certain demographic groups. Understanding these factors is essential for developing targeted interventions that ensure equitable access to telehealth services, particularly for underserved populations within pediatric hematology and oncology. By examining the intersection between telehealth and SDOHs, this research aims to inform strategies that can optimize the delivery of virtual care and improve health outcomes for all patients, regardless of their social or economic circumstances.

Abstract Name: Exploring Awareness and Perceptions of Hospice Care Among Meals on Wheels Clients: A Mixed-Methods Study Through the Visiting Nurse Association

This research study investigates the awareness levels and perceptions of hospice care among clients receiving Meals on Wheels (MOW) which is being conducted through the Visiting Nurse Association (VNA). We hypothesize that clients will exhibit varied levels of awareness regarding VNA services, which correlate with their overall attitudes toward hospice care. Our study explores two main hypotheses: (1) a significant portion of clients will demonstrate limited awareness of VNA services, particularly concerning hospice care, leading to negative associations with these services; and (2) clients with higher awareness will exhibit more positive attitudes towards hospice care, influenced by their understanding and information received. Moreover, we expect there to be a correlation between the amount clients pay for MOW services and their awareness of all services. Additionally, the study addresses the need for services as shown in client responses regarding their primary care providers, medications, and the assistance required for managing daily tasks and assistive devices. By analyzing these factors, we aim to better understand the connection between awareness of VNA services and clients' needs for more comprehensive care. Using a mixed-methods approach, we are going to collect data from approximately 30 clients, examining demographic variability and identifying patterns between awareness, perception of hospice care, and the necessity for supportive services. We will employ qualitative coding and statistical analyses, to uncover relationships between these variables. A thematic analysis will show common themes in client responses, which will magnify misconceptions and positive associations with hospice care.

Abstract Name: Understanding Students' Judgements During Laryngeal Image Interpretation

Overview Developing a future clinician's ability to make visual-perceptual judgments about video recordings obtained during diagnostic laryngeal imaging procedures is a key component of Speech-Language Pathology (SLP) education. These recordings are commonly obtained using a scope passed through the nose or mouth and capture real-time vocal fold vibrations. Such imaging allows for a more detailed analysis of the voice and voice disorders. This study aims to understand how students learn to interpret laryngeal imaging through the use of eye-tracking technology. Eye-tracking provides insight into cognitive processes (e.g. memory, decision-making, and associative learning) being used when examining laryngeal imaging samples.

Method/Procedures Students in the 1st, 3rd, and 5th years of the SLP Program at Duquesne University were asked to sit in front of a computer to watch videos while their eye movements were tracked using the Gazepoint eye tracker, galvanized skin response, and the iMotions software. The study included three experiments where students were asked to make judgements about laryngeal exam videos given case histories, rate physiologic variables (e.g. glottal gap, mucosal wave) and provide how confident they were in that rating, and visually label/verbally describe anatomical structures. **Results** The impact of experience (student seniority and exposure to laryngeal imaging in class content) on necessary knowledge & skills associated with laryngeal exam interpretation will be discussed. Additionally, this study evaluated students' ability to integrate their knowledge of anatomic and physiologic deficits with applicable diagnostic details. Finally, students' confidence of decision when evaluating vibratory characteristics was investigated. Together, these results can have significant implications for teaching students to interpret laryngeal exam findings and may be able to generalize to inform new competency-based techniques to assess student learning.

Abstract Name: The Relationship between Temperature and the Binding of Surface Ligands on Cesium Lead Bromide Nanocrystals

Recently, there has been an increased interest into the research of nanocrystals and their properties. This is due to their facile synthesis and bright photoluminescence emission. One facet of nanocrystal research focuses on the ligands that bind to the crystal's surfaces and play an important role in their physical and chemical properties. This experiment is focused on understanding how the connectivity of ligands bound to cesium lead bromide nanocrystals is influenced by temperature. Cesium lead bromide nanocrystals will be synthesized using oleylamine through the ligand-assisted reprecipitation method under controlled conditions in the laboratory. The bound and unbound populations of ligand molecules were monitored using proton NMR at various temperatures. This data was then used to do a pseudo-Van't Hoff analysis to get thermodynamic trends. This analysis will help us gain a deeper understanding of nanocrystal surface chemistry and the strength of ligands-nanocrystal interactions when variables like temperature are introduced.

Abstract Name: The Effect of Obesity Stigma on Chronic Pain and Opioid Prescription

Previous research has determined that obesity is related to poor health outcomes, particularly due to the associated comorbidities and stigma. Weight stigma is defined as devaluation because of one's weight. Chronic pain is a common comorbidity for obesity. There is an intersection between weight stigma and pain stigma as a study determined a positive correlation between BMI with weight bias and BMI with pain stigma, pointing to an overlap between these two forms of stigmatization. This review explores a biopsychosocial approach to weight and pain and how obesity stigma affects chronic pain treatment, particularly in the prescription of opioids. One study determined that obese patients have a higher burden of pain and adults who are overweight are more likely to receive pain medication than people of normal weight. There is a gap in research looking for correlations between obesity and over prescription of opioids. Additionally, there is a lack of studies determining if opioids are effective in facilitating weight loss. Opioids are prescribed to improve quality of life and reduce suffering. This is at odds with the likelihood of harm – addiction and overdose. Long-term use of opioids for pain management is linked with increased risk of opioid use disorder. Opioids should be used conservatively and in conjunction with other methods for pain control. Particularly for obese patients, weight loss is associated with pain relief. If opioids help facilitate weight loss, there is a reason for increased instances of prescribing to patients. However, if opioids hinder weight loss, the trends observed in increased prescription to obese patients points to overtreatment. This may also stem from physician bias, which indicates that comprehensive treatment plans for chronic pain may be lacking. This review also discusses other behavioral and medical interventions for weight loss and pain management and highlights provider-level interventions.

Abstract Name: Spectral Cartography of Exoplanet Atmospheres

Hot Jupiters are giant gaseous exoplanets in close orbits to their host stars. Their proximity results in high (>1000 K) atmospheric temperatures, providing the best opportunity for observational characterization of exoplanets to date. High-resolution emission spectroscopy has been on the frontier of characterizing hot Jupiter atmospheres, as the spectral features of these atmospheres provide critical insights into their atmospheric dynamics and composition. In particular, hot Jupiter atmospheres are expected to exhibit large day-night temperature differences, suggesting that the emitted spectra may vary depending on the region of the planet under observation. While 3-D models of hot Jupiter atmospheres exist, isolating and analyzing spectral features from specific atmospheric regions has yet to be explored. In this project, we have adapted code to calculate regional spectra and analyze the spectral features using 3-D atmospheric models of the quintessential hot Jupiter WASP-76 b. We find differences in spectral features between the east and west sides of the planet, which may likely indicate distinct chemical and thermal structures for each region. This project expands the field's knowledge of exoplanet atmospheres by understanding their physical properties regionally rather than exclusively globally. Combining this with cutting-edge observational techniques, we can further our understanding of hot Jupiters as complex 3-D objects.

Abstract Name: Neural Plasticity and Affective Pain Behaviors in a Preclinical Model of Pain Associated with Burn Injury

Burn injuries cause severe, long-lasting pain that is challenging to manage, and many patients transition to intractable chronic pain following resolution of the initial injury. Current treatments for burn pain include opioids, non-steroidal anti-inflammatory drugs, and gabapentinoids; all of which come with serious, limiting side effects. To support the discovery of novel therapeutics, it is necessary to improve our understanding of burn pain mechanisms. Preclinical studies are largely conducted in rodents where similar tissue damage, inflammation, and pain occur following burn injury. However, most preclinical studies measure reflexive pain responses and only test male subjects, which limits clinical relevancy. In the present study we examined the affective aspects of pain using the Mechanical Conflict Avoidance System as a clinically relevant behavioral assay. We hypothesized that full thickness thermal injury to the hindpaw evokes significant affective pain behavior in male and female rats. We tested baseline latency to cross nociceptive (injurious) probes from a lit to a dark (preferred) chamber. We re-tested latency 72 hours post-injury, a time point we previously reported reflexive pain behaviors to peak. We report both male and female rats with thermal injury displayed significantly longer latencies to cross the nociceptive probes as compared to sham-injured (negative control)

rats. Following behavior testing, blood was collected, rats were perfusion fixed, and spinal cords were extracted and sectioned onto glass slides. We are currently using fluorescent immunohistochemistry and cytokine arrays to quantify sensory nerve fibers, pain-generating ion channels, and inflammatory mediators to determine changes following burn injury that could ultimately be targeted to reduce burn pain and its chronification. Our data indicate burn-injured rats displayed a significant increase in several key inflammatory mediators known to increase in burn-injured humans. We have further observed a significant increase in pain-generating ion channels that likely contributes to burn pain chronification.

Abstract Name: Investigating Bacteria Resistant to Pathogens in Remediated versus Non-Remediated Soil

The investigation aimed to incorporate Tiny Earth, a student research initiative focused on discovering new antibiotic-producing microbes from soil samples. Soil samples were collected from three different sites at Kettle Moraine State Forest in Wisconsin. Sampling selection was based on differences in soil characteristics of the three sites investigated. The three sites investigated were a burned, sterilized, & remediated site, a burned & sterilized site, and a control site providing a natural representation of the environment. Soil samples were analyzed through microbiological methods, including staining procedures, fermentation testing, motility testing, respiration preference, and more. The primary objective of this investigation was to determine the probability of discovering bacteria with antibiotic-producing capabilities in the different sites sampled. The number of bacteria with antibiotic-producing capabilities, compared to the total number of bacteria tested, resulted in the following probabilities: 0% for the solely sterilized sample, 1.25% for the sterilized and remediated sample, and 3.75% for the control sample. The percentages indicate that the discovery of antibiotic-producing bacteria within all sites sampled is rare. The probability suggests there is a low but greater chance of discovering bacteria with antibiotic-producing capabilities in the undisturbed sites.

Abstract Name: Tensile Testing of Hyaluronic Acid-Chitosan Polyelectrolyte Complex Hollow Fibers

Polysaccharide based hollow fibers have shown promise as a platform for tissue engineered implantable tissues. Specifically, glycosaminoglycan (GAG)-chitosan hollow fibers have shown to support the growth and differentiation of myoblasts as a potential treatment for volumetric muscle loss (VML). This study investigated how fiber composition and structure influenced their suitability as muscle fiber scaffolds by characterizing mechanical properties such as elastic modulus, breaking strain and maximum stress. Fibers formed with varying concentrations of hyaluronic acid (HA), chondroitin sulfate (CSA), and collagen were

fabricated and tested. Hollow fibers were fabricated using a coaxial extrusion process via a 3D-printed coaxial extrusion nozzle, using HA/CSA/collagen as the core fluid and chitosan as the shell fluid. Ionic interactions between the two fluids forms a polyelectrolyte complex constituting the wall of the extruded hollow fiber. Tensile properties of the fibers were measured using a custom-built apparatus comprised of a load cell and a linear actuator to control strain and strain rate. Stress-strain data was collected for fibers of varying GAG concentrations under various strain rates to evaluate the fiber's response to physiological loading. Preliminary results showed that higher HA concentrations and with the incorporation of CSA both increased the elastic modulus. Increasing the GAG concentrations increased the fiber wall thickness, which improved the fibers tensile strength. At higher strain rates, fibers exhibited a higher elastic modulus, indicating viscoelasticity behavior of these ionic complex materials. Future research includes advanced testing, such as stress relaxation and cyclic loading, to further understand fiber behavior. Additionally, preliminary cultures of endothelial cells and smooth muscle cells in hollow fibers to assess responses to varying GAG compositions.

Abstract Name: Disease, Populations and Maize Cultivation

The presence of disease in prehistoric North America is a difficult concept to study due to the lack of physical evidence that is available to study, as most ailments aren't preserved in bone. However, with diseases such as iron deficiency anemia and osteoarthritis leaving evidence on human remains, archaeologists and early historians have been able to draw certain connections between the prevalence of these conditions, the emergence of large-scale agriculture and the boom in populations that we see happen within these communities. Explored will be how each factor, disease, agriculture, and population, affected each other in North America prior to European contact. Most previous scholarly work focuses on one or two of these factors, but not much found in the process of researching was able to connect all three together. Most common was the tie between agriculture and disease, and agriculture and population boom. Archaeological findings and examination is a large part of the information known of diseases, as there was no written language, and most cultural artifacts do not imply disease as a major factor in life at the time. However, there is knowledge of mythological beliefs that can also help with the understanding of the cultural impact of these different factors, along with the scientific evidence such as mtDNA and radiocarbon methods. Research was conducted through both online and physical sources, the University of Kentucky's library database allowing for much of the information to be found. Considerable ties between agriculture, disease and population change are found through combining scientific, archaeological, and mythological evidence, pointing to all three factors working together to create similar conditions as to how we as humans live today. The spread of disease, large-scale agriculture and malnutrition, and a growing population has carried on since it began to become prevalent in North American prehistoric populations.

Abstract Name: Redacted or Otherwise: Religious Exemptions to the COVID-19 Vaccine

The COVID-19 pandemic presented the most rapid development of vaccines of all time, and, in response, scientists introduced a new type of vaccine: one that uses mRNA. The novelty of the vaccine mechanism, the speed at which they were produced, and the involvement of fetal stem cell lines in growing viruses or testing efficacy caused an unprecedented number of people to reject the vaccine on religious grounds. One major difficulty for the government in trying to control vaccination rates is the fact that there is no federal standard for evaluating exemption requests. As such, when certain states and private companies mandated the vaccine, there was no format for approval or denial, and the burden fell largely on Human Resources employees to make the call on whether a belief was sincerely held; the result was sweeping approvals, generally regardless of reasoning. This presentation, based on my Senior Honors Thesis, examines over 1,000 letters submitted by American employees in public and private sectors requesting religious exemptions to the COVID-19 vaccine, obtained through public records requests. The thesis differentiates those that were based on truly religious reasons (objections to fetal stem cell lines) from those that were not (e.g., fears over the chemical contents of the vaccine). It has been widely reported that Evangelical Christians are the group most likely to believe in conspiracy theories and reject the vaccine, so the question is: to what extent are the ideas surfacing in COVID-19 vaccine exemption request letters Evangelical? How are these ideas disseminated via the internet and social media? These findings will be used to inform a new framework for evaluating religious exemptions to civil law that is fair to those who have religious beliefs and also does not threaten public health and safety.

Abstract Name: Modeling Reconstruction Of Fragmented Bones Using MRI Imaging And AI

Background: Traumatic events can cause severe bone fractures, leaving bones fragmented and requiring intricate reconstruction by surgeons. Traditionally, x-ray imaging has been the primary tool for locating breaks and guiding bone realignment. However, x-rays are limited in detecting tissue damage, small bone fragments, and depth details. Increasingly, MRI imaging is used for severe fractures due to its superior contrast and depth capabilities. These features also enable software-based analysis to map bone outlines. Augmented Reality (AR) enhances spatial reasoning, making it a valuable tool in preoperative planning, particularly for complex cases like skull reconstruction. Methods: Using MRI imaging combined with machine learning (ML) to identify and differentiate between bone fragments and imaging artifacts. A mixed-reality (MR) approach will be employed to visualize and assist in the reconstruction process, enhancing spatial understanding for surgeons. The ML model will analyze MRI images to identify bone fragments and propose reconstructions, which will be visualized through AR for surgeon evaluation. We plan to evaluate the approach by comparing the Euclidean distance between key anatomical points in surgeon reconstructions and ML-assisted reconstructions, assessing precision and spatial accuracy. Results: While data collection is ongoing, preliminary testing with simulated MRI data demonstrates the potential of ML models to outperform human accuracy in differentiating bone fragments from image artifacts. Conclusion: The integration of ML, MRI imaging, and AR offers significant potential to enhance surgical planning, particularly in complex cases like

skull reconstruction. AI-assisted MR visualizations could improve preoperative planning accuracy and efficiency, enabling surgeons to achieve better alignment and faster reconstructions. By bridging the gap between imaging and spatial reasoning, this approach could redefine fracture management and improve patient outcomes.

Abstract Name: Effects of Rainfall on Conductivity in the Spearford Gully, Houston, TX

This study investigates whether sediments deposited into the water by rainfall influence the conductivity levels within the Spearford Gully at Lone Star College-University Park. Previous research in this gully in 2022 determined that temperature had a measurable effect on the quality of the stream water and that an unknown factor influenced the conductivity of the water (Flores, 2022). Conductivity is a key metric for evaluating water quality, especially in streams, due to its ability to detect the introduction of organic material. Data collection for this research involved hourly monitoring of conductivity, depth, and turbidity over 24 days in March 2024 with a water sonde placed into the Spearford Gully. A nearby Harris-county rainfall gauge was used to collect rainfall data for this period. In the five recorded rainfall events, heavy rainfall resulted in increased sediment turbidity and decreased conductivity, confirming the effect of rainfall on turbidity and suggesting a potential relationship with conductivity. However, further data on larger rainfall events is necessary to confirm this relationship. Additional unexplained external factors (e.g., human activity) affected the data, highlighting the complexity of natural water sources and the various ways water quality can be influenced. This investigation into how rainfall affects conductivity is a significant step toward better understanding the factors impacting water quality such as organic material content. Post rainfall events, lower conductivity values (i.e., fewer dissolved ions or impurities within the water) indicate higher water quality in the Spearford Gully.

Abstract Name: Chimaera: a tethered UAV enhancement to proximal sensing carts and UGVs

Small Uncrewed Aerial Vehicles (sUAVs) are a commonly used tool for agricultural remote sensing due to their capability of carrying a variety of sensors including hyperspectral and LIDAR. Tethered Uncrewed Aerial Vehicles (tUAVs) offer theoretically infinite endurance while maintaining most of the flexibility of a UAV. Proximal sensing carts (PSCs) and Unmanned Ground Vehicles (UGVs) offer large payloads and increased endurance compared to UAVs. Combining UAVs and PSCs can be used to provide a flexible sensor mounting platform that is less dependent on the terrain, is flexible in height, and offers dynamic flexibility in

positioning the sensors, all while increasing endurance. Presented here is a bolt-on solution for a marsupial tethered UAV designed to operate either in tandem with or independently from its mother vehicle. It is designed to work either as a part of a Manned-Unmanned Team (MUM-T) with a human powered cart or work autonomously with an UGV. The tradeoffs of the system are analyzed focusing on weight, cost, and complexity. The use of a tUAV is demonstrated by gathering hyperspectral imagery from local area winter crops. Usability can then be determined by comparing it with ground based and non-tethered UAV sensing by using IMU data and changes in the Modulation Transfer Function to determine the stability of the drone and image quality of the camera, respectively.

Abstract Name: Clashes in American Civics Education: Tulsa, Philadelphia, and Generation Citizen

The importance of civics education is well studied in the field of American education. The Political Science and Politics journal has recognized civics' role in a functioning democracy since the early 2000s. Although most Americans agree on the importance of civics, an increasingly politicized climate has created tensions over how it should be taught. My research addresses the disagreements within the field and examines the underlying causes of these tensions in American communities. Focusing on the case studies of Tulsa and Philadelphia—two cities with very different responses to the civics program Generation Citizen—this study sheds light on the factors that shape how civics education is implemented and perceived. Through interviews with school board members, Generation Citizen staff, participant observation, and local research, I highlight the role of grassroots organizations, local politics, and specific civics pedagogy in shaping the perception of a civics program. Additionally, the project explores the role of civics in different political communities and the concept of neutrality in the American classroom. These insights contribute to the broader conversation about the civics education gap and the growing political polarization in the United States.

Abstract Name: Environmental Predictors of Mosquito-Borne Diseases

Some mosquito species are vectors of diseases like Malaria, Dengue, Yellow fever, West Nile virus (WNV), and more. The culex species is the main vector of WNV, the predominant mosquito-borne disease in Oklahoma. This project aims to understand how different environmental variables contribute to the abundance of mosquitoes and the presence of certain species and create models to predict mosquito abundance and the diseases they carry. Google Earth Engine (GEE), leveraging advanced remote sensing

technologies, was used to obtain datasets from which environmental variables (air temperature (Modis), solar radiation (NLDAS), precipitation (GPM), wind speed (GLDAS), soil moisture, and relative humidity (Gridmet)) were examined, visualized, and extracted. Scripts made in the GEE code editor were translated into Google Colab, which was used to update and expand the code to examine, visualize (using charts, tables, and interactive maps), and extract the environmental data for mosquito trap sites in Central Oklahoma and Tulsa. To ascertain the accuracy of the remote sensing & modeled data, they were compared to reference data collected from the Oklahoma Mesonet, a network of ground-based environmental monitoring stations. ANOVA was used to determine if the differences between the data from the various sources were statistically significant. The ultimate goal is to identify which environmental variables and land cover characteristics are the best predictors of mosquito abundance, potentially revealing species-specific conditions that could inform disease transmission risk. Initial results indicated that maximum temperature data from 2018-2023 obtained from Modis was significantly different than that of Mesonet with p-values much less than 0.05.

Abstract Name: Advance textiles as heterogeneous photocatalysts for synthesizing complex organic compounds

The use of textile materials as substrates for heterogeneous catalysts can revolutionize the synthesis of pharmaceutical drugs and fine chemicals. The state-of-the-art protocols to synthesize complex organic compounds suffer from the use of toxic heavy metals as reagents or homogeneous catalysts. Extensive purification must be performed to remove these metal contaminants, which makes the overall process less efficient and more expensive. Herein, I propose a method to develop cleaner and greener heterogeneous photocatalysts by covalently attaching metal-free molecular photocatalysts to textile substrates such as glass wool and cotton. These metal-free photocatalyst-dyed textile substrates will have low toxicity and drive organic reactions under visible light illumination. In this research, I will assess how the extent of photocatalyst loading on textile substrates affects the reaction yields and selectivities. Moreover, the textile substrates will greatly facilitate the recycle and reuse of these catalysts, making organic syntheses more sustainable. We're in the process of synthesizing sulfoxides through the oxidation of sulfides, which are important functional groups used in pharmaceutical drugs.

Abstract Name: How does one allow another to be an Other? Philosophical dimensions of guilt and forgiveness

Present-day cultural commentators often call attention to the increasingly siloed character of modern society: more and more, it seems that when people do gather, it tends to be with those who are already like

themselves. This tendency to gather only with those who are like us reflects the violence that philosopher Emmanuel Levinas diagnosed as the reduction of the Other to “the same,” that is, to what one already knows, expects, or is comfortable with. In response to this violence, Levinas developed an ethics of Otherness, based on preserving the otherness of the Other in our encounters with her. However, this ethics of otherness risks its own violence—for example, keeping the other at a distance—as pointed out by James Olthuis in his recent book *Dancing in the Wild Spaces of Love*. My project uses Olthuis’ understanding of “non-oppositional difference” to develop an ethics of community that avoids these twin violences, based on a radical vision of love as healing division without erasing otherness. To do this, I explore the influence on Olthuis’ thinking of philosopher and psychoanalyst Julia Kristeva, whose discussion of guilt and forgiveness explores how both meaning and healing can come through the linguistic encounter in which psychoanalysis is conducted. Together, Olthuis and Kristeva chart a path toward reconciliation and community that requires us to relearn and redefine the ways in which we encounter one another.

Abstract Name: Nina Simone for Social Change

Music has been used globally and historically as a tool to bring about change. It’s a way to amplify voices that may otherwise not be heard and to share ideas on a broad scale. Nina Simone (1933-2003) was an American singer and pianist who used music to advocate for change, to address oppression and the need for equality of every kind. Her early training was as a classical pianist and Gospel musician, but she grew to make music that also encompassed jazz, Blues, Soul, Rhythm & Blues, pop, and protest. She was sometimes seen as a controversial figure both because she did not fit into one defining musical genre, and, more so, because she unapologetically spoke out against societal injustices of every kind. In this paper, I address the following research question through the lens of the social theory of feminism: How does Nina Simone use anger, grief, and self-determination in her music to address marginalization and fight for social justice? After briefly explaining my personal connection with Nina Simone’s music, I will introduce my perspective on the social theory of feminism. My approach is particularly informed by bell hooks, who defined feminism as “to want for all people, female and male, liberation from sexist role patterns, domination, and oppression.” I will then consider Nina Simone in relation to feminist movements. I will explore reasons that the second-wave feminism of the 1960s and beyond did not resonate with Simone as an African-American woman, but also argue that Simone’s life and works can be considered instead as resonant with modern conceptions of feminism in intersectional contexts. Finally, I will analyze three of Nina Simone’s songs in light of such an intersectional feminism: “Mississippi Goddamn” (1964), “Pirate Jenny” (1964), and “Four Women” (1966).

Abstract Name: Children's Generalizations of Other's Fairness and Competency

How do children pick peers to cooperate with or be friends with? Prior research has shown that children can use prior behavior to predict future behavior; however, the findings on how this occurs are mixed. They may assume that people who are good at one thing are good at all things, or they may be able to identify specific character traits. Two important behavioral domains related to children are competency (behaviors indicating task performance) and fairness (behaviors indicating sharing tendencies). This pilot study examined if children generalize behaviors within domains (within competency or fairness) and between domains (from competency to fairness and vice versa). Participants included 31 children aged 5–10. Half of them observed a child performing well or poorly on a task (competency manipulation), and half observed a child sharing equally or unequally (fairness manipulation). After this observation, the children predicted how well this child would perform on a task and how fairly they would share. We hypothesized that children would generalize within the competency domain to a lesser extent than they would generalize within the fairness domain. Opposed to this, preliminary results found that the competency manipulation had a larger effect on later competency predictions ($d = 1.29$) than the fairness manipulation had on fairness predictions ($d = 0.63$). Furthermore, the fairness manipulation had a larger effect on later competency predictions ($d = 0.82$) than the competency manipulation had on fairness predictions ($d = 0.49$). This suggests that 5- to 10-year-old children do generalize within and between domains; however, future research will analyze a larger sample size to investigate the effect of age and draw more accurate conclusions on if and how children generalize between and within domains.

Abstract Name: Dimensional variability in 3d prints

In this research we try to find out the causes for the difference found between print dimensions and design dimensions. When a part is designed on a computer, the dimensions measure slightly off after being printed. We came up with a simple “pin” geometry that was printed and measured with a micrometer many times, changing different variables. The variables studied were, layer height, print speed, nozzle temperature, and variability between printers. Geometry was kept the same, filament stayed as PLA, and infill stayed at 10%. Design-of-experiments was used to analyze the data and draw conclusions as to what variables affected dimensional variability the most. We found that nozzle temperature had the greatest effect on dimensional variability. Using the results of this research 3d printed parts can be designed with greater accuracy and less guesswork. Further research will help to someday eliminate measurable variability when printing.

Abstract Name: How Making Decisions on the Behalf of Others Influences Temporal Discounting

People often value rewards less when they are delayed, leading to a preference for smaller immediate rewards over larger delayed ones; this is called temporal discounting. The context of these decisions influences discounting severity and can promote self-control (choosing the delayed option) or impulsivity (choosing the immediate option). In particular, social distance is important when people decide on behalf of others; however, the limited existing research has provided mixed results. There are open questions regarding how the subjective value of rewards depends on who receives the reward and how many people are impacted. This study aims to investigate how temporal discounting rates are influenced by choosing between smaller immediate and larger delayed rewards for others. I will recruit 200 online participants through Cloud Connect. Participants will be randomly assigned to conditions in a 2 (social relationship: friend or acquaintance) x 2 (group size: individual vs. group) fully crossed between subjects' design. Based on condition, participants will choose between monetary rewards for one friend, one acquaintance, five friends, or five acquaintances. I will utilize analysis of variance to test for main effects of each independent variable and the interaction terms between both variables. I hypothesize that (1) participants deciding for friends will discount more than those deciding for acquaintances, (2) those deciding for five friends will discount more than those deciding for one, and (3) those deciding for five acquaintances will discount less than those deciding for one. This would indicate that, when people make decisions for people they do not know, they are more likely to focus on long-term consequences; however, when people make decisions for people they know well, they are more likely to focus on short-term consequences. Additionally, when people make decisions for groups, the increased number of people exacerbates the tendencies already shaped by social relationships.

Abstract Name: Mommy's Gone Down the Rabbit Hole: Understanding the Intersection Between Motherhood and Conspiracy Theories in the United States From the 1970s to the Present Day

When picking up my sister from school, I noticed a woman wearing a shirt that read, "Unvaccinated, Conservative, Meat Eating, Gun Owner. How else can I piss you off today?" Such provocative messaging reflects the growing polarization in the United States over the past decade, accompanied by a surge in conspiracy theories. Historically, women have often been overlooked as active participants in conspiratorial thinking, yet motherhood frequently serves as a driving force behind such ideologies. This phenomenon is visible in groups like Moms for Liberty and viral school board confrontations, as well as in QAnon's "satanic pedophile deep state" conspiracies. While these trends are often framed as new, their roots run deep. This study examines the work of Mae Brussell, a prominent figure in the 1970s and 80s whose obsession with the JFK assassination and "deep state" conspiracies mirrors modern rhetoric. Interestingly, Brussell was embarrassed by the far left, including figures in the Yippie movement, highlighting an earlier, left-leaning orientation in conspiratorial discourse. How has the pendulum shifted from left to right in conspiracy thinking? How does gender influence conspiratorial belief and the motivations behind it? By exploring the intersection of motherhood and conspiracy theories, this study provides historical context to better understand these contemporary dynamics.

Abstract Name: Individualizing Memorialization Practices of Mass Death

Efforts to memorialize cases of mass death, such as war, genocide, or epidemics, face the challenge of remembering both the enormity of loss and the individuality of victims. In this paper, I investigate the way that communities and loved ones seek to individualize victims of mass death, through the case study of quilts made to commemorate those killed in 9/11. I draw from a body of research by anthropologists and historians who study cultural memory, memorialization, and individuation. Although anthropological research on the topic of memorialization and personhood is available, there is a lack of anthropological research on practices of individuation in contemporary memorialization. I seek to bridge this gap by utilizing the work of historians and other memory studies scholars who document trends of memorialization throughout history. A purposive sampling interview with experts and practitioners in the field of 9/11 memorialization serves as the foundation for my detailed analysis of quilts made in memory of victims who died in 9/11. The 9/11 Memorial and Museum's collection of quilts is an assemblage of multimedia quilts of varying scales and sizes, made by both amateur and professional quilters across the world. They cover a variety of themes, ranging from peace and spirituality to memorials for both individuals and groups of victims. Out of the larger collection, I have chosen to analyze a sample of four quilts which best display the diversity of individualizing techniques often used in these projects, such as naming, images, symbols representing the victim's life and interests, 3D objects, and representation of the loved ones left behind. Each of these elements documents the life and personhood of the victim, combating the anonymity that mass death often imposes on victims.

Abstract Name: Modeling Blood Flow Dynamics and Arterial Wall Mechanics in Stenting Surgery Using COMSOL

Stenting surgery is a critical intervention for restoring blood flow in occluded arteries, yet it alters the biomechanical environment of blood flow and arterial walls, which can influence long-term outcomes. This research investigates the dynamics of blood flow and arterial wall mechanics before and after stenting surgery using computational modeling. The study aims to address the central question: How does stenting affect hemodynamic parameters and arterial wall stress, and what insights computational models can provide for optimizing stent designs. The project builds on prior research highlighting the interplay between blood flow dynamics and arterial wall responses with a focus on improving patient outcomes. However, this study uniquely integrates pulsatile blood flow modeling and arterial wall deformation using COMSOL Multiphysics 6.2, providing a comprehensive analysis that bridges fluid dynamics and solid mechanics. The methodology involves creating a 3D model of a stenosed artery, stimulating pulsatile blood flow using the Navier-Stokes equations, and coupling it with the structural mechanics module to analyze arterial wall deformation. Pre- and post-stenting conditions are compared to evaluate changes in flow patterns, wall shear stress, and strain distributions. Expected results include identifying critical regions of altered flow and stress that could predict restenosis or complications. The findings will be contextualized within clinical considerations, offering insights for stent design improvements and personalized surgical planning. By

integrating advanced computational tools and physiological modeling, this research aims to contribute to the optimization of stenting procedures and enhance vascular health management.

Abstract Name: Development of Data Processing Procedures to Facilitate Detection of Lucid Episodes in Dementia

Lucid episodes (LEs) are described as an unexpected return of abilities previously believed to have been lost among individuals with Alzheimer's disease and related dementias (AD/ADRD). Due to the early stage of lucidity research, standard definitions have not yet been developed and their rare presentation makes them difficult to study. Audiovisual observations can advance research on this phenomenon and support progress toward a precise definition. But the time-intensive nature of processing high volumes of audiovisual data presents challenges for timely detection of LEs and subsequent analysis. As part of a prospective observation study, over 1800 hours of audiovisual data have been collected from participants living with AD/ADRD in a dementia-specific hospice unit. Standardized data processing methods were developed to 1) support systematic review of data to detect LEs and 2) create segments to facilitate analysis. All data is reviewed for significant variations from a participant's expected routine fluctuation in abilities, thereby identifying potential LEs, and prioritized for further analysis of verbal/nonverbal activity within identified LEs and baseline segments. Video data is classified and parsed into two categories: codable and non-codable data. Codable data contains participant verbal and/or nonverbal activity, included within the pre-defined coding scheme (e.g., eye gaze, gestures, vocal communication). These data segments are advanced to coding and analysis procedures, along with identified LEs. These procedures present opportunities for increased efficiency of audiovisual data processing, review, and analysis. This is important when LE validation relies on informant appraisal, conducted in close temporal proximity to the occurrence. However, subtle LEs, defined as non-apparent LEs, are challenging to detect through an expedited data review and will not be detected unless indicated in previously prioritized codable data during analysis. Overall, these procedures achieve the goals of expedited LE detection and efficient data segment creation for coding and analysis.

Abstract Name: Structural Basis for HIV-1 Matrix Maturation

Considerable interest is directed towards identifying the structural determinants of Human Immunodeficiency Virus Type 1 (HIV-1) assembly and maturation. In recent years, numerous discoveries and advancements in technology have contributed toward understanding assembly but the structural basis of HIV-1 maturation is not well understood. During the late phase of the HIV-1 infection cycle, the newly synthesized Gag polyproteins are targeted to the plasma membrane (PM) for assembly, a process mediated by interactions between the matrix (MA) domain and phosphatidylinositol 4,5-bisphosphate (PI(4,5)P₂). Recruitment of the envelope (Env) protein to the PM for incorporation into virus particles occurs concurrently with Gag assembly. Mounting evidence suggests that a well-formed MA lattice is essential for Env incorporation and infectivity of the mature virus. Recent studies revealed that the MA forms distinct lattices during assembly and upon maturation. Moreover, it has been shown that a small peptide in Gag, spacer peptide 2 (SP2), plays an integral role in MA maturation. The structural details of mature and immature MA lattice bound to lipid membranes emulating PM, factors that govern the MA conformational switch, and components that (de)stabilize the lattice during assembly and upon maturation are still lacking. Our lab employs biochemical, biophysical and structural biology techniques (cryo-electron microscopy (cryoEM), NMR, and x-ray crystallography) to investigate HIV-1 assembly, maturation and Env incorporation. We devised a “controlled assembly” approach coupled with cryoEM to generate biologically authentic substructures of the immature and mature MA lattices. We also used these techniques to directly explore and map the interaction of SP2 with HIV-1 MA. Our discoveries may pose an opportunity to develop new targeted antiviral therapeutic agents that precisely disrupt assembly, MA maturation, and ultimately virus production.

Abstract Name: Discrimination of the Hoa: Historical Tension, Threat Perception, and the Country-of-Origin Effect on the Ethnic Chinese Community in Vietnam

In the richly intertwined history of China and Vietnam, the Hoa, or ethnic Chinese communities, have long existed in both rural northern regions and urban centers such as Saigon, developing a mixed identity. By the end of 1979, following the Sino-Vietnamese War, 250,000 Hoa sought refuge across Southeast Asia due to discrimination against their Chinese identities. Since then, similar incidents of discrimination have arisen in Vietnam. Often in response to protests against the People's Republic of China, such as the 2014 protests over the South China Sea, protests have led to the burning of Chinese-owned businesses. In recent years, the geopolitical rivalry between China and Vietnam has intensified, particularly over territorial disputes and Chinese foreign direct investment. This paper explores whether discrimination against the Hoa is driven by nationalism—defined as loyalty to one's country—or by ethnonationalism, rooted in shared cultural and ethnic attributes. It also examines how Vietnamese citizens define national identity, or "Vietnameseness." The study conducts a survey-embedded question-wording experiment with 600 Vietnamese citizens currently residing in Vietnam, focusing on individuals with college or higher education. Additionally, the study compares attitudes toward discrimination across different ethnic migrant groups in Vietnam, such as the Hoa, Thai, and Khmer, to determine whether discrimination is generalized or driven by specific ethnic identities. Understanding the form of nationalism is crucial for determining whether discrimination is a response to geopolitical tensions or whether it is a broader social phenomenon independent of such tensions.

Abstract Name: The Gut-Brain Axis of Alzheimer's Disease: Understanding the Cellular Changes in the Gut and Its Implications for Future Diagnosis Approach

Alzheimer's Disease (AD) is a neurodegenerative disorder that leads to gradual decline in cognitive function. This study examines the difference between goblet cell counts in healthy individuals and AD patients, and how those differences, if any, correlate with AD pathology. Recent studies suggested that AD might manifest its pathologies in the enteric nervous system via the gut-brain axis. The gut-brain axis is a bidirectional communication network between the central nervous system (CNS) and the enteric nervous system (ENS), which is the collection of nerve cells lining the gut. The ENS, also known as the "second brain", directly communicates with the CNS via the vagus nerve. Within the ENS, goblet cells play a critical role in maintaining homeostasis in the colon and small intestine by synthesizing and secreting mucus. Depletion in goblet cell counts, which results in a lack of mucus, can lead to intestinal inflammation in the ENS and subsequently neuroinflammation in the CNS. Rats that expressed Alzheimer's symptoms had a significant goblet cell loss in both the colon and small intestine. Such decrease in goblet cells associates with AD's pathology. We collected colon and small intestine samples from healthy individuals and AD patients, followed by comparing the goblet cell counts from collected tissue samples between the two groups. We expect to see less goblet cells in AD patients in comparison to healthy individuals, which would align with how there was less goblet cells in AD-rats than control-rats. With our expected result, we could potentially improve the current diagnosis process by monitoring goblet cell counts in at-risk AD patients before their symptoms onset, thus making this a more definitive diagnosis method.

Abstract Name: Associations Between Recalled Memories of the ICU Stay, Delirium, and Mental Health Outcomes in Critical Illness Survivors at 1-Month Follow-Up in a Critical Illness Recovery Center

Rationale: Critical illness survivors often experience anxiety, depression, and PTSD due to traumatic experiences, sedation, and delirium. Early interventions of psychological support may help mitigate mental health deficits post-ICU. Memory of the ICU stay may play a key role in addressing trauma. We sought to determine the relationship between ICU memory recollection, in-ICU delirium, and mental health outcomes at 1-month follow-up in a critical illness recovery center. Methods: We analyzed data collected at 1-month follow-up in a critical illness recovery center seeing adults who had ICU stays of ≥ 4 days with sepsis,

respiratory failure, or delirium. Patients were asked, “Do you remember your experience in the ICU, and if so, can you describe your most impactful memories?” and we qualitatively coded responses for presence and type of memories described. We analyzed associations between demographic, clinical, and mental health measures and memory recollection using unadjusted comparisons. Results: Among 196 patients seen at 1-month follow-up, 96 (49%) reported memories of their ICU stay. Of these, 44 (46%) described support they received in the ICU, 36 (38%) recalled delusions and/or hallucinations, 35 (37%) remembered specific treatments, and 33 (34%) described symptoms. Baseline characteristics and critical illness features are shown in the Table. Those without memories had more delirium days than those reporting memories ($p=0.02$). Although PTSD and anxiety symptoms at 1-month follow-up were not associated with memories, patients who remembered their ICU stay had fewer depression symptoms ($p=0.04$). Conclusions: One month after critical illness, half of survivors recalled their ICU experience, with memories ranging from supportive interactions to distressing experiences. Memory recollection was associated with fewer depressive symptoms during follow-up. Memories of the ICU may provide a therapeutic foundation for interventions targeting depression after critical illness, like exposure therapy or ICU diaries, which may improve mental health outcomes in critical illness survivors.

Abstract Name: Severe Hypoglycemia causes Neuronal Inflammation and Cell Death

Background: Severe hypoglycemia is a serious complication for individuals with insulin-treated diabetes, and may cause brain damage resulting in memory deficits and cognitive impairments. The areas most affected by severe hypoglycemia are the learning and memory areas of the brain, such as the hippocampus. This project aims to examine pathologic mechanisms by which insulin-induced severe hypoglycemia induces brain damage in a novel rodent model. Methods: To induce brain damage, 10-week-old male Sprague-Dawley rats underwent a single episode of severe hypoglycemia (10-15 mg/dL for 90 minutes) via a subcutaneous injection of Humulin R insulin (15U/mg.kg) and compared to a control cohort of saline injected rats that maintained euglycemia (90-120 mg/dl). One week following the intervention, the animals were sacrificed, perfused and their brains extracted. To identify potential mechanisms by which neuronal damage from severe hypoglycemia occurs, brain sections (40 μ m) of the hippocampus were obtained for immunohistochemistry staining using Iba-1/CD68 (microglial immunoactivity marker), Cleaved-Caspase-3 (CC3 – marker for apoptosis), and Fluoro-Jade-C (FJC -marker for neuronal degeneration). Stains were analyzed using ImageJ software and total number of cells were analyzed using a Student's t test. Results: In comparison to control rats, rats that underwent insulin-induced severe hypoglycemia had four-fold more FJC+ cells ($p<0.05$). Similarly, the severe hypoglycemic group had a four-fold higher number of cells that expressed CC3 in comparison to control animals ($p<0.001$). Iba-1/CD68 staining was five-fold higher in the severe hypoglycemic group in comparison to controls ($p<0.0001$). Conclusions: In this novel rodent model, insulin-induced severe hypoglycemia caused hippocampal brain cell death indicated by increased FJC and CC3 immunohistochemistry staining. Severe hypoglycemia also caused neuronal inflammation indicated by Iba-1/CD68 staining. Identifying mechanistic pathways of brain cell death induced by severe hypoglycemia will help direct potential treatment modalities

Abstract Name: Development of Synthetic Palliative Care Data through Generative Adversarial Networks

In this study, we developed a method to generate synthetic palliative care data utilizing a Generative Adversarial Network (GAN) architecture comprising a generator and a discriminator, in compliance with the standards outlined in the Palliative Care Clinical Data Set: Guidance and Definitions. Initially, the Faker library was employed to create a preliminary dataset that emulates real-world palliative care data, including variables such as patient initials, birth dates, gender, ethnicity, referral dates, care settings, and various health status indicators like functional status, pain levels, breathlessness, and anxiety distress. The dataset underwent normalization via MinMaxScaler and was divided into training and testing subsets to prepare for GAN training. The generator model was architected with dense layers and batch normalization to produce realistic data samples from random noise inputs, while the discriminator model was designed with dense layers and dropout regularization to effectively distinguish between authentic and synthetic data samples. Both models were compiled using the Adam optimizer and a binary cross-entropy loss function to optimize performance. The GAN underwent training over 10,000 epochs, during which the generator incrementally enhanced its capability to produce data that the discriminator could not differentiate from actual data, thereby refining the quality of the synthetic outputs. Post-training, the generator was employed to generate new synthetic data, which was subsequently rescaled to its original value range using inverse normalization techniques. The resultant synthetic dataset was saved in CSV format for ease of use in subsequent analyses. This approach not only illustrates the potential of GANs in generating high-fidelity synthetic palliative care data but also provides a framework that can be leveraged for research and analytical purposes, particularly in areas where data privacy and scarcity are significant concerns. We want to thank the Kingfisher Institute Mini-Seminar for supporting our research.

Abstract Name: Evaluating Protective Effects of Vitamin B12 on Amyloid-Beta Toxicity in *Caenorhabditis elegans*

Previous studies have demonstrated a neuroprotective effect of vitamin B12. This study investigates these effects on paralysis induced by amyloid-beta in *Caenorhabditis elegans* (*C. elegans*) to determine an effective dose of vitamin B12. The transgenic strain CL4176, which expresses amyloid-beta upon a temperature shift, was used to model toxicity and subsequent paralysis. A paralysis assay was conducted over eight hours to evaluate time-to-paralysis in four experimental groups: control, and animals grown on plates supplemented with 75 nM, 150 nM, or 300 nM vitamin B12. Our results show that *C. elegans* expressing amyloid-beta

exhibit an 80% reduction in motility compared to the wild-type strain CL802. However, motility was rescued in animals grown on plates containing vitamin B12, regardless of the concentration. Immunostaining confirmed amyloid-beta aggregation following the temperature upshift, although vitamin B12 treatment did not reduce aggregate size. This study builds on existing research by reaffirming vitamin B12's neuroprotective effects against amyloid-beta toxicity and highlighting the complexity of its mechanisms. These findings contribute to a deeper understanding of potential therapeutic interventions for amyloid-beta pathology.

Abstract Name: Environmental Factors Affecting E.coli Levels in Kinnickinnic River

The purpose of this investigation was to determine the environmental factors affecting E. coli levels in the Kinnickinnic River at three sampling sites in Milwaukee: Zablocki Park, Wilson Park, and Jackson Park. This research holds significant value for the community, as the data collected is shared with Milwaukee Riverkeeper, a nonprofit organization dedicated to monitoring the river's overall health. E. coli, a pathogenic bacterium found in waterways, can cause illness in humans, making it crucial to monitor its levels to ensure public safety and health. During the summer, water samples were collected four times from each of the three sites along the Kinnickinnic River. These samples underwent a series of tests, including a presumptive test, a confirmed test, and a completed test. The presumptive test is when the water sample is aseptically added to lactose broths; tubes were incubated for 24 hours at 37°C. Durham tubes with a gas bubble of 5mm or greater were marked as positive. Second, the confirmed test is where an Eosin-Methylene Blue (EMB) agar plate was inoculated for every positive lactose tube and incubated at 37 °C for 24 hours. After 24 hours, all plates with metallic green were recorded as positive for E. coli. Last, the completed test is where all EMB plates that were positive for E. coli were used to inoculate an agar slant. The slants are gram stained, and microscopy is used to determine the presence of E. coli. The results indicated that E. coli levels were impacted by water and air temperature, water velocity, pH levels, trash, and wildlife.

Abstract Name: d-translated Unit Sensitive Primes

Erdős first introduced the concept of covering systems in order to study the integers with a finite set of arithmetic progressions. In recent years this technique has been replicated to construct arithmetic progressions of Sierpiński numbers, Riesel numbers, Brier numbers, digitally delicate numbers, widely digitally delicate numbers, and many more. We use this technique to construct an arithmetic progression of unit sensitive and

d-translated unit sensitive integers. Let an integer be d-translated unit sensitive when translating the number d digits forward and changing the new unit digit to any base 10 digit results in a composite number. We provide the first known example of such a prime number that is d-translated unit sensitive for any positive integer d.

Abstract Name: Behavioral and Developmental Effects of Lead Acetate Exposure in Embryonic Zebrafish

Lead toxicity poses a major threat to organisms exposed to high concentrations, particularly affecting development and behavior. This investigation uses AB strain zebrafish (*Danio rerio*) as the model organism to examine environmental lead's effects on both development and behavior. Zebrafish were harvested post-fertilization and exposed at gastrulation to 0.4 and 0.8 $\mu\text{g/mL}$ lead acetate concentrations. Following two days of lead exposure, the embryos were washed and incubated for three or seven days. The zebrafish exposed to 0.4 $\mu\text{g/mL}$ concentration underwent the light/dark locomotion test seven days post-fertilization. This assay uses Zebrabox for automated tracking of speed and distance. Light/dark locomotion test results showed lower activity in response to light/dark compared to controls. The optomotor assay, which examines response to simulated current, found reduced response in exposed compared to controls. For circle swimming behavior, a video of the response to light/dark was recorded three days post-fertilization. The fish exposed to 0.4 $\mu\text{g/mL}$ and 0.8 $\mu\text{g/mL}$ at three days showed circle swimming in the groups treated with lead, which was absent in controls. The 0.4 $\mu\text{g/mL}$ concentration group showed slightly more circle swimming behavior than the group treated with the 0.8 $\mu\text{g/mL}$ concentration. For the thigmotaxis behavior assay, the measurement of larvae staying near dishes periphery, a video of the response to light/dark was recorded seven days post fertilization. Thigmotaxis increased in the group treated with 0.4 and 0.8 $\mu\text{g/mL}$ concentration, relative to untreated controls, but the group treated with the 0.8 $\mu\text{g/mL}$ concentration was unexpectedly less than 0.4 $\mu\text{g/mL}$ concentration. Future steps include examining morphological defects.

Abstract Name: Using the Black Immigrant Literacies Framework to Establish Relevance to Teaching

My co-authorship of a book review of Black Immigrant Literacies: Intersections of Race, Language, and Culture in the Classroom examines the Black Immigrant Literacies framework that Dr. Patriann Smith proposes to support Black immigrant students by redefining the standard of "acceptable literacy." She proposes leveraging their unique literacies and lived experiences to establish relevance to teaching. My co-author and I compiled the book review by analyzing other works by Smith, connecting to relevant educational theory, and by sharing our lived experiences. Research will continue to be conducted by referencing scholarly

articles and engaging in discussions with educators. Smith's framework consists of five key pillars: the claim to the struggle for justice, the myth of the model minority, a transraciolinguistic approach, a focus on local-global approaches, and the use of holistic literacies. Three elements of her framework—the claim to the struggle for justice, the myth of the model minority, and the repurposing of local-global approaches discuss the unique struggles that Black Americans and Black immigrants face within the United States, but they also recognize that both Black Americans and Black immigrants still possess literacy rates well below the standard, which creates a need for unification to bridge the literacy gap. The transraciolinguistic approach discusses how understanding the interplay between race, language, and culture, contribute to how we make meaning of the world by examining literacy through a metalinguistic, metaracial, and metacultural approach. This framework equips educators to explore how reshaping the standard of literacy to be more holistic will leverage student assets and funds of knowledge to inform pedagogy.

Abstract Name: Touch Chemistry: Detecting Over the Counter Drugs (OTC) in Developed Fingerprints

Latent fingerprints can be key evidence in criminal investigations because they are unique identifiers. However, more information than just the identity of the person can be found in fingerprints. Touch Chemistry examines fingerprints for other materials or substances that have previously been touched. This is based on Loccard's exchange principle that says when two items come into contact there will be an exchange that results in physical evidence. Touch Chemistry can have practical applications to identify both the substance that was handled as well as the individual handling it. Substances that can be detected include explosives, paints, blood, and drugs. This research will focus on detecting drugs. There have been many forms of drug testing in the forensic science field over the years, including blood and urine testing. However, Touch Chemistry can allow forensic scientists to test for the presence of drugs from fingerprints. It has been found through various instrumentation that drugs can be extracted from undeveloped fingerprints. However, minimal research has been performed to analyze the effect of fingerprinting techniques on the detection of drugs from fingerprints and none of them utilized liquid-chromatography triple quadrupole mass spectrometry (LC-QQQ-MS) for analysis. This research will evaluate a variety of fingerprinting techniques to determine if the development will interfere with the detection of over the counter (OTC) drugs by LC-QQQ-MS. Popular fingerprinting techniques such as black powder, magnetic powder, ninhydrin, DFO, and cyanoacrylate fuming will be tested. OTC drug contaminated fingerprints will be deposited onto glass slides and paper. Various methods for collection, extraction, and detection will be utilized and analyzed by LC-QQQ-MS. The results will show the effects of the fingerprinting techniques on the detection of the drugs.

Abstract Name: The Gangster Buffs of Charleston: Jewish Safety in a Small Southern City

This project revolves around understanding and closely examining the history of Jewish refugee trauma and immigrant search for safety and kinship within the racial and capitalistic community in Appalachia. Our aim is to better understand how the Ashkenazi Jewish community came to the Appalachian region, specifically the small city of Charleston, West Virginia, USA, and how they adapted to life there. Our primary methods in doing so revolve around genealogical research pertaining to the family of Dr. Rachel Buff and exploring the history of West Virginia, which includes studying the Native tribes of the area and impactful events that would have affected the Buff family in this region, such as the Coal Miners Unions and the KKK.

Abstract Name: Finding the Wnt Signaling Pathway in Labidocera Copepods

The Wingless-Related Integration Site (Wnt) Signaling Pathway is an evolutionarily conserved pathway crucial to numerous biological processes, including embryonic development, cell polarity, immune system regulation, stem cell production, gene expression control, and tissue homeostasis. The purpose of this research is to confirm the existence of this pathway in copepods, specifically Labidocera. Labidocera copepods are zooplanktonic crustaceans that are amongst the most numerous multicellular organisms on planet Earth, making them very desirable as potential model organisms for therapeutic drug research. However, based on current research context regarding this species of zooplankton, one major obstacle holding them back from usage in clinical research is that their recorded genome is mostly incomplete, including crucial proteins found within the Wnt signaling pathway. As such, we seek to identify two of these important proteins: β -Catenin and Frizzled (Fz). For our methodology, we will use an immunofluorescence staining protocol to demonstrate the presence of these proteins in Labidocera. To prepare for immunofluorescence, we embedded our samples in paraffin wax molds and serially sectioned each sample into 7-micron slices using a rotary microtome. Following this, we mounted each section to histological slides to be exposed to fluorescent-tagged secondary antibodies targeting β -Catenin and Fz. Finally, we will confirm the presence of these proteins utilizing a fluorescent light microscope. Based on the evolutionarily conserved nature of the Wnt Signaling Pathway, we expect to find these proteins and confirm that this pathway is conserved in Labidocera copepods. This outcome has the potential to significantly impact clinical research as the discovery of these proteins in an inexpensive, accessible species like Labidocera copepods will allow for increased rates of medicinal drug synthesis and experimentation for potentially treating severe conditions involved in this pathway such as colon cancer induced by mutated APC.

Abstract Name: Exploring the competitive role of a RsmE-regulated type-VI secretion system in a crowded population of *Pseudomonas fluorescens*

Bacteria secrete diverse compounds that collectively manifest a complex extracellular matrix, which helps individual cells to stick together and on surfaces to form a densely structured biofilm. In a colony model of *Pseudomonas fluorescens* Pf0-1, we have previously demonstrated that a post-transcriptional regulator, RsmE, modulates the production of an extracellular polysaccharide (EPS) and a biosurfactant that collectively function to create localized space of low cellular density within an overcrowded population. However, how this space prevents the encroachment of neighboring cells that do not produce these secretions remains a mystery. Global transcriptomics and proteomics profiling of the wildtype and its rsmE knockout isolate revealed numerous RsmE-specific secretions, including a bioinformatically predicted type VI secretion system (T6SS). T6SSs inject degradative effector proteins directly into neighboring cells to function as an effective weapon in competition for space and resources. We thus hypothesize that the T6SS plays a key role in preventing the encroachment of neighboring cells into the low-density space. Knocking out the T6SS indeed reduced the relative fitness of the mutant in direct competition with the wildtype and confocal microscopy confirmed death of wildtype cells within the low-density space. However, knocking out the T6SS in an isolate that lacks both the EPS and biosurfactant did not further reduce its relative fitness, which suggests that the T6SS plays a relatively minor role. To gain further understanding of the molecular interactions among the RsmE-specific secretions, we are currently knocking out the T6SS in an isolate that lacks the EPS and also in an isolate that lacks the biosurfactant to assess additive effects with individual secretions. Understanding both individual and additive functions of diverse extracellular secretions that are commonly produced across the bacterial taxa carries broad implications in industrial, environmental, and clinical settings.

Abstract Name: An AI-Driven Framework for Assessing Intersection Infrastructure and Accessibility

Collecting pedestrian intersection infrastructure data has typically been a tedious process, requiring manual in-person efforts, or more recently, crowdsourcing this data using street view images. This time-consuming and costly process has left many cities with incomplete or outdated datasets. To address this challenge, we developed a cost-effective and efficient system using a YOLOv8-based deep learning computer vision model trained on over 10,000 street view images. To ensure robust performance, we addressed class imbalance during preprocessing and included diverse images representing variations in infrastructure design from four U.S. cities: Logan, Utah; Salt Lake City, Utah; Fort Smith, Arkansas; and Manhattan, Kansas. The model automatically detects eight key intersection features with an overall accuracy of 88.75%: pedestrian signs (93.22%), crosswalks (95.98%), stop signs (97.45%), traffic light poles (92.24%), traffic signals (81.54%), traffic buttons (80.36%), curb ramps without tactile paving (82.24%), and curb ramps with tactile paving (86.83%). These eight key intersection features were implemented in the proposed system which aims to compute infrastructure and accessibility metrics for each intersection based on OpenStreetMap road hierarchy and federal standards. The scoring metrics were validated, achieving correlations of 80% and 91% with

human assessments for infrastructure and accessibility scores, respectively. Finally, we generated citywide visualizations using infrastructure and accessibility scores to provide city planners with intuitive, quantitative insights into intersection quality, highlight pedestrian-friendly areas, and identify locations needing improvement. The proposed AI-driven framework is easily scalable, with potential for refinement by incorporating additional training data from diverse rural and urban areas. It can also integrate with other urban planning tools, offering a fast, cost-efficient way for city planners to collect and assess pedestrian infrastructure and accessibility data and prioritize infrastructure and accessibility improvements.

Abstract Name: Enhancing Learning Platforms for Individuals with ADHD

Individuals with Attention Deficit Hyperactivity Disorder (ADHD) often face unique challenges in digital learning environments, including difficulties with sustained focus, task organization, and managing cognitive load. This study seeks to address these challenges by developing a segmented learning intervention, which breaks down instructional tasks into smaller, more manageable steps and incorporates brief pauses after each segment to reduce cognitive load. We conducted a controlled experiment comparing the experiences and performance of ADHD and non-ADHD participants using both traditional instructional videos and segmented videos. Results indicate that segmented videos significantly reduced errors and hesitations for individuals with ADHD, enhancing their task performance and comprehension. These findings underscore the importance of tailoring educational tools to neurodivergent individuals and offer valuable insights for creating more inclusive digital learning platforms. This work holds implications for educators, researchers, and policymakers aiming to improve educational outcomes for neurodiverse populations.

Abstract Name: Differences in Health Related Quality of Life Domains among LGBTQ+ Cancer Caregivers by Relationship to Care Recipient

Background: Cancer caregivers experience health related quality of life issues (HrQOL). Limited information exists on caregiving HrQOL among LGBTQ+ caregivers, particularly differences by relationship to care recipient. Methods: The UPLIFT study is an ongoing cross-sectional survey of LGBTQ+ cancer caregivers' experiences across the United States. HrQOL domains were assessed using the PROMIS-Short Form 4-item version of depression, anxiety, fatigue, and sleep disturbance. Relationships to the care recipient were

categorized into caring for a spouse/partner/ex, sibling, parent/parent-in-law(pil), child, grandparent, friend, and other. Domain T-scores were calculated by converting raw summed scores for each domain using PROMIS Health Organization conversion tables (T-score greater than 50 indicating worse HrQOL). Differences in mean T-scores for each outcome across relationship types were assessed with ANOVA tests and post-hoc Tukey sensitivity tests. Results: To date, of the n=294 caregivers who have participated, 43.7% were lesbian/gay, 47.7% were bisexual and 13.9% were transgender/gender diverse. Most respondents were White (58%), Black (25%), or Asian (10%). Mean T-scores were as follows anxiety (59.57), depression (56.46), sleep disturbance (53.91), and fatigue (54.71). The ANOVA tests showed significant differences between groups by relationship to care recipient across all outcomes ($p < 0.005$). Tukey post-hoc sensitivity tests demonstrated that those caring for siblings had better HrQOL: less anxiety than those caring for parents/pils or others; less depression than individuals caring for parents/pils, child, grandparent, or others; less sleep disturbance than individuals caring for parents/pils or others. Conclusion: Among LGBTQ+ cancer caregivers, those caring for siblings may be at lower risk for poor HrQOL compared to those caring for other types of family members. Interventions aimed at improving HrQOL among LGBTQ+ cancer caregivers should consider relationship to care recipient.

Abstract Name: Innovative Exoskeletons: Enhancing Safety and Efficiency in Heavy Lifting Tasks

Heavy lifting injuries are a persistent issue in industries such as warehousing and transportation, often leading to overexertion and bodily strain. These injuries account for billions in annual costs and productivity losses, emphasizing the need for innovative prevention strategies. This project addresses the central question: How can we design a cost-effective and ergonomic exoskeleton to reduce lifting-related injuries while improving workplace efficiency? Existing lifting aids, including mechanical exoskeletons, often face limited adoption due to high costs and complex operation. By integrating principles of biomechanics and human motion dynamics, this research aims to develop a novel exoskeleton that enhances user support during heavy lifting. The proposed design includes a unique locking/releasing mechanism synchronized with the arm's angle, ensuring intuitive and seamless functionality. The methodology involves conceptual design through detailed sketches, theoretical modeling, and ergonomic analysis to optimize compatibility with human motion. Early-stage prototypes will be tested through simulation and user studies to evaluate the system's effectiveness in reducing physical strain and enhancing productivity. Expected results include a cost-efficient, user-friendly solution that minimizes injury risk and enables broader workforce inclusion by reducing the physical demands of heavy lifting tasks. This design has the potential to transform workplace safety by offering an accessible alternative to current market options. Findings will be discussed in the context of improving occupational health, addressing labor shortages, and fostering innovation in injury prevention technologies. By addressing both economic and operational challenges, this project aims to make a unique contribution to the fields of workplace ergonomics and injury prevention through a practical and inclusive solution.

Abstract Name: Study of Programming Behaviors by Preschoolers and Its Impact on Their Math Abilities

Tangible robots such as the Beebot have opened up programming for children as young as preschoolers. Recent studies have explored the value of programming for children's overall development and found positive results. However, few studies have identified the specific programming behaviors demonstrated by preschoolers or studied their impact on specific content development, such as Math. In this study, eleven preschoolers of mixed-age and gender, worked in groups of 2 or 3, on four sets of intentionally planned programming sessions with a Beebot. All sessions were recorded and later analyzed for evidence of select programming behaviors culled from previous studies. Children's Math's abilities were measured, before and after the programming sessions using the Tools for Early Assessment in Math. Findings revealed that preschoolers demonstrated several programming behaviors including planning and explaining the programming. Of these behaviors, modularity (breaking up a task to smaller components) and representation (symbolically representing planned programming commands with gestures) both significantly impacted the preschoolers' post-Math scores. Additionally, planning (deciding on a path) was positively correlated with behaviors associated with recognition of problem (as in identifying an error in their programming commands), subsequent solving of problem (or debugging), and explaining the sequence of codes. None of these findings were impacted by age or gender. These results offer deep insights into young children's development and care. First, programming is a viable and effective teaching strategy for enhancing Math in the early years. Second, modularity, often a skill purposefully practiced by adult programmers is evidently both possible and helpful for young children also. This, along with representation (acknowledged as an effective cognition tool), could both be encouraged and modeled for young children by teachers, to further support their growth. Children may also benefit from distinct planning time during class projects.

Abstract Name: Using WebMO to Introduce Computational Chemistry at the University of Southern Mississippi

Computational chemistry is a rapidly evolving specialty within the field of chemistry. Computational chemistry utilizes theoretical calculations to simulate properties of molecules and chemical reactions. Computation is vital to many different industries like medicine, engineering, and environmental. Despite its significance, there are currently no computational chemistry courses offered at the University of Southern Mississippi (USM). This study investigates the integration of computational chemistry into the undergraduate laboratory curriculum using WebMO. Computational laboratory exercises were developed for Organic Chemistry I and II laboratories. The first lab was designed to help students visualize molecular shape and structure and includes Newman projections, dipole moments, functional groups, and isomers. The second lab is to aid students in viewing key molecular orbitals as they play a significant role in reactions such as electrophilic aromatic substitutions. These exercises were administered to students in conjunction with their regular laboratory content as a hybrid lab, with the computational exercises added as bonus. Surveys were administered both pre- and post-lab. This presentation will detail the exercises, describe the impact on student

learning, and give suggestions for how to improve in the future. The ultimate goal of the research is to incorporate computational chemistry throughout the curriculum and within the research group.

Abstract Name: Evaluating Hydroxyl Radical-Generating Device (Strl Air) Against Pathogens Linked to Healthcare-Associated Infections

Healthcare-associated infections (HAIs) are a major health concern as they are actively contributing to increased morbidity and mortality and affecting approximately 136 million people globally each year. Emerging studies on the use of hydroxyl radicals to treat bacterial and fungal infections have offered a potential new approach to antimicrobial treatment for HAIs. A previous study of the Hydroxyl Radical Generating Device (Strl Air) in a hospital setting in India showed that surfaces exposed to Strl Air showed lowered fungal and bacterial load; however, it was unclear whether the device effectively eliminated HAI-related pathogens. Therefore, this study aimed to address this uncertainty by analyzing and assessing the effectiveness of the portable Strl device in inactivating HAI pathogens: *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*. In a 2 x 3 factorial design experiment, we examined the effectiveness of the device on proximity (1 foot, 2 feet, and 3 feet) and time (24 hours, 48 hours, and 72 hours) of microbial exposure. Two-way ANOVA ($p < 0.05$) showed that the percent of bacterial reduction on nutrient agar plates was significantly lower compared to the control as the time of exposure to the device increased. However, the relationship between percent bacterial reduction and proximity of the device remains uncertain. This uncertainty might be related to the less studied hydroxyl radical circulating pattern, which may be a confounding variable in our experiment. Additionally, we observed the effect of Strl Air on a fungal pathogen, *Aspergillus niger*, grown on Cornmeal peptone dextrose agar plates and found that the device exhibited a fungistatic effect on the pathogen. These findings suggest that Strl Air can be used as a preventive measure for HAI in clinical settings. However, more in-depth studies are required to maximize the effectiveness of the device, especially in combat settings.

Abstract Name: Role of IDH1-R132H in the epigenetic rewiring of Senescence and Immune modulation in glioma

Glioblastoma is an aggressive form of brain cancer that has a low 5-year survival rate of 5%. There are many

challenges when it comes to treating this: tumor heterogeneity, treatment resistance, an immunosuppressive tumor microenvironment, and the blood-brain barrier. In the glioma, the mutant isocitrate dehydrogenase-1 can produce the oncometabolite 2-hydroxyglutarate (2HG). 2-HG was found to epigenetically modulate the DNA repair mechanism, reduce the resistant property of the tumor, and modulate the immune microenvironment of the glioma. This is one of the main focuses of the Castro-Lowenstein lab: the impact of the IDH1-R132H through epigenetic modifications on the glioma tumor microenvironment. Since 2-hydroxyglutarate reduced the proliferation rate of the tumor, the lab inferred the possibility of senescence playing a role throughout this mechanism. Literature has found while senescence stops tumor cells from reproducing, these senescent tumor cells create a microenvironment that suppresses the immune system, leading to the proliferation of new tumor cells. Even with the use of chemotherapy and radiotherapy, the microenvironment allows for new gliomas to proliferate. This could be a cause of cancer remission. Based on this background, the lab is investigating how the IDH1-R132H mutation rewires senescence through epigenetic modulation and immune modulation as well as how these mutations modulate the response to radiation. We are investigating these topics through the use of in vitro and in vivo genetically engineered mouse models, human models, and patient-derived tumor biopsies. The research done in the Castro-Lowenstein lab can provide valuable insight as to the reasons why the recurrence of glioma in the brain is so high despite methods like surgery as well as ways to utilize the immune system to combat glioma.

Abstract Name: From Awareness to Action: Tackling Racial Disparities in Educational Settings Across Pennsylvania

This research investigates the racial representational inequities prevalent in Pennsylvania's education system, encompassing both K-12 and higher education, and their detrimental effects on student outcomes and overall well-being. It emphasizes the significant role that classroom teachers and higher education institutions play in both perpetuating these disparities and fostering equitable environments. The study will analyze critical statistics, analyzing the demographic makeup of teachers in the field, as well as university students going into the field of education. Our research is rooted in an initial literature review that reveals the racial representational disparities in education as well as teacher attrition rates in Pennsylvania. We have also conducted a set of interviews to share insights from current teachers as well as students preparing to go into the field. By implementing Universal Design for Inclusion (UDI) within a Diversity, Equity, and Inclusion (DEI) framework, this research aims to create inclusive educational settings that celebrate diverse identities. Strategies will be outlined to address these inequities, including data-driven equity audits, proactive recruitment of diverse faculty, and culturally relevant professional development for educators. Additionally, the presentation will highlight the importance of an inclusive curriculum that reflects a variety of perspectives, thereby enabling all students to see themselves represented in their learning environments. Ultimately, this presentation seeks to contribute to the ongoing efforts aimed at establishing a more equitable educational landscape in Pennsylvania, with broader implications for educational policy and practice nationwide.

Abstract Name: Unpacking Disparities, Building Community: Culturally Responsive Solutions for Equity in Special Education

This research investigates the persistent disparities in special education that disproportionately impact students of color, significantly affecting their educational experiences and outcomes. The study highlights how students of color are frequently overrepresented in subjective disability categories, such as intellectual disabilities or emotional disturbances, often leading to placement in lower-quality programs with reduced expectations. Using a literature review methodology, it explores the historical roots and systemic biases—such as implicit bias, testing inequities, and socioeconomic disparities—that contribute to these inequities despite legislative efforts like IDEA. Central to this research is the introduction of Culturally Responsive Teaching (CRT), an approach that recognizes and values students' diverse cultural backgrounds as assets rather than deficits. CRT empowers educators to create inclusive learning environments that validate students' identities, foster belonging, and encourage active engagement. The presentation provides attendees with an understanding of the historical context surrounding these disparities while offering practical strategies for incorporating CRT into special education settings. These strategies include integrating culturally relevant curricula, fostering positive teacher-student relationships, and addressing systemic biases through professional development. By leveraging CRT principles, educators can disrupt deficit-based perspectives and promote equity within classrooms. Ultimately, this research aims to equip educators and stakeholders with the tools needed to address the root causes of inequity in special education. It contributes to ongoing efforts toward creating culturally responsive communities where all students have equitable opportunities to thrive academically and socially. The findings also have broader implications for educational policy reform aimed at reducing racial disparities in special education nationwide.

Abstract Name: Providing a Creative Environment for Students Pursuing the Arts

Over the years, school districts have had to make the hard choice of cutting art programs such as drama, music, and visual arts due to budget constraints and the focus on state and national academic priorities that focus on math and English achievement. Schools with access to private resources, such as independent and private institutions, have been able to withstand these budget cuts by raising private funds, and these cuts have mainly happened to low-performing and low-income schools. However, the arts offer many benefits to students, including enhancing student achievement, critical thinking, self-expression, confidence, and self-esteem. This project aims to create an environment where students can express themselves while learning about the professional world of the arts, preparing them to transition smoothly into the professional industry. Using precedent studies of art academies around the United States of America helps form the foundation of the fine arts academy. Also using literature reviews to understand the construction and things needed for schools, and art academies that will make it practical. This project was designed to accommodate 500–800 middle and high school students, offering six major areas: writing, dance, music, theater, visual arts, and business. The major design strategies are acoustic considerations, creativity-enhancing features, space planning considering wayfinding, and attention to safety, security, mental health, and ergonomic functions. The layout includes specialized spaces and classrooms for each major, alongside core classrooms for general

studies. Private and group study rooms, practice spaces, collaboration rooms, and staff and student break areas are also incorporated. The main theater is designed to replicate a professional stage, providing students with real-world experiences and lessons. In conclusion, implementing these design solutions in an arts academy will create a learning environment that helps students learn and pursue the arts, ultimately preparing them for success in their careers.

Abstract Name: Comparing Long-Read and Short-Read Whole Genome Sequencing for Genetic Clustering of Healthcare-Associated Bacterial Pathogens

Background: Whole genome sequencing (WGS) and the use of core-genome SNP (single nucleotide polymorphism) comparisons enable precise clustering of genetically-related pathogens for outbreak investigation in healthcare settings. Historically, SNP-calling has been limited to short-read WGS data due to concerns over base-calling accuracy in long-read WGS data. Recently, improved base-calling algorithms have raised the possibility of using long-read SNP comparisons in outbreak investigations. We conducted SNP-based analyses for multiple healthcare-associated bacterial transmission clusters from a single hospital using both short- and long-read WGS. Methods: Study isolates were collected from clinical cultures and sequenced on the Illumina (short-read) platform as part of the Enhanced Detection System for Healthcare-Associated Transmission (EDS-HAT). Included isolates were collected between November 2021 and November 2024 and contained transmission clusters with low SNP distances (≤ 15 SNPs) and known epidemiological linkages. All isolates were re-sequenced on the Oxford Nanopore (long-read) platform, and pairwise core-genome SNP comparisons were generated using Snippy(Illumina) and bcftools(Nanopore) between consensus sequences of clustered isolates with $\geq 75\%$ of the genome at coverage $\geq 10\times$. Agreement between Illumina and Nanopore SNP-based clustering was assessed. Results: Using Illumina and Nanopore, we sequenced 48 total bacterial isolates across nine species of hospital-associated pathogens; 21 isolates (7 clusters) passed QC for both sequencing methods. We calculated SNP distances between isolates of the same genetic lineage using each sequencing method, and assigned clusters using a stricter, epidemiologically-relevant threshold of ≤ 10 SNPs. Nanopore and Illumina agreed on cluster assignments for 25 out of 27 SNP comparisons made, demonstrating substantial agreement ($\kappa=0.81$, 95%CI:0.56–1.00). Nanopore SNP distances were slightly higher than Illumina distances for the same pairwise comparisons (median difference=1 SNP). Conclusions: Our results indicate that SNP-based comparisons using Nanopore long-read WGS only are consistent with those from Illumina short-read WGS and could potentially be used for bacterial hospital outbreak investigations.

Abstract Name: Monitoring Water Quality Throughout Stages of Sewer Infrastructure Construction Within the Walnut Creek Watershed in Southeast Raleigh, North Carolina

In the City of Raleigh, efforts to improve the sewer infrastructure, particularly the downtown area, and its impact on water quality in Little Rock Creek have been the initial focus of this study. The sewer pipe replacement project, which began in Fall 2021, brought about concerns regarding the water quality within the lower portion of the Walnut Creek Watershed. Others in the training program have studied the impact before and during the sewer project. Since the completion of phase one, the purpose of this monitoring study has been to determine the impact of the water quality after the project's completion. The objectives are to (1) collect and measure several parameters over time and (2) compare the findings before, during, and after the infrastructure improvement. Water quality parameters such as dissolved oxygen (DO), specific conductivity (SPC), pH, nutrients, and bacteria with weather patterns will be of importance to the Southeast Raleigh residents in the understanding and effectiveness of the sewer infrastructure improvement project. The expected result of this study is an improvement in water quality compared to data collected last year as a result of this sewer infrastructure project. The results of our study will be important for creating inferences regarding the current water quality of the greater Walnut Creek Watershed and the effectiveness of sewer infrastructure improvements in Southeast Raleigh for the residents living there. These results can be used to inform future work completed by the City of Raleigh concerning sewer infrastructure.

Abstract Name: Investigating the Impact of Haptic Vibrations on Cursor Movements in Virtual Reality Systems.

As Virtual Reality (VR) continues to redefine immersive experiences, the precision of sensors is vital in accurately translating users' real movements into the virtual realm. From apps simulating high-speed races to those used for educational purposes, the accuracy of VR devices significantly impacts the realism of the user experience. This research aims to evaluate the performance of hand controllers during haptic vibrations by developing an application in Unity to analyze the IMU sensors of Meta Quest 2 Hand Controllers. By accessing the raw data of an accelerometer within Unity, we collect users' positions, rotations, button presses, and corresponding timestamps in the presence of haptic feedback. The primary objective of this research is to explore whether IMU sensors mistakenly interpret haptic vibrations as true user movements, potentially undermining the precision of motion capture. Preliminary findings demonstrate that the application effectively tracks and logs user interactions with high precision, yielding data essential for comprehending user movements. Future research will concentrate on rigorously analyzing the impact of haptic feedback on IMU sensor recordings under various conditions, aiming to enhance the quality of VR interactions.

Abstract Name: Characterization of the Microhabitat of Encroaching Shrub *Morella cerifera*

Shrub encroachment into grasslands is a worldwide phenomenon. When shrubs encroach, ecosystems can shift from being dominated by grasses to being dominated by shrubs. A shift in plant dominance can impact wildlife habitat, plant species richness, and ecosystem structure. This transition of plant dominance from grass to shrub has occurred rapidly on Hog Island Virginia, a Long-Term Ecological Research site. On Hog Island, plants experience warmer winter temperatures that contribute to the expansion of native shrub, *Morella cerifera* into grasslands. The presence of shrubs is not ubiquitous throughout the grassland. The purpose of this study was to compare differences in microhabitats that may contribute to shrub presence. Understanding these differences can allow researchers to anticipate which conditions favor shrub encroachment and allow scientists to model future expansion. The study established five plots in grass-dominant areas (grassland plots) and five in shrub-dominant areas (transition plots). Within these plots differences in woody plant cover, relative water content, and soil chlorides were examined. For plant cover in the grassland plots, the results show that woody species make up 1% of the plant cover, whereas in the transition plots, woody species make up 41%. The relative water content for each plot was $12.13 \pm 0.78\%$ (grassland) and $12 \pm 0.72\%$ (transition) $p=0.75$. These plots were not significant for relative water content. Differences in soil chloride were $93 \pm 22.81 \mu\text{g/g}$ and for the transition plots, it was $395 \pm 139.7 \mu\text{g/g}$, $p=0.70$. Even though there are stark differences between woody plant cover in the grassland and transition plots, it does not appear to be due to relative water content or soil chlorides. More research is needed to determine other potentially relevant factors.

Abstract Name: Women in Journalism and Lack of Newsroom Leadership Response to Inequality

The experience of women in journalism is rife with hurdles not often given attention by newsroom leadership and by the journalism field. Struggles that come into play for women include: lack of leadership opportunities (Arguedas, et al., 2024, Urbániková, M., & Čaladi, T. 2024), underrepresentation for minority groups and people of intersectional identities (Bharat Dhiman, Dr., 2023, Wallace, L.R., 2019, Urbániková, M., & Čaladi, T. 2024), variance in beat assignments (Kassova, L. 2020), economic inequality (Bharat Dhiman, Dr., 2023), harm and harassment (Kelly, A. 2024, Khan, I. 2021), unreasonable aesthetic expectations for female broadcast journalists (Engstrom, E., & Ferri, A. J., 1998, Bernard, P., et al., 2020), lack of acceptance in sports journalism (Hardin, M., & Shain, S. 2006), and physical considerations such as menstruation and pregnancy (Ponzo, S., et al. 2022). Newsroom leadership and the infrastructure currently in place do not include methods for easing the strain and inequality female journalists experience, despite evidence suggesting that efforts towards equality from newsroom leaders could have

overwhelmingly positive outcomes (Kassova, 2020). Historical context illustrates that female journalists have experienced unique struggles and have been advocating for themselves for generations (Whyte, M. 2017). Despite this, stumbling blocks for female journalists remain across the field, from broadcast to print, and across all professional journalistic titles and positions. This project, informed by a 25+ page literature review, tells the stories of female journalists in podcast form. This podcast features several episodes and includes lived experiences of adversity, inequality, and forward/backward motion from journalists in the field, as well as interviews with journalism leaders in order to investigate paths forward to address these issues. This podcast seeks to explore whether the potential steps forward discussed in this review are attainable and feasible, either at this point in the journalism landscape or in the future.

Abstract Name: Utilizing Human Brain Organoids to Understand How APOE4 Influences Inhibitory Neuron Susceptibility to SARS-CoV-2 Infection

Worldwide, over 750 million people have contracted SARS-CoV-2, the coronavirus responsible for the COVID-19 pandemic, with over 7 million of these infections resulting in death. Although primarily a respiratory virus, up to 30% of COVID-19 patients also report acute and chronic neurological symptoms following infection. Recent studies show that APOE4, the leading genetic risk factor for sporadic Alzheimer's Disease (AD), is associated with severe SARS-CoV-2 outcomes, such as patient hospitalizations and more severe SARS-CoV-2 neurotropism in human stem cell-derived cortical neurons and astrocytes. In AD, APOE4 also contributes to GABAergic interneuron dysfunction and circuit hyperexcitability, suggesting GABAergic neurons are more vulnerable to APOE4. While APOE4's impact on SARS-CoV-2 neurotropism has been explored in cortical neurons and astrocytes, it is unknown whether APOE4 makes GABAergic inhibitory neurons selectively vulnerable to SARS-CoV-2. To address this question, we generated human ganglionic eminence organoids (GEOs) enriched with GABAergic interneurons from induced pluripotent stem cells (iPSCs) derived from patients with either the neutral APOE3/3 or at-risk APOE4/4 genotype. Eight months in vitro, when organoids express mature inhibitory neurons and astrocytes, we infected GEOs with SARS-CoV-2 for 1 hour and harvested tissue 7 days post-infection for RT-qPCR and immunohistochemistry. Preliminary results suggest that there are no genotype-dependent differences in overall levels of SARS-CoV-2 infection. However, infected APOE4 GEOs show elevated expression of immature neuron marker doublecortin and a reduction in mature neurons. These findings suggest that APOE4 may influence COVID-19 susceptibility and severity by increasing GABAergic neuron vulnerability. Understanding the mechanisms by which APOE4 influences COVID-19 susceptibility will help identify potential long-term outcomes in at-risk populations and possible therapeutic targets.

Abstract Name: Parental Abuse in Asian American Families during the COVID 19 Pandemic

This study focuses on reported parental verbal and physical abuse among Asian American high school students during the COVID-19 pandemic. As in many immigrant groups, domestic violence is a taboo subject in Asian American households. Additional stressors during the pandemic, including anti-Asian rhetoric and violence, may have further aggravated parental abuse. In this project, data from the 2021 Adolescent Behavior and Experiences Survey (ABES) were analyzed, specifically self-reported verbal and physical abuse among Asian American students. Participants were asked, “During the COVID-19 pandemic, how often did a parent or other adult in your home swear at you, insult you, or put you down?” and “During the COVID-19 pandemic, how often did a parent or other adult in your home hit, beat, kick, or physically hurt you in any way?” Overall, female and male Asian American students reported similar rates of parental abuse. However, female students reported significantly higher rates of verbal abuse than male students. These findings support the literature about gendered cultural norms in Asian American communities and the disproportionate burden of emotional labor on women and girls. The finding that both male and female students reported similar rates of physical abuse may challenge some gender role expectations but may also indicate the greater acceptance of corporal punishment among these families.

Abstract Name: Multi-disciplinary Study of the Material Composition of Ceramics Fragments from the Soline Bay Roman Villa in Croatia

The multidisciplinary approach of material culture investigation using physical methods from the natural sciences is known as archaeological science or archaeometry. In the past two decades archaeometry studies of ancient pottery from archaeological digs from the Mediterranean and Adriatic Coasts have illustrated the ability of physical methods to enrich our knowledge about the composition of pottery dating back to the Roman and Hellenistic periods. At the University of St. Thomas, a group of faculty and undergraduate students from history, art history, geology, and chemistry have studied ancient artifacts from an archaeological site on the island of St. Clement, off the Dalmatian Coast of the Adriatic Sea. Our analysis ranges from examination of the texture of pottery fabrics to semi-quantitative analysis for major and minor elements with X-ray fluorescence (XRF) and internal morphology with scanning electron microscopy (SEM). While the diverse members of the group have different goals aligned with their disciplines, the goal of the research is to uncover insights into the provenance, production techniques, and trade networks of the Roman era on the island. Undergraduate students have travelled with faculty, dug and surveyed the site, collected data at the site and brought samples back to the University of St. Thomas. In several summer and academic year research projects we have studied the XRF spectra of pottery sherds from the site. Applying quantitative chemical and geological approaches, we are attempting to relate our results with those from the archaeological literature on other Dalmatian sites. In this presentation we will show the results from X-ray fluorescence collected by students in collaboration with chemistry and art history faculty and explore the potential of this project to advance learning and the future careers of young researchers.

Abstract Name: SLE-associated risk alleles, TASL and SLC15A4, show strong genetic synergism among lupus male subjects.

SLE is a systemic autoimmune disease that predominately affects women, with a female-to-male ratio of approximately 10:1. SLC15A4, TLR7, and TASL are known SLE risk genes that play a role in TLR7-signaling IFN production which is related to common pathogen-mediated immune responses. We predict the presence of these associated risk variants could adversely affect IFN and autoantibody production in male SLE subjects. Our goal, through genotyping, is to assess the presence of SNPs SLC15A4, TLR7, and CXorf21 in SLE-affected and unaffected male subjects, and measure genetic synergism. We genotyped the DNA samples of 95 male SLE subjects and 132 unaffected male subjects from the OMRF Lupus Family Registry and Repository. For each subject, We ran Taqman probes TLR7(RS3853839), SLC15A4(RS1059312) (RS1385374)(RS10847697), and CXorf21(RS887369) using the real-time polymerase chain reaction (PCR) TaqMan-based allelic discrimination assay. To assess genetic synergism between the associated SLE risk variants we will initially calculate the Synergy factor for each binary combination of the three genes in question – namely, SLC15a4xCXorf21, SCL15a4xTLR7, and CXorf21Xtlr7. We found that SLE-affected AA male subjects were at least 3 times more likely to have Cxorf21 and SLC15A4 risk alleles than healthy male controls (p-value: OR, CI). Additionally, genetic synergy calculations suggest positive gene-gene interaction in all groups of SLE subjects. These data suggest that the presence of RS887369 and RS1053912 risk variants among SLE-affect men may be important in predicting disease susceptibility.

Abstract Name: Inside Out: Breeding Critically Endangered Goodeids (*Ameca splendens*) in Vice City (Miami)

The butterfly splitfin (*Ameca splendens*), native to Mexico, is critically endangered due to water pollution, competition with nonnative species, and habitat loss. Conservation efforts by various groups, including aquarists and hobbyists, have focused on raising awareness, developing captive breeding programs, and preserving natural populations and habitats. Educational institutions, such as schools and colleges, play a crucial role in these efforts through integrated lesson plans and captive breeding projects. At Miami Dade College, during the Fall and Spring semesters, we conducted a study to compare the reproductive success of butterfly splitfins in different environments. Paired butterfly splitfins were raised in large indoor aquariums and outdoor tubs over several months to determine whether natural or controlled conditions, indoors or outdoors, would yield more offspring. Our results indicated that while more offspring were produced in

outdoor tubs, the difference was not statistically significant. This suggests that both indoor aquariums and outdoor tubs are viable breeding habitats for these fish. Future research will extend this project into the summer months, addressing the additional challenge of high temperatures in Miami.

Abstract Name: Research and Development of a Hands-Free Jar Opener for Consumers with Limited Arm Strength

Background: From baby food to pickles, food jars are a common find in American homes. Unfortunately, the task of opening a stiff jar lid can be very difficult for consumers with lower grip strength, parkinsons, or arthritis. While there are a variety of products on the market to help make this easier, there exist few jar openers that can be used by these consumers. Objective: This project aimed to research and develop (R&D) an improved hands-free jar opener that is accessible for consumers with the most advanced cases of limited arm strength. Methods: R&D followed a Design Thinking approach with the phases of Discovery, Synthesis, Exploring Solutions, and User Testing. The Discovery phase included a market analysis of current jar opening solutions and need-finding interviews with community members. The Synthesis phase involved synthesising the gathered data into actionable insights and tools to keep the product design user-centered. In Exploring Solutions, a variety of concepts were explored as potential jar opening solutions through physical and digital prototyping. User Testing took the form of interviews with potential users where they were presented with the proposed solution and asked questions to validate the design and gather feedback. Results: A review of current products on the market revealed that there are only two hands-free jar openers available. Interviews with stakeholders showed that participants or someone they knew would greatly benefit from an improved solution to open stiff lids. Concept exploration yielded a hands-free appliance as the most successful design. User testing validated the functional and aesthetic design of the proposed solution and revealed that the target user group would like to have this.

Abstract Name: what remains: the cyclicity of the material and the immaterial

“What Remains” is a multimedia exhibition that explores the intricate interplay of identity, memory, and transformation, as shaped by the emotional and intellectual journey of a young women entering into her 20s. The central question driving this project is how experiences of love, loss, vulnerability, and resilience coalesce into the “becoming” of an individual. Through 10-15 mixed-media artworks, the exhibition invites viewers to reflect on their personal narratives while engaging with universal human themes. Drawing inspiration from Daniel Eakin’s hyperrealism, Magdalena Abakanowicz’s textural anatomies, and Shirin Neshat’s symbolism, “What Remains” fuses technical precision with emotive depth. Eakin’s detailed portraits

ground the work in raw emotional realism, while Abakanowicz's fragmented forms influence the layered representation of complex identities. Neshat's use of cultural symbolism informs the integration of materials like fabric, plaster, and glass, allowing the works to convey stories of growth, pain, and renewal. Methodologically, the project employs diverse techniques including charcoal portraits, ceramics, plaster, wire, fabric, and oil paintings that layer textures and narratives. Highlights include a diptych of intergenerational self-reflection, triptych diving into the emotional cycle of growth, vessels representing the cyclical nature of life and death, and glass sculptures symbolizing the fragility and resilience of the human psyche. Each piece is meticulously crafted to evoke a tactile and visual dialogue, bridging the gap between personal and shared experiences. Preliminary findings suggest the works successfully provoke visceral and intellectual engagement, though balancing cohesion across varied media remains a challenge. This exhibition serves as a capstone for me, synthesizing skills and insights gained through rigorous academic and professional experiences. "What Remains" not only solidifies a foundation for future artistic endeavors but also underscores the transformative power of art to connect diverse audiences through shared emotional landscapes. It is a celebration of identity's fluidity and the universal quest for self-discovery.

Abstract Name: The Impact of Propionate on Glioma Cell Migration: A Potential Therapeutic Target

Glioblastomas are an aggressive type of brain tumor and are the most common primary malignant brain tumor in adults. Due to their invasiveness, glioblastomas are highly challenging to treat, driving research into potential strategies to improve patient survival. Studies have shown that manipulating the gut microbiome can alter the brain's signals; this relationship is called the gut-brain axis. The gut microbiome has a variety of functions, including nutrient metabolism, regulating immune responses, and helping control brain processes. Disruptions to the body's "normal" microbiome are likely related to a decrease in immune system responses, enhance tumor proliferation, and affect the outcome of immunotherapies. Within the gut microbiome, metabolites, like propionate, serve as an energy source for cells, reduce inflammation, and support metabolism. However, the effect of metabolites on cancer growth remains controversial, with some suggesting it inhibits tumor growth, while others suggest it may promote it. Elevated propionate levels have been found in HuM1 naive mice models, indicating a potential role in immune response and tumor suppression. This T-scratch experiment aimed to investigate the effect of propionate on glioma cell migration. Glioma cells were cultured in a multiwell plate and were exposed to either a serum-free or 10% FBS media with increasing propionate concentrations for 72 hours. Although the T-scratch analysis was not statistically significant, a trend was observed: propionate increased the area of invasion in serum-free media compared to the control. These preliminary results suggest elevated levels of propionate may influence glioma cell migration, but more data is needed to validate.

Abstract Name: Optimizing Alginate Biospheres For Microbe Viability During Drug Delivery

Inflammatory bowel disease (IBD) describes chronic health disorders characterized by inflammation and pain in the gastrointestinal tract. IBD prevalence is rising, proving necessity for engineered therapeutics that can reduce gut inflammation and improve quality of life. Our lab has genetically engineered a strain of *Saccharomyces boulardii* (*S. boulardii*) with the ability to secrete therapeutics and enhance probiotic effects in the gut. However, if left unprotected to travel through the gastrointestinal (GI) tract without encapsulation, there is degradation due to environmental factors such as pH variations. To address this issue, we propose a novel drug delivery method of loading *S. boulardii* and other therapeutic microbes into alginate biospheres to improve microbe viability and transport. Particles were produced by releasing droplets of 2 % w/v sodium alginate into a 0.05 M CaCl_2 crosslinking bath using the syringe infusion pump system and the electrospray technique. Particle diameters were identified and the data was statistically analyzed. The results show that as the needle gauge diameter or sodium alginate concentration decreased, the crosslinked particle diameter decreased. Other factors such as calcium chloride concentration didn't have an effect on particle diameter. The trends show that parameters such as particle composition and needle gauge diameter influence particle size and shape, and these parameters can be optimized to load engineered *S. boulardii* into the particles for maximum viability. Our research justifies that this is a promising drug delivery method to improve microbe retention and containment during transport through the GI tract.

Abstract Name: Transit in Theory and in Practice: The Undervalued Influence of System Unreliability and Lived Experience on Transit Accessibility and Justice

Transit accessibility, the degree to which individuals can access opportunities (eg. jobs or grocery stores) by transit in a given timeframe, has been well studied in American cities in an effort to promote transportation equity. However, there is often a discrepancy between the findings of studies utilizing system-level data such as scheduled travel times (processes) and the actual experiences of transit users (outcomes). Studies of transit outcomes have shown various additional factors, including unreliability, safety, and comfort, to greatly impact the degree to which one can access opportunities via transit. I therefore propose a new method for evaluating transit accessibility that integrates process-based methods with user outcomes in order to more accurately identify transit gaps and inequities. The implementation of this new method is demonstrated by creating a model that calculates transit accessibility using schedule data from regional transit agencies in Chicago (using the General Transit Feed Specification (GTFS)), weighted by official spatial data on transit system performance, customer satisfaction, walkability, and other transit outcome metrics. By comparing the results of this model with another model that utilizes unweighted schedule data alone, I will identify locations in which traditional methods may under- or overestimate transit access and characterize them by their demographics to highlight any equity issues this could cause. My preliminary results concerning walkability suggest that traditional, process-based methods greatly overestimate transit access in areas with poor pedestrian infrastructure and land use, which in Chicago tend to be low-income, majority-Black areas. This innovative method will therefore not only provide a more accurate transit access measure, but can

additionally highlight issues of equity that might otherwise be overlooked under traditional approaches, thus allowing decision makers to plan transportation improvements in a manner that better meets the needs of underserved populations.

Abstract Name: Fluorescence Excitation-Scanning Hyperspectral Imaging with AI for Colorectal Cancer Detection in Mice

Colorectal cancer is the third most prevalent type of cancer, behind lung and breast cancer, and is one of the leading causes of death of all types of cancers. With most diagnoses occurring at a late stage, early detection is key in improving the prognosis of the patient. Artificial Intelligence (AI) has been used in many health-based applications, especially in those related towards cancer detection. In the case of colorectal cancer detection, AI can be used to show areas where cancer is present that may be overlooked, or not easily noticeable, which can occur during a colonoscopy. This project seeks to develop an AI model that can detect colorectal cancer in images of mouse tissues in an accurate and efficient way. A mouse colorectal cancer model was selected due to the ability to reproducibly induce primary tumors that can be imaged at selected time points, allowing assessment of different size (different grade) tumors. The AI model was developed from a previous model that detected colorectal cancer in images of human tissues through the use of transfer learning. This previous model was very accurate with the human data, but took a long period of time to process its dataset. Additionally, human tissues were only available for late-stage cancers, and the AI model was likely insensitive to more subtle changes that occur in early cancer development. Future progress will involve refining the transfer learning techniques to improve the accuracy with the new data, and finding ways to make it run fast and efficiently, so that it can eventually run on an edge device in real time, detecting colorectal cancer during a colonoscopy. This work was supported by NSF OIA2218046 and the Alabama EPSCoR Graduate Research Fellowship.

Abstract Name: Visualizing Agricultural Digital Twin Data

Digital twins, virtual representation of physical objects, offer significant benefits for visualizing agricultural output. By integrating real-time data from sensors and drones, digital twins enable farmers and agronomists to monitor and accurately predict crop growth, soil health, and environmental conditions. For this, we are designing a front end, in JavaScript, and a back end, in Rust programming, of a website to make all the data

from the Experimental Smart Farm (ESF) accessible. All the primitives displayed on the front end are various models that contain the data which is queried through the back end. As a result, agricultural workers can easily visualize the impact of different variables, such as weather patterns and irrigation schedules, on crop performance. This enhances their ability to implement precise agriculture practices, therefore improving sustainability. In essence, digital twins represent a transformative tool for agriculture, driving innovation and efficiency to achieve optimal agricultural output.

Abstract Name: The Emerging Role of Telemedicine in Managing Glaucoma

It is estimated that 50% of people with glaucoma worldwide remain undiagnosed. Glaucoma is an eye disease that involves the deterioration of the optic nerve, which can cause vision loss and even blindness that is irreversible. Since it is such a slow-progressing disease, many people do not realize they are experiencing symptoms of the disease until a significant amount of their vision is impacted. Due to the detrimental impact of this disease, it is essential for physicians to monitor the onset of glaucoma, especially if the patient is part of one of the groups that are predisposed to the disease, including elderly populations of 60 and over, people with a family history of glaucoma, young adults of African American descent, and people with diabetes. An up-and-coming method to efficiently monitor glaucoma is through telemedicine. Since the COVID-19 pandemic, telemedicine has been further developed and is now used more commonly in the medical field. In the field of ophthalmology, many tests have become available through virtual visits, such as visual acuity tests like basic psychologic, neurologic, external adnexal, pupil, motility, alignment, anterior segment, iris, and corneal light reflex exams. This work focuses on the recent developments and efficiency of telemedicine and why it is essential in monitoring and managing the detrimental disease of glaucoma. Research shows that telemedicine allows patients to successfully get treated for their conditions in a convenient manner before the disease progresses beyond recoverability. Despite the optimism that comes with this newly growing field of technology, further study will be done to resolve the many issues that come with telemedicine and explore the limited amount of treatments available for glaucoma.

Abstract Name: The Role of Racial Stress on College Student Academic Outcomes

College students face academic, personal and professional challenges that cause elevated levels of stress. Stress can be modulated by additional factors associated with a person's identity, including race, socioeconomic status (SES), sexual orientation, etc. Our study was conducted at a university in the Southeastern United States where race impacts societal inequities. While there have been many improvements in racial tension, marginalized groups still experience unconscious biases, racial microaggressions and systemic discrimination which impact academic success. This study's purpose is to determine the role of

stress on academic outcomes, and to determine if race and racial stress impacts academic success. Qualtrics was used to collect data for the following validated tools: Brief Cope: Abbreviated Coping Orientation to Problems Experience (BC), Generalized Anxiety Disorder – 7-item (GAD-7), Minority Student Stress Scale (MSSS), Perceived Stress Scale (PSS), and Patient Health Questionnaire – 9 (PHQ-9) for depression. High school demographics and SES were gathered from the National Center for Education Statistics (NCES). Participants self-reported their Grade Point Average (GPA) on a 4.0 scale. The data is currently being analyzed. It is hypothesized that stress will have negative outcomes on student academic success, with racial minority students experiencing higher levels of minority and perceived stress than their white peers. We anticipate different academic responses to anxiety, depression and coping skills based on race. Lastly, we hypothesize that SES may have an impact on all students' stress levels, psychological well-being, and overall academic success. These results will help us to better understand ways to improve student academic outcomes by modulating stressors.

Abstract Name: A Thematic Analysis of Psychiatric Pharmacists Navigating Suicide Grief

This study presents a thematic analysis of de-identified qualitative data gathered from the Living Through Loss survey conducted by the American Association of Psychiatric Pharmacists (AAPP). Participants included 15 practicing pharmacists asked to reflect on their experience with suicide loss in their career field. The survey explored the varied experiences and coping mechanisms of psychiatric pharmacists navigating the complexities of suicide loss in patients, students and co-workers. We identified common themes that emerged from participants' narratives, shedding light on their emotional journeys and the support systems they engage during difficult times. Utilizing a systematic approach to thematic analysis, the data revealed nuanced perspectives on personal experiences of these types of losses, highlighting the intersection of mental health and grief in these professionals following the suicides. Participants shared stories reflecting a range of emotions, including sorrow, hope, and resilience, offering a rich tapestry of lived experiences that contribute to a deeper understanding of the grieving process for these non-family losses. Most notably, the participants described guilt about their role in not preventing these suicides even though there was actually little they could have done. In addition, they expressed a desire to change stigma and increase outreach to fellow pharmacists after these losses. The findings inform clinical practices and support strategies for individuals experiencing work-related suicide exposure emphasizing the importance of empathetic engagement and tailored therapeutic interventions. By illuminating the voices of those who have navigated suicide loss in the course of their work, this research contributes to the ongoing discourse surrounding grief, providing valuable implications for mental health practitioners and care providers. Overall, this thematic analysis serves as a foundation for future research in understanding the psychological impact of work-related loss and the diverse healing pathways individuals may pursue.

Abstract Name: Exploring the Impact of Health Literacy and Language as Barriers to Accessing Autism Diagnostic Services in the Latine Community

Background: Latine children face greater disparities in autism diagnosis which may be attributed to differences in caregiver understanding of the healthcare system and access to interpretation and related services. Objectives: This project examines how health literacy influences access to autism diagnostic services and experiences with medical interpreters in Spanish-speaking Latine families. Results: Participants were 11 Spanish-speaking Latine mothers (M=31 years; M=6 years lived in US; M=44% completed 13+ years of school; M=73% monolingual Spanish) of children with autism (M=28 months; 82% male) who completed an autism diagnostic evaluation. Mothers completed a social validity interview and survey on experiences obtaining a diagnosis (86 items across 8 domains rated on a 4-point Likert scale: “strongly disagree” to “strongly agree”) and demographics. 73% of mothers did not know where to go for help prior to their child’s diagnosis (M=1.82). When asked about the best ways to improve the diagnostic process, 36% of caregivers noted that interpreters should be more available for families that need them. Although 91% of mothers found medical interpreters helpful (M=3.64), the process of getting an autism diagnosis caused stress within families (M=3.09) and caregivers found it difficult to understand how the medical system worked (M=2.60). Discussion: Spanish-speaking families, particularly those who recently immigrated to the United States, do not feel fully equipped to make well-informed health decisions for their children with autism. Although medical interpreters are a useful tool, they are not the solution to the health literacy barrier experienced in the Latine community.

Abstract Name: Assessing Qualitative Perspectives for a Novel Hands-Free EMG Controller Training Platform

Amyotrophic lateral sclerosis (ALS) causes progressive deterioration in motor neurons, which can inhibit independent use of a joystick-based wheelchair. To improve patient autonomy, a wheelchair interface controlled by electromyographic signals from the temporalis muscle was developed. The wheelchair operates based on the magnitude of muscle contraction, with a “hard” flex indicating a forward movement, a “medium” flex corresponding to a right turn, and a “light” flex initiating a left turn. A clinical trial conducted at Mayo Clinic evaluated the efficacy of this interface among ALS patients. Although independent wheelchair control was established, the trial participants expressed the need for a training platform to facilitate learning muscular discretization. Limbless Journey, a serious video game, was developed as a training platform that simulates the controls required to operate the wheelchair. The game’s virtual environment minimizes stress and helps users practice flex discretizations while supporting learning of the temporalis muscle-controlled interface. To explore additional options for autonomous practice, interaction with the computer interface via

eye-tracking technology was examined. To evaluate and improve training, both quantitative and qualitative data were collected during a usability study. Quantitative data collection methods included the Game User Experience and Satisfaction Scale and the Systems Usability Scale. Both measures showed positive perceptions of the game. Qualitative data was collected using a think-aloud methodology, encouraging users to verbally express their thoughts during gameplay. These recordings were transcribed and coded into categories such as game environment, user interface interactions, and controller usability to assess user sentiment. Positive comments primarily referred to the game environment, while negative perceptions focused on flex controller usability challenges. The user feedback will be implemented into desktop and virtual reality versions of the game for expanded autonomy and access.

Abstract Name: Developing Color Fundus Laser Speckle Contrast Imaging for Investigating Ocular Biomechanics and Hemodynamics

Glaucoma is a leading cause of progressive and irreversible vision loss. While the cause of glaucoma is not clear, it is believed that this condition is related to the interplay between intraocular pressure (IOP) and cerebrospinal fluid pressure (CSFP), which alters the biomechanical and hemodynamic environment within the optic nerve head at the back of the eye. Existing imaging modalities, such as optical coherence tomography angiography and super-resolution ultrasound, provide valuable insights into structural details or blood flow but lack the capability to comprehensively visualize and quantify both. To address this limitation, we developed a color fundus laser speckle contrast imaging (CF-LSCI) platform that enables comprehensive visualization of vascular structures and quantification of blood flow within the optic nerve head, offering new perspectives on vascular health and ocular conditions. The CF-LSCI platform consists of two primary subsystems: an illumination subsystem and an imaging subsystem. The illumination subsystem uses a low-power red laser diode to generate laser speckles for blood flow quantification, while the imaging subsystem incorporates a 20D ophthalmic lens to create retinal conjugate images, which are captured using a dual-sensor camera. To evaluate the platform's performance, an anatomically accurate eye phantom was developed using 3D printing and silicone tubing to simulate blood vessels. Whole milk, chosen for its light-scattering properties analogous to blood, was used as the flowing medium, with a syringe pump regulating flow rates to mimic physiological blood velocities. Benchmark testing demonstrated the platform's reliability in maintaining consistent flow rates and capturing high-resolution images of ONH vessels. The CF-LSCI platform successfully acquires detailed vessel images and flow quantification within a circular region approximately 10 mm in diameter. Future work will focus on integrating CF-LSCI with an ex vivo eye model to explore the effects of IOP and CSFP on ONH structural and hemodynamic behaviors.

Abstract Name: A Smarter Compiler Framework Empowered by Large Language Models

Traditional compilers are good at translating and optimizing code but have serious limitations. They rely on predefined rules and static algorithms, which makes it hard for them to handle the complex requirements of modern software development. For example, during the optimization phase, compilers can accidentally introduce security issues called Compiler-Introduced Security Bugs (CISB), like memory corruption or race conditions. While machine learning (ML) techniques have been added to compilers to fix some of these problems, ML-based approaches also have their downsides, such as needing to be more focused on specific datasets and helping to adapt to different coding scenarios. This project suggests an approach using a large language model (LLM)-based compiler. LLM-based compilers go beyond traditional and ML-based compilers by being more flexible, adaptable, and better at understanding code context. They can be fine-tuned for specific tasks like spotting security vulnerabilities, such as CISB, or optimizing performance. For instance, an LLM trained on security datasets can find subtle issues like buffer overflows or suggest optimization strategies suited to specific systems. Our project uses the CodeT5-small LLM as part of an LLM-compiler toolchain. We chose CodeT5-small because it is specifically designed for code-related tasks, unlike general-purpose language models like GPT-4, which focus more on natural language. CodeT5-small is pre-trained on code, which helps it understand complex code structures, such as syntax and logical flow. When compiling C code, the LLM reviews the Intermediate Representation (IR) after the optimization phase and identifies any potential issues. We trained the LLM using a dataset of Compiler-Introduced Security Bugs (CISB) to enable it to detect these security vulnerabilities automatically. LLM-based compilers improve on traditional and ML-based systems by combining flexibility, adaptability, and task-specific training. They make software development safer and more efficient.

Abstract Name: The Role of Emotional Intelligence in Managing Anxiety, Burnout, and Stress in Health Care: A Meta-Analysis

Objective: This study meta-analytically examines the effect of emotional intelligence on reducing anxiety, burnout, and stress among healthcare professionals. **Background:** Emotional intelligence (EI) is the ability to recognize, understand, and manage one's own and others' emotions. EI has garnered increasing attention as a potential protective factor against mental health challenges. Given the prevalence of burnout, stress, and anxiety in healthcare, understanding EI's role is critical. This meta-analysis evaluates the association between EI and burnout, stress, and anxiety among healthcare workers and students. **Methods:** We conducted a meta-analysis of studies from 2001 and 2024 on PubMed examining the relationship between EI and burnout, stress, or anxiety in healthcare workers and trainees. Studies published in English with quantitative analyses focusing on healthcare professionals or students were included. Analyses assessed whether theoretical and methodological moderators influenced effect size heterogeneity. Effect sizes and moderator analyses were conducted using Comprehensive Meta-Analysis (Version 3) software, based on the Hedges and Olkin (1985) approach. Based on reports of means and standard deviations, zero-order correlations, raw proportions, t-tests, and F ratios were conducted. **Results:** We examined the effect sizes between EI and anxiety, burnout, and stress. Results showed significant negative effect sizes for EI, indicating higher EI is associated with lower

anxiety ($r = -.23$, $k = 6$), burnout ($r = -.39$, $k = 24$), and stress ($r = -.29$, $k = 22$). The 95% confidence intervals excluded zero for anxiety ($-.31$, $-.14$) and burnout ($-.66$, $-.02$), but not for stress ($-.59$, $.09$). High heterogeneity in all three effects indicates significant variance across findings, warranting further investigation into theoretical and/or methodological moderators. Discussion: These findings indicate that higher EI correlates with lower burnout, stress, and anxiety among healthcare professionals, highlighting the importance of developing tools to enhance EI in medical training and healthcare workers to mitigate mental health challenges in this sector.

Abstract Name: Advancing Meta-Analysis in Medical Research Through Open-Source MATLAB Models

The rapid advancements in computer technology have significantly accelerated the generation of medical data, particularly in drug testing. Early-stage drug testing often involves multiple research groups with varying opinions and outcomes, leading to potential confusion for readers. Meta-analysis has emerged as a powerful method for synthesizing such conflicting data. However, existing commercial meta-analysis tools are often prohibitively expensive and lack transparency due to restricted access to their underlying code, limiting their adaptability. To address this gap, this study introduces open-source meta-analysis models developed in MATLAB. Data were sourced from the Harvard Library's extensive collection of medical databases. Three MATLAB models were designed to perform meta-analysis using fixed-effect and random-effects approaches. The fixed-effect model supports both continuous and binary data, employing corrected standardized mean difference (Hedge's g) and odds ratios to measure effect sizes, respectively. The random-effects model incorporates variability across studies, accommodating differing true effects. The models estimate effect sizes with high accuracy and evaluate their robustness across the analyzed datasets. Statistical significance of summary effects was assessed using Z-values, enabling testing of null hypotheses and generating deeper insights from the data. These models were validated using diverse datasets from established meta-analysis databases in the medical domain, including studies on heart failure, diabetes, and obesity. Meta-analysis results were cross-verified with findings reported in the literature. For example, six obesity-related studies yielded a computed standardized mean difference of ~ 0.4145 with a 95% confidence interval ranging from 0.2-0.54, a Z-value of 6.47, and statistically significant P-values for both one-tailed and two-tailed tests (< 0.0001). These results align closely with published findings by Borenstein et al. Results indicate that the MATLAB models are accurate, robust, and scalable for synthesizing diverse medical datasets. This presentation will detail the model designs, validation results, and their broader implications for advancing medical data analysis.

Abstract Name: Care Intervention in Aphasia Among Nursing & Speech and Hearing Undergraduates

This study examined interdisciplinary roles between speech and hearing- and nursing students toward care interventions for aphasia. Previous researchers discovered a significant contrast in competence between nursing and speech-language pathologists when working with patients with aphasia. The objective is to assess a potential need for workplace or educational training for aphasia. Participants were interviewed about their knowledge and experiences with aphasia using a qualitative, structured interpretative phenomenological approach that identified and evaluated shared trends and perspectives on interdisciplinary pre-professional roles among the interviewees. Interviews suggested speech and hearing students (n = 3) possessed limited knowledge of aphasia. Despite the lack of knowledge, the students recognized a nurse's capabilities when aiding aphasia patients. Similarly, nursing students (n = 3) understood speech pathologists' role in care intervention but were more aware of aphasia. When asked about nursing intervention tactics for aphasia, nursing students understood the responsibilities within their field. Their knowledge came from exposure to aphasia in classroom and practicum settings. Overall, participants from both disciplines had various levels of expertise about aphasia, and only nursing students could define care interventions and relate the concept to aphasia. However, both groups recognized the other occupations' role in aphasia. Future directions for this research will be expanding the sample size and academic level of participants and working with those interested in aphasia focusing on care interventions rather than general knowledge of aphasia. Keywords: aphasia, care intervention, nursing intervention, nursing undergraduates, speech and hearing science undergraduates, interdisciplinary roles

Abstract Name: Asexuals of Color: Experiences of an Invisible Identity

Asexualism, or the lack of sexual activity attraction or low sexual interest, is a relatively new and growing orientation within the LGBTQIA+ community. The identity's meaning and related history have continued to be studied by anthropologists, scientists, and activists as the community continues to find acceptance and understanding. As asexuality became more mainstream in Queer and youth culture, the orientation has continued to expand its representation. However, due to the lack of accurate and open-minded knowledge, the orientation has become white-centric and discouraged by minority groups due to cultural contrasts and racial stereotypes. This study delved into the shared experiences and stories of ten participants who identified as an Asexual of color. This project utilized Interpretative phenomenological analysis- a qualitative methodology that identifies trends in data to create assumptions about a population or demographic. The study conducted private-personal interviews consisting of eight open-ended questions and found five central trends across the participants' testimonies: (1) Becoming and identifying as Asexual, (2) Disclosure of identity, (3) Sexualization and Fetishization of BIPOC Asexuals, (4) BIPOC Asexuals within Queer and Asexual community (5) Self-acceptance. This research aims to bring attention to asexuality and the lived experiences and journeys of Asexuals of color. Keywords: asexuality, people of color, racial minorities, aromanticism, Queer community

Abstract Name: Evaluation of an *Acinetobacter baumannii* Multi-epitope Vaccine, AMEV5

Multi-drug resistant (MDR) *Acinetobacter baumannii* (Ab) is an opportunistic pathogen associated with hospital-acquired infections. Patients with the highest risk of acquiring Ab infections include immunocompromised individuals and those hospitalized for an extended duration. The most frequent clinical manifestations of Ab infection are ventilator-associated pneumonia and catheter-related bloodstream/urinary infection. The extensive MDR and increasing prevalence of Ab underscores the urgent need to investigate and develop alternative strategies such as vaccines as immunotherapeutics to combat Ab infections. Our lab previously developed a multi-epitope vaccine, AMEV2, and demonstrated its ability to provide partial protection to mice against a lethal challenge with a virulent strain of Ab. To improve the efficacy of the AMEV2 vaccine, we incorporated two additional antigenic peptides into the construct design named AMEV5. This study was conducted to evaluate the protective efficacy of AMEV5 against *Acinetobacter* septicemia. The AMEV5 vaccine was constructed using an Ab thioredoxin A (TrxA) leading protein sequence followed by 7 peptide antigens ranging from 37 to 67 amino acids which we identified using immunoinformatic analysis. The His(6x)-tagged recombinant AMEV5 (rAMEV5) was expressed in an *E. coli* system, purified to high homogeneity using metal affinity chromatography, and its sequence was confirmed by LC-MS/MS. BALB/c mice (n=10 per group) were subcutaneously immunized with rAMEV2 (10 µg) or rAMEV5 (10 µg) emulsified in the AddaS03 adjuvant and then boosted twice at two-week intervals. Mice that received AddaS03 alone served as mock control. Immunization with AMEVs result in high antibody titers to the antigen and the constitutional peptide components. AMEV2 and AMEV5 immunized mice were protected from a lethal intraperitoneal challenge with a hypervirulent strain of Ab, 4 weeks post-final vaccination, and achieved survival rates of 70% and 90%, respectively. This study underscores the utility of immunoinformatics in developing expedient and efficacious immunotherapeutic alternatives to combat MDR infections.

Abstract Name: Protecting the Girls: Innovating Breast Protection Gear for Athletes through Technology and Customization

Designing sports equipment that ensures proper fit is crucial for safety and performance, creating a biomechanical system between the athlete's movements and how the gear responds. As the market shifts towards customized gear, technologies like 3D scanning, 3D printing, and extended reality, enable the creation of personalize gear unique to an athlete's body. An estimated 7 million female athletes in the U.S., and 50% will sustain a contact breast injury (CBI) during their careers. However, only 10% of these athletes report their injuries to coaches or medical staff. Most breast injuries go unassessed or untreated, despite the potential for symptoms that can last for weeks. Unaddressed CBIs can lead to chronic, and perhaps lifetime, conditions such as breast fat necrosis, fibrous lumps, deformities, asymmetries, and damage to the milk ducts. The shift to customized equipment and emerging material innovations has transformed the industry, such as mouthguards and swimwear, making tailored gear essential for enhancing performance and reducing

injuries. This research aims to leverage customization to protect against contact breast injuries in women participating in contact sports. This research hypothesizes that customized breast protection, tailored to an athlete's unique body shape, will reduce the risk of contact breast injuries while enhancing safety and performance. To assess female athletes' awareness of breast injuries, the availability of breast protection gear, and the role of breast protection in medical assessments, I am conducting a participatory survey. Data collection is ongoing through Google Forms, with 11 multiple-choice questions, 1 multiple-response question, and 1 open-ended question. Early insights from the responses are already informing the design and feature decisions for the customized breast protection prototypes. I anticipate that this protection will lower the rate of contact breast injuries in female athletes participating in high-impact sports.

Abstract Name: Differences in Dipping Status: Relationships Among Dipping Status, Demographic Differences, and Subjective Sleep Quality

BackgroundNocturnal blood pressure (BP) dipping, a phenomenon where BP decreases by 10% during sleep, is a critical marker of cardiovascular (CV) health. Non-dippers have worse CV outcomes overall. Perception of sleep duration (over or under recommended amounts) and quality are also linked to worse CV outcomes. This study investigated how demographic factors and perceived sleep parameters are associated with dipping status.**Methods**We analyzed data from 30 adult participants in Alabama who completed 24 hours of ambulatory blood pressure monitoring and a consensus sleep diary as a part of the Sleep and Circadian Contributions to Nighttime Blood Pressure (SCN-BP) study. Chi-square tests were used to determine differences in dipping status based on race, sex, perceived sleep duration, and perceived sleep efficiency (SE) categories. Sleep duration was analyzed in groups of short (<7 hours), recommended (7-9 hours), and long (>9 hours) duration. SE was divided into two groups: recommended ($\geq 85\%$) and poor SE ($< 85\%$).**Results**The sample was 60% male and 40.0% White, 36.7% Black, 16.6% Middle Eastern/North African (MENA), and 6.7% Asian. Among this sample, 26.7% of participants had short sleep duration, 50.0% had recommended sleep duration, and 23.3% had long sleep duration. Ninety percent of the sample had recommended SE. Chi-square tests showed no differences in dipping status among sex, sleep duration, or SE groups. However, disparities in dipping status among different racial categories were found $\chi^2(3, N=30) = 8.97, p = 0.03$.**Conclusion**There are disparities in dipping status among racial categories, with Black individuals most likely to experience non-dipping, Asian and White individuals most likely to experience dipping, and MENA individuals falling in between. There were no differences in perceived sleep duration or quality on dipping status. Future research should focus on mechanisms and solutions to nocturnal BP regulation across diverse populations.

Abstract Name: Exploring the Intersection of Tradition and Modern Science: The Medicinal Potential of Sri Lankan Herbal Medicine

This research explores the intersection of traditional Sri Lankan herbal medicine and modern scientific validation. The central research question addresses how traditional remedies, passed down through generations, align with contemporary scientific understanding of their medicinal benefits. While Sri Lankan herbal medicine is widely practiced by Vedamahaththayas (traditional healers), its role in modern healthcare remains underexplored. By analyzing both the cultural significance and scientifically-backed benefits of widely-used herbs like Gotu Kola, Cinnamon, Polpala, and Tulsi, this study aims to bridge the gap between folklore and pharmacology. The research contextualizes traditional practices within the broader scope of global herbal medicine, emphasizing the unique contribution of Sri Lankan herbs to modern health practices. The methodology involves interviews with Vedamahaththayas, supplemented by a review of scholarly literature and clinical studies on the pharmacological properties of the selected herbs. Data analysis cross-references traditional healing practices with findings from peer-reviewed studies, particularly focusing on the chemical compounds and therapeutic applications of the plants. Preliminary findings indicate that many of the herbs traditionally used to treat conditions such as urinary diseases, skin issues, and inflammation are supported by scientific studies that confirm their bioactive properties. For instance, Gotu Kola is shown to improve cognitive function, while Polpala demonstrates potential diuretic effects. These results suggest a promising integration of traditional medicine into modern healthcare systems, enhancing the therapeutic potential of herbal remedies. This study contributes to the growing body of research on ethnomedicine by demonstrating the value of integrating traditional knowledge with modern scientific methods. It encourages future studies to further validate the efficacy of these remedies and promote their incorporation into global health practices.

Abstract Name: Deposition of Mesoporous HKUST MOF via Surfactants in Solvothermal Deposition and its Absorption of Crystal Violet in Aqueous Solutions.

MOFs (Metal Organic Frameworks) are novel materials that have garnered significant interest in the last 30 years due to their remarkable absorptivity and high surface area. MOFs consist of metal ions and organic linkers to form larger crystal structures with micropores within the lattice. To artificially increase the surface area of these structures and create larger pores (mesoporosity), surfactants can be used in solvothermal synthesis of MOFs. This project explores the solvothermal deposition of HKUST, one of the most studied MOFs to date, the use of a surfactant to make these MOF films mesoporous, and its application to increase the absorption of crystal violet in aqueous solutions. This presents possibilities for increasing the absorbance of MOF films for wastewater treatment. Both regular and mesoporous HKUST will be synthesized as a powder and deposited on to a variety of substrates. These powders and films will then be tested using FT-IR, X-Ray Diffraction, and scanning electron microscope analysis to confirm characterization and determine morphology.

Abstract Name: Title: Impacts of Blood Feeding and Rearing Conditions on the Mosquito Microbiome: Insights from *Culex pipiens*

Mosquitoes are vectors for numerous pathogens, including malaria, yellow fever, West Nile virus, and Zika, posing a critical global public health challenge. In attempting to control the spread of the above diseases, recent research has identified the mosquito microbiome as a promising target for vector control strategies. Despite blood-feeding being essential for egg production in female mosquitoes, how blood-feeding affects bacterial load and species composition within the mosquito microbiome remains poorly understood. Our study aims to characterize prokaryotic microbiome changes in female *Culex pipiens* mosquitoes following blood feeding under typical laboratory-rearing conditions. To accomplish this, midgut samples from blood-fed females, non-blood-fed females, and male *Culex pipiens* mosquitoes were homogenized and cultured on broad-spectrum and selective agar media. Individual bacterial colonies were subcultured, and bacterial DNA was amplified using universal primers via PCR. The resulting amplicons were visualized by gel electrophoresis and sequenced to identify bacterial isolates at the genus level. These procedures were repeated three times using three independent blood-feeding events. Preliminary findings revealed a marked increase in bacterial diversity and density in blood-fed females compared to both non-blood-fed females and males. What drives these differences in bacterial communities is currently being analyzed. This study contributes to the expanding body of research exploring how the mosquito microbiome varies with sex, reproductive status, and laboratory-rearing conditions, within the broader aim of identifying universal patterns within the microbial community of *Culex pipiens*.

Abstract Name: Secretion Patterns of Salamander Biofluorescent Skin Glands

Biofluorescence is characterized by the absorption and re-emission of light in living organisms. Biofluorescence is widespread in amphibians, but the function is unknown. I study *Desmognathine* salamanders, which have a highly glandular skin rich in biofluorescent skin glands. To gain insight to the function of the biofluorescent skin glands, it is important to understand the stimuli that cause the glands to empty. I hypothesized that the skin glands empty in response to contraction of myoepithelial cells surrounding the glands. I predict that the number and size of biofluorescent skin glands will decrease after application of a weak transcutaneous electrical stimulation. To test this, I imaged biofluorescent glands using a fluorescence microscope before and after transcutaneous electrical stimulation. Changes in the biofluorescent glands were analyzed using an image processing software. I also used standard histological stains to determine if biofluorescent skin glands correspond to mucous or granular glands. I found that transcutaneous electrical stimulation did not cause biofluorescent skin glands to empty. I am currently analyzing skin samples using histological stains. These results will increase understanding of a potential signaling or antimicrobial function of animal biofluorescence.

Abstract Name: Queer Experience in the Manga of Oshimi Shuzo

The purpose of my research is to analyze themes of adolescent sexuality in the work of Japanese manga artist Oshimi Shuzo, specifically his two series *Inside Mari* (2012-2016) and *Welcome Back, Alice* (2020-2023). In both of these series, Oshimi presents normative gender and sexuality as a stifling, constraining force from which his characters try desperately to escape. In *Inside Mari*, I argue that this force is represented by the gaze, borrowing Laura Mulvey's term from film studies. In *Welcome Back, Alice*, I apply Judith Butler's theory of gender performativity to understand how cissexism and strict gender roles influence the characters and their resistance strategies. I also argue that these two works show a development of Oshimi's thinking about gender, with *Welcome Back, Alice* depicting gender as more fluid, eroticized, and central to ones' identity than *Inside Mari*. In my analysis of these works, I pay special attention to Oshimi's use of imagery and comic tropes. Imagery plays a large role in both the cinematic gaze and gender performance, making graphic novels an especially apt medium to explore these themes. Oshimi also critically engages with and subverts common tropes in manga, especially manga aimed at teenage audiences, such as high school drama, romantic comedy, erotic fan service, and cross dressing. While there has been a lot of research into queer manga in general, there has been no academic English-language study of Oshimi's work, despite his popularity and critical success. I hope to help bring Oshimi's work to the attention of other scholars of manga and queer literature, as I believe his entire body of work is unique, complex, and fruitful for further study.

Abstract Name: Qualitative Analysis of the Viral Genome Harbored by *Dermacentor variabilis* in Hancock County, Ohio

The increasing prevalence of emerging tick-borne diseases presents a significant public health concern, driven by the northern shift in tick species distribution facilitated by climate change. Ticks have been known to harbor various pathogens, ranging from bacterial infections like Lyme disease to viral illness such as tick-borne encephalitis. Accurate estimations of tick species populations are critical for effective disease prevention and biosecurity. To address this, 374 ticks were collected from April 2024 to July 2024, in order to analyze the species present in Hancock County, Ohio and examine their seasonal prevalence. Collection numbers increased throughout the period, peaking in mid-June, consistent with previous research on seasonal fluctuations. Historically, ticks of the species *Ixodes scapularis* (Deer tick) and *Dermacentor variabilis*

(American Dog tick) have been common in this region. However, all ticks collected in this study belonged to the species *D.variabilis*. This unexpected overabundance of a single species, compared to historical data, raises important questions about its implications for disease transmission dynamics in this region. Pathogens are often shared between tick species, but the absence of a species in a region could alter transmission pathways. Given the dominance of *D.variabilis* in this region, understanding its role as a potential vector of disease requires further molecular investigation. The viral genome harboured by these ticks is of particular interest, not only as a public health concern, but also due to the symbiotic relationships that may be at play. Identifying the viruses these ticks harbour will provide crucial insights into the dynamics of virus transmission and the potential public health impact in this area.

Abstract Name: Digging Deeper into Public Archaeology: Redefining Best Practices to Educational Programming in Archaeological Practice

Public Archaeology is an important approach in the discipline that helps archaeologists engage with the public in a number of ways with the goal of getting the public invested in archaeology and with stewardship of the past. Education is an significant component to this approach, serving as one of the primary means of bringing archaeology to the public, and it can take many forms, ranging from K-12 classroom visits to working with local libraries to participating in large community events. The Antonio J. Waring, Jr. Center for Public Archaeology is explicitly concerned with educational programming to help achieve its goals of community engaged work. While the Waring Center has certain methods in place to educate and engage with the public, it is always important to periodically assess the effectiveness of these methods. Recently, a SWOT (Strength, Weakness, Opportunity, and Threat) analysis was conducted to analyze the different methods and strategies of the Waring Center. As with all SWOT analyses, weaknesses and threats were identified for each method. This poster focuses on proposing solutions to those weaknesses and threats. Drawing on some of the recent literature on the effective use of SWOT analyses, these solutions will make use of alternative options that can be developed by crossing the SWOT matrix to create areas of innovation. All solutions proposed are based solidly within well-defined pedagogical frameworks, especially those found within embodied learning and experiential learning, and public archaeology literature. The primary goal of this research is to determine new guidelines for best practices in Public Archaeology work, which can help inform not only the methods used at the Waring Center but also those used by other Public Archaeology programs across the globe.

Abstract Name: Weather Event Impacts on Soil Characteristics of a Salt Marsh in the Barataria Basin, Louisiana

Hurricanes and other storms can greatly affect salt marsh soil characteristics. Thus, marsh soil characteristics can be used to determine when different weather events occurred. Elements in the soil are proxies for marine vs terrestrial factors. Marine indicators are more typical of storm surges than terrestrial indicators are. A salt marsh near the Coastwide Reference Monitoring System (CRMS) 0224 station in the Barataria Basin was chosen as our study site. Three cores were taken at 1 m (core ID: M1), 5 m (M5), and 30 m (M30) from the marsh edge. Each core was 4 meters long and taken in 50 cm increments using a Russian peat Borer with twenty four 50 cm cores in total. Back in the laboratory, X-Ray Fluorescent Spectroscopy (XRF) was used to measure elemental composition of all cores in 1 cm increments. The XRF data projected elemental concentration changes with depth in each core. Potential storm layers and fluvial flooding correlated across all three cores. Each core showed 2 or 3 storm surges in recent history and a transition zone with fluvial flooding leading to several more storm surges. To further identify storm surge events, the cores were sliced into 5 cm or 10 cm layers and analyzed for water content, bulk density, loss on ignition, grain size, as well as carbon and nitrogen content. The continued research will focus on groundwater exchange along with soil characteristics in relation to weather dynamics.

Abstract Name: Investigating Anti-Inflammatory Properties of Pomegranate Gold Nanoparticles and Punicalagin

The investigation of polyphenols as a potential therapeutic strategy to reduce chronic systemic inflammation has become an area of interest. Many plant-derived polyphenols induce anti-inflammatory responses in different cell lines. Previous research suggests that punicalagin, a polyphenol found in pomegranates, exhibits anti-inflammatory effects in murine cell lines. This study examines the potential anti-inflammatory effects of pomegranate gold nanoparticles (POM AuNPs) as well as pure punicalagin on the THP-1 human monocytic cell line. POM AuNPs were synthesized using gold chloride and pomegranate juice. THP-1 monocytes were differentiated into macrophages and treated with lipopolysaccharide (LPS) to simulate an infection in the absence or presence of increasing concentrations of POM AuNPs or punicalagin. Cell viability (XTT) assays showed no decrease in cell viability as a result of either treatment. Preliminary data obtained through enzyme-linked immunosorbent assays (ELISAs) suggests that punicalagin may reduce the production of pro-inflammatory cytokines in THP-1 derived macrophages.

Abstract Name: An Examination of Parental Knowledge and Beliefs about Dual Language Development and its Impact on Dual Language Learners

Whether a child will grow up to be bilingual or not is largely determined by their parents. This study reviews current literature to examine major paradigms of parental knowledge and beliefs about dual language development. Two major belief structures are explored: (1) the belief that dual language development is harmful because learning two languages simultaneously may cause language delays or hinder English acquisition, and (2) the belief that bilingualism provides opportunities for success as well as maintenance and appreciation for cultural heritage. The literature also reveals that these belief structures vary across cultural groups and often reflect the collective struggles of that particular cultural group. As society progresses toward becoming multilingual, and the cognitive and educational benefits of bilingualism are more broadly understood, these findings indicate that it is crucial to educate parents on this topic in a culturally responsive manner. Future studies should further examine how socio-economic class influences parental ideologies about dual language development. Such insights could provide a more comprehensive understanding of the factors affecting bilingualism in children and guide more effective educational strategies for parents across different socio-economic backgrounds.

Abstract Name: Does stock popularity on social media impact short-term equity performance?

This study attempts to determine if small retail investor interest on social media can have an impact on short-term equity performance. For each stock in a given portfolio, investor interest is determined by the frequency of mentions and other data measures, including upvotes. Related literature exists primarily between 2020 and 2022, the so-called “meme stock” era. Similar research is performed on Reddit but using a smaller portfolio and a longer data period, as well as on Twitter, Discord, and Stocktwits to correlate social media sentiments with return. This study builds upon said previous work by observing more recent 2024 data within the context of rampant growth of overall social media usage. This study utilizes the Reddit forum r/wallstreetbets, one of the most active social media sources of investor activity. To perform this research, a custom Python program was created to search the forum’s comments and aggregate the frequencies of tickers mentioned. For each stock, an analysis is run of its mentions against its short term performance over the next few days, controlling for market capitalization, book-to-market ratio, and past 12-month returns. I expect to find a measurable relationship between social media interest and subsequent performance which can depend on the stock, firm industry, market cap, etc. Understanding which stocks are most sensitive to retail investor popularity can inform future investment strategies, predict the next emergence of potential viral meme stocks, and provide insights into social media investor attitudes and sentiment.

Abstract Name: Integrating Generative AI in Data Warehousing: Bridging the Educational Gap for Future Graduates

Data warehousing is a system that stores and manages large volumes of structured data from various sources for analysis, reporting, and decision-making, often using solutions like SAP BW. The increased growth of Generative AI in recent years has led to advancements in data warehousing. An example includes integrating machine learning algorithms in Extract, Transform, and Load (ETL) processes for improved data quality. Nevertheless, the radical innovation of Generative AI also brings in a gap between undergraduate curriculum in Business School in the States and the latest state of warehousing methods. The goal of our research is to examine the status quo and suggest ways in which higher education can integrate GenAI use cases into data warehousing curriculum, aiming to provide timely skills to recent graduates. With an increased adoption of GenAI solutions in the workforce, it is imperative to prepare students with these skills. To accomplish this, we study the role of GenAI in data warehousing throughout the past and the present at both higher education and professional levels using two approaches. First, we examined the course offerings in the undergraduate business education by referring to the recommended curriculum framework from the related professional associations and university accreditation, supplemented with information collected from university websites. Second, we surveyed professionals about their working experiences of data warehousing and thoughts on the future of GenAI in this field. This research contributes to the heated discussion of GenAI in industry through the angle of student preparedness in higher education. The findings identified the missing pieces in current offerings and recommends topics, tools, and approaches to prepare this generation of students for the future workforce.

Abstract Name: Exploring the Impact of Medical Interpreters in Simulation on Nursing Students' Knowledge and Competence

Purpose: To explore the impact of medical interpreter-mediated communication education on final semester prelicensure student nurses' knowledge, clinical competency, and perceptions of interprofessional simulation-based education (IPSE). Background: Culturally competent care is becoming more critical in nursing practice due to the increasingly diverse population. An essential component of culturally competent care is effective communication between healthcare providers and patients. Language barriers are one of the greatest challenges in providing effective communication in the clinical setting, often requiring the use of medical interpreters. However, existing resources to prepare medical professionals for these competencies, and studies exploring their effectiveness are limited. To address this gap, a learning module and nursing student simulation were implemented utilizing medical interpreter students and a non-English language preference (NELP) patient. Methodology: Retrospective analysis of nursing students' pre/post-evaluation of a student-developed knowledge-based module. Nursing and medical interpreter students completed the Students Perceptions of Interprofessional Clinical Education - Revised 2 (SPICE-R2) Instrument pre/post-simulation. The nursing students' application of competency-based knowledge was evaluated by faculty during the simulation. Expected Results: Data collection is complete, and analysis will be completed January 2025. Preliminary results suggest positive student perceptions of IPSE increased following the simulation experience. The analysis can enhance understanding of IPSE effectiveness and will be utilized for data-driven decision-making regarding the module, and student competency utilizing interpreter-mediated communication to engage with NELP patients in professional practice. Future studies exploring structured IPSE programs across all classifications and levels of nursing programs in nursing education may promote a healthcare environment that more heavily prioritizes cultural competence.

Abstract Name: Four- Coordinate Lanthanide Azadipyrrromethene Chelates in Near-Infrared Region

Bioimaging is a vital, non-invasive technique that plays a crucial role in the identification and treatment of diseases. Among the techniques available, fluorescence imaging has emerged as a powerful method, using molecules capable of absorbing and emitting light to illuminate cancerous tissues. For clinical usage, these molecules must be water-soluble, cost-effective, and exhibit minimal side effects. To achieve deep tissue tumor imaging, fluorescence dyes must operate within the near-infrared (NIR) region, as NIR wavelengths penetrate tissues effectively while minimizing damage to surrounding organs and structures.

Azadipyrrromethene (aza-DIPY) cores represent an underexplored class of NIR-fluorescent molecules, typically chelated to Group 13 metals. However, their potential when chelated to lanthanide metals, forming a unique four-coordinate system, remains absent in the current literature. In this study, a novel aza-DIPY core was synthesized and chelated to various lanthanide elements to investigate its NIR activity and photophysical properties, paving the way for innovative advancements in fluorescence imaging.

Abstract Name: Carbon and Nitrogen Influence on Enzyme Production in *Batrachochytrium dendrobatidis*

Batrachochytrium dendrobatidis (Bd) fungus has contributed to global amphibian decline and extinction. Bd infects the skin of amphibians, causing ion imbalances and death. The exact nutrients and carbon to nitrogen (C:N) ratios of amphibian skin is unknown. Amphibian-produced antimicrobial peptides and bacterial-produced metabolites are known to impact the growth of the fungus. The fungus produces a broad range of proteases to help degrade skin components, but the impact of nutrition on their production has not been researched. Altering the C:N conditions for Bd could alter production of virulence traits. The goals for the project are: 1) determine sub-lethal C:N ranges of Bd, 2) analyze gene expression of secreted proteases in sub-lethal C:N ratios, and 3) determine protease activity in each condition. The growth of Bd in different C:N ratios was completed in 96 well plates using a spectrophotometer with a wavelength of 492 nm over 7 days. The sublethal conditions of Bd were C10N1 and C1N5, with C1N1 and C0N1 being optimal conditions. Gene expression was analyzed by extracting RNA from Bd grown in C:N conditions on day 4 of growth by converting RNA to cDNA and using Real Time qPCR with 5.8S rRNA as an internal standard and protease specific primers designed through IDT PrimerQuest. Elastase activity was monitored using a fluorometric dye

on day 4 intracellular and extracellular proteins. Day 4 data suggests protease genes are expressed higher in carbon conditions while protease activity is higher in nitrogen conditions. Future studies will look at gene expression and elastase activity over growth from Day 2 to Day 5. By understanding how nutrients can impact the virulence of the fungus, susceptible amphibians could be identified and treatment plans customized.

Abstract Name: Analysis of the ARID-1 complex during aging in *C. elegans*

Cellular identity-the structural and functional features common to particular cell types that distinguish them-is established when cells differentiate as epigenetic mechanisms permit specific constellations of genes to be expressed while silencing others. During aging, changes to chromatin structure disrupt transcriptional regulatory programs that maintain cellular identity. This leads to dysfunction at the tissue level, eroding health later in life, and limiting lifespan. We discovered that in the roundworm *Caenorhabditis elegans* ARID-1, an ortholog of the mammalian ARID4a chromatin organizing protein, is expressed in neurons during adulthood and is required for both innate immunity and longevity. Prior studies showed that, similar to ARID4a, ARID-1 functions as a part of a multisubunit complex in the *C. elegans* germline. However, the composition of this complex in other tissues and in postreproductive animals is unknown. To determine the function of the ARID-1 complex during aging and to identify its constituents, I first used a reverse-genetics strategy to ask whether products of candidate genes cooperate with ARID-1 to confer immunity and thus likely encode ARID-1 complex subunits. In adults, *suds-3* knockdown phenocopies RNAi targeting *arid-1*, causing increased susceptibility to bacterial pathogens. This suggests that SUDS-3 and ARID-1 may be part of the same protein complex in older animals. Further functional analyses of additional candidate genes are underway. In parallel, I pursued a biochemical strategy to isolate the ARID-1 complex by immunoprecipitation. Using growth conditions that I optimized, I have increased the number of animals in our age-synchronized *C. elegans* cohorts by 80-fold. This is expected to generate sufficient starting material to pull-down a FLAG-tagged version of ARID-1 from fractionated *C. elegans* lysates for downstream analysis. We anticipate that our studies will have implications for the importance of maintaining chromatin structure to preserve critical functions during aging in diverse organisms, including humans.

Abstract Name: How does an infant's sleep impact problem-solving skills during a motor task?

Background: Infant sleep is essential for both cognitive and physical development. Healthy sleep consists of appropriate timing and adequate duration with no disturbances. It is recommended by the National Sleep Foundation that infants between 4-11 months sleep between 12-15 hours per day. It is possible that sleep quality plays a unique role at differing times during infant development, but research results have been mixed. For example, 6-month olds sleep quality was positively associated with a cognitive task the next day (Konrad, 2016), but 12-month olds sleep was not associated in the same study. Further evidence is needed to understand if an infant's sleep quality is linked to learning and cognitive performance particularly under conditions of an early motor milestone, sitting independently. Purpose: The goal of this project is to determine if an infant's sleep quality impacts their abilities to solve a reaching task challenging their newly gained sitting balance control. Methods: 6 to 8 month-old infants were recruited for this study via public announcements in Brooklyn NY and Pittsburgh PA. All infants could sit independently but were not crawling and were typically developing. A reaching task was done to quantify movement with the infant reaching for toys in alternating locations through a reaching board. The infant's sleep was tracked with a sleep monitor to measure duration and number of wakings. Factors quantifying problem-solving included reach time, postural control, and look time, which were measured via Datavyu video coding. Conclusions and Expected Results: We predict that infants with better sleep quality will show faster reach time and look times. We also expect there to be a trade-off between posture control and reach time, such that infants with less postural control will take longer to problem-solve and thus have longer reach and look times.

Abstract Name: Testing a New Tool for Psycholinguistic Experiment Stimuli Development: The A-maze 2.0

The Maze Task is an experimental method used in linguistics to study how people process and understand the meaning of sentences. In the task, participants choose the correct word (out of two options) that continues the sentence in a grammatically correct way. However, because of the difficulty of generating stimuli (the alternatives, or "incorrect" options), the Maze Task had not been widely used until recently. Thus, the development of the A-maze (automatic-maze) software which generates stimuli automatically by Boyce et al. has been greatly beneficial. Building upon the A-maze by Boyce et al., we have built a new A-maze "2.0" to generate stimuli for more languages (previously was just English) and to make the software more accessible to more people. This study aims to analyze the results of the A-maze "2.0" and compare how well it performs to the original A-maze, namely by comparing error rates. To collect data, participants are asked to complete several trials of the improved Maze Task online over an Ibex platform, where sentences are purposely ambiguous in some way. Then, the data and error rates associated with each word are compiled and compared with Boyce et al.'s A-maze. We expect the A-maze "2.0" to perform similarly well, with similar levels of error, although the study is currently ongoing and results will be reported. Ultimately, this new A-maze is crucial to further developments in psycholinguistics, as it expands research into other less studied languages, and the Google Colab interface allows more people with less programming experience to access the software.

Abstract Name: Enhancing Validity in Alcohol Research: The Case for Multi-Participant Alcohol Administration Studies

Background: Since the 1930s, researchers have studied alcohol's effects on emotions, behavior, and cognition in laboratory settings to understand factors that may contribute to alcohol use disorders (AUD). While most real-world drinking occurs in social settings—whether with friends, family, or strangers—laboratory studies seem to be overwhelmingly focused on solitary drinking. This discrepancy raises concerns about the ecological validity of laboratory alcohol administration studies and may limit our understanding of alcohol's effects in naturalistic social environments. Here, we aimed to quantify how much laboratory alcohol administration studies have incorporated social drinking contexts. **Methods:** A systematic review was conducted of laboratory alcohol administration studies published through 2023, adhering to PRISMA guidelines. Searched in PsycINFO, PubMed, and Web of Science identified 5,690 records, from which 989 studies were included. Studies were coded for whether drinking occurred in solitary or social settings (see pre-registration for additional details <https://osf.io/njvzd>). **Results:** Of 989 studies identified, 90.8% administered alcohol in solitary settings, with less than 10% featuring a social context. Most multi-participant studies were conducted prior to 1990 and were methodologically limited by small sample sizes and inadequate statistical methods to account for interdependent participant interactions. More recent, well-powered multi-participant alcohol administration studies demonstrate alcohol's robust effects on social bonding and tension reduction, mechanisms critical to understanding AUD risk. **Conclusion:** Current laboratory research largely overlooks the social nature of drinking, creating a gap in understanding alcohol's typical effects and AUD risk factors. Well-designed multi-participant alcohol administration studies are urgently needed to address this gap, as they offer the potential to uncover social mechanisms underlying alcohol use and its associated harms. Prioritizing such research will improve ecological validity and may inform public health strategies for mitigating alcohol-related risks.

Abstract Name: Chemogenetic Activation of Corticotropin Releasing Factor-Expressing Neurons in the Central Nucleus of the Amygdala Influences Cocaine-Related Behaviors in a Sex- and Session- Dependent Manner

Cocaine misuse in the US has steadily risen throughout recent decades, leading to ~28,000 cocaine-related deaths in 2022 alone. Positive feedback loops underlie addiction, where drug taking and associated rewarding effects promote further drug seeking in a self-sustaining cycle. Negative emotions such as stress and anxiety emerge during withdrawal. The Corticotropin releasing factor (CRF) neuropeptide is enriched in the central amygdala (CeA) and is key at modulating affective states and behaviors related to stress, anxiety, fear, and pain. Previous studies show an increase in CRF neuropeptide and neuronal activation during cocaine withdrawal. However, the role of CRF neuronal activation during active cocaine intake is not well-

understood. To investigate this, control AAV or AAV encoding a novel cocaine-activated Cre-dependent chemogenetic Na⁺ channel (termed coca-5HT3) was stereotactically injected into the CeA of CRF-Cre rats bilaterally. Immediate behavioral and physiological response to intraperitoneal (i.p.) cocaine was measured for locomotion, anxiety- and irritability-like behaviors, and mechanical nociception. Cocaine seeking was assessed by short access (ShA) and long access (LgA) intravenous self-administration (IVSA) after jugular-vein catheterization. We hypothesized that activation of CeA CRF neurons by cocaine during IVSA could either induce withdrawal-like symptoms and subsequently increase intake in an attempt to arrest the symptoms, or decrease cocaine intake by learned association between aversive effects of CRF neuronal activation and cocaine. Here, we show that coca-5HT3 resulted in various effects dependent on sex and IVSA session length. Coca-5HT3 promotes an increased heart rate upon i.p. cocaine injection and higher weight gain overtime. Following ShA IVSA, Coca-5HT3 suppressed active lever presses in females during footshock (FS). Moreover, Coca-5HT3 during LgA IVSA facilitated an earlier escalation of active lever presses without affecting the number of cocaine infusions. These results suggest that CeA CRF neuronal activation during cocaine exposure impacts cocaine-related behavioral responses dependent on the time-course of IVSA.

Abstract Name: Experimental Design for Optimizing Plant Growth Using a Programmable Farming Robot

The goal of this research was to create an experimental design that can be applied more broadly to research how to optimize the growth of any plant species by systematically adjusting relevant variables and measuring their effects. A programmable farming robot, FarmBot, was used in collaboration with Chippewa Valley Bean to grow dark red kidney beans in a controlled greenhouse environment. The FarmBot platform provides several attachments that enable the monitoring or manipulation of various agricultural variables. In this case, we used its watering nozzle and camera. Plant growth was monitored for two months by regularly photographing each individual plant. The photographs were then downloaded and organized into folders specific to each plant. The variable chosen to investigate for its impact on plant growth was the volume of water applied. Each section of the farm bed received a different water volume, ranging from 30 ml to 60 ml, and the experiment was conducted in a greenhouse to eliminate the influence of weather variability. The plants were spaced in a way that allowed for individual plant monitoring, using canopy cover as a proxy for growth. This experimental approach can be used to efficiently test various factors that may affect plant growth, enabling researchers to develop better agricultural models and ultimately improve crop yields in the field. Our experimental design can be expanded to explore other variables, such as soil type, to investigate their influence on plant growth. Additionally, the collected photographs could be processed to identify early signs of diseases, pests, and other potential threats to the plants.

Abstract Name: A Retrospective Exploration of the Relationship Between Executive Functions and Social Skills Among College Students with Autism

The diagnostic criterion for autism spectrum disorder (ASD) identifies social communication deficits as a persistent characteristic of the condition. Additionally, executive dysfunction has been identified as a concomitant feature of autism. Executive functions are defined as those cognitive and meta cognitive skills that provide for the capacity to regulate, adapt, and control our behaviors, responses, and actions for present demands and act as a foundation for future-oriented goals. Research indicates that executive functions are significantly associated with social impairments in children with ASD. Additionally, research suggests that both social deficits and executive dysfunction in individuals with autism persist into adulthood, but there is no research exploring the relationship between executive functions and social impairment in adults with autism. The aim of the current study is to determine the relationship between executive functioning and social skills in college students with autism based on self- and parent-evaluations on the Behavior Rating Inventory of Executive Function® - Adult Version (BRIEF-A) and the Social Responsiveness Scale, Second Edition (SRS-2). The current study will utilize retrospective data in a correlational research design. Data will be analyzed using the Pearson correlation coefficient (r) to determine the direction and strength of the relationship between BRIEF-A and SRS-2 scores. Results will provide insight into the relationship between executive functioning and social skills in college students with autism.

Abstract Name: Echoes of Service: Veteran Identity Explored Through Photovoice and Lyric Analysis

Our study utilized photovoice and lyric analysis, both qualitative community-based participatory action research (CbPAR) techniques, to explore how Veterans define their post-service identities. Many Veterans experience “reverse culture shock” after leaving the military, impacting relationships and leading to isolation. Photovoice empowers Veterans to tell their stories through photographs, while lyric analysis allows reflection on songs resonating with their experiences. Veterans responded to the prompt “What does being a Veteran mean to you?” by taking photos and identifying songs that reflected their identities. They participated in semi-structured interviews discussing these images and lyrics. Transcripts, song lyrics, and other artifacts were analyzed using a phenomenological approach to uncover themes related to Veteran identity. Member-checking was used to establish external validity. Preliminary results reveal common identity themes such as honor, integrity, pride, isolation/loneliness, duty, sacrifice, humanity, identity conflict, and loyalty. Despite common themes, Veteran identity is not a monolith; each participant processed their experiences uniquely. These methods foster trust between historically exploited and excluded groups in science (HEEGS) and researchers, amplifying marginalized voices. As a final showcase, we hosted an interactive gallery of Veterans’ photos and songs, including live performances and displays of highlighted lyrics and photos. Qualitative, CbPAR methodologies, such as photovoice and lyric analysis, not only facilitate more ethical and empowering research with Veterans, but also help rebuild trust with HEEGS.

Abstract Name: Healthcare Utilization in Neuro-Oncology

Neuro-oncology has the highest total care costs for any cancer, yet the sources of healthcare utilization (HCU) are not well identified. The purpose of this study was to identify the most common neuro-oncology HCU following diagnosis. A cross-sectional descriptive survey was administered via patient support groups. Patients (N=41) identified use of healthcare resources and potential barriers to HCU using a modified version of the Health Care Access and Utilization survey. Descriptive analyses were completed using SPSSv29.0.1. The majority of respondents were female (83%, N=34), diagnosed with either a glioma (39%, N=16) or meningioma (24%, N=10), and were between 41-60 years of age (58%, N=24). The most commonly used

resources included the neurosurgery team (56.4%, N=22), neuro-oncologist (63%, N=22), and support groups (53%, N=17). Resources patients reported using the least were social work (24%, N=5), occupational (18%, N=7) or physical (42%, N=17) therapy, palliative care (9%, N=4), and neuro-psychology (12%, N=5). For the least used resources, the reason for not making use of these services was that they were either not needed or not suggested. Patients who are diagnosed with brain tumors may limit HCU to the most necessary and time sensitive providers, who also represent a group of high-cost providers. Data also reveal a lack of use of supportive care resources, which is surprising given the high mortality and morbidity rates within this population. More targeted questionnaires to a larger sample would provide insight into not only sources of healthcare costs, but also to the accessibility and acceptability of support care providers.

Abstract Name: Climate Anxiety and Contempt Among Gen-Z: Relationships with Efficacy and Policy Support

This study examined feelings of climate anxiety and climate contempt among 758 Gen-Z residents of North Carolina. Data was collected in May 2024 through polling company Dynata. Within this survey study, participants were measured on their levels of contempt and anxiety about climate change using five-point scales. Using t-tests and correlations, analyses tested whether males or females tended to have more or less climate contempt or anxiety and whether contempt and anxiety varied with political ideology or extent of science knowledge. Analyses also examined levels of collective efficacy and pro-environmental policy support, and how they varied with climate anxiety and contempt. Results showed that those with more climate contempt were more likely to be politically conservative and male, less likely to support environmental policies, and had less science knowledge. Conversely, those with greater climate anxiety were more likely to be politically liberal, more likely to support environmental policies, felt more collective efficacy about helping the climate, and had more science knowledge. Analyzing these findings allow a greater understanding of how key demographic groups perceive climate change and what they are willing to do about it. Implications may include ways to more effectively communicate about climate change and promote pro-climate policies to partisans. Reducing climate contempt is a significant goal as it correlates with lower collective efficacy and lack of support for pro-environmental policy. Intervention could begin early with better science education which could reduce climate change contempt. Although climate anxiety directly correlates with collective efficacy and support for pro-environmental policies, future research should explore ways to promote a sense of urgency about the climate crisis among Gen-Z without triggering anxiety.

Abstract Name: Enhancing Precision: The Application of Exoscope Technology in Spine Surgery

Minimally invasive surgeries (MIS) are becoming increasingly popular techniques for spinal decompression as they reduce postoperative complications such as recovery time, blood loss, pain, scarring, and hospital stay. Unlike conventional microscopes used in neurological surgery, which can lead to surgeon fatigue and poor ergonomics, the exoscope offers surgeons and their teams a highly detailed view of the surgical field in neutral or upright position. This improves precision, fosters stronger collaboration, and enhances patient outcomes. In this case series, we present the successful use of an exoscope in three posterior decompression surgeries to alleviate pain from lumbar radiculopathy, and one thoracic myelopathy case. A robotic exoscope was used by the surgical team for four patients undergoing spinal decompression surgeries. The team analyzed clinical and surgical data to evaluate the exoscope's utility in spinal surgeries. Three patients (75%) had lumbar radiculopathy while one patient (25%) presented with thoracic myelopathy and progressive pain. Three patients underwent a posterior decompression, with the exoscope enhancing visualization during the procedure and microdissection, whereas one patient underwent a lateral thoracic retropleural MIS discectomy. In all patients, the exoscope enabled adequate decompression of the required anatomical areas, namely the lateral recess, traversing nerve roots, and central thecal sac. It enhanced visualization, depth perception, collaboration, and overall surgical convenience. There were no surgical complications or intraoperative neuromonitoring issues, and at two-week follow-up, all patients reported reduced preoperative symptoms. Three-dimensional robotic exoscopes were proven to be extremely beneficial in high-precision procedures like microdissection and decompression. The exoscope enhanced visualization for the surgical team, leading to greater precision and unremarkable postoperative outcomes.

Abstract Name: Investigation of Post Translational Modifications on Copper Chaperone for Superoxide Dismutase

Copper is an essential metal for biological systems and plays critical roles in numerous intracellular pathways. Dysregulated copper homeostasis can lead to the development of various diseases, highlighting the importance of maintaining its intracellular balance. Copper chaperone for superoxide dismutase (CCS) is a key metallochaperone protein and delivers copper to the redox protein superoxide dismutase (SOD1). CCS has three domains, with copper-binding sites in domains 1 and 3. Domain 3 is intrinsically disordered and contains a serine residue between the two copper-binding cysteine residues. This serine can be phosphorylated, which we hypothesize may influence copper binding and CCS function. To investigate the role of this post-translational modification (PTM), we synthesized WT and phosphorylated peptides encompassing domain 3 of CCS using Fmoc-based Solid Phase Peptide Synthesis (SPPS). These synthetic peptides will be used to study copper-induced structural changes using Circular Dichroism (CD) spectroscopy. This will help to elucidate the functional impact of serine phosphorylation within domain 3 of CCS.

Abstract Name: In/visibility of Caste: An Analysis of Second-Generation Indian Americans' Caste Discourses

While caste serves as a fundamental organizational principle across much of South Asian society, its implications often appear less readily visible to members of the South Asian diaspora born and raised outside the region, especially in comparison to their more salient identity as a racially and ethnically nondominant group (see Chandrashekar, 2024). This study explores second-generation Indian Americans' discourses to better understand how they communicatively construct caste in relation to their identities. Using critical thematic analysis (Lawless & Chen, 2019), we examined comments across 26 threads related to caste on the subreddit ABCDesis (American Born Confused Desis) that were posted between 2022 and 2024 and identified four themes. First, they echo frames of colorblindness (Bonilla-Silva, 2018), including minimization, naturalization, and abstract liberalism, to construct a "casteblind" narrative that rationalizes caste/ism and, for many, maintains their caste privilege. Second, they rely on a disconnected power analysis (Jayakumar & Adamanian, 2017) to distance themselves from caste/ism, instead blaming it on first-generation immigrants, British colonization, and/or on a backwards Indian culture. Third, they create a sense of victimhood to contest endeavors to combat casteism in the United States, alleging Hinduphobia and/or reverse discrimination against Brahmins or by prioritizing racism faced by the community over casteism. Lastly, some discourses demonstrated critical reflexivity (Mudambi et al., 2023) to challenge casteism by recognizing their own caste privileges within the larger sociohistorical context of South Asian immigration. This research highlights the importance of caste as an analytic framework to better understand dis/privilege within the South Asian diaspora. Keywords: Caste, Casteism, South Asian diaspora, Hinduphobia, Critical Reflexivity

Abstract Name: Elucidating the Role of HD5 in Colonic Wound Healing

Introduction Crohn's colitis (CC), a type of inflammatory bowel disease (IBD), causes chronic inflammation in the large intestine, resulting in malnutrition, diarrhea, and severe pain. Early and accurate diagnosis of CC is essential, as misdiagnosis with ulcerative colitis can lead to inappropriate treatment and worsened outcomes. Innate immune peptide, human alpha-defensin 5 (HD5), is upregulated in CC, but not UC, and may play a role in disease pathogenesis. Preliminary data in our lab indicates that HD5 impairs wound healing in colonic epithelial cells. **Hypothesis** We hypothesize that HD5 increases RNA and protein levels of COL4A3, EGF, and MMP1 while decreasing ACTB expression, thereby affecting colonic wound healing in CC. **Methods** Wound healing assays will measure the effect of HD5 on epithelial cell migration and closure. RNA and protein extractions will be performed on HD5-treated NCM460 cells, followed by qPCR and Western blot analyses to assess gene and protein expression levels of COL4A3, EGF, MMP1, and ACTB. **Expected Results** We anticipate that HD5 treatment will reveal altered expression of genes and proteins critical to wound healing. These findings will help elucidate HD5's role in CC pathogenesis and identify potential molecular targets for therapeutic intervention. This study aims to advance understanding of

HD5's influence on epithelial repair and its contribution to CC, ultimately informing more effective treatment strategies.

Abstract Name: Off the Cliff: Case study of drug overdose deaths in Georgia

From 2019-2022 drug overdose deaths in Georgia increased by 76%, but in 2023, there was a small decrease of 6%. However, government statistics, epidemiological research and descriptive research, show that black people are dying at a higher rate in Georgia compared to their white counterparts. The figures for other ethnic groups show slight increases but not as large as those for blacks and whites. For example, the nominal number of black overdose deaths in 2023 continued to rise especially in urban populations from 791 deaths in 2022 to 818 deaths. I am researching drug overdose deaths in Georgia because I want to know why certain populations are being disproportionately affected compared to others. The objective of this research is to present policy recommendations to reform drug intervention policy in Georgia with the aim to help reduce the overdose deaths in all communities, but especially those affected more disproportionately. This is a case study of Georgia to use as a base line as a comparison across all states who have a similar problem.

Abstract Name: Faking Reality - Ethical and Legal Concerns

This study looks at the ethical and legal problems surrounding deepfake pornography, focusing on issues of consent, privacy, and the societal impact of this technology. Deepfakes make it easy to manipulate someone's image into explicit content without their permission. This not only invades their privacy but also puts them at risk of public humiliation and mental health challenges, especially for women, who are the primary targets. We explore how this growing technology harms individuals and society while existing laws fail to provide enough protection. For example, outdated legal frameworks leave many victims with no way to hold perpetrators accountable. The study also examines efforts to address these issues, such as stricter laws in states like California and Virginia, and the need for better detection tools. The findings highlight the urgent need for stronger federal laws, faster detection methods, and accountability for platforms that allow this content. By addressing these gaps, we can work toward reducing the harm caused by deepfakes and protecting people's rights in the digital age.

Abstract Name: The effects of obstructive sleep apnea on muscle tissue oxygenation during exercise

Obstructive sleep apnea (OSA) is characterized by recurrent arousals and episodic oxyhemoglobin desaturations during sleep. Patients who suffer from OSA have reduced exercise performance, although the mechanisms for this reduction are not clear. Purpose: To examine the tissue oxygen saturation (StO₂) of the tibialis anterior (TA) muscle in adults with OSA during a graded exercise test. Methods: Near-infrared spectroscopy (NIRS) was used to measure StO₂. All participants walked at 2.5 mph on a treadmill for six stages of progressively steeper grades (0%, 3%, 6%, 9%, 12%, 15%) or until volitional fatigue. Each stage lasted three minutes and StO₂ was averaged over the last minute of each stage. The severity of OSA was determined using an at home sleep testing system and characterized by the apnea-hypopnea index (AHI) and time during sleep spent under 90% oxygen saturation (T90). Body composition was measured using dual energy X-ray absorptiometry. Results: Nineteen adults (men:10; women:9; age=43+9 years, BMI=34.4+8.1 kg•m⁻²) enrolled in the study. Thirteen subjects completed the exercise protocol, whereas six subjects stopped after completing Stage 4 (2.5 mph @ 9%). Trunk fat was lower (45+21 kg vs. 68+18 kg, p=0.028) and T90 was less (3.9+4.0 min vs. 0.8+2.4 min, p=0.048) in those who completed the protocol compared to the non-completers. No difference between groups in AHI (p=0.486) or StO₂ at Stage 4 (p=0.633) were observed. Among the non-completers, those with the lowest StO₂ at Stage 4 had greater T90 compared to those with the highest StO₂ at Stage 4 (7.3+2.5 min vs. 0.5+0.4 min, p=0.039). However, no differences in AHI (p=0.513), or trunk fat (p=0.211) were observed. Discussion: These data suggest greater hypoxia during sleep, rather than the total number of apneic events, limits exercise performance and suggests that treating OSA could enhance exercise tolerance in OSA patients.

Abstract Name: The Role of the Military Industrial Complex in Nuclear Modernization Programs

The question central to this research is: What institutional mechanisms explain the persistence of nuclear modernization programs? This research employs within-case analysis and process-tracing to investigate the role of the actors of the military-industrial complex (MIC) in sustaining U.S. nuclear modernization programs, with a focus on the Sentinel Program, formerly the Ground Based Strategic Deterrent (GBSD). These findings present the possibility of a causal chain linking the persistence of nuclear modernization programs in the U.S. to the alignment of economic, political, and strategic interests among defense contractors, Congressional stakeholders, and military leadership. The dependent variable is the persistence of nuclear modernization efforts like the Sentinel Program, while the independent variable includes the institutional mechanisms guided by economic interests of defense contractors, political priorities of Congressional stakeholders, and strategic imperatives articulated by military leadership. Primary literature, such as the annual assessment process of the U.S. Nuclear Weapons Stockpile serves as the basis for content analysis of decision-making processes, linking institutional evaluations to policy outcomes. Secondary literature, including Mayer's *The Political Economy of Defense Contracting*, McNaugher's *New Weapons, Old Politics*, and Fox's *Arming America: How the US Buys Weapons*, frames the analysis within the broader political and economic dynamics of defense contracting and policy inertia. The findings show a new way of

examining if nuclear deterrence is successful, which often focuses solely on the absence of nuclear conflict since 1945.

Abstract Name: Optics-free Spatial Genomics for Mapping Mouse Brain Aging

Spatial transcriptomics has drastically transformed our understanding of cellular dynamics in aging and disease by allowing for detailed mapping of molecular and cellular organization across anatomical regions. However, despite these advances, current spatial transcriptomics technologies have limitations in throughput and cost that hinder their application in comprehensive studies. To overcome these limitations, we present IRISeq (Imaging Reconstruction using Indexed Sequencing), a novel and optics-free spatial transcriptomics that removes the requirement of predefined capture arrays or extensive imaging, allowing for rapid and cost-effective processing of several tissue sections simultaneously. IRISeq reconstructs spatial images through the sequencing of local DNA interactions, enabling tissue profiling without constraints on size and at varying resolutions. These local DNA interactions are captured through barcoded receiver beads that capture cellular mRNA and barcoded sender beads with photocleavable linkers. IRISeq was utilized to investigate gene expression and cellular dynamics across thirty brain regions of adult and aged mice in order to elucidate region-specific changes in gene expression associated with aging. Additionally, cell type-focused analysis was conducted to identify age-related cell subtypes and complex changes in cell interactions that are specific to spatial niches in order to elucidate unique region-specific aging processes. These investigations highlight the varied and diverse effects of aging across the brain spatially. The cost-effectiveness, scalability, and simplicity of IRISeq give it the potential to be a versatile tool in mapping region-specific gene expression and cellular interactions across biological systems.

Abstract Name: Factors Associated with a Type 1 Diabetes Diagnosis

Type 1 diabetes (T1D) is caused by an autoimmune reaction in which a person's body mistakenly attacks their insulin-producing beta cells in the pancreas. Scientists are unsure what exactly causes this reaction, but it is hypothesized to be a combination of genetic and environmental factors, like exposure to certain viruses (e.g., COVID-19). Interestingly, T1D incidence has been on the rise over the past few decades, and the exact reason

for this increase is not fully understood. Research on T1D is crucial to understanding potential causes and improving treatments. Although we cannot determine causality, our research is a cross-sectional study that aims to explore factors associated with a T1D diagnosis. We are using data from the 2021 National Health Interview Survey from the Centers for Disease Control. We are analyzing data for both children, with almost 8,000 observations and 30 T1D cases, and adults, with 25,000 observations and 235 T1D cases. Each data set contains data for numerous other factors that are potential causes or correlates with T1D. The binary variable T1D will be our response variable, and we will use logistic regressions to estimate odds ratios along with 95% confidence intervals. Preliminary results suggest that for both children and adults, general health status is highly associated with having been diagnosed with T1D. Children with a perceived poor or fair health status are 11.2 (95% CI 3.4 to 36.4) times more likely to have a previous T1D diagnosis than those with a perceived excellent health status. Adults with a perceived poor or fair health status are 10 (95% CI 5.7 to 17.6) times more likely to have a previous T1D diagnosis than those with a perceived excellent health status. Moving forward, we will fit models that assess multiple factors simultaneously.

Abstract Name: "Is it America first or is it not?": The Daughters of the American Revolution and U.S. Nationalism during World War I

The National Society of the Daughters of the American Revolution, known as the DAR, is a lineage-based service organization for women who are descended from individuals who contributed to the American Revolution. Established in 1890, the organization works to promote education, patriotism, and historic preservation. With the outbreak of war in Europe in 1914 and America's initial but contested neutrality, rising anxieties began surrounding the query of where its citizens would place their allegiance became necessary for the American government. The state became active in promoting patriotism and intolerance of other political viewpoints. The DAR endorsed this effort and sought to preserve patriotism and combat dissenting ideologies throughout the war, incorporating the growing antiradical and Americanization movement of the late 1910s into their mission. This research seeks to explore the role of the DAR in promoting the war, the relationship between the Revolutionary War and World War I, and the usage of the relationship in promoting the war effort amongst Americans. This project establishes how the Daughters of the American Revolution endorsed patriotic and nationalist rhetoric during World War I, serving as a point of reference to understand the changing political climate during World War I and the role of a female patriotic organization in promoting nationalist and nativist values. Examining the climate of the DAR's patriotism alongside American neutrality and growing nationalism during the Great War showcases how the Daughters of the American Revolution contributed to the creation of a distinct war culture during World War I. This research establishes an additional understanding of the effects of American patriotic groups and their promotion of "America First" in their mission during World War I, providing historical context to the rise of U.S. nationalism and the way in which patriotism can be used to develop the ideology.

Abstract Name: Automated Bruise Detection in Fruits Using AI-Driven Instance Segmentation for Enhanced Quality Control

Effective quality control is essential in agriculture to reduce fruit loss, with bruise detection being critical to ensure product integrity from farm to market. This research introduces an advanced AI-driven system that leverages convolutional neural networks (CNNs) to automate bruise detection in fruits. By utilizing Detectron2's instance segmentation and object detection capabilities with a ResNest-50 backbone, our system accurately identifies bruised areas on fruit surfaces, addressing a key need in post-harvest processes. Bruising in fruits often arises from increased metabolic and physiological changes as they ripen, making them susceptible to damage even from minor external forces. Detecting bruising early can significantly reduce post-harvest losses. Our method relies on a dataset of 100 annotated high-resolution images, developed with the help of RoboFlow and tailored to capture bruising variations across fruit types like apples and pears. The dataset was divided into training, validation, and testing sets, with 70 images used for training, 20 for validation, and 10 for testing. The model was trained using augmented images to enhance generalization and evaluated on the validation set to tune its parameters. Final testing on a separate test set demonstrated the model's high recall and precision, effectively detecting and segmenting bruised regions. This automated approach reduces dependency on manual inspection, minimizes human error, and is scalable for large-scale operations, making it suitable for integration into commercial sorting systems. In addition to enhancing operational efficiency, this solution reduces labor costs, minimizes waste associated with undetected bruises, and promotes sustainable practices by extending produce shelf life. The proposed solution reflects a forward step in precision agriculture, marking a significant advancement toward data-driven, modernized quality control in the fruit industry.

Abstract Name: Incidental Finding of Zoonotic Larval Cestodes During Autopsy

Introduction: Larval cestodes (tapeworms) adapted to other hosts are occasionally found in human tissues. Spirometra species are endemic worldwide and can cause sparganosis in humans, characterized by larval migration into superficial or visceral tissues including the pleural cavity, vitreous fluid, pericardium, abdominal cavity, and central nervous system. A few thousand cases have been reported worldwide, mostly in Asia, in association with the ingestion of infected copepods, consumption of raw meat from amphibians and snakes, as well as application of medicinal poultices prepared from infected animals to open wounds. Case: A 44-year-old female presented to the hospital with a pertinent medical history of schizophrenia, bipolar disorder, sepsis, rhabdomyolysis, chronic and acute kidney disease, and hypertension. She presented to the ER with ventricular fibrillation and underwent aortic valve replacement and repair of an aortic root abscess. The operation was complicated by arrhythmia and unstable hemodynamics, and she passed after failed attempts to wean her from cardiopulmonary bypass. In autopsy, incidental findings of hepatic multifocal subcapsular nodules (1-3 mm), with histologic characteristics of a zoonotic larval cestode, prompted microbiology consultation. Discussion: Histologic findings showed a focal granuloma of the liver with a central necrotic core containing foreign material. PAS, GMS, and AFB stains were negative for fungal and acid-fast organisms. The slides were reviewed by microbiology, who identified it as a zoonotic larval cestode

based on pathognomonic calcareous corpuscles as well as a myxoid matrix with loose smooth muscle fibers surrounded by an eosinophilic acellular tegument. Due to post-mortem diagnosis, a thorough history of travel, animal exposure, dietary intake, or poultice utilization was not available. Molecular confirmation was not performed but sparganosis was highest on the differential.

Abstract Name: The Relationship Between p21 Expression and PKD1 Cyst Formation

Polycystic kidney disease (PKD) is a genetic disorder caused by mutations in the PKD1 and PKD2 genes. My project focuses on Pkd2, the gene responsible for 15% of PKD cases. Mutations disrupting PKD2 result in uncontrolled cyst development and a decline in kidney function over time. Recent research in my lab has indicated that a protein, p21 a cyclin-dependent kinase inhibitor, may regulate cyst initiation and expansion in PKD2 models. The goal of my research is to determine how p21 contributes to cyst formation. I am using mouse models to study when p21 expression is upregulated relative to cyst initiation and whether the number of p21-expressing cells correlates with the cystic burden. My research findings show that there is an increase in p21 levels before cyst expansion, suggesting an initiation role. My immunofluorescence analysis shows that cells expressing p21 are in and near cystic epithelium during a time course of cyst expansion, further supporting the initiating role. I am still analyzing whether the percentage of p21-expressing cells is linked to the rate of cyst formation and whether the p21-expressing cells directly contribute to the cysts. These outcomes support an important role for p21-expressing cells in cystogenesis. Correlating spatial information regarding cyst-initiating patterns and the location of p21-expressing cells, I want to explore how p21 expression contributes to cyst initiation and expansion in polycystic kidney disease. This research can provide a foundation to determine if regulating p21 expression could be used to prevent or delay cyst initiation or disease progression.

Abstract Name: LiDAR-based Streetscape Awareness for the Dynamic Interactions between Vehicles and Pedestrians in a Microscopic Digital Twin Simulation

This project harnesses LiDAR technology and 3D virtual simulation to construct a digital twin of West Palm Beach, Florida. The primary focus is to enhance understanding of the dynamic interplay between vehicles and pedestrians. The simulation provides an immersive and highly detailed 3D representation of the city, offering an interactive platform to visualize and analyze urban infrastructure and traffic dynamics at a street level. By integrating data from LiDAR sensors, the system precisely tracks the movements of both vehicles and pedestrians, mirroring their actions within the simulation. The system operates frame by frame, processing LiDAR data to determine the precise positions of vehicles and pedestrians. This data is then used to dynamically place 3D models in the appropriate locations within the Unity simulation, creating a realistic and

continuously updated virtual environment. This approach ensures a high level of accuracy and responsiveness, making the simulation suitable for a wide range of applications, from traffic flow analysis to pedestrian safety studies. One of the key objectives of the project is to demonstrate how the integration of LiDAR and digital twin technologies can revolutionize urban planning and traffic management. By modeling both vehicles and pedestrians, the simulation enables stakeholders to assess interactions between different road users, identify potential congestion points, and explore the impact of proposed infrastructure changes in a virtual setting. This detailed modeling also provides insights into pedestrian behaviors, allowing for safer and more efficient urban designs. Beyond traffic and mobility applications, this project highlights the broader potential of digital twins in smart city development. By combining precise sensor data with an interactive, visually rich 3D environment, the system offers a powerful tool for policymakers, city planners, and engineers. It supports data-driven decision-making, reduces reliance on costly real-world testing, and fosters innovation in designing sustainable, efficient, and responsive urban systems.

Abstract Name: Ruling from the Shadows: Why Regime Leaders Install and Remove Nominal Executives

This research investigates why some autocratic regime leaders employ “nominal executives” — heads of state or government who hold formal titles but lack actual governing power — and how these appointments impact regime stability and leader duration. Through coding and analyzing a newly compiled cross-national dataset of nominal executives in authoritarian regimes since 1946, this project offers the first systematic data on this phenomenon. It enables scholars of authoritarianism to identify dictators (regime leaders) who "rule from the shadows" by installing and removing one or more presidents or prime ministers who rule in name only. This first-of-its-kind data and accompanying case study narratives of the (mis)use of nominal executives may help political scientists explain patterns of leader duration, regime (in)stability, and (lack of) democratization. A key question this research seeks to answer is: why do dictators appoint nominal executives instead of concentrating power in their own hands? Indeed, we observe that factors such as term limits, appeasing opposition and international backers, and the incentive to shift blame for regime failures onto others may all contribute to the use of nominal executives. For instance, term limits facilitated nominal executives in a well-known example occurred in 2008 Vladimir Putin stepped down as president due to Russia's constitutional two-term limit and installed Dmitry Medvedev as a nominal president. While taking on the less powerful role of Prime Minister, Putin retained effective control, bypassing constitutional restrictions without relinquishing real authority. With over 1500 total cases, our dataset also tracks how the nominal executives entered and exited office, their roles, and who was the actual leader in charge during their tenure. Furthermore, we analyze how many different times each nominal executive was in office, and if and when they flipped from head of government to head of state.

Abstract Name: Modifying Poly(beta-amino ester) Hydrogel Formulations to Achieve Sustained Release of Bupivacaine Anesthetic

The current standard of care for treating post-operative pain is opioids. Opioids are powerful pain blockers but are highly addictive substances responsible for many overdose deaths. Nerve blocks can reduce opioid use but typically last no more than 4 hours with an anesthetic, Bupivacaine, injection. Another option is the sustained-release nerve block, Exparel®, which provides pain management for 72 hours. The challenge with Exparel® is that facial surgery requires at least 7 days of post-operation pain relief, meaning the highly addictive opioids are still prescribed. This work aims to improve upon the current sustained release of nerve-blocking anesthetics to reach the needs of more patients. In this research, a variety of formulations and structures of Poly(beta-amino ester) (PBAE), a biodegradable hydrogel, have been tested to achieve a more sustained release of Bupivacaine, which is an anesthetic with a long half-life. The PBAE used was formed from diethylene glycol diacrylate (DEGDA) or Poly(ethylene glycol) diacrylate (PEGDA) and isobutylamine (IBA). All formulations kept a molar ratio of 1.2:1 diacrylate to amine, but the molar ratios of the diacrylates were differentiated: molar ratio 3:1 DEGDA to PEGDA and a homopolymer of DEGDA. The purpose of having a formulation with just DEGDA as the diacrylate is to increase crosslinking, due to its shorter chain length within the PBAE, to have a more sustained release over time. The structures of each formula were tested in a particle format and various disc thicknesses. Release studies showed that utilizing the homopolymer formulation had a more sustained release of bupivacaine over 7 days than the copolymer formulation. However, this release profile was only seen in disc form and did not extend to microparticles. Overall, this suggests future developments will need to keep the integrity of the hydrogel structure to achieve a sustained release with this formulation.

Abstract Name: The Isolation of Acetylated Triterpene Saponin from *Agrostemma gigatho* L. for Medicinal Chemistry Studies

Saponins are widely distributed across more than 100 families of dicotyledonous and monocotyledonous plants and found in various plant parts such as the stems, roots, flowers, bark, leaves, and fruits, representing a rich source of natural products with high potential for pharmaceutical applications. Exhibiting excellent biological activities, saponins have been investigated for their potential as immunomodulatory, anti-cancer, wound healing, analgesic, and various other types of pharmaceutical agents. Notably, saponins have garnered attention for their ability to treat a variety of cancers, by inducing cell death through apoptotic, necrotic, and autophagic cell death pathways. Additionally, their modulation of cell signaling pathways, such as ROS generation, activity on organelles, and permeabilization of the outer mitochondrial membrane, offers advantages as new chemotherapeutic agents. Another application of saponins lies in their potential as Endosomal Escape Enhancers (EEEs) to augment the efficacy of anticancer protein/peptide drugs. Research shows that most protein drugs internalized into cells via receptor-mediated endocytosis tend to become sequestered within endosomes, with only about 10% escaping into the cytosol to exert their bioactivity. Despite the potential of saponins as chemotherapeutics or EEEs, their capabilities in these areas are underexplored. The lack of systematic studies on SAR, particularly concerning the application of saponins as

EEEs, can be attributed to the lack of structurally diverse and well-defined pure saponins. This study details our efforts to isolate an acetylated triterpene saponin from *Agrostemma githago* L. The isolated natural product will undergo comprehensive SAR studies to develop new, improved leads for chemotherapeutic and EEE applications.

Abstract Name: The Synaptic Composition of layer 4B and layer 6 of Primary Visual Cortex in Macaque monkeys.

The primary visual cortex (V1) plays a vital role in visual processing by receiving input from the retina and transmitting information to higher-order visual areas. This study investigates the structural and functional organization of layers 4B and 6 in V1 of macaque monkeys, focusing on their distinct roles in visual processing and feedback modulation. Layer 4B, responsible for rapid signal integration, is hypothesized to contain densely packed excitatory neurons specialized in processing raw visual data, while layer 6, which houses pyramidal neurons, is involved in feedback regulation to fine-tune this information. Using advanced imaging techniques, specifically focused ion beam scanning electron microscopy (FIB-SEM), we conducted high-resolution, three-dimensional reconstructions of the neuropil in layers 4B and 6 of the primary visual cortex. Our aim was to investigate whether the neuropil in each layer exhibits unique structural characteristics that correlate with their distinct physiological properties. Data collected from over 200 axonal boutons revealed that larger axons in layer 4B exhibited more complex PSD morphologies, indicating stronger synaptic connections in this layer. Over 50% of PSDs in layer 4B displayed macular morphology, consistent with its specialization in integrating visual signals. In contrast, layer 6 displayed a diverse synaptic composition with smaller boutons and less complex PSD morphologies, reflecting its role in feedback modulation. Preliminary three-dimensional reconstructions revealed that layer 4B neuropil contains densely packed excitatory neurons with large mitochondria, supporting rapid signal processing, while layer 6 exhibits more variable synaptic structures with smaller mitochondria, consistent with its regulatory function. These findings enhance our understanding of the structural and functional differences between layers 4B and 6 in the macaque V1, highlighting their distinct contributions to visual processing and feedback mechanisms.

Abstract Name: The Adar D1113H mutation in the ADAR1 catalytic domain results in early-onset and MDA5-dependent encephalopathy with IFN pathway activation in the mouse brain.

Aicardi-Goutières syndrome is a severe progressive genetic disorder in young children presenting with symptoms such as encephalopathy, developmental delays, loss of intellectual abilities, and motor control

impairments. Symptoms of AGS typically present themselves within the first year of life, with early-onset beginning at birth and later-onset developing within the first few weeks to months of life. AGS has been linked to mutations in seven different protein-coding genes that are involved in DNA/RNA metabolism and sensing. However, the molecular mechanism by which these mutations impact the neuropathogenesis of AGS remains unclear. As a result, there are no effective treatment measures to stop the progression of AGS. To study the mechanism behind these mutations, we created a mouse model by introducing a mutation at the ADAR1 coding gene, one of the identified protein-coding genes, through the use of CRISPR/Cas-9 technology into the mouse genome. Through breeding, a double gene mutation, ADAR1 and MDA-5, mouse model was developed. RNA sequencing analysis was used to measure the levels of RNA editing in brain mRNA substrates of ADAR1. Additionally, phenotype, gene expression, innate immune pathway activation, and pathologic studies (such as RNA in situ hybridization and immunohistochemistry) were used to identify potential disease mechanisms in the mouse model. Through the mouse model, we established the underlying mechanism of the ADAR1 mutation in AGS. This mutated mouse model exhibited changes in RNA editing of neural transcripts, resulting in heightened IFN-stimulated gene expression. The in situ hybridization showed increased expression of ISG in specific cell-types. Mutant mice presented with early-onset astrogliosis and microgliosis and late-stage calcification in deep white matter. ISG activation and neuroglial reaction are blocked due to the removal of the cytosolic RNA receptor MDA-5. The ADAR-1 mutation results in early-onset encephalopathy leading to IFN pathway activation in mice, which is MDA5 dependent.

Abstract Name: Acetate Protects from Ferroptosis in Breast Cancer Brain Metastatic Cells

Breast cancer kills approximately 40,000 U.S women annually, primarily from widespread metastasis to major organs such as the brain. Investigating the unique metabolic needs of brain metastatic tumors offers a compelling therapeutic opportunity to disrupt their energy supply and effectively "starve" them to death. Healthy brain tissue relies almost exclusively on glucose for energy, consuming approximately sixty percent of the body's total glucose at rest. Thus, while most tumors rely on glucose as an energy source, brain metastatic tumors must turn to alternative energy sources. The brain region harbors the second-highest level of acetate — another potent energy source — in the body. Acetate can be converted to acetyl-CoA by the enzyme acetyl CoA synthetase 2 (ACSS2). Previous research by our group has shown that breast cancer brain metastatic (BCBM) tumors rely on ACSS2 to protect from cell death via inhibition of ferroptosis. To explore acetate's role in BCBM cell survival, we examined breast cancer brain tropic cells in an acetate-rich medium, using both in vitro and ex vivo models. Preliminary experiments with RSL3 reveal that acetate pre-treatment significantly reduces RSL3-mediated BCBM cell death, as observed through crystal violet staining and flow cytometry. We are currently testing whether increasing levels of acetate can protect from other ferroptotic inducers (Erastin, Sulfasalazine, and Sorafenib) and chemotherapeutics used to treat BCBM patients (Cisplatin, Olaparib, and Capecitabine). Our study aims to uncover the range of BCBM cellular processes supported by acetate, including resistance to ferroptosis and chemoresistance. Understanding acetate's role in breast cancer brain metastases could significantly influence the development or refinement of future therapeutics targeting brain metastatic tumors.

Abstract Name: Nonpharmacological & Pharmacological Interventions for Anxiety & Stress

Introduction: The adult population often experiences symptoms of anxiety and stress, requiring interventions to prevent dysfunction during activities of daily living. Research has addressed the sustainability and effectiveness of pharmacological methods to manage symptoms of anxiety and stress while acknowledging the adverse effects associated with medication treatment. Other research has highlighted various nonpharmacological methods to manage symptoms of anxiety and stress through holistic interventions that pose minimal to no risks. Sustainability and effectiveness of nonpharmacological interventions are being explored as alternative treatment and in conjunction with pharmacological interventions.

Nonpharmacological interventions as alternatives to pharmacological interventions are safer for those unable to maintain medication treatment related to adverse effects and physiological functioning, but also allows reduced dosing for those requiring medication treatment. Nonpharmacological alternatives are also beneficial for those who struggle to maintain medication compliance. **Purpose:** To discover if nonpharmacological methods are more sustainable and/or effective than pharmacological methods for treating symptoms of anxiety and stress in the adult population. **Methods:** This study uses a descriptive, quantitative design by utilizing surveys with questionnaires to obtain data from individuals that experience symptoms of anxiety and stress. The data retrieved will be based on each participant's perception of their symptoms and how their symptoms respond to nonpharmacological and/or pharmacological interventions used. **Conclusion:** Pharmacological methods are effective with questionable sustainability related to tolerance, dependence, compliance, and adverse effects. Nonpharmacological methods are effective and sustainable when used. More research is required to comprehensively compare sustainability and effectiveness of nonpharmacological methods with pharmacological methods. **Keywords:** nonpharmacological interventions, pharmacological interventions, anxiolytic tolerance, adult anxiety, adult stress

Abstract Name: Effects of Marathon Running on Inflammatory Cytokine Levels: Acute Increases and 48-Hour Resolution

Purpose/Hypothesis: Marathon running requires multiple hours of exertion that can result in significant changes in inflammatory markers even days after the competition. We investigated how running a marathon affects inflammatory cytokines before, immediately after, and 48 hours post-race. We hypothesize that inflammatory cytokines will increase post-race and return to baseline after 48 hours. **Methodology:** Blood samples were collected from 24 Ogden Marathon runners at three time points: pre, post, and 48 hours after the race. Plasma levels of TNF- α , IFN- γ , IL-4, IL-10, IL-6, and IL-1 β were measured using Luminex® MAGPIX® multiplex assays, with differences analyzed using repeated measures ANOVA. **Results:** IL-6 levels increased significantly from pre to post (3.1 ± 1.2 vs 70.8 ± 18.1 , $p = .002$) but returned to baseline after 48 hours (3.1 ± 1.2 vs 2.4 ± 0.1 , $p = .22$). IL-10 levels also rose post-race (21.5 ± 7.1 vs 98.8 ± 21.4 , $p = .001$) but fell below baseline at 48 hours (21.5 ± 7.1 vs 14.1 ± 4.8 , $p = .035$). No significant change was observed in

TNF α pre to post (25.8 ± 4.9 vs 27.6 ± 4.6 , $p = .74$), but a significant decrease was noted at 48 hours (27.6 ± 4.6 vs 17 ± 3 , $p = .046$). Discussion/Conclusion: Muscle contraction results in the secretion of cytokines IL-10, IL-6, and TNF α which were expected to increase after running a marathon. IL-10 has potent anti-inflammatory and pro-resolving properties; the return to below baseline levels observed after 48 hours is likely due to finalizing the resolution process of inflammation. IL-6 induces the secretion of anti-inflammatory cytokines, induces glucose production, and triggers fatty acid oxidation, which is a process favored during long-distance running.

Abstract Name: Investigating the role of GOT2 in kidney development

Proliferation of nephron progenitor cells (NPC) is essential to maintain and expand the progenitor pool during kidney development. Proliferation depends on mitochondrial aspartate biosynthesis to fuel nucleotide synthesis. Glutamic-Oxaloacetic Transaminase 2 (GOT2) is a mitochondrial enzyme that catalyzes the transamination of glutamate and oxaloacetate to form aspartate and α -ketoglutarate. While GOT2 is essential for nucleotide synthesis and proliferation in cancer cells, the role of GOT2 during kidney development is unknown. Using publicly available scRNAseq datasets and immunofluorescence (IF) staining, we show Got2 is broadly expressed during kidney development. To determine the necessity of GOT2 we took a genetic approach to knockout a conditional (floxed – fl) Got2 allele in NPC using Six2Cre. Western blot and qPCR analyses of newborn mice confirmed efficient ablation of Got2 using this approach. Histology and gross analyses found that Six2Cre;Got2^{fl/fl} mice have smaller kidneys at birth. IF staining using both anti-Six2 and anti-Pax2 found a reduction in the size of the NPC population in Six2Cre;Got2^{fl/fl} mice compared to Six2Cre;Got2^{fl/+} littermate controls. Our findings suggest that GOT2 is essential to maintain and/or expand the NPC population. In light of these findings, future studies evaluating the effects of Got2 ablation on proliferation and apoptosis are warranted.

Abstract Name: +55 Active Adult Residential Community Design Promoting Health, Wellness and Longevity Based on The Blue Zone Project.

With the aging U.S. population, particularly baby boomers transitioning into retirement, there is a growing demand for lifestyle-oriented housing that supports independence and wellness. This project aimed to design a +55 active adult residential community, The Grove, promoting longevity and adaptability by integrating Blue Zone Project values. The Blue Zone Project promotes creating healthier environments to naturally nudge people towards healthier choices. The research on longevity and wellness coincides with the 9 traits based on the Blue Zone project research: move naturally, right outlook with purpose and downshift, eat wisely with the

80% rule, plant slant, wine at 5, and connect, positive pack, loved ones first and belonging. Drawing inspiration from Sardinia, Italy—a recognized Blue Zone region—The Grove incorporates Mediterranean design elements such as vibrant citrus-inspired colors, terracotta tiles, and lush communal gardens. These elements blend with modern architectural practices to enhance quality of life. Additionally, this project focused on creating an inclusive and age-friendly environment that fosters social engagement, security, and health for residents aged 55 and older. The methodology combined a literature review, case studies of similar active adult communities, and interviews with target participants to define essential design features, including walkability, social integration, and adaptable layouts. Expected outcomes include a mixed-use building offering diverse apartment units, resort-style amenities, and communal spaces that encourage interaction while maintaining privacy. Key design features include ADA-compliant designs, natural lighting, and health-focused spaces to support residents' evolving needs and well-being. By addressing the stigmas associated with senior living, this project redefines perceptions of active adult communities, distinguishing them as vibrant hubs for active aging. This design will work as a precedent for sustainable, community-oriented housing solutions, enhancing well-being and fostering longevity among older adults.

Abstract Name: The Human Factor: What Energy Systems Engineers Have Been Missing

Amidst a rapidly changing environment due to climate change and pollution, along with a global rise in energy demand, creating relevant and accurate energy systems models has become imperative to not only meet the rising energy demand, but also do so while mitigating carbon emissions. Moreover, those who are in most need of access to energy and who are most vulnerable to climate change, pollution, and the disastrous effects that come along with them, are rural communities. A potential solution that is versatile enough to meet rural energy demand while decreasing carbon emissions and dependence on fossil fuels is the use of hybrid renewable energy systems (HRES) in rural electrification (RE) projects. There exist numerous techniques for optimizing HRES models, and in many cases, these systems have been shown to be economically feasible for various rural communities. However, once implemented in the real world, the majority of these systems and RE projects tend to fail, end prematurely, or even cause negative after-effects in the community. For too long, energy systems models have prioritized cost-effectiveness and profits while omitting crucial externalities that significantly affect their success, and most importantly, the people in the affected rural communities. This research explores social and ecological factors, as well as effects of RE projects in rural communities often overlooked by energy systems engineers and how incorporating these factors in all stages of modeling, design, and implementation can help increase chances of long-term success while allowing rural communities to maximize the potential benefits of electrification. Through a human-centered, multidisciplinary approach, an HRES will be optimized in GAMS (General Algebraic Modeling System program) for a typical rural community in Ghana considering the unique meteorological, ecological, techno- and socio-economic constraints of the region with linear programming as the main optimization method.

Abstract Name: Factors in Decision Making of Political Candidates

What factors impact the decision to run as non-partisan over one of the major US parties? It is essential to analyze this phenomenon to determine the real motivations of candidates and the party they represent because they impact society as a whole. The candidates' ideologies and how the candidates feel representing the parties' ideologies are the main reasons for choosing non-partisan over one of the major US parties. This occurs because humans tend to work where they feel comfortable and in places with the same values and ideologies as them. It is the same in the case of candidates; they look to represent a party with whom they share ideologies. The dataset is taken from the Campaign Finance in Local Elections: An Eleven City Study, 1989-2007, which provides essential data on local politics. Specifically, data shows that the likelihood of candidates running non-partisan might decrease based on the type of political office.

Abstract Name: Violin Shoulder Rest

The violin shoulder rest is an optimal tool used by musicians to help alleviate some unwanted stress and weight during a performance. The shoulder rest focuses on three major components that include comfort, stability, and durability. The three components are taken into consideration in the design process and when considering materials, in today's market it seems that some of these traits are not completely included leaving out one or the other. Some common issues seen in shoulder rest today stem from the two-legged design that many companies incorporate, with the shoulder rest not being tightly secured onto the instrument causing slipping and coming out of place even during performance. Another main issue with the two-legged design can be seen in beginners as they lack the knowledge of the correct positioning of their shoulder rest to maximize comfort resulting in a painful playing experience. The materials used when constructing the shoulder rest seemed to be cheap and saw a lot of wear and tear over time, not compensating for the large price tag they come with. Our goal is to create a modular design that implements comfort, stability, and durability while focusing on lowering the overall price to allow all skill levels to have access to our product. With that being said, we also want to focus on the customizable aspect of our design making it versatile to all types of players by making the legs adjustable to fit any sized instrument from violas to violins, to include customizable padding to fit all types of shoulder rest to enhance longevity.

Abstract Name: The Role of pou4f4 in Neurogenesis: Testing for Compensation and Sufficiency

The goal of this project is to determine the role of the POU Class IV family of transcription factors in neurogenesis. Data shows that the paralog pou4f4 is expressed in neuronal progenitor cells such as Rohon-Beard neurons and cranial ganglia. Rohon-Beard neurons are a transient population of cells that function as the early peripheral nervous system during larval stages in amphibians and fish. However, when pou4f4 is knocked out in zebrafish, there is no observed change in phenotype after 24 hours post-fertilization. A possible mechanism responsible for this may be through upregulation of a similar gene within the POU class IV transcription factors. I previously conducted qPCR to test for compensation in the absence of pou4f4. My data shows that the paralog pou4f1 is upregulated in pou4f4 mutants, suggesting that pou4f1 may compensate for pou4f4. This project will use zebrafish that will undergo CRISPR/Cas9 mediated mutations to create a pou4f4 and pou4f1 mutant background to test if compensation occurs when a nonsense mutation is introduced. If compensation occurs, I expect to see an altered phenotype, such as decreased cell numbers in the cranial ganglia of embryos after 24 hours post fertilization, and decreased numbers of Rohon-Beard cells in the trunk of the embryo. This project will also address the role of pou4f4 in cell differentiation. To test this, zebrafish embryos will be injected with pou4f4 mRNA to overexpress the gene, and imaged through immunofluorescence. If pou4f4 has a critical role in determining cell fate, we should expect to see higher numbers of axons, and higher cell counts of the cranial ganglia and Rohon-Beard cells.

Abstract Name: Analyzing Racial Disorientation Through Predictive Processing

In *Disorientation: Being Black in the World*, Ian Williams explores the feelings of uneasiness and uncertainty that he experiences after racial encounters. He terms this feeling racial disorientation, “the effect of racial encounters on racialized people, the whiplash of race that occurs while minding one’s own business.” In *The Experience Machine*, Andy Clark provides a new model for human perception and cognition. He explains that rather than experiencing the world directly through our senses and constructing a picture of the world from what we see and hear, the brain functions much more like a prediction machine. Humans already form predictions about their experiences prior to any sensory input. Our brains then subtract that predictive model from sensory data, leaving behind residual errors: the discrepancy between expectation and reality. In this paper, I will argue that racial disorientation is caused by a residual error in one’s racially inflected encounters with another by way of the brain’s comparison of its predictive model to actual sensory data. This error arises from the stark contrast of a person’s predictive model for everyday social encounters and the reality of unexpected racial interactions. Through this lens, the paper aims to explore the cognitive underpinnings of racial disorientation.

Abstract Name: Ignition of Aviation Fuels and Surrogates in Hot Air Atmospheres – Parametric Analysis on the ASTM Injection System

The ignition properties of aviation fuels and surrogates are assessed in the ASTM-E659 standardized test apparatus. A small volume, 0.1-0.5 mL, of liquid fuel is injected with a syringe into hot air within a flask contained in a temperature-controlled furnace. Given that the test results strongly depend on injection characteristics, we use an automatic injection system to control the height, speed, and duration of the syringe's needle inside the hot atmosphere. We investigated how injection parameters influence ignition behavior using the temperature signals inside the flask. After conducting one hundred tests, we found that different injection parameters significantly affect the initial temperature condition and fuel volume in the flask. If the needle stays inside the flask for more than 10 seconds, approximately 150% of the initial fuel volume vaporizes. We also found that vaporization influences the temperature decrease more than the needle itself. To prove this, we visualized the injection jet with a high-speed camera in a transparent rectangular cell heated by a hot plate. This test showed that vaporized fuel enters the container even without injection, validating our hypothesis. This finding suggests that the injection in the standardized ASTM-E659 test should last less than 10 seconds to have accurate results.

Abstract Name: Can Exercise Protect against Forever Chemicals in Female Mice?

This project aims to determine whether exercise can affect overall tissue distribution and excretion of long-lasting forever chemicals. Per- and poly-fluoroalkyl substances (PFAS), a family of synthetic chemicals characterized by strong carbon-fluorine bonds, are of concern given their ubiquity and persistence (forever chemicals). Prenatally, PFAS are known to contribute to growth restriction and influence the risk of chronic diseases later in life. The research community must identify lifestyle interventions to diminish PFAS-associated children's health impacts. Therefore, we set up a mouse model to test the hypothesis that voluntary wheel running will decrease PFAS levels in mouse serum and tissues compared to sedentary mice. To test our hypothesis, 30 8-week-old female C57BL/6J mice were singly housed and fed either a low- (10 kcal% fat) or high-fat diet (60 kcal% fat) with access to unlocked (exercise) or locked (sedentary) running wheels (n = 5 per exercise and diet group). After 5 weeks of exercise, mice were fasted for 3 hours and exposed to a PFAS mixture (0.4 mg of PFAS per 1 kg of body weight) via oral gavage. Urine and feces were collected after 24 hours. The mice were then treated with a 2nd dose of PFAS after one additional week, and mice were euthanized after 24 hours. Serum and tissues were collected, flash-frozen, and prepped for PFAS quantification. We expect PFAS levels in exercising mice to be lower than those in sedentary mice in the serum and tissues. However, the PFAS levels in the feces will be higher in the exercising mice because of lower uptake or higher excretion. If exercise positively influences PFAS body burden, future studies will determine whether exercise during pregnancy can protect offspring from developmental exposures to PFAS. These studies may generate new avenues for interventions to mitigate the impacts of PFAS exposures on future generations.

Abstract Name: The Implications of Public Housing on Resident's Mental Health

Public housing offers affordable housing options for residents with low-income. However, the current conditions of public housing developments have significant implications for the overall well-being of residents. Without the proper resources to support their physical, mental, or social needs, public housing residents will be at further risk for more problems. This poster will discuss the impact public housing has on mental health on the socially vulnerable and what can be done to alleviate their struggles. This study employed a cross-sectional research design with a convenient sample of 211 African Americans residing in public housing. Participants were recruited through posting of fliers within the housing developments where they resided and through a snowball sampling technique. Of the 211 participants, 70% were female, and 33% identified as head of household with 75% having an associate degree or less. Data was collected using the Qualtrics online platform. The questionnaire included demographic variables and self-administered standardized scales including the CESD depression scale, Anxiety Sensitivity Index, Subjective Neighborhood and the Self-efficacy scales. Preliminary data analysis revealed that 50% of the sample is both clinically depressed and anxious with a mean score of 17.9 and a standard deviation of 11.5 and mean score of 21 with a standard deviation of 5.77 respectively. This research identifies the psychological impact of residing in public housing on public housing residents. The preliminary results suggest that the current conditions of public housing continue to be a stressor for residents. The result for this study has implications for those who work directly in housing, where they can reevaluate how to meet the specific needs of public housing residents. In correlation with public policy, this study provides valuable data that can be used to push for more policies that recognize the importance of proper mental health in critical housing conditions.

Abstract Name: Creating a Digital Twin of the Human Heart Using Machine Learning

Personalized simulations of the left atrium enable professionals to create patient-specific models that replicate the unique electrophysiological and biomechanical behavior of the atrium. Segmentation of patient-specific CT/MRI data is used to create finite element analysis (FEA) meshes, which enable precise modeling. However, manual segmentation is time-consuming and prone to errors. Additionally, existing neural network-based tools fail to capture detailed anatomical features limiting their use for FEA simulations and personalized treatment planning. The aim of this research is to develop an automated neural network-based tool to accurately segment the left atrium and create a ready-to-use FEA mesh for left atrium simulations. Our approach addresses these challenges by focusing on the intricate anatomy of the left atrium, including the appendage and trabeculations, to improve both segmentation accuracy and simulation quality. To achieve this, we will train a neural network using 120 3D CT/MRI images from public datasets and 100 CT images from Emory University collaborators. The images are then manually segmentate to render a replica of the left atrium through the SimVascular workflow. The segmentation is then smoothed using the software tool

Meshmixer to create high-quality training datasets. Data augmentation will enhance the dataset. We will implement a HeartDeformNet-derived neural network for segmentation, using 150 images for training, 20 for validation, and 50 for testing. The predicted meshes will be compared with manually segmented ones using the DICE score and other quality metrics. The predicted FEA mesh will be integrated with a 0D lumped-parameter model to simulate full-cycle left atrium function based on patient-specific inputs such as ECG signals and pressure measurements. We expect this tool to reduce segmentation time and effort while improving simulation accuracy, contributing to better pre-surgical planning and personalized cardiovascular treatments.

Abstract Name: Use of Untargeted Mass Spectrometry-based Metabolomics to Profile Texas Wines

Vitis vinifera is economically one of the most important plant species. Worldwide, the U.S.A. is the fourth highest wine producing country, where 87% of grapes harvested from *Vitis vinifera* are used for wine production. Comprehensive characterization of metabolites and biomarkers to uncover signatures specific to the producing regions has been accomplished by leading producing countries. Texas is one of the oldest and major wine producing states in the U.S.A. Wines contain a complex-versatile metabolome signature, including flavonoids, organic acids, sugars, and other phenolic compounds. Wine metabolites can be affected by factors such as grape varietal, ripening stage, regional environment, and the winemaking process. Central Texas endures harsh environmental conditions such as heatwaves and drought during the growing season. Interestingly, wine produced in this region is considered of singular high quality, showing a major increase of wine production in the last decade. Thus, it is imperative to identify wine biomarkers specific to the region. To our knowledge, there is no research precedent on metabolite profiling of wines produced in Central Texas. Herein, the goal is to characterize for the first time, the metabolomic profile of 8 wines produced from 4 vineyards located in Central Texas using mass-spectrometry based metabolomics. The second aim is to analyze the produced multivariate data to obtain information about correlations, similarities and differences between measured metabolites and grapevine varietal using Compound Discoverer and MetaboAnalyst. The following metabolomic workflow stages have been accomplished: 1) collection of wine samples, 2) extraction of metabolites using a liquid-liquid extraction method 3) experimental analysis using high-resolution mass-spectrometry for untargeted metabolomic profiling and 4) identification of over 300 metabolites. Principal Component Analysis, Partial Least Squares Discriminant Analysis, and Heatmaps were utilized to elucidate important patterns and relationships between varietals and their metabolites.

Abstract Name: Adolescent Depression Among Chinese Immigrants and American Youth: A Comparative Study Before and After the COVID-19 Pandemic

Adolescents are susceptible to depression during a critical developmental period, negatively impacting their social relationships. Depression impacts various cultures, including Americans and Chinese immigrant adolescents. A literature review that examined depressive symptoms from before and after the COVID-19 pandemic reveals that during the pandemic the prevalence of depression in both American and Chinese adolescents significantly increased. Notably, research indicates higher increase in prevalence of depressive symptoms among Chinese adolescents in immigrant families, in comparison with American adolescents, primarily due to acculturation being an added stress. A crucial factor for adolescent mental health is their relationships with their peers. Academic pressure and reduced opportunities for in-person interactions related to the COVID-19 lockdown likely intensified symptoms of depression in adolescents. In contrast, a positive and uplifting environment amongst peers provides support for someone who may be depressed. Future research should focus on developing better social skills and tracking rates of depressive symptoms in adolescents, focusing on acculturation with Chinese immigrant adolescents.

Abstract Name: U Stressed? Do Library Employees Experience More Technology Eustress Or Distress?

This research project has developed in response to ongoing conversations regarding library technology usage and its impact on work-related stress. We inquire whether library employees experience more technology eustress or distress on the job. This was inspired by Tarafdar's (2017) "The Technostress Trifecta." Our study explores a facet of her theoretical framework, specifically the relationship between motivating (eustress) and discouraging (distress) technology stress. The research project uses a mixed method of survey and follow-up interview. Study participants receive a recruitment email through a Minitex newsletter—read by people who work in public, private, and tribal libraries in Minnesota—to complete a scaled questionnaire. They are then invited to an optional, semi-structured interview to collect qualitative responses about their workplace and techno-stress. We hypothesize employees feel more techno-eustress than distress. The discussion of techno-stress includes factors such as uncertainty, overload, and training. This study provides a frame of reference to identify areas of growth for programs and more nuanced discussions about technology in libraries.

Abstract Name: Khaana Khazana: Food Labor in Cosmopolitan India

This work aims to understand the relationship between food workers, gender norms, and class dynamics within economically and culturally diverse Indian cities. While food workers, specifically chefs and food makers, inhabit a central role in urban food consumption and cultural systems, their labor and positionality transcend the spatial confines of a restaurant. However, present research focuses on food workers as products of their occupation, rather than considering their positionality within larger sociopolitical dynamics and how

they shape these processes. This gap has manifested in both the subjugation of food workers to the boundaries of the restaurant and a dearth of insight into their perspective regarding ideological principles and values that govern their work, based on class hierarchies and gender roles/norms. Restaurants reinforce class divisions, only intensifying since the end of the COVID-19 pandemic; the space thus provides ethnographic glimpses of ethnic food spaces, while the food laborers reveal wider implications about social values from their position in local and global political economies. The research bridges these gaps through the triangulation of participant observations, interviews, and menu analysis of four eateries in Mumbai, with the data collected over a week. Using open coding to analyze the data, the study finds that the experiences of food workers, however varying, display characteristics of broader sociopolitical frameworks; the differing roles of gender within the workspace and within the household was represented throughout the data. The occupational limitations and systemic inequity faced by chefs in urban Indian eateries also contributed to their views; Western ideals and influence in the Mumbai's restaurant scene shaped how some food workers approached their work, while fiscal necessity motivated others. This research suggests important findings regarding the interplay between political economy and sociopolitical factors, like class, gender, and Westernization, for food workers in major cities of the Global South.

Abstract Name: Absolute Quantification of Amino Acids in Female and Male Ocular Tissues

Purpose: The eye is one of the most metabolically active organs within the human body; the metabolites it uses are affected by gene expression, diet, and exposure. Metabolic dysregulation can lead to diseases such as diabetic retinopathy and age-related macular degeneration (AMD), the number one cause for blindness for the elderly. It is known that women are more susceptible to AMD, cataract, and glaucoma, but the biochemical basis for these sex differences is unknown. This study aims to both quantify and contrast the metabolic pathways of certain amino acids within ocular tissues in relation to time of day and sex. Methods: We collected four different tissues, including retina, retinal pigment epithelium (RPE), cornea, and lens of 8-week old wild type (WT) C57BL/6J mice; male (6) and female (6), at either 10 am or 2 pm. We were able to differentiate the metabolic usages between sex and different times of the day. These samples were run through a Shimadzu LC, paired with a Qtrap 5500 mass spectrometer using a metabolomics assay. Results: Multivariate analysis helped identify key metabolic changes that are sex and tissue specific. There was no difference in male retina or RPE based on time. The female displayed differences in isoleucine, leucine, and lysine in the retina, as well as metabolites in the TCA and glycolysis cycles in RPE. In cornea there is downregulation of taurine in both sexes at 2 pm. Females show a decrease in 21 metabolites whereas males display only 4. Remarkably, metabolites associated with nucleotide and glutathione pathways are upregulated in male lens tissue only. Conclusion: These results suggest time of day has a greater impact on amino acid abundance in females in comparison to males in their retina, RPE, and cornea; the opposite is true for the lens.

Abstract Name: From Grace to Guilt: How Spirituality Affects Regret

Problem or Major purpose: Current regret literature suggests a psychological difference in how people cognitively evaluate their own role in suboptimal outcomes, in terms of actions taken. Initial studies report a robust action effect (Kahneman, 1982); however. Subsequent studies have challenged these findings and suggest that it is the inactions that elicit greater regret (e.g., Gilovich & Medvec, 1995). When facing the consequences of our most impactful decisions, spirituality may significantly impact the decision-making process, in turn the amount of regret experienced. It will explore the role of spirituality with regards to experience of regret. It is expected that spirituality will affect regret, and the directionality of the effect is contingent on the presence of a negative or positive spiritual styles. Procedure: This study will examine the interactive effect of decision type (action vs. inaction) and level of spirituality (low vs. high) on the intensity of regret using a scenario paradigm. Participants will be asked to complete the Religious Coping Scale (RCOPE) (Kenneth, Bockrath & Donna, 2011), after which they will be instructed to imagine themselves either changing or sustaining a regretful decision. Participants will then rate the amount of regret they would experience upon a negative outcome. Results: Approximately 60 participants. will be recruited. We expect to find a main effect of decision type—individuals will report experiencing more regret following a (failed) action. Additionally, a significant interaction between the level of spirituality and decision type is expected. D. Conclusions: This study is expected to shed light on spirituality as a contributing factor to experience of regret following (failed) action/inactions based on the religious coping styles. Positive religious coping styles are expected to produce less feelings of regret from their failed actions whereas negative religious coping methods should experience greater difficulty in absolving personal guilt following a change in decision (action).

Abstract Name: The Impact of Adversarial Attacks on Remote Sensing Applications

This research investigates the vulnerability of remote sensing systems to adversarial attacks, focusing on datasets used for object classification. Remote sensing technologies are vital for automated surveillance, environmental monitoring, and disaster management. However, these systems are susceptible to adversarial attacks, where subtle, deliberate modifications to input data can mislead machine learning models, compromising their performance in detecting and classifying objects. In this study, we demonstrate the impact of adversarial perturbations using the Fast Gradient Sign Method (FGSM). Using the UC Merced dataset, we first train a model that achieves 87% accuracy. After applying FGSM attacks, the accuracy plummets to 32%, underscoring the vulnerability of remote sensing systems to such attacks. This significant drop highlights the importance of developing robust defense mechanisms. To counteract these attacks, we implement two defense strategies: ensemble learning and Projected Gradient Descent (PGD). Ensemble learning combines the outputs of three models, averaging their scores to boost accuracy to 55%, demonstrating moderate resilience against FGSM attacks. PGD, a more robust defense technique, effectively mitigates the effects of FGSM by training with adversarial examples, restoring the model's accuracy to 84%, nearly matching the original performance. This demonstrates that PGD is significantly better at mitigating the effects of adversarial perturbations and ensuring system reliability. The findings emphasize the critical need for secure remote

sensing systems and provide actionable strategies to improve their robustness. Remote sensing systems are integral to both public and private sectors, and securing them against adversarial attacks is essential for maintaining their effectiveness in real-world applications. This research contributes to the development of more secure machine learning systems for remote sensing, ensuring their reliability in crucial applications such as surveillance and environmental monitoring. The results underscore the importance of advanced defense mechanisms in safeguarding the accuracy and integrity of remote sensing technologies.

Abstract Name: What are the Capabilities and Pitfalls of LLMs on Integral Calculus Problems with Zero-Shot Reasoning?

This paper investigates the challenges faced by Large Language Models (LLMs) in accurately solving complex calculus problems. LLMs are increasingly applied to diverse tasks, offering solutions across a broad range of topics. Our research examines the limitations of LLMs, focusing specifically on their performance in solving geometric calculus problems, such as calculating areas of cross-sections, areas between curves, volumes of solids of revolution, surface areas of revolution, and triple integrals in rectangular coordinates. We assess the accuracy of ChatGPT-4.0 mini and Microsoft CoPilot by analyzing both their successes and inconsistencies in the integration steps required for these multi-step calculus problems. A grading rubric is employed to evaluate each model's reasoning accuracy, with particular emphasis on their geometric capabilities. After identifying patterns in their performance, we assess the significance of these patterns to address specific types of calculus challenges. We will report our findings. Ultimately, our findings highlight critical areas for improvement in LLM-driven calculus computation, providing insights that can potentially inform future model development.

Abstract Name: Genome Variation Analysis between Different American Populations to Improve Precision Medicine

Precision medicine, which focuses on how mutations affect human drug response and susceptibility to diseases, needs more genetic diversity. Our purpose is to address this issue, making healthcare more equitable. Native Americans are among one of many American populations facing underrepresentation in genomic studies, facing lower life expectancies compared to other populations according to the Office of Minority Health. Our central research question considers whether a personalized medical approach is needed among different American populations due to genetic variation. Our objectives include discovering novel variants, analyzing their relationship to drug-response, and connecting these results to prevalent diseases in American subpopulations, especially those facing health inequities. We hypothesize that our analysis will yield notable clinical recommendations thereby reducing health inequity. Our research methodology includes epidemiology research to identify major disease trends based on literature from the National Institute of Health and other sources, variant calling using Genome Analysis Toolkit 4, and identifying significant pharmacogenetic recommendations through the Pharmacogenomics Clinical Annotation Tool (PharmCat) and the PharmGKB database. The results of our PharmCat analysis of variants from the Alaskan Native sample yielded 54 strong clinical recommendations, across 33 drugs and 9 clinically-relevant genes. Out of these 54 recommendations, there were 10 recommendations for alternatives to 4 drugs: citalopram, clopidogrel, escitalopram, and simvastatin. In the 52 Paleo-Eskimo samples, we identified 15 clinically significant variants among 11 genes affecting response to drugs for depression, addiction, HIV, cancers, and other diseases. In conclusion, we have found clinically significant variants and genotypes identified in our samples, which we hope can lead to better health outcomes for modern Indigenous populations in the Canadian Arctic, Alaska, the Aleutian Islands, Chukotka, and East Siberia. Overall, our research advances the field of precision medicine, using clinically significant recommendations to improve healthcare outcomes, especially for underrepresented groups across the nation.

Abstract Name: Optimization of Adipogenic Differentiation Potential of Lipedema-Origin Adipose-Derived Stem Cells (ADSCs)

Lipedema, a chronic disorder characterized by metabolic and inflammatory abnormalities, as well as, disproportionate subcutaneous fat accumulation affects 11% of women worldwide. Despite its prevalence the disease remains underdiagnosed, poorly understood, and lacks effective treatments which highlights the need for deeper exploration. Adipose-derived stem cells (ASCs), with their accessibility and ability to differentiate into adipocytes, present a valuable tool for modeling adipose tissue disorders. This study aims to create a reliable in vitro model that replicates the diseased state, enabling further exploration of Lipedema-specific metabolic dysfunctions and fostering advancements in diagnostic and therapeutic strategies. Furthermore this study tailors adipogenic differentiation for Lipedema-ASCs, offering insights into disease-specific behavior and metabolic resistance that are distinct from lean and obese controls. ASCs were isolated from SAT samples of lean, obese, and Lipedema donors. Cells underwent adipogenic differentiation using various treatments, including full (14 day) and half (7 day) durations of Rosiglitazone, a Ppar γ agonist, and Adipoqual, a commercially designed differentiation protocol. Differentiation success was evaluated by quantifying lipid accumulation through Oil Red O staining and analyzing key adipogenic markers (e.g., Ppar γ , Fas, and SCD-1) through qPCR and chemiluminescent western blotting. Comparing results across sample groups assessed the distinct responses of Lipedema-ASCs under optimized conditions. Preliminary findings suggest that Rosiglitazone treatment yields the highest adipogenic differentiation, with Lipedema-ASCs demonstrating unique metabolic characteristics compared to lean and obese counterparts. These results provide a foundation for future studies to investigate the metabolic resistance and thermogenic deficiencies associated with Lipedema. By bridging the gap in understanding Lipedema's pathophysiology, this study provides important foundational information for improved diagnosis and treatment of this debilitating condition.

Abstract Name: Determining The Effects of Ankle Fatigue on Division III Gymnasts vs Non Gymnasts With Varying Levels of CAI

Introduction: Gymnasts use their ankles in diverse ranges of motion and have high proprioceptive abilities. Despite this, their ankles are the most commonly injured joints. Gymnasts have reported high rates of chronic ankle instability (CAI) which is related to muscle fatigue. This study aims to compare the effects of muscle fatigue in gymnasts and non-gymnasts with varying levels of CAI. The clinical significance of this study will be to provide a better understanding of the muscles of a gymnast to design ankle rehabilitation protocols specific to this population. Methods: The study recruited 10 female gymnasts and gender matched non-gymnasts. Participants self-reported their levels of CAI. The muscle activity of the medial Gastrocnemius (MG), peroneal longus(PL), and tibialis anterior(TA) was measured using a Noraxon Electromyography system. Multiple rounds of a strenuous activity protocol, which involved hopping, shuffling and running, was performed by participants until they reported a level 9 or 10 on the BORG scale. The ankle stability tests such as the Y-Balance, single leg stance (SLS), and single leg hops (SLH) were performed before and after the strenuous activity protocol. Results: Significant differences between the two groups were observed. MG post strenuous activity was significantly higher in the gymnasts compared to non-gymnasts when performing single leg hops on the right leg. During the Y balance test, post strenuous activity: the gymnasts demonstrated almost no change, while the non-gymnasts reached significantly lesser distance. Conclusion: The study observed different behaviors between the gymnasts and non-gymnasts, but not sufficient differences to prove significance. This could be due to the small sample size. In summary, there were some instances where gymnasts out-performed non-gymnasts after the strenuous protocol. However further research needs to be conducted to confirm our hypothesis.

Abstract Name: Enhancing Preconception Care Awareness to Improve Maternal Health Outcomes in Marginalized Communities: A Focus on Reducing Health Disparities in Alabama

Maternal mortality rates in the United States have been rising despite global declines, with Alabama experiencing particularly high rates at 36.4 deaths per 100,000 live births in 2020. This trend persists despite improvements in in-hospital delivery and prenatal care, highlighting underlying systemic issues. Marginalized communities, especially women of color and those in rural areas, face significant barriers to healthcare,

including limited access to prenatal care, provider shortages, socioeconomic disparities, and systemic racism. These factors exacerbate maternal health disparities, particularly as more women experience chronic conditions like obesity, hypertension, and diabetes at younger ages. Poorly managed chronic conditions increase the risk of pregnancy complications, including maternal and neonatal death. Consequently, there is a critical need for healthcare interventions that prioritize women's health before conception, during the inter-conception period, and throughout their reproductive years. This project seeks to improve awareness and knowledge of preconception care among women of childbearing age in marginalized communities in Alabama. Data collection will take place at three community health centers: Chambers County Community Health and Wellness Center, AU Health and Education Clinic, and Opelika's Neighborhood Mobile Wellness Clinic. Participants will complete surveys assessing their knowledge of chronic conditions, physical activity, nutrition, substance use, and medication habits. Based on identified knowledge gaps, individualized group teaching sessions and one-on-one consultations will be implemented. Post-intervention surveys will measure changes in knowledge, health behaviors, and motivation to adopt healthier practices. The objective is to empower women to understand the impact of their health behaviors on future pregnancy outcomes, improve their self-efficacy, and motivate them to take an active role in their health. This intervention aims to promote healthier behaviors among reproductive-aged women, ultimately improving maternal and infant health outcomes in Alabama and similar communities.

Abstract Name: Comparative Analysis of Experimental and Modeling of a High-Power LED Panel Performance using ANSYS Modeling

High-energy LED panels find diverse applications, such as indoor or space agriculture. However, LED panels generate excessive heat, reducing their efficiency and posing a risk of permanent damage. In this study, an effort is made to combine two passive cooling techniques by designing a heat sink with embedded thermosyphons operating at a low pressure. Refrigerant within the thermosyphons evaporates, which then condenses at the condenser end, efficiently releasing heat to the environment. 144 rectangular pin-fins, each with a 3mm embedded hole, were attached to a vapor chamber filled with R134a refrigerant at a low pressure. The fluid activates the thermosyphon process at elevated temperatures, effectively transferring heat away from the LED panel. The lower vapor chamber is sealed, and the LED panel is affixed beneath it. Thermal paste is applied to enhance heat conduction and minimize air pockets between surfaces. The temperature data is collected using k-type thermocouples attached to the top and bottom of 8 different pins around the heat sink. The LED panel is turned on, and the temperature readings are recorded through a multiplexer PCB connected to a Raspberry Pi. The experimental results were compiled and completed, and we noted that without any cooling devices, the LED panel reached nearly 120 degrees C. With cooling fans, the panel's temperature peaked at roughly 40 degrees C. The LED surface temperature with thermosyphons measured around 42 degrees C, closely aligning with the target temperature achieved with the cooling fans. Our new work focuses on theoretical measurements and simulations using Solidworks, and Ansys. We aim to prove that the thermosyphons are in effect and model the temperature gradient along the fins to gain an in-depth view of the system. We will present the completed theoretical work and simulations at the upcoming conference alongside a brief overview of our experimental results.

Abstract Name: Development and Evaluation of Advanced Machine Motion Table for Kinematic and Dynamic Motions

The objective of this project is to develop an advanced machine motion table capable of demonstrating and testing various mechanical, kinematic and dynamic motions, specifically focusing on linkages and gears that transmit rotational forces. This is intended for use in educational settings to enhance students' understanding of different mechanical systems and motion. The kinematics, dynamics, and mechanical design of the system are described. The new design will incorporate increased power and linkage capabilities, allowing for experimental validation of theoretical concepts and providing a more hands-on approach to engineering technology education. To achieve this, SolidWorks and other prototyping methods are utilized to simulate multiple design iterations, significantly aiding the design process. Finite Element Analysis (FEA) using ANSYS was conducted on the tabletop and table base. Additional FEA analysis was done on the linkage accessories and motor carrier using SolidWorks Simulation. This ensures all components met the safety, strength, and validity of requirements. The electric motor for the table must have a power output between 0.1-0.5 horsepower. The new table will be large in size to accommodate an increase in power and linkages but must still fit through a standard doorway. The integration of SolidWorks for design simulation and ANSYS for component analysis will ensure the table's safety and performance, contributing to a robust educational tool for mechanical engineering studies.

Abstract Name: Campus Collections: Status Building in Higher Education

In an academic world where higher education has become increasingly competitive, colleges and universities must build their reputation and prestige in order to maintain relevance and attract a community. Studies show that reputation and status are essential for the success of higher education institutions by focusing on parameters such as acceptance rates, qualifications of faculty, difficulty and diversity of courses, and post-graduation placement rates. My research takes a different approach by focusing on the role of museum and archival collections in creating and maintaining reputation, prestige, and status for colleges and universities. Using three collections at the College of Wooster as a case study, I aim to identify if and how higher education institutions build and maintain status through collections. Incorporating ethnographic interviews with relevant faculty and staff alongside content analysis of collection and institutional documents, this

research explores archival collections, statuary and public art, and archaeological collections as status building tools. At the College of Wooster, Special Collections provide privileged access to rare materials and preserve the history and traditions of the College. Campus statues embody economic connections to donors, as well as the values and identities of the campus community. The Pella at Wooster archeological collection symbolizes shifts in institutional goals and educational missions. Overall, these collections represent the complex history and identity of the College, stand testimony to its economic and social ties, and, consequently, affect issues of belonging, representation, and involvement. Collections are essential for holistically understanding how colleges and universities produce reputation, status, and prestige.

Abstract Name: The Effect on Lifespan and Oviposition of *Callosobruchus maculatus* with Four Different Legumes

Bean beetles (*Callosobruchus maculatus*) are invasive granivores that choose specific beans for ovipositing, or egg laying, and have shown various outcomes among different bean types. There is little information known about the relationship between *C. maculatus* oviposition and bean type, as well as the correlation between bean type and *C. maculatus* lifespan. To test both biological relationships, *C. maculatus* were raised on black-eyed pea, chickpea, yard-long, and mung beans. Two male and two female adults were separated into 4 containers with 7 grams of each bean type, and the resulting offspring were counted and separated into their own containers, dispersed by sex. 1 gram of the same bean type was added to the female offspring, and the lifespan of both female and male beetles were measured. The *C. maculatus* females produced the highest oviposition on the yard-long beans ($\mu = 30$), compared to the black-eyed pea ($\mu = 23$), chickpea ($\mu = 23$), and mung bean ($\mu = 19$), on average. Interestingly, despite similar averages of oviposition for chickpeas and black-eye peas, yard-long ($\Sigma = 66$) and mung ($\Sigma = 61$) beans produced more offspring, meaning that they may be the more favorable host for *C. maculatus*. In contrast, the chickpeas produced the lowest offspring production ($\Sigma = 27$), likely due to their hardshell being less suitable for reproduction. Black-eyed peas were in the middle for offspring production ($\Sigma = 47$). Additionally, the longer average lifespan of *C. maculatus* on yard-long beans ($\mu = 12.74$) suggests these beans may offer better nutritional or developmental support compared to mung ($\mu = 11.41$), chickpea beans ($\mu = 10.56$), or black-eyed peas ($\mu = 6.95$), respectively. Therefore, the high oviposition rates, offspring production, and longer average lifespan on yard-long beans infers their suitability as a host, due to optimal nutritional content that support the development and survival of *C. maculatus*.

Abstract Name: Investigation of epigenetic landscape of taste receptor cells

Chromatin is the nucleoprotein polymer that regulates propagation and interpretation of genetic information in eukaryotes. Four histones – H2A, H2B, H3, and H4 – form the protein core of the nucleosome. Combinatorial post-translational modification of histone residues by “writer” enzymes, and their interpretation by “reader” effectors, provide the platform for epigenetic regulation of gene regulation, and are integral to development and differentiation. Polycomb system consists of two factors, Polycomb Repressive Complex 1 and 2 (PRC1/2). Defects in PRC1/2 are frequent in malignancy and developmental disorders, driving precocious differentiation, or, conversely, de-differentiation of tumor cells. Mechanistically, PRC1 is a ubiquitin ligase of histone H2A lysine 119, while PRC2 is a methyltransferase of histone H3 lysine 27. Yet how individual cell types establish and maintain Polycomb domains in chromatin, and the consequences of PRC1/2 loss in specific tissues and cell types, are critical yet poorly understood questions in cell biology. We utilize a taste receptor cell (TRC) model, to delineate the contribution of Polycomb to the differentiation of a terminal, post-mitotic cell lineage. TRCs are specialized epithelial cells, providing multiple sensory inputs to the central nervous system. TRCs are thus uniquely suited to explore the mechanism of cell specialization in development. Immunofluorescence analyses of chromatin landscape revealed remarkable differential accumulation of Polycomb subunits and associated chromatin modifications specifically in TRCs, but not in surrounding epithelial cells or underlying tissues. We documented high levels of PRC2 subunits EZH2, EED and SUZ12, as well as H2AK119 ubiquitylation and H3 K27 di- and trimethylation, unique to terminally differentiated TRCs, identified by accumulation of Cytokeratin-8. Curiously, all tested TRC subtypes, identified by the subunits TRPM5 and Car4, accumulate Polycomb proteins and associated histone modifications, suggesting this as a universal feature of terminally differentiated TRCs, and Polycomb activity may be required for their differentiation.

Abstract Name: PET Imaging of Urokinase-Type Plasminogen Activator Receptor (uPAR) in Aggressive Thyroid Cancer

Background: Aggressive thyroid cancers, including poorly differentiated thyroid cancer (PDTC) and anaplastic thyroid cancer (ATC), represent more than half of annual mortality despite accounting for less than 5% of annual cases of thyroid cancer. The purpose of this study was to assess urokinase-type plasminogen activator receptor (uPAR) as a target for aggressive thyroid cancers. uPAR is a cell membrane receptor which facilitates cell invasion and migration during wound healing and embryogenesis, but becomes overexpressed in many cancers including breast, prostate, ovarian, and colorectal. Methods: Cancer specimens originating from twenty-one patients with PDTC and eighteen patients with ATC were immunostained for uPAR. Western blot and immunohistochemistry were used to identify cell lines with membranous uPAR expression. uPAR-targeted peptide, AE105, was radiolabeled with PET radioisotope ^{68}Ga ($t_{1/2}=68$ min) in order to create a uPAR PET-imaging agent. uPAR-positive cell lines were used to conduct in vitro cell uptake studies and in vivo PET imaging in a subcutaneous xenograft model with the uPAR-targeted radiopharmaceutical

[68Ga]Ga-NOTA-AE105. Results: Immunohistochemical analysis revealed 19% of PDTC patients (4 primary) and 28% of ATC patients (3 primary and 2 metastatic) were uPAR-positive. Western blot identified one PDTC and two ATC cell lines with strong endogenous uPAR expression: THJ529T (PDTC), THJ560 (ATC), and JEM493 (ATC). In vitro uptake of 1 nM [68Ga]Ga-AE105 was $7.4 \pm 2.9\%$ bound/mg in uPAR-positive THJ529T cells. Uptake was significantly reduced ($p < 0.001$) to $1.2 \pm 0.7\%$ bound/mg by addition of excess AE105. PET imaging 20-minutes postinjection showed that the mean standardized uptake value (SUV_{mean}) in THJ529T (PDTC) xenografts was 1.3 ± 0.1 , 2-fold higher than background organs, and 1.2 ± 0.3 in JEM493 (ATC) xenografts, 3-fold higher than background organs. Conclusions: In vitro uptake and in vivo PET imaging suggest uPAR is promising target for diagnosis and therapy in aggressive thyroid cancers that are uPAR-positive

Abstract Name: Central Auditory Processing Disorders: A National Survey of Assessment Practices

The etiology of auditory processing disorder (APD) remains unclear but does not exclude neurological disorders, lesions in the auditory pathway, aging, and genetics. Symptoms of APD include problems localizing auditory input, hearing in acoustically challenging environments, and poor auditory processing amid competing acoustic stimuli. The presence of APD can make it difficult to converse in a busy environment and to understand multi-step directions. At present there is no “gold standard” test battery for APD assessments. The American Speech-Language-Hearing Association suggests criteria of at least 2 standard deviations below the mean on two or more APD test batteries, but does not specify the use of one or both ears. The American Academy of Audiology requires 2 SD or more below the mean for at least one ear on two test batteries. The British Society of Audiology has no specific criteria for APD diagnosis but recommends using indirect and direct standardized tests. Other recommendations are that an APD test battery include temporal resolution and a dichotic listening test. Before performing an APD test battery, a hearing screening should rule out a potential audiologic issue that can be resolved with amplification. Whether an individual is diagnosed by a speech-language pathologist or audiologist can change the assessment outcome. A struggle with phonemic identification evaluated by an audiologist may conclude an APD diagnosis, one by an SLP may lead to a phonemic discrimination issue. Currently, only 45% of audiologists report offering APD assessment. Testing for APD is different than a diagnostic hearing evaluation; APD is not well predicted in decontextualized situations in sound-controlled environments. A nationwide survey adapted from Chermak et al. (1998) was distributed. Responses were analyzed to identify the audiology programs that currently offer APD testing and, among those that offer APD testing, to identify the test batteries and protocols used in assessments.

Abstract Name: Unified Study of the Classical Hall Effect

We conduct experiments on different types of germanium samples; some are doped with acceptors (p-type) and some with donors (n-type). Our experiments reveal carrier concentrations of $6.73 \times 10^{20} \text{ m}^{-3}$ for the n-type sample and $1.16 \times 10^{21} \text{ m}^{-3}$ for the p-type sample. These experiments were conducted for the standard Hall effect (Hall voltage versus magnetic(B) field) as well as conductivity and Hall voltage versus temperature for different B-fields. The zero-field results allow us to obtain band gaps (E_g). For the n-type we found that $E_g = 0.663 \text{ eV}$, while for the p-type sample $E_g = 0.618 \text{ eV}$. While it is commonly known that the Hall voltage is linear with B-fields, not so common is the behavior of the Hall voltage with temperature, especially for both n-type and p-type samples. Thus, we derived a general Hall voltage theory for semiconductors that unifies the understanding of both n-type and p-type carriers. Our experimental results are analyzed with the unified theory using MATLAB.

Abstract Name: Effusive and Explosive Properties of a Volcanic Vent East of Olympus Mons, Mars

The surface of Mars is covered in numerous small volcanic vents. Specifically, the Tharsis volcanic province has ~1,100 identified volcanic vents. Previous studies have assumed the primary construction process for many of these vents is effusive volcanism. Meaning they are constructed by overlapping layers of multiple lava flows. However, with the increase of high spatial resolution visible and topographic datasets on Mars, this assumption is beginning to be questioned. We present a morphologic analysis of a volcanic vent east of Olympus Mons to identify evidence of explosive and effusive features. Analysis of the vent utilized high resolution visible and topographic data from the High Resolution Imaging Science Experiment (HiRISE) instrument on Mars Reconnaissance Orbiter. The vent has a similar morphology to terrestrial fissure vents but covers an area of ~4.2 km². This is ~2 orders of magnitude larger than the equivalent terrestrial fissure vent. Using the high resolution visible and topographic datasets, we identify evidence of effusive (e.g., multiple lava flow channels and overlapping sheet flows) and explosive (e.g., constructed spatter ramparts) volcanism. Initial results from this research indicate that explosive volcanic activity was more present in the Amazonian (~3 Ga to present) than previously thought. Identification of explosive volcanism during the Amazonian would lead to a greater understanding of the volcanic processes and environmental conditions when the vent was emplaced.

Abstract Name: Using Ground Penetrating Radar (GPR), Archival Data, and Survivor Testimony to Locate Holocaust Mass Burials in the Livas Cemetery in Liepaja, Latvia

The Jewish section of the Livas Cemetery in Liepaja, Latvia, shares a history with many other European cemeteries in that it was used as a burial ground by local Jewish communities, in some cases for centuries. During World War II, Nazi Germany and local collaborators sometimes used these cemeteries for mass burial of Jews murdered as part of the Holocaust. The main objective of this research was to use technology, archival data, and Holocaust survivor testimony to determine if previously unknown mass grave(s) are present in Livas Cemetery. Specifically, ground-penetrating radar (GPR), which uses high-frequency pulsed radio waves emitted from a transmitter antenna and collected by a receiver in the GPR system, was used to image the subsurface. Interpreting GPR data collected within the cemetery can indicate subsurface anomalies (disturbances). Archival sources and Holocaust survivor testimony suggest that in June 1941, Jews were killed and buried in three shallow mass graves at Rainis Park in Liepaja. After several weeks, because of the smell emitted from the decaying bodies, they were exhumed and moved to a mass grave(s) in Livas Cemetery, approximately three kilometers away. In 2023, GPR data collection focused on an area where two distinct surface mounds exist in an area of the cemetery devoid of gravestones. In 2024, we collected GPR data in the vicinity of monuments created to memorialize the atrocities associated with the murder of Jews in Liepaja during the Holocaust. These preliminary investigations indicated a sizable subsurface anomaly near the two surface mounds and no apparent anomalies were present in the memorialized area. Future research includes expanding the search area to include another area devoid of gravestones, additional archival and testimony studies, and incorporating other geophysical techniques to determine if a mass grave(s) exists in the cemetery.

Abstract Name: How do Toddlers on the Autism Spectrum Explore and Use Objects During Toy Play in the Home Environment?

Children on the autism spectrum have been observed to explore and play with objects differently than children with typical development. For example, they may focus intently on objects, gather them, or use objects in a repetitive manner by sorting or organizing them into lines. Children with autism are also less likely to show joint engagement with others during play, and they may show delays in symbolic and imaginary play with their peers. For these reasons, speech and language interventions for children on the autism spectrum often include teaching of functional, symbolic, social, and pretend play. However, very little research has examined play development in young autistic children. In this study, two trained student researchers coded actions with objects during toy play from naturalistic, video-recorded home observations in a sample of 50 autistic toddlers at a mean age of 20 months. Videos were coded using Noldus Pro Observer XT software for a variety of exploratory, functional, constructive, symbolic, and imaginative play actions. Twenty percent of videos were double coded to ensure adequate inter-rater reliability. The aim of this research study was to identify and describe patterns of object exploration and use in this sample. Findings from this study will deepen understanding of the development of play in very young children on the autism spectrum. It is important to increase our understanding of early play skills in this population so that speech-language pathologists can build on children's strengths, help them make meaningful connections with other people, and take a neurodiversity-affirming approach to teaching social interaction and play.

Abstract Name: Bridging Academia and Industry: The Beehive Design Practicum

This presentation highlights a graphic design practicum course within the NWPA Beehive Program, a collaborative hub for community innovation. Students engage in professional projects for local clients, emphasizing creative problem-solving, client management, and teamwork. By refining their skills, assuming leadership roles, and collaborating on projects, students build confidence, adaptability, and professional portfolios. Through examples of student work and classroom dynamics, this talk demonstrates how the practicum bridges academic learning with real-world practice. Attendees will gain strategies for guiding students through ideation, managing client relationships, and fostering collaborative, growth-oriented environments.

Abstract Name: Novel RNA-Binding Proteins Interacting With tRNA Fragments in Glioblastoma

Introduction: Glioblastoma (GBM) is a very aggressive and fast-growing brain tumor with a poor patient prognosis. We aimed to identify potential targets for GBM therapies by discovering novel RNA-binding proteins (RBPs) that interact with glioma-prognostic tRNA fragments (tRFs) in GBM cells. tRFs often work by interacting with RBPs and regulate protein translation, gene silencing, and cancer cell proliferation. These small non-coding RNAs are formed from mature or precursor tRNA cleavage and often play a regulatory role in cancer. We identified and focused on three tRF-3s prognostic for poor survival in low-grade glioma (LGG) in The Cancer Genome Atlas (TCGA) database: tRF-3009a (Leu), tRF-3021a (Ala), and tRF-3030a (Tyr). **Methods:** The RBPs binding with the glioma-prognostic tRFs were identified using an RBP microarray in vitro, including NOVA1, NOVA2, EIF4B, PTBP3, and PCBP4. For each RBP, I investigated the function, upregulation in gene expression, correlation with patient survival in TCGA, and role as an oncogene or tumor suppressor. RNA Bind-n-Seq data from ENCODE was used to determine if the tRF-3 sequences had enriched motifs for the RBPs, and AlphaFold 3 formed potential predictions for these interactions. **Results:** Bind-n-Seq data showed that PCBP4 preferentially binds to a sequence motif in tRF-3009a, but no other matches could be validated due to limitations in available datasets. AlphaFold 3 predictions demonstrated that NOVA1 and NOVA2 binding tRF-3009a and PCBP4 binding tRF-3009a, tRF-3021a, and tRF-3030a are likely (iPTM>0.6, low PAE). **Significance:** Identifying novel RBPs that interact with glioma-prognostic tRFs may highlight further areas of study in the direction of new treatments for GBM. For example, targeting RBPs or tRFs associated with poor patient survival could prove to be a promising strategy for enhancing GBM patient outcomes.

Abstract Name: Identifying Mechanisms of Capsaicin Treatment in Breast Cancer Cell Lines

Breast cancer will kill approximately 1 in 40 women, making it the second leading cause of death in women. Roughly 50% of HER2 cancers develop drug resistance; this study hopes to fight those statistics. Capsaicin has shown an ability to kill MCF-7 and MDA-MB-231 breast cancer cell lines, but the mechanism of cellular death that it enforces is still unknown. Three different assays were utilized to analyze the possibility of the Warburg Effect playing a role; lipid peroxidase, CyQuant, and oxygen plate analysis. The lipid peroxidase assay showed little change in oxidative stress from the DMSO control and the capsaicin treated cells. The CyQuant assay showed minimal differences in cellular death rates with varying concentrations of capsaicin. The oxygen plate analysis showed that different concentrations of capsaicin had only small changes in oxygen consumption. This data indicates that capsaicin kills cells through an alternate mechanism to the Warburg Effect. Moving forward, data collection will assess the possibility of an alternate pathway in the endoplasmic reticulum: Unfolded Protein Response (UPR), more specifically the activation of IRE1 α protein coupled with GRP78 protein, and the activation of CHOP protein ultimately triggering a caspase cascade that forces cell death.

Abstract Name: Fear of the People: The Undemocratic Origins of the U.S. Constitution

The origin of the U.S. Constitution is one shrouded in mystery due to the closed-door meetings and invite-only admittance to participate in the Constitutional Convention proceedings. Thanks to the meticulous notes taken by some of the framers, like James Madison, and the efforts of the Federal Government to preserve those records, historians have been able to glimpse what was happening behind those closed doors. In 1913, historian Charles Beard published his interpretation of the origins of the U.S. Constitution titled *An Economic Interpretation of the Constitution of the United States*, making it one of the first publications to analyze the economic and financial interests at play during the drafting of the U.S. Constitution. This opened up avenues for people like Woody Holton, author of *Unruly Americans and the Origins of the Constitution*, to further research the class conflict that resulted in today's Constitution. Through analysis of Woody Holton's work, along with primary sources from Max Farrand's volumes of *The Records of the Federal Convention of 1787*, I have been able to research my own interpretation of the origins of the Constitution. By breaking down the framers' intentions to that of economic superiority, political superiority, and social superiority, I have concluded that the U.S. Constitution that resulted from the Constitutional Convention of 1787 sought to restrict the peoples' access to democracy and establish a baseline for who the political elite should be.

Abstract Name: Surgical Precision during Haptic Virtual Reality

Over the last several years, Haptic Feedback in Virtual Reality (VR) has seen significant developments allowing users to feel virtual objects. Haptics offers the possibility of tasks, like surgeries, to be performed remotely across the world and in the classroom. A question posed is how precise the actions of surgeons are when performing teleoperated surgical tasks. This study uses a "Hoop Wire Game" within a VR environment to quantify the differences in fine motor skills between novices and skilled surgeons. The game requires participants to guide a virtual wire loop along a winding path without touching the edges, simulating the delicate movements required in surgery. By tracking movement and measuring the size of errors (contacts with the "hoop"), smoothness of movement, and number of finger adjustments in the game, we aim to establish objective metrics for evaluating performance. The task will be performed using commercially available haptic gloves that provide touch sensations through pressurized air. Based on these metrics, we will evaluate the comfort levels and learning curves associated with VR training in different media. The same precision task will be performed within the simulated virtual environment, teleoperated using a physical robot that mirrors the surgeon's VR movements, and in a non-virtual environment. These comparisons address the crucial question of whether proficiency in VR translates directly to improved skills in traditional settings, particularly for experienced surgeons who may have less familiarity with VR technology. The expected result is for there to be no significant differences between the conditions. Lessons learned in this study can help to inform the way that tele-surgical and surgical training interactions are designed.

Abstract Name: Improving Exercise Performance by Modifying External Environment

This study examined the effect of environmental stimuli on resistance exercise performance in college aged athletes using leg extensions. We utilized biofeedback and proprioception to analyze muscle activation and its correlation with perceived effort to determine whether knowledge of the weight being lifted affected physiological responses in resistance training. Previous studies had initial results that indicated that squat 1-repetition maximums increased with weight covered. In our study, we explored stamina using 60% of a 5-

repetition maximum on a leg extension machine. Participants first reported and performed their 5-repetition maximum. Then, participants performed repetitions until failure with the weight stack covered (perception of effort set). After completing this set, participants filled out a modified POMS survey, took a three-minute break, and repeated the assay after being told the weight they would be lifting, which was the same as in the first set. While we found that visual awareness of the mass to be lifted did not affect higher quadricep activation, the speed of the repetition was found to be different. We observed that the control set (2.65 ± 0.50 s) compared to the perception of effort set (3.18 ± 0.64 s), with a significant difference ($p = 5.38E-15$). Additionally, the first repetition of the perception of effort set showed a significantly lower difference in muscle activity, shown by an increased bicep femoris activation, compared to subsequent repetitions ($p = 0.02$) and the first repetition of the control set ($p = 0.008$). These findings suggest that while the perception of weight has some effect, it does not increase muscle activation as initially hypothesized. This research contributes to our understanding of how psychological factors like perception of effort and proprioception can impact performance in resistance training.

Abstract Name: Implementing Storytelling into the Elementary School Classroom: A Best Practice Guide with Adaptable Lessons

Incorporating storytelling projects and activities in the elementary classroom helps students become more engaged and interested in what they are being taught. Often, there is not enough time in the day to cover all the material, let alone teach students these concepts in fun and engaging ways that every student deserves. Therefore, teachers should be given the resources to help their students learn the material in a fun and appealing way, such as through storytelling. Previous research has shown that storytelling is a multisensory project that reinforces literacy and language skills, increases students' retention of the information presented, and increases their active engagement (Stanley & Dillingham, 2009). Storytelling is a research-proven and effective method of instruction that can be used to further teach children the six language arts (NCTE, 1996), story comprehension (Campbell & Hluske, 2015), and the parts of a story while encouraging critical thinking, problem-solving, and collaboration (Lisenbee & Ford, 2018). I have collected data from various research articles and scholarly books that have detailed explanations of three types of storytelling (traditional storytelling, digital storytelling, and performance literacy storytelling). This data will be analyzed in a narrative and informational format style. All relevant data is compiled into an informational guide that will give teachers the information they need to easily and effectively implement storytelling into their elementary school classrooms with sample lesson plans for various elementary grade levels and subject areas.

Abstract Name: Glocal Identity of Contemporary Estonian Music Culture

Despite political and cultural impositions dating back to the 12th century, Estonia, a small Baltic country bordering with Russia, has maintained a unique musical identity through preservation and celebration of traditional vernacular music and ongoing singing festivals, coupled with the effective absorption of outside influences. The “Estonian Composer” of any time has never been a clear-cut image, and the leading contemporary classical (or “art music”) composers of the nation have become exceptionally diverse in their styles of writing, including electronic, sacred, spectral, and jazz music. And, while music of Estonian composer Arvo Pärt has become a subject of most textbooks on Western Music History, his “spiritual minimalism” or “new simplicity” style does not necessarily represent Estonian art music at-large. In fact, the majority of the works written by the composer’s contemporaries are stylistically dissimilar to Pärt’s music, embracing a vast range of influences, but also commonly containing unique elements or references to Estonian language, traditions, and sensibilities. Often used in social sciences, the term “glocalization,” according to Roudometof & Dessi (2022), is “understood as a hybridization requiring the interplay of both ‘global’ and ‘local’ factors” (3). This study recontextualizes the term to form a better understanding of the identity of Estonian contemporary music culture. After briefly outlining a turbulent geo-political history of Estonia and touching upon the country’s main cultural markers, I utilize selected works by Lepo Sumera and Helena Tulse to argue that the Estonian model of cultural identity is glocal in its essence, embracing the nation’s cultural past and promoting enriching and productive creative encounters while resisting the limitations of traditional nationalistic constructions.

Abstract Name: The Literary Analysis of Video Games as Texts: Psychoanalysis and Postcolonialism in Disco Elysium

How can literary theories of psychoanalysis and postcolonialism uncover new dimensions of narrative/gameplay in video games like Disco Elysium? This project draws upon psychoanalytic and postcolonial literary theories to analyze the video game, Disco Elysium, exploring how critical literary theories unravel the non-traditional medium of video game storytelling, and how players' interactive role enhances narrative elements. Previous research has investigated role-playing opportunities in interactive storytelling and the general application of literary theory in critical analysis. This project addresses the gap in existing research by exploring how literary analysis reveals gameplay mechanics as being narrative elements that reinforce role-playing choices and complement the literary storytelling in video games. Using psychoanalytic and postcolonial literary criticisms, the research explores the 24 personality-based skills used in gameplay, the narrative arc of the protagonist produced through role-playing decisions, and how dialogue choices intersect with narrative elements. In Disco Elysium players control an amnesiac detective who lost all epistemological knowledge while solving a lynching. Players inhabit the protagonist's shattered identity and navigate a postcolonial setting, discovering a conspiracy beyond the lynching. Psychoanalytic findings indicate that in-game psychosomatic skills are recontextualized as building blocks of the subconscious rising to the conscious, emphasizing the protagonist's lack of a cemented personality; players thus impose their personalities through gameplay. Postcolonial findings indicate players also become vulnerable to mimicry — the protagonist's ungrounded sense of self inhibits resisting radicalization when adopting preexisting ideologies during gameplay. Utilizing a close reading and interviews, gameplay reflects the Estonian developers' experiences witnessing conflicting ideologies fighting over national identity after the USSR's collapse, providing insight into the critical landscape of Disco Elysium. These conclusions contribute to ongoing applications of literary theory in the critical analysis of video games, and how non-traditional storytelling mediums provide opportunities for expanding narrative into spaces of audience interaction.

Abstract Name: Human and Artificial Intelligence Communication: Strengths and Weaknesses of Conversing with AI for Coding Mathematical Models

This project examines the efficacy and limitations of artificial intelligence in generating Mathematica code for calculus applications. Mathematica is a computational software used for complex mathematical, scientific, and engineering problems that also includes a “chat-enabled notebook,” allowing users to interact with an AI assistant embedded within the notebook environment. By exploring five models representative of core calculus topics, this study compares code responses from OpenAI’s ChatGPT and the chat-enabled notebook within Mathematica, also provided by OpenAI software. This study also analyzes how each artificial intelligence platform reacts to different styles of queries during the code creation and debugging process. My comparison revealed that ChatGPT generally provides reliable, functional rudimentary code, whereas Mathematica’s chat notebook demonstrates a greater capacity for complex and realistic model creation, however, often with more bugs. Additionally, both platforms produced better results when queries were phrased as questions rather than direct commands. This analysis highlights the differing strengths of AI tools in computational code generation for mathematical applications and helpful methods for successful human to AI interaction.

Abstract Name: Golf, God, and The Hunger Games: The Usage and Social Implications of the ‘Magical Negro’ Trope in Film

Films over the last 25 years such as The Legend of Bagger Vance and The Hunger Games have paired black characters along with the movie’s white lead in an effort to promote better representation of African Americans in cinema. While these films make small strides toward more positive representation, their use of a black character to advance the white protagonist’s growth classifies them as ‘Magical Negro’ (MN) films. The MN trope within cinema is problematic because it testifies to society’s perception of unbalanced power between black and white Americans. This paper aims to critique the tolerance of semi-positive and seemingly harmless portrayals of African Americans in film through an analysis of the MN trope. After investigating the common elements and patterns within MN films, most notably the patterns of economic deficiency and temporary presence, the paper argues that these stereotypes negatively impact the audience. The paper concludes with an examination of how modern audiences should interact with MN films. These films’ potential negative impact warrants intentional education so that an audience can still appreciate the valuable aspects of the film without internalizing the negative stereotypes they perpetuate. The relationship between harmful characterizations and real-world impact as demonstrated with MN films warrants attention because cinema is an influential tool for enforcing racial attitudes that should be held accountable.

Abstract Name: Exploring Biofluorescence in Desmognathine Salamanders: Sex Differences and Glandular Sources

Biofluorescence occurs when organisms absorb light at one wavelength and emit it at another. Biofluorescence is widespread in animals and has recently been discovered in salamanders. Salamander skin is a mosaic of different skin glands, a source of biofluorescence. In Red-back salamanders, males exhibit a higher density of biofluorescent speckling on their ventral tail than females, suggesting a function in social interactions related to reproduction. This study investigates biofluorescence patterns in Desmognathine salamanders and the gland source of biofluorescence in *Desmognathus ochrophaeus*. First, we hypothesized that male-biased sex differences in biofluorescence are widespread among salamanders. To test this, we characterized biofluorescent patterns in males and females of three species of salamanders in the *Desmognathus* genus. Salamanders were anesthetized and biofluorescence was observed under a fluorescent microscope that was exciting the salamander skin at a wavelength of 480 nm and emitting light at 535 nm. The density of biofluorescent glands was measured using Image J. Contrary to expectation, females in all 3 species had a significantly greater density of biofluorescent glands compared to males throughout the body, including the ventral and dorsal tail, and the ventral head. In the second experiment, we hypothesized that biofluorescent glands and modified granular glands are synonymous in *D. ochrophaeus*. We took fluorescent images as described previously and then compared the density of biofluorescent glands to the density of modified granular glands in cryosectioned and tri-stained skin samples. Overall, we conclude, that there is an established pattern of greater biofluorescence in females than in males in the *Desmognathus* genus. Also, we conclude that modified granular glands are not the glandular source of biofluorescence in *D. ochrophaeus*. These findings will inform future research that will seek to determine the function and source of the biofluorescent glands.

Abstract Name: Going the Extra Mile: investigating the relationship between bikeshare and public transit

Bikesharing has emerged as a popular response to the growing need for sustainable, flexible transportation options in urban areas. With the ability to bridge the gaps in traditional transit networks, bikesharing offers a potential solution to the first-mile/last-mile problem, making it easier for commuters to connect to and from public transit options. Despite its rapid adoption, little is known about how bikesharing trips interact with public transit usage on the aggregate. This research studies the complex interplay between bikesharing and public transit in three major U.S. cities: Chicago, New York City and Los Angeles. We use bikesharing trip data along with historical general transit feed specification data to investigate the extent to which bikesharing trips integrate with or substitute against public transit in these geographically and demographically distinct cities, as well as how various spatial, temporal and socioeconomic factors may influence these dynamics. Our

findings reveal that modal integration is associated with higher service frequency of public transit, while modal substitution tends to be more common in dense urban cores. The interaction between bikesharing and public transit is also shaped by individual and neighbourhood-level social factors. Younger commuters, particularly in college towns, and individuals from socioeconomically disadvantaged neighbourhoods are more likely to integrate bikesharing with public transit. Built environment differences between the three cities also influence how bikesharing is used in relation to public transit. These findings support the critical need to account for built environment and socioeconomic factors when planning for effective integration between bikesharing and public transit systems and, ultimately, sustainable and equitable urban transportation systems.

Abstract Name: Multidimensional Sleep Health in Retired Day Shift Workers and Retired Night Shift Workers

Introduction: Night shift work is associated with poor sleep quality and sleep disorders during employment and retirement. Most studies surrounding sleep and shift work draw from self-reports, clinical diagnoses, or laboratory observation, but few examine sleep patterns from a multidimensional perspective in retirees exposed to shift work. This study compared sleep health in retired day workers (RDW) and retired night shift workers (RNSW). Methods: 76 RDW and 61 RNSW provided an average of 6.88 days of sleep diary and actigraphy data. Multidimensional sleep health was quantified using wrist actigraphy measures of sleep efficiency, timing, duration, and regularity, a diary measure of sleep satisfaction, and the Epworth Sleepiness Scale to measure daytime alertness. Components were dichotomized and summed as a composite score (0-6); higher values indicated better sleep health. Linear regression tested associations of shift work exposure group, years of night shift work, and recency of shift work with multidimensional sleep health and its individual components, adjusting for age, sex, race, educational attainment, physical health (RAND-12), and depressive symptoms (CES-D). Results: RNSW exhibit marginally worse multidimensional sleep health compared to RDW ($\beta=-0.174$, $p=0.060$) and poorer sleep satisfaction ($\beta=-0.178$, $p=0.045$). Other individual components were not associated with shift work exposure. Neither the duration nor recency of night shift work was associated with multidimensional sleep health. Conclusion: Retired night shift workers exhibit worse overall sleep health and sleep satisfaction compared to retired day workers. Importantly, duration and recency of night shift exposure do not mitigate these effects. These results further link night shift work and poor sleep, which may lead to worse health outcomes in old age. Future research could assess changes in shift workers' sleep health longitudinally. Research into the physiological consequences of night shift work could rule out the possibility that individuals with poor sleep health self-select into night shift work.

Abstract Name: The Weight of Beauty: How Body Size Affects Gender Perception of Attractiveness

The current cultural issues surrounding body shaming and fatphobia in the United States has led to the need for the present study to examine whether perceived attractiveness depends on body type, gender, or if body type has an effect on perceived attractiveness depending on gender. The present study was conducted as a 2 x 2 between-subject experimental design. The data was collected through an online survey and the survey link was distributed by student researchers via text or email. Surveys were administered electronically through the Google Forms application. The data was submitted to SPSS 25 for analysis, using a Two Way ANOVA, with an alpha level of .05. The present study consisted of 74 participants ranging in ages 18 to 76 (M = 27). The results revealed thin body types were perceived as significantly more attractive than thick body types. However, no significant interaction was found between body type and gender on attractiveness ratings. The study's findings align with previous research that suggests a cultural preference for thin body types and a gender difference in attractiveness perception. However, limitations such as the use of animated images and a relatively small sample size may have affected the results. Furthermore, a manipulation check failure occurred with one of the images, suggesting the need for improved stimuli in future research. The study underscores the persistent influence of societal norms on body image and attractiveness, despite movements toward body positivity. Future studies should consider using real-life images of models and increasing the sample size to enhance validity. Additionally, the influence of factors such as hunger on attractiveness perception should be explored further to understand the nuances of body size preferences across different contexts.

Abstract Name: Leveraging High School/College Partnerships to build Research Interest and Experience

The Seneca Valley High School Center for Biotechnology began with the creative ideas of a faculty member, the support of an administrator and a parent with biology expertise. The Center was developed and is funded through a combination of school district money, grants and charitable donations from philanthropic organizations. This presentation describes the development, implementation, growth and impacts of a dedicated STEM research space and training program for high school students. Initiated as an opportunity for gifted students, the center began as a partnership with a faculty member at Westminster College who identified equipment needs and offered technique training sessions for students. Over the past 8 years the space and program have grown, now working with partners from Westminster College, University of Pittsburgh School of Medicine, Duquesne University, Penn State University, United States Geological Survey, United States Fish and Wildlife Service, and the Pittsburgh Zoo. The center has reached 72 students, through various research scenarios, including investigations into conservation genetics, biofilm producing bacteria, synthetic biology, fluorescent microscope mitochondria detection, environmental detection of microbes and genetic edits in produce. Due to the terrific growth in student involvement, the laboratory matched demand with an increase in faculty staffing. Most of the students contribute projects to local and regional science fairs and some earn research internships with local institutions. As the early participants have gone off to college, we have begun to see the lasting benefits of this experience in their transition into undergraduate research. Notably, the alumni communicate that their experience in the lab opened opportunities for earning research positions early in their post-secondary education. These students have also returned to speak at the Center's

Open House, a student-initiated event to share stories of success and confidence as they approach potential research mentors and integrate themselves into college level laboratory experiences.

Abstract Name: Investigating the Relationship Between Brain Microstructure and Behavioral Heterogeneity in Autism Spectrum Disorder

Autism spectrum disorder (ASD) is a neurodevelopmental condition characterized by deficits in social communication and repetitive behaviors, with significant variability in presentation. Current diagnostic methods rely on behavioral assessments, but no biomarkers reliably connect these measures to underlying neurobiology. Previous findings from our lab identified that g-ratio, a measure of axon to myelin diameter, and conduction velocity, which is associated with speed of a neuronal signal, may be associated with ASD, correlating these microstructural differences with behavioral and cognitive performance. Using data from the NIH Autism Centers of Excellence (ACE) network, I observed associations between brain microstructure and behavioral subscales, revealing distinct neuronal profiles that may be masked by composite test scores. Machine learning analyses further highlighted age as a critical factor, identifying ASD subtypes characterized by restrictive behaviors versus sensory sensitivity and language performance. Building on this foundation, my ongoing research investigates how g-ratio and conduction velocity evolve as participants transition into early adulthood. Utilizing diffusion magnetic resonance imaging (dMRI), I aim to determine whether microstructural differences persist across development and to explore potential sex-based differences following puberty. Anticipated results include sustained microstructural abnormalities and emerging sex differences, providing insights into how developmental trajectories influence ASD heterogeneity. This research seeks to bridge the gap between behavioral assessments and neurobiology, advancing the potential for neuroimaging biomarkers to improve early diagnosis and personalized interventions in ASD.

Abstract Name: Isolating and Analyzing Fungi for Purposes of Bioremediation

The use of microorganisms to chemically degrade crude-oil derivatives, which often take the form of inert aliphatic and/or aromatic compounds and polymers, has been proposed as a potential means to reduce pollutant levels in global ecosystems and to recycle material into biologically active forms. Fungi have a

unique array of enzymes and structural characteristics which allow for efficient and highly-specific organocatalysis of substrates inaccessible through most metabolic processes. . The aim of our research has been to isolate suitable strains of local, fungal species in different environments with varying levels of exposure to petrochemicals in the form of motor oil, and to perform extractions and tests for secondary metabolite analysis. Research in this area has shown promising results which demonstrate the efficacy of specific fungi, changes to chemical composition of polluted samples, and have shown trends correlating to specific enzymes. An inadequacy found in much of the literature published, however, is the reliance upon wild soil substrates for sample collection which excludes important fungal groupings such as sapotrophs. Lignin peroxidase and laccases, abundant in wood-degrading funguses, have been used for the benign treatment of wastewater due to their ability to break-down hazardous phenolic compounds. In this project, specimen are collected from several environments using open agar plates which are coated in motor oil. Prevalent organisms are then further cultured under similar conditions with varying substrates including emulsified, liquid broth and polluted wood pellets of differing types. Metabolite extractions are performed using standard solvent-based techniques, as well as column chromatography, and HPLC. Products are analyzed using gas chromatography and IR-Spectroscopy. DNA-extractions are performed on each species and indexed via barcoding.

Abstract Name: In the Middle of Migrant Medicine: Perceptions of Appalachian Folk Healing

This qualitative study explores folk healing practices among Appalachian migrants, focusing on how intergenerational knowledge and regional stigma influence folk healing practices and beliefs. Central to this project rest questions like: how do Appalachian migrants perceive, practice, and perpetuate folk healing? How is this influenced by stereotypes often associated with Appalachian identity? These questions are addressed by delving into the role of Appalachian identity in folk healing practices, paying particular attention to how participants identify with and carry forward these traditions in new environments while balancing potential complexities related to self-identification with an ethnic group. Existing literature posits Appalachian migrants as possessing unique ethnic and cultural identities, understanding the Appalachian Diaspora related to migrant relationships and Appalachian identity (Trent 2006). Specific care has been taken to understand how stereotypes impact self-identification with Appalachian ethnicity (Krok-Schoen et. al 2015). Findings suggest that migrants of later generations tend to identify less with the Appalachian ethnic group, suggesting a turning away from Appalachian identity (Ludke et. al 2012). This project proposes that stereotypes that impact self-identification with Appalachian ethnicity have a potential impact on migrants' self-identification with cultural practices such as folk healing. However, literature examining this intersection is scarce. To address this lapse, this study emphasizes the emic understanding of folk healing amongst Appalachian migrants while critically examining and engaging with existing etic reports. Through personal narratives, approximately 12 participants reflect on remedies they utilized to treat illnesses and injuries, examining the continuity and adaptation of practices across generations. Emphasizing practical and spiritual dimensions, the study considers how regional ethnic identity influences participants' engagement with and perception of healing practices, contributing to a broader understanding of Appalachian folk medicine and identity in contemporary contexts related to migrants.

Abstract Name: Increasing the Accuracy of Tree-Ring Data Processing to Improve Models for Reconstructing Climate

Tree-ring data is used to reconstruct past climate and to predict future climate trends. In each year of a tree's lifespan, a distinct ring is added to the tree's width, and the widths of individual rings vary depending on the climate that year. To process tree-ring data, two cores from each tree are typically extracted, and then all cores are combined before analysis. We aim to improve the modeling of future climate scenarios using tree rings by assessing the accuracy of tree-ring data collection. Our investigation of data from the International Tree-Ring Data Bank found that cores sampled from the same tree do not necessarily have the same ring widths, and trees with low correlation may have a worse correlation with local climate data. These findings imply that only trees with moderate or better internal correlation should be used for climate modeling. To more directly target differences among tree-ring data processing methods, we collected 47 tree cores from Virginia pines (*Pinus virginiana*) in Elon University Forest. With this data, we combined and correlated the widths of the rings on each core with local climate data. We compared the existing standard method of combining cores for processing with a new method. The standard method treats each core in the stand independently despite each belonging to a pair or triplet of a single tree. We proposed a new method that processes measurements on the tree level instead of a core level. We compared each method to recommend the approach that produces better fits with local climate data. The proposed method produces a higher correlation for annual average temperature ($r = 0.20$) and precipitation ($r = 0.12$) data than the standard method ($r = 0.13$, $r = -0.01$, respectively).

Abstract Name: Identifying Zoonotic Bacteria in Indoors and Outdoors Mouth of Dogs

This research highlights the critical role of oral care and nutrition in mitigating the risk of zoonotic bacteria transmission from dogs to humans. The study was conducted in two parts. First, a systematic review of existing literature examined bacteria commonly found in dogs' mouths, their potential health effects, and best practices for oral care. The second part utilized microbiological techniques, such as streaking for isolation and Gram staining, to identify and differentiate bacterial species. *Pasteurella multocida*, *Mycobacterium* spp., and *Salmonella* spp. are the most common bacteria found in dogs' mouths. These bacteria can cause symptoms in dogs such as tremors, swollen gums, and painful urination. Additional pathogens, such as *Serratia marcescens* (a red-pigmented Gram-negative bacterium) and *Pseudomonas aeruginosa* (a highly resistant aerobic bacterium), were also identified as zoonotic risks capable of causing infections in both humans and animals. For the mixed unknown culture, the bacteria isolated were identified as *Serratia marcescens* and *Pseudomonas aeruginosa*. Preventive measures to reduce zoonotic bacteria in dogs include maintaining good oral hygiene, feeding properly cooked meat, practicing food safety, ensuring proper nutrition, and scheduling regular dental checkups. These measures aim to improve overall dog health and minimize zoonotic risks.

Abstract Name: "A Home Designed to Enhance the Daily Living Experience" – Housing Design for Individuals with Diabetic Retinopathy

Many commercial and residential spaces are not designed with inclusivity in mind for individuals with visual impairments. This lack of extensive design can limit the functionality of these spaces, and can cause discomfort and prevent individuals from completing daily tasks. Research conducted through a knowledgeable speaker in home design for the visually impaired, and a case study of a space designed for those who are legally blind showed that incorporating specific design elements can enhance the quality of life for people with visual impairments. These elements include features such as materials that create sound, high-contrast materials, wayfinding solutions, and textured surfaces. While these designs are beneficial to everyone, they are especially transformative for individuals with visual impairments. The purpose of this project is to analyze the effects of diabetic retinopathy and to propose a residential design to cater to the needs of individuals living with this condition. Diabetic retinopathy is a complication of diabetes caused by high blood sugar levels, which damage the back of the eye. Advanced symptoms of diabetic retinopathy can include increased eye floaters, distorted vision, poor night vision, and loss of vision. Specific design elements were implemented within the space to meet the needs of the client. These include high contrast in color to help distinguish objects and surfaces, textured fabrics for sensory engagement, wayfinding solutions using painted wall guides to help the user to navigate through the home, and lighting layers and proper illumination to accommodate for eye sensitivity and poor night vision. Additionally, the home design meets the International Residential Codes and ADA Standards to ensure accessibility, safety, and inclusivity. In conclusion, this design creates a functional and supportive living environment that meets the needs of individuals with diabetic retinopathy, ultimately improving their daily living experience within their home.

Abstract Name: Chapel Attendance Patterns

We studied the chapel attendance data at a private Christian university in the south central United States. Because the university considers chapel to be an essential community experience, students are required to attend a minimum of 25 chapels per semester. We discovered that students attend chapel differently depending on their personal characteristics. For instance, we discovered that there are more male students that attend chapel than female students. We also discovered that student athletes are more likely to attend daytime chapel services than evening chapel services when compared to non-student athletes.

Abstract Name: Message in a Bottle: Train Graffiti in the US and Spain in the 1970s

Throughout history, graffiti has been an integral part of urban, social, and political culture. In the 1970s United States, graffiti was produced inordinately by youth in retaliation to the marginalization of people of colour in specifically New York high poverty, urban ghettos. Similarly, graffiti in Spain developed into a highly political and social means of protest primarily in the years following the fall of Spanish military dictator, Francisco Franco Bahamonde, in 1973. In both societies, graffiti on trains was a significant part of the graffiti culture. I argue that graffiti on trains can be understood like the message in a bottle, as a system of taking thoughts, expressions, and protests beyond their original geographical and cultural confines. This paper examines how graffiti on American and Spanish trains works as public communication aimed at large and diverse audiences in the 1970s. In both societies, I demonstrate, this traveling “message in a bottle” helps marginalized groups assert their presence and challenge systemic inequalities. Keywords: Graffiti, Train, United States, Spain, Political Protest

Abstract Name: Dynamometer Testing as a Predictor for MS-Related Disability Burden in MS Patients

Multiple Sclerosis (MS) is a chronic neurodegenerative disorder of the central nervous system characterized by inflammatory demyelination and progressive neurological disability. Current clinical assessments of MS-related disability are often impractical due to their complexity and time-intensive requirement. Grip strength, as measured using a dynamometer, is a quick, simple, and sensitive measure of muscle weakness, a common symptom in MS. However, few studies have examined its clinical utility. This single-center cross-sectional study examines the extent to which grip strength correlates with standard objective and patient-reported measures of MS disability, and tests whether greater discrepancies between dominant and non-dominant hand grip strength are associated with greater MS disability burden. 516 MS patients completed grip strength testing of dominant and non-dominant hands and standard MS disability measures, including objective measures [eg, Expanded Disability Status Scale (EDSS), Age-Related MS Severity (ARMSS), Timed 25-Foot Walk (T25W), 9-Hole Peg Test (9-HPT), Symbol Digit Modality Test (SDMT)] and patient-reported outcomes [eg, Patient-Determined Disease Steps (PDDS), Multiple Sclerosis-Related Scale-Revised (MSRS-R)]. Multivariate regression models assessed grip strength and inter-hand discrepancies in relation to standard MS disability measures, adjusting for demographic and clinical confounders such as age, gender, race/ethnicity, MS subtype, disease duration and disease-modifying therapy. Dominant and non-dominant grip strength significantly correlated with 9-HPT, T25W, EDSS, and MSRS-R, while differences between dominant and non-dominant grip strength significantly correlated with PDDS, EDSS, and MSRS-R. Notably, reduced dominant grip strength (estimate = -0.021, $p < 0.05$, 95% CI = [-0.040, -0.003]) and greater inter-hand discrepancies (estimate = 0.0458, $p < 0.001$, 95% CI = [0.021, 0.072]) significantly correlated with patient-reported MS disability severity (as measured by PDDS). These findings highlight grip strength testing as a practical measure of MS disability progression, with potential for broader clinical application. Further validation is warranted to confirm its clinical utility.

Abstract Name: A general mechanism for sizer size control in yeast

Size is a key physiological variable for cell growth. Subjected to noise, cells must employ active size control. However, the mechanistic origins of size control remain elusive. One possibility is that cells have molecular thresholds for key molecules that must be reached for division to commence. Eukaryotic cells (e.g., fission yeast) are believed to follow a concentration-based molecular threshold for size control. Additionally, it has been found that yeast cells follow a “sizer” control mechanism, targeting a specific size before division. The mechanistic origins of sizer control in yeast remain unclear. Here, we introduce a generic model that relies on multiple concentration checkpoints for different cell proteins. Our results show that if at least one checkpoint relies on a molecule whose concentration is proportional to volume, then sizer control dominates over cell size control. We show that this model is consistent with experimental data, and suggests that size control is separate from division control in yeast.

Abstract Name: Bridging the Gap: Challenges in Housing Accessibility for Black Residents in Hampton Roads After COVID-19

The COVID-19 pandemic profoundly disrupted global social and economic stability, creating challenges for securing basic necessities, particularly housing. This research focuses on the pandemic’s impact on housing accessibility for Black residents in Hampton Roads, Virginia. Historically, Black individuals have faced systemic barriers to homeownership due to discriminatory policies and practices. This study investigates whether the pandemic further exacerbated these challenges and explores potential solutions to address them. Using a mixed-methods approach, the research incorporates quantitative data analysis of local real estate trends, census information, and lending policies, alongside qualitative insights from interviews with real estate professionals, community activists, and affected residents. Findings reveal how stricter lending standards, surging home prices, and income-based disparities in loan approval rates have disproportionately affected Black homebuyers in Hampton Roads. These obstacles, compounded by the pandemic, highlight the systemic inequities Black residents continue to face in accessing housing. To address these issues, the study proposes solutions ranging from immediate actions to long-term strategies, including increasing housing supply, diversifying Virginia’s housing stock, implementing targeted financial assistance initiatives, and raising awareness through education. These solutions aim to foster a more equitable real estate landscape in Hampton Roads and beyond. This research serves as a call to action for policymakers, financial institutions, and community stakeholders. By addressing housing disparities worsened by the pandemic, it charts a path toward systemic change and a fairer future in housing accessibility for Black communities.

Abstract Name: Resolution of a Hox Gene-Mediated Size Control Mechanism in the planarian *Schmidtea mediterranea*

Animals grow to a body size that is characteristic to their specific species. However, the intrinsic mechanisms establishing final body size are poorly understood. The planaria *Schmidtea mediterranea* is a regenerative flatworm with the ability to asexually reproduce to generate unlimited clonal copies of themselves. Planaria, therefore, have the potential to grow that extends beyond the size of an individual body, but they still exist at a limited size. This model provides an opportunity to uncover mechanisms by which body size is established via the restriction of growth potential. We identified a Hox gene, *post2b*, that restricts body size in planaria. Our research question asks what the downstream genes of *post2b* are and how they regulate body size. RNA sequencing analysis was performed to identify the downstream mediators, followed by RNA interference (RNAi) screening to identify functional effectors. The number and size of the RNAi worms were quantified using FIJI software. We identified two categories of genes that altered body size: asexual reproduction-dependent genes and inhibitory body growth genes. Further literature research and sequence analysis was conducted to identify and determine the potential mechanisms of the genes. The genes varied in putative functions, including metabolism, hormonal signaling, cell proliferation, cell differentiation, and more. This study contributes to planarian research and can be applied to other areas of research as well. For instance, understanding these mechanisms that typically restrain the growth of tissues has the potential to be applied to research studying uncontrolled growth, such as cancer.

Abstract Name: An Investigation into Body-Weight Supported Treadmill Running on Ground Reaction Forces Utilizing A Single Subject Design

Body-weight support (BWS) treadmills offload part of the user's body weight, allowing them to exercise with less strain on the body. The Lever Movement System (LMS) is a type of BWS system that utilizes elastic bands to suspend the user from an aluminum frame attached to the treadmill. The biomechanical effects of the LMS have not been well studied, so this study aims to investigate how offloading changes a runner's vertical ground reaction forces (VGRF). Four collegiate distance runners participated in a cross-over randomized control trial that compared two 30-minute treadmill runs at 100% and 80% body weight with the LMS. VGRF was collected with the Loadsol, an instrumented insole worn within the shoe. VGRF data was compressed into 100-point time series curves for each footstep at each time interval. Statistical parametric mapping (SPM) was used to compare the time series force curve of two running conditions. SPM calculates a 't' statistic for each time point of the time series curve and allows for statistical analysis between conditions within a single subject, alpha .05. VGRF was significantly reduced for most of the stance phase during the bodyweight support conditions for all four subjects. VGRF was most different between 40-60% of the stance

phase. The 0-15% of the stance phase was the least different between the two conditions, with 2/4 subjects demonstrating a non-significant difference during this portion of stance phase. All participants saw reduced VGRF when running on a treadmill equipped with the LMS. The greatest reduction was during the mid-stance portion of the running gait cycle when VGRF is greatest. The smallest reduction was during the load acceptance portion of the stance phase. This is meaningful because tissues that are loaded during different times within the stance phase may experience differences in load reduction when using the LMS.

Abstract Name: Creation of the Greenback as U.S. Money by President Abraham Lincoln

Janis Richards, richards.j896865@stu.sanjac.edu, U.S./Texas – San Jacinto College, North Campus, Honors Program, Paralegal Studies Student Why was President Abraham Lincoln's creation of the Greenback Dollar important when he did it, and how would recreation of the Greenback experience impact the United States today? Since U.S. money is currently being created and circulated by the private sector, under the auspices of the Federal Reserve, this process is in violation of the Constitution. The Federal Reserve is not a government organization. It is a private cartel of 10 powerful private banks, each of which has the sole responsibility of earning a profit for its investors. The function of earning a profit interferes with the function of working on behalf of the public. Consequently, the U.S. is currently experiencing a pricing structure that harkens runaway inflation. There are no elected officials on the Federal Reserve who are responsible to the American public. The methodology of the Federal Reserve is opaque. It was originally created under questionable circumstances in 1913. Historical precedent described from scholarly research verifies the unconstitutionality of private creation of U.S. money. Research methodology will consist of proof from numerous case studies which confirms the thesis. The conclusions will show that U.S. money can only be created and circulated by the Congressional branch of the U.S. Government. These conclusions will be discussed in the context of historical experience with current evidence of the danger of this private system of money creation to the American public and the world, as was evidenced in 2008.

Abstract Name: Prescriptions of the Past: Archaeological Correlates of Illness in Early 20th century Atlanta

The medicines people choose can reveal not just the illnesses they face but cultural values about how to treat them. Archaeological materials can serve as a proxy for illnesses that were experienced by different communities in Jim Crow-era Atlanta. My research project explores how cultural perceptions of illness manifest in materials that were collected from archaeological excavations conducted when the Metropolitan Atlanta Railroad Transit Authority (MARTA) rail lines were installed in the late 1970s. To do so, I aim to analyze the economic value of discarded medical bottles, with a focus on the medical implications they present. I will specifically focus on materials from the site "9FU91" as my control group, a site which served

as the city's dumping ground from the late 1800's until the early 1920's. Paired with similar archaeological data from excavations conducted on the west side of Atlanta, my comparison seeks to investigate how the upper-middle class families in North / central areas of Atlanta and the lower-class families in Western parts of Atlanta defined and treated illness, as well as attempting to find and compare this data with health trends from the time. Countless individuals in Atlanta during this period had their lives intertwined with consumerism and pharmaceuticals. While the geographic location of the site is known, the populations by which these sites were utilized are unknown. I plan to demonstrate the value of depositional medicinal materials as indicators of socioeconomic factors, and to possibly show racial and class disparities in health care.

Abstract Name: Developing "Lucy and Star's New Neighborhood Adventure": Story Crafting and Readability

This project explores the creation of a children's book designed for second and third-grade readers by a PreK-4 teacher candidate, focusing on both the creative writing process and the integration of educational themes. The story follows a girl and her dog who become lost in their new neighborhood, emphasizing themes of staying calm, problem-solving, and finding help when needed. These themes align with key social-emotional learning competencies in the Collaborative for Academic, Social, and Emotional Learning Framework. The process began with research into effective children's literature, including appropriate word count, sentence complexity, and the structure of picture books. Brainstorming and a plot diagram helped shape the initial draft. Multiple revisions followed, with particular attention paid to simplifying language, improving readability, and aligning the story with the developmental needs of the target audience. Readability tools were used to refine the text, ensuring it met the desired grade level. Feedback was also incorporated to strengthen the narrative and make it more engaging for young readers. This project demonstrates the interplay between creativity, research, and revision when developing a story that is both entertaining and educational. The result is a thoughtfully crafted children's book that supports young readers' literacy and social-emotional growth.

Abstract Name: Exploring the Impact of Seasonal Variation on Microbial Community Composition and Diversity in Rainwater Harvesting Systems Across Central Virginia

Increasing global water scarcity has sparked interest in more sustainable water sources such as rainwater harvesting (RWH). Because these systems utilize roof-runoff for collection, they can easily be contaminated with environmental bacteria from animal feces and leaf litter on the roof surface, potentially degrading water quality. Thus, questions remain about the safety of harvested rainwater for human use due to our current limited understanding of the microbial communities contained within it. To our knowledge, there is little to no published research on the microbiome of rainwater harvesting systems (RWHS) within the continental

U.S. This study aims to characterize the bacterial diversity and community composition of RWHS across Central Virginia. Water samples were collected from 10 systems in four cities, spanning rural farmland, small towns, and urban areas. Rainwater samples were filtered through 0.22 μm membranes to capture resident bacteria which were then analyzed using Nanopore sequencing of the 16S rRNA gene to determine the microbial composition. A total of 50 samples have been analyzed, including one from each system in summer 2023 ($n = 10$) and in winter 2023 ($n = 10$), and three from each system in summer 2024 ($n = 30$). All samples contain highly diverse bacterial communities. Preliminary results indicate differential composition of microbes between summer and winter of 2023 and summer of 2024. Shifts in the relative abundance of genera at the same site were observed with increased community evenness in the winter. Current work is focused on completing a two-year cycle of seasonal sampling by sequencing samples from the winter of 2024 ($n = 30$) to determine if there is annual variation in the composition of microbial communities in RWHS.

Abstract Name: On Productiveness and Complexity in Real Function Analysis through Hilbert's 10th Problem

In David Hilbert's 1900 address, he introduced 23 problems, with the 10th problem questioning whether an algorithm exists to determine if a Diophantine equation has integer solutions—a challenge we now refer to as Hilbert's 10th Problem (HTP). A Diophantine equation is a polynomial with integer coefficients that can involve any number of unknowns. Extensive research, primarily done by Matiyasevich, has shown that it is undecidable to determine whether an arbitrary Diophantine equation has an integer solution. He established that every recursively enumerable (RE) set has a Diophantine representation. Building on this foundation, Daniel Richardson proved the undecidability of the "equivalence to the identically 0 function" problem for a set of elementary functions using many-one reductions from HTP. In this work, we introduce the concept of productiveness, a stronger form of non-recursive enumerability. A productive set, S , is not recursively enumerable; moreover, for any effective axiomatic system F , there is an effective procedure to construct an element in S that is not provable in F . We extend the undecidability results of HTP and the "equivalence to the identically 0 function" problem to the context of productiveness, demonstrating that both problems are not only undecidable but also unprovable. The productiveness of the "equivalence to the identically 0 function" problem over different domains is also investigated. Furthermore, our findings indicate that many predicates within the theory of real functions, such as those determining the continuity or differentiability of an arbitrary function, are as hard as the "equivalence to the identically 0 function" problem through highly efficient many-one reductions. Intuitively, these efficient reductions preserve almost any level of complexity, allowing us to prove undecidability and complexity results simultaneously.

Abstract Name: Drinking Water: Household Source and Awareness of Dunn County Water Quality

This study investigates the relationship between a household's water source and their awareness of local water quality in Dunn County, Wisconsin. Using surveys conducted with county residents, the research aimed to measure levels of awareness regarding water quality issues, particularly local nitrate problems. Quantitative analysis revealed no statistically significant relationship between water source and overall awareness. However, correlations were found between awareness and demographic factors such as age, gender, education, income, and housing status (renting vs. owning). Additionally, machine learning techniques were employed to predict awareness levels concerning local nitrate issues among renters and homeowners. Renters were found to be less aware of the nitrate issue while homeowners who watch the news are more aware of the nitrate issue. These findings provide valuable insights for local government officials and community leaders, highlighting the importance of targeted educational initiatives to enhance community awareness of water quality and its implications.

Abstract Name: From Trauma to Trails: A Nature-Based Processing Method for Greater Lafayette Youth

When prompted by Purdue University undergraduate researchers, the mayor of Lafayette, Indiana responded that the greatest problem in the Lafayette community is youth trauma. He has seen this reality manifest generationally, one bad life decision to the next, diminishing quality of life. With over 47,000 individuals under the age of 18 in the Greater Lafayette area, our community faces the critical issue of a large youth population with few constructive outlets for trauma processing. Partnering with the city of Lafayette, multiple participating high schools and grade schools, and a group of dedicated Purdue student engagement researchers, our team is working to address this local city-expressed problem. Research suggests that for youth populations, intentional engagement with nature and nature-based therapies can improve mental health. This intentional engagement has formed the basis for our approach to combatting this established problem. We have chosen the Wabash Heritage Trail, an expansive 18-mile nature trail, as our ideal and accessible medium for building intentional engagement with nature. Having newly launched the project, our process includes: 1) brainstorming ideas by drawing on our own experiences with nature, 2) conducting a review of published research and existing engagement tools, and 3) hiking the Wabash Heritage Trail, collecting our own data from notes, pictures, and experiences. Finally, by synthesizing these approaches, we are producing a nature guidebook. This guidebook is a tool to help youth directly engage with nature and informally help them process trauma. We will then distribute these guidebooks, teaching Heritage Trail facilitation methods to pre-established local high school service learning teams. In this manner, distributing our guidebook to even 40 students in one such leadership club at only one of many high schools has the potential to impact thousands of local youth and help them process their trauma in a nature-directed manner.

Abstract Name: Freeing Emotions Through Jazz: A Video-Based Analysis of Performance

My University's Honors College Jazz course, sparked my interest in jazz research and helped me develop a conceptual framework of jazz. Writing projective verse, aurally analyzing jazz genres, and writing/performing unique jazz-inspired pieces are the scaffolds of my framework. Focusing on these jazz-inspired pieces, my research demonstrates that musicians and non-musicians alike visibly express their emotions in a performance setting. Students in my Honors college must plan and complete a knowledge-generating research project. To fulfill this, I developed a method to qualitatively analyze the class' jazz performances and apply this work to the aforementioned Jazz class for community engagement. My project will help future jazz students think more critically about their own performances, provide a potential educational model for performance-based classes, and consider the implications of jazz for student authenticity and vulnerability. The question then: For a group made up of different levels of musicianship, does having weekly jazz performances allow for those same students to free themselves from emotions, both positive and negative, seen through visible expressions? To collect data I rewatched the recorded performances from Jazz class and observed five individuals', at different levels of musicianship, visible expressions. Visible expressions were split into three categories: facial expressions, body language, and audible expressions; each with their own subcategories. Results have shown that the students who had the least musical experience show more expressions as they perform more, indicating that they are more freely expressing their emotions through jazz. I have also constructed a thematic map using the software application Gephi to illustrate the connectedness of the various expressions.

Abstract Name: Predictive Modelling of Wildfire Dynamics: Analyzing the Park and Borel Fires through Satellite Imagery to Enhance Fire Management in California

California had two of the largest fires in state history in 2024: the Park Fire and Borel Fire. According to the California Air Resources Board, of the twenty largest fires in California history, eight have occurred since 2017. The purpose of this project is to use data from the NASA Earth Observatory satellite images to create function models for the perimeter and burn area estimates for these two fires. Can the average rates of change be used to predict future wildfires? The focus of this research project is unique because these two recent wildfires are significant to residents of California. Calculating Riemann Sums for satellite images, this project estimates the burn area of wildfires day-by-day, and it can be used to predict the burn area and the fire perimeter of future wildfires and to stop wildfires from spreading further. From the NASA satellite images, I gathered aerial images from regular occurrences from the two fires. The fire perimeter distances at various times during the fire growth are being calculated. Using regression, I have thus far found functions modeling the rate of change of the burn area and fire perimeter of the two wildfires. I am hoping that my research can be used to help deter climate change in California and to prevent future wildfires from spreading further, impacting California residents.

Abstract Name: The Likelihood of Collectivist Cultures Exhibiting Protective Factors Towards Male Perpetrators of Sexual Violence

After the rise of the #MeToo movement, support for survivors has entered mainstream media setting the tone that Sexual Violence (SV) will not be tolerated. Even so, the ways in which SV is handled in individualistic versus collectivist cultures vary greatly. This study investigates the likelihood that collectivist cultures will express protectiveness over male perpetrators of SV. Participants, including St. Edwards University students and the general public, completed a survey that measured protective factors towards male perpetrators in four hypothetical scenarios. This study used a mixed methods research methodology. Qualitative measurements were utilized to explore whether participants were exhibiting protectiveness over perpetrators. Then, quantitative measurements of demographics were collected in order to examine whether or not there was a correlation between collectivist cultures and exhibiting protectiveness over male perpetrators. The duration of this study was eight-weeks, and we collected data from a total of 86 participants. The results indicate that there was no significant difference when measuring for race/ethnicity. However, a significant difference was found when measuring gender, with non-binary/third-gender individuals being more likely to show protective tendencies towards male perpetrators of sexual violence compared to both male and female individuals. Together, this study is contributing to our understanding of the ways in which social norms as well as the oppression of marginalized groups contribute to the prioritization of protecting group image over protecting the survivors of sexual violence.

Abstract Name: Comparative Analysis between a French and African Female Statue: Different Aesthetics but Similar Social Significance

This study examines the statues of women of the French and Bamana people and their social meaning within their respective cultures. The French statue, Standing Woman, is from the 16th century and the Statue of a female Ancestor is from the 19th century. This comparative examination focuses on the aesthetic and the cultural meaning of the artworks Standing Woman and Statue of a Female Ancestor to decipher their similarities and differences. The comparative assessment of both artworks demonstrates both societies created images of women with different aesthetics, but both shared cultural idealization and sexualization of women with the pure purpose of sexual arousal and childbearing. I will use a formal examination of the artworks and academic gender studies and social context studies to support my argument. This study is important considering limited comparative art historical research, in favor of emphasis on cultural differences based on aesthetic values, or national and geographical art historical studies.

Abstract Name: The Integration of Colombians, Argentinians, and Ecuadorians in Madrid and Barcelona: Discrimination, Trust in Institutions, and Sense of Belonging

Spain is often characterized as a "new" immigration destination. Between 1998 and 2022, the country's population increased from 40 million to 47.5 million, driven mainly by international immigration. By 2022, Latin American immigrants constituted 43 percent of Spain's foreign-born population. In light of this recent surge in immigration, there has been growing debate among citizens, policymakers, and scholars regarding the extent to which Latin American immigrants successfully integrate into Spanish society. A common misconception is that these immigrants integrate easily due to their shared language, cultural similarities, and historical ties with Spain. Therefore, this study examines the integration of first-generation Colombian, Argentinian, and Ecuadorian immigrants in Madrid and Barcelona from 1998 to 2024. More specifically, if these nationality groups perceive discrimination, trust in public institutions, and feel a sense of belonging in their respective cities. Focusing on the same nationality group across different contexts in different cities, this case study explores how integration experiences may vary between nationality groups and across autonomous communities in Spain. This paper analyzes fourteen semi-structured interviews conducted in June and July of 2024; I found that Latino-on-Latino discrimination, citizenship status, use of social networks, and time in Spain became prominent themes that impacted the integration of these nationality groups. Additionally, I identified the role of Catalan language acquisition as a crucial dimension of the integration process in Catalonia. This study has broad implications for future integration policy in Spain across autonomous communities, as well as implications for the European Union in creating an updated standard integration framework for EU countries to follow.

Abstract Name: Party Minority Impact on In-Party Financial Contribution

In the United States Congress, are parties in the minority more likely to be cohesive? With member-to-member financial contributions, I examine party cohesion networks in the United States Congress. This question is important as it examines what parties in the minority will do in order to get out of the minority. Parties have an easier time getting things done when they have a majority. Therefore, parties are motivated to get out of the minority. Data that I examine is financial contributions between members in multiple Congresses including the 103rd, 109th, 111th, and the 115th. Running a modularity test in Gephi on the data from each Congress, I find clustering of Congress members in order to determine if there is financial cohesion in minority parties. After I have applied the results from the modularity tests that I run on each Congress, I am able to find that there is a link between parties being in the congressional minority and intra-party financial contribution cohesion.

Abstract Name: Interaction of Metal Oxide Nanoparticles with Nitrifying Bacteria in Soil

Zinc oxide (ZnO) nanoparticles (NPs) are widely used in consumer products such as agrochemicals, paints, and antimicrobial agents. While beneficial in various applications, ZnO NPs pose risks to soil ecosystems due to their antimicrobial activity, particularly impacting the nitrogen (N) cycle by inhibiting nitrifying bacteria. These bacteria play a vital role in converting ammonia to nitrate, a process essential for soil fertility and plant growth. Disruption of this cycle by ZnO NPs can reduce microbial diversity, enzyme activity, and overall soil health, ultimately affecting agricultural productivity. This study investigates the impact of ZnO NPs on soil nitrifying bacteria through physiological, transcriptional, and metabolic analyses. Soil microcosms were prepared with ZnO NP concentrations of 10, 100, and 500 mg/kg, alongside controls. Samples were collected over 20 to 100 days, and enzyme activities of ammonia monooxygenase (AMO), nitrite oxidoreductase (NXR), nitrite reductase (NIR), and nitrate reductase (NAR) were measured. To assess AMO activity, soil samples were incubated with phosphate-buffered saline containing ammonium sulfate and potassium chlorate, followed by potassium chloride extraction. The methodology ensured precise conditions to evaluate enzymatic responses to ZnO NP exposure. Preliminary findings suggest that higher ZnO NP concentrations significantly inhibit enzyme activities, supporting the hypothesis that ZnO NPs adversely affect nitrifying bacteria and nitrogen cycling. The nitrogen cycle is crucial for ecosystem stability, plant photosynthesis, and agricultural sustainability. Disruption by ZnO NPs threatens food security and ecological health. This research underscores the need for alternative, less toxic materials or mitigation strategies to reduce environmental impacts. By understanding ZnO NP interactions with soil microorganisms, this study aims to inform the development of sustainable nanoparticles that preserve soil health and agricultural productivity amidst increasing nanoparticle usage.

Abstract Name: Association Between Psychosocial Factors and Pain Perception in Elderly Individuals in the U.S.–Mexico Border Region.

Evidence shows that the elderly population are more likely to experience chronic pain than younger individuals. Chronic pain perception in elderly individuals is influenced by a dynamic interaction of psychosocial and physiological factors, especially in the U.S.-Mexico border region. However, evidence is

still not clear on the influence of psychosocial factors on pain perception. The purpose of this study is to explore how psychosocial factors such as resilience, acculturation and pain catastrophizing influence pain perception in elderly populations. The preliminary analysis included 38 participants (60.5% females), 22 Hispanic, (Mean age=67.21 years, SD=5.92). After signing informed consent, validated questionnaires such as the Brief Resiliency Scale (BRS), Short Acculturation Scale for Hispanics (SASH), and Pain Catastrophizing Scale (PCS) were provided. Participants underwent quantitative sensory testing, including thermal pain threshold and tolerance, Temporal Summation (TS), and Conditioned Pain Modulation (CPM). Correlational analyses were performed to assess associations between psychosocial factors and pain perception. Analyses revealed a negative correlation between resilience and conditioned pain modulation ($r = -.370$, $p = .024$), as well as a negative correlation between acculturation and conditioned pain modulation ($r = -.536$, $p = .001$). Additionally, findings revealed a significant negative correlation between pain catastrophizing and pain tolerance ($r = -.357$, $p = .033$). Findings highlight the importance of psychosocial factors in shaping pain perception among elderly individuals in the U.S-Mexico border region. Lower resilience and higher pain catastrophizing were associated with diminished inhibitory capacity and tolerance respectively. The study highlights the importance of accounting for psychosocial factors, in pain management particularly in aging populations. Future studies should explore this with a larger sample size to assess the true role of resilience, acculturation, and pain catastrophizing in pain perception.

Abstract Name: Tap, Music, and Dance History: Shifting Tap Pedagogy by honoring Oral Traditions

This research study aims to preserve and honor the foundational elements of tap dance through archival investigation and the study of oral pedagogical traditions. Tap dance by nature is interdisciplinary, both music and dance, and is a blend of African rhythmic footwork and European dance influences. It reflects a vital form of African American cultural expression, rooted in jazz performance. Reflecting oral traditions, tap has been passed down through generations, belly to belly through experience. However, modern tap dance education often emphasizes memorization, disconnecting students from tap's musical and historical context. Without efforts to preserve the historical knowledge and pedagogical methods, tap dance faces the risk of losing its cultural significance. Professor Cornell studied under influential tap practitioners such as Eddie Brown, Steve Condos, Cookie Cook, Harriet Browne, and Buster Brown, and is among the last generation of tap dancers to have worked directly with these pioneers. Her extensive archives, including rare footage of these tap masters—largely unavailable to the public—were invaluable to this study. Through archival digitization, interviews, and direct analysis of their pedagogical methods, this research preserves the techniques of these tap pioneers and ensures the continuation of their oral teaching traditions. This study highlights the importance of oral transmission in tap dance—a living art form at risk of losing its authentic voice and human connection. The resulting pedagogical framework serves as both a tribute to the art form and a call to action for preserving the legacy of oral teaching methods in tap dance education. Although this project will be ongoing for a significant period of time, the goal is to initiate a fluid transmission of content throughout its life. I've chosen to create a mini documentary for my contribution to this research.

Abstract Name: One Piece: Commentary on Society and politics, and the human condition

The story of One Piece, Created by Eiichero Oda, is a story that is acclaimed by many as one of the greatest manga works of all time. This statement is said because of its characters, Worldbuilding, and story. One question that comes to mind is, Why? One piece talks about ideas about political corruption, generation trauma, and the idea of human dreams. These ideas all blend into the ideas of the human condition. Oda weaves these ideas throughout the story to tell a grand narrative about piracy and freedom and how Oda uses human history and mythology to tell his story through a fantasy lens. How does the story illustrate these ideas through its characters and story? With not only its setting but with how the fictional world operates. From the main characters to the many story arcs our characters find themselves in. We will talk about some characters' backstories and how they illustrate this idea, and we will go into how Oda builds the world of one piece—talking about the story overall, from the most recent chapters to the story's start! This abstract presentation will discuss these things, using the evidence throughout the story to illustrate them and show why one piece is a transcendent work of art. And how Eiichero Oda uses all these ideas to talk about political corruption through systemic oppression, racism, and segregation with generation trauma to show how dreams are formed. How Oda creates a high fantasy setting and uses it to talk about the politics of history and both worlds at large.

Abstract Name: Forgotten Soviet Nationalism: Viktor Djorbenadze's Wedding Palace

Soviet architecture is often viewed in the west as entirely monolithic in style. This is not always true. In the later years of the Soviet Union, national identities and cultural revival of member states were fostered and encouraged through both public sentiment and under Brezhnev's policy of "Developed Socialism". Many architectural projects utilized national iconography to work towards this goal. Viktor Djorbenadze's Wedding Palace (1984) in Tbilisi is an underappreciated embodiment of this cultural period. The ways in which the Wedding Palace stands out will be explored through comparative formal analysis of similar cultural projects of the time, Djorbenadze's own architectural and social influences, as well as an examination of its unique historical and political context. By contradicting typical Soviet architectural styles through its use of Georgian cultural symbols, but maintaining a distinctive aesthetic through modernist forms, Djorbenadze's Wedding Palace is able to defy categorization as singularly "Soviet" or "Georgian". Built as a symbol of growing cultural pride, but imbued with certain Soviet functionality, the Wedding Palace is representative of its particular circumstances in history, including the particular support from Georgia's head of state, Eduard Shevardnadze. While Viktor Djorbenadze managed to gain approval for his eccentric projects during this time, his works were largely forgotten and shunned after Georgian independence in 1991. Djorbenadze's Wedding Palace is individual in its integration of Soviet functions, religious and cultural symbols, and modernist forms. Djorbenadze's Wedding Palace serves as a prime example of innovative and timeless design of Soviet projects that defy western expectations.

Abstract Name: Antifungal Mechanisms of Action by Dendritic Cell Lysosome Proteins

Cryptococcus neoformans is an opportunistic fungal pathogen that primarily affects immunocompromised individuals and can cause cryptococcal meningitis. Approximately 152,000 cases of cryptococcal meningitis occur annually in HIV/AIDS patients, leading to 112,000 yearly deaths. Very few antifungal drugs are available to treat cryptococcal infection, and those are ineffective or toxic. In addition, fungal pathogens such as *C. neoformans* have become resistant to many types of treatment. Previous studies in our lab showed that proteins from the dendritic cell (DC) lysosome have antifungal activity against *C. neoformans*, including NOSTRIN, human neutrophil elastase (HNE), matrix metalloproteinase 25 (MMP25), myeloperoxidase (MPO), and coronin. In this study, we tested the antifungal activity of the compound NOSTRIN against the *C. neoformans* strain H99 using different concentrations of the drug. First we calculated the minimum inhibitory concentration (MIC). Then, fluorescence microscopy was used to examine structural changes in *C. neoformans* post-treatment, and mutant libraries were utilized to find genes that exhibited resistance or susceptibility to NOSTRIN. Results showed that NOSTRIN had a similar MIC to the antifungal drug Amphotericin B, with NOSTRIN around 0.25 ug/ml and Amphotericin B around 2 ug/ml. Fluorescence microscopy showed that fungal cells treated with NOSTRIN are releasing intracellular contents following incubation, indicating damage to the fungal cell wall or membrane. Mutant library analysis showed that the deletion of genes such as INM101 increased the percent of surviving mutant cells, while the deletion of NDX6 decreases the percent of surviving mutants. In future studies, we will continue to examine NOSTRIN and other antifungal DC lysosome proteins utilizing microscopy and cryptococcal mutant libraries in order to identify their mechanism(s) of antifungal activity. By researching the presented topics, we hope to gain a better understanding of the effects that these proteins have on *C. neoformans*, which could potentially lead to more effective therapies for cryptococcosis.

Abstract Name: Determination of Ehrlichia and Anaplasma (multiple species) prevalence in Amblyomma americanum ticks collected in central Pennsylvania

Amblyomma americanum, also known as the Lone Star tick, has historically been found in the southeast and midwestern United States; however, according to the U.S. Centers for Disease Control, current species distribution extends up the eastern coast into Maine. It is suspected that the movement of Lone Star ticks into northern climates is due to recent, milder winter conditions that allow for over-wintering; additionally, the expansion of white-tail deer populations is also hypothesized to be a contributing factor. Due to its aggressive host-seeking behavior and its role as a vector of a variety of biological agents, including the causative agents

of ehrlichiosis and anaplasmosis, the Lone Star tick has become epidemiologically significant. Our research analyzed *A. americanum* ticks (individual adult ticks, pooled larvae, and nymphs) collected at Letterkenny Army Depot and Fort Indiantown Gap from 2019-2024 for the presence of *Ehrlichia* and *Anaplasma* species, including *E. ewingii*, *E. chaffeensis*, *E. canis*, *E. ruminantium*, and *E. muris euclairensis*, as well as *A. ovis*, *A. Marginale*, *A. centrale*, *A. platys*, *A. bovis*, and *A. phagocytophilum*. These species act as serious nuisance pathogens to both humans and animals (domestic and peridomestic), enhancing the need for additional knowledge regarding the threat they pose to Pennsylvania and its inhabitants.

Abstract Name: Dosage-dependent effects of mbk-1 Down syndrome orthologous gene in *Caenorhabditis elegans*

Down syndrome (DS), also known as Trisomy 21, is a genetic condition characterized by the presence of three copies of human chromosome 21 (Hsa21). Abnormal expression of a gene of interest, dual specificity tyrosine-phosphorylation-regulated kinase-1A (DYRK1A), contributes to phenotypes such as delayed development of motor and cognitive skills. Identification of functional contributions of DYRK1A to behavioral phenotypes can be facilitated in genetically modified organisms in which the gene of interest is functionally deleted (full knockout), but mammalian models are not capable of modeling a full knockout of DYRK1A from conception as it is embryonic lethal. *C. elegans* possess an orthologous gene to DYRK1A, minibrain kinase 1 (mbk-1). Knockout (EK228) and overexpression models in *C. elegans* may be helpful in understanding effects of DYRK1A dosage in development. We hypothesize that mbk-1 knockout and overexpression models of *C. elegans* will display altered mobility and impaired learning when compared to the wild-type N2 strain. Motility is assessed by measuring the distance traveled over a 24-hour period. Testing revealed motility deficits in knockout strains. Future testing of mobility (body bends assay) will further analyze possible movement deficits of overexpressing strains compared to knockout strain. Learning in *C. elegans* is assessed using classical conditioning of associations between neutral chemosensory cues (conditioned stimuli, CS) NaCH₃COOH and NH₄Cl with the manipulated presence or absence of a food source (*E. coli*) (unconditioned stimuli, US). Ongoing studies of classical conditioning have resulted in inconclusive preference for the conditioned stimulus requiring future adjustments. These studies will allow for the analysis of potential roles of mbk-1 in learning and neurodevelopment in *C. elegans* and will provide a model to help identify the role of DYRK1A in the behavioral patterns and neurological function in DS.

Abstract Name: Study of a Private Lithics Collection from Southeast Missouri

This project involves the cleaning, labeling, cataloging, photographing, and identification of Native American lithics. The collection includes arrowheads, spearpoints, knives, an atlatl weight, and a hand axe. These artifacts, which were found in Bollinger County Missouri, are part of a private family collection. The collection includes hundreds of specimens. This project focuses on the best-preserved artifacts in the collection, about 150 pieces. As this is a private collection, the artifacts have been removed from their original context, meaning that they do not have provenance. The lack of information based upon where the artifacts were found makes them difficult to study. Despite the abundance of private collections like this, there have been few studies of their contents. However, to gain as much information as possible from these private collections they must be studied. As there has been little archaeological work in the area, due to it primarily consisting of private farmland, this study provides meaningful information pertaining to native populations of the area which would otherwise be unknown. The collection was originally displayed in picture frames. Because of this, the artifacts had to be removed from these frames and glue residue removed in order to be properly persevered. Then, each artifact was assigned a catalog number based on which family member originally owned the artifact. This was done to work with the needs of the owners while still being an effective study. Each lithic was then photographed before each identifiable artifact could be dated. By completing this study, I hope to not only share my work but also share this family collection. As an archaeology student, I have learned the importance of sharing history. It is crucial that this vast collection of lithics, as well as other private collections, are not only studied but made available to others for further research.

Abstract Name: The Relationship between Telomere Length, Age, Disease, and Performance in Livestock Animals

The purpose of this study is to identify any gaps within previous literature discussing the correlation between telomere length (TL), age, disease, and performance in various livestock species such as cattle, horses, sheep, goats, pigs, and chickens. In this extended literature review, a two-stage screening process was implemented

to ensure systematic and efficient selection of relevant articles. Within the first stage, the titles and abstracts of all identified articles were reviewed using predetermined inclusion and exclusion criteria. Each article that passed the initial screening went on to an in-depth review which focused primarily on the methods and results sections to ensure relevance and quality. A total of 245 articles were screened with only 31 being included in this review. The general trend across species correlated TL with age, determining that as age increased, TL decreased. Within all other measurements, there were mixed results regarding any correlation whether positive or negative. Across all livestock species, it is evident that more research is needed to determine TL's effects on disease susceptibility and immunity. With continued research focused on those health factors and performance traits, this could lead to improved breeding strategies and enhanced animal health.

Abstract Name: Examining Implications of Diagnostic and Therapeutic Ambiguity in Medical Scenarios

It is common to see ambiguity in the medical fields specifically surrounding how severe the course of a disease might be or how effective a particular treatment is (Han et al., 2011; 2019). Generally, patients are hesitant to make decisions when given ambiguous information, and ambiguity aversion is a well-documented phenomenon in the medical domain (Han, 2016). However, few researchers have directly compared whether patients react differently to different types of ambiguity. In the present research, we compared diagnostic ambiguity (operationalized as uncertainty surrounding the severity of the disease) to therapeutic ambiguity (operationalized as uncertainty surrounding how well a vaccine works). 351 participants were presented with one of 3 hypothetical medical scenarios – one with only diagnostic ambiguity, one with only therapeutic ambiguity, or a control condition with no ambiguity. Despite theoretical reasons to expect different reactions, there was no significant difference in willingness to receive the vaccine between conditions, suggesting that patients do not distinguish between different types of ambiguity. Implications of these findings and avenues for future research are discussed.

Abstract Name: Teaching Art Criticism in K-12 Art Classrooms

This lesson introduces an innovative approach to teaching art criticism through interactive methods like Think, Pair, Share and See, Think, Wonder, using Gabrielle M nter's painting Snow and Sun as the focal point. The lesson is built around the key principles of "Investigation, Exploration, and Imagination," which serve as a framework for guiding students through the stages of art analysis and critique. These principles

encourage students to observe, reflect, and share their insights with peers, fostering an environment of inquiry and creativity. By employing these interactive teaching methods, the lesson promotes active participation in both group discussions and individual artistic expression. The aim is to enhance students' understanding of art not only by encouraging them to explore different perspectives but also by helping them articulate their viewpoints. This approach also strengthens their critical thinking skills, as students are prompted to engage deeply with the artwork rather than passively observing it. Research data for this lesson was gathered through the observation of student interactions at various stages of the lesson. Special attention was given to how critical thinking was integrated into each phase of the process, from initial investigation to final discussion. The findings indicate that this structured and interactive approach significantly improves students' ability to engage with and analyze artwork meaningfully. By encouraging them to explore, imagine, and critically assess the art, the lesson helps develop their analytical abilities and enhances their capacity for creative self-expression. Through planned exercises, this Art Criticism Game seeks to support students' growth in visual literacy, improve their capacity to express their reactions to art, and boost their self-assurance in their analytical abilities.

Abstract Name: Survey for Insect Pests of Cut Flowers in Utah

Cut flower production is a relatively new industry in the state of Utah and little research concerning management of the plants has been conducted. One issue producers face are insects that harm the plants in ways such as feeding damage and transmission of diseases. Currently it is unknown which insects target different species of cut flowers in Utah. Morphological identification of genera and species is often difficult or impossible because of the small size of many of the insects and minute differences between species. This project uses PCR and DNA sequencing to identify the genus and species of insects that were captured while residing on cut flowers in Utah. The resulting sequences were compared to other known sequences using the NCBI BLAST search. To date 21 species have been identified on 14 species of cut flowers grown on 12 cut flower farms across Utah. This information allows producers to proactively take measures against specific species of insects.

Abstract Name: Daphnia in the Water Column: Migration Strategies, Coping with Predators, and Hypoxic Dead Zones

Water columns of lakes and oceans are heterogeneous environments in which factors like temperature, dissolved oxygen (DO), food availability, and predation risk often vary with depth. Organisms will select for particular depths and times that maximize their ability to survive and reproduce. Animals possessing traits

that improve survival under hypoxic conditions commonly found in deep water would likely have a competitive advantage, being favored by natural selection. Hemoglobin (Hb) production by *Daphnia*, a common freshwater zooplankton, is a trait that can increase survival in hypoxic environments. However, a trade-off exists: *Daphnia* with higher Hb concentrations are brightly colored, making them more vulnerable to visual predators. *Daphnia pulex* were collected at different depths from the water column of Mary Lake (northwestern Minnesota) during the daytime and at night. Individuals were assayed for Hb level and genotype at the Glucose 6-Phosphate-Isomerase (GPI) allozyme marker. We hypothesized that 1) *Daphnia* collected from low oxygen depths would have higher Hb content, 2) *Daphnia* with higher Hb levels wouldn't be found in daytime surface waters (due to vulnerability from visual predators), and 3) *Daphnia* of different GPI genotype would differ in their vertical migration behavior and/or Hb content. We found that average Hb content of *Daphnia* differed significantly among depths and between day and night. We also found positive correlations between Hb concentrations and *Daphnia* density at given depths. This indicates a possible connection between migration patterns and Hb levels. However, we also found lower than expected densities of *Daphnia* in nighttime surface waters, possibly due to predation risk from *Chaoborus* (phantom midges), non-visual predators that were abundant at those depths. Understanding factors that affect vertical migration patterns could enable ecologists to predict population response to increasing effects from climate change, which cause increased thermal stratification and worsening hypoxia ('dead zones') in deep water.

Abstract Name: Large Language Models for Hiring Automation: Evaluating GPT-4 for Robust, Consistent, and Accurate Resume Screening

This research investigates the potential of large language models (LLMs), specifically GPT-4, in hiring automation and resume selection. A comprehensive literature review and a bibliometric analysis were conducted to understand the current research landscape, key themes and topics, and influential researchers and institutions. The study also examines the robustness of LLMs against challenges such as keyword manipulation and content overload. We aim to address these research questions: How accurate, consistent, efficient, and precise are LLMs for automating the task of resume screening? Also, what are the advantages and limitations of LLMs in this domain? These questions will contribute to a more broad concept of their overall reliability. The research, currently in progress, follows a mixed-method approach and involves both quantitative evaluation of accuracy and time efficiency, as well as qualitative assessments of consistency and precision in repeated candidate selection. Preliminary observations indicate that while LLMs show promise in accuracy and efficiency, they may struggle with precision and consistency, particularly when faced with malicious or overly complex inputs. This work aims to reveal the advantages and limitations of LLMs in task automation, offering insights into their application in hiring workflows and emphasizing the importance of careful oversight to mitigate potential risks.

Abstract Name: FilterINg the Noise: A Digital Method in Composing with Filters and Recorded Sounds

Subtractive synthesis has been a primary method in musicians' use of analog synthesizers since their popularization in the 1950s-1960s. The process involves playing pitches made of basic waveforms with their sound softened through audio filters. I propose a new way of passing audio through filters to synthesize pitches from sound sources such as field recordings or white noise. Using digital tools, a bandpass filter is given a small bandwidth (approx. 4Hz to >1 Hz) and when applied over a harmonically rich sound source, the resulting sound is perceived with a sinusoidal tone. Then, virtual instruments can be programmed to synthesize tones using multiple filters. This application of filtered sound can be further extended with the manipulation of the source audio, such as changing field recording or noise generation techniques. This project explores the utilization of sound source and the filtered tones both independently and in combination with one another to create a multi-functional virtual instrument. Introducing granular synthesis concepts have also been investigated as a way to create a "brighter" and more dynamic tone. Building on principles of subtractive synthesis, this method allows the artist to control a musical instrument which produces sounds mirroring the inflections of the original audio.

Abstract Name: Use of Raman Spectroscopy as a Noninvasive Tool for Cancer Detection in Human Saliva

Cancer now tops heart disease as the number one cause of death in the United States, and it is the second leading cause of death globally. Cancer symptoms are often not specific, and, in many cases, they are either absent or minimal until the tumors have already metastasized. Early cancer detection is the hallmark of successful treatment. In an attempt to develop a rapid, reliable, and noninvasive method for cancer detection and screening, Raman spectroscopy, a powerful analytical technique, has been employed to conduct a comparative analysis of the saliva samples of healthy individuals and breast and lung cancer patients. This vibrational spectroscopic technique identifies unique fingerprints of molecules present in a sample based on the inelastic scattering of monochromatic light. Herein, the preliminary results of our comparative study will be presented.

Abstract Name: Island of Truth and Fiction: Robinson Crusoe, Verisimilitude, and Contemporary Films Within

Robinson Crusoe is considered a 'classic' and canon within the field of literature, leading to an expansive collection of scholarly articles, journals, dissertations, and film adaptations. The novel has garnered attention from scholars and general audiences alike. This research will analyze the novel Robinson Crusoe (RC) by Daniel Defoe, the castaway motif, and the techniques of verisimilitude. I will provide an example of the influence of Robinson Crusoe on the motif, adaptations of the motif in film and how the castaway motif adapts to its audience. To show how the castaway motif adapts to its audience, the movies "The Martian" (science fiction film, 2015) and "Cast Away" (drama film, 2000) have been selected. The castaway motif and verisimilitude play an important role in the popularity of RC as well as the adaptations for the current generations. This research allows for a broader view of the castaway motif and it explores how media can evolve for its audiences.

Abstract Name: The Role of The Black Church during Jim Crow

During the Jim Crow era, the black church served as a safe haven and a "symbol of community" for African Americans. In 2024 I conducted an oral history interview with my devout and church-going grandmother, Priscilla Turner, who grew up in Alabama during the mid-twentieth century. My grandmother's stories gave me insights about what it was like to experience racism and the crucial role of the black church in a time when miniscule state or federal protection was provided. It piqued my interest to learn more, so I consulted a variety of additional sources including newspaper articles, academic books, and oral history interviews conducted by the Southern Oral History Program at UNC-Chapel Hill. This personal and academic dive into the personal and communal trials of and resistance to Jim Crow, provided me with two understandings which are examined at depth in my paper. First, the horrid events of Jim Crow happened over decades and we are not drastically removed from them in our current time. They remain very real memories for members of America's older generation and the impact of these experiences continue to this day. Second, marginalized communities have always created a space for themselves where they can be safe within their expression. For many twentieth-century black Southerners, one of those important spaces was the church.

Abstract Name: FOXI3 Regulation of Prostate Cancer Cell Behavior in the Bone Microenvironment

Introduction: Prostate cancer (PCa) is a leading cause of cancer-related deaths in men, with bone metastasis significantly contributing to morbidity and mortality. The bone microenvironment is a fertile "soil" for metastatic "seeds." Understanding the molecular mechanisms governing PCa bone metastasis is crucial for developing effective therapies. This study investigates the role of FOXI3, a member of the Forkhead-box (FOX) family of transcription factors, in PCa bone metastasis. While the functions of some FOX proteins in cancer are well-established, the specific role of FOXI3 in PCa remains largely unexplored. Recent studies suggest FOXI3 is involved in bone development and homeostasis. **Methods:** An indirect co-culture experiment using a transwell plate will be used to examine the interaction between PCa cells and bone marrow stromal cells. PCa cell lines will be seeded in the bottom chambers of 6-well plates (100,000 cells/well, 2mL media). Bone marrow stromal cells will be cultured in upper chambers (100,000 cells/1mL media). After a 24 and 48-hour co-culturing, gene expression will be assessed using RT-PCR and qRT-PCR for FOXI3. Protein analysis will be measured using Western blot. Additionally, we will repeat co-culturing and investigate the effects of bone-derived factors (FGF8 and TGF- β) on FOXI3 expression and PCa cell behavior. **Results:** As this is a research proposal, results are pending. We anticipate exposure to bone marrow stromal cell-conditioned media will increase FOXI3 expression and other pro-tumorigenic factors in PCa cells. We expect that FOXI3 removal will reduce prostate cells' invasive and metastatic potential in the simulated bone microenvironment. **Conclusion:** This research aims to elucidate the interplay between FOXI3 and the bone microenvironment, potentially uncovering new therapeutic targets for PCa bone metastasis. Understanding these mechanisms could lead to improved treatment strategies and better outcomes for patients with advanced prostate cancer.

Abstract Name: AI Fairness and Its Relationship to Cultural Contexts

The rapid growth of artificial intelligence (AI) technologies has amplified concerns regarding cultural biases, perpetuated social inequalities and the disproportionate effects on marginalized communities. A significant factor preventing more responsible AI is that many tools are deployed that do not account for local context in

which they operate, fail to consider the diverse needs and lived experiences of the affected populations, or the values of those who are governed by such technologies. To address these challenges, our research focuses on developing a framework that incorporates context and values to produce culturally sensitive AI systems. Our current efforts involve crowdsourcing pre-audits where laypeople (with local knowledge) evaluate AI projects. These audits capture how cultural contexts influence perceptions of AI systems and their potential biases. Vital components of this research include teaching laypersons about AI, crowdsourcing evaluations, developing machine learning algorithms to automate the evaluation of the audits, and designing auditing reports to communicate community insights. By analyzing these findings, we aim to classify recurring patterns and highlight focal points for designing equitable AI systems that respect cultural diversity. While this research is ongoing, the implications of this work extend to fostering more inclusive AI technologies that reduce cultural harm and promote justice in global applications.

Abstract Name: Evaluation of Sexual Function in Spinal Cord Injury Patients in the Epidural Stimulation After Neurological Damage (ESTAND) Study

Sexual dysfunction can have a significant impact on quality of life, leading to other health problems. The ESTAND trial, which stands for Epidural Stimulation After Neurological Damage, is ongoing and aims to optimize the use of epidural spinal cord stimulation (eSCS) to restore functions that enhance patient quality of life. In this study, sexual function was assessed using the Orgasm Rating Scale (ORS). The ORS is a list of adjectives describing orgasm experiences that was created based on the experiences of able bodied college students. The effectiveness of this scale within the SCI population prior to this study was unknown. The adjectives were categorized into physical sensations (PS), emotions (E), and interpersonal relations (IR). Patients underwent surgical implantation of the eSCS and attended 13 follow-up visits where they underwent a series of motor and autonomic assessments and completed surveys evaluating bladder, bowel, and sexual function, as well as overall quality of life. Average female and male ratings for each category of the ORS were calculated for the first visit and final visit and a paired t-test ($p < .05$) was conducted. The data we obtained from the ORS did not indicate any difference in sexual function in females or males over time. Previous studies done on the effects of eSCS on female sexual function using two alternative scales have demonstrated improvement over time with each patient visit, however this data does not reflect similar trends. It is plausible that the ORS did not accurately capture the sexual experiences of individuals with a spinal cord injury (SCI). Future research might aim to use different tools to gain additional insights from our ESTAND participants on how eSCS has impacted their quality of life and sexual function.

Abstract Name: Mapping the Serotonin Transporter Using Crosslinking-Mass Spectrometry

Neurological dysfunction is responsible for disorders such as anxiety and depression. Selective serotonin reuptake inhibitors are used to treat these neurological disorders by targeting the serotonin transporter (SERT). However, they often have negative side effects and are only successful in 40-60% of patients. To learn more about its structure, a mutated form of SERT containing a single reactive cysteine (Cys) at position 310 was overexpressed in Sf9 insect cells. After purification and reconstitution into lipid vesicles, SERT will be crosslinked with MTS-benzophenone (MTS-bzp). V310C SERT may then be isolated on a gel. Proteolyzed and extracted peptides will be analyzed in bottom-up mass spectrometry to provide information on the structure of SERT by identifying crosslinking sites near the mutated region of SERT. This information will give a better understanding of the structure and function of SERT to help design medications that are more specific and effective at treating anxiety and depression.

Abstract Name: Rights of Nature in an Extractive Economy: Corruption and Corporate Influence in Ecuadorian Environmental Governance

In 2008, Ecuador became a global pioneer in environmental governance by enshrining the Rights of Nature in its Constitution, granting ecosystems the legal right to exist, regenerate, and be restored. However, despite this progressive framework, Ecuador's economy remains deeply reliant on extractive industries, creating a complex dynamic between environmental protections, corporate interests, and governance. This research explores how corruption and corporate influence shape environmental governance in Ecuador, focusing on the intersection of constitutional protections and the nation's economic dependency on resource extraction. Using a mixed-methods approach, the study analyzes public discourse, judicial rulings, and policy implementation to answer three key questions: (1) How do government and corporate entities frame environmental issues when addressing the public? (2) What role does corruption play in the Constitutional Court's interpretation of Rights of Nature cases? (3) To what extent do corporate interests influence executive decision-making and environmental policy outcomes? The research employs content and discourse analysis to investigate public communications, media framing, and judicial language, revealing patterns of narrative manipulation and policy capture. Findings will contribute to understanding how corporate actors coopt environmentalist rhetoric to deflect responsibility and advance extractive agendas, often at the expense of indigenous communities and ecological integrity. By illuminating the systemic corruption and structural challenges undermining Ecuador's environmental protections, this study aims to inform global discussions on sustainable governance and the practical enforcement of environmental rights.

Abstract Name: Recording of cellular physiological histories along optically readable self-assembling protein chains

The ability to view cellular activity and processes is important for understanding both normal and diseased processes. In this project, protein-based systems—expression recording islands (XRIs)—are designed to record cellular physiological events over a period of time. The XRIs include multiple components that allow them to store cellular information, such as epitope tags—which allow for the use of fluorescence to visualize when a stimulus asserted a response in the cell. To transport XRIs into the cell, viral vectors are used. The delivered XRIs will then start to grow and indicate a cellular response by activating the epitope tags, which can be visualized with conventional optical microscopy. Key findings of this study include successful applications of this scaffold in cultured neurons: an unbroken XRI that displays the appropriate fluorescence. Despite these successes, the system has limitations, including the need for standardization and the inability to track events in dividing cells. Future research will focus on improving the replicability of this model and extending the time the XRI can record. This study implies a new cellular recording technique that offers a non-invasive method to monitor cellular events in real time. Due to its non-invasive implications and ability to record events in real time, this technology may become transformative for researching gene regulation and disease progression.

Abstract Name: Membrane Protein Chaperone Influences Tau Aggregation Kinetics and Morphology: A Therapeutic Approach for Alzheimer's disease

The most common type of dementia, Alzheimer's disease (AD), is a progressive neurodegenerative disease that initially consists of mild memory loss, but could eventually lead to loss of ability to communicate or react to their environment. A microtubule-associated protein, Tau, aggregates causing neurotoxicity and inevitably neuronal cell death, which is hypothesized as one of the leading causes of the pathogenesis of AD. Abnormal hyper-phosphorylated Tau proteins clump together (aggregate) to form neurofibrillary tangles, which are toxic to neurons and force cell death. The amyloid hypothesis suggests that protein aggregate accumulation in the brain is the primary culprit driving AD pathogenesis. Consequently, inhibiting or reversing this protein aggregation has potential for future therapeutic treatments. Chloroplast signal recognition particle 43, cpSRP43, is a membrane protein chaperone that has shown to efficiently reverse protein aggregation through chaperone and aggregation-prone substrate interactions. This process does not require the use of ATP because cpSRP43 selectively binds to hydrophobic amino acid residues, stabilizing these interactions and preventing the client proteins from ever aggregating. Through the use of Thioflavin T dye, we obtain the aggregation kinetics of Tau aggregation and determine that cpSRP43 prevents Tau aggregation in a concentration-dependent manner. In addition, the electron microscopy shows that the morphological contrast of Tau aggregate in the presence of cpSRP43, indicating that cpSRP43 can inhibit the Tau aggregation. Our results open the opportunity to prevent the Tau aggregation by utilizing unique anti-folding and disaggregation properties of cpSRP43 and emphasize the special role of the membrane protein chaperone in the treatment of protein aggregation-prone disease.

Abstract Name: Multivariate Analysis of the IR of Honey Samples

This study explores the chemical composition and authenticity of various honey types, including wildflower, clover, pure, and organic unfiltered honey, utilizing Attenuated Total Reflectance Fourier Transform Infrared (ATR-FTIR) spectroscopy coupled with multivariate statistical analyses. The ATR-FTIR spectra revealed key vibrational bands that indicate the presence of hydroxyl groups, aliphatic hydrocarbons, and carbonyl functionalities, highlighting significant moisture content and sugar composition common to all samples. Principal Component Analysis (PCA) demonstrated that the spectral data variances primarily reflected differences in floral sources, with wildflower and clover honeys clustering closely due to their analogous chemical profiles. Conversely, pure honey distinguished itself with a more standardized chemical constitution, while organic unfiltered honey exhibited unique characteristics linked to its less processed nature. Hierarchical Cluster Analysis (HCA) reinforced these findings by visually representing the relationships among honey types, confirming that floral sources and processing methods critically influence chemical diversity and authenticity. This research underscores the potential of PCA and HCA as effective tools for evaluating honey quality, supporting industry efforts to ensure product integrity and consumer confidence.

Abstract Name: Postpartum PTSD is Linked to Maternal Exposure to Unpredictability During Childhood

Background: Approximately 20% of mothers experience the onset of a mental health disorder, including post-traumatic stress disorder (PTSD), after childbirth. Maternal psychopathology is known to negatively impact the health, well-being, and development of both the child and the mother. One risk factor for PTSD in other populations, such as combat veterans, is exposure to unpredictable environments in childhood. In this study, we aim to assess the role of exposure to childhood unpredictability in risk for maternal PTSD after a traumatic versus non-traumatic birth. Methods: Participants included 137 mothers (Mage = 32 years, SD = 5; 56% Latina). We used the Questionnaire of Unpredictability in Childhood (QUIC; total possible range = 0-38; M = 8.8, SD = 7.3) to measure exposure to unpredictability and the PTSD Checklist for Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (PCL-5; total possible range = 0-80; M = 6.9 SD = 9.1) to measure childbirth-related PTSD symptoms. Two researchers independently coded birthing narratives as non-traumatic (n = 88), possibly traumatic (n = 27), and traumatic (n = 20) and discussed discrepancies to

reach consensus. We will employ multiple linear regression to test moderation effects of childhood unpredictability on the association between traumatic birth and PTSD symptoms. Expected Results: We expect maternal exposure to childhood unpredictability to increase likelihood of more severe PTSD symptoms after experiencing a traumatic childbirth. Conclusions: These expected results are consistent with previous research on exposure to unpredictability and psychopathology. Findings from this investigation can be implemented to identify mothers at greater risk of postpartum PTSD symptoms due to their childhood experiences of unpredictability and mobilize targeted support.

Abstract Name: Sacred Syncretism: Native American Influences on Catholic Rituals in Colonial New Spain and Mexican Folk Catholicism

In my study, I examine the influence of Native American spiritual practices on Catholic rituals in colonial New Spain, analyzing how these practices shaped Mexican folk Catholicism through processes of religious syncretism. Following the Spanish conquest, indigenous spiritual beliefs—such as animism, ancestor veneration, and ritual festivals—intersected with Catholicism, creating a rich fusion of religious expressions. By focusing on specific instances of syncretism, including the reimagining of indigenous deities as Catholic saints, the alignment of indigenous festivals with Catholic holy days, and the incorporation of sacred natural elements into Catholic rituals, I explore the adaptive strategies indigenous communities employed to preserve their cultural identity within imposed religious frameworks. My analysis includes emblematic figures and practices that embody this blending of spiritual traditions, such as the Virgin of Guadalupe, whose veneration integrates aspects of the Aztec goddess Tonantzin, and the celebration of Día de los Muertos, which synthesizes indigenous ancestral veneration with Catholic observances of All Saints' and All Souls' Days. These case studies highlight the resilience and agency of Native American communities under colonial rule, who, rather than abandoning their spiritual customs, transformed them within a Catholic context. This project contributes to a deeper understanding of how colonized communities navigate and retain cultural identity through religious adaptation. By illuminating the dynamics of Mexican folk Catholicism as a distinctive cultural identity rooted in syncretic practices, offering insights into the broader themes of cultural resilience and adaptation in the face of colonial domination.

Abstract Name: Exploration of active site dynamics and substrate specificity among short chain fatty acid

(SCFA) kinases

Numerous studies reveal the importance of gut microbiome-derived short chain fatty acids (SCFA), such as acetate, propionate and butyrate, in signaling, metabolic, and health outcomes for animal hosts. Colonic microbiomes in Western human populations are generally dominated by species belonging to two bacterial phyla, Firmicutes and Bacteroidetes, which engage in a complex metabolic network that adjusts SCFA levels within an individual. Bacteroidetes includes well-recognized commensal and mutualistic species that serve to break down complex polysaccharides in the gut and generate products such as carbohydrates, propionate, and acetate that can serve as nutrients for the host and other microbial community members. In turn, Firmicutes utilize available resources (carbohydrates, acetate, etc.) to produce metabolites including an array of SCFA through fermentation. One SCFA metabolic pathway recognized within these species involves two distinct enzymes: 1) a SCFA kinase and 2) an acyltransferase. Together, these enzymes can reversibly interconvert SCFA with their acyl-CoA derivatives. Among the SCFA kinase protein family, several variant enzymes exhibiting amino acid substitutions predicted to influence substrate preferences compared to previously characterized SCFA kinases can be identified among key gut microflora species, including *Bacteroides mediterraneensis* (BM), *Bacteroides thetaiotaomicron* (BT), *Phocaeicola vulgatus* (PV), and *Roseburia intestinalis* (RI). Heterologous expression of histidine-tagged variants of the BM, BT, PV, and RI enzymes in *E. coli* has allowed characterization of biochemical properties regarding these variants. Novel, commercially-unavailable substrates have been synthesized and utilized in this study to enhance characterization of these enzymes. Results from these experiments provide insights regarding potential physiological roles for these enzymes in short chain, branched-chain, and medium chain fatty acid metabolism that may influence gut community dynamics and human health.

Abstract Name: Analyzing Nintendo's Demand Forecasting to Optimize Production and Minimize Market Risk

With an aim to identify how Nintendo can use demand forecasts to optimize production schedules and minimize risks of overproduction and stockouts, this research examines sales data and market trends from 1998 to 2024. As a leading game developer and console manufacturer, Nintendo has faced challenges in managing production and maintaining supply chain efficiency, particularly during periods of fluctuating consumer demand and market volatility, such as the COVID-19 pandemic. This study employs a quantitative time-series analysis using unit sales data from 1998 to 2024. A study by Felix Richter (2024) was used to investigate hardware sales trends and their implications for production strategies. Additionally, findings from Shankar et al. (2003) were utilized to assess the impact of network effects on console sales and market competition. The findings indicate that while Nintendo's sales conform to expected product lifecycle trends, the sustained success of the Nintendo Switch reflects changing consumer preferences and evolving market dynamics. As a result, Nintendo combines current market data with traditional forecasting methods, proving essential for aligning production with real demand and improving supply chain management precision. Future research should investigate how digital platforms like eShop and subscription models could further enhance Nintendo's ability to synchronize production with demand forecasts.

Abstract Name: Investigation of Nucks1 Gene Expression Following Chronic Ethanol Consumption:

Nucks1, nuclear casein kinase and cyclin-dependent kinase substrate 1, is highly expressed in the mouse cortex and hippocampus, and was recently associated with progressive increases in ethanol intake in mice and with number of drinks per week in a human genetic association study (GWAS). We recently found that overexpression of Nucks1 in the mouse prefrontal cortex decreased ethanol intake during chronic ethanol access and we suspect may be involved in escalating intake and ethanol dependence. Nucks1 modulates chromatin structure and regulates replication, transcription, and chromatin condensation. Nucks1 expression is high in stem cells and the brain and is expressed in neurons and glial cells. Nucks1 has also been identified as a potential susceptibility gene for Parkinson's disease and bipolar disorder. In the present study, we interrogated Nucks1 mRNA expression following chronic ethanol consumption to test whether ethanol drinking regulates Nucks1 expression. Twenty C57BL6/J male mice were exposed to voluntary ethanol or water consumption and the PFC was collected after nine weeks of ethanol intake. Four primer sets were designed to target all regions of the Nucks1 gene. Primers were tested, and gel electrophoresis was run to determine the most efficient primer set. Complementary DNA was then synthesized from each of the samples and quantitative rtPCR was run to examine levels of Nucks1 expression across both treatment groups. Following a t-test, no significant differences in Nucks1 expression were found between the samples exposed to chronic ethanol and the control group, but certain exons showed trends to be higher expressed in ethanol drinking mice, suggesting potential differential splicing of the Nucks1 gene. Surprisingly, Nucks1 expression was not correlated to ethanol intake in this study. Future analyses will use deep RNA sequencing to investigate if voluntary ethanol drinking alters differential exon usage or transcript variants of the Nucks1 gene.

Abstract Name: The Last of Us: The Quest for Uninfected Monarch Butterflies in South Florida

The monarch butterfly (*Danaus plexippus*) is an iconic species that has long been a flagship for insect conservation, habitat restoration, and the promotion of butterfly gardens. In efforts to support monarch populations, enthusiasts and educators often plant milkweed in gardens and schools. However, in South Florida, the nonnative tropical milkweed (*Asclepias curassavica*) has become dominant in these gardens. Monarchs that preferentially select tropical milkweed are often exposed to higher levels of *Ophryocystis elektroscirrha* (OE), an obligate parasite known to negatively impact monarch growth, flight, and survivorship. To explore the prevalence of this parasite, we captured and tested monarchs for OE spores at three distinct sites: 1) residential butterfly gardens, 2) school butterfly gardens, and 3) natural fields in the Everglades. Our results show that monarchs from residential and school gardens were predominantly heavily infected, whereas monarchs from the Everglades exhibited significantly lower levels of infection. These findings suggest that, despite the prevalence of OE in garden environments, the Everglades may provide a

natural refuge that helps mitigate the effects of parasitic infection, potentially offering healthier individuals that could support broader conservation efforts. Future studies should further investigate milkweed availability and parasitic loads in Everglades habitats to better understand how these factors influence monarch health and conservation.

Abstract Name: Neurodivergence in the Brain

Neurodivergence is the term used to describe significant divergence of neurocognitive functioning from the social norm. Those who function within the norm are what are referred to as “neurotypical”, while those who function outside of that norm are referred to as “neurodivergent” (Walker, 2014). What defines neurodivergence is not entirely well-specified – some believe neurodivergent disorders are a few neurodevelopmental disorders, while others include disorders you can develop over your lifetime. Perspective in recent years has shifted towards viewing neurodivergency as a natural form of cognitive diversity and away from the idea that there is a “correct” cognitive structure (referred to as the social and cultural models of disability, and in part the Neurodiversity Paradigm [Sarrett, 2016; Walker 2014]). The neurodivergent disorders considered in this review include autism spectrum disorder (ASD), attention deficit/hyperactivity disorder (ADHD), Tourette’s syndrome, dyslexia, dyspraxia, and dyscalculia. Approximately 185 pieces of literature were reviewed – with 13 of them highlighted. This literature detailed the structural brain differences (that deviate from the norm) within these disorders. Structural differences were noted throughout the entire brain, more specifically the amygdala, corpus callosum, throughout the cortex, temporal lobe, frontal lobe, basal ganglia, cerebellum, and parietal lobe. Other structures also noted abnormality. These findings may imply structural roots for various symptomology in the associated disorder and further study could lead to research into alleviating more debilitating symptoms associated with certain neurodivergent disorders. This review has already been conducted and data appropriately assembled.

Abstract Name: Brewing Identity: Starbucks' Cultural Transformation and the Evolution of Japanese Café Culture

Japanese café culture has undergone a remarkable transformation, evolving from traditional kissaten to modern, pop culture-themed establishments, mirroring the nation's changing social dynamics. This evolution offers a unique lens through which to examine Japan's shifting consumer behaviors, cultural identity, and its complex relationship with global brands. The Japanese café scene, once dominated by local establishments, now features a blend of traditional aesthetics and contemporary trends, creating a distinctive landscape where global coffee chains like Starbucks coexist uniquely with Japanese café concepts. The integration of

international coffee brands into Japan's café culture presents a fascinating case study of cultural adaptation and localization strategies. Starbucks, for instance, has successfully navigated this cultural transition, blending elements of traditional Japanese hospitality with modern pop culture to create a brand identity that resonates with local consumers. This success stands in stark contrast to the brief entry and exit of other international chains like Caribou Coffee, highlighting the intricate balance required to thrive in Japan's competitive café market. This research highlights how Starbucks adapts its brand to align with Japan's distinctive café culture, investigating the localization strategies employed and their resonance with Japanese consumers. By exploring the history of café culture in Japan and its connection to Japanese pop culture, this study uncovers how Starbucks has successfully integrated its services and products into Japanese society while maintaining its core brand identity. Additionally, it investigates the factors that led to Caribou Coffee's withdrawal from the Japanese market, providing a comparative perspective on the challenges of adapting to Japan's unique café landscape.

Abstract Name: The Symbiotic Nature of Plant Microbiomes for Plastic Degradation

Bioplastics, such as polylactic acid (PLA), are designed to reduce environmental impact but degrade slowly in natural soils, with only about 10% of PLA mass decomposing in a month under unconditioned soils. Bacteria like *Bacillus* spp., known for their bioplastic-degrading abilities, thrive in the rhizosphere, where root exudates promote their colonization. We hypothesized that bioplastic degradation rates would increase in the rhizosphere due to enhanced microbial activity. To test this, we examined the degradation of three bioplastics—PLA, polyhydroxyalkanoate (PHA), and a PLA/PHA blend—over three months. Synthetic plastic acrylonitrile butadiene styrene (ABS) served as a control. Degradation was assessed by weight loss every 30 days, and microbial community dynamics in the rhizosphere were analyzed using next-generation sequencing. This study highlights variations in degradation rates and microbial diversity across different plant species and plastic types, offering insights into leveraging plant-microbe interactions to enhance bioplastic breakdown in soil environments.

Abstract Name: The Influence of Maternal Depression and Parenting Styles on Children's Emotional Expression under Stressful Conditions

Maternal mental health and parenting practices are fundamental to children's emotional and psychological

development. Maternal depression, a prevalent mental health challenge, is linked to less adaptive caregiving practices, potentially compromising children's emotional regulation under stress. This research investigates how maternal depressive symptoms and parenting behaviors influence children's emotional expressions during stress-inducing tasks, addressing gaps in understanding these interconnected dynamics. Mothers completed the Parenting Behaviors and Dimensions Questionnaire (PBDQ), a validated tool assessing emotional warmth, punitive discipline, autonomy support, permissive discipline, and anxious intrusiveness. Simultaneously, children participated in a stress-inducing matching task, with their facial expressions, vocal tones, and behaviors coded for emotional response patterns. Data from the PBDQ and emotion-coding assessments were integrated to explore relationships between maternal depressive symptoms, parenting behaviors, and children's stress-related emotional responses. Findings revealed significant correlations between maternal depressive symptoms and punitive discipline ($r = .29$, $p = .001$), highlighting the impact of maternal mental health on parenting behaviors. Adaptive parenting practices, such as emotional warmth and autonomy support, were linked to positive emotional responses, including problem-solving and persistence. In contrast, punitive discipline and anxious intrusiveness were associated with emotional dysregulation, such as frustration and withdrawal. Children from supportive households demonstrated superior stress management, whereas those exposed to punitive or permissive parenting exhibited heightened stress sensitivity. This study underscores the critical role of maternal mental health and adaptive caregiving in fostering children's emotional resilience under stress. The findings inform interventions aimed at enhancing maternal well-being and caregiving practices, promoting environments conducive to healthy emotional development. By identifying protective and risk factors in maternal mental health and parenting, the research contributes to advancing clinical, policy, and educational strategies to support families and mitigate the intergenerational impacts of maternal depression.

Abstract Name: The Invisible Wounds Encompassing PTSD in Veterans

Post-Traumatic Stress Disorder (PTSD) is a mental health condition that is a silent detrimental issue effecting many military veterans today. Since 2001, one third of U.S. military veterans who served in the Afghanistan and Iraq wars have been diagnosed with PTSD. The economic, physical, and psychological burdens such as hyperarousal, social avoidance, re-occurring traumatic incidents, and emotional numbness can leave an overwhelming collision in the mind of a veteran. This halts them from completing a proper transition back into civilian life and greatly impacting their professional, social, and educational welfare. Unfortunately, the numbers surrounding this issue are much greater than what is reported. This is due to the underreporting from veterans, often because of the stigmatization they receive for wanting to seek mental health treatment while in the military and the culture of the military. This has led to multiple mental health issues such as depression, anxiety, night terrors, panic disorder, and in severe cases, suicide amongst those veterans. There needs to be a more concise psychological strategy built around these issues and statistics to better serve the veterans that have served our nation. There is also a great need for collaboration of efforts amongst the social service and psychology professionals for a more cost-effective way of delivering psychotherapy treatments. To conclude, if one were to combine the quantitative data from all the epidemiological studies obtained, while using the qualitative perspectives of the veterans that are directly affected, researchers could institute a well-versed investigation into the effects of the invisible wounds encompassing veterans. This would lead to larger success rates which would ultimately provide the proper assistance in supporting the veterans, and get them back on track, and minimize the effects that PTSD has on them.

Abstract Name: Lessons from Yalta: Perpetuating Geopolitical Tensions in Asia into the Modern Age

This study seeks to determine the long-term impacts of the policy agreements between the United States and Soviet Union in East Asia following the Yalta Conference in February 1945 and continuing into the 21st century. The Yalta Conference, in trilateral agreements, primarily focused on the relationship between the Allied Powers and the coming end of Nazi Germany. However, the concessions made at Yalta concerning East Asia, particularly Japan, Korea, and China, have led to long-term impacts on geopolitics and the balance of power dynamic. The USSR and US' involvement in the region set the stage for an extensive cold war and several proxy wars following World War II. Yet, the framework of the relationship built within the Yalta agreement and the vacuum created after the fall of the Soviet Union at the end of the 20th century has caused a new struggle for the title of regional hegemon. The conducted research will be analyzed qualitatively into three periods: the conference itself through the start of the Vietnam War, the Vietnam War through the fall of the Soviet Union, and finally the 1990s through the election of Xi Jinping as the leader of the People's Republic of China. Primary research will be conducted through perusing primary and secondary sources including press releases, first hand accounts from the world leaders present at the conference, and geopolitical analysis of critical events in East Asia in the decades following the conclusion of the conference. This examination refutes the belief that Yalta was only Eurocentric, and instead proposes the notion that Yalta had more severe consequences, for better or for worse, in East Asia than previously thought.

Abstract Name: Using GCMS to trace conversion of fructose to short-chain fatty acids in the Western diet.

The Western diet of high fructose and high fat has led to a rise in metabolic diseases such as obesity and diabetes due to its effect on metabolism and nutrient availability throughout the body. Short-chain fatty acids (SCFAs), such as butyric, acetic, and propionic acids, are made by microbiota in the gut from ingested nutrients. SCFAs have a role in promoting healthy immune and gut function, as well as maintaining overall intestinal homeostasis. Enterocytes that line the gut lumen use SCFAs as an important energy source, as well as converting fructose into glucose. However, a high fructose intake may overwhelm the process, causing unconverted fructose to reach the colon where the microbiota converts the fructose into SCFA's, feeding liver lipogenesis. Due to the low concentration of SCFAs throughout the body and their volatile nature, these SCFAs may be difficult to measure. Gas Chromatography and Mass Spectrometry (GCMS) have been the preferred methods for analyzing SCFAs for its high sensitivity. By studying biological samples from mice fed a diet of high fructose and fats, we hope to measure changes in the metabolic production of SCFAs from C13-enriched fructose through isotope tracing. Measuring labeled and unlabeled fatty acids within the biological samples of mice fed with controlled diets shows that a high-fat diet alters SCFA production by the microbiota, leading to the negative effects of consuming a Western diet.

Abstract Name: The Accent of your Class: How Language Adapts and Changes Through The Movie Nueba Yol To Represent The Caribbean migrant Experience.

This presentation takes a critical linguistic approach to analyze the 1995 film Nueba Yol by director Ángel Muñiz. The film is about Balbuena, a Dominican man who travels to the United States in search of the American Dream. On the surface, it is a lighthearted comedy about the antics of a stereotypical Dominican man and his quest for a better life in the United States. While the comedic elements clearly define the film's tone, the film also interestingly uses language codes, register changes, and dialectical intonation unique to the Dominican dialect to explore more serious social issues such as immigration and the lived experiences of marginalized classes. Indeed, the colorful cast of characters deploys different language forms based on the social circumstances they find themselves in, demonstrating not only a tactical ability to negotiate cultural differences but also reflecting how the 'American experience' changes them. Most notably, the protagonist Balbuena adapts to American culture in the big city by partaking in capitalist habits, climbing the social ladder, and shifting to an individualistic mindset, and these shifts in his identity are linguistically reflected in his pronunciation, morphosyntax, and vocabulary choice. An examination of linguistic differences will therefore not only shed critical light on the Caribbean migrant's modern experience but also on the pivotal role that language plays in the formation of Hispano-American identities.

Abstract Name: Secretory mitophagy is a novel pro-survival and pro-growth mechanism for Neurofibromatosis Type 2 cancers.

Neurofibromatosis Type 2 (NF2) is a hereditary cancer caused by a chromosomal mutation which induces loss-of-function of the tumor suppressor protein Merlin. The physical effects of the mutation-induced tumors include hearing loss, tinnitus and a loss in balance. Currently, most therapies available are palliative and involve treatments to minimize pain and neurologic dysfunction, rather than destroying the cancer. There is a need to study new mechanisms of tumor growth. A hallmark of cancer is metabolic reprogramming. Under oxidative stress, mitochondria undergo changes (fission or fusion) to support the metabolic needs of the cancer. Autophagy, or self-eating, is a process to recycle damaged or unwanted proteins within a cell to the lysosome to survive. Mitophagy is the removal of damaged mitochondria regulated by mitochondrial fission molecules (FIS1 and PINK). Our team discovered an alternative pathway known as secretory mitophagy, which is the export of damaged mitochondria into extracellular vesicles. We observed Merlin, FIS1, and PINK1 within these vesicles. We hypothesize that secretory mitophagy is a cell survival and pro-growth mechanism used by cancer cells to withstand oxidative stress and export tumor suppressor molecules. Chemically induced oxidative stress and lysosomal blockade of meningioma cancer cells lead to increased

cell survival and greater levels of secretory mitophagy. Merlin co-located via immunoprecipitation of PINK1+ EVs. A siRNA knock-down of FIS1 with oxidative stress reduced secretory mitophagy and cell survival. Overall, secretory mitophagy is an adaptive pathway used by cancer to endure greater levels of toxicity and export tumor suppressor molecules for unchecked growth.

Abstract Name: Advantages, Risks and Challenges of the Implementation of Artificial Intelligence (AI) in the jurisdictional process with emphasis on the Colombian Executive Process through the Exactis tool

The purpose of this research project is to explore the use of Artificial Intelligence (AI) in judicial processes, examining its advantages, risks, and challenges. The study investigates potential cognitive biases in AI tools, their impact on procedural activities, and their implications for judicial oversight. The project focuses specifically on executive proceedings in Colombia, as these are the legal mechanisms employed to access justice in relation to claims based on enforceable legal instruments. According to statistical data, executive proceedings account for the majority of cases handled by civil judges in Colombia. Thus, integrating AI assistance into these processes could significantly improve the country's judicial performance indicators. The methodology applied follows the framework of socio-legal research, involving an extensive analysis of the current influence of technology, particularly AI and its underlying algorithms, to assess their potential impact on judicial processes. The research led to the development of a prototype named "Ex Actis" which was created using the chat GPT 4.0 platform. Among its identified benefits are ensuring reasonable timelines, providing technical support to judges, and contributing to the unification of case law. These advantages are evident in the prototype's functionalities, which focus on expediting the reading of promissory notes and drafting judicial orders to initiate payment proceedings. The tool demonstrates significant potential to enhance judicial efficiency while being subject to human oversight to ensure impartiality, effectiveness, and adherence to ethical considerations, as required by legal doctrine and Colombia's Constitutional Court. The findings and the prototype have been and will continue to be shared in academic forums and with judicial operators to foster understanding and adoption. This is the link for the Ex Actis tool: <https://chatgpt.com/g/g-jL76UaJsA-exactis-2-0-asistente-de-procesos-ejecutivos>

Abstract Name: Unraveling the Tritrophic Interactions Between a Seed Predator (*Gibbobruchus mimus*) and Parasitoid Wasps Among Eastern Redbud (*C. canadensis*) Cultivars

Eastern Redbud (*Cercis canadensis*) is a horticulturally important pod-bearing tree in the legume family (Fabaceae), which is host to complex tritrophic interactions consisting of Redbud seeds, their bruchid beetle predator, *Gibbobruchus mimus*, and multiple species of wasp parasitoids of the bruchid beetle larvae. Along with native *C. canadensis* species, many cultivars are commercially available. Previous research on other legumes has found seed beetle predation varying among cultivars. Here, we test the hypothesis that seed predation by *G. mimus* may be higher in Eastern Redbud cultivars due to reduced genetic diversity when compared to the native population. To investigate this, Eastern Redbud pods were collected from 10 cultivars (60 pods per tree; 3 or 4 trees per cultivar) at the National Arboretum in Washington, DC. Seeds were classified as either intact, beetle exit hole, wasp exit hole, aborted seed, or irregular seed. We predict that phenotypic differences among cultivars will influence rates of predation and parasitoidism. We are also interested in whether seed predation by the beetle always leads to death of the plant embryo, as the label “predator” implies. Our initial findings show viable embryos can be found in seeds following the emergence of the beetle, suggesting the designation “seed predator” may not be accurate. To determine if seed predation by *G. mimus* causes embryo death, we will stain seeds sorted into the forementioned categories with tetrazolium chloride, which changes color if cellular respiration is present. Additionally, we will cold stratify and germinate seeds to determine if they could produce viable offspring, even after damage. If seed damage leaves an intact embryo and improves water imbibement, we expect to see an increase in germination rates for seeds that have bruchid beetle or wasp exit holes compared to intact seeds. Such findings could lead to a reclassification of these tritrophic interactions.

Abstract Name: Analysis of Permeable Concrete Compositions and Mechanical Properties

This study investigates the permeability of concrete mixes composed of varying ratios of cement, gravel, and sand. The objective was to find the most permeable mixture while maintaining AASHTO specifications by testing different combinations of these materials. In this experiment, three different ratios were tested and compared to various pervious and standard concrete composites. Each of the tested ratios had a volume of 432 cubic inches. The ratios that were tested were formed by a volume percentage as follows: 50:50 cement to gravel, 50:45:5 cement to gravel to sand, and 50:35:15 cement to gravel to sand. For each mixture, the time was recorded for a gallon of water to fully pass through the slabs. The weight of each slab was measured before and after to see how much water was trapped by the concrete after the timer was stopped. The permeability of each sample was calculated using Darcy’s law. In addition, a tensile test for each of the samples was run using a dog bone mold, poured separate from the original slabs. The results were converted from tensile to compressive strengths for trials 1-3 as follows: 4067 PSI, 11963 PSI, and 6961 PSI respectively. The results of the test showed that the most permeable sample was the 50:50 ratio with an average permeability constant of , compared to the 50:45:5 which was and 50:35:15 which was . The results show that a more permeable concrete contains less sand, as the sand fills the gaps between the concrete and gravel thus absorbing more water. The findings of this study provide valuable insights between material proportions and concrete permeability, offering guidance for future concrete mix designs focused on preventing storm water flooding on roadways.

Abstract Name: Molecular Docking to Identify Possible Drug Candidates for Neglected Tropical Diseases

Neglected tropical diseases remain a greatly under-researched topic, despite the global impact they have. This project studied potential drug candidates for a selected tropical disease with the goal to identify viable alternatives for a known inhibitor for the chosen tropical disease, ideally with higher specificity and lower side effects. To make candidates easily accessible and affordable, the candidate pool was selected from known drugs already approved to treat other diseases (drug repurposing), such as those contained in the Pandemic Response Box. Cheminformatics tools such as ChemMine were employed to identify candidates similar to known inhibitors as a starting point. In the next phase of the study, candidates with high similarity to known inhibitors were selected for further investigation. These candidates were then subjected to molecular docking studies which investigated the binding to target proteins to assess their potential use as inhibitors. The target protein structures were obtained from published X-ray crystallography studies, if available, or from machine learning approaches for protein structure prediction, such as AlphaFold2. The binding pockets of selected candidates were investigated to better understand the intermolecular forces between the protein and the ligands. Several candidates were identified to have binding energies comparable to known ligands, thus making these interesting targets for further studies.

Abstract Name: Interpreting Ambiguous Communications and Ghosting in Online Dating: The Role of Rejection Sensitivity and Dating Experience

Research indicates that emerging adults increasingly use online dating apps (i.e., Hinge and Tinder) to seek out romantic relationships. Although this use of technology can be helpful in connecting to potential romantic partners, it could also be detrimental to one's mental health, particularly for those who are more sensitive to rejection. Studies have indicated that those who are "rejection sensitive" are more likely to experience rejection, even when the intent to reject is ambiguous, and are more likely to be distressed by perceived rejection. This is relevant to online dating because when you communicate with only words and no facial expressions or tone of voice, rejection sensitive individuals may interpret ambiguous text messages (SMS) as rejection and be more distressed by them. This may be particularly true at the beginning of an online dating relationship when you are getting to know someone based only on messages exchanged. This quantitative study examines how emerging adults respond to hypothetical ambiguous and ghosting online dating scenarios based on their rejection sensitivity and prior dating experiences. Participants will be approximately 200 college students between the ages of 18 and 25 who are attending a small university. They will complete an anonymous online survey consisting of the following measures: Rejection Sensitivity Questionnaire (RSQ), Inventory of Dating Stress (IDS), and Responses to Ambiguous Dating Communications Questionnaire. Data will be analyzed using correlation and regression analyses. We predict that individuals higher in rejection sensitivity and who report more negative dating experiences will be more likely to interpret ambiguous online dating scenarios as rejection and respond with more distress. We also expect that "ghosting" communications will be experienced as more distressing by those higher in rejection sensitivity.

Abstract Name: The Intersection Between Intellectual Disability and Capital Punishment from a Constitutional Lens

In 2002, the Supreme Court ruled in *Atkins v Virginia* that those with intellectual disabilities cannot constitutionally be sentenced to execution. In an effort to explore the relationship between intellectual disability and capital punishment, this paper analyzes four buckets of research. It begins by discussing the differences in the history of death penalty law in specific states: those that maintain legalization of the death penalty and actively use it. The paper then reviews Supreme Court jurisprudence on the 8th amendment to gain a well-rounded understanding of how both the definition of "cruel and unusual" as well as the utilization of specific applications of the death penalty have changed over time, smoothly transitioning into a deep dive on *Atkins* specifically. The chapter regarding *Atkins* functions to discuss the ethical dilemma of the death penalty and the philosophy of punishment in addition to the questions that the Court leaves unanswered on

intellectual disability. The focus moves to revisit the previously discussed states to determine how they have attempted to answer these questions themselves, including what constitutes an intellectual disability, how inclusive this definition should be, and what burden of proof should be required to prove intellectual disability. This project concludes by summarizing commonalities and differences found between the states. It also calls for legislative and/or Supreme Court action to provide further guidance to decrease variation between states since the lack of legal imposition of the death penalty toward those with intellectual disabilities was ruled a constitutional protection in Atkins.

Abstract Name: Controlled Radiation Capsule Device with High-Density I-125 for Enhanced Dose Rate in Precision Cancer Therapy

Radiation therapy plays a crucial role in cancer treatment, with approximately 50% of patients undergoing it at some point, contributing to 40% of curative cases. Brachytherapy, a form of radiotherapy, offers two main options: High-Dose Radiation (HDR), which is effective in shorter sessions but poses higher risks to healthy tissues, and Low-Dose Radiation (LDR), which is safer for surrounding tissue but requires prolonged treatment times. This study proposes a novel implantable device that combines the advantages of HDR and LDR by controlling radiation release directly toward the tumor while minimizing exposure to healthy cells. Our design features an implantable capsule with a magnetic-actuated window that opens only when directed at the tumor site. The device combines a permanent magnet and an electromagnet to control the release of radiation, allowing for high precision and reduced collateral damage to adjacent tissue. Monte Carlo Damage Simulation was conducted where it simulates the damage made in the cell by radiation. In Montecarlo Damage Simulation, the capsule delivers a high-dose rate of 10Gy/min of I-125 which shows a lot of damage to cancer cells making significant double strands breaks every minute. The capsule optimizes both dose rate and beamwidth for targeted treatment. We conducted feasibility testing with TOPAS, a specialized simulation tool in medical physics, comparing conventional LDR treatment (1 Gy/day) to our capsule's proposed rate of 10 Gy/min. Simulation results confirmed that the capsule effectively blocked radiation except through the designated window, achieving controlled, targeted treatment. This innovative device potentially enables high-dose LDR brachytherapy, optimizing safety and reducing treatment duration. Applications for this capsule include intracavitary cancer treatments, such as for esophageal and cervical cancers, offering a promising approach for more efficient, precise, and safe radiation therapy in cancer care.

Abstract Name: Repair of insertion/deletion errors generated by Pol α as a marker for Pol δ extrinsic proofreading

DNA replication involves sophisticated tag-team polymerase activity. The primary lagging strand polymerases α and δ are involved in Okazaki fragment synthesis, with a handover occurring after the pol α -primase complex synthesizes about 10-30 nucleotides of RNA/DNA primer. Surprisingly, while the pol α -primase complex only synthesizes about 1.5% of the genome, it is more error prone than the other major polymerases because it lacks proofreading ability. Previous studies indicate that pol δ may be able to extrinsically proofread errors made by pol α during the handover using its exonuclease. A double mutant of pol1-L868M pol3-5DV in *Saccharomyces cerevisiae*, containing a mutator form of pol α and an exonuclease deficient form of pol δ , exhibits high rates of indels in long homopolymer runs. Here, we aim to determine if repair of indels by pol δ could serve as a marker for extrinsic proofreading. By transforming select yeast with construct DNA containing mNeonGreen, a drug resistance gene, and an A homopolymer run, indel mutations within the homopolymer run should result in a fluorescent signal. Currently, we've been able to construct DNA containing the target genes and homopolymer track of A's. Remaining steps include successful transformation into wild-type, pol1-L868M single mutant, pol3-5DV single mutant, and double mutant yeast. Following successful development of the assay, we plan to screen mutant libraries of pol δ for other mutations that may impact extrinsic proofreading.

Abstract Name: Facilitating Reuse of Wood and Engineered Wood Products

Wood's ability to store carbon dioxide and lower carbon emissions in its manufacturing process make mass timber a sustainable alternative building material. However, tearing down timber structures before the end of their service life limits these benefits and generates significant wood waste. Salvaging and reusing this timber in new construction would maximize the material value and potentially reduce the overall construction cost. The mechanical properties and performance of cross-laminated timber and used light timber frames were characterized through a literature review. The review aimed to define degradation and durability, identify the biological, environmental, and physical factors that impact them, and determine timber's residual properties. This was achieved by creating multiple sets of relevant search terms, such as "timber" and "degradation", and performing searches on Google Scholar of each combination of terms across sets. Relevant papers were compiled and analyzed. Much of the literature focused on environmental and biological factors, including weathering, fungal decay, insect damage, and especially moisture content. These factors often provide visual cues that indicate whether timber can be reused, repaired, or not used. Physical factors, such as duration of load, had inconsistent effects on the mechanical properties of timber. When it came to short-term strength tests, salvaged timber at first had a similar probability of failure before rapidly increasing. Other mechanical properties varied greatly, making it difficult to make conclusive estimates. Attempts to model the cumulative damage of salvaged timber have been made, with some coming close to matching experimental results, but further data is needed for reliable modeling.

Abstract Name: Algorithms for Characterizing Motion-Based Energy Harvesting Reproducibility

With energy demands estimated to double by 2050 and climate change creating pressure to reduce emissions, there's a need to develop alternative energy sources (US Department of Energy). To adapt to new energy requirements, scalable triboelectric devices--capable of converting motion into electrical output--are promising power supplies that have harvested energy from rotating tires to beating hearts. However, triboelectric generators (TEGs) struggle with reproducibility and variable power output. Further, characterizing inconsistencies can be challenging due to instrument limitations. This project addresses characterization challenges by developing algorithms to enhance existing equipment and track device reproducibility. The first algorithm enhances a widely used material science instrument by expanding its frequency capabilities and offering precise control over frequency, force, and distance variables. Triboelectric power output depends on these variables, so keeping them constant during each test is critical for measuring device reproducibility. The second algorithm measures voltage and current output consistency by automatically scanning the TEG's electrical output data. Current metrics focus on maximum current and voltage peaks. Alternatively, this program provides the average relative maximum and minimum peaks. We used this information to evaluate output consistency between three TEGs made with manufactured cellulose and Kapton tape, with a 99% confidence interval. While confidence intervals are the gold standard for comparing results in various fields, they are not commonly incorporated into TEG research. Applying this algorithm to past and future studies offers a quantitative look into how device modifications and manufacturing practices influence power generation, bringing us closer to producing reliable alternative energy harvests.

Abstract Name: Parental Decision-Making About After School Programs for their School Aged Children

The purpose of this research project is to examine parental preferences of characteristics of after-school care for their children. According to Sacks et al.'s (2024) study of the potential need for "out-of-school time" (p. 1) care for school-aged children using data from the 2012 and 2019 waves of the National Survey of Early Care and Education, approximately 25% of school-aged children in the US experienced non-parental care outside of school hours in 2019 (about the same as in 2012). Children from lower income groups and certain ethnic groups experienced a decrease in participation in 2019 from 2012. Understanding why these trends occur is crucial for making sure that children are well cared for in their school aged years when not in school, how parents decide which after school programs to use, as well as whether they choose to use them over available alternatives. Increased knowledge about the influence of different characteristics of care may help educational professionals better design after school programming that is attractive to parents, while still being developmentally appropriate. While research exists on parental preferences in these child care arrangements, less research exists on which characteristics are most influential to their decision-making. This quantitative

research study will examine this via conjoint analysis by asking parents of school-aged children to indicate their likelihood of choosing various hypothetical after school program scenarios. These hypothetical choices will include 5 characteristics of care, varying at 3 levels, to determine which characteristics of care are most influential to their ultimate decision. Therefore, we will recruit 156 parents of school-aged children (ages 5-12 years of age) to complete an anonymous, online survey, allowing us to examine which characteristics of care are most influential to parental choice, as well as what trade-offs they may make when choosing this care for their children.

Abstract Name: Creating and Implementing a Program to Promote Undergraduate Research: Pioneering Discovery: An Undergraduate/Graduate Mentorship Program

Describes the development and implementation of a program offering undergraduate students a unique opportunity to engage in collaborative research and increase leadership skills; with a primary goal to empower undergraduates to feel confident and comfortable engaging in original research, and presenting their findings to wider audiences. Because our university has a primary focus on educating women, who comprise less than 35% of researchers globally, we are well-situated to address the goal of increasing women in research and leadership roles. Undergraduate students in the program received mentoring from doctoral students, under the guidance of a faculty mentor, and a stipend to support their research endeavors. They also participated in leadership trainings, with pre- and posttest data collected to evaluate program efficacy. We have completed Year 1, and Year 2 is currently underway. Applicants had to identify leadership goals, research interests, agree to attend leadership trainings and cohort meetings, and work with their partnered doctoral and faculty mentors to conceptualize, develop, and implement a research project; as well as analyze the results, submit a proposal of the findings for presentation or publication, and attend a professional conference to either present their findings and/or to participate in the networking and knowledge acquisition available from conference attendance. The conceptualization, funding search, implementation, and initial findings of our program will be explained. We will also describe pitfalls we encountered and possible solutions to surmounting them for those that may want to establish similar programs. We will also describe the structure and topics of the training sessions that we included to help the participants foster their leadership, research, and advocacy skills, as well as resources to assist with providing them.

Abstract Name: Executive/leading women and their relationship to apologies in the workplace

This project explores the relationship between executive/leading women and apologies in order to better understand how these specific communication patterns function in relation to the often-marginalized positions that women hold in the workforce. The way and the frequency in which women employ apologies reveal how women's socialization re(inforces) their historically minimized place in the public sphere. The goal of this project is to produce thoughtful research that engages the voices of the target group, giving them an opportunity to be involved in the conversation about their experiences. According to the World Economic Forum in 2023, only 32.2% of senior leadership roles belong to women (Shine). The number of women in these executive positions are small, which gives more reason for their stories to be recognized. The experiences of these women can not only act as a blueprint to those following in their footsteps, but they can also serve as a window into the oppression they may face in the workplace. The research methodology used will be qualitative, using semi-structured focus groups and/or interviews to collect data. This study is phenomenological in the nature of its methodology and analysis. Based on prior literature review, the anticipated findings will reveal that women perceive more offenses as calling for apologies as well as view apologies as a vehicle to achieve social harmony, explaining the high frequency of women apologizing in the workplace.

Abstract Name: Exploring the Relationship Between Pregnancy and Mental Illness Among Incarcerated Women

In the 1980's, the United States experienced substantial growth in correctional populations, so much so the decades since have been labeled the era of mass incarceration. During this time, research has consistently demonstrated an increase in the number of women in the incarcerated population. The number of incarcerated women increased by over 500% between 1980 and 2021, a rate twice that of incarcerated men. Despite these findings, research largely overlooks the role gender plays in prison life. This is problematic for several reasons. One example that is largely unexplored is the experience of pregnancy among incarcerated women. In 2016, the Pregnancy in Prison Statistics study became the first systematic examination of pregnancy while incarcerated, with 1,396 admissions of pregnant people occurring in their sample of federal and state prisons. Simultaneously, the number of persons with mental illness in the prison setting has increased substantially; correctional facilities have become the largest mental health service provider in the United States. However, the experience of mental illness among the incarcerated is not equally distributed in terms of gender; incarcerated women have higher rates of mental illness than incarcerated men. Thus, two unique needs exist among incarcerated women that have not been fully explored in correctional scholarship: pregnancy and mental illness. We seek to answer the following research question: are women who are pregnant in prison more likely to experience mental illness than those who are not pregnant? We will explore the relationship between pregnancy and mental illness using a series of logistic regression models and the Survey of Inmates in State and Federal Correctional Facilities, a large, publicly available and nationally representative sample of incarcerated persons in the United States. We hypothesize that pregnancy and mental illness are directly related and that pregnant women will have an increased chance of experiencing mental illness.

Abstract Name: Unholy Desires: The Evolution of Christianity and Sexuality in Vampire Film and Television

This paper examines the chronological evolution, from the 1920s to today, of the vampire in film and television in relation to society's attitudes towards Christianity and sex. The vampire in popular culture has gradually transformed from a creature of moral and sexual depravity into a symbol of sexual freedom and self-expression; these changes reflect Western society's shifting relationship to Christianity. Much scholarly research explores the relationship between Victorian vampire literature and Christianity, as well as Christianity and sexual norms; however, little scholarship examines the influence of Christianity on current vampire media or the intersection of sexuality, Christianity, and vampire cinema. An initial qualitative review of existing literature was conducted regarding cinematic depictions of vampirism, Christian influences in society, and Christian rhetoric in sexuality discourses. Following this review, 20 popular American and British movies and television shows in the vampire genre were watched and thematically analyzed for their depictions of sex and Christianity. Such research found that early vampire movies established the vampire as a villain, driven by perverse and anti-Christian motivations. This idea prevailed until the 1960s sexual revolution and the cultural decentering of Christianity that accompanied it; 1960s vampire movies began utilizing sensationalism to create veiled messages that condemned the culture of repression within Christian society. In the 1980s, as secular viewpoints gained further legitimacy in sexuality discourse, vampires functioned as metaphors for sex as a form of self-discovery. The 1990s to 2010s, in tandem with the evangelical-led purity movement, popularized sympathetic vampires that yearned to be released from their shameful nature. Modern vampire media transforms again, embracing the vampire's appeal to disempowered people and ability to create meaning outside of religion. This research ultimately aims to identify and deconstruct the ability both of Christianity to shape popular culture and also of fiction to investigate Christian standards within society.

Abstract Name: Characterization of Additive-manufactured Novel Cold Plates for Efficient Heat Removal

Integrated Circuit (IC) chips are the fundamental building blocks of modern computers. Various fields require the use of high-power IC chips to perform various computationally intensive tasks, and while they are remarkably effective, they must be cooled to maintain chip functionality and reliability. Looking at various thermal management solutions, we focused on cold plate as the starting point for an improved liquid cooling solution. Generally, more intricately designed cold plates with more complex internal structures would yield better thermal management results. With the absence of constraints posed by conventional manufacturing methods, additive manufacturing (AM) processes can be adopted for the design and fabrication of more efficient and effective cold plate structures. In this presentation, we will introduce our research project on characterizing both the cooling efficiency and power consumption of novel cold plate designs fabricated by AM technology. In particular, the design considerations and experimental verification of several cold plate structures to remove local hotspot in IC chips will be presented. Experimental data will also be compared

with simulation results from finite-element modeling to address the potential opportunities of leveraging AM, numerical simulations, and real-time temperature distribution monitoring to tackle the challenges in thermal management of advanced IC technologies.

Abstract Name: Exploring the Effects of Chemotherapy-Induced Senescence in the Tumor Microenvironment

Ovarian cancer is one of the most lethal gynecological malignancies with a five-year survival rate of just 25-35%. The current foundational chemotherapy regimen for initial treatment combines Carboplatin (CPT) and Paclitaxel (PCT). This combination is known to induce senescence, a cellular state marked by the loss of proliferation, in ovarian cancer cells. However, the full effects of chemotherapy-induced senescence within the tumor microenvironment (TME) are still unknown. We have demonstrated that CPT and PCT can induce cellular senescence in ovarian cancer cells, as confirmed through cell cycle analysis. To investigate the potential effects of CPT and PCT on leukocytes, which are critical components of the TME, we exposed primary human Peripheral Blood Mononuclear Cells (PBMCs) to this chemotherapy combination in vitro. Cellular senescence was assessed through staining for established senescence markers and analyzing marker expression via flow cytometry. Preliminary analysis of senescence markers indicate that chemotherapy does induce senescence in PBMCs and induces T cell dysfunction that is characterized by reduced effector function. In the future, chemotherapy-treated ovarian cancer cells will be cocultured with untreated PBMCs to determine effects on immune cells. We will investigate the production of inflammatory cytokines by the PBMCs to see if chemotherapy or the ovarian cancer cell-PBMC coculture affects leukocyte effector function. We also plan to assess the effects of senescence on tumor tissues from ovarian cancer patients before and after undergoing CPT + PCT chemotherapy. We hope that by studying senescence induced by CPT and PCT, we will gain newfound understanding to improve patient outcomes for women with ovarian cancer.

Abstract Name: 269

American Judaism, Jewish Americanism is not dead. Despite an increasing popular sentiment that Jewish Americans have passed our peak culturally, intellectually, creatively, and religiously we are still here. Seven point five million Jews live in the United States. Depending on who you define as Jewish this is more than the number that resides in the state of Israel. The majority of these people are presumably happy to live in the U.S. as Jews and yet many have given up on the term Diaspora. The Diaspora must be taken seriously, and its future existence defended. Scholars such as Daniel Boyarin, and Shaul Magid critique Zionism from a political and cultural standpoint. This paper begins by analyzing this existing literature on the cultural and religious implications of living in a Jewish state. However, the paper continues beyond a negative defense of

the Jewish Diaspora through a critique of Zionism, to a positive defense of the Diaspora and why it must be protected as a necessary and unique component of Jewish history. Building on the writings of Jewish historian and philosopher Simon Dubnow, this project considers how the Diaspora can be conceptualized without Israel. Zionism can have a place but does not have to be the center of Jewish identity, life, and imagination. The paper concludes by setting a path forward, examining existing Jewish Autonomous projects in the U.S., and proposing ideas for how the Diaspora can be revitalized. Above all else, this author argues the importance of Diasporism for the Jewish people and suggests ways to reignite it as a vital philosophy in the collective consciousness of Jews globally.

Abstract Name: Effect of siRNA knockdown of the *icaA* and *icaD* genes on biofilm formation in *Staphylococcus aureus*.

Staphylococcus aureus is a prominent infectious agent due to its ability to produce a biofilm that protects against the host immune response, enhances attachment to surfaces and aids in antibiotic resistance. Organisms that produce a biofilm possess a biological advantage that often leads to post-surgical infections because they can coagulate on the surfaces of medical devices. One mechanism for biofilm production in *S. aureus* is the production of a polysaccharide intercellular adhesin (PIA) molecule that is encoded by the *ica*-operon. The *ica*-operon encodes 4 genes: *icaA*, *icaD*, *icaB*, and *icaC*. The *icaA* gene encodes for an N-acetylglucosaminyl transferase that is responsible for expressing the PIA molecule. The *icaD* gene produces a protein that is responsible for enhancing the enzymatic activity of *icaA*, and thus production of the PIA molecule. The goal of this study was to determine if siRNA knockdown of the *icaA* and *icaD* genes can decrease biofilm formation in *Staphylococcus aureus*. In this study, *S. aureus* cells were treated with 10µg of *icaA* siHybrids, 10µg of *icaD* siHybrids, or 20 µg *icaA* and *icaD* siHybrids, combined. After treatment, the cells were stained using crystal violet to quantify the amount of biofilm produced. The results from this study indicate that individual suppression of the *icaA* gene and combined suppression of the *icaA* and *icaD* genes using siHybrids leads to a significant decrease in *S. aureus* biofilm formation.

Abstract Name: Effort Expenditure for Rewards: Differential Associations with Symptoms Based on Risk for a Severe Mental Illness

Background: Humans are constantly using information about reward, probability of reward receipt, and effort to guide their effort expenditure. Research has shown that there are individual differences in effort

expenditure decisions, but little research has examined how these decisions differ in groups at putative high risk for severe mental illnesses. **Methods:** The current study evaluated whether groups at putative elevated risk for a severe mental illness demonstrated reductions in the willingness to expend effort for rewards and whether these impairments were associated with greater symptoms. Participants included 80 participants with elevated risk for a severe mental illness and 74 participants without this risk. All participants completed the Effort Expenditure for Reward Task (EEfRT). **Results:** Groups did not significantly differ on effort expenditure performance and chose to exert similar levels of effort across all trials. However, among those at increased risk for a severe mental illness, greater positive symptoms (e.g., subclinical delusions, hallucinations) and associated distress were associated with increased effort expenditure. On the other hand, in the group with reduced risk, associations were opposite – greater effort expenditure was associated with reduced positive symptoms and associated distress as well as lower negative symptoms (e.g., reduced motivation). **Conclusions:** Findings observed differential relationships between effort expenditure in at-risk participants versus participants at reduced risk for a severe mental illness. Associations suggest that in those at elevated risk, subclinical positive symptoms may interfere with effective decision making.

Abstract Name: Disability Etiquette and Equity Initiative in Inclusive Recreation

Project Purpose: Our initiative promotes the use of disability etiquette in inclusive recreation. **Background:** In Coconino County, Arizona, 15% of individuals are living with a disability. High Country Adaptive Sports (HCAS) serves those with various disabilities (athletes) by promoting inclusive recreation. HCAS contributes to positive physical and mental health outcomes within this population, having served 5,000+ athletes. In regard to stigmatized topics, like disabilities, trainings create positive change and instill skills and confidence. Trainings address negative attitudes and stigma around a topic in order to reduce prejudice and discrimination. Disability etiquette consists of treating all individuals with disabilities with respect by using appropriate language while communicating and not assuming one's ability. The annual training for the HCAS staff and volunteers had not previously included the topic of disability etiquette. **Methods:** Our intervention included an impact report, panel discussion, and disability etiquette training. We created a visual snapshot of the successes of HCAS in order to encourage donations and volunteerism within the non-profit organization. Lived experiences and insight were collected from individuals with disabilities, parents of those with disabilities, and those who work in the disability field, which were incorporated into our disability etiquette training. This training was created and implemented to equip HCAS staff and volunteers on appropriate disability etiquette strategies to utilize when interacting with HCAS athletes, to promote an inclusive environment. **Conclusions:** Following the disability etiquette training, a post-test was conducted revealing that trainee's confidence increased by 11.4%, 94.4% of trainees identified three correct disability etiquette strategies, and 83.3% of trainees strongly agreed they will utilize the learned disability etiquette strategies in working with HCAS. Looking ahead, HCAS will continue to implement this successful training in their annual training for their staff and volunteers.

Abstract Name: From CT to 3D: Building Accurate Anatomical Models of Organisms for Teaching and Research

Utilization of tactile or virtual 3D models as teaching aids improves understanding of structural and functional properties of anatomical specimens. However, there are not many available resources for anatomically identified 3D models of various organisms, and model formats are limited. Our project is part of a National Science Foundation (NSF) funded collaboration that aims to create a free repository (MorphoCloud) and novel software tools for generating and sharing 3D models of representative organisms. This is achieved through the use of 3DSlicer, an open-source software for 3D rendering and analysis of visual data. This specific project also employs the SlicerMorph extension, which offers extensible visualization of volumetric and surface scans. Data is imported from high resolution computed tomography (microCT) scans of an organism, and is then converted into a 3D image through a range of tools. The SlicerMorph extension also allows multiple users to modify and export the virtual specimens for a variety of uses, such as 3D printing of didactic models or virtual animations. The work resulting from this project encourages scientific discovery and has potential significant applications in the field of evolutionary biology. This semester, our contribution to the project showcases the modeling of the African Clawed Frog (*Xenopus laevis*), with a focus on how 3DSlicer and SlicerMorph applications were used to generate the end result. Ultimately, this software provides opportunities for researchers, students, and even the public to collaboratively build accurate models of various organisms. This work includes applications for teaching and research, as well as encourages the use of 3D models for hands-on education and public outreach.

Abstract Name: Queer Self-Expression, Community, and Resource Availability: A Comparative Analysis of NCSU with Japanese Universities

University can be a difficult period for young adults to navigate, balancing school, social life, and other responsibilities for the first time. For those in the LGBTQ+ community, these issues may be exacerbated by discrimination and feelings of isolation. This study aims to highlight these issues related to being LGBTQ+ based on a survey conducted both at various universities in Japan as well as NCSU. LGBTQ+ rights and community in a transnational context have been studied extensively both in Japanese and English, but few studies have looked at the lives of college students specifically. Survey questions included things related to social situations, discrimination, personal safety/comfortability, and the responsibility of social institutions (universities, government) in mitigating these issues. By conducting this comparative analysis, the hope is to outline both the issues currently being faced by each group, as well as already existing solutions and their efficacy. Preliminary analysis shows that although both groups indicated discrimination in some capacity, those from NCSU tended to fear harassment and physical harm, while Japanese students tended to worry about ostracization, bullying, and social discrimination. By understanding the socio-cultural contexts that invoke these differences, policies can be adopted, adapted, and applied to properly address the needs of LGBTQ+ students, hopefully leading to general solutions regarding LGBTQ+ rights globally.

Abstract Name: Childhood Adversity, Inflammation, and Race in Chronic Low Back Pain

Chronic low back pain is the second leading cause of disability in the world, but for 90% of people, it cannot be traced to a pathoanatomic cause. Recently, the biopsychosocial model has been utilized to understand the condition as a result of interacting physiological, emotional, and external factors. This study utilized measures such as adverse childhood experiences (ACEs), racial demographics, and C-reactive protein (CRP) concentration via blood draw from Non-Hispanic Black (NHB; $n = 116$) and White (NHW; $n = 61$) participants with non-specific chronic low back pain. A positive correlation of $r = 0.152$ was found between the number of ACEs and CRP concentration, and there was a significant difference ($p = < 0.001$) in the average CRP concentration for NHB vs. NHW participants. However, the difference in ACEs experienced between NHB and NHW was insignificant, with a p -value of 0.54. These results suggest a regional similarity in childhood adversity experienced by NHB and NHW participants, but a significantly higher rate of systemic inflammation as represented through [CRP] in mg/dl in NHB than NHW. On average for both groups, the incidence of ACEs and [CRP] in mg/dl trends upwards, suggesting a correlational relationship supported by previous research. Future mechanistic studies are needed to investigate the mechanisms of how chronic stress becomes systemic inflammation, and future correlational studies are needed to better understand how region and socioeconomic status play into the experience of race in healthcare outcomes.

Abstract Name: Advancing Electric Network Frequency Detection through Deep Neural Networks

In this paper, we present advancements in Electric Network Frequency (ENF) detection using deep neural networks. ENF is a critical tool for verifying recording timestamps, determining recording locations, detecting tampering, synchronizing multimedia, identifying deep fakes, and authenticating videos. We analyze the choice of the ENF-WHU dataset with an 8000 Hz sampling rate, evaluating its advantages and limitations compared to higher rates like 44.1 kHz, particularly in terms of frequency resolution and the detection of subtle ENF variations. Additionally, we investigate the impact of recording bit depth by comparing 16-bit and 32-bit recordings to assess whether increased bit depth enhances ENF signal detection. Furthermore, we revisit the traditional ENF attenuation formula, which is inversely proportional to the square of the distance between the microphone and the nearest power source, incorporating factors such as electromagnetic power fluctuations and environmental influences that may affect the recorded signal. This research aims to refine ENF detection methodologies, improving accuracy and reliability for diverse forensic and authentication applications.

Abstract Name: Global Positioning System Metrics and Injury Prevalences in DII Collegiate Female Athletes

In the athletic realm, preventing injuries is a top priority among coaches and players as statistics have revealed that among NCAA athletes, injuries are exorbitant and severe as many result in critical care and terminate an athlete's athletic career. However, research has disproportionately focused on male athletes. The lack of research specific to female collegiate athletes and injuries led to this project's focus. The goal of this study was to determine the correlations among various Global Positioning System (GPS) metrics associated with injury prevalence in DII collegiate female soccer players. This project hypothesized that GPS metrics could predict injuries in collegiate female soccer athletes and that injury prevalence would correlate with poor nutritional choices and/or sleep hygiene. Anonymous GPS data was obtained through the TITAN Sensors website and statistically analyzed through Jamovi. The results revealed no predictive correlations between GPS metrics and injuries in this specific population and concluded that the variables used to analyze were not prognostic. This matters because the analyses did not predict injuries and suggest that these variables may not be effective along with utilizing a different approach and/or metrics to predict injuries. The results of this study warrant further research within this field and population to improve the methods and metrics used in the statistical analyses. Although predictions were not discovered, this research project captured the ineffectual metrics and opened the door for further studies to support the success of female student-athletes.

Abstract Name: The Psychological Impact of Media: Developing Effective Communication Skills For Adolescents

The forms of communication have advanced, creating new avenues to interact with others online and in-person; including text messaging, calling, video chatting, and socializing online. These new platforms, along with the traditional avenues of communication, have become the foundation to strengthen interpersonal relationships and social skills. This new way of communication has transitioned into the primary method to interact due to in-person conversations becoming less and less frequent. Acquiring adequate communication skills and understanding Emotional Intelligence are essential to adolescents' transition into adulthood; such as regulating their mental health, changing in behavior, and overcoming social trauma. I propose to demonstrate how online communication platforms influence interpersonal relationships, including how it has become a complex psychological system. This lecture presents how developing effective communication skills for adolescents impacts their Emotional Intelligence, trauma resilience, and interpersonal relationships through various forms of online media.

Abstract Name: The Children's House: Review of Prekindergarten Education in a Laboratory Setting on a University Campus 1972 – 2022

The education and care of young children has occupied humankind since the beginning of human life. Immigrants brought concepts of organized 'kindergarten' programs to the United States in the middle 1800s. In the United States in the early 1900s, education and care of young children began to be professionalized, with the expansion of nursery schools, day nurseries, and other forms of programming. In 1972, in a rural southern Minnesota city, early childhood professionals conceived a new program: The Children's House. This program had several purposes: early childhood education and care, teacher education, demonstration, special projects and events, such as professional development and continuing education opportunities. The purpose of this investigation was to trace the development of The Children's House at Minnesota State University from its establishment in 1972 to the close of the 2022 school year. The researchers reviewed archival data which included documents, theses, photographs, artifacts, contributions from past staff members and oral histories. Information was collected about program philosophy, design and curriculum, funding, staffing, facilities. Potential outcomes of this research project include: (1) documentation of historical development; (2) insight into evolving education practices; (3) reflections on funding and resource allocations; and (4) recommendations for policies and programs. This comprehensive analysis has the potential to contribute valuable insights to both the history and future of early childhood education, emphasizing the importance of adaptable and reflective program design in response to evolving educational needs and trends. This is a multi-year project. Presentations in 2025 will discuss methodology and initial findings.

Abstract Name: Effects of Blood Flow Restriction Cuff Chamber Design on Acute Cardiovascular Responses

This study aimed to investigate the impact of the blood flow restriction bladder type (single- [SC-BFR] vs. multi-chambered [MC-BFR]) on cardiovascular responses with exercise sessions incorporating multiple sets to volitional failure in a randomized, crossover experimental design. Twenty-seven healthy, physically active participants (11 females; age: 22.6±5.7; BMI: 25.0±4.1 kg/m²; ~93% reported regular resistance training within 6 months) randomly performed wall squats to failure (4 x sets to failure, 20% 1RM, 60% limb occlusion pressure, 1 min rest between sets) in each of three conditions: SC-BFR (using the Delfi

Personalized Tourniquet Device), MC-BFR (using the BStrong Cuffs), and N-BFR (no BFR control). Hemodynamic assessments and indices of arterial stiffness were monitored immediately before and after each exercise session. SC-BFR blunted post-exercise increases in carotid-femoral pulse wave velocity ($p = 0.328$) whereas the other conditions showed elevations ($p < 0.05$). The bladder design of a BFR cuff impacts the acute responses to exercise, as SC-BFR mitigates post-exercise arterial stiffness responses compared to MC-BFR and N-BFR.

Abstract Name: Cinematic Crossroads: Recent Trends in the Cultural, Political, and Industrial Decoupling of US-China Film Relations

In the context of the Chinese government's persistent pursuit of a Zero-COVID policy during the pandemic, the year 2021 marked a turning point for domestic film companies and the Chinese Communist Party (CCP). Notably, Chinese theaters achieved a historic milestone, surpassing global competition by collectively grossing the highest box office share for worldwide box office revenue. With approximately 1.7 billion movie tickets sold and \$7.3 billion USD in earnings, this achievement raises questions about China's evolving position in the global film industry. The absence of international films in the top 20 highest-grossing films of 2021 underscores China's potential for self-reliance, as Hollywood productions took a backseat. Only 12% of that year's total box office sales came from US-imported movies, while eight of the top ten highest-grossing films were domestic productions. In 2023, China's domestic film market continued to thrive, with 83.77% of the total box office revenue (over \$7.75 billion) generated by local productions. Notably, all top 10 films were domestic, led by the historical thrillers and sci-fi genres. Although 88 foreign films were imported in 2023 (the most since 2019), Hollywood's share of China's box office remains limited. For example, Disney and Marvel films returned after a hiatus but did not make significant box office gains. This shift prompts inquiries into the motivations and strategies behind China's move toward self-sufficiency in its film industry and what this means for film distribution as a soft power tool. This paper seeks to analyze “decoupling” through interdisciplinary methods such as qualitative analysis by examining causal relationships and testing hypotheses using evidence from journalism, established political science research, and government documents. The report comprises multiple case studies and delves into how the US and Chinese film markets respond to changing bilateral relations and how Hollywood producers navigate an increasingly polarized environment.

Abstract Name: Music for Young Listeners with Autism: A Student's Perspective on Music Theory, Interdisciplinary, and Community-Engaged Research

How might community-engaged learning create opportunities for music students to engage in applied, interdisciplinary research while learning fundamental course content? Problem-based learning (PBL) is a pedagogical approach where students develop and apply newly acquired knowledge in order to solve a problem (Duch, Groh, and Allen, 2001). PBL promotes problem solving through team learning, critical thinking, and creativity; it also increases students' learning retention (Albanese and Mitchell, 1993). This paper explains how a music-theory centered, community-engaged, PBL project developed into a multi-year, interdisciplinary, and grant-supported research agenda that defined the author's undergraduate experience and helped her establish a path toward graduate study. Music for Young Listeners with Autism Spectrum Disorder (ASD) launched from a first-year honors music theory course, where students addressed a societal problem through collaborative partnerships and knowledge synthesis. This project, inspired by the author's experience as a musician with a sibling with ASD and auditory-sensory sensitivities, led the author on a journey of discovering how to make sensory-friendly music for individuals with ASD who are overstimulated by certain sounds. This included learning how to establish partnerships with community organizations, develop interdisciplinary teams to build complex solutions, submit IRB proposals, write grant applications, and conduct human-subjects research over an extended timescale. This paper dives into the research's key outputs, such as the song template used to create modular music, examples of the modular music, and details about the device that makes the magic happen, uCue. The development and testing of uCue's sound library through four IRB-approved studies is described, as well as the preliminary results found from them. The ultimate goal of this research is to collect user-interaction data sets large enough to identify preference patterns for both individuals and groups of people with ASD so future sensory-friendly music can be created for music therapy and education settings.

Abstract Name: Cubane: A Stable Molecule with Unstable Bonds – Advances in Synthesis and Characterization

Cubane is a molecule that has caught the attention of chemists due to its paradoxical nature, namely a high stability even though it contains multiple 90° bond angles. Typically, a ring system with a bond angle below 109.5° becomes unstable the lower the angle is, but cubane remains highly stable in spite of these structural features. These bond angles do contribute to cubane being extremely energetic where a large amount of energy is released when the bonds are broken. The molecule was first theorized to be possible by William Weltner Jr. in 1953, it was originally named tricyclooctane. Eaton and Cole synthesized this 11 years later, however the overall yield was abysmally low (around 12%) due to the long synthesis pathway used. Over time this was improved, and the current yields of cubane are around 47%. Yields remain low due to the photochemical step required to create the cube, where a α -halo ketone undergoes nucleophilic substitution (Favorskii rearrangement) which is typically used to convert cyclohexane rings into cyclopentane rings. For this rearrangement to occur UV-B light is needed, however, such lamps are costly. Cheaper commercial UV sources can be used, but doing so reduces the speed of the reaction and makes it prone to side reactions contaminating the product. For this reason, new methods are being developed to enable this reaction to occur in UV-A light that is safer and less expensive. In this work, the synthesis of cubane methyl ester was performed, the photochemical step was modified to see any improvements could be made, and products of this synthesis were all characterized by NMR.

Abstract Name: 'It's a Slap in the Face': Exploring Sense of Belonging and Challenges Among Undocumented Students in Higher Education

Sense of belonging (SB) is a basic human need that describes the extent to which people feel personally accepted, respected, and involved in their respective communities. Research has consistently demonstrated the positive implications of a heightened SB, including improved academic performance, engagement, motivation, and mental and emotional well-being. Although its importance is well established, many underrepresented students suffer from lowered SB compared to their White peers. SB is consistently shown to be lower for women, minorities, and underrepresented populations. Therefore, the aim of this study was to describe the factors that influenced undocumented students' SB at the University of California. Twenty semi-structured interviews were conducted to explore this research question. Results demonstrated that these students face additional barriers, compared to their documented peers, due to their legal status. They are frequently unable to participate in internships or research opportunities that require citizenship. Additionally, undocumented students face increased financial challenges because they are unable to obtain on-campus employment. This lack of experiential learning opportunities led to feelings of invalidation, isolation, and a decreased sense of belonging. From these results, we aim to produce an actionable set of recommendations to enhance SB among undocumented students.

Abstract Name: COX-2 upregulation in hippocampal astrocytes of a parkinsonian mice model: implications for blood-brain barrier damage

Parkinson's Disease (PD) is the second most common neurodegenerative disease in the world. However, many aspects of its pathogenesis and development remain an enigma. Blood-brain barrier (BBB) damage in PD because of chronic neuroinflammation is a relatively unexplored area of research, but literature suggests that these factors contribute to neurodegeneration. Due to astrocytes' primal function of supporting the BBB, these cells pose an ideal subject to study changes in BBB integrity. On the other side, cyclooxygenase-2 (COX-2) synthesizes prostaglandin E2 (PGE2) under inflammatory conditions, which is a potent vasodilator, and in excess could have a detrimental impact on BBB stability. In our study, we use immunofluorescence to detect COX-2 overexpression (through SP21 monoclonal antibody) by GFAP-positive astrocytes in hippocampal tissue of saline treated (control) vs. paraquat-treated mice, which is known to emulate parkinsonian conditions in rodents. The tissue samples were further observed under confocal microscopy and quantitative analysis of the images demonstrated changes in astrocyte morphology corresponding with PD-characteristic reactivity, such as irregular shape and thickened processes, along with spatial co-existence of COX-2 in astrocytes processes and cell body, and a significant increase in signal intensity of SP21, not seen in control samples. These findings suggest not also the instrumentality of COX-2 in the chronic inflammatory cascade propagated by astrocytes and its potential effect in the stability of the BBB, but also novel contributions to a field in which vascular morphology of Parkinson's has been widely understudied, broadening the horizons for therapeutic development and new paradigms.

Abstract Name: Constitutional Absolutism? Feudal Kingship in Late Restoration Royalism, 1679-1688

Following the Glorious Revolution of 1688, the “absolutist” kingship of the deposed Stuart kings was condemned by the victorious Whig party as an illegal subversion of the limited monarchy established by England’s “ancient constitution.” While modern scholarship on medieval England has found powerful kings who ruled the kingdom as their private property or patrimony, a historiographical consensus remained that Stuart absolutism was ahistorical and unconstitutional. This study aimed to challenge the still-widespread belief in the historicity of Whig limited monarchism and thereby vindicate the Stuart absolutist interpretation of English kingship as constitutional. To do so, the polemics written by royalists in the late Restoration period—wherein medieval feudalism was cited as the source of the absolute power of the Stuart kings—together with the praxis of this royalist theory by the said monarchs, were reexamined and substantiated according to an emphasis placed on royal patrimonialism. It was determined that an English kingship that was patrimonial and feudal must also be autocratic, and therefore England was historically an absolute, not a limited, monarchy. Not only does this conclusion exonerate Stuart absolutism from the charge of unconstitutionality, but it also busts the myth that limited kingship was the historical form of the English monarchy.

Abstract Name: Fool For You

This piece intends to showcase through dance the longing associated with wanting to be involved with something greater than oneself, or to simply be connected to others. It explores the emotions of desperation and the willingness to struggle to reach a goal or dream. I choreographed this piece to Linger by the Cranberries, drawing inspiration from the song’s almost ethereal composition and how it contrasts with its distressed lyrics. Because of its intriguing composition, I created choreography using both the music’s lyrics and beats. The music itself, Linger, was what originally sparked my desire to create. The methodology utilized throughout the construction of Fool For You always started with determining what kind of movement quality I intended to use for each specific section. From there, I was able to formulate choreography and intricate movement. Using what I had created, I would then place the movement on my dancers and play with facings, pace, and directional changes. Being able to see my work fully performed by a cast always further influenced how I proceeded with the next segment of the work. Designing Fool For You and translating ideas I originally had to a stage taught me how I can correlate movements to a contrasting musical composition. Although Linger has sound quality more often associated with styles such as ballet, I chose a combination of lyrical and contemporary movements. I felt that this approach better represented the yearning I intended to portray. Through this number, I hope to show audiences how concepts such as longing or desperation can be

painful, but are also beautiful signs of feeling. Wanting to be connected with others, part of a larger story, or even pining for love are all parts of the magnificent human experience.

Abstract Name: Attachment, Emotional Invalidation, Cognition, and Complex Posttraumatic Stress Disorder

Abstract: Complex posttraumatic stress disorder (CPTSD) affects 3.4% to 7.7% of the population and involves emotional dysregulation, interpersonal difficulties, and a negative self-concept (Cloitre et al., 2019; Hyland et al., 2020). Relational trauma—a specified form of interpersonal trauma—is defined as persistent rejection and abandonment from a close other (e.g., a parent or romantic partner; Gómez et al., 2016) and is a significant predictor of CPTSD, often disrupting attachment systems and impairing cognitive and emotional processes. In the present study, we examined the relationships between attachment insecurity, emotional invalidation, and CPTSD symptomatology, as well as the mediating roles of cognitive flexibility and posttraumatic cognitions. Using data from 273 participants in the United States with histories of relational distress, the proposed model showed an excellent fit. Path analysis revealed that insecure attachment and perceived emotional invalidation had a positive direct relation to CPTSD symptoms. Posttraumatic cognitions, such as self-blame and negative beliefs about others, significantly mediated these relationships, underscoring their role in the development and maintenance of CPTSD symptoms. Cognitive flexibility did not mediate these relationships. However, cognitive flexibility was negatively associated with emotional invalidation, suggesting that as emotional invalidation increases, there is a small yet significant reduction in cognitive flexibility. The present results highlight the complex mechanisms that inform the corresponding relationship between relational trauma and CPTSD symptomatology, therefore emphasizing the need for trauma-informed and attachment-focused treatment for individuals impacted by relational trauma. Limitations, future areas of research, and practice implications are discussed.

Abstract Name: "Get the Boot off Our Necks:" The Impact of the United Packinghouse Workers of America in Chicago

From the 1930s through the 1950s, Chicago was the center of early industrial meatpacking, being dubbed the 'hog butcher of the world.' The low wages, terrible working conditions and high rates of injury led workers to organize unions, including the United Packinghouse Workers of America in 1943. Historians of American labor unions have both underestimated racism and overstated some unions' claims to be racially inclusive. This paper uses oral histories and interviews to show how, in contrast, the UPWA was unique in its interracial leadership policies and in confronting racism among its own workers. By uniting workers across racial, ethnic, religious and gender lines, the UPWA was able to improve conditions for packinghouse workers.

Abstract Name: Mission-Driven Mentoring: Broader Purpose, Bigger Goals, Deeper Relationships

This session will spotlight the transformative nature of mission-driven mentorship in higher education. Though the missions of institutions are highly individualized and vary in the degree in which they permeate university life, the tenets of each mission can provide a framework for individual mentorship and subsequent student scholarship. Such a mission-driven framework is beneficial for faculty planning and student focus. At the same time, these experiences of shared language and goal setting can lead to enhanced trust, strengthened relationships, heightened creativity, and elevated outcomes. The emphasis on academic excellence, societal impact, and community connections can be identified across the missions of many, if not all, institutions of higher education. Explicitly embracing, discussing, and letting the mission of the institution guide the mentoring process may lead to competent and intellectually curious graduates who are also leaders, advocates, and empathetic professionals with enhanced levels of self-efficacy and sense of purpose. Examples of implementing a mission-driven framework for one-on-one mentoring will be provided using the Spiritan charism and mission of Duquesne University. A summary of mission statements across other colleges and universities will be presented and ways to extend some of these examples will be considered. Lastly, students and faculty in attendance will be led to reflect on the mission of their home institution and the potential benefits and challenges of utilizing a mission-driven approach to mentoring.

Abstract Name: Quantitative Analysis of Predictors of Self-Perceived Recovery from NSSI

Non-suicidal self-injury (NSSI) is the intentional injuring of one's body without the intent to die (Lewis et al., 2019). Efforts are needed to understand the motivation and recovery process of NSSI (Liu et al., 2024). Recovery can be experienced differently by individuals and may be influenced by various mechanisms (Lewis & Hasking, 2021). Andersson et al. (2024) qualitatively found three themes of recovery that encompass facets of self-compassion, social support, resiliency, and mental health distress. Most studies investigating NSSI recovery utilize qualitative methods (Lewis & Hasking, 2021) and our study expands this work by quantitatively examining variables related to perceived NSSI recovery. We hypothesized that self-perceived recovered individuals would score higher in self-compassion, social support, and resiliency and lower in mental health distress and self-criticism. We also explored which of these factors would predict perceived recovery. Participants included 712 young adults from a Midwest University (Mean age = 19.55, SD = 1.46, 73.4% female, 90.8% White) recruited through email to complete an anonymous online survey of constructs related to NSSI recovery. A 3x5 ANOVA revealed significant differences between groups and Bonferroni-adjusted post-hoc tests indicated self-perceived recovered individuals scored higher than unsure and not recovered individuals on social support and resiliency, and unsure individuals scored higher than not

recovered individuals, all $p < .05$. Unique group differences existed in self-compassion, self-criticism, and mental health and will be discussed. Linear regression analyses identified that all variables studied were significant predictors of perceived recovery, $F(8) = 12.16$, $p < .001$, accounting for 14.1% of the variance. Results indicate the recovery process is influenced by self-perceptions and general mental health. Although qualitative research indicates individual differences at various phases of recovery, the variables quantitatively studied should be accounted for when creating a plan for NSSI recovery.

Abstract Name: From the Stage to the Screen: The Evolution of the Amphitryon Theme

The Amphitryon theme has inspired numerous plays over the centuries, along with operas, musicals, and a full-length film. The Roman author Plautus wrote the first surviving play developed from the legendary story of Amphitryon and the engendering of Hercules. In doing so, not only did the Latin dramatist provide an enduring template that playwrights have followed more or less closely for the last two millennia, but also captivated writers beyond the theater. Written and directed by Reinhold Schünzel, the 1935 German musical film *Amphitryon: Luck Comes from the Clouds* offers a unique adaptation of the popular theme. This presentation will examine how film, as a medium, presents distinct advantages over theater in conveying the Amphitryon story. By analyzing Schünzel's filmic adaptation, I will explore how cinematic techniques enhance and transform the traditional elements of the Amphitryon theme. One advantage of film is its ability to exploit space in a way that stage productions cannot. In a theater production, space is inherently limited by the physical confines of the stage, which restricts the scope of the action. By contrast, the Amphitryon film uses the spatial freedom of the medium to expand the narrative far beyond the limitations of a stage. The film is able to seamlessly shift between locations—from the divine heights of Olympus to the mortal world below—using wide shots to highlight the scale of Jupiter's interventions and the contrast between the realm of gods and humans. Ultimately, the transition of the Amphitryon theme from stage to screen highlights the unique strengths of film as a medium. While theater has long succeeded in portraying the humor and complexity of mistaken identity, film provides opportunities to amplify that humor through hilarious visuals and exaggerated effects.

Abstract Name: Moldova: Impact of FDI and Corruption on GDP per Capita

This research studies the impact of foreign direct investments (FDI) inflows and corruption on the economic

performance of Moldova. Data is compared to peers like Romania, Estonia, Ukraine, and other countries from the former Eastern bloc. Previous papers concluded that higher FDI inflows paired with strong business relationships through free economic trade zones are beneficial for economic growth. Moldova plans to join the EU, which would be another favorable factor. Corruption is one of the factors that impacts economic growth negatively. Former USSR countries handled corruption differently. Some were more successful and others are still experiencing high levels of government and business corruption. A multiple regression model with 21 countries was used to compare different independent variables to the dependent variable GDP per capita. After six rounds of the regression, four of the seven independent variables made it to the final model. Results of the multiple regression model show that a low unemployment rate, government expenditure, trade balance, and lack of corruption had a significant impact on the GDP per capita.

Abstract Name: Investigation of Shared Therapeutic Targets in Lysosomal Storage Disorders

Lysosomal storage disorders (LSD) are a class of genetic diseases defined by a loss of lysosomal activity resulting in a pathological accumulation of biomolecules. LSD's individually are rare, but it is estimated that 1 in 8,000 are living with an LSD, and very few have a drug in development let alone FDA approved. Many companies struggle to develop therapeutics for LSD's, because there is not a large enough market for commercial use. Therefore, identifying a common therapeutic target is essential. Previous work on Niemann Pick Type C (NPC) revealed that lysosomes fail to project membrane tubules, thereby resulting in pathological accumulation of cholesterol and sphingolipids. This ultimately leads to impaired mitophagy and cell death. Although this pathway is compelling it is unclear if the other LSD's would see the same results. NPC is defined by impaired cholesterol transport through a membrane, whereas the other LSD's involve impaired enzymatic activity. However, because lipids other than cholesterol accumulate in NPC disease, it is possible that disorders involving these lipids, such as Hurler Syndrome, would see decreased lysosomal and mitochondrial activity in a similar manner. To investigate the commonalities, we induced Hurler Syndrome in COS-7 and N27A cells with ML-S1 and observed lysosomal and mitochondrial activity through live cell microscopy. We found that although there were some common morphological changes, there were some different between the two disorders.

Abstract Name: Repurposing Grape Pomace as a Bioadsorbent for Removal of Methylene Blue

In California, pomace, the product of wine pressing, is discarded in thousands of metric tons each year. The use of bioadsorbents in the removal of heavy metals and dye contaminants is an emerging field of study, often focusing on the repurposing of regional biowaste into a cost-effective solution. Dye contaminants have widespread negative effects on water systems, and the cationic dye, methylene blue (MB), is one of the leading water contaminants globally. Addressing both modern challenges, this study investigates the pomace biochar (PB) as an adsorbent by examining the effects of contact time, exposure method, and pH levels on the PB adsorption of MB from aqueous solutions. PB was prepared using sulfuric acid and low-temp firing to minimize ash content, maximizing adsorption. Of the exposure methods evaluated, mesh strainer containment produced the most consistent data. Green pomace biochar (GPB) adsorbed optimally at pH conditions of 7.0 to 11.0, the black pomace biochar (BPB) adsorbed optimally between 4.0 and 7.0, and became unstable in basic conditions. Both reached equilibrium between 45 to 60 minutes, and reached maximum percent removals between 45% and 65%. Analysis of the kinetics concluded that across trial methods and pH conditions both GPB and BPB align with the pseudo-second-order kinetic model. This study shows that PB is a fast-acting, efficient adsorbent of MB.

Abstract Name: Cultivating and Identifying Soil Bacteria with Antimicrobial Activity

The Tiny Earth Project aims to discover novel antibiotics from bacteria in local soils. There is a pressing antibiotic crisis where numerous bacteria and pathogens become untreatable due to increased antibiotic resistance. This dire situation is resulting in loss of lives and continues to claim more unless alternative antibiotics are developed to combat the resistance. In our contribution to the Tiny Earth project, we dedicated our efforts to exploring techniques for cultivating and identifying bacteria demonstrating antimicrobial activity. We conducted rigorous tests on soil samples from three distinct sites in our Milwaukee, WI community to identify soil bacteria present and evaluate their antimicrobial potential. Our primary goal was bacterial identification, and we have identified four colonies demonstrating resistance to either *B. subtilis*, *A. baylyi*, or both. Both are considered Safe ESKAPE pathogens, in other words relatives of pathogenic bacteria that do not cause disease and are safer to use. The next step in this research will be to further characterize the four colonies that displayed antimicrobial properties against safe ESKAPES.

Abstract Name: Evaluating Flavonoid Content in Black Beans (*Phaseolus vulgaris* L.) For Medical Advances

Various species of beans across the market are consumed by both humans and animals, particularly black

beans, as sources of nutrients like protein, fiber, and potassium. Existing literature proposes possible medicinal benefits for diabetes, heart disease, inflammation, and decreased risk of certain cancer cells offered through black beans. A plausible interpretation of this can be linked to the flavonoid content present in these beans. Flavonoid compounds contain antioxidant properties, cardiovascular protection, and anti-inflammatory properties that benefit the human body and lower the severity of many general sicknesses. Researchers have also begun to study black bean flavonoids as potential anticancer drugs as they may stop cancer cells from multiplying and decrease the risk of getting certain cancers. The primary source of these nutrients is fruits, plants, roots, and nutrients with a high level of aroma, such as coffee and beans. Previously, researchers at SJSU evaluated and compared the results of flavonoid content in Liberia, arabica, and robusta coffee species. They specifically looked for the concentration of catechin-based flavonoids across the 3 coffee species. The conclusion gathered is that the robusta species has a much higher concentration of Catechin and antioxidant capacity than the other species and may serve as a starting point for the pharmacological evaluation of coffee. The purpose of our project is to strengthen the connection between black beans and medical advances using the flavonoid content levels.

Abstract Name: Enhancing inter-material bond strength in multi-material 3D printing using a custom adhesive application toolhead

The integration of multiple materials in Fused Filament Fabrication (FFF) 3D printing presents significant opportunities to enhance the versatility and functionality of additively manufactured parts. However, inadequate inter-material bonding continues to hinder the mechanical performance and reliability of these components. This research seeks to address this challenge by developing and implementing a custom toolhead for FFF 3D printers, designed to deposit an adhesive layer at the interface of dissimilar materials during the printing process. Experimental investigations include lap-shear testing to evaluate the bond strength of multi-material parts produced using various material and adhesive combinations as well as resolution testing is conducted to determine the minimum feature size compatible with the adhesive application process. It is predicted that the incorporation of adhesives significantly enhances inter-material bond strength compared to conventional multi-material printing techniques. Furthermore, the resolution capabilities of this method are expected to enable the fabrication of intricate features that surpass the limitations of alternative bonding methods. This study highlights the potential of adhesive-enhanced 3D printing to overcome critical inter-material bonding challenges, paving the way for advanced multi-material applications in diverse fields, including biomedical devices, electronics, and structural components. The findings underscore the versatility and scalability of this approach, offering new possibilities for multi-material additive manufacturing.

Abstract Name: Having the Linguistic Upper Hand: The Dynamics of English as a Lingua Franca in Contemporary Social and Political Contexts

This study examines the role of American English as a global lingua franca and its implications for cultural identity and language preservation among Arabic-speaking second-language English users. I focus on the sociolinguistic aspects of English's global dominance and its influences on linguistic standards, cultural identity, and multilingual communication. A series of interviews with Native and heritage Arabic-speaking participants focused on their use of English in personal, professional, and contemporary political contexts. I explore the challenges in maintaining their native language and strategies for cultural preservation. Thematic analysis revealed recurring themes of global mobility, identity negotiation, and language loss, highlighting the complex interplay between linguistic adaptation and cultural resilience.

Abstract Name: Examining Gender Differences in the Relationship between Stigma, Help Seeking Intentions, and Substance Use

Between 2002-2022, the age-adjusted overdose rate in the US was 32.6 per 100,000 people. Although men are more prone to overdose deaths, a trend published by the National Center for Drug Abuse Statistics shows that women are experiencing an increase in annual overdose deaths. Moreover, recent studies show that women are more likely to face barriers that prevent treatment-seeking for substance use. Furthermore, stigma is one of the most salient, complex, and least understood barriers to substance use help seeking. This project investigates the impact of gender and the role of stigma on help seeking intentions for substance use. It is critical to investigate the impact of perceived stigma and personal stigma on intentions to seek treatment in order to further inform our understanding of help seeking in substance use and to improve accessibility and feasibility of seeking help for substance use. A nationally representative sample from the 2019-2020 Healthy Minds Study was used to examine the relationship between gender and help seeking intentions in those who admit to substance use and if there is a difference between the impact of perceived and personal stigma on the help seeking intentions on help seeking intentions. Statistical analysis via comparison of means and chi-square analysis provide insight into the nature of stigmas relationship on help seeking intentions among gender and substance use.

Abstract Name: Costs of Quality: Transaction Cost Economics in Higher Education Accreditation

This paper examines the transition from input-based to output-based quality assessment in U.S. higher education over the last century. Initially, the high cost of collecting output data led to the formation of voluntary accreditation associations focused on input metrics. Recent critiques have highlighted how accreditation limits competition by controlling market entry. Yet the economic dynamics behind accreditation's development still need to be explored. I propose that the evolution of accreditation standards is closely tied to the relative costs of measuring inputs and outputs. *Ceteris paribus*, outputs are preferred for quality assessment. However, inputs have been used when measuring outputs was cost-prohibitive. As the cost of gathering output data decreased through the 20th and 21st centuries, there was a noticeable shift towards using output metrics. This study analyzes accreditation standards from three distinct periods: before World War II, 1960-1990, and post-2020. For each era, I detail the specific input and output criteria set by accreditors, using comparative analysis to illustrate shifts over time. Standards were sampled from the seven regional accreditors. The findings reveal a clear trend towards output-based assessment. Suggesting that as output metrics become more cost-effective, colleges can manage quality assessment independently. The shift to outputs could reduce the significance of accreditors in quality assurance and open the higher education market to more competition.

Abstract Name: The Impact of Podcast on Mental Health in High-school Students within the U.S.-Mexico Border Region

Mental health concerns in high school students are especially pronounced during life transitions, such as the shift from high school to college. These periods often lead to heightened anxiety, stress, and maladaptive coping mechanisms, negatively affecting overall well-being. Due to the cultural stigma associated with mental health, high school students within the U.S-Mexico border region often refrain from seeking help, which makes it difficult to manage their emotional well-being during important life transitions like getting ready for college. This service-learning project in collaboration with The 100-Solution Organization, aimed to assess the impact of podcasts as an educational tool to enhance mental health literacy among high school juniors and seniors, raise awareness about local resources, and address cultural stigma. To help break down stigma and provide resources involving mental health, we collaborated with a licensed counselor to answer a series of questions surrounding the topics of cultural stigma on mental health within the border region and transitional periods in students' lives. Using the podcast room at The University of Texas at El Paso, we recorded and distributed a podcast to students and school counselors. Participants were surveyed using a modified impact survey to evaluate the podcast's effectiveness. The results revealed significant positive outcomes. Fifty-six percent of participants were previously unaware of local mental health resources. Notably, 100% of participants found the podcast helpful, and 96% expressed a willingness to share the information with peers, highlighting the podcast's relevance to their needs. Overall, this project highlights the promise of innovative, accessible educational tools like podcasts to improve mental health literacy and support high school students, particularly in border communities, during critical life transitions.

Abstract Name: The Role of AI-Driven Gaming Platforms in Fostering Understanding of Neurodiversity Among University Faculty and Staff

This study examines the potential of AI-driven gaming platforms to enhance understanding and acceptance of neurodivergent individuals among faculty and staff at the University of Michigan. Neurodivergence, encompassing conditions such as autism, ADHD, and dyslexia, continues to be accompanied by misconceptions and stigma within academic and professional environments. These biases hinder the development of inclusive institutional practices that address the diverse needs of all individuals. By leveraging the immersive and interactive capabilities of AI-powered gaming, this research aims to simulate the lived experiences of neurodivergent individuals, fostering empathy, promoting awareness, and challenging entrenched stereotypes. The project employs a mixed-methods approach, integrating both technical development and user engagement. The engineering component involves the creation of AI-driven gaming prototypes using platforms such as Unity for interactive environments and Unreal Engine for high-fidelity simulations. Additionally, the project incorporates adaptive AI technologies such as Reinforcement Learning to tailor challenges to player responses, simulating scenarios like sensory overload or difficulties in executive functioning. Examples of similar approaches include games like *Hellblade: Senua's Sacrifice*, which used audio-visual elements to depict mental health struggles, and *Auti-Sim*, a game designed to simulate sensory experiences of individuals with autism. Faculty and staff participants will engage with the platform, and their experiences will be evaluated through gameplay analytics, pre- and post-engagement surveys, and qualitative interviews to assess changes in empathy and understanding. Preliminary findings indicate that AI-driven gaming platforms offer significant promise as educational tools, allowing users to connect with neurodivergent perspectives in transformative ways that traditional methods do not achieve. This project underscores the critical role of innovative technologies in addressing stigma and advancing neurodivergent inclusivity within higher education. The study contributes actionable insights for institutions seeking to implement effective diversity and inclusion initiatives, while also challenging the persistent taboos associated with neurodivergence in professional and academic contexts.

Abstract Name: Decoding Mixed Microbial Communication Through Stereoisomeric Enantiomers of 12-Hydroxystearic Acid

Bacterial species use signaling molecules to communicate, but the mechanisms underlying communication in mixed-species environments are not well understood. In our study, we identify several signaling molecules produced by Wheatgrass mixed microbial culture (MMC). Notably, Wheatgrass MMC predominantly produces the (R)-isomer of 12-hydroxystearic acid (HSA), which is commercially available, alongside a smaller quantity of the (S)-isomer, which is not commercially available. Using the Mitsunobu reaction, which can be used to invert the stereochemistry of secondary alcohols, we successfully produce the (S)-isomer for further investigation of its role in biofilm formation. While the individual effects of each isomer on biofilm formation are explored, we also examine their combined effects, as interspecies communication appears to involve both enantiomers. This raises an intriguing question: how do varying ratios of these isomers influence bacterial behavior, potentially signaling them to form biofilms or adopt a planktonic state? To address this, we test different (R) and (S)-isomer ratios on biofilm formation, revealing new insights into how bacteria in mixed microbial cultures, mirroring their natural environments, communicate through stereochemical differences. Understanding these mechanisms is critical, as biofilms pose significant challenges across healthcare and industrial sectors, contributing to antimicrobial resistance and contamination. By gaining a better understanding of how bacteria chemically "talk" using (R) and (S)-12-HSA isomers, we may unlock innovative strategies to disrupt harmful biofilms, raising the question of whether manipulating these stereochemical signals could hold the key to controlling bacterial behavior in complex ecosystems.

Abstract Name: Maternal Nutrition and Its Impact On The Risk of Birth Defects

Pregnant women often underestimate the critical role nutrition plays in their health and their baby's development. This research aims to highlight the importance of a balanced diet during pregnancy, detailing the best food sources for essential vitamins and minerals. Studies show that malnutrition is a leading cause of various birth defects and illnesses. Waldrop et al. (2024) emphasize that fetal neurodevelopment and visible traits depend on the timing and type of nutrient deficiencies, as different brain regions have unique nutritional needs. A lack of key nutrients during fetal development can impair brain function and physical traits, affecting both the mother and child. The findings reveal the specific roles of vitamins and minerals in fetal growth, the risks of deficiencies, and the recommended daily allowances for pregnant women. While much attention is given to the baby's health, this study underscores the need to address the risks poor nutrition poses to mothers, such as complications and illness. Future research should explore these gaps, focusing on the mother's health alongside fetal development to ensure comprehensive care during pregnancy.

Abstract Name: Sublethal effects of piperonyl butoxide, a common insecticide synergist, on bumble bee microcolonies

Piperonyl butoxide (PBO) is a common insecticide synergist used in agricultural products throughout the U.S. PBO increases the effectiveness of insecticides by blocking insect detoxification mechanisms. On its own, PBO is considered relatively non-toxic to non-target organisms such as honey bees. However, little research has evaluated its toxicity and sublethal effects on other bees, such as the common eastern bumble bee (*Bombus impatiens*). Using Environmental Protection Agency (EPA) guidelines, we calculated a field-realistic concentration of PBO and dosed bumble bee microcolonies. Mortality, sucrose consumption, and the total number of brood cells and nectar cups were compared between control and PBO-dosed microcolonies. In general, we found limited effects of PBO on any bumble bee response variable. Future studies should evaluate a larger range of field-realistic doses on bees in addition to measuring other sublethal effects such as behavior and physiology.

Abstract Name: The Relationship between Alcohol Myopia and Susceptibility to Illness Among College Students

Alcohol is woven throughout our culture – especially among college students. Despite more recent interventions and research on the detrimental effects of drinking, alcohol-related consequences persist on college campuses. One potential explanation for this may be explained by Alcohol Myopia theory. Alcohol Myopia is defined as the constraint of attention to solely the present moment due to the effects of acute alcohol use on attention processes. Alcohol's myopic effect can be split into three categories: relief, excess, and self-inflation. Relief is alcohol's ability to cause someone to pay less attention to their problems. Excess is the tendency of someone under the influence would exaggerate their feelings, actions, and beliefs, and self-inflation is defined as the feeling of grandiosity an intoxicated person tends to feel. These effects may limit one's focus leading to potential negative consequences. Perceived Susceptibility is a construct from the Health Belief Model, representing the belief of how vulnerable one is to illness. Given alcohol's known myopic effects there is a possibility that during drinking episodes, individuals may not attend to cues or perform behaviors that would limit exposure to or protect from illnesses. Therefore, the focus of the current study is to examine the relationship between alcohol's myopic effects and perceived susceptibility to illness among college students. Participants will be university-attending students and will engage through an online survey. We will be using the Alcohol Myopia Scale and a Perceived Susceptibility to Illness Scale. Expected results are that as there is an increase in the effects of alcohol myopia would lead to a decreased level of perceived susceptibility to illness. Though data collection is ongoing, results from this study can be used to develop interventions regarding illness protection strategies while drinking.

Abstract Name: Testing the efficacy of topical RT175 for enhancing pigmentation

Stem cell dysfunction is one hallmark of aging. In an attempt to identify small molecules that rejuvenate stem cells or promote tissue regeneration we utilize the pigment system of the hair. Melanocyte stem cells, which reside in the hair follicle, are required to regenerate the differentiated melanocytes that produce hair color. Failure in this system results in an easily identifiable gray phenotype, providing an ideal model system for this research. Previously, we used the immunophilin ligand RT175 in combination with drugs cyclosporin A and minoxidil to determine their effects on pigmentation in gray haired mice. The results indicated that in combination these drugs induce hair growth and stimulate the production of pigment. We also showed that RT175 can affect melanocyte gene expression autonomously through in vitro treatments. We have now investigated the isolated effects of RT175 in vivo in mice by examining its regenerative properties in tissue, examining epidermal pigment production. The ears of one-year-old, male mice were treated with different doses (low, medium, and high) of RT175 or DMSO vehicle control for thirty days. Wholemount images of these ears demonstrated a change in pigmentation intensity and pattern based on treatment. To better quantify

these changes, tissues from ears of each treatment group were analyzed using the threshold function in the software Image J and indicated that pigmentation levels between groups trended upward in the medium dose but were not statistically significant. Future analyses will focus on defining novel methods to better quantify these pigmentary changes.

Abstract Name: Comparing Health Insurance Rates Among Non-Citizens in the California San Joaquin Valley Before and After Medi-Cal Expansions

The Central Valley, which is home to a large number of immigrants in California, faces several disparities involving health insurance coverage. Evidence from regional health reports suggests that statewide improvements through initiatives such as the Affordable Care Act and Medi-Cal eligibility expansions to all residents regardless of documentation status have provided some sense of relief. This study aims to capture the impact of these policy shifts on health insurance coverage for immigrants, in the San Joaquin Valley (SJV), the southern portion of the Central Valley. To measure this, annual data from the U.S. Census Bureau exported for the 2022 and 2015 SJV populations (n=8 counties). Tables were merged and cleaned in Microsoft Excel to create descriptive summaries for health insurance by county and plot trends by year using graphs. Maps were created using the data.census.gov interactive tool to visualize shifts. We found that the SJV experienced major increases in health insurance coverage, although between-county disparities persist. These results help highlight the importance of tailored policy interventions and resource allocation to address the unique health insurance coverage challenges faced by immigrants in the Central Valley. Furthermore, the findings underscore the necessity of ongoing support and monitoring to ensure that statewide health initiatives are effectively reaching and benefiting all communities, particularly those that are most vulnerable and underserved.

Abstract Name: Build-A-Mentor: Helping Undergraduates Understand the Value of Mentors and Mentorship

This presentation by Christopher Newport University administrators and students stresses the importance of undergraduate mentorship and the value of searching for an appropriate mentor for both research and general support. Based on a lesson for URCA 101: Introduction to Research and Creative Activity, the presentation identifies the best characteristics of a mentor and how to search for suitable potential mentors. The session highlights student experiences (several current students and alums will co-present) discussing their challenges, obstacles, and successes. By synthesizing insights from psychology, pedagogy, and management, we present a mentor-building framework that emphasizes interpersonal skills, domain knowledge, and

reflective practices. We suggest that investing in a structured mentor search can greatly enhance mentorship outcomes, benefiting both mentors and mentees and contributing to a stronger, more supportive research and creative community.

Abstract Name: Bioremediation of Uranium and Copper Contaminated Water using *Shewanella oneidensis*

Heavy metal contamination is a global concern. Bioremediation offers a sustainable and eco-friendly way of removing these contaminants. Bioremediation is the process of removal of heavy metal pollutants using biological systems. This study investigates using *S. oneidensis* for the sustainable bioremediation of uranium and copper in wastewater. This research evaluated the efficacy of *S. oneidensis* in heavy metal removal under aerobic and anaerobic conditions, using a UV spectrophotometric technique to measure. Two metals of significant importance, copper and uranium salts, were used as substrates for testing the efficacy of *S. oneidensis* in the bioremediation process. Uranium was significantly removed in all time intervals at 4mM. Still, significant removal was observed only after 1 month at 2mM. For copper, concentrations of 10mM and 20mM were effectively reduced under aerobic and anaerobic conditions. In anaerobic conditions, the efficacy of *S. oneidensis* in bioremediating both metals was high. The findings confirm *S. oneidensis*'s potential as an effective agent for removing hazardous metals from wastewater, offering a viable strategy for sustainable environmental management

Abstract Name: Enhancing Diagnostic Accuracy in Laryngeal Cancer: A Comprehensive CLE Scoring System

In the United States, an estimated 16,000 people are diagnosed with laryngeal cancer each year, with most patients being 55 or older, and Black men being the most vulnerable demographic. The five-year survival rate is about 50% [1]. Developing methods for real-time malignant cell detection can help ensure accurate tumor margins, prevent recurrence, and conserve physiological structures. Confocal Laser Endomicroscopy (CLE) allows real-time tissue microarchitecture assessment using a mini probe, providing cellular-level details

without compromising tissue integrity. Widely used across various specialties, CLE has found an additional role in head and neck cancer surgery. However, CLE often relies on subjective interpretation, causing variability in reporting. To improve accuracy and precision, a scoring system based on histopathological criteria, considered the gold standard in cancer diagnosis, can help create objective data for CLE image and video evaluation. This study proposes a modified LPCIS CLE scoring system based on the histopathological characteristics of dysplastic epithelium. The new system builds on a previous six-criteria scoring system for the larynx and pharynx, expanding it to eight criteria that reflect cellular changes typical of cancer in histopathological evaluations. This method allows observers to assign numerical values to images, similar to how pathologists examine tissue specimens. Using a “weighted” system with reference to the 14 Hallmarks of Cancer, a scoring criteria system/criterion was developed, with scores higher than 3 indicating an increased probability of being dysplastic. This approach enhances diagnostic accuracy and supports better clinical decision-making in managing laryngeal cancer, providing the potential for the introduction of CLE as a clinical standard during intra-operative tissue assessment in real time for during head and neck tumor resection surgeries.

Abstract Name: Inhibitor of Differentiation 1 (ID1) is Overexpressed in Oral Squamous Cell Carcinoma and Cervical Cancer Tissues

Both oral squamous cell carcinoma (OSCC) and cervical cancer (CC) disproportionately affect low-income and rural individuals in the United States. Developing quick, accessible testing methods for OSCC and CC provides an avenue to combat challenges low income and rural populations face and to obtain early detection, resulting in greater survivorship and reducing the inherent health disparities and barriers that exist among these communities. Inhibitor of Differentiation 1 (ID1) plays a key role in tumorigenesis and regulates cell proliferation. We propose an ID1-based detection methodology; however, the quantification of ID1 as a specific marker for both cancers is understudied. While ID1 expression has been characterized in literature, reports are limited, and display some discrepancies between cancer types. This project aims to evaluate ID1 as a relevant biomarker for OSCC and CC through immunohistochemistry (IHC) analysis in tissue microarrays. Using H-DAB immunohistochemistry with an ID1 primary antibody, 62 Stage I/II OSCC samples, 38 normal, and 22 chronic inflammatory samples were analyzed using QuPath, an open-source digital pathology software. Similar H-DAB IHC was conducted with various stages of CC tissues, totaling 99 samples and 10 normal tissues. Results indicate through optical density value comparison that ID1 is significantly ($p < 0.0001$) overexpressed in early-stage OSCC ($2.3e5 \pm 9e4$) tissues compared to both normal ($1.6e5 \pm 7e4$) and chronic inflammatory ($1.5e5 \pm 4e4$) samples. In CC, ID1 was significantly ($p < 0.05$) overexpressed in both early ($3e5 \pm 1e5$; $p = 0.0001$) and late-stage ($3e4 \pm 3e4$; $p = 0.0002$) tissues relative to normal tissue. The promising findings present opportunities for ID1 as a novel biomarker, namely through its incorporation in novel plasmid-based testing methods that indicate tumor presence.

Abstract Name: Temperature dependent sensitivity study of gas sensors based on polyaniline/TiO₂/graphene oxide ternary nanocomposites

In this work, the selectivity and sensitivity of polyaniline (PANI), synthesized via oxidative polymerization, to NH₃ and CO gases in chemiresistive sensors was investigated at the presence of nano-sized (25-90 nm) TiO₂ and graphene oxide (GO). Gas sensors were constructed on Pt interdigitated electrodes via spin coating of PANI-based composites. All sensing measurements were carried out under ambient conditions at room temperature with humidity levels of 45-75 %. Significantly improved sensitivity to the presence of NH₃ and CO, in concentration ranges of 10-150 ppm, was observed for the PANI-TiO₂-GO nanocomposites, compared to PANI alone. Easily detectable resistance changes of 10-60 Ohms were measured. The composite exhibited a sensitivity of 13-15 % at 50 ppm gas concentration. The response time was measured to be less than 5 seconds with recovery time dependent upon the gas concentration, which ranged from 5 min to 25 min. Further investigation into the temperature-dependence of gas sensitivity of PANI-based nanocomposites is currently underway. Details of this work will be provided in this presentation.

Abstract Name: Protecting Women in Higher Education: The Life and Activism of Bernice Sandler

Title IX of the Education Amendments of 1972 has influenced the American education system for over fifty years. Although activist Bernice Sandler played a central role in the amendment's creation, historical scholarship rarely mentions her contributions, and only usually to proclaim her to be the "Godmother of Title IX" without much explanation as to how she earned the title. General histories of Title IX primarily focused on the interactions between the amendment and athletics. When her work is included in scholarly texts, it is usually limited to her activism beginning in the late 1960s and leading up to the passage of Title IX in 1972. In reality, Sandler remained highly involved in the legislative process for implementation and her work continued until she died in 2019. By using Sandler's oral history with Indiana University, Congressional testimony, and newsletters, my research creates a more detailed analysis of the early origins of Title IX and its broader implications for sex equality in higher education beyond athletics. It is clear from the primary sources that Bernice Sandler's personal experiences in higher education pushed her to become an advocate for other women. Her innovative use of Executive Order 11246 and outreach campaigns greatly contributed to the passage of Title IX. Sandler also relied on a strong network of policymakers and activists to achieve legislative goals and increase national awareness. I argue that Bernice Sandler's strategies for activism and her use of a network were innovative and essential to the success of Title IX.

Abstract Name: Exotic to Iconic: The Story of Chinese People in America Through Cookbooks, 1911-2022

From the early 1900s through the present, Chinese cookbooks have reflected the history and status of Chinese Americans in the United States while also attempting to educate white Americans about Chinese culture and cuisine. Through Chinese cookbooks published from 1911 through 2022 and secondary sources that provide historical context, this paper traces the evolution of Chinese cookbooks from those geared toward predominantly white audiences with Westernized recipes to more authentic representations of Chinese cuisine. Chinese immigrants began to arrive in the United States after the start of the Gold Rush in 1848 and during the construction of the transcontinental railroad. Beginning in 1882, the Chinese Exclusion Act restricted the immigration of Chinese people into the United States. In these early years of Chinese cookbooks, the emphasis was on making Chinese food accessible to non-Chinese cooks and palates. Following World War II, Americans sought cheap and nutritious food, and Chinese cookbooks reflected this. Cookbooks by white and Chinese American authors aimed to demystify Chinese food for Americans and bridge cultural divides by simplifying or modifying recipes to suit American palates. However, as Chinese food gained popularity and the status of Chinese Americans changed, cookbooks began to present authentic recipes and dishes from different regions in China. They were increasingly written for wider audiences such as American-born Chinese people. The changes in Chinese cookbooks highlight the changing perceptions of Chinese food and Chinese Americans in the United States from an exotic curiosity to a culinary experience, signaling the growing acceptance and appreciation of Chinese food and culture in America.

Abstract Name: HEALTH AND ASSOCIATED FACTORS IN EAFIT UNIVERSITY MUSIC STUDENTS

Musical formal training has particularities in the academic experience, due to the intensity and personalization of their musical training from an early age. Likewise, there is previous evidence that suggests greater affectations in the health of music students in comparison with other university students. Therefore, this project seeks to identify the prevalence of emotional symptomatology and the factors that influence the health of this population, with the objective of developing specific interventions. The research method is mixed, combining a quantitative and qualitative phase. The research involved 32 participants, who were administered the Mini International Neuropsychiatric Interview (MINI) to assess mental disorders and semi-structured interviews to explore in depth the students experience. Analysis of the data collected includes

descriptive analyses for the quantitative results and thematic analyses for the qualitative interviews. Partial results shows that 32.1% of the participants have symptoms of major depression, 28.6% have generalized anxiety, and 17.9% are at risk for suicide. The interviews show that most of these students have scholarships to study, and they perceive a close relationship with their master of the instrument, comparing them to relationships with their mothers. However, this means that they feel stressed when they have tensions with their mentors, and their mentor's opinion about their performance usually affects their self-perception. Regarding habits, most of them spend more than 8 hours in the university studying, practicing and socializing, but they usually stay in their building, which means that they usually relate only to themselves. In terms of beliefs, we found that students don't think they can be successful if they stay in Colombia, that musical training must start early in life to be good, and that those who start later have a gap that is very difficult to fill.

Abstract Name: Teach Me Telugu: A Language Accessibility Project

Telugu is a Dravidian language of approximately 80 million native speakers and is spoken primarily in the states of Telangana and Andhra Pradesh in Southern India. When I first started learning the language in my Freshman year, I encountered many barriers that slowed down my progress, including lack of language learning resources and support from native speakers. That is why, in the fall of 2022, I created the "Teach Me Telugu" project, with a vision that accessing the Telugu language could become as easy as a mouse click. Over the years, the "Teach Me Telugu" project has gained traction and covered several milestones, including the creation of a short film, podcast, and website. By the time I graduate college, I hope to conclude the project by creating a free, high-quality Telugu alphabet course designed for an international audience, and redigitizing an old course called "An Intensive Course in Telugu" by uploading all 64 lessons (specifically, the dialogues and vocabularies) on Youtube as beginner-friendly podcasts with accompanying Telugu and English subtitles. My hope is that these resources will serve as a stepping stone for anyone eager to learn Telugu, no matter where they are in the world.

Abstract Name: The Use of Thermal Imaging to Compare Skin Surface Temperature in Long Distance Runners and Age-matched Controls After Running an 8-minute Mile

As a person's core body temperature rises during exercise, the body rids itself of excess heat through

sweating, conduction, convection and infrared radiant heat loss. Thermography measures radiant heat loss of skin covering actively contracting muscle. A Seek® thermal imaging camera was used to measure torso skin surface temperatures in collegiate long-distance runners (n=3), and non-athlete controls (n=3) to compare heat loss associated with actively contracting accessory muscles of respiration. All participants were photographed before and after running an 8-minute mile on an indoor track. It was hypothesized that an 8-minute mile would not require recruitment of accessory muscles of respiration in long-distance runners but would require recruitment of accessory muscles (Rectus abdominus, Pectoralis major and External obliques) in controls. Control runners showed a moderately significant drop in average temperature of the anterior torso (8% drop with $p=0.04$) but not in the posterior torso (5.6% drop with $p=0.06$). These data are consistent with active recruitment of anterior torso muscles and an associated need to dissipate heat after exercise. The drop in torso temperature was most pronounced in skin covering accessory muscles of respiration like the Pectoralis major, Rectus abdominus and External oblique muscles. The posterior torso contains few accessory muscles of respiration, therefore, a significant drop in posterior torso temperature was not expected. Although average torso temperature did drop slightly in long-distance runners following exercise, the results were not statistically significant on either the anterior (4.9% drop with $p=0.08$) or posterior (4.8% drop with $p=0.08$) surfaces. Thermography is a non-invasive tool to measure skin temperature above actively contracting muscle during exercise. Information gleaned from this technology may be used to assess athletic performance.

Abstract Name: Quantifying mineral content in different fertilizers and analyzing how it affects plant growth and amino acid content

The purpose of this research was to determine the effects of different fertilizers on plant growth and amino acid content. The plants chosen were lettuce and radish. Furthermore, some testing was done on three out of the four fertilizers used to compare and contrast the amounts of different minerals to the corresponding labels. The concentrations for most of the minerals tested were lower than expected, however this could be due to interferences on the atomic absorption spectrometer. The determination of amino acids on the high-pressure liquid chromatography machine was unsuccessful, two different methods were used but the only two amino acids present on the samples were isoleucine and phenylalanine. The plants showed a correlation between higher fertilizer concentration and growth.

Abstract Name: Fostering Civility in Nursing: Addressing Workplace Incivility to Mitigate Moral Injury, Compassion Fatigue, and ultimately Burnout!

Incivility refers to disrespectful and unprofessional behavior that violates workplace norms and undermines a positive and productive environment. In the nursing context, workplace incivility and bullying remain pervasive challenges that significantly contribute to compassion fatigue, moral injury, and burnout. These systemic issues disrupt teamwork, reduce job satisfaction, and increase turnover rates, posing severe consequences for healthcare delivery and patient outcomes (Ahmadi, S., et al. 2024). A systematic literature review to better understand how to address these issues reveals that leadership built on accountability, zero-tolerance anti-bullying policies, ethics support systems, and mindfulness programs are critical in mitigating incivility in the workplace. These interventions not only improve nurse retention but also enhance patient care delivery by fostering resilience, self-compassion, and collaboration among nursing and intra-departmental staff. Cultivating civility is essential to address systemic stressors in nursing workplaces, thus creating a culture that prioritizes nurses' well-being and advances positive patient outcomes.

Abstract Name: "The Impact of Nutrition on Academic Performance: Addressing Food Accessibility and Equity in Education"

The relationship between food and academic performance is widely studied, showing a strong connection between nutrition and cognitive abilities, which directly affect academic success. For the brain to function at its best, it requires essential nutrients, vitamins, and minerals. However, many students in the United States do not consistently receive these necessary nutrients, negatively impacting their academic outcomes. To fully understand the influence of food on learning, it is essential to examine how various diets affect individuals with different health conditions, recognizing that "healthy" is relative to each person. This research explores how healthy and unhealthy food choices affect academic performance in K-13 students and examines the impact of providing balanced, nutritious meals. By comparing food programs across different school districts, the study evaluates their effects on student outcomes. It also reviews the historical development of school lunch and breakfast programs, examining how policies and legislation have shaped access to healthier meals and their impact on student performance. The findings reveal that limited access to nutritious food is linked to poorer academic performance, emphasizing the need to address social disparities in food availability. Programs aimed at promoting healthier eating habits in schools show promising results, improving focus and cognitive function. On the other hand, diets high in sugar and low in quality contribute to reduced attention and learning capabilities. High-quality meals and balanced diets enhance scholastic performance and provide a foundation for equitable educational opportunities. Addressing food insecurity, fostering better eating habits, and ensuring all students' nutritional needs are met are critical steps toward improving academic success and bridging gaps caused by socioeconomic disadvantages.

Abstract Name: Olfactory system alterations in a novel model of dopaminergic loss by 6-OHDA injections in adult zebrafish

Parkinson's Disease (PD) is a neurodegenerative disorder characterized by dopaminergic neuronal loss and severe motor impairment. Olfactory loss is prevalent in over 95% of those with PD and is a symptom that precedes motor deficits in most individuals. However, the mechanisms linking PD and olfactory dysfunction are not well understood. It has been proposed that dopaminergic loss causing retrograde degeneration in the olfactory system might be underlying this phenomenon. Zebrafish provide an ideal model to study these processes, as their olfactory system is analogous to those of mammals and olfactory bulb (OB) contains a large population of dopaminergic neurons that mediate olfactory function. They exhibit lifelong neurogenic capability and neuroplasticity, an ideal model for studying possible repair processes in neurodegenerative diseases. We generated a model of dopaminergic loss in the OB of zebrafish by injection of 6-hydroxydopamine (6-OHDA) into the cerebrospinal fluid at the ventricular zone between the olfactory bulbs and the telencephalon. We aimed to target dopaminergic neurons in the OBs but not in posterior motor nuclei so as not to alter locomotion. We assessed dopaminergic neuronal loss, markers of inflammation, morphological changes of olfactory axons, and pre-synaptic markers following the injections using immunohistochemistry. We evaluated olfactory function utilizing behavioral assays, and observed a dramatic increase in the number of apoptotic cells in the OB 1- and 3-days post injection (dpi) as well as a significant loss of dopaminergic neurons, confirming a successful lesioning method. There was an increase in the neuroinflammatory response, using GFAP staining at both time points, and found disturbances in olfactory-mediated behavior suggesting olfactory functional alterations. Our results show that we successfully optimized a novel method for injection of 6-OHDA to target dopaminergic neurons in the olfactory system. We can use this model to further study the relationship between dopaminergic loss and olfactory alterations.

Abstract Name: Preserving a Faith in Humanity

One feature of present-day Western culture is its faith in inherent human goodness. While this faith has existed for a while, it has had to defend itself from challenges, with the atrocities of Nazi Germany being one of the sharpest. A society of "ordinary" people had either perpetrated or ignored the ugliest kind of evil, en masse. This could signify a fundamental depravity rooted in the human spirit, or it could signify the power of the pressure to conform to society. In order for human nature to be inherently good, it also had to be malleable, threatened or even overpowered by adverse influence. Consequently, in the period following the war, Western culture had to grapple with its beliefs about good and evil, individuals and society. An analysis of sources from this time period reveals a persistent faith in a good human nature and an attendant fear of influence and conformity. In *Eichmann in Jerusalem*, historian Hannah Arendt wrestled directly with the Nazi phenomenon. Thomas Merton, in his poetry, considered instead the U.S.A.'s atomic bomb. Artists expressed their concern about a stifled human spirit from different angles. Some even saw hope in a malleable human spirit, which the right influences might mold towards good. By integrating an analysis of these and other Western cultural products, it becomes possible to see the relationship between the faith and the fears. They express convictions about humanity still with us today. They also express the costs, and the immense responsibility, which such a faith requires.

Abstract Name: Fostering International Scholars: Course-Based Undergraduate Research Experiences at a US University

As tertiary education in the United States becomes increasingly diverse because of global migration, universities need to adapt and create opportunities for all students to participate in meaningful academic learning endeavors. Early research experiences are impactful for student learning and student retention. This presentation will explore the effective implementation of Course-Based Undergraduate Research Experience (CURE) at an internationalized university in the American Midwest. In a time where internationalization holds paramount importance, one primary goal for universities is to nurture competitive international scholars. Over the years, the presenters' research team proactively mentored more than 100 domestic and international students representing diverse backgrounds from Ecuador, Ethiopia, Uzbekistan, as well as students with bi-cultural identities. Despite limited prior exposure to academic research, these students brought with them invaluable international and intercultural perspectives that significantly enriched the research process. The presenters established and fostered mentor-mentee relationships among these students. By providing guidance, mentorship, and implementing a structured CURE framework, these students not only bridged the gap in their research skills but also utilized their unique international backgrounds to identify and explore innovative scholarly inquiries. The report highlights the successful approach to organizing CURE programs that are both inclusive and responsive to the diverse student body. These international and bi-cultural students' experiences serve as evidence of the potential of CURE in fostering early professionals in academic research. These insights will inform and encourage scholars and educators on effective strategies to cultivate the next generation of research professionals within the globalizing landscape of tertiary education.

Abstract Name: How Gender Inequality Drives the Human Trafficking Industry

There are currently more than 40 million people subjected to human trafficking worldwide. People living under forced servitude and sexual exploitation, people in forced marriages, and child soldiers all of which are victims of human trafficking. Research has shown that 71% of these victims are women and girls, making human trafficking a disproportionately gendered issue. However, does gender impact trafficking as a whole? The crux of this study uses a meta-analysis, a statistical combination of the results of multiple studies addressing a similar research question, to understand how gender inequality relates to human trafficking. The main variables this paper looks at are a country's gender development index score, the number of cases of human trafficking in a country, and the most prevalent types of trafficking in a given country. A country's gender development index score comes from the difference between men's and women's achievements in three categories: health, education, and command over economic resources. The purpose of using a meta-analysis is to gain evidence from multiple studies, increasing the statistical power to get more conclusive results. From the evidence taken from the meta-analysis study, we can expect that countries with higher

gender inequality index scores will have high rates of human trafficking and a lower Trafficking in Persons (TIP) Report score from the Trafficking Victims Protect Act (TVPA). The TIP Report is an annual status update on global anti-trafficking efforts. There are three tiers, and the lower a country's tier is, the worse its efforts against trafficking are. The research on gender and trafficking is limited. Still, it is crucial to research this issue further to widen people's understanding of human trafficking and the implication gender inequality has on trafficking to protect individuals better and combat trafficking every day.

Abstract Name: Examining the evolutionary divergence of duplicated genes that regulate yeast sulfur metabolism

Transcription, in which RNA copies of a gene is made, is a critical step in gene expression. We chose *Saccharomyces cerevisiae*, or budding yeast, as a eukaryotic model to study two proteins (Met31 or Met32) that allow the protein Met4 to activate the transcription of sulfur metabolism genes. Met4 can recruit transcription machinery but it cannot directly bind to the DNA of its target genes. Met4 must interact with either Met31 or Met32, which can bind to the target gene DNA. The MET31 and MET32 genes evolved through duplication and divergence. Although both Met31 and Met32 bind to the same DNA sequences in promoters (regions located in front of the gene that control when and how much that gene is expressed), Met31 and Met32 perform different roles in their ability regulate expression of sulfur metabolism genes. These differences are detected when we compare the growth properties of yeast strains in which either MET31 or MET32 is deleted (*met31Δ* or *met32Δ*). If Met31 and Met32 performed identical functions, the *met31Δ* and *met32Δ* strains would have identical growth properties. We have discovered that *met31Δ* and *met32Δ* strains differ in their ability to use certain sulfur compounds as sole sulfur sources. We also discovered that Met31 and Met32 have different expression profiles under inducing conditions. To assess whether the differences in Met31 and Met32 expression dictates their functional roles, we evaluated the effect of swapping the MET31 and MET32 promoters in the single delete strains. Will the promoter swap cause a *met31Δ* strain to behave like a *met32Δ* strain? Using a coulter counter, we evaluated growth rates and cell sizes of promoter swap and control strains in defined minimal media using with sulfate, sulfite, homocysteine, methionine, cysteine, glutathione, cysteate, isethionate, and taurine as sole sulfur sources.

Abstract Name: High Schoolers' Development of Entrepreneurial Skills within the Context of Engineering Courses and Robotics

Over roughly the last five decades, researchers and scholars have described how important it is to diversify STEM fields and increase the numbers of Black and Brown people who are working in sciences, technology, and engineering. This issue has been addressed through making STEM curricula in K-12 schools more culturally relevant and sustaining, inclusive, and just. But, what is often left out of the curriculum in these schooling experiences are focused on meaningful applications of STEM concepts for real-world and career focused skills. One of those important focus areas would be in the development of entrepreneurial skill-building. Opportunities to learn and apply business and entrepreneurial skills in STEM concepts will prepare all students for the next generation of STEM careers and crucially important skills for minority populations on building wealth and business ownership potential. In one university and district-based partnership, human-centered design and engineering coursework taught across grade levels is attempting to focus on these skills for high schoolers in a majority Black high school context. In this study, I follow a group of students in their senior engineering course and internship placements as well as observe the school's FIRST Robotics team to note the ways that entrepreneurial skills are being built. Through qualitative research methods of fieldnoting, observation, interviews and focus groups, I document the ways that students engage in business practices, skill building, teamwork, leadership, persistence, resilience, and problem-solving. Preliminarily, the study is conducted with the expectation that the school's engineering classes do indeed indirectly promote business and entrepreneurial skill building, but the effect is greater in a setting where there are shared competitive tasks and outcome, such as on a robotics team. This work offers important insights into supporting entrepreneurial mindsets and skill building, specially working with Black and Brown students looking to enter STEM professions.

Abstract Name: Raspberry Pi GPIO Functionality through Interactive Learning

In a world of constant change in technology the need for hands-on experiential learning is paramount. This interactive learning exercise explored both the role of Raspberry Pi's role in education and information sciences and technology learning and student-led learning. A classroom of 15 students led by 2 student researchers completed a hands-on lab of GPIO functionalities applying programming concepts through using the Sunflower Raspberry Pi and Arduino Kit, specifically the Pi 5 (Python). Through an analysis of student data feedback, we were able to investigate how effective the interactive exercise in teaching Raspberry Pi GPIO basics and Python programming was for our students. Also, consider whether student-run technology exercises develop students' scientific inquiry and research skills. There were four intended learning outcomes in the overall project: (1) develop circuit-building and Python skills, (2) enhance understanding of logic flows, delays, and hardware–software interaction, (3) strengthen technical collaboration through teamwork and problem-solving, (4) develop scientific thinking-processes and research skills. While not a traditional CURE (Course-based Undergraduate Research Experience) student researchers were employed to lead the research efforts for this exercise. While further reporting and analysis of the quantitative survey is needed, the preliminary student sentiments were positive. Student participants stated it was: "wonderful, amazing, fascinating." These key findings indicate that this interactive exercise effectively supports the learning of abstract concepts like logic flow and GPIO control. Future research could focus on expanding these exercises to include more complex GPIO functionalities, such as integrating sensors or motors, to provide a more comprehensive understanding of physical computing and coding principles.

Abstract Name: Reducing Impostorism: How an Interdisciplinary Education Affects Scientific Identity and Belonging

Throughout the years, STEM fields have failed to promote a sense of belonging and identity in students and professionals, thus promoting impostorism, negatively impacting career persistence (Chang et al., 2022). Impostorism is characterized by feelings of self-doubt regarding one's competence, ability, and deservingness (Jiyun & Lytle, 2024). Between 56 and 82% of college students, graduate students, and other professionals experience impostorism at some point in their careers (Bravata et al., 2019). Belonging is described as feelings of deep connection with distinct groups, places, and collective experiences (Allen et al., 2021). The components of belonging: competencies, opportunities, motivations/desire, and perceptions, overlap with the three factors that constitute a "scientific identity": performance, recognition, and competencies (Pfeifer et al., 2024). Interdisciplinary courses addressing these components may help reduce impostorism and increase persistence in academia. This research investigates the effect of an interdisciplinary science education on scientific belonging and identity through the lens of impostorism to understand possible ways to reduce impostorism in aspiring scientists. To investigate this question, I examined data from the interdisciplinary course, History of the Scientific Research Article (SRA) since 1665. Students analyzed the SRA through a historical perspective which encompassed the rhetorical and scientific aspects of the SRA and the "how" of science. The objectives of the course were to develop critical scientific skills, a holistic understanding of scientific communication, and scientific identity and belonging. I analyzed pre and post course surveys and interviews, focusing on student beliefs, identity, confidence, and their scientific and humanities image. Preliminary data suggests that an interdisciplinary science education may facilitate scientific identity and belonging. Therefore, my findings seem to indicate that interdisciplinary courses may reduce impostorism by promoting scientific identity and belonging in aspiring scientists. Thus, interdisciplinary courses may be another faithful tool to further explore in efforts to improve persistence in STEM.

Abstract Name: Blossom Tales: Designing a children's book to introduce a unique plant-pollinator interaction to reduce plant awareness disparity

Plant Awareness Disparity (PAD)—previously known as Plant Blindness—refers to a lack of awareness and appreciation towards plants, which can be detrimental to the environment as it instills less incentive to protect plants, leaving them vulnerable to irreversible harm and extinction. The extent of this phenomenon is reflected within the societal and professional association of Biology, primarily focusing on humans and other animals rather than applying plants as exciting models. This mindset is frequently perpetuated in children's books featuring animal and human characters, while plants are simply background or completely absent. This designation is then passed along to readers, who maintain this lack of awareness throughout adulthood and potentially impart it to children in their circle of influence. Blossom Tales is a children's book focusing on a

distinctive and exciting plant in an attempt to combat this cycle. This story focuses on Millie, a *Nesocodon mauritianus* plant endemic to Mauritius, east of Madagascar, whose flower produces yellow nectar that changes to blood red, attracting gecko pollinators. Using this unique plant and animated expressions will hopefully draw children's attention. The book is illustrated to showcase the plant at different angles with various expressions that relay different emotions. Regarding visual style, simple shapes were chosen to be visually appealing while preventing distraction from the story's proper focus of the plant-gecko interaction. Drafting language for the story will use impactful and humorous wording to appeal to elementary school kids. Work in progress includes finishing sketching the storyline and finalizing the illustrations. The final goal is to publish this book and perform readings in local elementary schools to survey awareness perceptions using simple questionnaires. This project aims to give readers an increased appreciation for plants.

Abstract Name: Photochromic and Thermochromic Anils in Polymeric Films

Thermochromism and photochromism, characterized by heat- and light-induced color changes, respectively, are widely used in consumer products, climate control technologies, and military design applications. Anils, a class of Schiff bases formed by the condensation of aldehydes and anilines, exhibit these properties. However, the structure-function relationships governing their thermochromic and photochromic behavior, particularly in solvent systems and polymer films, remain underexplored. This study aims to investigate how electron-withdrawing and electron-donating substituents, solvent polarity, polymer matrix polarity, and the ability to undergo excited-state intramolecular proton transfer (ESIPT) influence anil properties. Anil compounds will be synthesized via reflux and characterized using FT-IR and ¹H-NMR spectroscopy. Results are expected to reveal trends in chromic behavior that can inform industrial and medical applications. These findings will be discussed in the context of optimizing material design for functional chromic applications.

Abstract Name: Graph Neural Network Particle Reconstruction for DUNE's Prototype Near Detector

DUNE (Deep Underground Neutrino Experiment) is the upcoming flagship neutrino accelerator experiment in the United States. It plans to utilize a pixelated and modular liquid argon time projection chamber as the primary detector of its Near Detector complex. This detector's design is currently being tested with four prototype modules in a 2x2 arrangement at Fermilab. In order to observe particles that deposit energy outside of the limited 2x2 prototype volume, the prototype is being supplemented with an upstream and downstream detector. These detectors are sets of scintillator planes, which are from a previous neutrino experiment, MINERvA. The goal of the work presented is to extend the machine learning architecture that already exists for the 2x2 prototype to analyze and incorporate data from the MINERvA planes. The training data for this project originates from simulated particle interactions, which are fed into a detector response simulation for

the MINERvA detector components. The output of these simulations is interpreted as geometric information about particles present in the detector, which is fed into a graph neural network that identifies particle tracks. This work builds key connections and functionality in the framework that will eventually be used to interpret and analyze the data from DUNE's Near Detector.

Abstract Name: Photodegradation of Ciprofloxacin and Levofloxacin using Au@ZnO Catalysts

The degradation of organic pollutants in water is crucial for protecting environmental and human health. Organic contaminants such as pharmaceutical residues, industrial chemicals, and pesticides accumulate in aquatic ecosystems, disrupting biodiversity and destabilizing ecological balance. Among these pollutants, antibiotics are particularly concerning due to their overuse and improper disposal, which leads to significant repercussions. Once in water systems, antibiotics contribute to the emergence and spread of antibiotic-resistant bacteria, posing a major threat to public health by complicating the treatment of infections. Moreover, these pollutants can bioaccumulate in aquatic organisms, entering the food chain and potentially harming human health. To address these challenges, it is imperative to develop advanced water treatment technologies and implement policies to minimize antibiotic misuse, thereby safeguarding water resources for future generations. In this study, we investigated the photocatalytic degradation of two fluoroquinolone antibiotics, Ciprofloxacin and Levofloxacin, in aqueous solutions. Gold-doped zinc oxide (Au@ZnO) catalysts with varying gold compositions (1%, 3%, and 5%) were synthesized and evaluated for their photocatalytic activity under UV light. The incorporation of gold nanoparticles onto the zinc oxide surface significantly enhanced the catalysts' surface area and photocatalytic efficiency. Ciprofloxacin degradation reached 96% using the 5% Au@ZnO catalyst within 60 minutes, while Levofloxacin degradation achieved 99% with the 3% Au@ZnO catalyst in the same timeframe. Notably, catalytic efficiency for Levofloxacin began to decline at gold compositions exceeding 3%. These findings demonstrate the potential of gold-doped ZnO composite catalysts as effective agents for antibiotic degradation and underscore their relevance in developing innovative solutions for water pollution remediation.

Abstract Name: BRIDGING FAITH AND SOCIAL CONNECTIONS

This study explores the relationship between religious orientation, social-behavioral skills, interpersonal relationships, and emotional intelligence. Previous literature signaled possible connections between these variables. Based on that, it was hypothesized that religiousness scores would correlate with emotional intelligence, as well as with social-behavioral skills and interpersonal relationships. Additionally, emotional intelligence was hypothesized to also positively correlate with both social-behavioral skills and interpersonal

relationships scores. The sample comprised 95 participants from research methods, concepts of math, statistics for science, senior seminar and marriage and interpersonal relationships classes at a small southeastern university. Data were collected using the Religious Orientation Scale (ROS), Brief Emotional Intelligence Scale (BEIS), and Social-behavioral skills and Interpersonal Relationships Questionnaire. Upon Institutional Review Board (IRB) approval, data collection involved voluntary and confidential participation, and results were analyzed using correlational methods. Findings revealed that higher levels of religious orientation are weakly associated with higher emotional intelligence, and small but significant positive correlations were found between religious orientation and social-behavioral skills, as well as between religious orientation and interpersonal relationships. Additionally, emotional intelligence demonstrated a moderate positive correlation with social-behavioral skills. However, no significant correlation was found for intelligence and interpersonal relationships. These findings suggest that while religiosity is weakly associated with key social and emotional factors, emotional intelligence may play a bigger role in fostering said skills. Limitations included the homogeneity and size of the sample. Future research should incorporate more diverse populations and explore other study designs to better understand the relationships among these variables. Key words: religious orientation, social-behavioral skills, interpersonal relationships, emotional intelligence, faith, social connections

Abstract Name: Hands-On Happiness: Social Touch, Happiness, and Loneliness as predictors of Well-being

This study explored the predictors of well-being among undergraduate students, focusing on social touch, happiness, and various dimensions of loneliness. A review of previous literature highlighted potential connections between these variables and overall well-being. Based on these findings, it was hypothesized that social touch scores, happiness scores, social loneliness scores, romantic loneliness scores, and family loneliness scores would predict well-being scores. Participants included 128 undergraduate students from Precalculus, Issues in Science, General Psychology, and Behavioral Science Statistics classes. The study utilized the Psychological General Well-Being Scale Index-Short Version, the Social and Emotional Loneliness Scale for Adults (Short Form), the Social Touch Questionnaire, and the Subjective Happiness Scale to collect data. Instrument packets were administered with professor approval, ensuring voluntary and confidential participation. The data was analyzed using multiple regression analysis via SPSS. Results revealed that happiness and family loneliness were significant predictors of well-being, while social touch and other loneliness dimensions did not show significant predictive power. Limitations included the lack of cultural diversity and the relatively small sample size. Future research should aim to diversify the sample population and further investigate the relationships between social touch, happiness, loneliness, and well-being. Keywords: social touch, well-being, happiness, loneliness, family relationships

Abstract Name: Neutral effects of brexpiprazole (REXULTI®) on neurobehavioral recovery after experimental traumatic brain injury

Introduction: Agitation is common after traumatic brain injury (TBI). To manage this behavior, antipsychotic drugs (APDs) are provided despite the risks on cognition. APDs that exhibit D2 receptor antagonism have been shown to impede recovery after TBI and therefore it is important to evaluate APDs that may not hinder recovery. Brexpiprazole is a third-generation atypical APD with partial D2 and 5-HT1A receptor agonist properties. Previous work has shown that pharmacotherapies with such actions improve neurobehavior after TBI. Hypothesis: Brexpiprazole will improve neurobehavior after controlled cortical impact (CCI) injury in adult male rats. Methods: Anesthetized male rats received either a CCI of moderate severity or sham injury and then were randomly assigned to receive brexpiprazole (1 mg/kg) or saline/DMSO vehicle (1 mL/kg), resulting in the following groups: TBI+brexpiprazole, TBI+vehicle, Sham+brexpiprazole, and Sham+vehicle. Treatments began 24h after surgery and were administered intraperitoneally once daily for 21 days. Motor function was assessed on post-operative days 1-5 and cognitive function was assessed on days 14-19. The behavioral data were analyzed by repeated measures ANOVA followed by the Newman-Keuls post-hoc test to determine group differences. Results: There were no differences in any endpoint measured between the brexpiprazole and vehicle-treated sham groups ($p > 0.05$), and thus the data were pooled. As expected, the sham group performed significantly better than both TBI groups in motor and cognitive function ($p < 0.05$). Moreover, there were no motor or cognitive differences between the TBI+brexpiprazole and TBI+vehicle groups ($p > 0.05$). Conclusions: Brexpiprazole had no beneficial effects on outcomes after TBI, which does not support our hypothesis. Importantly, brexpiprazole did not exert deleterious effects, which may make it a more viable option for managing clinical TBI-induced agitation without impairing recovery as has been reported with APDs with D2 antagonistic properties.

Abstract Name: An Investigation of Oxygen and Nitrogen Reactive Species in Helium Plasma-Water Interaction for Wound Healing Applications

In this study, the plasma-water interaction phenomenon was investigated. Non-thermal DBD plasma has wound-healing applications due to its low temperatures. However, the interaction between plasma and the wound is complicated and requires further analysis. As plasma jets interact with water, they entrain the surrounding air, which contains nitrogen and oxygen, and this facilitates the formation of reactive oxygen and nitrogen species (RONS) within the liquid. Medical research shows that RONS play a vital role in all phases of wound healing including hemostasis, inflammation, proliferation, and remodeling. This study investigates what is the impact of different experimental conditions on plasma-water interactions. The DBD plasma torch was operated at 10-12 kV on nitrogen at 10 SLPM to produce a plasma jet of 20-30 mm long. The first set of experiments investigated the impact of nitrogen plasma on the characteristics of deionized water. Increasing the treatment distance by 2 cm and exposure time by 10 minutes established a positive relationship between

these two conditions and the water's absorbance. Absorption spectroscopy was conducted to identify the absorbance of the radicals at each concentration. A standard set of data was determined for each radical by measuring absorbance at varying concentrations of a reference solution. Then, a calibration curve that depicted the concentration of each RONS within the plasma-activated water sample at different UV-VIS wavelengths was established for the nitrogen plasma jet. However, preliminary experimentation with helium plasma demonstrated an increase in absorbance in certain wavelength ranges. In this work, our initial nitrogen calibration curve will be presented, and our further experimentation into the impact of helium plasma on RONS concentration will be explained as well.

Abstract Name: Advancing 3D Car Model Reconstruction Using Neural Radiance Fields in the Automotive Industry

Neural Radiance Fields (NeRFs) have revolutionized 3D scene reconstruction by enabling photorealistic rendering from novel viewpoints. Despite their success, applying NeRFs to detailed 3D car model reconstruction has been limited due to practical challenges. Traditional methods like LiDAR scanning and photogrammetry, while accurate, are cost-prohibitive and require specialized equipment, hindering widespread adoption. Manual 3D modeling is another route but is labor-intensive and often inconsistent. Our project introduces an innovative application of NeRFs for reconstructing detailed 3D car models using only standard camera equipment. By capturing multiple images from various angles and employing advanced techniques such as structure-from-motion for precise camera pose estimation, we achieve high-fidelity reconstructions of car geometries. Building upon our initial findings, several key improvements were implemented. The NeRF architecture was optimized to enhance clarity, enabling finer detail capture in complex regions like reflective surfaces and intricate design elements. Additionally, we integrated accelerated training algorithms and efficient data preprocessing steps to significantly reduce computation time, addressing previous speed limitations. The resulting models facilitate interactive rendering from any viewpoint and can be seamlessly integrated into applications for automotive design, virtual showrooms, and augmented reality (AR). The method adopted in this work not only provides a cost-effective and scalable solution but also maintains high accuracy and detail. Experimental results confirm that our improved NeRF-based approach outperforms earlier models in both quality and efficiency. This advancement demonstrates NeRF's potential as a transformative tool in the automotive industry for creating accessible and detailed 3D car models. We will present a comprehensive analysis of our methodology, detailed results, and the developed software at the conference, highlighting the practical implications and future applications of our work.

Abstract Name: *Providencia alcalifaciens*: Role of Putative Lipases in Bacteria-Containing Vacuole Lysis

Providencia alcalifaciens is a Gram-negative bacterium within the order Enterobacterales. It has garnered attention for its dual identity as an environmental inhabitant and an opportunistic pathogen associated with diarrheal outbreaks and antimicrobial resistance. Evidence from recent studies of its ability to invade human intestinal epithelial cells and proliferate in the epithelial cytosol has opened new avenues for questions about the mechanisms that enable its intracellular lifestyle. This study investigates the possibility that predicted lipase-encoding genes - *pssA*, *yjjU*, and *pldA* - participate in bacteria-containing vacuole lysis, which is an important developmental stage that precedes cytosolic replication. This study used targeted gene deletions in *P. alcalifaciens* to verify if the predicted lipases participate in vacuole escape. The *yjjU* and *pldA* genes are predicted to encode a patatin-like phospholipase, and phospholipase A, respectively; both are associated with vacuole membrane disruption in other bacterial pathogens. The *pssA* gene is predicted to encode a phosphatidyl transferase important for membrane biosynthesis. Targeted gene deletion by using overlap extension PCR, cloning into the pRE112 suicide plasmid, and *sacB*-based allelic exchange yielded deletion mutants of *yjjU* and *pldA*. At the same time, attempts to delete *pssA* were unsuccessful, implying a possible requirement for its bacterial viability. Phenotypic assays showed that neither $\Delta yjjU$ or $\Delta pldA$ mutants were affected for vacuole lysis, indicating that these lipases are not the prime mediators of this process. However, these are initial results; more data will be required to arrive at definitive conclusions. The immediate continuation of the work will focus on constructing the $\Delta pssA$ mutant and a $\Delta yjjU \Delta pldA$ double mutant. The present study sheds light on some of the mechanisms that may be involved in the proposed contributions of lipases to the pathogenic strategies of *P. alcalifaciens*.

Abstract Name: Smart Printing: Precise Fiber Alignment in Stereolithography (SLA) 3D Printing of Composite Polymers

Over recent decades, 3D printing, or additive manufacturing (AM), has experienced remarkable growth, finding extensive applications in consumer and light industrial sectors. Despite its advancements, the technology remains constrained by material limitations and challenges in producing composite materials with tailored properties. Stereolithography (SLA), a prominent rapid prototyping technique that utilizes a focused ultraviolet (UV) light beam, offers distinct advantages over other methods due to its exceptionally high resolution. By printing ultra-thin layers, SLA achieves precise replication of intricate details, making it a preferred choice for complex designs. However, commercially available SLA printers face inherent challenges, including anisotropic mechanical properties and difficulties in achieving controlled fiber orientation during composite production. Controlled fiber alignment is critical for composite applications in industries such as aerospace, medicine, thermal management, and computing due to its direct impact on mechanical, thermal, and electrical properties. In these fields, precise fiber orientation enhances load-bearing capacity, structural integrity, and thermal and electrical performance of materials, meeting stringent operational requirements. This paper proposes a novel solution by integrating an electromagnetic fiber alignment system into an in-house-developed SLA 3D printer. By employing electromagnets to manipulate reinforcing fibers in real-time during the printing process, this system ensures precise and consistent alignment at 0 and 90 degrees. The resulting composites exhibit significantly improved mechanical properties, addressing the key limitations of traditional SLA 3D printing. This innovation enables the production of components with enhanced strength, durability, and specialized thermal and electrical characteristics, paving the way for breakthroughs in manufacturing. The proposed approach holds transformative potential for industries including aerospace, automotive, medical, computing, and consumer goods, offering a new horizon for the fabrication of high-performance materials and components.

Abstract Name: IOAgent and Tracebench: Developing and Evaluating the Performance of AI-Based HPC I/O Performance Diagnoses

The purpose of this research is to create an automated tool to alleviate I/O issues in High-Performance Computing (HPC) applications and benchmark the performance of I/O diagnosis tools. As the prevalence of HPC applications' grows, so does the complexity of optimizing them, particularly their data and metadata access (I/O) efficiency. To alleviate such deficiencies, scientists have historically relied upon a limited number of I/O experts to analyze traces of I/O behavior—an approach that has become unfeasible as the number of HPC applications rapidly increases. The recent advent of robust large language models (LLMs) seemingly provides an avenue to develop an automated tool to make I/O issue diagnosis more accessible, but they are limited by factors such as their propensity to hallucinate fictitious details and inadequate knowledge of HPC I/O. In this collaborative research effort, our team is developing IOAgent, an innovative tool designed to address these challenges. IOAgent combines a trace preprocessor, a curated knowledge base of HPC I/O concepts employable by the LLM via dynamic retrieval, and an iterative summarization approach to extract nuanced I/O issues from application traces, all while mitigating the shortcomings of traditional LLMs. IOAgent aims to provide scientists with comprehensive explanations for the I/O performance issues in their applications and an interactive chat interface that allows researchers to comprehend their I/O problems further. In this project, as the undergraduate researcher, I contribute to the creation of TraceBench, a test suite that evaluates the performance of I/O diagnosis tools according to three key metrics: accuracy, interpretability, and utility. TraceBench utilizes a variety of application traces for its assessment, ranging from synthetic logs simulating isolated I/O issues to real application traces collected on production HPC systems. Evaluation with TraceBench reveals IOAgent can outperform state-of-the-art I/O diagnosis tools, while also providing interactivity previously unobtainable by HPC users.

Abstract Name: Generation and Use of Biallelic-dual Fluorescence Reporter Cell Line of BCL11B to Understand T-cell Development via Human iPSC-ATO System

Human and murine T-cells develop from progenitors in bone marrow. The migration of CD34+ progenitors to

the thymus initiates T-cell differentiation. In mouse models, stages of differentiation have been delineated and the effects of transcriptional factors on T-cell development have been studied. One such factor is BCL11B (B-cell lymphoma/leukemia 11B), which is critical for T-lineage commitment. Moreover, recent studies reveal potential differences between the two alleles of BCL11B in regulating T-cell fate. A recent murine study suggests that one BCL11B allele may be silenced and activated days later to ensure differentiation (Pease et al., 2021). However, there are species dependent differences in T-cell development (Parekh et. al., 2012) and there are few studies on the role of human BCL11B in development. One study suggests that Notch1 expression differentially regulates BCL11B leading to TCR $\alpha\beta$ and TCR $\gamma\delta$ T-cell fates (Dolens et al., 2020). However, they do not address differences in human BCL11b allelic expression. BCL11b's bi-allelic role in human T-cell development is unknown. With our lab's artificial thymic organoid (ATO) system, human induced pluripotent stem cells (iPSCs) develop into T-cells, faithfully mirroring the developmental stages found in endogenous human thymi. To answer how BCL11B acts during T-cell development from human iPSCs in the ATO system, CRISPR-Cas9 gene editing will be used to create a bi-allelic BCL11B fluorescent reporter iPSC line. CRISPR-Cas9 allows for precise knock ins of edited genes (donor template) into endogenous DNA. This enzyme system uses a designed guide RNA (gRNA) that directs the Cas9 enzyme to a specific site of DNA cleavage. Utilizing homology directed repair, the cell fixes the break with the exogenous DNA template. With the bi-allelic iPSC reporter line and monitoring of thymopoiesis in the ATO system, this study will provide insights on how each allele of BCL11B regulates T-cell fate in iPSC-based T-cell development.

Abstract Name: Debility of American Transgender Adults: An Analysis of Sociocultural and Medical Factors on Transgender Well-Being

Debility has been a topic of interest in the sociological sciences since Jasbir Puar, former director of the Rutgers University Department of Women's Studies and Gender Studies, popularized the term. However, minimal work has been done to understand the factors resulting in the debilitation of the transgender community in the United States. This paper discusses how the convergence of socioeconomic and cultural factors cause the debility of the American transgender community. The scope of this project spans debilitating factors which fall under the umbrella of systemic discrimination, resulting in disability, lower socioeconomic status, as well as discrimination in health care settings. Ultimately, these factors lead to an inability to pursue or address unmet health needs, resulting in the slow death that is characteristic of biopolitical debilitation. This research outlines models of debility and applies it to the transgender community in the United States. It also utilizes statistical evidence of the outcomes of sociocultural and medical discrimination to substantiate the claims of debilitation of the transgender community in the United States. The evidence presented henceforth is indicative of the lower quality of life which transgender Americans live due to debilitation. Transgender Americans are, overall, more likely to have unmet health care needs, more likely to have lower socioeconomic status, more likely to have lower educational attainment, and more likely to be disabled. The cycle of debility is perpetuated through a lack of social mobility for transgender Americans, facilitated by systematic transphobia. For the cycle of debility to end, it is important to destigmatize transgender Americans in the eyes of broader American society. It is additionally necessary to substantiate the spread of social awareness through infrastructural changes, protecting transgender Americans through more effective legislation, and improving access to health care and participation in the job market.

Abstract Name: An Comprehensive Audit of Dialysis Waste and Recommendations to Reduce Waste Production at VCU Health

Patients with suboptimal kidney function undergo dialysis, a process which can take many forms but which generally subsidizes or replaces the kidneys' filtering capabilities to filter their blood, multiple times per week. Dialysis produces waste from plastic tubing, single-use needles, and dialysis membranes that goes to landfills or is incinerated, producing microplastics and aerosolized pollutants. These pollutants are typically found in the vicinities of communities of low-income, exacerbating poor health outcomes associated with socioeconomic marginalization. In addition to generating adverse environmental and health consequences, needless waste in dialysis poses a serious financial problem for medical institutions. Virginia Commonwealth University Health Systems is one of the largest medical institutions serving central Virginia, and in particular, provides dialysis services at several locations, including the main hospital located in downtown Richmond. In the dialysis clinic, we will categorize the waste streams generated over the course of a single dialysis session into biological, hazardous, plastic, and general waste and quantify the generated waste by weight. The waste collected will be qualitatively described by material and composition and quantitatively recorded before relevant statistical analysis will be conducted. Future comparisons between clinics based on differences in patient population, such as chronic or acute status, as well as adult or pediatric identity, would serve to pinpoint which type of clinic generates the most waste, and how best to mitigate excessive waste. After identifying major contributors to dialysis waste, we will discuss avenues to reduce waste, including educating staff/patients, lobbying for more sustainable practices with VCU management, and identifying vendors for recycling non-hazardous waste.

Abstract Name: Finding the Optimal Relationship Between Aircraft Attributes and Balance Using AI/ML

An optimal weight and balance ratio is critical for the safety, efficiency, and performance of an aircraft. For this reason, this research investigates the optimal relationship between various characteristics of an aircraft (maximum speed, weight, etc.) and its optimal balance. Our hypothesis was that machine learning could be used to predict with reasonable accuracy the optimal balance of an aircraft. The hypothesis was evaluated by using machine learning to predict the balance of the aircraft based on characteristics like maximum speed, empty weight, and number of passengers. The relevant dataset was taken from Kaggle and contained 25,000 data points of aircrafts along with their metrics. Using IBM Watson, a data-analytics processor, multiple

machine learning models were created using these datasets, with enhancements such as HPO-1, HPO-2, and FE. Various other metrics were also used to analyze model success such as the ROC curve and modal accuracy. We predicted that the most important attributes impacting balance are Empty Weight, Wing Loading, and Tail Loading of the aircraft. The Snap Random Forest and XGB Classifier algorithms were the most accurate, achieving an accuracy of about 50%, which we hope to improve further by utilizing balancing of the data and other model improving techniques. Meanwhile, the ROC curve had an area of about 50% underneath, indicating mid-level performance of the models. The results indicate that the Altitude, Number of Passengers, and Landing Weight columns had the biggest impact on the balance. Overall, by implementing the Snap Random Forest model with enhancements, we were able to predict the optimal balance of aircraft with mid-level accuracy that we hope to improve further.

Abstract Name: Evaluating Probiotic Delivery of Angiotensin (1-7) for Cognitive and Pathological Improvement in TgF344-AD Rats

Alzheimer's Disease (AD) is a progressive neurodegenerative disorder characterized by cognitive decline and behavioral impairments, both of which cause a loss of independence, as well as hallmark pathological features such as amyloid-beta plaques and neurofibrillary tangles of tau protein. Despite extensive research and ongoing advancements in understanding its pathology, current treatments only alleviate symptoms and fail to halt or reverse disease progression. Angiotensin (1, 7) [Ang (1,7)], a vasoprotective peptide in the renin-angiotensin system, has shown promise in reducing inflammation and mitigating Alzheimer's-related pathology. Its potential to improve cognitive function as a therapeutic modality has made it a target for research, but its clinical application has been impeded by challenges in delivery. Previous studies in *Drosophila melanogaster* models of AD demonstrated that the genetically modified probiotic, *Lactobacillus paracasei* expressing Ang(1,7) (LP-A), improved memory performance, providing a foundation for exploring the gut-brain axis as a therapeutic target. Therefore, we orally administered LP-A to assess the effects of chronic Ang 1,7 exposure on reducing cognitive and pathological deficits in TgF344-AD rats, a transgenic rat model of AD. We aim to assess behavioral performance on a variety of behavioral tasks including measures of spatial navigation, object memory association, fear conditioning and anxiety-like behavior in TgF344-AD rats. We compare cognitive performance across three groups: a control group, a probiotic control group (LP), and a probiotic treatment group (LP-A). LP-A administration has been shown to significantly alter gut microbiome composition and can modify behavioral performance. Thus, suggesting that this intervention may serve as a potential avenue for improving cognitive outcomes in AD in future clinical trials.

Abstract Name: Electrical Properties of Semiconducting Films for Infrared Detector Applications

Photonic devices, including infrared (IR) detectors, are supported by materials that are sensitive to IR radiation, with applications in thermal imaging, night vision, and detection of invisible gases, such as carbon dioxide and methane. Typical IR photodetectors are based on semiconductors exhibiting a narrow, direct bandgap that corresponds to low excitation energy. Germanium (Ge) and its alloys with tin (Sn) have a narrow bandgap that is suitable for the IR; however, Ge does not have a direct bandgap, and Sn is not readily incorporated into the Ge lattice to make high-quality, uniform GeSn films. Instead, the growth methods lead to impurities and dislocations that affect electrical conductivity and impact potential photodetector device performance. Here, the charge carrier transport of remote plasma-assisted chemical vapor deposition (RPA-CVD) grown $\text{Ge}_{1-x}\text{Sn}_x$, with $x = 0\%$, 2.6% , and 8.5% , was investigated using terahertz (THz) time-domain spectroscopy. Charge carriers in these films, grown on sapphire substrates and of approximately 200 nm thickness, were photoexcited in short pulses, and the transmitted THz electric field was detected using electro-optic sampling. The alternating current conductivity of each film was determined for a temperature range of 4 K – 300 K, and experimental results were fit with the Drude-Smith conduction model to determine carrier concentration and scattering time. It was found that the charge carrier concentration decreased with Sn concentration and increased with temperature, while the scattering time increased with Sn concentration and decreased with temperature. These results suggest favorable electronic quality of RPA-CVD GeSn for optoelectronic applications.

Abstract Name: Shared Clinical Decision-Making on Vaccines Among Community Pharmacists

Background: Shared clinical decision-making (SCDM) on vaccination involves an open dialogue between a patient and their healthcare provider, including pharmacists, to make a vaccination decision based on the patient's needs and potential benefits. SCDM recommendations apply to five vaccines when only specific groups of people can benefit from the vaccines. These include- HPV vaccine for those aged 27–45; Meningococcal B vaccine for adolescents and young adults aged 16–23 years; PCV20 or PCV21 for those 65 and older who completed previous pneumococcal series, Hepatitis B vaccine for adults aged 60 and older with diabetes mellitus, and 3rd+ dose of COVID-19 vaccine for immunocompromised individuals.

Objectives: While the CDC provides guidelines for SCDM conversations, it is up to the provider to decide whether to initiate such conversations. Given community pharmacists' increasing role in immunization and their high accessibility in society, this study aims to: 1) identify community pharmacists' barriers and facilitators to engaging patients in SCDM for recommended vaccines and 2) describe how pharmacists determine which patients to approach for SCDM discussion. The findings will inform interventions to bridge the gap between the best practice of SCDM and real-world practice. Methods: The recruitment is on-going.

Pharmacists currently are recruited from the Rural Research Alliance of Community Pharmacies (RURAL-CP) network, the Harrison College of Pharmacy's alumni list, and the Alabama Hayes pharmacist directory. Semi-structured interviews will be conducted until saturation. Transcriptions will be thematically coded, and analyzed to identify patterns. Participants receive a \$100 Amazon gift card as an incentive for participation. Preliminary Results: Preliminary results indicate varying levels of understanding and implementation of SCDM guidelines among pharmacists. Pharmacists who conduct SCDM use their dispensing software to identify qualifying patients. Barriers to SCDM include time and patient's existing knowledge and attitudes. Facilitators include pharmacist knowledge of and attitudes towards SCDM.

Abstract Name: Evaluating the Population and Movement of Round Goby (*Neogobius melanostomus*) in Elk Creek, a Lake Erie Tributary

Round gobies, *Neogobius melanostomus*, are an invasive fish detrimental to the stability of aquatic ecosystems, competing for space and resources with native species. While round goby are well-established in Lake Erie, their population size, demographics, and movement in Lake Erie tributaries are unknown. Thus, this study aimed to estimate the population size, understand demographic features, such as size and sex, and assess the movement of round gobies in Elk Creek, a Lake Erie tributary, through a mark and recapture study. For 10 weeks in the Summer of 2024, nine designated 60-m sections in Elk Creek were kick-seined for 30 person minutes to collect round goby. The gobies collected in each section were measured, sexed, and given a section-specific color of a visual implant elastomer (VIE) tag. Recaptured gobies were recorded and retagged with the color of the section in which they were recaptured. Over the 10-week sampling, 1545 gobies were marked, with eight recaptures. Based on the Schnabel Index, the round goby population in Elk Creek is estimated to be 133,188 (95% CI: [78671, 433788]) gobies. There was no significant difference in the size of males and females, but juveniles were significantly smaller than both sexes and the most abundant in mid-June and mid-August. As the summer progressed, fewer gobies were collected overall and within sections. Goby size and sex did not differ significantly over the summer and between sections. Recapture data cannot indicate certain movement patterns, but suggests that significant movement is unlikely. Given this, sections abundant with goby should be targeted consistently for round goby management.

Abstract Name: The Choice of Your Life

"What do you want to do with the rest of your life?" This question evokes a lot of complex emotions, fear, anxiety, and the weight of uncertainty. The process of answering can feel like a storm of tangled thoughts: butterflies, twisting guts, or the crushing sensation of self-doubt. This abstract design serves as a visual

representation of those emotions: messy, scattered, and twisting, yet threaded with the freedom and hope that choice provides. It captures the tension between the chaos of indecision and the subtle joy of realizing we have the power to choose, even when the journey is uncertain and fraught with trial and error. This work draws inspiration from observations of everyday life conversations on campus, visits home, and fleeting moments scrolling through social media. The shared struggle to answer life's most pressing question resonates deeply with me. Through this piece, I hope to convey the universal nature of this experience while reflecting my personal journey. I've discovered that creation feeds my soul, even if the process is arduous. The work invites viewers to embrace the trial-and-error nature of self-discovery and find comfort in the idea that uncertainty is part of growth. As a graphic designer, I used Adobe Illustrator to explore abstraction to its fullest potential. Each element was intentionally pushed, twisted, and refined to mirror the emotional complexity of facing life's most daunting questions. This iterative process allowed me to build a design that embodies the raw and unstructured nature of seeking purpose. Both life and art are nonlinear journeys, filled with trial and error. This abstract design reflects that messy, unpredictable process, an emotional snapshot of a deeply human experience.

Abstract Name: Understanding nuclear quantum effects in the solvation structure and hydrogen bond dynamics of fluoride hydration using many-body potentials

Ion hydration is integral to biological functions, pharmaceutical applications, and future green-energy endeavors. Fluoride compounds, in particular, are known to react with water and play a major role in the stratospheric chemistry of chlorofluorocarbons. Classical molecular dynamics simulations have been able to predict numerous properties of fluoride hydration in agreement with experiment. However, classical simulations omit significant effects arising from the presence of light nuclei like hydrogen and the weakening of covalent OH bonds from the presence of FH bonding, or nuclear quantum effects. A complete understanding of fluoride hydration then necessitates treating these systems quantum mechanically. In this study, we employ path-integral-based quantum dynamical methods, along with MB-pol and MB-nrg, highly accurate data-driven many-body potentials for water and fluoride, respectively, to study the role of nuclear quantum effects in fluoride hydration. For our analysis of hydration structure as a function of solvation shells, we calculate radial and angular distribution functions. In our radial distribution functions, we observe a widening of peaks in each solvation shell due to the delocalization of H nuclei. In our angular distributions, we expect to find lower average HOH bond angles in water due to the electronegativity of fluoride. For hydration dynamics as a function of solvation shells, we calculate diffusion coefficients, mean residence times, and infrared spectra. Due to the strength of the FH bond, we expect lower diffusion coefficients and higher residence times with lower-numbered solvation shells. In our infrared spectra, we observe a second higher-frequency peak in the librations mode, higher frequencies in the bending mode, and lower frequencies in the asymmetric stretching mode of water, attributed to the presence of fluoride, delocalization of H nuclei, and the weakening of local OH bonds, respectively.

Abstract Name: Lathrop Lineage: A Family History of Free Africans in Antebellum America

The purpose of my research project was to find, analyze, and summarize all accessible documentation of my ancestors. In this presentation, I share the results of my continuing document research uncovering the story of three generations of free Africans in Connecticut, beginning with the first in this ancestral line to be emancipated back to the 18th century. The stories of these ancestors give historical insight on the experiences of enslaved Africans in the North and free Africans during the antebellum period. In exploring this history, I discovered an indirect crossing of paths between one of my ancestors and an ancestor of my mentor who guided me in this study.

Abstract Name: Factors Influencing Expressions of Gratitude: Behavioral observations of pedestrians using a crosswalk

It has been demonstrated that expressions of gratitude boost the subjective wellbeing for both parties involved—the benefactor and the beneficiary of a gratitude expression. However, the impact of behavioral and environmental variables on expressions of gratitude in daily contexts hasn't been determined, such as a pedestrian thanking the driver of a stopped car when crossing the street. This gap in positive psychology research inspired this study. Trained research students observed and recorded various human dynamics occurring after a vehicle stopped for a pedestrian in downtown Blacksburg and on the Virginia Tech campus, including the pedestrian's facial expression (smiling/not smiling), social interactions (walking alone/walking with others), gratitude (expressed/not expressed), age category (under 18, 18-30, 30-50, 50+), and phone use (using/not using a cell phone). Independent sample t-tests showed a significant difference in frequency of gratitude expression between the downtown and campus locations (50% vs. 18% of pedestrians expressing gratitude). Gratitude frequency varied significantly between people who were smiling (64%) and those who were not smiling (28%). Also, substantial differences were observed in the frequency of gratitude expressions as a function of the pedestrian's age. Those in the age ranges of 30-50 and 50+ showed gratitude 49% and 51% of the time respectively, while those pedestrians in the 18-30 age category showed gratitude only 30% of the time. These findings are skewed by a larger proportion of observations of pedestrians aged 18-30 occurring on campus, a location that evidenced less gratitude for all age categories. These findings were analyzed with a linear probability model (LPM). Controlling for location, pedestrians ages 30-50 were 8 percentage points more likely to express gratitude than the reference group (ages 18-30) ($p = 0.028$), and pedestrians aged 50+ were 12.5 percentage points more likely to express gratitude than the same reference group ($p = 0.019$).

Abstract Name: 3D MODELS OF PROTEIN CONFORMATIONS: AraC, An Activator and a Repressor in One

All complex biological processes rely on enzymatic activity and protein binding – a concept that is emphasized in the biology curriculum. These mechanisms rely on the varying conformations of proteins to either activate or inhibit gene expression. However, textbooks tend to portray these proteins in cartoon-like figures that don't accurately represent the protein. Therefore, despite preaching that "structure determines function," these figures don't provide students with a strong concept of accurate scientific structures of proteins. To combat this learning gap, I am developing 3D physical models and graphics to create scientifically accurate protein structures, specifically looking at the AraC protein which is a transcriptional regulator of gene expression for genes involved in arabinose catabolism to degrade arabinose sugar – an alternative energy source to glucose. AraC is unique in its ability to act as both an activator and repressor depending on its conformation. This project aims to demonstrate these conformational changes, specifically looking at AraC – the protein crucial to the regulation of the arabinose operon, a molecular mechanism allowing cells to utilize arabinose as a source of energy and carbon. Using PDB crystallography proteins 1BL0, 2ARA, 2ARC, and 2K9S, I will create 3D physical models to show the dynamic properties of AraC in a scientifically accurate manner. My goal is to use AraC to accurately show protein versatility to aid students in courses such as Biology, Genetics, and Microbiology to better understand protein structure.

Abstract Name: The Effect of Social Comparison on Children's Cognitive Reflection

Previous research suggests that adults are more likely to engage in critical thinking when assessing the reasoning of other people. For example, adults who are told they are receiving information from a specific source (e.g., a prior research participant) are more likely to question the logic of the information as opposed to when it is presented without a source. However, research has not yet examined whether children are more likely to engage in critical thinking in social versus non-social settings. The present study investigates whether children demonstrate more cognitive reflection (the ability to answer tricky brain teasers) in social versus non-social conditions. In an online study, we measured the cognitive reflection of 5-12 year old participants using the CRT-D (example item: "What do cows drink?") before and after a short training activity. In the non-social condition, children practiced generating reasons for why their initial answers on a guessing activity may be incorrect. In the social condition, children practiced generating reasons for why

peers' initial answers on a guessing activity may be incorrect. Data collection is ongoing (current n = 35). Preliminary results suggest that children in the social condition improve their critical thinking (i.e., performance on the CRT-D) more than children in the non-social condition. The results from this study will not only help us better understand ways to reduce thinking biases in children, but also highlight social comparison as a vehicle to improve critical thinking.

Abstract Name: Parental Alienation, Cult Brainwashing and Belief in Dictatorship: Understanding and Overcoming the Power Dynamics at the Micro, Meso, and Macro Level

The purpose of this project is to bring together different literatures by a thorough review with a theme of how power divides on different levels. This work examines the similarities in personality, behavior, strategies and narcissistic abuse patterns of a parental alienator, cult leader and dictator and how this connects to the micro, meso, and macro levels of society. Divisive concepts are an important topic to understand in the 21st century. Due to the social and technological changes of the last 50 years, there has been a rapid increase of narcissism globally. It is of great import to bring awareness about alienating behaviors and how this is linked to individuals, groups, and society. The intent of this inquiry is to educate and inform on nonviolent ways to counter the destruction that factious tactics procures.

Abstract Name: The Effects of Tao Hong Si Wu Tang on Melanoma Cancer Cells

Melanoma skin cancer is difficult to treat and can quickly become life-threatening when it metastasizes, meaning that there is an urgent need for new therapeutic approaches that can induce apoptosis in these cells. We observed the effects of Tao Hong Si Wu Tang, an herb mixture used in traditional Chinese medicine, on melanoma skin cancer cells from the SK-MEL-5 cell line. Our hypothesis was that if we treat melanoma cancer cells from the cell line SK-MEL-5 with Tao Hong Si Wu Tang, apoptosis will occur because Tao Hong Si Wu Tang has been shown to kill breast cancer cells by mechanisms such as decreasing vascular endothelial growth factor (VEGF), which is also found in the epidermis. We started with both positive and negative controls so that we can compare the effects of the treatment. Our positive control was using media without Fetal Bovine Serum, while our negative control was caring for our cells as usual. We tested the mixture of the herb to find if it causes apoptosis, with the goal of separating and testing the individual components if apoptosis occurs. We dissolved the tea pills in our media and tested four different concentrations, 1.5 mg/ml,

3 mg/ml, 6 mg /ml, and 12 mg /ml. We monitored these cells for apoptosis by monitoring the cell growth and death over the span of five days for each different concentration, along with a control group. We will present our results.

Abstract Name: Reconsidering Queer Identity in New Taiwan Cinema: on Dear Ex (2018) and Your Name Engraved Herein (2020)

This research project dives deeper into why LGBTQ+ representation in Taiwan's media entertainment challenges people's understanding of identity, nonconformity, values, and empathy. This project examines the portrayal of queer characters through two Taiwanese films, *Your Name Engraved Herein* (2020) and *Dear Ex* (2018). It explores how Taiwan's evolving queer consciousness challenges heteronormative society and traditional familial customs from 1987 to the present. Taiwan has become a leading nation in advocating LGBTQ+ rights in Asia, and with its 2019 legalization of same-sex marriage, it marked a significant achievement in the country's progressive shift toward accepting queer individuals. This essay considers how Taiwan's history of LGBTQ+ activism, social struggles, and political milestones have influenced media depictions of queer life. Both films reflect the social challenges queer individuals face, addressing themes of self-identity, societal expectations, and the complexities of love. *Dear Ex* explored the relationship between a widow, her late husband's former gay lover, and their teenage son, delving into the emotional and social struggles stemming from her husband's hidden queerness. The characters' battle against grief, acceptance, and societal rejection dramatizes the conflict between traditional family values and queer ideals of love, empathy and family kinship. *Your Name Engraved Herein* is set in 1987, the year after the lift of Taiwan's martial law period. The film features the romantic relationship between two high school boys, A-Ho and Birdy, whose bond is challenged by homophobia and societal stigma by their peers, instructors, and family members. The film reflects on the enduring emotional scars of first love, the pain of separation, and the struggle to reconcile personal identity. This essay emphasizes how Taiwanese films offer insight into queer experiences, portraying the emotional and societal challenges queer youth face in their pursuit of love, identity, and acceptance in a society that is gradually becoming more inclusive.

Abstract Name: Hello, Darkness, My Old Friend; The Effects of Lighting on Monsters, Mothers, and Heroes in Beowulf

Beowulf has long been considered a crucial work to the English literary canon. With stage adaptations from lyricists such as Ken Pickering to full length films directed by Robert Zemeckis, the Old English poem has remained relevant within academic and casual spaces. This project explores the relationship between lighting and the moral disposition within Beowulf's cast of characters. My initial inquiry when developing my research was investigating the purpose and power of lighting in medieval prose; specifically, how lighting and

spectacle can foreshadow, reveal, or affect character motivation. By using the framework and ideas popularized by Aristotle's Poetics, I work to prove how “good” and “evil” characters are influenced by their physical conditions and descriptors, such as Grendel’s attacks happening exclusively under the cover of darkness. This absence of light prompts his gruesome and grotesque assaults, in conjunction with his devilish lineage. Simultaneously, I challenge the common perception that Grendel’s Mother and the Dragon are inherently monstrous. Rather, these two characters are driven to act in monstrous ways because of their optical setting. By drawing from Seamus Heaney’s translation of Beowulf and Herbert Wright’s scholarship examining the study of joy and evil in the Old English text, I conclude lighting, as a narrative device, has a direct effect on the motives, actions, and perceptions of Beowulf’s leading characters.

Abstract Name: The Abstract and Artistic Values of Galla's 40 Preludes for Horn

Jacob Schear Abstract Art Proposal Introduction There are many abstract and artistic components of Jacques-François Galla's (1787-1864) 40 Preludes For Horn opus 27 (edited by James Chambers). Galla is a historical staple in the horn community for his many works for the including concertos, various chamber pieces, and most notably, his etude books. In addition to being a composer, Galla was a horn player, as well as a teacher at the Paris Conservatory. An unmeasured prelude is designed to be up to the performer's interpretation. Exploring one's own personal interpretive decisions can be based on historical performance practices and personal expression. In most circumstances these pieces switch back and forth between rhythmically strict passages as opposed to the more lyrical cadenza type phrases. The beauty of these etudes is that everyone plays them a little differently, because every musician is unique. For aspiring musicians, coming up with new ideas and strengthening one's musical creativity by stretching and shaping the music is an essential skill. Learning when to push and pull any given melodic line is an instinct that a player can develop over time. My Experience I perform a new Galla prelude every week for my lessons at WVU. In working through this book, I have quickly improved my ability to communicate dynamics, musical phrasing, and musical creativity. Creating a contrast between these preludes as opposed to more technical exercises has been a key focus for me. The aspect that interests me the most when working on these is that I can try hundreds of different styles before I find the one that resonates with me. Through Galla's preludes, any horn player can gather experience on how to play so much more than what is on the page.

Abstract Name: A Systematic Review the Provision of Augmentative and Alternative Communication by Registered Nurses

Systematic reviews provide a high level of bias-resistant scientific evidence for busy, evidence-based healthcare practitioners. This systematic review of five databases was completed following consultation with

a university research librarian, research ethics training, and use of Covidence to implement each stage of the review. Included studies were peer-reviewed, written in English and (a) a patient participant study featuring hospitalized patients who used AAC to communicate; (b) a tutorial for healthcare providers using AAC to support hospitalized patients; or (c) an interview or survey study detailing experiences of healthcare providers or hospitalized patients who used AAC. The systematic search yielded 154 articles narrowed to 58 meeting inclusion: 33 patient participant studies of hospitalized patients, five tutorials on using AAC with hospitalized patients, and 20 studies of providers and/or previously hospitalized patients. AAC systems were similar across study types and included gestures; non-electronic eye gaze systems, books, boards, and pain scales; electronic eye gaze systems and speech-generating devices. Patient populations were mainly adult males, 28% of participants were female, suggesting that females may be underrepresented in this research. Thirty-six percent of patients could not communicate due to surgical intubation; 25% due to traumatic brain injury; 12% had a stroke; and remaining diagnoses included autism and dementia. Patients used AAC systems to communicate about pain (25%), self cares (19%), medical decisions (14%), control of the environment (8%), and to gain providers' attention (7%). In addition, patient participant studies described the desire to reminisce, discuss psychological state, express difficulty breathing or needing suctioning, describe medication needs, provide information, communicate with unfamiliar people, and ask how to operate the AAC system. Findings also include a summary of patients' reported desired to communicate about more than basic needs and a summary of SLPs' and RNs' need to engage in interprofessional education and interprofessional collaboration regarding AAC.

Abstract Name: Perception Beyond Reality: Investigating Temporal Awareness in Virtual Reality

Virtual reality (VR) has become an increasingly popular tool across various sectors, offering users immersive experiences in simulated environments. While much of the research on VR has focused on its applications in gaming, therapy, and training, less attention has been given to how it impacts users' perception of time. This study investigates the effect of immersive VR environments on time perception, particularly in an atypical setting. Participants were exposed to a 15-minute VR experience where they interacted with sea creatures in an underwater environment. The primary objective was to determine whether the immersive nature of VR alters the users' perception of time, specifically whether they perceive time to pass more quickly or slowly than it actually does. Results showed a significant distortion in time perception, with participants consistently underestimating the duration of their VR experience. This suggests that immersion in VR environments may cause users to lose touch with temporal cues from the real world, leading to a skewed sense of time. These findings highlight the need for further exploration of how the length and type of VR exposure influence time perception, with implications for the design of VR experiences in various fields. Future research should consider examining the relationship between time distortion and factors such as user experience, environment realism, and task complexity to better understand the cognitive effects of VR.

Abstract Name: Applied Behavior Analysis, SCERTS Model, and Daily Life Therapy: A Continuum for Teaching Students with Severe Autism Spectrum Disorder

Autism Spectrum Disorder (ASD) is “a complex developmental condition involving persistent challenges with social communication, restricted interests, and repetitive behavior” and it is estimated that one in 36 children have been diagnosed with ASD. With ASD being such a prevalent percentage of students served within special education it’s important for teachers and schools to know what their philosophical values are for teaching these students. Current research focuses primarily on Applied Behavior Analysis or ABA, however there are numerous other, lesser-known philosophies out there. These philosophies being so different presents the idea of a continuum. This project analyzed the continuum of philosophical interventions used to support students with severe autism. Project activities included reviews of program websites and documentation, site visits to each private residential school program, and focus group interviews conducted with teachers from each school. These data sources created a basis for analysis and a variety of conclusions to describe the contrasting philosophical approaches employed by each program. The summative analysis of the project activities provided greater understanding of the complex continuum of philosophical intervention strategies designed to support students with ASD.

Abstract Name: Analyzing the Impact of Changing Planet Location on Large Orbiting Mirrors Experiencing Radiation Pressure

Terraforming is the process of altering a planet, moon, or other celestial body to make it more habitable. One potential solution is to use large, lightweight mirrors in orbit around the planet to redirect starlight. An extraterrestrial civilization on a tidally locked planet within a star's habitable zone might also wish to direct starlight onto the planet's permanently dark side. However, the effects of radiation pressure (RP) on the orbit stability of large, lightweight mirrors are not well known. Our research group is studying the stability of mirror orbits through extensive simulations of mirrors orbiting potentially habitable planets around various types of stars. Whether mirrors survive when experiencing RP depends on the simulation details. Physically, the acceleration caused by RP relative to the star and planet's gravitational accelerations should be important. The ratio of the planet and mirror orbit periods will also influence the outcome, due to the differing RP direction as the planet orbits the star. Initially, we simulated mirrors at different distances from Earth-sized planets at the inner edge of the habitable zone for different star types, as these planets are more likely to be tidally locked. Mirror orbits were initially circular and had several different orientations. We were unable to statistically model the outcomes as a whole because of gaps in the values of these physically important factors. I have expanded the simulation parameter space to include planets at the middle and outer edges of the habitable zone. I will present an analysis of how a planet's location within the habitable zone affects mirror orbit stability, and evaluate how much these additional simulations have filled the gaps in values of the physically relevant quantities.

Abstract Name: Dragging All Stories into the Room: Mentorship and Making Space in Creative Nonfiction

Essayist Leslie Jamison writes that empathy is “a choice we make: to pay attention, to extend ourselves.” Mentorship within the arts requires a similar sense of exertion. For this research project, I examine several creative nonfiction essays that have served as “mentors” for my own writing, specifically for my essay, “Mudfoot,” which explores the unresolved nature of trauma. As a first-generation student, the process of reading and analyzing craft choices from writers I admire—guided by my faculty mentor—is a crucial element of mentorship both within the classroom and beyond. In *Body Work: The Radical Power of Personal Narrative*, writer Melissa Febos recounts how, at a literary conference, a male editor responded to a female audience member’s question about writing her trauma by stating, “I mean, I’m not sure we need any more of those stories.” In a patriarchal society, silencing is power. And in my work, I argue that these stories are absolutely necessary, particularly given the fact that creative nonfiction continues to be male-dominated. In 2022, for instance, only 26.5% of nonfiction books reviewed in Britain’s newspapers were written by women, and *The Best American Essays* anthology has not consistently reached gender parity. How can students cultivate fulfilling mentoring relationships and challenge the historically male-dominated canon? The texts I consult for my project are written exclusively by women, and my presentation will emphasize the importance of cultivating diverse voices through mentorship. Attendees will leave with the knowledge that literary mentorship acts as a catalyst for developing emerging writers, especially first-generation students and members of marginalized communities. I hope to expand the concept of mentorship into a wider perspective, addressing the resources available for students outside of the male-dominated classroom. The presentation will end with a short reading of my own work demonstrating craft choices in practice.

Abstract Name: Analyzing the effectiveness and uses of a low-cost particle counter

Research on particulate matter (PM) and its impacts has grown in popularity significantly over the past few decades, due primarily to its impact on human health. Particulate matter is solid or liquid particles suspended in the atmosphere, categorized by their size. The EPA regulates emissions of PM_{2.5}, the particle size category recognized as most harmful to humans. This is because exposure to particulate matter smaller than 2.5 microns in diameter is linked to cardiovascular diseases and premature death. Due to this link, the EPA’s Air Quality Index (AQI) uses PM_{2.5} and PM₁₀, along with other pollutant concentrations, to categorize air quality. Optical particle counters using laser diffraction to count and sort particles and then convert these values to a mass surfaced in the early 2000s, but they were too expensive for widespread use. In recent years, smaller and more affordable particle counters have emerged on the market, however, they are just starting to become widely utilized. This study aims to determine if a low-cost particle counter can uncover trends in local air quality and evaluate its usefulness for research. Methods involve evaluating the low-cost sensor (Sensirion SEN55) compared to a research-grade particle counter to determine its accuracy. Data will also be collected on a mobile platform to identify any trends in air quality. So far, readings of PM_{2.5} between 2 and 20 µg/m³ have been observed on a well-traveled local road. The expected outcome of this study is a more comprehensive understanding of the accuracy and applications of the Sensirion SEN55 particle counter.

Abstract Name: Amidst the Storm: The Role of Demonic Conflict in The Writings of Jerome

In recent decades, there has been an explosion of research surrounding the role of demons in the stories of early Christian Saints' Lives, discussing the way demonic combat delineated the powers, roles, and expectations of early monks. The new revelations concerning the literary role of demons in the formation of monastic identity warrant a re-evaluation of theological and polemical passages related to demons, a task admirably begun by historians like David Brakke, who analyzes the intersection of theological instruction and hagiographical depiction, and Gregory Wiebe, who crafted a cohesive summary of Augustine's demonology. This paper, modelled on Wiebe's work, develops this dynamic field by investigating the demonic thought of a distinctive, influential early monastic figure—Jerome of Stridon, translator of the Vulgate. Unlike his famous contemporary Augustine, Jerome never lays out a cohesive demonology, which likely accounts for the relatively small amount of scholarship. Instead, he discusses demons as enemies whose strategies we ought to comprehend and combat. This creates a highly practical body of work, in which demonic rhetoric acts as a marker of unacceptable behavior. This paper investigates the nexus of human-demon relations in the writings of Jerome, highlighting common vocabulary, circumstances, instruments, and markers of demonic influence. In doing so, it reveals how Jerome's writings use demonic language to delineate proper monastic identity or—as he was deeply enmeshed in intellectual networks and debates over orthodoxy—vilify his theological opponents. Jerome views the battle against demons, within the individual and the church, as a battle to preserve “virginity,” to prevent mixing of boundaries and maintain internal purity, giving us new insight into the bodily and gendered aspects of early monastic identity. Jerome's demonic rhetoric reveals an essential, yet overlooked, dimension in his promotion of asceticism and maintenance of orthodoxy, the most fiercely debated issues of his time.

Abstract Name: Yoga Therapy affects changes in NSSI and Eating Disorder Symptoms

Non-suicidal self-injury (NSSI) and eating disorders (ED), which often co-occur, require a disregard for one's body to engage in these maladaptive behaviors. Previous literature has shown that a lack of self-compassion and body appreciation are associated with greater NSSI and ED symptoms, but could be mitigated through therapies such as yoga, which emphasize the union between body and mind. Our study aimed to investigate if body appreciation and self-compassion act as mediators between participation in an integrative yoga therapy and changes in NSSI urges and ED behaviors among a sample of treatment-seeking adults. To date, 37 participants have completed the study (Mage = 31.23, SD = 12.2; 45.9% cisgender female, 46.8% white/European). Linear regression mediation analyses were conducted using the PROCESS macro (model 4)

in SPSS. The full model was not significant for either outcome ($p = .34 - .42$) and there were no observed indirect effects. Aligned with prior literature, self-compassion had a significant direct relationship with changes in NSSI urges ($b = -0.31$) and body appreciation had a direct effect on changes in ED symptoms ($b = -0.56$). The non-significant effects could be due to having a limited amount of preliminary data. Additional data is currently being collected. At the time of the conference, updated analyses and results will be presented. Current results suggest that yoga treatment may not meaningfully affect body appreciation and self-compassion among treatment-seeking adults so alternative treatments may need to be considered.

Abstract Name: Degradation of Cyanoguanidine by Nitrile Hydratase

Anthropogenic biguanide compounds are commonly used in agriculture, industry, and medicine, thus ubiquitous in our environment. Widespread use of biguanide compounds, such as cyanoguanidine, guanylurea, and metformin, has resulted in their accumulation in waterways as pollutants. The purpose of this research was to investigate the microbial degradation of cyanoguanidine, a biguanide compound commonly used as a slow release fertilizer that is persistent in soil and water. We hypothesize that high concentrations of cyanoguanidine in wastewater have acted as a selective agent for microbial cultures capable of metabolizing this compound, and sludge-derived microbial cultures may serve as a source to isolate these microorganisms. The experimental approach consisted of establishing microbial cultures using wastewater treatment plant sludge and growth medium with cyanoguanidine as the only nitrogen source. Aliquots of the microbial cultures were plated on minimal media containing cyanoguanidine to isolate bacteria with the ability to break down this compound. High Performance Liquid Chromatography analysis (HPLC) was conducted to track and measure a decrease in cyanoguanidine, which served as a marker for its microbial degradation. These experiments demonstrated the breakdown of cyanoguanidine and the formation of a product identified as guanylurea. DNA sequencing identified two bacterial isolates responsible for this process: *Pseudomonas stutzeri* strain T13 and *Pseudomonas mendocina* strain YMP. Bioinformatic analyses were employed to identify candidate enzymes responsible for cyanoguanidine degradation, which led to the discovery of nitrile hydratases in both organisms. These findings suggest that nitrile hydratases may be responsible for the metabolism of cyanoguanidine in wastewater bacteria. Future work will focus on the purification and characterization of these enzymes to establish their kinetics, regulation, and role in cyanoguanidine metabolism. These new findings contribute to the development of biotechnological solutions for removing cyanoguanidine and structurally similar compounds from the environment.

Abstract Name: Understanding Antioxidant Activity through Available Polyphenols in Green Tea

Excessive oxidative stress is a significant health hazard with a wide array of causes that can impact many different people. Traditional tea, brewed from the *Camellia sinensis* plant, has been shown as a consistent source of antioxidants due to the polyphenols present in tea. The method of fermentation of the leaf distinguishes different kinds of tea such as black, green, white, and oolong and these methods of preparation create different profiles of polyphenols with catechins and theaflavins, formed from oxidized and polymerized catechins. Research has shown that green and black teas tend to have the highest antioxidant activity. Within the category of green tea, there are further differences in preparation which impacts the final product. In this study, varieties of green tea were examined for antioxidant content variations through ABTS assay. The ABTS radical provides a great mechanism of quantifying scavenging power as the change that ABTS undergoes causes a color change that can be measured through absorption in UV/VIS. The results are compared to a Trolox (a phenol with a single -OH group) equivalence curve. Preliminary results indicate that gunpowder green tea has the highest antioxidant content followed by young hyson, sencha green, then dragonwell green. Further research will be conducted to examine the quantity and identity of the polyphenols present in these green teas to shed light into the mechanism of antioxidant activity.

Abstract Name: Statistical Analysis of Regional Variation in Material Properties of the Vertebrae for Predator-Escape Response in Yellow Perch (*Perca Flavescens*)

Morphology of animals often reveals how functional design optimizes performance for specific behaviors and adapts to better meet functional demands. We aim to understand how the different sections of the fish vertebrae are built in responding to mechanical stress imposed on them during predator escape behavior. The response is initiated with a rapid “C” shape motion, involving greater turning rate of the head and tail than the mid section of the body, indicating the vertebral column experiences section-specific stresses. Preliminary data showed higher stress-bearing capacity for the upper trunk and the caudal peduncle than the mid and lower trunk vertebrae. The vertebrae in these sections may have undergone differential calcification or mineralization due to varying mechanical stresses. The vertebrae from all four sections were extracted from 20 perch specimens and placed under axial compression tests until failure. Processes and data collected above were conducted by Professor Takashi Maie and his research team. Our statistical analysis aims to develop a standardized and automated process for extracting Young’s modulus, yield strength, and tensile strength for each bone from the stress-strain data from the compression tests. The automation will allow the extraction process to be easily replicated for each bone and in future studies, enabling large datasets of fish to be studied. Once the automation process is complete, we will use ANOVA to compare the different bone regions and determine if there are significant differences between their material properties. Additionally, we plan to utilize a multilevel model to address the variability between fish and account for differences in fish size and shape.

Abstract Name: Effects of DLAN on Circadian Rhythms of APP-SAA Alzheimer's Mouse Model

Alzheimer's disease (AD) is a prolific neurodegenerative disease, impacting 7 million Americans. It is characterized by amyloid plaques and neurofibrillary tangles in the brain. Circadian rhythm disruption, such as fragmentation, often precedes AD onset and is an AD risk factor. Female sex and exposure to dim light at night (DLAN) are also AD risk factors. Using an AD mouse model, we tested the hypothesis that DLAN disrupts circadian rhythms and accelerates AD pathology and that females are more affected than males. This study used the SAA mouse model of AD that expresses 3 humanized APP gene mutations and wild type (WT) mice of both sexes. The mice were 12-13 months old, an age at which amyloid plaques have begun to accumulate. Mice were singly housed in cages with infrared motion detectors interfaced with a circadian rhythm recording system (ClockLab). All mice were exposed to a 12 h light (L):12 h dark (D) cycle for 1 week of baseline recording. Then, one group of mice stayed on the 12L:12D cycle while the other group was exposed to a 12 h light:12 h dim-light (5-10 lux) cycle. We recorded daily activity rhythms and nesting behavior, which enhances sleep in mice. After 8 weeks, the mice were euthanized and brains collected for measurement of amyloid-beta and neuroinflammation in the hippocampus and neocortex, regions regulating cognition that exhibit neuropathology in AD patients and AD model mice. Circadian rhythm analysis of the daily activity data revealed that DLAN disrupted rhythms by increasing fragmentation and decreasing inter-daily stability. We are currently analyzing nesting scores and neuropathology markers, and predict that DLAN will adversely affect these endpoints, probably more severely in females. The total results will help to elucidate how DLAN and female sex affect the risk and progression of AD.

Abstract Name: The Butler Did It: Science and Religion's Justifications of Transphobia

The putative dichotomy between science and religion often finds its grounding in the idea that science deals only with facts, while religion deals with beliefs, which are supposedly disconnected from facts. However, in both scientific and religious rhetoric, one can find arguments insisting that one's expressed gender is only "correct" insofar as it aligns with their sex assigned at birth. In scientific arguments this often culminates in a declaration of "biological sex" as the ultimate determining factor of expressed gender, and in religious rhetoric a cisnormative binary is often insisted upon as being "natural." Using Judith Butler's 2024 book *Who's Afraid of Gender*, I construct a definition of dogmatism, then, in examination of biological texts detailing the complexities of the relation between genetic sex and expressed gender, along with texts examining Catholic narratives of the gender binary, I show that both scientific and religious arguments can have dogmatic bases. Further, using examples of forced sex assignment surgery for intersex people, I show that scientific means can be used towards unjust ends. In conclusion, I suggest ways in which both scientific and religious arguments may be engaged, with an understanding that ideology underlies all arguments, so it must not be ignored, but confronted. Furthermore, I suggest that neither be taken with absolute piety or rejection until their bases have been thoroughly examined.

Abstract Name: Republican Cosmopolitanism Requires Justice as Non-Domination and Non-Oppression

This paper examines the limitations of the neo-republican conception of non-domination as a global justice approach. Neo-republican global justice interventions argue that globalization's erosion of state sovereignty and domestic democratic decision-making are forms of domination. Though globalization is understood as a natural force of market liberalization driving international development, liberalization perpetuates the economic and political disempowerment of citizens and states. As globalization exacerbates inequalities between high-income countries (HICs) and low-and-middle-income countries (LMICs), it simultaneously erodes the capacity for all states to be sovereign bodies, routinely subjecting states and their citizens to interferences of more powerful states, multinational enterprises, and multilateral institutions. Republicans have debated what is required to ensure international justice as non-domination while suggesting that the primacy of non-domination as a common good makes these obligations of justice morally cosmopolitan. These debates preemptively focus on the institutional arrangement necessary to execute this shared moral responsibility by assuming that the prevailing conception of non-domination is sufficient to capture the domination associated with globalization. Neo-republican Phillip Pettit's account of domination has been critiqued for missing ways systemic and structural inequality undermine the freedom of particular social groups. While Pettit's conception of domination effectively understands how interpersonal inequality impedes agents' freedom, his emphasis on agential, intentional, and commonly known interference is incompatible with redressing the systemic and unconscious barriers to freedom characteristic of many contemporary limitations to agency. I argue that these obstructions to freedom are best understood in terms of oppression: the limitations of agency emerging from structural and collective patterns of privilege and power that subordinate social groups. To combat the various ways agents find their freedoms constrained, republicans must incorporate freedom as non-oppression alongside freedom as non-domination. Realizing the duties of non-domination and non-oppression allows for collective, citizen-motivated approaches to countering dominating and oppressive global institutions, systems, and ideologies.

Abstract Name: Exploring the Role of Key Events and Technological Innovations in Shaping Attendee Experience at the State Fair

As new technologies continue to evolve, organizing State Fair events has become an increasingly dynamic process that relies heavily on innovation, requiring data-driven strategies to optimize attendee experiences. Considerable research has been conducted to explore the social and psychological factors that influence attendance and satisfaction at events (e.g., Fernandes & Krolikowska, 2022). However, the role of key events (e.g., grandstand shows, live music, amusement park rides, attractions, booths and showcases, and livestock shows) in shaping attendees' attitudes toward the event warrants more scholarly attention.

Moreover, as emerging technologies have been increasingly introduced to fair attendees in recent years, the specific role of event information software (e.g., websites and mobile apps) in enhancing user experiences remains relatively understudied. Based on the Experience Value Promise (EVP) (Berridge, 2012) and the Technology Acceptance Model (TAM) (Davis, 1989), this proposed research aims to assess attendees' experiences at the 2024 Minnesota State Fair as a case study. The primary objective is to identify which elements of the fair were successful and which areas need improvement for the 2025 fair. The following hypotheses guide this inquiry: H1: Key events at the Minnesota State Fair will have a positive impact on attendees' attitudes toward the fair. H2: The perceived ease of use and perceived usefulness of event information software will positively impact attendees' attitudes toward the fair. To test these hypotheses, an online survey will be administered via Qualtrics software and promoted through social media or email blasts in early 2025. Participation will be voluntary, and participants must be at least 18 years old, having either attended the Minnesota State Fair in 2024 or expressed an interest in attending in 2025. The survey will focus on questions related to attendees' EVPs, with a particular emphasis on the key events examined in this research.

Authors:

Abstract Name: Police Officers' Perceptions of Dropped Charges

Law enforcement officers are the first form of contact with the Criminal Justice System for many individuals. Often, these interactions end in an arrest of an individual who will then be charged with a criminal penalty; however, for some individuals the charges are dropped and the case is dismissed, often due to lack of evidence. To date, not many academic studies have focused on how dropped charges affect the duties and opinions of police. Most studies have focused on the aspect of arrest, the social injury towards the public, and the negative impacts on the arrestee. Also, when discussing dropped charges, most studies have focused on probable cause, Fourth Amendment, and warrant issues, not on the dropped charges themselves. This study examined the experiences and perceptions of law enforcement officers regarding dropped charges. Another area for exploration was how police think dropped charges affect the public's trust in their ability to effectively perform crime-control duties. In-depth, semi-structured qualitative interviews were conducted between October and November 2024 with four officers of the Columbus Police Department with different racial backgrounds. Qualitative data analysis was performed to explore themes and patterns within the data. Themes that emerged from the data include: when making an arrest, law enforcement officers abide by legal standards and procedures; arrest may be seen as the best course of action at the time and serves as a "wake up call" for an arrestee; officers insist that dropped charges negatively influence the public's trust in them to do their jobs well, and the officers question their success and productivity when charges are dropped. The findings of this study serve as the beginning for filling a hole in the literature on dropped charges.

Abstract Name: EFFECTS OF THE MENSTRUAL CYCLE ON BALANCE

Postural control is an important factor in balance and normal movement function. Because estrogen levels are known to affect postural control and muscle strength, this study examines the extent to which estrogen levels impact postural control by assessing balance during two phases of the menstrual cycle: menses (days 1-5) and the luteal phase (days 15-24). It is hypothesized that balance performance will decrease during menses when hormone levels are lowest. A repeated measures design was used to test subjects on three balance assessments: Force Plate Standing (Quiet Stance), Tandem Walking Test, and 4-stage Balance Test. The Force Plate Standing Test measures the center of pressure displacement as subjects stand relaxed with closed eyes for 30 seconds. The Tandem Walking Test counts the number of steps out of line as participants walk heel-to-toe for 10 steps. The 4-Stage Balance Test involves holding four progressively challenging positions for 10 seconds, focusing on balance maintenance without moving the feet. This study is ongoing. The results from six subjects are reported. The average mediolateral sway during quiet stance was 11.63 ± 3.4 during menses and 16.3 ± 15.5 during the luteal period. The average anteroposterior sway during quiet stance was 32.9 ± 11.4 during menses and 37.8 ± 24.5 during the luteal period. The current data sets suggest an effect of estrogen on postural control. Postural sway has no significant effect. Tandem and 4-Stage Balance Test is better off cycle. Given the small sample size thus far and the variability between subjects, more data should be collected before asserting confidence in the hypothesis.

Abstract Name: Epinephrine increases the occurrence of arrhythmia under low-glucose conditions in isolated rat hearts

Severe hypoglycemia accounts for up to 10% of deaths in individuals with insulin-treated Type 1 diabetes. Previous research in the Fisher lab has demonstrated that severe hypoglycemia induces fatal cardiac arrhythmias. The counterregulatory response to hypoglycemia triggers a marked increase in epinephrine levels that may contribute to these fatal arrhythmias. We wished to test the hypothesis that the arrhythmias associated with severe hypoglycemia result from elevated epinephrine levels rather than reduced glucose availability. To test this hypothesis, we utilized an isolated heart model. Briefly, hearts were extracted from 10 week-old Sprague-Dawley male rats. Aortas were cannulated and retrograde-perfused with Krebs-Henseleit (KHB) buffer containing glucose concentrations of 5, 2.5, 0.5, and 0.1 mM, with or without epinephrine (1 μ M) using a Langendorff perfusion system. Electrodes positioned in the heart recorded ECG data, allowing us to analyze heart rate, isolated arrhythmic events, and the duration of arrhythmic episodes. Low-glucose (0.5 or 0.1 mM) alone did not significantly increase arrhythmic duration compared to normal glucose levels (5 mM glucose). However, the presence of epinephrine (1 μ M) significantly prolonged arrhythmia duration under low-glucose (0.1 mM) conditions compared to control (5 mM glucose). These results suggest that severe hypoglycemia-induced cardiac arrhythmias may be mediated by synergistic effects of elevated epinephrine levels and low blood glucose.

Abstract Name: Doing "Other Stuff": Negotiating Sexual Identities in Christian Communities

This study explores how individuals within Christian communities negotiate their sexual identities through language. The research focuses on the use of euphemisms and conjunctions when discussing sexual experiences among heterosexual and queer individuals to discern underlying ideologies of sexual superiority or inferiority. The analysis examines how these linguistic choices reflect and reinforce cultural conceptions of sex, often rooted in heteronormative and phallocentric ideologies. The study draws on interviews with participants from diverse Christian denominations, analyzing their experiences and the language they use to describe their sexual identities and practices. Key findings indicate that queer individuals often leave Christian communities to reconcile their sexual identity due to feelings of invalidation and ostracization, leading them to use less euphemistic language. In contrast, heterosexual participants, whether currently or formerly active in their Christian communities, tend to use more euphemisms and conjunctions, reflecting a sense of sexual superiority through culturally sanctioned norms. The research underscores the complex interplay between language, religion, and sexual identity, revealing the broader implications of sociocultural Christian constructs and how individuals navigate these challenges to affirm their sexual selves.

Abstract Name: Personality and Frustrated Driving

In 2021, the Foundation for Traffic Safety surveyed the U.S. driving population at approximately 245.3 million. That same year, the National Highway Traffic Safety Administration reported a significant increase in police-reported traffic crashes from 5.25 million in 2020 to 6.10 million in 2021. Notably, 12,330 fatalities in 2021 were attributed to speeding behaviors (National Center for Statistics and Analysis, 2023). As the population of drivers rises, the cases of roadway accidents are on the rise. A proactive approach is needed to see what behaviors are leading drivers to these accidents. Keinath et al. (2017) noted driving violations tend to occur in the presence of emotional impairments such as anger. The risk associated with human behavior in vehicle accidents prompts inquiry into whether some personality traits predispose individuals to higher levels of driving errors. Trait theory has been used to predict enduring behaviors; the relationship is complex. Researchers like Monson et al. (1982) showed that personality can predict behavior in certain situations and cannot in others. Researching the relationship between personality traits and frustration could lead to possible prevention of accidents and fatalities on roadways. Traits such as neuroticism (Luo et al., 2023), extraversion (Harris et al., 2014), and boredom proneness (Mugon et al., 2018) may predispose individuals to aggressive tendencies that lead to unsafe driving. In contrast, a trait like conscientiousness (Harris et al., 2014) has been shown to have more safe driving performance. Using simulated driving for research will allow an investigation into the inclinations of certain driving behaviors like speeding, centerline crossings, proper turn usage, and collisions.

Discipline: Dance

Authors:

Abstract Name: Innovation in Motion: The Intersection of Dance and Technology in Performance Art

Introducing additional technological elements into live performance offers a more immersive and captivating experience for the audience members. In dance composition, when complex technological advancements are incorporated, the creative process is often centered around reacting to and engaging with the specific technology rather than using it to supplement a preexisting idea. However, this research takes a previously created contemporary ballet choreographic work titled anywhere but now and explores how applied scientific and digital investigations could enhance the movement, uncovering deeper interpretations of the concept. The intention of adding technological components is to create a more impactful performance without shifting too much attention away from the dancers and the carefully calculated movement. As a result of applying additional technology that complements the choreography, the piece could gain momentum with a population that does not regularly attend dance performances. Through investigating the potential for 3D interactive projection mapping, virtual reality, the metaverse, and artificial intelligence, this research seeks to curate an experience that amplifies the physical and emotional themes the dancers are portraying by inviting a personal encounter that resonates deeper with viewers. Layering these technologies on an established concept encourages a greater sense of engagement for audience members by fostering curiosity, stimulating internal contemplation, and extending appreciation for the art form. Expanding the creative process for choreographers and dancers beyond standard technical design elements such as lighting, staging, and costume paves the way for innovation in how live dance performances are imagined. Artists can question the possibilities that lie in disrupting the barriers between the physical and digital realms and how to create increasingly captivating projects that broaden the audience that is interested in dance.

Abstract Name: Installation of low temperature transimpedance amplifier to improve the performance of a scanning tunneling microscope

Scanning tunneling microscopy (STM) is a well-established technique used to study and characterize the topographic and electronic properties of material surfaces with atomic resolution. We outline an undergraduate research project aimed at restoring and improving the performance of a custom built low-temperature STM. Along with diagnosing and troubleshooting various system components, this restoration involved the building of an in-situ transimpedance amplifier to boost system signal-to-noise ratio (SNR). We conducted a survey to identify a commercially available op-amp candidate that was high vacuum compatible, low-temperature compatible, had sufficiently high bandwidth, and had low input bias. We then carried out ex-situ Bode plot analysis of op-amps in liquid nitrogen to screen for the best performing devices. Multiple rounds of compatibility and installation design testing were performed, followed by a final installation and a significant reduction in 60Hz noise in tunnelling current. Using the installed amplifier, we demonstrate

atomic resolution and spectroscopy capabilities, at room temperature and at low-temperature (77K). Finally, we use the instrument to carry out STM measurements of epitaxially synthesized 2D quantum materials.

Abstract Name: From Fair Play to Power Play: The Political Evolution of Anti-Doping Regulations in International Sports

How have doping policies in the Olympics altered the symbolic balance of power and claims to legitimacy between states? How have anti-doping regulations evolved in response to political pressures made upon institutions like the International Olympic Committee (IOC) and the World Anti-Doping Agency (WADA) and international relations? Anti-doping regulations are shaped by health and fairness concerns, while geopolitical considerations, national interests, and global power dynamics also influence them. The use of performance-enhancing drugs, also known as doping, has been a pervasive problem in international sport. Since the 1960s, the IOC has struggled to eliminate the use of such drugs. A few countries, particularly Russia, have been repeatedly accused of state-sponsored doping, resulting in Russia's ban from the 2020 and 2022 Olympic Games. They have met these controversies with accusations of unfair treatment and criticized the international institutions responsible for these sanctions as biased and selective in their responses. The battles taking place in the international sports scene are a vital indicator of shifting perspectives on legitimacy and strength. The significance of this research lies in uncovering the often overlooked political motivations behind doping policies, demonstrating the ways in which nations like the United States and Russia have manipulated the practice of rule-making and enforcement to make claims of sabotage, cast doubt on the role of international institutions, and assert dominance globally. Taking on a critical lens, this research highlights the political motivations behind doping regulations. Arguing that anti-doping measures serve as tools of soft power and global legitimacy, it reviews the history of the last decade's doping scandals in winter sports, the evolution of WADA policies, state-led responses by the United States and Russia to these policies, and the changes made by the United States and Russia to take advantage of these regulations.

Abstract Name: Taking the Russia out of the Soviet: Derussification of Federal Language Laws in Post-Soviet Latvia

This paper investigates the relationship between federal language laws, population demographics, and international political events in twenty-first century Latvia. The Latvian federal government has implemented laws restricting the use of the Russian language and mandating minimal proficiency in the Latvian language. Previous research has examined the predominance of the Russian language over native national languages in post-Soviet countries on language displays and the enforcement of language laws on public and private displays. This research will utilize derussification, the process of removing Russian influence to make space for native, national cultural influence. I will thematically code Latvian federal language laws by sociopolitical sphere, severity, and language of restriction. I will then compare the years of law implementation to international events as reported by major Latvian newspapers and to trends of population demographics as reported by the Central Statistics Bureau of Latvia. This project expects to find international events provoke the implementation of federal language law, then in turn provoking changes in population demographics. As future research expects to see international events impact language laws and population demographics, this research project may show derussification could rebuild national identity in other post-Soviet countries.

Abstract Name: Naturally Derived UV Filters: Comparison of Sun Protection Properties of a Library of Hydroxycinnamic Esters.

Chemical UV filters approved for use in US sunscreen formulations are under increasing scrutiny due to their potential undesirable effects on human health and the environment. Concerns exist over long-term endocrine disruption and developmental toxicity that the sustained use of sunscreens might pose. Plant-based hydroxycinnamic acids (HCAs) and their corresponding esters are safer alternatives, and are known to absorb in the UVB-UVA (290–400nm) region of solar radiation. This study sought to evaluate and compare the potential of HCA esters for use as main UV filters in sunscreens using as performance benchmark existing commercial UV filters. In the first phase of the project, three naturally occurring HCAs, ferulic acid, sinapic acid, and 3,4-Dimethoxycinnamic acid were each converted into their respective esters by Fischer esterification under microwave irradiation, using alcohols of increasing molecular weight C2-C5. Following isolation and purification by column chromatography, each ester product was incorporated in 8% weight in

combination with up to 3% avobenzone into a sunscreen emulsion and subsequently applied as thin film in polymethylmethacrylate plates. The ability to block solar radiation was measured via UV transmittance spectroscopy prior and after irradiation under a solar simulator. Proliferation assays of new compounds were performed on human skin cell. HCA esters were found to be non-toxic, and typically less toxic than commercial counterparts. We have shown that sunscreens containing approximately 8% weight of any one ester with 3% avobenzone compare well a commercial broadband sunscreen with SPF+50 containing 22.5% of a mixture of homosalate, octisalate, and octocrylene with 3% avobenzone. Calculated sun protection parameters were within 90-95% of the corresponding values of the commercial sunscreen. The in vitro data generated from this study suggest that each of the naturally sourced HCA-esters has the potential to replace or reduce the use of three commercial synthetic UV filters.

Abstract Name: The Relationship Between LGBTQ+ Mental Health and American Politics

Introduction: Over the past year, over 520 anti-LGBTQ+ bills were introduced in the U.S., with 70 becoming law (Peele, 2023). Such climates contribute to internalized stigma, minority stress, and poor mental health for LGBTQ+ individuals (Gonzalez et al., 2022; Pulice-Farrow et al., 2023). This study builds on existing research by examining the impact of LGBTQ+ political insecurity across different presidential administrations (Trump vs. Biden), congressional acts, and Supreme Court decisions. It aims to understand LGBTQ+ individuals' emotional responses to these political changes and their mental health effects. Method: With IRB approval, 25 LGBTQ+ participants (Mage = 19.9, SDage = 2.59) were recruited through social media, listservs, the university's SONA pool, and snowball sampling. They completed a 30-minute semi-structured Zoom interview with eight demographic and 16 open-ended questions about community involvement, political security, and well-being. Qualitative Analysis: The Principal Investigator (PI) developed thematic codes from recurring interview patterns, reviewed with the co-PI, and coded participant narratives. Results: Seventy-two percent of participants stayed informed about LGBTQ+ politics, with 80% feeling politics significantly impacted their lives. During Trump's administration, 72% felt insecure, compared to 36% during Biden's. Despite Biden's improvements, 36% reported ongoing insecurity. Sixty-four percent viewed the Supreme Court's LGBTQ+ protections negatively, and 48% were concerned about Congress's role. Forty-four percent reported negative effects on well-being, with another 44% expressing anticipatory anxiety. Conclusion: This study adds depth to Minority Stress Theory (Meyer, 2003) and suggests future research should use participatory action models to improve LGBTQ+ political security and well-being.

Abstract Name: The In Vivo Study of Clove Essential Oil against Aflatoxin B1 Production in *Aspergillus flavus* Contaminated Georgia Peanuts

Georgia produces half of U.S. peanuts, but the southeast loses \$25M annually due to aflatoxins from *Aspergillus* spp. contamination. *Aspergillus flavus* produces aflatoxin B1 (AFB1), affecting humans, livestock, and crops globally. AFB1, a class 1 human carcinogen, is the most toxic, according to the International Agency for Research on Cancer (IARC). Synthetic fungicides degrade slowly, harming ecosystems, while biological controls like genetic engineering and antimicrobial compounds have had limited success against *A. flavus*. Therefore, the need for biological controls, such as plant-based antimicrobials against crop-damaging molds, is increasing. Our previous in vitro study confirmed the anti-aflatoxigenic properties of clove essential oil (EO) against *A. flavus*. Our current in vivo study evaluates the effectiveness of clove EO against *A. flavus* and its production of AFB1 in peanuts harvested from contaminated Georgia seeds. Seeds were exposed to clove EO at 250 ppm, 500 ppm, and 2000 ppm for 24 hours in sealed flasks, with five replicates each. Exposed and unexposed seeds were sown with Miracle-Gro potting mix in a greenhouse and watered as needed. Seedlings were monitored weekly, with few showing signs of disease or remaining stunted before harvest. Peanuts were harvested, shelled, and air-dried after seven months. AFB1 in harvested peanuts was quantified using Liquid Chromatography-Mass Spectrometry (LC-MS) with Selected Ion Monitoring (SIM). Unexposed seeds served as a negative control, and seeds exposed to a synthetic fungicide served as a positive control. Our findings demonstrate a strong negative correlation between clove EO in exposed seeds at different concentrations and AFB1 production. We observed that with an increase in concentration, there was a decrease in AFB1 production ($IC_{50} = 63.15$ ppm, $R^2 = 1.000$), which corroborates with our previous in vitro findings. Since the magnitude of inhibition was marginal, we plan to investigate further the potential of clove EO under field conditions.

Abstract Name: Social Determinants of Substance Use Disorders and Addiction Treatment: Evidence From Arbor Place Professionals

Drug addiction has been on the rise in the United States over the last ten years, with more individuals being diagnosed with a substance use disorder (SUD). Traditional discourse surrounding drug addiction tends to focus on genetic and biological factors that can lead to the development of SUDs, with less discussion of the environmental, social, and financial aspects that also contribute. In addition, some of this discourse has exhibited a victim-blaming stereotype surrounding individuals with drug addictions. In order to better understand the complex causes of SUDs, I take a holistic and intersectional approach by collecting the narratives of professionals who work in the SUD field. Specifically, I seek to answer the following questions: How do different demographic factors impact the development of substance use disorder and influence the process of recovery? How do financial difficulties impact access to treatment and other support programs? To address these questions, ten interviews were conducted with clinical substance abuse counselors and other staff at a treatment center in Menomonie, WI. In analyzing their narratives, the following themes emerged: the impact that trauma has on substance use and recovery, the significant intersection of socioeconomic status and geographic location, and the benefits of having support systems in place. This information is crucial to understanding the social and environmental aspects which contribute to SUDs among different demographic populations. Through obtaining a meaningful understanding and raising awareness on this social problem,

new strategies and clinical approaches can be developed to assist people who struggle with addiction. Responses from clinical staff bring awareness to and attempt to discredit these stereotypes through recounting firsthand experiences, highlighting financial barriers, and addressing environmental aspects which render these stereotypes inaccurate and develop a new and precise understanding and representation of individuals with SUDs.

Abstract Name: Neurochemical Monitoring of Glutamate Content in Hippocampal CA1 Region of FusOLcKO Hypermyelinating mice

Oligodendrocytes play an important role in maintaining the integrity of neuronal circuits. Our lab developed a hypermyelinating mouse model by conditionally knocking out Fused in Sarcoma (Fus) in oligodendrocytes (FusOLcKO). Electrophysiological recordings using microelectrodes implanted through the visual cortex to CA1 revealed sustained neural activity in CA1 of FusOLcKO mice compared to wild type (WT), suggesting oligodendrocyte regulated hippocampal neural signaling. However, the excitatory nature of the activity remains unclear. To address this, custom microelectrodes measured glutamate concentration in dorsal (d)CA1, medial (m)CA1 and ventral (v)CA1. A gradient of decreasing glutamate concentrations was observed from dorsal to ventral CA1 in both genotypes, suggesting spatial regulation of glutamate production. Glutamate concentration in (d)CA1 was higher in the FusOLcKO vs. WT mice. The increased glutamate content is consistent with the enhanced neural activity in CA1. We hypothesize that elevated glutamate in FusOLcKO mice reflects increased synaptic density in CA1. To investigate the neuroanatomical and cellular basis underlying the electrophysiology, we localized the electrode tracts in brain sections by staining for mouse IgG leakage at implantation sites. Cellular environments at recording sites will be characterized by immunohistochemical staining for glial markers GFAP (astrocytes) and Iba1 (microglia), myelin markers MBP (Myelin Basic Protein) and MOG (Myelin Oligodendrocyte Glycoprotein), and axonal marker NF200 (Neurofilament Heavy Chain). Additionally, excitatory synaptic density will be quantified using markers for presynaptic (vGLUT1) and postsynaptic (PSD95) proteins. This study aims to elucidate the relationship between myelin integrity and excitatory neurotransmission in the CA1 hippocampal region, providing insights into pathologies where hippocampal synapse degradation is prominent.

Abstract Name: Do ERBB4-ERBB2 heterodimers drive ERBB4-dependent, ERBB2-dependent, BRAF WT melanoma cell lines?

Melanomas are aggressive and deadly subtypes of skin cancer. Approximately 50% of melanomas harbor a gain-of-function mutation in a BRAF allele and these tumors respond to immune checkpoint inhibitors (ICIs) or a combination of BRAF and MEK inhibitors. Unfortunately, the ~50% of melanomas that possess wild-type BRAF alleles (BRAF-WT melanomas) are not responsive to targeted therapeutics and ICIs are not highly effective against these tumors. Thus, our long-term goal is the development of agents that are effective against BRAF-WT melanomas. Four BRAF-WT melanoma cell lines are driven by elevated transcription of wild-type ERBB4 or gain-of-function mutant alleles of ERBB4. ERBB4 encodes a receptor tyrosine kinase that is closely related to the Epidermal Growth Factor Receptor (EGFR), ERBB2 (HER2), or ERBB3 (HER3). Moreover, three of these ERBB4-dependent, BRAF WT melanoma cell lines are also dependent on ERBB2. Since ERBB4 homodimers inhibit tumor cell proliferation, we hypothesize that ERBB4-ERBB2 heterodimers drive these ERBB4- and ERBB2-dependent, BRAF-WT melanoma cell lines. To test this hypothesis, we are evaluating the activity of mutant alleles that affect the cytoplasmic ERBB2/ERBB4 dimer interface. We are testing whether mutations in the N-lobe of the ERBB4 kinase domain cause loss-of-function phenotypes (reduced signaling and stimulation of proliferation) and whether mutations in the C-lobe of the ERBB2 kinase domain cause loss-of-function phenotypes. Finally, we will test whether loss-of-function ERBB4 N-lobe mutant alleles can be rescued by loss-of-function ERBB2 C-lobe mutant alleles. Positive results would suggest that ERBB4-ERBB2 heterodimers drive the proliferation of ERBB4- and ERBB2-dependent melanomas and that such melanomas will respond to combination therapies that feature FDA-approved anti-ERBB2 agents, including pertuzumab and lapatinib.

Abstract Name: The Art of Consent

This piece of visual art is titled, "The Art of Consent," it was sourced from the original consent form for Jonas Salk's poliovirus vaccine trials. It was made using plywood and acrylic. The design was created using Adobe Illustrator and made tangible through the use of a laser engraver. The artwork is meant to show how consent forms have developed over time. The piece consists of a plywood back and frame, various plastic-colored pieces, and a cover made out of plywood. When the cover is lifted, it reveals the artwork underneath. Each plastic-colored piece represents a different section of a modern-day consent form. The pieces fit together in a specific way showing how each section is essential to provide a full picture of consent for a participant. The artwork is interactive, as you can take the plastic pieces out of their place and put the work back together. On the back of the cover reads Jonas Salk's original one-paragraph consent form. The presence of the original consent form allows for a comparison between the past and the present. This interactive piece is meant to show the intricacies of consent forms today. The piece should raise certain questions to the audience about the changing nature of consent and its relationship to liability, both for and on the participant as well as the company or entity delivering the informed consent.

Abstract Name: The Exploration of Art Education in Character Development and Self-Actualization: A Focus on Gratitude

This study aims to examine how art education can empower primary students to self-actualize their identity, values, and social-emotional strengths. Stable values and the ability to know oneself can aid individuals in advocating for themselves and others. Based on research by The National Endowment for the Arts, The American Academy of Arts and Sciences, and The Journal of Aesthetic Education, art education classroom experiences can facilitate free expression about prosocial values and behaviors. This study will examine how middle school students express ideas about gratitude in an art education experience. It will explore what gratitude means to them and their identity, which may help develop critical thinking skills that will foster a more positive community. Semi-structured individual interviews with ten students will be conducted to elicit responses about their experiences within a small art class before the art lesson that reflects on the value of gratitude, observe that classroom's experience during the lesson, and interview each student after the lesson to evaluate their ideas about gratitude and their own identity. Using thematic analysis to analyze both the students' interviews and artwork made during the lesson allows me to evaluate how the ideas expressed in their interviews are demonstrated through their artwork. With this information collected, I want to determine how art education curriculum can intertwine with social-emotional learning and self-discovery. This research aims to better our education and communities with a further understanding of how using art education as a vehicle of self-expression and reflection can develop stable and kind character development for our future.

Abstract Name: The Impact of OECD Population Aging on Economic Growth and Productivity

Population aging is expected to slow economic growth. A recent paper by Maestas et. al (2023) finds that a 10% increase in the US population share of individuals aged 60+ decreases GDP per capita by 5.5%, and attributes approximately two-thirds of this decline to a slower growth in labor productivity, using the variation in the predetermined component of aging. I expand this research to all OECD nations, using a similar identification strategy. I find that a 10% increase in share of a nation's population aged 60+ decreases labor productivity per worker by 0.348 percentage-points and decreases GDP growth by 0.375 percentage-points. Additionally, these results are stronger for earlier members of the OECD, indicating that older nations are at greater risk of economic stagnation due to these demographic shifts.

Abstract Name: Sleep, Napping, and Their Impact on Academic Performance

On average, 60% of college students report poor sleep each night (Mbous et al., 2022). Sleep deficiency is frequently caused by factors such as poor work-life balance, social obligations, and extracurricular activities (Liu et al., 2023). Lack of sleep can lead to negative student health outcomes and increased distress (Liu et al., 2023). However, many students may need to be made aware of how inadequate sleep affects their academic performance (Ye et al., 2015). Sleep deprivation, particularly late bedtimes and irregular sleep/wake cycles can impair concentration and academic performance. Students will often compensate for lack of sleep by napping during the day, but this behavior can further disrupt their nighttime sleep patterns (Taylor et al., 2013). This study aims to examine the association between sleep quality, napping behaviors, and academic performance among college students. The primary objective is to determine whether students who get adequate sleep perform better academically and if napping can mitigate the effects of poor nighttime sleep. A sample of students from first-year seminar and psychology courses at a small liberal arts college will complete a survey on sleep quality and napping habits. This survey study assesses sleep using the Pittsburgh Sleep Quality Index (PSQI; Shahis et al., 1989), while napping behavior is measured with the Napping Behavior Questionnaire NBQ; Lovato et al., 2014). Participants will indicate their current GPA, in addition, data from the registrar will be used to assess academic performance at the end of the semester. Multiple regression analyses will be conducted to explore the relationship between sleep, napping, and academic performance. Initial findings suggest that sleep quality is not strongly correlated with academic performance, but further data collection is ongoing. Understanding the role of napping behavior will allow for more specific recommendations regarding sleep among college students.

Abstract Name: Imidazo[1,2- α]pyridine Derivatives from Synthesis of α -bromoacetophenone

Imidazo[1,2- α]pyridines are nitrogen-containing bicyclic aromatic molecules studied due to their biological activity. They may act as antiparasitic, antibiotic, anti-inflammatory, and other biological agents which make them useful as drug candidates, and the potential for these structures to exhibit excited-state intramolecular proton transfer fluorescence applies them to molecular switches and biomarkers. Existing methodologies to synthesize imidazo[1,2- α]pyridines focus on the condensation of 2-aminopyridine and acetophenone in basic conditions. We propose the synthesis of α -bromoacetophenone derivatives from acetophenone derivatives, and experimentation of one pot and two-step synthesis methods to determine the preferred methodology for the condensation of α -bromoacetophenone and 2-aminopyridine in the synthesis of imidazo[1,2- α]pyridines capable of fluorescence. The chosen methodology will alleviate the limitations from previous literature including low yield and restrictions of available starting materials for a more efficient and cost-effective synthesis of imidazo[1,2- α]pyridine derivatives. Once the desired products are synthesized, a mixture of products in poly(methyl methacrylate) plastic films will be created by solution casting to observe their fluorescence in an application setting.

Abstract Name: Targeted Knockout of oprM Gene in Pseudomonas Species to Investigate its Role in Toxin and Antibiotic Resistance

An understanding of how efflux pumps contribute to antibiotic and toxin resistance is crucial for the development of strategies to combat bacterial infection and environmental pollution. One example is the MexAB-OprM efflux pump which is most well known in *Pseudomonas aeruginosa* for its clinical applications, as well as in other species such as *P. fluorescens* and *P. mendocina* for its role in expelling toxins and drugs from the cell. The objective of this experiment was to perform a targeted knockout of the oprM gene using CRISPR-Cas9 technology to interpret the role of OprM in toxin and antibiotic resistance. This study investigates the function of the OprM protein in expelling toxins and antibiotics from multiple *Pseudomonas* species, using ethidium bromide (EtBr), heavy metals (Cu, Zn), and antibiotics (tetracycline, ciprofloxacin) as model substrates. Following oprM knockout, toxin and antibiotic resistance in these bacterial species will be observed to indicate the role of the OprM subunit in the efflux pump, and thus give insights into its role in bacterial antibiotic resistance and toxin defense.

Abstract Name: Few Places to Learn, Few Spaces to Talk: Reproductive Health Literacy Among Gen Z Women

The present study investigates reproductive health literacy among Generation Z women aged 18-29, focusing on their understanding of fertility and (in)fertility. Despite the peak fertility window for women occurring in their late teens to early 30s (Delbaere et al., 2020), existing research specific to women in Generation Z remains lacking, suggesting that young women lack knowledge about reproductive health (Martins et al., 2023). This study examines women's knowledge levels specific to fertility and infertility treatment using a modified version of Kudesia et al. (2017), Fertility & Infertility Treatment Knowledge Score Survey (FIT-KS). Results suggest a gap in knowledge specific to fertility and reproductive health among Gen Z women. Few spaces or places encourage dialogue specific to fertility, and those that do, such as a doctor's office, are still perceived as "uncomfortable" by some (26%), and 58% "never" to "rarely" discuss reproductive health with their doctor. Respondents were split between those who feel informed about their fertility (40%), those who do not (48%), and those who feel neutral (12%). More research is needed to define what "informed" means for Gen Z, to examine the information of Gen Z, and how to improve access to health education.

Abstract Name: Systematic Analysis of Parameter Variations in a Stochastic Fibrin Fiber Degradation Model

Fibrinolysis is the biological process where fibrin, the main structural protein in blood clots, is broken down. This process is critical in wound healing and maintaining blood flow by preventing excessive clotting that could lead to thrombosis. Dysregulation of this process can lead to heart attack and stroke. Fibrinolysis is mainly achieved by the enzyme plasmin, which is activated from its precursor plasminogen by tissue plasminogen activator (tPA). We present a stochastic model of the enzymatic degradation of a single fibrin fiber. This model uses the Gillespie algorithm which is a stochastic method for simulating the time evolution of systems with random events. It calculates when the next reaction occurs and which reaction it is, based on reaction probabilities and random numbers. Model outputs include cleavage time (time for fiber to degrade) and cleavage success rate (proportion of simulations that resulted in cleavage). We systematically alter various parameters to obtain cleavage times and success rates for a range of physiological and pathophysiological conditions. Our results are then compared to in vitro experiments from collaborators to obtain a better understanding of the underlying mechanisms driving fibrinolysis.

Abstract Name: THPP-1 PDE10A inhibitor mitigates the hyperdopaminergic state in a neurodevelopment model of schizophrenia.

Schizophrenia (SCZ) is a complex neuropsychiatric disorder marked by significant disruptions in brain function, including dopamine (DA) dysregulation in the ventral tegmental area (VTA), which is driven by hyperexcitability in the ventral hippocampus (vHipp). Current antipsychotic treatments primarily address positive symptoms of SCZ, but are limited in reducing vHipp hyperexcitability. Phosphodiesterase 10A (PDE10A) inhibition has emerged as a novel therapeutic strategy to treat multiple symptom classes of SCZ. Our study examines the effects of THPP-1, a PDE10A inhibitor, on DA dysregulation and vHipp activity in rats. This is investigated using a well-established neurodevelopmental rodent model of SCZ induced by prenatal exposure to methylazoxymethanol acetate (MAM) injection on gestational day 17 (20 mg/kg, i.p.). Adult male offspring of pregnant MAM-treated or Saline-treated rats were administered acute (3 mg/kg, i.p.) doses of THPP-1. Electrophysiological recordings were used to assess changes in DA neuron activity in the VTA and pyramidal neuron activity in the vHipp. Our findings indicate that acute THPP-1 administration reduced the abnormal, elevated number of spontaneously active DA neurons only in MAM-offspring rats ($p < 0.05$, $F_{1,24} = 9.2$, two-way ANOVA) without affecting the average firing rate and spikes in burst of DA neurons ($p > 0.05$, Kruskal-Wallis). The saline-offspring rats were unaffected by THPP-1 treatment in all measures. In the vHipp, THPP-1 did not alter the number of spontaneously active pyramidal neurons ($p > 0.05$, two-way ANOVA) and spikes in burst ($p > 0.05$, Kruskal-Wallis). THPP-1 was also unable to decrease the enhanced firing rate of pyramidal neurons observed in MAM rats ($p > 0.05$, Kruskal-Wallis). Our results demonstrate that THPP-1, a PDE10A inhibitor, normalizes the hyperdopaminergic state in the MAM phenotype but does not normalize vHipp hyperexcitability. Therefore, THPP-1 may modulate a different brain circuit to mitigate the VTA hyperdopaminergic state in the MAM model of SCZ.

Abstract Name: Synthesis and Analysis of Antifungal Peptoid Dendrimers

Fungal infections, particularly those caused by *Cryptococcus neoformans*, present a significant global health burden, with high mortality rates in immunocompromised populations. There are several antifungal treatment options available, but they exhibit high toxicity levels and drug-resistant variants of *C. neoformans* have become increasingly common. Peptoids, derivatives of peptides, offer a promising alternative due to their high antifungal activity, excellent half-life, low toxicity, and quick-killing kinetics. This study focuses on enhancing RMG8-8, a peptoid developed by our lab with high antifungal activity against *C. neoformans*, by synthesizing peptoid dendrimers to allow for more potent treatment options. Dendrimers are macromolecules with a unique branched structure that has been shown to improve drug efficacy by increasing the drug's half-life, solubility, and localized concentration. This presentation will show the results of the synthesis of peptoid dendrimers, accomplished through a mix of solid-phase synthesis and convergent synthesis. The resulting dendrimers are verified, characterized for their size, surface charge, and purity, and tested against *C. neoformans* using an MIC assay to determine antifungal properties.

Abstract Name: Examining the Effects of Enculturation on Narratives and Interpretation of Music Excerpts

This study investigated how participants' imagination is impacted by enculturation, specifically the imagination of narratives in response to instrumental excerpts. Participants were grouped into three cohorts; one from an isolated rural setting in Dimen, China; one from Springfield, Arkansas; one from East Lansing, Michigan. Each participant was tasked with listening to instrumental music and describing any narrative they imagined in response, including momentary imagery or full-fledged narratives. Some musical excerpts elicited narratives describing the same topics, themes, and words across all cohorts. For example, all groups reported imagining themes of grief while listening to a track titled "Groans of the Sick", and all three mentioned Tom and Jerry while listening to "Four Etudes for Orchestra, No.4: Allegro con moto" by Stravinsky. The latter phenomenon inspired our creation of the term the "Tom and Jerry effect", which we use to describe niche pop culture references that appear in narratives across all the examined cultures. Western and Chinese listeners also mentioned themes that were not observed in the opposite culture. For example, Disney was only mentioned by Western cohorts, and the Chinese Grand Song was only referenced by Chinese listeners. As we investigate these moments of cultural alignment and divergence in music inspired stories, we point toward an innovative model for linking specific structures and tempo in music to the kinds of stories

people hear. Through this presentation, moreover, we aim to provide a comprehensive overview of when and why instrumental music yields culture-influenced narrative listening. There are important applications of musical narratives analysis in reducing cross-cultural misunderstandings, and research examining the role of music in manipulating emotional state.

Abstract Name: Impact of Rebates on Home Loan Interest Rates and Homeownership

This research examines the impact of home loan interest rate rebates on homeownership rates among middle-income families, addressing the central question: Do interest rate rebates significantly increase homeownership by reducing borrowing costs? Rising housing unaffordability and escalating interest rates have created substantial barriers to homeownership for middle-income families. Policymakers and financial institutions have implemented interest rate rebate programs as a potential solution to reduce borrowing costs, but their effectiveness remains underexplored in the literature. This study seeks to fill this gap by analyzing the relationship between interest rate rebates and homeownership rates, while also identifying areas for further investigation. Using a mixed-methods approach, we analyzed historical mortgage data from financial institutions to assess changes in homeownership rates following the implementation of rebate programs. Preliminary findings reveal a positive correlation between the availability of rebates and increased homeownership among middle-income families. Specifically, rebates have been shown to reduce monthly mortgage payments, making homeownership more accessible significantly. These quantitative results are supplemented by qualitative insights from surveys and interviews with recent homebuyers, highlighting how interest rate rebates influenced their decisions to purchase homes. Building on these findings, future research will expand the dataset to include longitudinal studies across different regions and demographic groups, providing a more nuanced understanding of the long-term impact of interest rate rebates. Additionally, we plan to explore how such rebates interact with other housing policies and economic conditions to influence homeownership trends. By identifying best practices, this research aims to inform policy recommendations for expanding rebate programs to promote housing affordability and economic equity. This study contributes to the broader discourse on affordable housing solutions, emphasizing financial incentives in addressing systemic barriers to homeownership. The findings provide actionable insights for policymakers, and financial institutions, fostering a collaborative approach toward creating a more equitable housing market.

Authors:

Abstract Name: A Dramaturgical Examination of The Life of King Henry the Fifth by William Shakespeare

This paper serves as a digest of the historical and theatrical context of Shakespeare's "Henry V," as well as an investigation of the question central to all dramaturgy: why this play now? The project approximates the sort of informational packet that a director, actor, or designer might expect to receive to aid in the development and production of the play to provide a deeper contextual and thematic understanding of "Henry V." The information is structured to be digestible and flow thematically; it begins with the historical context in which Shakespeare wrote, outlining the broad strokes of Elizabethan England, particularly as concerns the Church and the Queen, but also the lives of ordinary men; then an explanation of the history play as a genre, which was at its peak of popularity at the time, and the genre into which Henry V falls; then a biography of Shakespeare himself. An analysis of the play ends the digest; first the play is placed within the context provided at the beginning of the paper. There is a summary of the action, a breakdown of three of the main historical characters as compared to the real men and woman, and a comparison between three productions of the play: Laurence Olivier's 1944 film adaptation, Kenneth Branagh's 1989 film adaptation, and the fall 2024 Chicago Shakespeare Theater production. The conclusion explores whether Shakespeare's work, specifically "Henry V," remains relevant today. The paper ultimately concludes that the works of Shakespeare, specifically "Henry V," remain relevant and timely even today. Literary and historical research, utilizing sources from resource texts, the books and articles of Shakespearean scholars, film productions, and a contemporary stage production, comprise the body of sources that are the foundation of this project.

Abstract Name: Numerical Computations of Advanced Water-Cooled Cold Plates for Thermal Management of Microchips with Hotspots

Computers lie at the heart of today's technological world, powering everything from simple web searches to the development and testing of sophisticated systems like spaceships. Computer chips are the core component that allows for such a world to exist, and their processing power is continuously increasing. This demanding increase in performance brings many challenges. Overheating and uneven temperature distribution in microchips is a significant issue that undermines their reliability and lifespan. Traditional cooling methods, such as air cooling, often fail to address these challenges effectively, as they do not have an adequate heat transfer rate and struggle to dissipate heat from localized high-temperature regions known as hotspots. To enhance the thermal management of the chips, liquid cooling solutions have emerged as a promising alternative, utilizing convective heat transfer. Inside the cold plate, the use of pin fins within the regions of

high heat flux allows for a targeted approach to combating hotspots. This study investigates the influence of cold plate geometrical parameters on its thermal and hydraulic performance using finite element analysis in COMSOL. The results indicate that cold plates designed with an increased density of pin-fins near the hotspot significantly outperform conventional designs in terms of thermal efficiency. This level of thermal efficiency is further improved with higher flow rates. However, the advantages come with trade-offs; higher flow rates require increased pump power, which directly translates to higher energy consumption and higher operational costs. These findings underscore the importance of carefully optimized designs that balance superior thermal performance with energy efficiency, ensuring practicality and sustainability in real-world applications. Finding this balance is the critical objective of this research.

Abstract Name: Student-to-Teacher Expressions of Gratitude: Impact of a “Thank You” on Subjective Well-Being

The Actively Caring for People Movement—www.ac4p.org—integrates humanism and behavioral science (i.e., humanistic behaviorism) to promote the occurrence of interpersonal acts of kindness and/or prosocial behavior. This ongoing research has been assessing the impact of expressing interpersonal gratitude on various mood states of students after they deliver a customized thank-you card (TYC) to the instructor of their university class. As a benefactor of personal gratitude, a research student delivered a TYC to his/her instructor after class. The benefactor, as well as a second randomly-selected student in the class (i.e., in a control group), completed a mood survey before and after the class. The survey employed a Likert Scale to assess 19 mood states (e.g., vulnerability, confidence, interest, and happiness) from 1 (untrue) to 10 (true) in order to reflect the student’s current emotional feelings. The TYC included a section for the benefactors to express personal words of appreciation to their professor/instructor. Qualitative analysis revealed uniformly positive emotions from all instructors and from each of the 64 students who delivered a TYC. The quantitative analysis demonstrated a significant 36% increase in the students' overall positive mood states, after delivering a TYC to their professor/instructor, compared to the control group that showed no significant change in the positive mood states that were assessed. The results of this study support the notion that expressing interpersonal gratitude can enhance a person’s subjective well-being (SWB) across multiple mood states. This study also highlights an advantage of designing and implementing interventions to increase occurrences of interpersonal expressions of gratitude among individuals, perhaps with a customized TYC, as an evidence-based strategy for enhancing SWB. Thus, this research accentuates the significance of gratitude expression for the enhancement of interpersonal relations and SWB, as well as the beneficial application of humanistic behaviorism to cultivate an AC4P culture.

Abstract Name: C7-T1 Anterior Cervical Discectomy and Fusion for Cerebrospinal Fluid Leak Repair

Introduction: Cerebrospinal fluid (CSF) leaks can be spontaneous, traumatic, or iatrogenic and can result in potentially serious complications such as CSF hypotension leading to headaches and neurologic dysfunction. In most spontaneous cases, an epidural blood patch is successful in sealing the leak. However, in severe cases unresponsive to less invasive treatments, surgical intervention may be necessary. Anterior cervical discectomy and fusion (ACDF) is a rarely reported treatment for spontaneous CSF leak. Herein, we present a unique case of repair of spontaneous ventral CSF leak with ACDF to treat symptoms of CSF hypotension. **Methods:** The patient presented with intractable, positional headaches and associated nausea/vomiting. Initial brain and spine imaging revealed a spontaneous CSF leak with signs of CSF hypotension and CSF buildup ventral to the spinal canal at the C5-T3 levels. A non-targeted blood patch provided minimal relief. Dynamic computed tomography (CT) myelogram demonstrated evidence of a focal CSF leak at the C7-T1 level associated with a ventral osteophyte. ACDF was performed in standard fashion with removal of the posterior longitudinal osteophytes. A small subcentimeter dural defect was noted at the C7-T1 level and repaired with two 7-0 prolene sutures followed by Tachosil fibrin sealant and Duraseal. Valsalva maneuver showed no further egress from the defect prior to graft and plate placement. **Results:** Postoperatively, the patient noticed significant improvement in positional headaches. Recurrent frontal headaches were determined to be from prolonged cerebrospinal fluid loss, and gradually improved as expected. The patient sustained a recurrent laryngeal nerve injury resulting in minor dysphonia from surgery that was improving at six-week clinic follow-up. **Conclusion:** Spontaneous CSF can result in refractory intracranial hypotension leading to headaches and potential neurologic dysfunction. When unresponsive to traditional treatments such as blood patch, an anterior cervical approach can be utilized to repair accessible ventral spontaneous CSF leaks.

Abstract Name: iGAIT: A Smartphone-accessible Early Screening Tool of Autism Spectrum Disorder for Children Using Video-based Gait Analysis

One in 36 children are autistic in the U.S. We are experiencing a public health crisis related to autism diagnosis. Although children show clinical signs of autism early in their development, many children are not diagnosed until well into preschool years, and children from minority, low-income, and rural backgrounds are diagnosed at an even later age. This autism equity crisis is due to lack of access to reliable and appropriate tools for screening as well as the proven racial and gender biases in existing tools. Without a timely diagnosis, autistic children are prevented from receiving early intervention services. There is a critical need for accessible, innovative, less subjective, and more inclusive tools for early detection of autism. We created a website, called iGAIT, as a free mobile-accessible web-based application developed to provide easy accessibility for early screening of Autism Spectrum Disorder (ASD) in children using video-based gait

analysis. This new screening tool leverages computer vision algorithms and deep learning models to screen for autism based on gait parameters extracted from user-recorded videos of children walking. Preliminary tests on a dataset of 41 children (16 autistic, 25 non-autistic, aged 5-12 years) demonstrated promising accuracy of up to 90%, with ongoing enhancements and validation underway. Powered by the university's high-performance computing cluster and commercial cloud-based computing and storage services, iGAIT can generate results in less than one minute, providing a fast and efficient experience for families worldwide. This tool is friendly to non-speaking children and children of any gender and race. The tool could lower the barrier to autism screening and diagnosis for low-income families, raising autism awareness and reducing delays in intervention. The research also advances gait-based health evaluation technology.

Abstract Name: Beacons of Alliance? Mapping the Fading of Lesbian Bars in the United States

Third spaces provide a place of refuge outside the bounds of home and work. Particularly for women, these spaces also provide solidarity, a place to affirm identity, and socialize in community without fears of being harmed and ostracized. For lesbian women, dedicated bars have provided this refuge, but it is quickly disappearing. From 200 lesbian bars to less than 30 in the span of 45 years, lesbian communal culture has shifted gears in the United States. The definition of lesbian bars differ among the queer; interpretations include bars for just lesbian women and bars for all marginalized queer who are empowered by the label of lesbian. The aim of the project is to map the disappearance of lesbian bars in the United States over the last 50 years and analyze reasons for why these shifts occurred. Building on previous research on queer experiences in queer-labelled spaces, this study will approach the gradual shift in the physical presence of bars to explore if and how these queer spaces provided a safe space where people were able to affirm, appreciate and explore their identity, whether gender or desire. Queer experiences of populations along the LGBTQIA+ spectrum being considered allows interpretations of the limitations that lesbian-labeled spaces stage in queer culture. Community is central to groups facing systematic discrimination. To combat isolation and move towards progress, the process of community building and being "communally queer" is a form of advocacy and an act of resistance to the social exclusion faced. An analysis of the locations and general phasing out of the lesbian bars will reveal how acts of resistance through community building and the presence of safe spaces show a directional movement in the changing queer culture.

Abstract Name: Bridging Divides: The Impact of EU Immigration Policies on Economic Assimilation and Political Polarization

Immigration is a defining feature of the 21st century, reshaping the social, economic, and cultural landscapes

of Europe. The European Union, with its diverse member states, presents a unique arena to examine how immigration policies influence the economic assimilation of immigrants and contribute to political polarization. This research explores the multifaceted relationship between these policies and their societal outcomes, addressing the central question: How do the immigration policies of EU countries affect the economic assimilation of immigrants and fuel political polarization? The study employs a mixed-methods approach, combining interviews with immigrants, policymakers, and scholars, analysis of economic data from EU statistical agencies, surveys of immigrant and native populations, and social media content analysis. These methods aim to uncover the nuanced dynamics of policy implementation, economic integration, and public sentiment across diverse policy regimes. By integrating qualitative insights with quantitative metrics, the research offers a comprehensive perspective on the effects of EU immigration policies. Preliminary findings suggest that perceptions of immigrant contributions to the economy are shaped not only by policy frameworks but also by broader societal narratives, often amplified through social media. This research aims to provide actionable insights for policymakers, highlighting the interconnectedness of economic integration and political stability. By doing so, it seeks to inform more inclusive and effective immigration policies, fostering harmony in an increasingly diverse Europe.

Abstract Name: Genomic Epidemiology of *Staphylococcus aureus* Sequence-type 72

Staphylococcus aureus (SA) is a gram-positive bacterial colonizer and pathogen commonly carried on the skin and in the anterior nares of humans. SA colonization may lead to a variety of non-invasive (e.g., skin and soft tissue infection, SSTIs) and invasive (e.g., bacteremia and osteomyelitis) infections. The SA population is comprised of multiple lineages that can be delineated through multi-locus sequence typing (MLST), which compares nucleotide sequences within seven housekeeping genes. Strains belonging to an MLST share a common evolutionary history as well as phenotypic characteristics such as antibiotic resistance or virulence. As a result, the epidemiology of lineages can be distinct from one another. One such MLST, sequence type 72 (ST72) is an emerging community-associated (CA) and healthcare-associated (HA) lineage made up of both methicillin-resistant and methicillin-susceptible (MRSA and MSSA) strains. To characterize the epidemiology of ST72 and track its emergence, we performed an extensive literature review and meta-analysis of SA genome sequences belonging to ST72. We found that ST72 has been associated with healthcare transmission and is frequently isolated from blood, sputum, and SSTIs among patients hospitalized in the ICU. Individuals who are immunocompromised or have had recent surgery are at a higher risk of ST72 infection. This lineage is prominent in the United States, China, and South Korea and is known for its antibiotic resistance and virulence. In eastern countries, ST72 has also been associated with zoonotic infections, which may have potentially contributed to its spread. Currently, we are performing genomic and phylogenetic analysis to assess the geographic distribution and rate of spread.

Abstract Name: circRNA Accumulation on Neurodegeneration and Fitness in *Drosophila melanogaster*

Circular RNAs (circRNAs) are a class of ubiquitous eukaryotic RNA created by back splicing. They accumulate in postmitotic cells, such as neurons, and are a hallmark of cellular aging. circRNAs are also linked to neurodegeneration in Alzheimer's Disease and repeat expansion diseases such as ALS. To limit the contribution of circRNAs to aging and pathobiology it will be essential to understand how turnover of these molecules is regulated. Unfortunately, it is not clear which enzymes are responsible for degrading circRNAs in neurons. This study evaluates the roles of four ribonucleases potentially involved in neural circRNA turnover using the model fly *Drosophila melanogaster*. Transgenic flies with ribonuclease inactivation induced by a mifepristone-activated Gal4/UAS gene switch were assessed for locomotion, lifespan, neural circRNA accumulation, and overall neurodegeneration through immunohistochemistry. If a candidate ribonuclease is involved in circRNA turnover, inactivation would result in hyper-accumulation which will lead to impaired neural function as measured by decreased movement, shorter lifespan, increased circRNA levels, and heightened neurodegeneration. These results will provide novel insights into our understanding of circRNA turnover in neurons and may inform potential therapeutic strategies to mitigate aging and neurodegeneration phenotypes.

Abstract Name: All You Have In Life Is Your Name: Uncovering My Family's Story

The purpose of my research was to use any available documents to uncover the story of my family by working my way from my parents backward from one generation to the next. In this presentation, I will discuss the process and results of my ongoing genealogical research, which I began this past summer under the guidance of my faculty mentor. Through gathering and analyzing oral histories, family documents, legal records, and documents from digital databases, I am able to craft a narrative of several generations of my family history. As a senior citizen returning to pursue my educational goals, this project has been fulfilling in ways that I had not imagined. Through telling my family's story, I am able to offer an intimate understanding of the history of African Americans.

Abstract Name: Investigating the Impact of Plasma Power on Total Flavonoid Content Across Robusta Coffee

Flavonoids are known for their therapeutic potential in treating diseases such as cancer, Alzheimers, and other neurological diseases. This study follows a preliminary experiment focusing on investigating the flavonoid content in Robusta, Arabica, and Liberica coffee beans. In the second phase of this experiment, we explore how plasma treatment might influence flavonoid levels in these species at various power levels. Our hypothesis is that increased plasma exposure will increase flavonoid content across Robusta coffee. In the first phase, filtered extracts were collected from each coffee species using hydroethanolic solvents and water-bath extraction to maximize the yield of bioactive compounds. The total flavonoid content (TFC) was then measured using a colorimetric aluminum complexation assay. UV-Visible spectroscopy was employed to analyze differences in flavonoid content across the coffee species. The absorbance values for the Total Flavonoid Content assay were compared against a calibration curve of (+) Catechin. Results indicated that Robusta coffee beans had significantly higher levels of total flavonoid content (mg Catechin/mL) compared to Arabica and Liberica beans. In the second phase, Robusta coffee beans were exposed to a DBD plasma jet. Experiment was performed to measure the plasma powers at various operating conditions. The colorimetric aluminum complexation assay and UV-Visible spectroscopy were employed to analyze the differences in flavonoid concentration between the different plasma exposures and powers. It was found that for 24 Watts plasma input power, 15 minutes plasma exposure was able to increase the flavonoid concentration, and with higher exposure duration, flavonoid content significantly decreased. This experiment shows that around 15 minutes was the optimal duration to ensure the highest flavonoid concentration for Robusta coffee. The experiment is now being repeated at various plasma input powers to find the optimal plasma power for highest flavonoid concentration. Experimental results will be included in the final presentation.

Abstract Name: Addressing the Mental Health Crisis in Allegheny County Jail: Failures, Reforms, and Comparative Insights

The ongoing mental health crisis within correctional systems presents substantial challenges, as evidenced by systemic failures such as inadequate staffing and insufficient resources. This research examines these issues through a focused investigation into the conditions within the Allegheny County Jail (ACJ), where legal cases such as *Howard v. Williams* (2020) and *Lagrotteria v. Allegheny County* (2023) highlight the severe consequences of neglect, including unmet health needs and preventable deaths. Special attention is given to the human effects of this crisis by analyzing the direct harm experienced by ACJ inmates, drawing on recommendations and mortality reviews conducted by the National Commission on Correctional Health Care (NCCCHC). These evaluations reveal systemic gaps in suicide prevention, crisis intervention, and healthcare integration, emphasizing the need for immediate reform. The study evaluates the potential of Mental Health Courts (MHCs) as diversionary systems designed to address the root causes of criminal behavior through treatment rather than incarceration. Additionally, it explores the potential effects of trauma-informed systems of incarceration, including California's "California Model," Oregon's rehabilitative approaches, and Norway's internationally lauded prison system. These models prioritize humane treatment, dynamic security, and rehabilitation over punitive practices, offering innovative frameworks to address the crisis. Furthermore, the research investigates the detrimental effects of inadequate staffing and resource shortages at ACJ on inmates and staff. These shortages not only harm inmates but also burden staff with extended hours and unreasonable expectations beyond their professional capabilities. Consequently, alarmingly low rates of job satisfaction, increased stress, and high turnover rates are observed. A financial analysis demonstrates the cost-effectiveness of investing in mental health services, vocational training, and educational programs. Such investments, as exemplified in alternative corrections approaches, substantially reduce recidivism rates and

associated costs. Ultimately, this transformation of correctional systems into equitable and rehabilitative institutions benefits both individuals and society.

Abstract Name: Long Conserved 3'UTRs

3' untranslated regions (3'UTRs) were previously considered junk DNA. However, research has identified sequence elements in 3'UTRs essential for mRNA stability, localization, and translation in the last two to three decades. With the advance of multi-omics, efforts have been made to annotate the diverse biological functions of sequence elements in the 3'UTRs. This project aims to unearth long (>200 bp) and conserved sequence fragments in 3'UTRs of mammals, followed by functional annotation. Phenotypic information from databases such as COSMIC and miRbase will be mapped on the conserved fragments in humans, shining light on their biological functions. This study focuses on five mammals: human, mouse, cow, rat, and platypus. The UTR sequences of these species were downloaded from UTRdb, a curated database of 5' and 3' untranslated sequences of eukaryotic mRNAs. The files were read and processed using the R-package seqinR. Specialized R-codes were curated to isolate only the 3'UTR sequences and their corresponding gene symbols. Mammalian orthologous gene information was obtained from NCBI Datasets. The 3'UTRs of orthologous genes from the five targeted mammals were grouped and aligned by the multiple sequence alignment program MAFFT for conservation analysis. The top 50 genes containing the longest conserved fragments were shortlisted for further analysis. Their descriptions from the NCBI Gene database and OMIM were collected and analyzed by a ChatBot, such as Google Gemini. Although subject to frequent mutations, certain paralogs, e.g., PURA and PURB, of the top 50 genes have shown significant similarity in their 3'UTRs, suggesting that duplication occurs before speciation. The extent of conservation will be obtained by multiple sequence alignment across the five mammals. The information extracted should help to elucidate the biological functions of 3'UTR conservation in gene regulations, and the mechanisms underlying the retention of these sequences across species.

Abstract Name: The importance of pericytes in the stability of microvascular tissues

Blood vessels form a complex network of arteries, veins, and capillaries that collaboratively transport blood, nutrients, and oxygen throughout the body, sustaining vital functions. Stability in blood vessels is essential for maintaining proper blood flow and pressure, preventing leakage or rupture, and ensuring the efficient delivery of oxygen and nutrients to tissues while removing waste products. Pericytes, a supplementary cell type, play a critical role in maintaining the stability of microvasculature. Here we explore the relative importance that

pericyte density plays in establishing vascular networks emerging from human umbilical vein endothelial cells (HUVECs) and pericytes co-cultures within a microfluidic device. Specifically, we varied the ratios of pericytes while maintaining the HUVEC density at 4,000,000 cells/mL. The ratios explored were 1:1, 1:2, and 1:10 pericytes to HUVECs. We found that our 1:10 ratio formed the most efficient vessels while the other two had little to no formation. While these vessels can form within the channels of microfluidic devices, their longevity remains a challenge.

Abstract Name: Ergot alkaloids in the fungus *Aspergillus leporis* affect the foraging behavior of the slime mold *Physarum polycephalum*

Ergot alkaloids produced by fungi affect mammals and insects. We hypothesized they also affect the interactions of fungi with protozoans. We investigated the interaction of the acellular slime mold *Physarum polycephalum* with the soil-inhabiting, ergot alkaloid-producing fungus *Aspergillus leporis*. Wild type *A. leporis* and a previously characterized *easD* knockout strain which differ in ergot alkaloid profiles were grown on sucrose yeast extract agar (SYE) for 6 or 13 days. Plugs (8 mm diameter; 400 μ L) of fungus-colonized SYE were removed and inserted into wells cut into water agar plates. Inoculum of *P. polycephalum* was placed equidistant between the two fungus sources. Observations of preference (or lack thereof) of *P. polycephalum* for either fungus plug was recorded 20 hr later. Ergot alkaloids were quantified from replicate plugs from the same cultures by high performance liquid chromatography. Total ergot alkaloids did not vary by strain and day, but 6-day wild type samples were dominated by lysergic acid α -hydroxyethylamide (LAH) which was converted primarily to lysergic acid by 13 days. Chanoclavine was the most abundant ergot alkaloid in both 6 day and 13 day samples of *easD* knockout. When presented with 6-day-old samples of SYE colonized with wild-type *A. leporis* (containing mainly LAH) or the *easD* knockout of *A. leporis* (containing mainly chanoclavine), *P. polycephalum* preferred the *easD* knockout strain over the wild type ($P = 0.0005$). In contrast, when given the same options at 13 days, the most common outcome was for *P. polycephalum* to not make a clear choice ($P < 0.001$). With these older samples, there was no preference for *easD* knockout over the wild type ($P = 0.42$), which by 13 days had lost most of its LAH. We conclude that ergot alkaloids affect the foraging behavior of *P. polycephalum*, which appeared especially sensitive to LAH.

Abstract Name: Consumer decision making behavior

In our world, every person wants something. Whether it is a toy for a child or a car for an adult, humans will

always have their eye on a product. A product is an article or substance manufactured or refined for sale. They are used in a person's daily life and are imperative for human living. For example, soap is used for cleaning or food for eating and health. During the 2021 pandemic, some products that were imperative for human living were tissue paper and disinfecting agents. The problem was that there was a shortage of these items. Stores had less and less as the demand went up. Some markets would even make their products much more expensive than average. As a buyer, what steps should one take to buy this product? How do they strategize to ensure they can find what they need? This study analyzed an individual consumer's economic decision-making and behavior about supply and demand. People behave and make decisions in supply and demand situations based on five steps: recognition, information search, alternative evaluation, purchase decision, and post-purchase evaluation. The study found that internal factors, such as attitudes, beliefs, and past experiences, and external factors, including social influences and marketing efforts, influence this process. This process helps businesses refine their marketing strategies and foster stronger customer relationships.

Abstract Name: Exploring Subterranean Microbial Dynamics of an Indiana oligotrophic cave ecosystem

Subterranean ecosystems, characterized by limited nutrient availability, offer critical insights into microbial adaptations to extreme environments. This study investigated bacterial communities and physicochemical properties of soil and water samples from four distinct locations within the Deep Darkness section of Indiana Caverns and reference sites outside of the cave. Results revealed significant spatial heterogeneity in bacterial carbon metabolism, microbial biomass ($p < 0.001$), sediment % N ($p < 0.001$) and percent total organic carbon [TOC] ($p < 0.001$). The low TOC (0.373 - 0.793%), % N (0.044 - 0.073%), and microbial biomass (6.55 - 76.16 nmol PLP/gdw) compared to the reference site (4.035%; 0.348%; and 122.51 nmol PLP/gdw, respectively) indicates the cavern is an oligotrophic environment. Metal concentrations in the cave and reference sites were comparable to Indiana state averages for potassium, aluminum, and calcium, lower for phosphorus, iron, and heavy metals, and higher for titanium and magnesium, indicating minimal anthropogenic impact in the cavern system. Principal Component Analysis (PCA) highlighted distinct metabolic profiles between sediment samples inside and outside the cave. PC 1 and 2 accounted for 59% of the variance observed in the bacterial community structure, differentiating sediment, water, and reference samples based on carbon utilization patterns within the 96-well BIOLOG Ecoplate. Sedimentary bacteria utilized Tween 40, Tween 80 (polymer), L-Asparagine (amino acid), Pyruvic Acid Methyl Ester (carbohydrate), γ -Hydroxybutyric Acid (carboxylic/acetic acid) disproportionately compared to cave stream bacteria which utilized more of D-Cellobiose, α -D-Lactose, and D-Xylose (carbohydrates). This study characterizes the Indiana Caverns as oligotrophic environments with low anthropogenic impacts and diverse metabolic groups that are important to conservation, providing a baseline for assessing future impacts like tourism or industrial development. Metagenomic analysis is needed to assess microbial diversity despite extremely low biomass in the Deep Darkness.

Abstract Name: The Effects of Therapeutic Frequencies on EEG Brain Output

Electroencephalography (EEG) is a technique that uses electrodes to measure the electrophysiological brain signals. Specifically, it focuses on measuring, amplifying, and interpreting postsynaptic potentials to understand how different stimuli influence brainwave patterns. EEG is often used to measure brain activity during events like sleep, stressful situations, concentration, etc. A specific stimulus to consider in the measurement of brain activity is therapeutic frequency. The use of different wellness frequencies to trigger various neurological responses is an emerging field within audiology and psychiatric disorders. This study aims to explore the effects of therapeutic frequencies on EEG activity (brain activity). Using a previous study done based on the effects of different monaural (played in one ear) and binaural (played in both ears) frequencies, this study further elaborates on the use of specific therapeutic frequencies rather than normal frequencies. Experimentation involved playing various wellness frequencies in both ears in order to measure the differences in EEG activity. A portable EEG headband with 4 electrodes was used, as well as the implementation signal processing softwares to average the different bands of frequencies from each electrode. Different waves such as alpha, beta, gamma, and theta waves were observed and relative changes in their pattern were observed during the testing. As such, the resulting impact of various signal bands are currently being interpreted and analyzed, with reference to existing literature to conclude the effects of different frequencies on brain activity. These findings can be valuable in understanding the role of frequency-based music in music therapy, personalized sound therapy, and mental health treatment. This presentation will include the details of the experiment, the data and analysis, and the conclusion of the results obtained.

Abstract Name: Use of Novel Acetylcholine Sensor, GRABACH3.0, to Measure Extent of Acetylcholine Changes in the CA1 Hippocampus Region after Optogenetic Inhibition of Septo-Hippocampal Cholinergic Projections

The goal of this project is to quantify to what extent optogenetic inhibition of septo-hippocampal cholinergic projection neurons in the medial septum/diagonal band of Broca (MS/DBB) in freely behaving mice reduces acetylcholine release at projection sites in the hippocampus (HC). Toward that end, I will combine optogenetic manipulation of cholinergic neurons in the MS/DBB with fiber photometry measurements of acetylcholine release in the HC. Using transgenic ChAT-Cre mice, I will perform stereotactically guided microinjection of a Cre-dependent adeno-associated recombinant virus (rAAV) coding for the inhibitory opsin Archaelrhodopsin T 3.0 into the MS/DBB. In the same mice, I will inject an rAAV coding for the fluorescent acetylcholine sensor (GRABACH3.0) into the HC and, in collaboration with other members of the lab, implant an optical fiber to enable fiber photometry measurements in freely behaving mice. After obtaining data pertaining to acetylcholine release as a function of optogenetic manipulations, the brains of the experimental mice will be harvested to verify, in brain slices of the MS/DBB, the location of the implanted

optical fiber and expression of the inhibitory opsin and, in brain slices of the HC, the expression of the GRABACH3.0 sensor. These data are important in the investigation of the causal effects of cholinergic neuromodulation on hippocampal activity underpinning hippocampus-dependent learning and memory

Abstract Name: The Oral Microbiome and Dental Hygiene: Assessing the Impact of Brushing and Mouthwash on Microbiome Composition

The human mouth hosts a diverse community of microorganisms, collectively known as the oral microbiome, which plays a crucial role in oral health. Imbalances in this microbiome can contribute to conditions like cavities, gum disease, and other oral infections. Dental cavities, which affect over 90% of adults globally, are among the most common health problems. While the role of diet and bacterial activity in cavity formation is well understood, the relationship between specific oral hygiene behaviors—such as daily use of mouthwash, brushing, or both—and the oral microbiome is less clear. This research aims to investigate the connection between oral hygiene habits and the composition of the oral microbiome, focusing on how specific practices influence microbial diversity and contribute to oral health. To collect data for this IRB-approved study, a group of college age students are being recruited at PennWest California to give buccal swab samples and complete an anonymized questionnaire about their oral hygiene habits, including whether they use mouthwash, toothpaste, or both, as well as history of cavities. DNA will be extracted from each sample and quantified. Illumina MiSeq metabarcoding will then be performed to identify the microbial species present. A secondary analysis will compare the microbiome results with cavity history, while controlling for oral hygiene behaviors. We aim to uncover microbial differences between students who use both toothpaste and mouthwash versus either alone, providing valuable insights into how oral hygiene practices influence oral health. Understanding the relationship between oral care habits, the microbiome, and dental health could lead to more personalized dental care strategies, improving prevention and treatment of oral diseases.

Abstract Name: Age-related changes in neural representations of binaural temporal fine-structure cues

Aging is associated with hearing deficits that often do not manifest as changes in overt hearing thresholds. Rather, middle-aged and older listeners experience difficulties listening in noisy environments. One reason for these deficits may be the progressive loss of afferent synapses in the cochlea with age, which remains “hidden” to current clinical tests. This cochlear deafferentation may affect the accurate, binaural representation of temporal fine structure (TFS) cues in speech, which are critical for speaker localization and

identification. Here, we use an objective measure of binaural processing in young and middle-aged listeners with normal hearing thresholds to ascertain the changes in binaural TFS representations. Binaural TFS processing were indexed using the inter-aural phase difference following response (IPDFRs). IPDFRs are phase-locked EEG-based neural ensemble responses that ‘follow’ periodic shifts in interaural phase. IPDFR’s were collected to a 520 Hz tone carrier with phase modulated at 6.8 Hz and amplitude modulated at 40.8 Hz. Phase was shifted at 0°, 22.5°, 45°, and 90° across each ear in opposing directions, and presented at a sound level of 85 dB SPL. IPDFRs decreased in amplitude with the degree of binaural separation, suggesting they are a sensitive metric of binaural TFS coding. IPDFR amplitudes were significantly lower in middle-aged adults, when compared to young adults. There was no change in amplitudes of the phase-invariant EFRs at 40.8Hz, confirming that the IPDFRs were selectively sensitive for binaural TFS coding, while the EFRs represented overall neural phase-locking abilities. EFR amplitudes were also significantly decreased in middle-aged adults compared to the young. Our data suggest that middle-aged listeners experience significantly reduced binaural TFS coding, and these binaural coding deficits may be driven by overall decreases in neural phase locking with age.

Abstract Name: Historical Redlining Practices: Influences on Rising Contemporary Infant Mortality Rates in Richmond, Virginia

Redlining was a discriminatory practice employed in the 1930s of denying loans, credit, and other services to families based on the economic status of their neighborhoods. The practice began when the Home Owners’ Loan Corporation (HOLC) drew maps of residential neighborhoods in 239 cities across the United States between 1935 and 1940 and assigned each neighborhood a grade. The practice of redlining was used to target neighborhoods that had large minority populations, thus reducing their social mobility and quality of life often leading to dramatic racial disparities in healthcare outcomes. The Fair Housing Act of 1968 banned redlining, but the consequences of this discriminatory practice still affect people living in these neighborhoods today. The purpose of this study was to analyze the effects of historical redlining on infant mortality rates in Richmond, Virginia. A literature search of relevant articles from electronic databases was performed from January 2010 to December 2024 to identify original research pertaining to the impact of historic redlining on current infant mortality-related healthcare outcomes. The redlining status of all the neighborhoods in Richmond, Virginia was analyzed to find patterns related to infant mortality, and infant mortality rates were found to be significantly higher in previously redlined neighborhoods due to less access to resources, worse environmental conditions, and racial disparities. Legislative actions to alleviate the effects of redlining such as building hospitals and healthcare facilities, improving access to educational resources, and increasing access to economic opportunities in these neighborhoods were recommended.

Abstract Name: Efficacy and Cytotoxicity of Texas Honey and Honey-Coated Nanoparticles on Wound Healing

Honey is a natural therapeutic agent with antibacterial, anti-inflammatory, antioxidant, and anti-biofilm properties, making it highly effective for wound healing. Silver nanoparticles (Ag-NPs) also exhibit strong antibacterial properties and have shown promise in wound healing. However, their high toxicity significantly limits their medical applications. To address this challenge, coating nanoparticles such as Ag, Se, and Ag₂Se with honey offers a promising solution. This approach may reduce the toxicity of nanoparticles while enhancing their antimicrobial activity and wound-healing potential. Using Pulsed Laser Ablation in Liquid (PLAL), honey-coated nanoparticles will be developed, aiming to improve both efficacy and safety in medical applications. This study focuses on the wound-healing potential of Texas honey by examining its effects on fibroblast cell migration through scratch assays and its antibacterial properties using zone-of-inhibition tests. Additionally, cytotoxicity assay is used to measure the toxicity of silver nanoparticles. This research could lead to innovative honey-based medical applications, including coated devices that prevent infections and biofilm formation, ultimately improving wound care.

Authors:

Abstract Name: Trina Robbins and the Empowerment of Women Through Comics

This paper explores the life and career of Trina Robbins, an American comic book illustrator, author, and feminist. Trina Robbins' everlasting impact on comic book history is detrimental to understanding feminist art and design history and the transformation the comic book industry underwent following the start of her career. The research collected in this paper strives to give insight into the life, motivations, and career of famous illustrator Trina Robbins, as well as the societal views surrounding women in the workplace that were present in the United States in the 1960s and 1970s. By better understanding the societal views involving women in the workplace, one can better understand the impact Trina Robbins had on the comic book industry and feminist history as a whole.

Abstract Name: Human Piezo2 Single Channel Conductance is Modulated by Alternative Splicing

Piezo2 is a mechanosensitive ion channel responsible for many sensational experiences including

proprioception and light touch sensitivity. Human Piezo2 has 6 alternatively spliced exons, producing various isoforms with tissue-specific expression differences. However, the effect of alternative splicing in human Piezo2 on intrinsic channel properties remains undiscovered. To address this, I first analyzed electrophysiological data collected in my lab measuring the sensitivity of human Piezo2 isoforms to membrane tension, the physical stimulus these ion channels sense. My analysis showed human Piezo1, human Piezo2, and isoforms of human Piezo2 differ in their sensitivity to membrane tension, suggesting that alternative splicing may control mechanosensing by human Piezo2. Second, I focused on the single channel conductance of human Piezo2 isoforms. Piezo2 has a high level of structural homology compared to Piezo1. The only splice variant of mouse Piezo1, mouse Piezo1.1, lacks amino acids known to form a structure that plugs the pore, thereby modifying its single channel conductance. Since an alternatively spliced exon in Piezo2, exon 33, corresponds to the same amino acids absent in mouse Piezo1.1, I asked if exon 33 in human Piezo2 affects single channel conductance. Through cell-attached patch-clamp electrophysiology, I recorded single channel opening events. I found that a construct lacking all exons (Piezo2Min) has a significantly greater single channel conductance ($g = 32.1 \pm 3.6$ pS) than a construct containing all exons (Piezo2Max) ($g = 20.4 \pm 2.2$ pS). These results indicate that alternative splicing in human Piezo2 modifies single channel conductance in addition to tension sensitivity. My current focus is on investigating the necessity and sufficiency of exon 33 in determining single channel conductance of human Piezo2. These findings indicate that alternative splicing in human Piezo2 is a mechanism of modulation for intrinsic channel properties and is utilized physiologically to meet tissue-specific mechanosensing and channel conductance needs.

Abstract Name: A Study on Multivariable Interactions Concerning Radar Cross Section Reduction through Geometric Attributes

Radar Cross Section (RCS) is a quantifiable measurement of radar stealth, often used in military application. Despite the presence of many studies concerning how radar cross section is impacted by geometric attributes, there is a lack of discussion on how different geometric variations may interact together to drastically impact the resulting RCS. This resolution 5 (2^5-1 factorial) study aimed to ascertain an understanding of the interactions between different geometries on the resulting RCS of a target. This experimental study utilized 16 custom specimens to quantify the effect of each variable on the specimen RCS, and to find potential interaction points. The results of the study are in line with the general understanding of the impact different geometries have on RCS and did not show any impactful interaction points, but did find that geometries can also influence the variance of measured RCS. It was concluded that typical attributes that reduce RCS also increase the variance of the measured RCS. Notably, an increased angle between the front face of a plate and the direction of the radar signal decreased RCS but increased the variance of the RCS measured. This research may be used to better understand the impact of geometric qualities on RCS variation, allowing for more efficient and stealthier design for military application.

Abstract Name: Does Treadmill Walking While Studying Increase Academic Performance in College Students

As we know college can be where young adults transform and become their true authentic selves, therefore the habits they create will follow them throughout their lives. Physical activity can be hard to promote on campus because college students think they do not have time for it, with other responsibilities they have. However, physical activity is crucial to student health and should be seen as a top priority along with other student obligations. The purpose of this project was to increase physical activity and improve academic performance in UCO students over the 2024-2025 academic year by using a treadmill desk in the Chambers Library while studying. A treadmill and desk were set up in the University Library where participants had access anytime they wanted during operating hours. Participants were required to fill out four questionnaires (i.e., QR codes) throughout the course of the study. The first QR code was a participant waiver and the second contained questions to gather participants' academic standing, exercise habits, and study habits. The third QR code had questions regarding if their test scores improved and if their ability to focus in school had improved - this questionnaire occurred after each time on the treadmill. The fourth QR code contained questions regarding the participants' GPA for the fall 2024 semester, how many times they walked on the treadmill, if their focus in school improved, and if their motivation regarding exercise and school occurred at the completion of the study. Data collection is still underway and data will be analyzed once the treadmill intervention ends in mid-March 2025. Walking is an everyday activity and as college students we also study daily. Being able to do two activities at once is beneficial to using our time wisely and may benefit student health and academics.

Abstract Name: A Data-Driven Analysis of Public Transportation Accessibility and Efficiency Amid Contentious Transition

Public transportation around the United States of America saw large changes in travel patterns following the COVID-19 pandemic, with decreased ridership and increased safety precautions (Federal Transit Administration, 2024). Specifically, in Pittsburgh, these changes that may never return back to normal caused the local public transit authority, Pittsburgh Regional Transit (PRT), to raise questions about the system's effectiveness and propose potential new route layouts (Deto, 2024). The thought of community-impactful changes, whether positive or negative, raised concern and caution among citizens (Pittsburghers for Public Transit, 2024). The purpose of this project is to identify flaws in the current (prior to PRT's redesign) system in terms of accessibility and operational efficiency, as well as identifying regions that could benefit from higher public transit presence. Previous work in public transit analysis has focused on developing methods for determining system operational efficiency, calculating a system's special coverage, and proposing networks using graph theory. This project focuses on PRT specifically, leveraging these existing tools while incorporating PRT's particular circumstances (topography, existing infrastructure, walkability, etc.) in order to assess accessibility and efficiency. I use open-source PRT data, Allegheny County census data, and self-collected vehicle counts to understand the effectiveness of Pittsburgh Regional Transit. Through this work, we can uncover which regions of Pittsburgh are underserved by PRT's current system, and what effects recently proposed changes will have. Additionally, findings may show redundancies in transit routes that are costing the organization.

Abstract Name: Isolation and partial characterization of a bacteriophage that effectively kills a clinical strain of the pathogenic bacterium *Pseudomonas aeruginosa*.

Background: *Pseudomonas aeruginosa* causes lung infections in subjects with cystic fibrosis and respirator users, skin infections in subjects with burn injuries, systemic infections in people with a compromised immune system, and ear, nose, eye, urethra, and soft tissue infections in healthy subjects. Many pathogenic strains of *P. aeruginosa* are multi-drug resistant (MDR), and some are extensively drug-resistant (XDR). This study aimed at isolating bacteriophages that can be used for phage therapy to treat MDR and XDR infections caused by *P. aeruginosa*. **Methods:** The MDR *P. aeruginosa* strain Boston 41501 (ATCC27853) was obtained from ATCC (Manassas VA). The strain was used to screen lytic bacteriophages found in untreated wastewater using standard phage-enrichment/overlay agar methods. Phages that created large clear plaques were plaque-purified to homogeneity and characterized. **Results:** We isolated one strain of bacteriophage that rapidly kills the bacterial strain and creates large clear plaques (~3 mm in diameter). The bacteriophage is stable in the refrigerator and at -80 °C for at least three months. The lack of formation of mesas on overlay agar plates infected at high multiplicity of infection indicates that the bacteriophage does not cause lysogenic infection and, thus, is potentially suitable for phage therapy. We have sequenced the genome of the bacteriophage and are planning on studying the genomics, virology, and therapeutic utilities of the bacteriophage. **Conclusions:** We have isolated a lytic bacteriophage that can have the potential of phage therapy to treat infections caused by MDR strains of *P. aeruginosa*. Detailed studies on taxonomy, genomics, virology, and clinical applicability of the bacteriophage using an in vivo model are underway.

Discipline: Criminology/Criminal Justice

Authors:

Abstract Name: Enhancing Police Response to Domestic Violence

There is a growing concern in the criminal justice field that shows police officers' poor effectiveness in responding to domestic violence calls. This inadequate response is not only increasing risk to victims but is also diminishing trust in law enforcement which potentially creates cycles of violence. This research will employ quantitative data on response rates and qualitative data on officers and victims. Some studies suggest that domestic violence calls are among the low priority, which further intensifies the issue. My research will explore three potential key interventions to improve these response rates: de-escalation instructor courses, scenario-based training, and implementing domestic violence response teams (DVRTs). Analyzing the impact

of these interventions aims to show how they can enhance officers' empathy and competence when responding to domestic violence calls. My poster presentation will show that incorporating these interventions in policing will ultimately reduce recidivism rates, increase community trust, and increase victim cooperation.

Abstract Name: Testing the Role of Rhythm in Auditory Selective Attention

Rhythms exist throughout our world, from locomotion to speech. Dynamic Attending Theory (DAT) proposes that there are internal attentional rhythms that can be entrained (synchronized) by external stimulus rhythms. This means that attention becomes aligned with the timing of temporally predictable events, thereby enhancing perception (Large & Jones, 1999). In several studies testing DAT-based predictions about the role of rhythm in selective attention to target speech, McAuley et al. (2020, 2021) found a background rhythm effect where disrupting the rhythm of background speech improves target recognition. This aligns with the Selective Entrainment Hypothesis (SEH), which proposes selective attention to target speech is facilitated by entrainment to target rhythms but can be disrupted by inadvertent entrainment by competing background rhythms. From this perspective, the background rhythm effect emerges because varying the background rhythm makes inadvertent entrainment unlikely. Two experiments test SEH using regularly and irregularly-timed tone sequences. In Experiment 1, participants listened to isochronous tone sequences presented with or without background isochronous sequences at different tempos. The sequences were followed by two tones marking out a time interval shorter or longer than the interval marked out by the target sequence. Participants made shorter/longer judgments about the final interval relative to the target while ignoring the background. Experiment 1 showed an overall background effect where performance was worse when the target sequence was presented with a background sequence than when it was presented alone. A tempo effect was also found where the tempo of background rhythms systematically biased duration judgments. Experiment 2 uses the same task as Experiment 1 but includes irregular background sequences. If the effects in Experiment 1 are due to inadvertent entrainment to the background sequence, disrupting the background rhythm should reduce the effects of the background in Experiment 2. Results will be discussed in the context of SEH.

Abstract Name: "Altogether A Most Improper Looking Spectacle:" Gender Transgressions and the Policing of Deviant Sexuality in Chicago's Levee Districts, 1893-1911.

Throughout the 1890s and 1910s, same-sex desire began to be increasingly understood as an identity rather than a set of behaviors as the primary framework through which queerness was understood shifted from theological to medical. This shift towards an identity-based model created a queer interior androgyny whose

expression was persecuted as a ‘gender transgression’ in a way that differed from other forms of sexual deviance like prostitution. Chicago’s red-light districts, known as the “Levee” functioned as a safe haven for all forms of vice, as an early gathering place for queer men, and a district through which the differential treatment between gender- and sex-based transgressions by policing and reform efforts can be analyzed. Using documentation around arrests, legal trials, and reform missions, I find that while (white, female) prostitution, much like alcoholism, was treated as a vice arising from circumstance and environment, this new understanding of same-sex desire as stemming from an internal characteristic caused gender transgressions to be treated as a dangerous and potentially corrupting force. Though both prostitution and same-sex desire were forms of deviant sexuality, the internally-motivated nature of the homosexual meant he could not be saved by Christian reformers, only repressed – and as ‘the homosexual’ became better understood as an identity he was assigned character traits through which police were able to persecute nascent queer communities on the basis of seeming queer without the proof of sodomy.

Abstract Name: Optimized Routing for Bio-Inspired Traversal (O.R.B.I.T)

This project will develop a robust algorithm to enable a bio-inspired spider robot to efficiently walk and navigate within uncontrolled environments. The robot is equipped with eight legs, making it stable after sustaining leg loss. However, if two or more legs are lost, the robot’s gait can become unstable. To maintain the gait stability, this algorithm will analyze information about the status of the legs. As limbs are removed, the gait pattern will be adjusted according to Cruse’s rules of motion and attempt to maintain a stable support polygon. There are several examples of gait adjusting algorithms in current legged robot research, however, this project will prioritize body stability. Since payloads will be mounted to the robot, the body must remain within nominal tilt parameters. The control policies are learned in a simulator and then deployed on the robot. The system will be closed loop, and the robot is mostly “blind”, only receiving proprioceptive data and simple obstacle feedback. The tilt will be monitored by internal sensors, and verified by external monitoring software. To gather the most accurate data, a leg will be fully removed when testing for stability after leg loss. For testing, the robot will run a predetermined course before and after a limb has been removed, and the mean tilt error (the difference between nominal parameters and maximum tilt) will be analyzed.

Abstract Name: Examining Routinized Math-Learning in Parent-Child Conversations: A Commognitive Analysis

The proposed study seeks to use discourse analysis to investigate how parents may create math learning

opportunities for their 4-year-old children during pretend grocery shopping. Past research focused on the quantity of math talk, e.g., frequency counts of number words and different categories of math talk, finding that the frequency of parents' math talk shows a small, but positive association with children's math skills (Silver et al., 2024). However, this approach does not address how learning may occur during these conversations. To address this gap, the current study will use Commognitive Theory to guide an in-depth discourse analysis. The Commognitive Theory states that learning mathematics is becoming a participant in a historically established discourse by individualizing the discourse without consulting an authority figure. There may be communicational gaps between the learner and the teacher that prevent the learner from completing the task, creating a discursive gap. Parents have the unique opportunity to act as knowledgeable others to help bridge those gaps for their child and guide their child through the math learning process. Transcripts and video recordings of 4-year-old children and their parents will be analyzed to identify patterns of routines, ritualization, de-ritualization, and discursive gaps, aiming to examine how math learning emerges during semi-structured parent-child interactions. This research is expected to provide deeper insights into math learning, emphasizing the language and discourse content employed during pretend play. Furthermore, this study aims to uncover how routines can aid in math learning and how parents and children may collaboratively close gaps.

Abstract Name: Imperial vs. Metric: Evaluating the Impact of Unit Choice on LLMs

Large Language Models (LLMs) excel in various natural language processing tasks such as text generation and contextual analysis. Because of their advanced capabilities, LLMs have become commonly used by people across the globe for a wide variety of applications. Evaluating LLMs requires understanding the factors influencing their accuracy across diverse task formats. Their ability to handle diverse measurement systems becomes crucial for maintaining reliability between cultural contexts. This concept of metrics is important for LLMs to understand because they may otherwise output improper conversions that users cannot easily correct or may miss entirely, leading to potential issues. This study systematically analyzes the differences in metric versus imperial units across multiple datasets (GMS8K, MAWPS, and ASDiv-A) to understand how these differences impact reasoning and accuracy with Math Word Problems. In our research, we will be testing the particularly popular models ChatGPT (4o and 3.5-Turbo), Llama (3 and 3.2), and Gemma (7B). We test against various models because of their differing parameter sizes and open or closed-source nature, allowing for a broad analysis. By isolating the influence of metric representation on these models' behaviors, this research can potentially help develop more accurate frameworks and inform the design of more reliable LLM models that can consistently handle real-world measurement variations in the future.

Abstract Name: The Student Loan Market and the Risk of Student Loan Asset-Backed Securities

Credit enhancements and strict underwriting standards have mitigated the market's vulnerability to systemic shocks (Xu & Ortiz-Eggenberg). Loan delinquency rates and correlations of previous defaults with broader economic conditions could hint at similarities with mortgage-backed securities' liabilities before the 2008 financial crisis (Duque). The SLABS' (Student Loan Asset-Backed Securities) securitization process, coupled with disadvantageous forbearance and deferment policies, will further exacerbate the financial burden on borrowers (Rall & Olin) and decrease market transparency, possibly destabilizing both the economic and educational landscapes (Rall & Olin). The framework of this research considers the perspectives of SLABS' financial risk and the socioeconomic accessibility of education. Similar to previous studies, data sources will include the Federal Reserve Board, the Securities Industry and Financial Markets Association, and Bloomberg. SLABS' market trends will be quantitatively analyzed with regression analysis from secondary data, namely factors such as the performance of securitization trusts, their delinquency rate, and the pattern of defaults likely to occur in such trusts. The expected outcomes of these risks will assess implications for public policy, including potential reforms to reduce reliance on securitized debt in the financing of higher education. This research contributes to understanding SLABS as both financial instruments and social determinants, thereby informing sustainable strategies for balancing investor interests with educational accessibility. Uniquely, this study aims to analyze how these macro trends in the student loan market could differently affect student borrowers based on their socio-economic background. Research Question: What are the risks of SLABS, and how do they affect the accessibility and affordability of higher education for students based on their unique socio-economic background?

Abstract Name: Screening for Dominant Pathways Underlying Mitochondria Transfer to GBM Cells from Neutrophils and Astrocytes Associated with Tumor Progression

Recent studies indicate that the expression of TREM1 is elevated with tumor grade and correlates with poor patient outcomes. The analysis of spatial TREM1 distribution found an accumulation of the protein in perinecrotic inflammatory loci in both human and mouse GBM. This project explores the transfer of mitochondria from neutrophils and astrocytes to glioma microenvironments, particularly to GBM cells, and the potential role TREM1 plays in this transfer. Using differentiated human neutrophils, we discovered mitochondria transfer between neutrophil-like differentiated HL-60 cells and human GBM xenolines. We noticed similar mitochondria transfer between human astrocytes and human GBM xenolines. To explore the mechanisms of this mitochondria transfer, we used a genome-wide knockdown library to look for genes essential for mitochondria transfer in both control and proinflammatory conditions. GBM genome-wide knockdown cells expressing EGFP were treated with neutrophils and astrocytes containing pre-labeled, red-fluorescent mitochondria. The GBM cells with acquired mitochondria (EGFP+RFP+ cells) were detected by flow cytometry techniques and separated from the GBM cells unable to acquire mitochondria (EGFP+RFP- cells). The genomic DNAs were isolated from the various populations of cells and DNA amplicons corresponding to gRNAs were generated and sequenced. Data will be presented on the prevalence of certain

gene knockdowns in each population of cells. The various populations of cells were grown in-vitro and in-vivo to evaluate proliferation speed. Data will be presented on the relative rates of in-vitro and in-vivo growth between mitochondrial transfer versus no mitochondrial transfer populations of GBM cells.

Abstract Name: Determining optimal conditions for His-tag protein purification and creating split GFP plasmids to confirm protein:protein interactions

T-cells are critical cells in the immune system, responsible for the coordination, development, and eventual suppression of an immune response in the presence of potentially harmful pathogens. T-cells detect antigens using T-cell receptors (TCRs), resulting in initiation of appropriate immune responses. Upon activation of mature T-cells, a protein called Nur77 is upregulated alongside other cellular functions including proliferation and acquisition of effector functions. During development of immature T-cells, Nur77 assists in apoptosis. Thus, the exact functions of Nur77 in different types of T-cells is unclear. In order to elucidate the role of Nur77 in T-cells, it is important to learn with which other proteins Nur77 interacts. Previously, our group used a yeast-two-hybrid (Y2H) screen to identify novel proteins that may interact with Nur77 in different types of T-cells. This study began to develop the appropriate protocols to confirm the Y2H findings: 1) bimolecular fluorescence complementation (BiFC) and 2) purifying His-tagged proteins. BiFC involves a circular DNA called a plasmid containing two portions that specify the instructions for making half of the Green Fluorescence Protein (GFP). DNA coding for Nur77 was added to one half of GFP and DNA coding for Notch1, a known binding partner for Nur77, was added to the other half of GFP. Once DNA coding for both proteins is added to the BiFC plasmid, we can use this system as a positive control for protein binding with unknown interactors. For the second goal, we used multiple protocols to determine which was most effective for purifying His-tagged proteins in the future by first purifying the His-tag on it's own. These experiments pave the way for future confirmation of novel protein:protein interactions with Nur77.

Abstract Name: Protocol for Live Imaging Vanessa Cardui Embryos

Embryonic development of *Vanessa cardui* (Painted Lady butterflies) involves large-scale cell and tissue movements. As a first step to characterize these motions and determine their driving forces, we developed a protocol to image these embryos live at the tissue level. Cell-level resolution could also be accomplished with

this imaging protocol with appropriate microscopy. It can even be combined with microinjections of targeted fluorescent dyes to track cellular features. With removal of the two outermost egg layers – the chorion and vitelline membrane – being necessary for imaging, a key part of the process was determining how to keep the embryos relatively still while ensuring that they can develop in a 3-dimensional way. Removing the embryo from these protective layers was reliably successful as early as 24 hours post-oviposition while keeping the embryo intact with its yolk – also necessary for continued development. We determined sustained life to be possible in a custom imaging chamber for at least 48 hours, with development for at least 20. However, development proceeds at a slowed rate and appears to stop prior to reaching the larval stage. The success of development within the chamber also depends upon embryonic age at time of dissection. Further, microinjection of nuclear dye shortly after collection appears to slow development. While this protocol shows promise – particularly for observing processes that take less than 20 hours and begin after 24 hours of development – we will continue to explore modifications that may further optimize it.

Abstract Name: Cytotoxic and immunogenic properties of an armed oncolytic adenovirus in osteosarcoma

Cancer immunotherapy enhances the immune response to target and recognize tumors in the tumor microenvironment (TME). However, there is limited research on the effects of immunotherapies in solid tumor cancers, such as osteosarcoma. Conditionally replicative oncolytic adenoviruses are specifically replicative in tumor cells and lyse only tumor cells without harming non-cancerous tissues. Oncolytic adenoviruses can remodel the tumor microenvironment and turn the “cold” tumor (immunity-wise) into a “hot” one. Another aspect to this immunotherapy is using immune checkpoint inhibitors such as PD-1 and PD-L1 which prohibit T cells from attacking cancer cells. By inhibiting this interaction between T cells and tumor cells it can allow T cells to recognize the tumor and kill it. We have modified canine adenovirus to generate CAV2-AU-M3 to replicate in tumor cells conditionally and to produce and secrete canine anti-PD-1 antibodies. We analyzed the cytotoxic effects of CAV2-AU-M3 in canine osteosarcoma cell lines (D17, D22, CF11, and MCKOS) in 2D and 3D models. Cell viability was determined using images and luciferase assays. Additionally, we plan to test the immunogenic properties of CAV2-AU-M3 by measuring INF- γ and TNF- α cytokine levels cytokines released by tumor cells after CAV2-AU-M3 infections using ELISA tests. CAV2-AU-M3 is effective at lysing canine osteosarcoma cells, and we expect infected tumor cells to release cytokines into the TME.

Abstract Name: Effect of Fiber and Stimbiotic on Growth Performance and the Gut Microbiome in Pigs Challenged With F18 Enterotoxigenic Escherichia coli (ETEC)

This study's intended purpose was to understand the effectiveness of dietary fiber treatments and stimbiotic on the sustainability of the F18 enterotoxigenic Escherichia coli (ETEC) challenge. A total of 216 piglets were blocked by weaning BW and randomly assigned to 1 of 4 dietary treatments, including corn-SBM based control diet (CC), high fiber diet (HF: 5.0, 3.8, 2.5% sugar beet pulp and 4.0, 3.0 and 2.0% soy hulls for phases 1, 2, and 3, respectively), CC plus 0.01% stimbiotic (CS: Signis, ABVISTA Marlborough, United Kingdom), and HF plus 0.01% stimbiotic (FS). Pigs were fed a four-phase feeding regimen: phase 1 (d0-9), phase 2 (d9-16), phase 3 (d16-22), phase 4 (d22-41). Dietary fiber and stimbiotic were provided from weaning (d0) to d22, and then a common diet was fed from d22 to the end of the trial. On d5 postweaning, all pigs were orally inoculated with 10 ml of F18 ETEC (108 CFU/ml.) One median BW pig from each pen was selected at weaning for fecal sampling on d8. Samples were used to quantify the live E. coli using 3M Petrifilm (3M Food Safety, St. Paul, MN) and virulence genes of the isolate were qualified using multiplex PCR. Of 466 colonies, 53 colonies that expressed F18 also presented LTb, Stb, and Stax simultaneously. Pigs fed high fiber diets (HF and FS) decreased the percentage of F18 encoded E. coli ($P < 0.0001$) than low fiber diets (CC and CS), while pigs fed stimbiotic (CS and FS) had higher percentage of F18 encoded E. coli ($P < 0.0001$) than diets devoid of Signis (CC and HF). Results of this study demonstrated that high fiber and stimbiotic had a distinguished result on the percentage of virulence genes expressed in live E. coli colonies thus suggesting a different mechanism to mitigate ETEC challenge.

Abstract Name: Family-School Partnerships in Low-Income Communities: A Critical Discourse Analysis of how Family-school relationships are communicated through Title 1 Missouri School Websites

Title I of the Every Student Succeeds Act (ESSA), the U.S. general education law, allocates funding to schools who educate high numbers of students from families with low incomes. These funds are designed for schools to enhance their programming and infrastructure to support students who are, or who are at the most at risk of, failing to meet state academic standards. In addition, given the criticality of family-professional partnerships on student, family, and professional outcomes, schools receiving Title 1 funding are required to “jointly develop with, and distribute to, parents and family members of participating children a written parent and family engagement policy, agreed on by such parents...” Despite the benefits of positive family-professional partnerships, barriers such as negative biases and assumptions, professional jargon. Despite

additional funding and support, such barriers are exacerbated in Title 1 schools. The purpose of this study was to address the following research questions: (1) What underlying ideologies are embedded within MO Title I school websites regarding families? (2.) How does language usage in MO Title I school websites reflect or reinforce power imbalances between families and school professionals? and (3) What underlying ideologies are embedded within MO Title I school Parent and Family Engagement Plan? The five-member research team employed Critical Discourse Analysis, to analyze language, accessibility, power, and ideologies reflected on over 200 Title 1 school websites in Missouri. Preliminary findings indicate a preponderance of school-centric and family engagement practices. The researchers also found limited accessibility to policies and practices relevant to families.

Abstract Name: Effect of Calibration Conditions on Measurement Error in Force Sensitive Resistors for Mechanical Counter Pressure Spacesuits

Current gas pressurized, extravehicular activity (EVA) space suits cause high injury rates and metabolic stress on astronauts due to bulk and poor indexing. Mechanical counter pressure (MCP) space suits may offer solutions to these challenges, but development and operational feasibility necessitate a method to accurately measure the pressure being applied to the body. Force sensitive resistors (FSRs) are the current gold standard to monitor on-body pressure but require calibration for the sensors to be reliable and repeatable. To determine the effect of radius of curvature, substrate material, and pressure application method on sensor output, we tested these sensors using three different setups to simulate on-body applications. Additionally, we compared calibration of the sensor on a hard surface and a human body analog material. Calibration of these sensors was conducted in a pressure range of 20-100 mmHg in increments of 20 mmHg, concurrent with relevant MCP magnitudes. Differences in conditions were determined through coefficients of each calibration curve and the variability within them. We found that the different material substrates used for the calibration setup had an effect on the analog sensor output. The curvature of the substrate was less impactful on sensor output than the material of the substrate. Calibrating the FSR sensors is important for determining the variability of the sensor output. Calibration curves were created from this data in order to analyze the effect of different material substrates had on sensor output. We used the calibration curves to compare different calibration setups and determine which variables change the accuracy and repeatability of the sensor. Future work will allow the continued development of MCP spacesuits technology as an alternative to gas pressure EVA space suits to enable planetary surface exploration.

Abstract Name: Using Basement Membrane Constituents to Study Endothelial Cell Growth and Glycocalyx Deposition In Vitro

The endothelial glycocalyx (EG) is an apical network of glycoproteins, glycolipids, proteoglycans, and glycosaminoglycans, predominantly heparan sulfate (HS), found to mediate many vascular processes. Despite its critical role in cardiovascular health, replicating the EG in vitro remains a persistent challenge, primarily due to its vulnerability under traditional cell culture conditions. Given the variability in substrate choice in prior research, this study aimed to evaluate the efficacy of five biologically relevant basement membrane-associated substrates: collagen types I or IV; a mix of collagen types I and III; laminin; and collagen type IV layered with laminin on bovine aortic endothelial cells (BAOEC). Due to the known prevalence of collagen type IV and laminin in the basal lamina, it was hypothesized that these substrates in a layered configuration would yield optimal confluency, classic morphology, and most identifiable EG deposition after a 24-hour culture period. Cell confluency and morphology were assessed via phase-contrast imaging while EG deposition was evaluated through HS biotinylated streptavidin antibody staining and immunofluorescence (IF) imaging. Cell morphology and IF signals were quantified using ImageJ, an open-source image processing and analysis program (NIH). The results indicate that collagen type IV with laminin yielded cells with high confluency, a classic elongated morphology, and a greater raw integrated density value per pixel, denoting IF signal, than the other substrates. Data also suggests that although laminin alone yielded cells with the least IF signal, a classic elongated morphology was observed; demonstrating that while laminin can augment BAOEC growth, it can not effectively induce EG deposition. These results add to the current knowledge base for optimal in vitro culturing conditions for BAOECs in conjunction with monitoring EG deposition via HS IF signaling using ImageJ quantification. Future research aims to optimize this system using laminar flow, assessing barrier function, and culturing in a microvasculature chip.

Abstract Name: Post-Fire Ecosystem Recovery in Yellowstone

Fire ecology and restoration are essential components of ecosystem management, particularly in landscapes like the Greater Yellowstone Ecosystem (GYE), where fire plays a crucial role in shaping the environment. This project aims to explore the long-term ecological effects of wildfires, focusing on how fire regimes influence vegetation dynamics and wildlife habitats over time. The research question to investigate is: What are the long-term ecological consequences of wildfires in the GYE, and how do fire regimes affect vegetation and wildlife habitats over time? The study will examine the recovery of fire-affected areas at 10-, 20-, and 30-year intervals. By understanding the mechanisms driving ecosystem recovery, the research seeks to inform fire management practices and enhance ecological restoration efforts. The project will involve comprehensive field surveys of fire-affected areas in GYE, evaluating vegetation, soil quality, and wildlife activity. This will help identify patterns of ecological succession following wildfires and provide data to inform decisions about park management and restoration. The findings will be valuable to both academic communities and conservation stakeholders. My background in Soil Science equips me with the skills to assess soil properties, a critical aspect of post-fire recovery. Courses in Ecology, Biology, and Environmental Sociology provide a strong foundation in ecosystem dynamics and the social aspects of conservation. My proficiency in scientific writing, statistical analysis, and drone technology will enhance data collection and analysis, offering a comprehensive approach to the project. Ultimately, this research will contribute to understanding fire ecology and restoration in GYE, helping to inform management strategies for conservation and ecosystem resilience. It also aligns with my long-term goals of sustainable land management, providing the tools to promote ecological resilience in both park restoration and my future farming endeavors.

Abstract Name: Optimization of Jet engine through structural, thermal and flow analysis

This research focuses on optimizing jet engine performance, particularly the compressor, through thermal, flow, and structural analysis. As global air traffic rises, the need for efficient, eco-friendly aviation solutions becomes critical. This study aims to enhance compressor designs, guided by the Brayton Cycle principles, to achieve optimal pressure ratios while ensuring durability and reliability. Using ANSYS software, we performed computational fluid dynamics (CFD) simulations with a Moving Reference Frame (MRF) approach on basic and modified compressor designs. These simulations provided key metrics such as pressure ratios, efficiency, and flow characteristics. Results revealed that the compressor performs external work on the fluid, increasing the total pressure at the outlet. Additionally, when operational, static pressure at the inlet transitions into dynamic pressure as kinetic energy is imparted to the fluid. To further investigate, we are incorporating the Euler turbine equation to evaluate energy dynamics within the compressor region. This enables us to determine the maximum fluid velocity achievable and analyze how blade angles, size, and configurations affect pressure and energy losses. CFD simulations will optimize blade geometry and number to maximize pressure output while minimizing losses. Our strategy includes designing advanced blade geometries and inlet configurations, selecting materials capable of withstanding high pressures and temperatures, and employing manufacturing techniques to enhance strength and durability. Currently, we have procured a testing kit to establish boundary conditions for validating simulation results through empirical testing. Future work will focus on completing simulations, testing new designs, and refining the compressor to achieve superior performance. This study contributes to the development of efficient, reliable compressors, addressing the aviation industry's growing demand for sustainable and high-performance solutions.

Abstract Name: Literature Review of the Role of Nursing, Students, Registered Nurses, and Nurse Practitioners Within Advanced Care Planning

Background: Advance care planning (ACP) is critically important to providing care consistent with the patient's wishes. Registered nurses (RN) and Nurse Practitioners (NP) are relied upon to lead ACP discussions with patients. RNs and NPs often struggle to have these conversations with their patients due to lack of confidence in their abilities to have these discussions, lack of time in the clinical setting, and concerns that ACP is outside their scope of practice. Incorporating ACP training into school curriculum would bridge

the gap between RNs and NPs educational preparedness in leading ACP discussions. Methods: A review of literature examined 16 articles that focused on the role of nursing students (NS), RNs, and NPs in ACP, RNs and NPs confidence about their role in ACP, and what has worked for ACP training events in the past. Key words searched included: ACPs, ACP training programs, NSs, RNs, and NPs. The databases CINAHL, MEDLINE, UpToDate, Web of Science, and PubMed were searched. Results: Sixteen articles were identified as eligible for the subject matter. The core theme of improving ACP education was highlighted throughout these articles. Conclusion: Current attitudes of NSs, RNs, and NPs reflect feelings of uncertainty about their role within ACP, how to initiate conversations about ACP, and improving confidence in leading these conversations. It was found that ACP training programs have been effective in increasing the number of ACP conversations. An ACP facilitation project's goal is to create an educational program that trains graduates and prelicensure NSs to facilitate ACP conversations. Keywords: Advance care planning; Advanced care planning training; Registered Nurses; Nurse Practitioners;

Abstract Name: Investigation of Copy Number Variance in Human Obesity Model Using Zebrafish

Obesity is a major problem in the world today, and in many eukaryotic organisms, it is seen to debilitate their immune systems. This causes these organisms to become more susceptible to disease and illness. The Centers for Disease Control and Prevention has provided data that shows that obesity has a strong correlation to the development of heart disease, type 2 diabetes, breathing problems, and musculoskeletal problems. The *Danio rerio*, also known as zebrafish, is a model organism for humans that is used in this study. A group of fish were fed a regular diet (0.006 g of artemia/day), and another group of fish were fed a high-fat diet (0.06 g artemia/day, resulting in normal and obese fish. The livers from these fish were dissected, and transcriptome sequencing was performed. The most overexpressed and the under-expressed genes in obese fish compared to normal fish were observed by RNA-seq. These were then put on a plot to be able to visualize what was happening between the different genes. Copy numbers were evaluated between obese and normal fish using R analysis. Copy number variation was examined one mb upstream and downstream of the transcription start to determine overlap with genes and direct and indirect effects. An eQTL using Spearman Rank Correlation was run to analyze associations between copy number variance and gene expression to determine what was different between the obese and normal fish. Understanding obesity in this manner could assist in the understanding of obesity-related human diseases.

Abstract Name: Facilitating Deployable Structures Utilizing Origami Structures and Semi-Living Composite Hinges

This study explores the use of composite materials in deployable architecture, specifically to minimize stress in load-bearing origami structures, currently a major issue in this field. This is done by utilizing origami structures and composite hinges, which offer a way to minimize the mass of deployable structures while not compromising strength and flexibility. Several simulated origami structures using facets made with stringers and honeycomb core paneling which were connected via composite hinges underwent a series of virtual loading tests, highlighting the best folding pattern and providing minimum strength for the hinges to withstand. Initial testing of composite coupons was performed using new manufacturing techniques, with variations to samples in the material used for the flexing region of the hinges, as well as varying materials used to prevent resin uptake into the flexible aramid fabric region. It was determined that Kevlar as the flexible hinge material and vegetable-based shortening as the resin uptake material were the most viable options based on their resistance to deformation under tensile loading. Testing was also performed to determine the strongest and most flexible hinge layup configuration for the intended application. The best-performing samples resisted more than fifteen times the maximum anticipated stress of the anticipated loading while maintaining $\pm 180^\circ$ of flexibility. Later, a scaled-down physical model of the faceted origami structure was constructed to showcase flexibility in real-world structures, and the hinge modeling method was updated to more accurately reflect this new physical structure. Current findings demonstrate the potential of this model for use in extraterrestrial surface habitats, as well as micro-g applications including deployable solar panels and thermal radiators. Future work will refine manufacturing methods and materials selected, minimize process variability, and test resin uptake prevention requirements.

Abstract Name: Associations between maternal and paternal spatial talk and toddlers' spatial skills

We use spatial skills to interact with and navigate the world around us. Spatial reasoning is often defined as processing the relations between and within objects and the space they inhabit (Uttal et al., 2013). Children's spatial skills develop and change throughout their childhood. Understanding the development of spatial skills in toddlerhood is particularly important as children are quickly acquiring language during this period and early spatial language skills are correlated with later spatial performance (Pruden et al., 2011). Individual differences in spatial skills may be influenced by aspects of children's environment, including parental use of "spatial talk", or discussions about spatial concepts like shapes, relations between objects, and directions (Fox et al., 2024). Importantly, prior work examining math activities between mothers and fathers and their children has indicated differences between how each parent engages with math concepts with their toddlers (e.g., Silver et al., 2023). However, no research has looked at potential gender differences in parents' spatial talk and associations with children's spatial skills. The current study seeks to examine how the frequency and diversity of child-directed spatial talk from mothers and fathers relates to their toddlers' concurrent spatial skills. Data were collected through two Zoom sessions consisting of a semi-structured parent-child interaction, assessments of toddlers' spatial skills, and a demographic questionnaire. Parents' interactions with children were transcribed and coded for usage of spatial words (e.g., above, tall, triangle). Spatial skills were measured through two tasks where children's shape and spatial relation comprehension were tested. Scores on these tasks were averaged to form a composite score. Final analyses will test whether mothers' and fathers' frequency and/or diversity of spatial talk relate to toddlers' spatial skills. These results can inform future spatial skill interventions especially in early childhood.

Abstract Name: Women's Gender Inequality & Leadership in *The Devil Wears Prada*, *Hidden Figures*, and *On the Basis of Sex*: Portraying Women in Power through the Cultivation Theory and Theory of Planned Behavior

This paper plans to examine the portrayal of women in leadership roles in the films *The Devil Wears Prada*, *Hidden Figures*, and *On the Basis of Sex* through the cultivation theory and the theory of planned behavior. By analyzing these portrayals, the paper plans to explore how popular films contribute to the stigmatization of real-life women in power and reinforce gender inequality in leadership positions such as CEOs. Hollywood and other mainstream media play a critical role in shaping societal perceptions of gender roles. This paper defines key terms such as cultivation theory, which examines how media consumption can affect a person's beliefs, and the theory of planned behavior, which states that people's intentions determine their behavior. The films chosen in this paper were due to their portrayal of female leadership. This paper plans to highlight how these portrayals of women in movies contribute to the real-life perception that women must overcome extraordinary barriers to succeed in leadership.

Abstract Name: Examining Clinician-Reported Barriers to Cultural Assessment

Evidence based treatments (EBTs) have mainly been created and tested in Western societies with predominantly middle-class, white populations, leading to a lack of systematic consideration of a client's culture and context. Conducting cultural assessment can help to support provider understanding of a client's cultural context (e.g. stressors and supports related to their social identity) and has been shown to increase family engagement in treatment, therapeutic rapport, and overall patient satisfaction, however, it is rarely implemented in routine practice. This study aims to understand clinician-reported barriers that prevent the implementation of cultural assessment. Clinicians (N=212) who treat youth with anxiety and OCD from across the United States were interviewed for a larger study focused on culturally responsive practices. The clinicians completed a survey including questions about their background, caseload, and barriers to cultural assessment. Descriptive statistics were used to analyze the frequencies of reported barriers to cultural assessment. Further, means testing was conducted to determine mean differences in barriers to engaging in cultural assessment between clinicians' training backgrounds. The descriptive analysis revealed that the two most common barriers were concerns about stereotyping the client (32.9%) and concerns about placing a burden on the client (31.1%). The Kruskal-Wallis H test revealed a statistically significant difference in barriers across the groups, $H(4)=12.87, p=.012$. Post-hoc pairwise comparisons using the Bonferroni-adjusted test indicated that clinical psychologists reported significantly more barriers to using cultural assessment compared to social workers ($p = .015$). There was no significant difference between any other groups. The findings suggest that clinicians hold some negative beliefs about the effects of cultural assessment on their clients, and that clinical psychologists encounter more barriers than social workers. Providing training and

education to change clinicians' perceptions of cultural assessment could improve clinicians' ability to provide culturally responsive care.

Abstract Name: Reshaping the Narrative of Leprosy: Reducing Stigma through Effective Physician-Patient Communication, Earlier Diagnoses, and Compassionate Care

Leprosy, known as Hansen's disease, has existed for thousands of years. The chronic condition is caused by the bacteria *Mycobacterium leprae* and results in nerve damage, primarily in the peripheral nervous system, such as the hands and feet. The disease has been highly stigmatized for centuries, making it more difficult for patients to cope. The social stigma associated with leprosy furthers its physical stigma. The illness seems to define the patient, who is often shunned from society. This is a predominant issue in developing countries, where a lack of knowledge causes patients to seek treatment later--in turn leading to the formation of more deformities and causing fear of the illness to increase. Stigmatization of the disease can also cause self and bodily dissociation, exacerbating physical symptoms due to self-neglect. The best way to reduce the social stigma is to have earlier diagnoses, which would lead to less severe symptoms and more effective treatments. My project examines the impact of leprosy patients' relationship with their physicians, especially regarding communication, patient outcomes, and the role stigma plays in the diagnosis, treatment, and recovery of their illness. My research strategy will utilize interviews with physicians and analysis of scholarly articles based on case studies, experiments, and longitudinal reports regarding the experiences of leprosy patients. The moment patients receive their diagnosis is critical because, from that point onwards, patients begin unconsciously spinning a story of what their life will entail for the next several years. If physicians do not give patients the complete story, such as explaining medicinal complications, patients may become overly optimistic. Then, if patients suffer from side effects, they might believe the medication is problematic, causing them to mistrust the physician. Medication's side effects can also worsen stigma because they bring physical symptoms to the attention of patients' co-workers and family.

Abstract Name: What Should A Woman's Body Look Like? Here's What Digital Media and Pop Culture Says...

My research will explore how the visual representation of women's bodies in media and pop culture over the past 30 years have influenced modern society's unrealistic body standards for women, as well as how these stereotypes have harmed our current generation. Research has shown that the body stereotypes of women shown in digital media have severely worsened body dysmorphia for generations of young girls. That dysmorphia lowers self-esteem, which often leads to symptoms of depression and anxiety. This has ultimately led to increased levels of self-harm, suicidal ideation, and other mental illnesses in adolescents. In addition to those findings, I will be looking at the correlation between women's bodies in video games and animated

movies/TV shows, and how the combination of those digital medias has resulted in reaching a wider audience. Over the years, the online misrepresentation of women's bodies has only continued to grow exponentially, through body-altering filters on social media apps such as tik tok and instagram, as well as celebrities who post pictures of themselves that are edited to make their bodies look closer to the ones the media keeps showing on screen. My methodology involves looking for existing studies that show the impacts of gender biases in digital media. I will also be using the other research strategies outlined in the Information Literacy portion of my FFC canvas program, which includes using the Leatherby Library database to find peer-reviewed articles and published studies. I envision that my research will clearly demonstrate that the popularity/exposure of animated women has direct linkage between changing the body standards society holds for real women. Evidence is also expected to show the detrimentality of these unfair stereotypes upon young girls in particular, but also the general population.

Abstract Name: Wood Type Specimens

The purpose of this project is to explore traditional letterpress production methods and create a set of hand-printed type specimens using wood type from the Triangle Poster & Printing Company, which was donated to West Virginia University in 2014. Triangle Poster is based in Pittsburgh, Pennsylvania, and was founded in 1905. Their body of work consists of posters, billboards and other advertisements for circuses, traveling road shows, auto races, and other local events. This project draws inspiration from a collection of letterpress posters, broadsides, and type specimens designed and printed by WVU, School of Art and Design faculty Cliff Harvey and Joe Galbreath over several decades. These samples pull inspiration from the history of the printing history, formal relationships of letterforms, and the evolution of type specimens from commercial to artistic. I examined historic specimen examples, books, and past Triangle Poster catalogs. The original purpose of type specimens was to showcase a type foundry's offerings and highlight each typeface's unique characteristics and visual capabilities. This project showcases a small selection of WVU's Triangle Printing Wood Type Collection, which includes an italic typeface, a rare find in wood. Each specimen's composition was created based on the typeface to enhance the letterforms characteristics. I focused on the elements of each letter and how they interacted with one another, as well as the positive and negative space within and around the letterforms. I was liberated from traditional specimen conventions and allowed the letterforms to reveal interesting formal relationships in the dynamic compositions. After initial research and examining the typefaces in the collection, my process began with sketches and digital renderings. Then physically hand inking proofs and using the letterpress, I have been able to fully develop the compositions. The process has been filled with trial and error - rearranging blocks until the composition feels complete.

Abstract Name: Emissions Study and Equipment Design/Build for Stripper Well Production

Global warming and the rise of greenhouse gasses in the atmosphere are at an all-time high and continue to increase. One of the major contributors to this is methane (CH_4) in natural gas from being released into the atmosphere. Government agencies, both domestically and internationally, have raised concerns about this rise in greenhouse gas levels, recognizing its harmful effects on the environment, as demonstrated by global warming. In response, these agencies have implemented laws requiring companies to decrease the greenhouse gas emissions released from their oil wells into the atmosphere. In the context of oil wells, about 80% of U.S. oil and natural gas production sites are classified as low-production or small well sites. In fact, these low-production wells release approximately 50% more methane than the entire Permian Basin, one of the largest oil and gas-producing regions globally. It is estimated that these wells are responsible for nearly half of all methane emissions from oil and gas operations, emphasizing the need for more effective emission control strategies for smaller sites. Conventional natural gas management methods are often inefficient or too large-scale for the limited methane produced by these wells. For this reason, our team has developed a compact flaring tower add-on designed to connect to smaller wells and burn off emitted methane, converting it into CO_2 and water. The goal of this project is to safely and efficiently reduce greenhouse gas emissions from smaller well facilities.

Abstract Name: Pt Cluster Doped molten-salt Carbon Nitride in Methanol Dehydrogenation

As fossil fuels are decreasing, hydrogen could be the next solution to our energy crisis. Hydrogen is a good source of energy that could be cost-effective, clean, and easy to transport. To produce and easily store it we would have to use methanol dehydrogenation. Methanol dehydrogenation is a chemical reaction that produces hydrogen and formaldehyde from methanol using aqueous methanol-reforming and anhydrous methanol decomposition. A good catalyst to use for methanol dehydrogenation is molten-salt carbon nitride (MCN). However, it does have its weaknesses as it can only absorb methanol weakly. To improve the performance of MCN, we composite the Pt13 cluster on MCN to form a Mott-Schottky photocatalyst. In this work, we use Density Function Theory (DFT) to compute the interaction energies of Pt13@MCN with reaction intermediates of methanol dehydrogenation, including CH_3OH , CH_2O , and H_2 , and the reaction energy of methanol dehydrogenation on Pt13@MCN. We also explore the charge distributions of Pt13@MCN before and after adsorptions of intermediates to understand the adsorption mechanism. We compare the Pt13@MCN with pure MCN to see how the Pt cluster can enhance the catalytic performance theoretically.

Abstract Name: Measuring Electromagnetic Radiation of an iPad

The electromagnetic radiation emissions (EMR) from electronic devices, such as iPads, have raised concerns about their potential effects on the human body due to their widespread use in daily life. This study investigates the radiofrequency (RF) emissions from an iPad Air Gen. 4 in three distinct operational states: off, on (idle), and during video streaming. These emissions were measured at varying distances of 5 cm, 10 cm, and 15 cm using a calibrated RF meter. The primary goal of this research is to assess how RF emissions fluctuate depending on the device's activity and the proximity of the user to the device. To ensure the accuracy and reproducibility of the results, all measurements were conducted in a controlled environment. The data analysis focused on calculating the average power density in $\mu\text{W}/\text{m}^2$, providing a standardized measure of RF exposure. The findings revealed that the highest RF emissions were observed when the device was actively streaming video, followed by the idle state, and the lowest emissions were recorded when the device was turned off. Additionally, it was found that RF power density decreased as the distance from the iPad increased, indicating that closer proximity to the device results in higher radiation exposure. These results underscore the dynamic nature of RF emissions, which are influenced by both the device's usage and the distance between the device and the user. The study provides valuable insights into the variability of RF exposure, highlighting the importance of considering both device activity and proximity when evaluating the potential health impacts of prolonged electronic device usage. The findings serve to inform consumer awareness and contribute to the development of safety standards regarding safe distances and usage habits to minimize RF radiation exposure.

Abstract Name: Characterizing the Diversity of Bacteria and Viruses Within the Fungus Didymosphaeria

Samples of fungi were previously collected from beech trees around Bowie State University. This research was conducted to identify and characterize the diversity of endo-hyphal microorganisms (mycoviruses and bacteriophages) and bacteria found within the beech fungus *Didymosphaeria variabile*. To characterize this diversity, fungus cultures were grown, DNA and RNA were extracted, sent for metagenome and metatranscriptome sequencing by Novogene, then bioinformatic analyses were performed. The results show a high diversity of mycoviruses, bacteriophages, and endohyphal bacteria within *Didymosphaeria*. Results also show the presence of several double-stranded DNA viruses. The most abundant groups of bacteria are Sphingobacteriia and Bacillota. The most abundant groups of viruses are Caudoviricetes and Megaviricetes. This study contributes to the knowledge of endohyphal viruses and bacteria diversity, shedding light on their potential interactions with its host.

Abstract Name: The Estimation of Natural Frequencies of Architectural Structures Using a Smartphone

Any object has a natural frequency: the speed at which an object can freely vibrate when hit by a force. The natural frequency depends on the mass and stiffness of the object. To prevent buildings from experiencing excessive movement subjected by external forces, it is important to understand, and estimate, the natural frequency. Due to the high strength of construction materials, use of computer-aided design, and the desire of architects and building owners to have long-span, column-free designs, modern architectural structures have become susceptible to large vibrations as a result of human movement. These vibrations generally occur at their natural frequencies. Accurate estimation of natural frequencies help engineers and architects design structures impervious to large vibrations. This will ultimately improve the lifespan of building sustainability as well as its ability to service its occupants. The main goal of this project is to determine the accuracy of an inexpensive, smartphone application in measuring natural frequency. There are a wide range of precedent research studies that estimate the natural frequencies of structures using high-end engineering equipment, however, said equipment tends to be expensive and not easily accessible. The research methodology of this project consists of conducting a heel drop or jump test on various architectural structures, such as building floors, staircases, footbridges, etc., to measure the natural frequencies from the generated vibrations. The results obtained by the smartphone application are compared to the results of a high-end accelerometer. The data suggests that, despite being inexpensive, the smartphone accelerometer provides adequate results. In the development of the technological age, the research supports the idea that high-end equipment is not always necessary to produce a valuable outcome.

Abstract Name: Examining the Use of an Emotional Learning App to Facilitate Social-Emotional Learning in Children

Educational applications and technology have been utilized to enhance children's learning in recent years. Children are increasingly using tablets and smart devices for learning at home and in classrooms. Research indicates that Social-Emotional Learning in children is crucial for their interpersonal relationships and future success, as it enhances their emotional intelligence (Greenberg, 2023). Technology-based SEL can contribute to improvements in emotional skills, peer relations, and prosocial behaviors (Low et al., 2023). However, the effectiveness of using technology and applications has not been fully examined. This study is thus aimed to investigate the effectiveness of an Emotional Learning App in facilitating social-emotional learning in preschool-aged children, using data from the larger Empathy Learning Project, which focuses on emotional coaching in community preschools. The present interdisciplinary study began with a computer science student developing an app using Swift. The app is designed to teach social-emotional learning (SEL) to improve emotional skills. It includes features to help children learn to identify facial expressions and customize them by interchanging various facial parts, encouraging imaginative play, and enhancing social-

emotional skills. The app is then used in a community preschool for children ages 3-5. Twenty-three children participated in the study. The accuracy of emotional recognition was first tested to establish a baseline (pre-test), and again followed by 2 months of SEL using the app and other methods. Teachers are asked to complete the Social Competence Behavior Checklist (SCBE, LaFreniere, 1998) before and after the SEL lessons. The data collection is underway. It is expected that using the app will promote emotional learning in children. Further details and implications of the app will be presented at the conference. These findings will contribute to the growing research on the importance of SEL in young children.

Abstract Name: Understanding the Synergistic Effects of the Combination of Polyphenols Indole and Curcumin in Breast Cancer Cell Lines to be used as a Preventative Treatment

Breast cancer is the second most common cancer worldwide and the leading cause of cancer death in women. This presents a need to develop a preventative treatment to control the manifestation of breast cancer. Polyphenols such as Indole and Curcumin are natural compounds that have the ability to regulate the epigenome, influence inflammatory stress, and induce apoptosis, resulting in the prevention of cancer. Indole, found in Brassica vegetables, is an HDAC inhibitor that prevents tumorous growth. It is also a negative regulator of estrogen that contributes to cancer progression at high concentrations. Curcumin, found in turmeric, is a DNMT inhibitor that reactivates silenced tumor suppressor genes. It also has an inhibitory effect on the NF- κ B pathway and Wnt/ β -catenin signaling that suppresses metastasis. While many polyphenols have been studied individually, there have been limited studies demonstrating the combinatorial effects of multiple polyphenols. Thus, this project focuses on analyzing the novel combination of Indole and Curcumin on breast cancer cells to observe if there is a synergistic effect in the inhibition of cancer to be used as preventative treatment. Through MTT assays, the combination treatment was shown to have a decrease in cell viability in the MD-MBA-453, MD-MBA-231, and MD-MBA-157 cell lines, demonstrating reduced cellular proliferation. In addition, there was limited toxicity for the control cell line MCF10A, indicating that the combinatorial treatment was not harmful for normal cells. Western blot results indicated that there was a decrease in HDACs and DNMTs with the combination of 200 μ M of indole and 0.25 μ M of curcumin. Additional studies are being conducted in RT-qPCR to evaluate the changes in gene expression of HDAC and DNMT targets. Overall, experimental studies showed a synergism between Indole and Curcumin, indicating that the combination can be utilized as a potential preventative treatment for breast cancer.

Abstract Name: Synthesis of Anabaenopeptins Using a Scalable Method: Applications Of Organic Chemistry

Cyanobacteria are photosynthetic microorganisms that dominate harmful algal blooms (HABs), which are increasingly prevalent in freshwater ecosystems due to climate change and agricultural runoff. HABs frequently occur in recreational waterways, exposing humans and animals to toxins that threaten public health. To defend against parasites, cyanobacteria produce various toxic metabolites, including Anabaenopeptins (ABPs), raising concerns about their potential health effects. However, detecting ABPs in the environment and studying their biological activity remains a challenge due to the limited availability of pure samples and detection difficulties. To meet the need for ABPs in environmental monitoring and biological research, we have developed a scalable synthetic route for ABP production. Our work includes efforts toward the total synthesis of novel ABPs, including those containing homophenylalanine, a feature recently identified in environmental samples.

Abstract Name: In vivo two photon imaging of cerebral blood flow in capillaries of Alzheimer's mice show decreases with age

Neurodegeneration associated with Alzheimer's disease (AD) leads to cognitive decline, dementia and behavior changes in diagnosed individuals as they age. The AD continuum spans decades beginning with prodromal brain changes that are unnoticeable by the affected person to obvious problems with memory and eventually physical disability. What specific vulnerabilities drive the conversion from mild cognitive impairment to severe dementia is still unclear, however the consensus is that the early disease events are driven by ageing, decline in vascular and immune health, genetic susceptibilities and socioeconomic factors. Changes in cerebral blood flow (CBF) play a central role in the pathology of AD, they are accompanied by decreases in oxygen and glucose delivery to the tissues and this further impairs the neural circuits and slows down the clearance of noxious cellular waste. Analyzing subtle blood flow changes in the small blood vessels of the brain can provide cellular insight into vascular disfunctions associated with AD. Because this cellular level data cannot be obtained in humans, we focused on mouse models of AD. We used longitudinal in vivo two-photon imaging through chronic brain optical windows to evaluate changes in red blood cell velocity in the brain capillaries. We applied image processing algorithms to quantify the red blood cell velocity and probed the relationship between age and volumetric flow rate. The linear regression model of the normalized volumetric flow rate showed significant decrease across age in AD mice compared to wild-type mice. Our results indicate that early decrease in blood flow is evident in small blood vessels in the prodromal stages of the disease prior to accumulation of hallmark proteinopathies of AD. Our work suggests that improving cerebrovascular health during midlife can slow down the progression of dementia.

Abstract Name: Comparing Tornado Magnitudes in Eastern and Midwestern States Using ARIMA, LSTM, and Prophet Machine Learning Algorithms

Tornado occurrences in the United States are becoming increasingly unpredictable due to global environmental changes. On average, tornadoes cause approximately \$400 million in damage each year. As extreme weather events may continue to intensify (Zhang et al., 2023), their impact on public well-being grows. Notably, Tornado Alley is shifting its borders toward eastern states (Texas, Georgia, Mississippi, and Tennessee) and midwestern states (Illinois and Indiana). Through the use of AI and machine learning, we have predicted tornado Enhanced Fujita (EF) scale rating based on the previous records of several decades for up to 10 years in the future, especially within eastern states, with accuracies of over 90 percent. We found that within Texas and Georgia mean EF is predicted to increase, whereas in Mississippi and Tennessee mean EF is predicted to decrease to lower values. We aim to compare tornado shifts especially within the eastern states and midwestern states. This research utilizes Auto-ARIMA, Prophet, and LSTM algorithms in Google Colab to forecast the future EF scale intensity of tornadoes through time series analysis of the date, state, and EF scale intensity of each tornado. Our dataset of the U.S., sourced from Kaggle's SB and NOAA's SWM, spans from 1950-2023. The data for the eastern states and midwestern states from 1950 to 2010 was to develop the model, while data from 2011 to 2023 served as test data to measure model accuracy, indicated by RMSE values for each state. While more sophisticated models exist, this research highlights the potential of AI and machine learning algorithms, their predictive capabilities, and their practical applications. Detailed results will be presented and discussed at the conference.

Abstract Name: Integrating Behavioral Health Features into Machine Learning Models for Enhanced Type 2 Diabetes Prediction

Type 2 diabetes (T2D) is a growing global health crisis, affecting millions and leading to severe complications such as cardiovascular disease, kidney failure, and premature mortality. Early detection is critical to preventing its progression and reducing healthcare burdens. While traditional predictive models focus on demographic and clinical features, this study explores the untapped potential of behavioral health variables—mental health, physical activity, and sleep—in improving the accuracy of machine learning (ML) models for T2D prediction. Building upon prior research that demonstrated the predictive utility of environmental metal exposure (Xu et al., 2023), this study tests whether behavioral health features can similarly enhance model performance. Two models were developed: Model 1, using a baseline set of demographic and clinical features, and Model 2, which combines these with behavioral health variables. Data from the National Health and Nutrition Examination Survey (NHANES, 2017–2018) provided a sample of 9254 respondents and 20 selected variables (11 baseline and 9 behavioral health variables). Behavioral health features included specific indicators such as "How often do you snore," "Moving or speaking too fast or slow," "Vigorous exercise," "Usual wake times," "Feeling down or depressed" et cetera. Feature selection involved correlation analysis, T-tests, Lasso regression for multicollinearity, and logistic regression for absolute predictivity. A soft voting ensemble model, incorporating Random Forest, XGBoost, and LightGBM classifiers, was trained and evaluated on the dataset. Preliminary results show that Model 2 achieved a higher area under the curve (AUC) score compared to Model 1, confirming the hypothesis that behavioral health features significantly enhance T2D prediction. These findings underscore the importance of incorporating

behavioral health variables into ML models, providing a more comprehensive tool for early T2D detection and advancing personalized diabetes prevention strategies.

Abstract Name: Creating a data processing pipeline for single cell RNA sequencing and spatial analysis on cells of the entorhinal and occipital regions of the brain using Seurat v5

Single-cell RNA sequencing (scRNA-seq) revolutionized the study of gene expression and RNA analysis. The study of spatial transcriptomics (ST) developed alongside it, allowing researchers to measure all gene activity in a sample and map where it occurred relative to all other activity. By using software developed to process raw scRNA-seq and ST data, researchers can determine the type of cell, how it is expressing genes, and its location inside a sample. This project aims to create a data processing pipeline for scRNA-seq using the Seurat v5 software, and test the pipeline on tissue samples from the entorhinal and occipital regions of the brain. These regions have well-documented cell types and gene expression, allowing testing of the effectiveness of the pipeline by comparing its results to known controls. Raw scRNA-seq and ST data was gathered from tissue samples using a 10x Genomics Xenium Analyzer, and was passed through multiple iterations of a data processing pipeline created using Seurat v5 toolkits. The pipeline's accuracy was measured by comparing cell types assigned by the pipeline to control cells found in the tissue samples, and by comparing gene expression results in astrocytes to control genes that express specifically in the astrocytes of the entorhinal and occipital regions. High expression of the PLP1 and MBP genes was found in the entorhinal astrocytes, which encode proteins that make up the myelin sheaths of oligodendrocytes. High expression of the ATP1A2 gene was found in occipital astrocytes, which encodes for a protein vital to maintaining Na⁺/K⁺ ion balances across cell membranes. This pipeline can serve as a control comparison to the development of future scRNA-seq pipelines that aim to process raw scRNA-seq data, and can be modified to fit specific needs such as looking for specific gene expression or cell types in samples.

Abstract Name: Designing a User-Friendly Preprocessing Software in Python for the Analysis of Functional Magnetic Resonance Imaging (fMRI) Data

Background: Functional magnetic resonance imaging (fMRI) is the workhorse for understanding cortico-cortical dynamics, spanning early brain development to neurodegenerative disorders. However, fMRI remains an active research area with emerging data analysis approaches that often use laboratory- or project-dependent, with multiple adjustable parameters, making reproducibility of conclusions challenging, even with

identical data. Although several preprocessing packages exist, they generally require expertise or are limited to singular execution, hindering novel analyses of the same data. Therefore, this study aims to develop an easy-to-use preprocessing routine for fMRI data analysis that ingests scanner-generated DICOM or anonymized NIfTI data, producing processed data ready for statistical evaluation. Methodology: We will develop a graphical user interface (GUI) and a command-line interface (CLI) subroutine to preprocess fMRI data. The key steps include MRI signal optimization and anonymization, skull-stripping, spin-echo correction for geometric distortions, motion correction and removal of patient-induced artifacts using MCFLIRT (Motion Correction using FMRIB's Linear Image Registration Tool), band-pass filtering to preserve signal quality, and regression of motion parameters. We will also exclude fMRI/BOLD (blood oxygenation level-dependent) data from cerebrospinal fluid (CSF) and white matter (WM). Additionally, images will be co-registered to a standardized template for easier hypothesis testing through statistical analysis. Results: We plan to create a routine that standardizes and streamlines fMRI data preprocessing, enabling the identification of functional connectivity disruptions linked to the scientific problem under study. This adaptable program will ensure reproducibility and can be applied to new fMRI datasets, advancing analyses of neural network abnormalities in brain development and neurodegeneration. Conclusion: Developing this routine marks a crucial step toward enhancing neural connectivity analysis using fMRI data. A standardized and adaptable framework will facilitate high-quality data preparation, enabling more accurate and reproducible identification of functional network disruptions and advancing our understanding of the neural mechanisms underlying brain development and neurodegeneration.

Abstract Name: Optimizing Digital Phylogenetic Tree Reconstruction through Algorithm Design and Computational Techniques

The development of digital evolution has offered a way to simulate its physical counterpart in a fraction of the time and with much more control, offering ways to answer overarching questions about evolution as a whole. Thousands, if not millions, of digital organisms that each have their own genetic code and behavior interact with each other through hardware, with their data extracted at the end of the simulation. One common method of analysis involves constructing a phylogenetic tree from the hereditary information of these organisms; however, with millions of records, these computations are no easy task, often taking dozens of compute hours and complex algorithms. With simulations becoming increasingly expansive, current methods eventually lack in efficiency and scalability. Therefore, this research aims to develop new techniques for phylogenetic reconstruction, optimizing everything from algorithms to low-level data handling. Several such techniques were developed as part of the 'hstrat' package, involving a direct naive approach, a smarter consolidation-based approach, and versions of each using different programming languages and data structures. It was found that using a search-table based consolidated C++ algorithm performed the best, processing data from over 6 million organisms in under a minute, which is several orders of magnitude faster than previous approaches. The algorithm can be even further optimized using parallelization, splitting tree construction across several subtrees, and combining them together at the end. By overcoming computational barriers, these findings pave the way for much larger-scale evolutionary simulations. Therefore, more complex, high-level conclusions can be made about evolution by simulating in hours what would otherwise take years.

Abstract Name: MD simulations of Alzheimer's disease-associated APOE isoforms, such as APOE3-Christchurch, highlight potential shared mechanism of protection.

The lipid carrier protein Apolipoprotein E (APOE) is the most prominent risk factor for late onset Alzheimer's disease (AD). The three most common alleles are APOE3, APOE2, and APOE4 which provide neutral, decreased, and increased risk of developing AD, respectively. Several rare variants in APOE have been identified to be protective against AD. One such variant is APOE3-Christchurch (R136S) which was identified in a case study of familial AD. ApoE3-Christchurch is thought to be protective, in part, due to its reduced affinity for apoE receptors by reducing spread of toxic proteins. ApoE, a lipid-transport protein, is largely lipid-bound in vivo and undergoes distinct structural changes upon lipidation to enable binding to receptors like low-density lipoprotein receptor (LDLR). To better understand how rare isoforms, like apoE3-Christchurch, affect receptor binding, we used molecular dynamics (MD) simulations to study lipidated apoE structure and apoE binding to receptors like LDLR. We have obtained a lipidated apoE structure, provided by Prakashchand et al., which was generated from coarse-grained MD simulation of a mutant apoE structure (PDBID: 2L7B) in the presence of DPPC lipid molecules. After energy minimization, we converted the mutant apoE to apoE3 and ran MD simulations to generate representative apoE3 structures which were converted to the remaining apoE isoforms using PyMOL. Three replicate simulations for each apoE isoform, each with 300ns of equilibrated simulation, were used for final analysis. We then docked apoE3 to a structure of LDLR (PDBID: 2FCW) to create a model of apoE bound to LDLR. We examined changes in apoE structure, conformation, dynamics, and binding interactions. Results indicate that apoE3-Christchurch has similar structure, conformational stability, dynamics, and binding to apoE2. Analysis of apoE3-christchurch provides insight into similarities and differences it shares with common apoE isoforms that could be predictive of downstream functional changes resulting in altered AD risk.

Abstract Name: Exploring Entanglement Transitions in the 4-Level Qudit Projective Transverse Field Ising Model

Quantum error correction is an indispensable step towards scalable quantum computation. Errors and syndromes in quantum systems can be modeled as stochastic measurements, which act as non-commuting, competing projections. These measurements drive entanglement transitions between topological phases, delineating regimes where projective measurements either preserve or destroy quantum information. These transitions are commonly studied via the 1D projective transverse field Ising model (PTIM), a quantum variant of the classical Ising model wherein nearest-neighbor and external field interactions correspond to

stochastic projective measurements of Pauli ZZ and X on a qubit chain. In this study, we extend the PTIM to 4-level qudit chains featuring three non-commuting generalized Pauli operators to identify novel entanglement transitions. We efficiently simulate entanglement dynamics via a cluster model whose runtime scales linearly with system size. By averaging the entanglement entropy and mutual information across thousands of quantum trajectories for different probabilities of the three measurement types, we demonstrate the existence of three distinct entanglement phases whose transition lines meet at a critical point along the boundary of the phase diagram. Moreover, we illustrate that the scaling prefactor of the entanglement entropy along the transition lines is equivalent to that of the qubit model along all points except for the critical point, where this value doubles. We corroborate this by demonstrating that the averaged entanglement quantities computed for two coupled qubit PTIMs are identical to those of the 4-level qudit model. Future work will involve an alternative derivation of these observations from a conformal field theory perspective via a mapping to bond percolation in addition to an investigation of the applications of these results to quantum error correction schemes.

Abstract Name: Who are the Hmong: Using Oral History and Community Based Qualitative Research to Retrace History and Explore Sense of Belonging in the Hmong Community of Colorado

This study explores how Asian Americans, specifically the Hmong community journeyed to the United States after displacement in Southeast Asia and forged a sense of belonging. It provides the opportunity to learn more about how the Hmong community experiences a sense of belonging as immigrants, refugees, or children of either, along with any significant factors that positively or negatively affect how they belong. An oral history and community based qualitative research framework were used to collect fifteen 30–45-minute interviews from Hmong individuals living in Colorado. Each interview was recorded and transcribed before comparison between each other to identify major themes or patterns. Preliminary results highlighted three common topics mentioned by each participant which were stories of migration, connections to culture, and the significance of storytelling. Through this perspective, Hmong Americans can be better understood as a part of the larger Asian American and Pacific Islander (AAPI) community. Some of the questions addressed in this study were: Who are the Hmong people and why did they come to the United States? How do they find a sense of belonging, and how does this sense impact how they stay connected to and preserve Hmong culture? Does this sense of belonging have any connection to age, generation or where a person lives? This research serves as one piece of the larger puzzle in identifying the ways AAPI communities face justice issues including racism and discrimination, offering insight as to why it is important to hear the stories of marginalized people.

Abstract Name: CC-115, a DNA-PK and mTOR kinase dual inhibitor, induces toxicity in p53 mutated lung cancer cells cultured in vitro

Increased genomic instability of cancer cells makes them sensitive to drugs which inhibit DNA repair enzymes. While targeting DNA repair pathways proved to be successful in clinical treatment of BRCA-deficient malignancies of breast and ovary, so far it showed little efficacy in lung cancer. Since this malignancy remains the number one cause of all cancer related deaths in the United States, identifying specific subtypes of lung cancer which could benefit from such targeted therapy is an object of intense research. This study was conducted using two lung cancer cell lines, H1975 and H1299, characterized by p53 inactivation mutation and resulting increased level of genomic aberrations. In vitro toxicological experiments tested sensitivity of these cell lines to three drugs targeting different DNA repair mechanisms – Olaparib, Ceralasertib and CC-115. Consistently with a few recent reports, we demonstrated that both cell lines are sensitive to CC-115, a DNA- PK and mTOR kinase dual inhibitor, while they are resistant to Olaparib and Ceralasertib. Combinations of these drugs did not produce additive or synergistic effects. Altogether, our study suggests that CC-115 could be tested as a sensitizer in a combinatory treatment with DNA damaging agents such as cisplatin or ionizing radiation.

Abstract Name: Thermal Analysis of Flexible Micro Patch Antenna Excitation in Tumor Detection

Infrared thermography (IRT) is a technique currently utilized in early breast cancer diagnostics, however, recent analysis has shown that this method is ineffective in detecting tissue anomalies between variations of human breast structure. In this research project, the process of using electromagnetic fields (EMF) via an array of microstrip patch antennas to excite breast tissue to thermographically detect tissue anomalies is analyzed. Because tumors have a higher metabolic rate than healthy, surrounding tissue, a hotspot, or region of significant temperature increase, can be associated with the presence of a tumor when exposed to the same amount of excitation. Furthermore, in this study, a more effective design method for EMF detection is proposed and analyzed. Through the use of a flexible substrate, polydimethylsiloxane (PDMS), the microstrip patch antennas can be curved to match breast structure in practical usage. Therefore, they can be manufactured with large dimensions to minimize gaps of tissue unexposed to excitation, which can be easily implemented in an effective arrangement for wearable devices. With the use of finite element modeling (FEM) in ANSYS, the designed flexible microstrip patch antennas were simulated on the breast of a 3-D human body model with assigned breast tissue material properties and an artificially-placed sphere with tumor material properties, while analyzing the thermal response of the tissue anomaly in comparison to surrounding healthy tissue. A steady-state thermal analysis of this model depicted a noticeable thermal hotspot in the region of the artificially placed tumor. Overall, this study serves as a precursor for the implementation of PDMS microstrip patch antennas in portable breast cancer detection by depicting its efficacy in thermographically detecting tissue abnormalities.

Abstract Name: Enhancing Anti-Tumor Immune Response in Non-Small Cell Lung Cancer by Targeting IL-6 Signaling and Immune Checkpoint Interactions

Introduction: Tumor-stromal interactions in the tumor microenvironment (TME) of non-small cell lung cancer (NSCLC) drive progression and therapeutic resistance, with interleukin-6 (IL-6) playing a key role by regulating immunosuppression. We hypothesize that targeting IL-6 signaling in combination with immune checkpoint inhibitors may improve treatment efficacy by reducing immunosuppression and enhancing anti-tumor immunity within the TME. Methods: Using an ex vivo perfusion culture platform, remnant tumor tissue specimens from 12 patients were cultured. Starting on day 3 of culture, tissues were treated with an immune checkpoint inhibitor (ICI, 10 µg/ml anti-PD-1, Pembrolizumab biosimilar) and an IL-6 receptor inhibitor (5 µg/mL anti-IL6R, Tocilizumab biosimilar) or ICI alone (11 days treatment, 14 days ex vivo culture). Flow cytometry, histologic analyses, and spatial transcriptomics were performed. Results: Tissue specific increases in apoptosis was observed in 70% of combination therapy treated tissues when compared to ICI alone ($16.4\% \pm 3\%$ (ICI + anti-IL6R) vs. $14\% \pm 3\%$ (ICI)). Tumor cell death was assessed using a viability dye, an increase in tumor specific death was observed in 91% of tissues when combination therapy is compared to ICI alone ($15.7\% \pm 6.3\%$ (ICI + anti-IL6R) vs. $9.8\% \pm 4\%$ (ICI), $p=0.03$). The ratio comparing CD8+ T cells to immunosuppressive myeloid derived suppressor cells (MDSC) was increased in a subset of tissues in response to combination therapy. Using spatial transcriptomics, pathway analyses were completed to assess immune exhaustion and T cell checkpoint expression in tumor, stroma, and CD8 T cell segments. In the subset of tissues that contained an increased CD8+ T cell to MDSC ratio, these pathways were downregulated in the CD8 T cell segments with combination therapy. Conclusions: This combination strategy may enhance long-term therapeutic outcomes by reducing immune suppression, but further study of cell-cell interactions and alterations in the TME are essential.

Abstract Name: Immersive Recycling: The Merging of Art and Audits to Encourage Behavioral Change

Strategies for the ways in which sustainability is incorporated in design education commonly revolve around “reduce, reuse, recycle”. Much attention in the interior design body of knowledge has focused on sustainable design practices, factors influencing the adoption, and integration of sustainable design knowledge into the curriculum. Although students from CIDA accredited programs are exposed to the principles of sustainable design and apply these strategies to their coursework, the actual materials often used in teaching and project submissions are paper-based. Thus, interior design students while learning about sustainability are simultaneously consuming the most prevalent item found in the waste stream. This is particularly important

because Americans produce daily almost three times as much waste as the global average. In fact, several of the most prevalent items in municipal solid waste could be recycled, such as paper-based products, plastics, and metals. This begs the question: Are interior design students integrating sustainability principles into their design projects without acknowledging sustainable actions in their own practice? Waste audits have proven useful to draw attention to the material consuming nature of the design process while art installations have been successfully used to advocate behavioral change. This research conducted a waste audit to understand what recycling occurred and what materials were incorrectly recycled by current design students. The waste audit included sorting all the recycling bins in the building and sorting them into different categories. At the completion of the audit, materials collected were then utilized to create an immersive piece of art with the goal of encouraging behavioral change towards sustainable practices within the teaching and learning of design. Furthermore, the use of different formats have been incorporated to reach students and inform them of better practices and options related to sustainability.

Abstract Name: Universal: The Blending of Musical Traditions in the Music of William Grant Still

William Grant Still was a pioneering African-American composer whose works had a significant impact on the development of classical music in the United States. At a time when much of the classical genre was still based on European models, William Grant Still chose to create a more American sound, which he referred to as the “universal idiom.” Often known as the "Dean of African American Composers," Still's legacy is marked by his ability to combine classical traditions with African American cultural elements, creating a unique and universal voice that resonates in American music. In what scholars believe was an early version of his essay “An Afro-American Composer’s Point of View,” Still discusses how he feels that he should write the music of his own people because that is what he knows best. Unlike many of his European contemporaries, Still avoided radical modernism, and instead focused on using and modifying folk forms and music of what he considered to be his people. This paper outlines the parallelisms between William Grant Still’s efforts to be an educated and successful classical music composer, with his compositions which transcended the very cultural and racial boundaries against which his own life struggled.

Abstract Name: The Art of Storytelling: An Educational Art Book

In the modern high school art classroom, students are tasked with projects structured around foundational artistic practices such as figure drawing, portraiture, and still life. These exercises, while grounded in art history and technique, can be seen as rudimentary and redundant when retaught year after year, becoming monotonous and dull. Specifically, there is a lack of personal engagement that can be put into these projects as the main goal is to produce the most “realistic” or “representational” copy of what has been placed in front of the artist. For this age demographic (about 14-18), the ability to infuse personal meaning into their artwork

—whether by incorporating elements of their identity, emotions, or the media they engage with—is essential for fostering a deeper connection to the creative process. The objective of this project, based on qualitative research, aims to address this gap between curriculum and student interest by blending traditional techniques with a more flexible, personalized approach to art instruction. Through the lens of an Advanced Painting and Drawing curriculum for high school students, the project integrates a contemporary "art book" that diversifies how core artistic techniques are taught, while also cultivating a space to help students learn how to visually create stories to express their own experiences.

Abstract Name: Eve in Chains: From Paradise Lost to Lucifer, Patriarchy Still Dominates the Story of the First Woman

The aim of this essay is to evaluate changes in perceptions and depictions of Eve, the infamous first woman, by examining how she is portrayed in John Milton's *Paradise Lost* (1667) and in the television show *Lucifer* (2016). Though Eve has undergone some crucial changes, many aspects of her story remain strikingly similar. In particular, the lack of agency Eve has over her fate, her subordination to male characters, and the stereotype of Eve as wife and mother are closely looked at. I also note that while *Lucifer* breaks new ground by exploring Eve as a queer character, the show still holds her to patriarchal standards in her romance with a female partner. Finally, the use of the male gaze in the cinematography perpetuates the same type of objectification Eve experienced in *Paradise Lost*. Comparing Milton's Eve to *Lucifer*'s Eve reveals that, despite the progress feminist movements have made, misogyny and traditional gender roles still have a powerful hold over the stories we tell.

Abstract Name: How Molecules Wind Down: Knowledge Based Searching for Optimal Correlated Torsional Angles of Conformers

Many biological functions are based on secondary properties, such as three dimensional conformation. Protein folding is a widely studied phenomenon, and is considered the foundation of protein function and malfunction. The same can be said about enzymes and drugs, as a molecule's shape determines how it interacts with a binding site. The majority of molecular variations are small: bond length and bond angle only vary by minute amounts (a few tenths of an angstrom or a few degrees), whereas torsional angles can vary by large amounts (up to 180 degrees in some cases). Most conformer determination methods use crystallographic databases to determine molecular geometry, limiting them to molecules that are able to be synthesized and crystallized. In this work, torsional preferences are determined by comparing molecular substructures using knowledge based searching methods. This work is particularly concerned with correlated torsional angles,

where changing one torsional angle impacts the stability of another. The goal of this project is to not only to build a predictive model for correlated torsional angles, but to build a model that works efficiently.

Abstract Name: FAVOR - Feasibility and Acceptability of Virtual Reality for Older Acute Stroke Patients

Background: Stroke is the 5th leading cause of death globally, and age is a predictor variable. Virtual reality (VR) has effectively improved patient outcomes in post-stroke rehabilitation across age groups, including Baby Boomers (born between 1946-1964), Generation X (1965-1980) and Millennials (1980-1996). Early VR use after stroke could accelerate recovery and improve patient outcomes. However, age-related patient perceptions regarding VR adoption during the acute phase of recovery has not been studied. Purpose: To explore the acceptability and feasibility of different age groups toward VR use to promote post-stroke recovery. Methods: This prospective non-randomized observational study enrolled stroke patients admitted to an acute stroke unit or neuroscience intensive care unit. Wearing a VR headset, patients played a standardized VR game that required movement of at least one arm for 5 minutes. After playing the VR game, the patients completed two validated measures: the Acceptability of the Intervention Measure (AIM), and Feasibility of the Intervention Measure (FIM). The lowest survey scores were imputed for participants who did not complete the VR game and/or survey. Results/Conclusion: The 30 patients included 21 Baby Boomers, and 9 Generation X. AIM and FIM scores were generally high. Among all subjects, VR was measured as implementable and seemingly possible (88.9%), seemingly doable (81.4%), seemingly easy (74%), appealing (81.5%) met their approval (85.2), 81.5% found VR to be a learning tool, and 84% welcomed VR. Among age groups, there was no difference in total AIM scores ($P=.25$) nor FIM scores ($P=.29$). Several subjects had never played video games and described VR as fun and engaging. One participant gained functional arm mobility during the VR intervention. VR is feasible and acceptable across age groups in acute and critical care settings. These findings support future studies exploring the impact of VR in early rehabilitation on patient outcomes.

Abstract Name: America's Pastime Under the Fog of War: A Study of the Impact of World War II on Major League Baseball's Finest

World War II was a crucial point in world history and many men could not escape the desire to fight and defend their country. One subsection of men that fought in the war is the many men that competed in Major League Baseball and its affiliate leagues, the minors and the Negro League. Players that served in the war lost valuable time in their playing careers, despite this many would eventually enter the National Baseball Hall of

Fame. This research aims to analyze the military service of Major League Baseball players and how that service impacted their careers. How did service in World War II impact the careers of Hall of Famers and did that service help or hurt their careers? This study will employ an analysis of primary and second sources to determine where players served and analyze their pre- and post-war careers. Primary sources such as newspaper reports and interviews with the players themselves provide insight into the impact of the war on these players. The case study specifically will look at the careers of Warren Spahn, Yogi Berra, Joe DiMaggio, and Ted Williams. This research seeks to deepen the understanding of baseball during World War II and shed light onto the oftentimes unknown stories of these baseball legends. Each of these four players had promising careers and were inducted into the Hall of Fame despite missing several seasons to military service.

Abstract Name: Effect of Temperature and Sulfuric Acid Concentration on Pattern Formation in BZ Chemical Reaction Systems

Waves and oscillation patterns are found at all levels of biological organization, from cellular to supracellular and even social organisms. For instance, the rhythmic beating of the heart is driven by the intricate spatiotemporal distribution of oscillatory signals in cardiac pacemaker cells, while Beta-cells in the pancreas release insulin in response to fluctuations in calcium concentrations. Similarly, amoeboid cells exhibit wave-like propagation patterns that generate movement. The Belousov-Zhabotinsky (BZ) reaction serves as a model for studying the dynamic behaviors of biological, chemical, and physical systems. This reaction involves the oxidation of an organic acid by bromate ions in acidic aqueous solution in the presence of a metal ion catalyst. When the precise conditions are met, this metal catalyst undergoes repeated oxidation and reduction cycles that can be visualized by alternating colors. Variations in the BZ reaction mixture and environmental conditions, such as temperature, affect oscillation and wave patterns. We report our investigations into the effects of temperature and sulfuric acid concentration on spontaneously propagating wave patterns in a quasi-two-dimensional BZ reaction-diffusion system conducted isothermally at temperatures between 3.0°C and 50°C. The average wave velocity, wavelength, and period measurements show a strong temperature dependence. At low acid concentrations, as temperature increases, the wave patterns transition from target to spiral and chaotic wave patterns, while in isothermal conditions, the wave patterns transition from target to spiral with increasing sulfuric acid concentration.

Abstract Name: The Phenomenon of Busyness: Leadership, Time Management, and Its Implications in Law, Economics, and Business

This study, conducted under the ODESI framework, explores the phenomenon of “busyness” in leadership within the fields of law, economics, and business. The research examines how leaders’ time management

affects their professional actions, personal decisions, behavior toward others, and career trajectories. By conducting interviews with CEOs and leaders from diverse firms, companies, and organizations, the study investigates the nature and functions of time management, examining both its positive and negative consequences. The methodology includes contacting potential interviewees, conducting interviews, transcribing them using Otter AI, and summarizing key insights into concise memos after analyzation. The study's core questions are: What is busyness? What are its functions? And what are its implications for leadership success? In its practical application, this study aims to enhance organizational effectiveness by fostering better communication across hierarchical levels, inspiring purpose-driven leadership, and supporting balanced, productive work environments. The research holds significant relevance for both academic and corporate fields by uncovering insights that contribute to building efficient teams and sustainable career paths. It is expected that the study will reveal how professionals manage their time and happiness in both their professional and personal lives by examining how they handle busyness. Additionally, the study aims to identify the most successful leadership structures for creating efficient and balanced work-life schedules. This research aligns with the shared vision that collaboration between industry and academia can drive innovative advancements benefiting society. By examining the effects of busyness and time management, it ultimately seeks to inform strategies for balancing professional and personal lives, promoting individual well-being and organizational productivity.

Abstract Name: Leveraging single cell transcriptomics to inform prediction and prioritization of biologically relevant candidate genes in emerging Parkinson's disease GWAS loci

Parkinson's disease (PD) is a common progressive neurodegenerative disease affecting motor control, with preferential loss of dopamine neurons in the substantia nigra (SN). Despite being extensively studied, a full understanding of the genetic causes of disease risk and progression in both familial and sporadic PD remains elusive. Through genome-wide association studies, more than 90 independent loci have been associated with disease; however, pinpointing the affected genes and causal variants within these loci remains a challenge. We leveraged single-cell transcriptomics to upgrade a computational scoring system to predict and prioritize top candidate genes within a 1 Mb window centered around the lead variant within 98 loci. Genes were scored using five different gene lists: genes with an average expression above 0.5 transcripts from SN cell populations in the scRNA-seq data from both Hook et al. (2018) and La Manno et al. (2016); genes that were differentially expressed between post-natal day 7 (P7) subset clusters; genes found to be specifically expressed in the P7 midbrain SN cluster; and genes enriched for PD in the weighted gene co-expression network analysis modules. Altogether, we predicted candidate genes for 97% of PD loci; 11.2% of loci had only 1 candidate gene; and 43.9% of loci had 3 or fewer scored candidate genes. For loci with more than 2 or more scored genes, the probability of loss-of-function intolerant was used to prioritize the top candidate gene. Our top gene candidates SNCA, KCNN3, and CPLX1 have been previously shown as directly associated with PD, supporting the use of context-specific data in prioritizing candidate genes in PD GWAS loci. This systematic approach facilitates the prioritization of biologically pertinent gene candidates for sporadic PD, informing PD genetic research.

Abstract Name: In the Eyes of the Consumer: Food Labels and Safety in America

The American food industry encompasses many characteristics that play crucial parts in the economy. However, increasing concerns have arisen regarding the ingredients in packaged foods available in U.S. grocery stores and their safety, due to substantial amounts of toxic additives and preservatives. While some see it as a deadly health problem, others are unaware of the issue. Motivated by this variation, I developed a survey to assess the public's knowledge regarding America's food system. Specifically, the project focuses on comparing male and female responses regarding how often they check food labels when grocery shopping and their perceptions of the safety of American packaged foods. The survey consisted of 16 questions and 152 responses were collected via the Amazon MTurk platform. After further analysis through IBM SPSS software, results revealed significant gender differences indicating that 88.3% of females check ingredient lists when grocery shopping very often or somewhat often, compared to 69.9% of males. This difference is statistically significant at the 1% level. Additionally, 7.7% of females perceive packaged food products in the U.S as somewhat unsafe, while only 1.4% of males share this view. This difference is statistically significant at the 1% level. These findings reveal significant gender-based differences, with females demonstrating greater attention to the American food industry. This research could have important implications for the future, particularly considering the knowledge disparities between females and males on this critical issue.

Abstract Name: Bridging the Gap: The Impact of Black Success through Equity, Support, and Representation

This research was grounded in identifying ways to promote racial equity by advancing research that disrupts anti-Black norms, values, and beliefs in science, technology, engineering, and math (STEM). This study aims to enhance Black students' academic and personal success in post-secondary education. The research participants included four undergraduate students of diverse STEM majors, sexes, and ethnicities. All four participants attend a Historically Black College or University (HBCU). During a 40-minute semi-structured focus group, the participants were led into a discussion designed to learn about the specific intersection of their identities. The focus group session was recorded via Zoom and transcribed verbatim. The transcripts were analyzed using an equity framework lens and coded for common themes. Through analysis of the transcription, common themes were discovered that impacted Black success in post-secondary education. The findings revealed that student-faculty relationships and role modeling were positive influences, and student-faculty relationships, colorism, and educational funding are examples of negative influences. These findings highlight the complex dynamics influencing Black student success in post-secondary education. We found that student-faculty relationships have positive and negative influences, emphasizing the inconsistency in

those interactions. Role modeling is also prevalent, as many students need to see successful individuals with similar backgrounds and present as role models for upcoming generations. Furthermore, students are affected by the systematic challenges of colorism and the barrier of underfunding that many HBCUs face. As a result of the findings, it is suggested that strengthening student-faculty relationships by nurturing supportive environments, advocating for increased funding, and implementing mentor programs or the visibility of successful alumni at universities are needed to increase black student success in post-secondary.

Abstract Name: Modern Ranch-Style Retreat

Modern Ranch-Style Retreat focuses on designing an accessible living environment for a family member diagnosed with severe myopia. Myopia is a refractive error due to the eyeball becoming too long, causing light to focus in front of the retina rather than directly on it. As a result of this elongation, light does not properly focus on the retina, making distant objects appear blurry, and unclear outside visual scope. The user can distinguish objects within five feet, but anything beyond that becomes unclear. Designing an accessible home for the family includes reviewing related articles, videos, and attending a live presentation from a guest speaker with a visual impairment. Myopia typically develops between ages 8-12 and progresses through childhood, often stabilizing in late adolescence. However, individuals with myopia are at higher risk of developing eye conditions like glaucoma, cataracts, macular degeneration, and retinal detachment later in life. Key design strategies of this project for the user are emphasizing thoughtful hardware placement, material reflectance values, and creating contrasts between furniture and structural elements. Additionally, wainscot railings as handrails, matte finishes to reduce glare, layered lighting with dimming switches, ADA-compliant grab bars in the bathroom, nightlights, laminate flooring, a recessed sprinkler system, and low-pile carpet were considered to support the user's navigation and safety within the home. Universal design principles were also incorporated to accommodate both visually impaired and sighted family members, such as widening the corridors, placing cabinetry at accessible heights, using sliding doors for closets, and using three-way switches for convenience in controlling lighting from multiple locations. In conclusion, the design effectively prioritizes the needs of all household members by implementing a universal design that is functional for everyone, and integrating ADA-compliant solutions throughout the home, to promote independence and comfort.

Abstract Name: Creating a High-Resolution, Immersive City Environment Model Through the Integration of Photorealistic 3D Mapping

The advent of Photorealistic 3D Tiles (P3DT) offers groundbreaking opportunities to better understand

streetscape infrastructure (e.g., buildings, street assets, roads, and vegetation) through high-resolution 3D mapping. This technology enables the creation of high-fidelity, immersive streetscape environments, a crucial step toward advancing next-generation, human-centered infrastructure design and optimizing streetscape functionality. The core objective of this project is to develop a 3D digital twin—an accurate, geographically aligned, visually and physically immersive representation of real-world streetscape elements including but not limited to buildings and road networks. The project focuses on producing detailed, photorealistic renderings of streetscapes, capturing the intricacies of multiple buildings, roadways, and pedestrian infrastructure. This goal was achieved through the integration of various software tools, including the Google Maps API, P3DT, Blender, and Unity. The workflow began with modeling buildings in Blender, incorporating data from OpenStreetMap (OSM), Google P3DT, and real-world terrain. Each building model underwent meticulous refinement to achieve high-quality, visually accurate results. OSM data guided the precise arrangement of streetscape components by providing critical details like building locations, road outlines, railway alignments, sidewalks, and forestry placements. After the buildings were modeled and placed, road and sidewalk systems were created by tracing OSM's road outlines. Once the streetscape modeling in Blender was complete, the components—including buildings, roads, and sidewalks—were exported to Unity. This step was essential, as Unity's cross-platform development environment supports the integration of advanced simulations, such as traffic modeling, predictive analytics, and agent-based interactions. These features enable the creation of immersive and functional 3D virtual streetscapes, bridging the gap between visual realism and practical application in urban infrastructure planning. This project demonstrates the potential of P3DT in revolutionizing streetscape modeling and urban development.

Abstract Name: When Tragedy Strikes!

What happens when students or faculty are caught in the crossfire in the hallway during an active shooting lockdown? Tragedy. Research shows that school districts implement lockdown protocols once a security breach occurs in the facility. During the lockdown, instructors are not allowed to open or unlock doors once they are shut for safety reasons. Individuals left on the other side of the door must find a place for refuge. Safety Pods are a unique solution essential in public education to protect students and faculty during active shootings. In 2022, 34 students and adults died, while more than 43,000 children were exposed to gunfire at school. The average Emergency Services response time is between 2–6 minutes. In 2019–20, there were a total of 25 school-associated violent deaths in the United States, which included 23 homicides and one suicide. Because of this terrible reality, it is imperative to construct the interior and exterior of the Safety Pod to withstand gunshots and support the person inside. The Safety Pod features life-sustaining qualities to increase survival rates for those accessing the pod. Features include air vents to circulate airflow, steel material applied to the front exterior to reduce the penetration of the bullet fragments, and Kevlar bulletproof padding and acoustic lining on the interior backside of the door. A first-aid safety kit and textured, antimicrobial fabric are incorporated into a seat inside the pod to help comfort users while waiting for rescue. The pods are recessed next to student lockers. The pods can also be stored next to restrooms, vending machines, and dead-end corridors as a freestanding single unit. The Safety Pod is a solution for everyone in public education stranded in corridors needing immediate shelter. The design safely accommodates users while waiting for law enforcement to secure the site.

Abstract Name: Food Insecurity and Sustainability in North Carolina

Community-driven initiatives in Johnston and Wake Counties, North Carolina, are transforming lives by addressing food insecurity, fostering sustainability, and empowering vulnerable populations. Central to these efforts, Nourish International collaborates with local organizations to cultivate leadership and promote social impact through food security programs and sustainable agricultural practices. Partnerships with organizations like the Benson Area Ministerial Association (BAMA), the Raleigh Food Corridor, and the Raleigh Relief Project emphasize providing essential resources such as food, financial support, and hygiene products to underserved communities. Educational initiatives like urban gardening workshops and sustainability projects aim to build long-term resilience and community empowerment. These programs embody a shared mission of compassion, collaboration, and meaningful social change.

Abstract Name: Exploring LLM-Assisted Gap Analysis for Cybersecurity Compliance Auditing

Ensuring adherence to cybersecurity frameworks and standards is a prevalent challenge that numerous organizations face. Conventional auditing necessitates extensive manual analysis that requires an excessive quantity of time and resources to verify compliance and discover gaps in adherence to best practices. Recent advancements in large language models (LLMs) have generated many new opportunities to streamline tedious tasks. Artificial intelligence and machine learning have been increasingly applied to numerous aspects of cybersecurity, including threat detection as demonstrated by Lee et al. (2019). However, the application of these technologies in compliance auditing, though, remains largely unexplored. This study proposes a novel approach that employs a specialized LLM that aids in cybersecurity compliance auditing by finding compliance gaps and providing actionable recommendations by analyzing organizational reports. To ensure pertinent gap analysis in a dynamic and evolving sector, we review numerous contemporary cybersecurity standards as a set of training data, including the National Institute of Standards and Technology (NIST) Cybersecurity Framework (CSF) and the North American Electric Corporation Critical Infrastructure Protection (NERC-CIP) Standards. Furthermore, we address the ethical and practical challenges of using LLMs, including issues of hallucinations, transparency, and potential data security risks. A user-friendly interface must also be emphasized to facilitate accessibility for individuals with limited technical expertise. Our preliminary findings indicate that the proposed LLM auditing process could significantly reduce the time required for compliance audits while maintaining relative accuracy. However, due to certain persistent and unvalidated issues, the jury is still out on LLMs. Notwithstanding these limitations, LLMs can still be tapped as a tool for regulatory compliance and audit as demonstrated by a proof-of-concept system resulting from this study.

Abstract Name: Transgenic Expression of Human CD20 in Mice Leads to Motor Coordination Deficiency.

Introduction: CD20 is a marker for B cells in humans, but not expressed endogenously on mouse B cells. Transgenic mice expressing human (h)CD20 can undergo B cell depletion with treatment with Rituximab. We showed that B cells can migrate into the brain after injuries, such as stroke, facilitating recovery and influencing motor function and control. To understand B cell-mediated mechanisms of neuroprotection we crossed tamoxifen (tam)-inducible hCD20 mice with floxed brain-derived neurotrophic factor (BDNF) mice, BDNF is a key protein for neuroplasticity and the growth, survival, and maintenance of neurons.

Methods: Transgenic 11 to 12-month littermate male hCD20tamCRE(+) and hCD20tamCRE(-) mice were used for this study as well as 13 to 14-month male hCD20tamCRE(+)/fBDNF(+/+) and hCD20tamCRE(-)/fBDNF(+/+). Mice underwent rotarod testing for 9 days, followed by RNA sequencing of the hippocampus and motor cortex. Results: We found that mice expressing hCD20 had a significant deficiency in motor coordination during rotarod testing compared to the control in the absence of brain injury. Additionally, the presence of floxed BDNF in these mice exacerbated this deficiency. RNA sequencing analysis showed that 18 genes in the hippocampus associated with muscle function and cell development were affected. Among which, SYNPO2 and NHLH2 have been shown to affect muscle development, including skeletal muscles, through positive regulation of actin filament bundle assembly and differentiation and regeneration of muscle tissue after exercise respectively. Additionally, NEGR1 and TIAM2 are involved in locomotion and BCOR plays a role in cell death and lymphoid development. Conclusion: Human CD20 expression in mice affects genes in the hippocampus leading to a deficit in motor coordination which is further exacerbated by fBDNF. The effect of hCD20 on those genes may play a key role in this deficiency and suggest a role for B cells in brain function and motor cortex coordination.

Abstract Name: Development of Nanoparticle-Based Lateral Flow Assay for Detection of Mercury in Drinking Water

Heavy metals (e.g., arsenic, mercury, and lead) contaminate water supplies through natural deposits and industrial and/or agricultural pollution. Consumption of heavy metals may cause brain and kidney damage, reduced growth of a fetus, generalized birth defects, and immune system issues in humans. One effective strategy to prevent heavy metal consumption is to test potable water to ensure its safety. Typically, these analyses are done using expensive instrumentation, such as F-AAS and ICP-OES, that are not as accessible in many areas. Our goal is to create simple and inexpensive paper-based lateral flow assay (LFA) to make heavy metal testing accessible to the general public. Lateral flow assays are rapid tests (5-30 mins) used to detect or quantify analytes in mixtures. Each LFA has a control line, which ensures the test's functionality, and a test line(s), which indicates the presence of the analyte(s). In this work, we developed pH-sensitive polymer nanoparticles (NRNP) for the control line, and mercury responsive nanoparticles for the test line. The control nanoparticles were synthesized using neutral red and poly (styrene-co-maleic acid) (PSMA), in acetone, with a 1% polyvinyl alcohol (PVA) solution. The resulting control line changed from yellow to red with the addition of a water sample. The control line was optimized by testing the optimal number of drops added to the test, the ideal volume of each drop, and the water sample size. ImageJ was used to analyze the intensity of the control line signal during the optimization. The test line nanoparticles were synthesized using a derivative of rhodamine b. The polymers and solvents used in the synthesis were optimized, and the sensitivity and specificity of these nanoparticles to mercury were also analyzed. Both nanoparticles were then incorporated onto test strips to be used for detection of mercury.

Abstract Name: The Impact of State Approved Student Voter IDs on College Students Voter Turnout

Following the Help America Vote Act (HAVA) of 2002, states began implementing voter ID requirements with a variety of strictness. Many scholars have identified these laws as a barrier to voting for certain groups, including college students. There has been significant research on the effects of these requirements on voter turnout, but the evidence is inconclusive. In an effort to lower barriers to voting for college students, some universities have sought to get their student ID approved as a valid form of voter identification. This research aims to answer the question: Is there evidence that having an approved student ID increases voting rates among college students? In order to achieve this, states who have the same voter ID requirement strictness level were paired together for most scenarios—one that allows student voter IDs to some degree and one that does not. A university in each state was selected and matched to another in the pair that fit the criteria. Schools in different states were matched based on type of institution—public or private, and size of the undergraduate population. Within each pair, one university had their student ID approved by their state, while the other did not. Results suggest that having an approved student ID as voter ID has a positive effect on turnout. As more states add voter ID requirements and young people become more of a focus for political scientists, this research works to combine these two areas into a project that could have policy implications throughout the country.

Abstract Name: Invalidation and Amplification: Medical Gaslighting's Role in Pain Perception

This study investigates the interplay of medical gaslighting (MG) and pain catastrophizing (PC). MG is defined by patient experiences in which they feel dismissed, invalidated, or inadequately treated by healthcare providers, often leading to doubts about their own health. These experiences may be amplified by social inequities such as gender, race, and socioeconomic status, which contribute to broader healthcare disparities. PC refers to an exaggerated focus on and fear of pain, causing a bidirectional effect on pain perception: pain can cause catastrophic thoughts, and those thoughts can, in turn, exacerbate the pain. We hypothesized that individuals who report more frequent experiences of MG would also display heightened levels of PC. Data was gathered via an online survey with 10 participants (ages 19 to 52). Participants reported on their experiences of MG and levels of PC using standardized scales. In line with our hypothesis, results revealed a statistically significant correlation between MG and PC. Possible contributing factors include the subjective nature of MG experiences, individual pain thresholds, and varying levels of psychological resilience. These findings underscore the complex interplay of the MG-PC, suggesting that different variables may influence this interaction. Further studies should aim to identify these factors and analyze how cultural and contextual differences shape the way MG and PC are experienced.

Abstract Name: Honoring the Tapu Wāhine Māori's voice in Rongoā Māori

The accelerating global environmental crisis fueled by climate change, biodiversity loss, and pollution has sparked a growing reinvestment in the knowledge, values, and practices of Indigenous peoples within their local communities. As the environmental crisis escalates, Indigenous knowledge is becoming increasingly recognized as critical to understanding the drivers and impacts of western modernization and the systems that derived from settler colonialism. The purpose of this qualitative case study research project was to listen to the perspectives of wahine (women) Māori about Rongoā Māori (traditional healing practices) in Whanganui, Aotearoa/New Zealand. It explored how returning to traditional healing practices aids in reciprocal restoration, where Rongoā Māori heals both the people and the land. This case study was conducted with a kaupapa Māori-centered approach and grounded in mana wahine theory through a three-month internship with the Healthy Families team at Te Oranganui, a Māori-led health organization in Whanganui. Qualitative methods were semi-structured interviews, participant observation, and an autoethnographic reflection of Afro-Indigenous. The findings revealed how Rongoā Māori operationalizes Māori philosophical concepts such as kaitiakitanga (guardianship of the environment), tangata whenua (people of the land), and wairua (spirit) to foster reciprocal restoration—healing that benefits both the people and the environment. Kaitiakitanga was practiced through the sustainable harvesting of medicinal plants, tangata whenua emerged as a deeply personal and collective sense of identity tied to place, and wairua was intricately linked to the efficacy of Rongoā Māori, connecting practitioners and recipients to spiritual dimensions often overlooked in western frameworks. These findings underscore Rongoā Māori as not only a culturally rooted alternative to western medicine but also as a transformative framework for environmental conservation grounded in traditional ecological knowledge (TEK). The study highlights the critical need for further research centering wahine Māori perspectives in both the Rongoā Māori space and broader conservation efforts.

Abstract Name: Positive Psychology and Relationship Outcomes: The Impact of Gratitude Expression on Romantic Relationships

This study examined the connection between romantic relationship satisfaction and gratitude expression in order to improve beneficial outcomes. By understanding these connections, couples can implement behavioral interventions to cultivate more fulfilling relationships. Although previous research has shown that these factors are positively correlated, there is a gap in the research with regard to including nonbinary participants. By including nonbinary participants in this research and adding gender inclusive language, the research team aimed to provide a safe space for individuals. Information regarding distance from a partner (long distance, living together, or living separately but in the same area) has also been overlooked. For this study, the participants (primarily Virginia Tech students) completed a 15-minute survey. They were asked a series of questions based on modified versions of the Couples Satisfaction Index (CSI) and the Appreciation in Relationships (AIR) Scale, which examine relationship satisfaction and gratitude expression, respectively. Demographic information about the participants and their partners was also collected, including distance from a partner and length of time in a relationship. Three main hypotheses guided this research: a) Higher levels of gratitude expression will be positively correlated with higher levels of relationship satisfaction, b) Gratitude expressions will decrease as the duration of a relationship increases, while reported relationship satisfaction will remain stable, and c) Participants who are living together will report lower levels of both gratitude expression and relationship satisfaction than will those who are long-distance partners or are living separately. The results showed that romantic relationship satisfaction and frequency of gratitude expression were moderately positively correlated. Satisfaction and distance from a partner were only weakly positively correlated. Satisfaction and length of time with a partner were also weakly correlated. Overall, these results showed that factors beyond duration and physical distance, like gratitude expression, can lead to satisfaction for individuals in relationships.

Abstract Name: Illuminating Sustainable Design: Teaching Design Students About Low-E Windows

The University of Kentucky College of Design recently relocated the Gray Design Building (GDB) which is a sustainably repurposed tobacco warehouse. This building is itself a learning opportunity for the students who study in it. One such opportunity is the use of Low-E windows to reduce unwanted interior heating by the sun. This is a sustainable design choice that is crucial to preserving energy use in the GDB, yet this information is not being shared with students and other building occupants. Through research into the science behind Low-E technology, exploration of various teaching tools, and an iterative design process, this project investigates how the technology of the Low-E windows can be creatively conveyed to design students. The project will result in an interactive art installation that manipulates sunlight to visually explain the scientific principles of Low-E technology, thus making the information digestible and engaging for students.

Abstract Name: The Impact of Fear of Falling on Brain Activity and Cognitive Performance in Older Adults

Elevated fear of falling (FoF) among older adults is associated with an increased risk of cognitive decline. Previous research has indicated that reduced electroencephalogram (EEG) alpha activity in frontal regions is correlated with diminished cognitive performance, particularly in areas of attention and executive function. Nevertheless, the interplay between FoF and brain activity related to attention and executive function remains insufficiently explored. This cross-sectional research aimed to understand the effect of FoF on resting-state EEG alpha power and cognitive performance in older adults. We hypothesized that older adults with high FoF would demonstrate reduced alpha power and decreased cognitive performance compared to older adults with low FoF. Twenty-two participants (age: 75 ± 7 years; 16 females) completed the Falls Efficacy Scale and were divided into low FoF (<18 ; $n = 14$) and high FoF (>18 ; $n = 8$) groups. They also completed a cognitive test battery (Montreal Cognitive Assessment, Hopkins Verbal Learning Test, Digit Span, Digit Symbol Substitution Test, Trail Making Tests, and Verbal Fluency) and a resting-state EEG. Independent Sample t-test results indicated that older adults with high FoF had lower alpha power in the anterior left region compared to those with low FoF ($p = 0.007$). While cognitive test scores did not significantly differ between groups, a trend towards lower Digit Symbol Substitution Test performance was observed in the high FoF group ($p = 0.05$). These results suggest that high FoF is associated with reduced alpha power and potentially impaired executive function and attention. Further research is needed to investigate the neurophysiological mechanisms underlying these observed relationships, as well as to determine the timing of changes in FoF, alpha brain power, and cognitive decline which can provide deeper insights into their interconnections.

Abstract Name: Measuring diversity and estimating density of ticks (Family Ixodidae) in Defiance County, Ohio

Tick-borne diseases are spreading with the range expansion of the black-legged tick (*Ixodes scapularis*). Black-legged ticks can survive cold winters by staying beneath leaf cover at the edge of woodland habitats. The spread of *I. scapularis* has been facilitated by terrestrial and aerial hosts as far north as Canada. One method to record this spread and better inform local health departments is to estimate the increase of tick-borne disease hosts through sampling. The goal of this project is to measure and compare tick species diversity in Defiance County, Ohio. Between December 2023 and October 2024, we drag-cloth sampled a heavily managed wildlife preserve (Thoreau Nature Preserve) and an unmanaged natural area (Penney Nature Center) in Defiance County, Ohio. We found a total of 44 ticks and two species between the two sites: 88.6% *Dermacentor variabilis*, and 11.4% *Amblyomma americanum*. Penney Nature Center had the highest abundance with 81% of all ticks collected. We suspect that controlled burns and targeted mechanical vegetation removal may have eliminated the leaf cover ticks rely on to overwinter. Overall, we found fewer ticks than expected, especially for the time period through the summer and fall. Unusual dry seasonal conditions may have driven ticks to lower, ground-level vegetation, thus precluding accurate sampling.

Abstract Name: Patterns and Characteristics Unique to AI-Generated and Human-Generated Text Responses

The recent advancements and broad applications of Large Language Models (LLMs) and Gen-AI tools, such as ChatGPT and Gemini, have a critical goal of effectively and efficiently identifying and modeling a multitude of complex patterns and characteristics associated with human-centric languages, in both spoken and written forms. Generally based on LLMs and Gen-AI algorithms, existing literature works have yielded performance success; however, at considerably different levels. For example, multiple research works have noted there were specific characteristics associated with the respective AI-generated and human-generated responses to a given input prompt. The current focus of our research is investigating natural language processing based solutions to identify hidden patterns and semantic constructs that are respectively unique to an AI-generated response and a human-generated response to a collection (dataset) of input prompts. Our preliminary work has been on data processing, such as removing punctuation characters, removing common stop words, and converting text to lowercase format. The initial dataset of our research project consists of approximately 2000 records where each record is associated with four attributes: full text of a published article; the AI-generated abstract of the article; the human-generated abstract of the article; and a class label for whether the given abstract is AI-generated or human-generated. A manual inspection of some records of the dataset revealed that several AI-generated abstracts contained text of the article's title. The to-date tasks

completed in our project include extensive related literature reviews, collection and preliminary analysis of multiple datasets best suited to the context of our current empirical goals. An ongoing step of our work is exploring various algorithms to effectively model text data as inputs to both traditional machine learning and deep learning algorithms. Such investigations are important for improving AI-detection tools, evolving LLMs responses to input prompts.

Abstract Name: Ruffs Dale Unwritten: Discovering the Roots and History of Our Hometown

This project, Ruffs Dale Unwritten, explores the untold history of Ruffs Dale, Pennsylvania, a small town with a rich yet largely overlooked past. Using a combination of archival research, oral history interviews, and community engagement, this work uncovers the town's significant contributions to national industry, railroads, and economic growth, as well as its role in pivotal historical events. From the French and Indian War and the Underground Railroad to the town's impact on the coal and coke industry, the research highlights the resilience and spirit of Ruffs Dale's residents—pioneers, Native Americans, enslaved individuals, immigrants, and laborers. The project began with exploring the town's name and quickly grew through vibrant community participation on social media, where hundreds of residents shared personal stories and historical insights. Visits to the town revealed forgotten landmarks like the Dillinger Distillery and roads named for pioneer families, while archival resources such as historic newspapers and historical biographies provided additional layers of detail. Key discoveries include the Ruff family's foundational role in the town's history, the presence of slavery and subsequent involvement in the Underground Railroad, and the forgotten narrative of Dillinger Distillery, which operated for over 80 years. This research not only reconstructs the town's history but also underscores the broader significance of local history in understanding cultural identity. This work aims to provide a comprehensive narrative of a town that history has forgotten. Ruffs Dale has largely impacted national industry and events, yet it has often been left out of our nation's history. This project demonstrates the power of local history to connect communities, preserve collective memory, and illuminate the stories that have shaped our shared heritage by illuminating a town that has been hidden for decades.

Abstract Name: "Investigating the Role of Human Alpha Defensin-5 (HD5) in Impaired Wound Healing and Pathogenesis of Crohn's Colitis: Implications for Diagnostic and Therapeutic Advancements"

Inflammatory bowel disease is a chronic illness that affects the digestive tract. It includes two subtypes, Ulcerative Colitis (UC) and Crohn's Colitis (CC). CC is a subset of Crohn's Disease that is localized to the large intestine. CC, specifically, and UC are commonly misdiagnosed. One promising preliminary discovery to help improve diagnostics is that the expression of innate immune peptide, human alpha defensin-5 (HD5)

is elevated significantly in Crohn's Colitis patients versus Ulcerative Colitis patients by as much as 118 fold. Our current study has two aims in studying the effect of this HD5 overexpression. We have preliminary data indicating that HD5 is impairing wound healing in colonic epithelial cells. Therefore, we would first like to measure the wound healing capability in NCM460 cells of the colon in response to HD5. Secondly, we would like to further measure the protein expression of VTN (Vitronectin), WISPI, and Wnt5a in NCM460 cells after exposure to HD5. This will be done with qPCR and Western Blots to look at the expression of these important wound healing proteins. Based on the preliminary data around HD5 and Crohn's Colitis patients, we know that HD5 decreases wound healing in the colon. So, we expect the HD5 peptide to decrease colonic wound healing in a dose-dependent manner. A preliminary wound healing array has also shown an increase in VTN, WISPI, and Wnt5a as the levels of HD5 rose. We expect our qPCR and western blot studies to validate this data. These experiments are important to elucidate the role of HD5 in CC, hopefully giving us more mechanistic insight to CC pathogenesis, which could lead to better treatments of the disease.

Abstract Name: Understanding Ion Channel Association in mRNA Decay

Dysregulation of the function and balance of cardiac ion channels can cause arrhythmias and sudden cardiac death. One critical component of this balance is the potassium channel hERG1, which conducts the delayed rectifier outward current I_{Kr} and contributes to the repolarization phase of the cardiac action potential. Mutations or dysfunction of hERG1 lead to Long-QT syndrome and arrhythmias. I_{Kr} is conducted by heterotetrametric hERG1 channels, which consist of hERG1a and hERG1b subunits whose mRNA has been found to physically associate during translation. Interestingly, depletion of one mRNA by subunit specific shRNA corresponds with a concomitant depletion of the other, observed in both HEK293 cells and iPSC-derived cardiomyocytes (iPSC-CMs). The mechanism underlying this "co-knockdown effect" is unknown. The study investigates this mechanism by probing two potential models of co-knockdown, that hERG1a and hERG1b mRNAs are degraded together or they are destabilized independently. Using HEK293 expressing both subunits, we will transfect hERG1a-specific shRNA and collect samples at 3-hour intervals post-transfection. The use of qPCR will be used to quantify mRNA levels in order to resolve the depletion time course for each transcript. If both transcripts are depleted simultaneously, it would suggest co-degradation into a shared complex. If hERG1b depletion is delayed, it may suggest a dissociation of the mRNA pair, followed by destabilization and degradation of hERG1b. A similar approach will be used in the physiologically relevant model, iPSC-CMs. This study will provide valuable insight into an important regulatory mechanism of cardiac ion channel biogenesis. We will also lead to future study further dissecting the co-knockdown mechanism in hERG1a/1b and in other co-translationally associated ion channels, and their implications for cardiac arrhythmia.

Abstract Name: Differences in Stress Between Freshmen and Seniors in College Focusing on Presenting

Stress is a prominent factor for all individuals, especially those within the college population. Understanding stress, its impacts, and how to manage it are strategies to improve daily lives of many. The focus of this research study was to determine the differences of stress levels between freshmen and senior college students when presenting. Using the Trier Social Stress Test (TSST), this lab-based stress-inducing task incorporates a presenting aspect which is highly applicable to the college student population. Another purpose of this study was to consider its results and understand stress levels in order to provide quality stress management skills in the future. The TSST used in this research study had participants spend 15 minutes preparing a 5-minute speech on a fake autobiography. The participants were then instructed to present the speech in front of a configured Zoom call audience which consisted of six faculty members from different departments at Roanoke College. Although this Zoom call was not live and rather used prerecorded videos of the faculty members, it was presented in a way to deceive participants into thinking it was live. This is a strategy to evoke stress. This study included self-report and physiological data collection. Specifically, surveys consisting of the State Trait Anxiety Inventory (STAI Y-6 and Y-2) along with heart rate. Data was compared between three segments: baseline, preparation, and presentation. Analyses indicate a significant difference in stress levels in segments for both physiological ($F(2, 29) = 101.94, p < .001$) and self-report ($F(2, 29) = 9.037, p < .001$) data collection – indicating the TSST accurately induces stress. However, there was no significant difference in class standing. Therefore, stress levels do not differ depending on presentation experience.

Abstract Name: Who Tells Your Story: The Implications of Historical Inaccuracies in Hamilton

While research into Hamilton and the genre of historical fiction as a whole often lends itself to the debate of historical accuracy, this research aims to understand how these historical inaccuracies impact an individual character's perception in society. In so doing, this research examines Lin-Manuel Miranda's Hamilton and its presentation of founding father Alexander Hamilton. First, an analysis of the impact historical fiction has on the real world helps us understand historical fiction's responsibility toward audience perceptions. Then, an analysis of the musical's framing of the Reynolds Affair and the presentation of the character of Alexander Hamilton as an abolitionist suggests that these misrepresentations serve as a glorification of American history and allow audience members to absolve themselves from any discomfort associated with the establishment of America. Lastly, this research examines Hamilton fan art to determine how audience members connected with figures inside the story of Hamilton; it discovers that, through its desire for a compelling narrative, Hamilton causes many audience members to view historical figures as simply characters inside a story. Findings suggest that Hamilton upholds the mythos of American creation and disguises a whitewashed history behind a multiracial cast, allowing audiences to bask in the ideals of the American dream without the shame of the American past.

Abstract Name: How Discourse Made Greece the Problem Child of Europe

The Eurozone Crisis saw financial struggle across the European Union, and no member country saw a more negative portrayal in politics or the media for their role in the crisis than Greece. Using discourse analysis, this paper examines how a lasting consensus was established on Greece's blame in the Eurozone Crisis. Pre-crisis cultural stereotypes and attitudes towards Greece as well as the hegemonic dynamics between EU member countries are found to be distinguishing factors in Greece's treatment and portrayal. While current literature chooses to focus on singular factors, this paper analyzes the discourse produced from cultural, hegemonic, and linguistic standpoints, and how those discursive strategies combined and intersected to create the narrative of blame toward Greece. Looking at the specific aspects of the crisis that the producers of this narrative chose to focus on also reveals more about how the discourse shaped Greece itself, not just its image to the rest of the world, as well as the implications of this narrative for the rest of Europe and the European Union. Comparing the discourses of speakers from different backgrounds regarding their economic and political status further determined how those different backgrounds influenced their use of discursive strategies. Cultural and economic prejudices seeped into how the political elite and general populations presented and perceived information about the crisis. Comparing those features allows for further conclusions to be made about discursive strategies, influences, and effectiveness. By examining the case of Greece during the Eurozone Crisis, this paper shows the strength and multitude of methods with which discourse can be used to shape the public perception of an entire country.

Abstract Name: Forging Ahead with New Perceptions about Disability through Book Study with Preservice Special Educators

This research was undertaken to answer the research question: How does reading young adult books impact the way teacher candidates view their future role as an educator? As well as the second research question: In what ways do young adult texts featuring disabled characters disrupt or reinforce how teacher candidates think about disability? This presentation advances the concept of positional empathy, a process-oriented empathy consisting of an individual's ability to a) empathize with the internal world of others, b) foster a sense of agency and responsibility, c) face discomfort in the pursuit of understanding, and d) to enact transcendent relational competency. We illustrate this stance through a qualitative analysis of a preservice educator book study featuring disability-centered young adult fiction. Positional empathy draws from theoretical notions of care and consists of theory-of-mind empathy which comes from consuming media, self-efficacy from modeled scenarios and discussions, relational competence developed through fiction, and the ability to put oneself in challenging and uncomfortable situations in order to gain understanding. A corresponding study of literature on the work of (special) educators, whose professional responsibilities involve care, connection, and proximity to young people with intersecting identities and vulnerabilities, supplements the concept of positional empathy. Findings on the effects of fiction coinciding with structured

discussion revealed nuanced, relational forms of empathy. This presentation supports participants to view the work of teaching through a lens of positional empathy.

Abstract Name: Therapeutic Alliances: Examining the Influences of Patient-Therapist Relationships on Recovery Outcomes

The relationship between a patient and their physical therapist is a critical factor in achieving successful treatment outcomes. This dynamic goes beyond just the technical skills or interventions applied; it encompasses communication, trust, empathy, and patient engagement, all of which can significantly influence a patient's motivation, adherence to treatment, and overall satisfaction. Research shows that a strong therapeutic alliance—a term often used to describe the relationship between healthcare providers and patients—can enhance a patient's perception of treatment efficacy and their likelihood of following prescribed exercises or lifestyle changes. To inform what we know about the patient-physical therapist relationship, I will conduct a comprehensive literature review of scholarly sources that focus on patient-physical therapist relationships and their impact on treatment outcomes. In order to do this, I will utilize google relevant scholarly databases to find peer-reviewed research on my chosen topic. This analysis will explore various examples of how a strong therapeutic alliance influences diverse patient populations and recovery scenarios, highlighting the depth of its effects on health outcomes, and suggest where future research is warranted. By enhancing awareness among both patients and practitioners, this study seeks to promote a deeper understanding of the therapeutic alliance in physical therapy. In doing so, the field can advance strategies for fostering trust, ultimately contributing to improved patient outcomes and long-term recovery success.

Abstract Name: Supporting Student Nutritional Health in Educational Settings to Promote Well-Being

Food insecurity is a prevalent issue affecting students at the University of Texas at El Paso (UTEP), with a recent survey revealing that approximately 61% identify themselves as food insecure. Based on this data, our team developed Empowered Rehabilitation Station, a service-learning initiative designed to support students pursuing a degree in Rehabilitation Sciences by providing nutritious bars. Our aim is to support students' academic and mental performance to foster their success and well-being. To implement the program, we first acquired a table and containers used to display the protein bars, along with a feedback box for students to add written comments. We stocked our table with protein bars, which is located in UTEP's Health Sciences

building, near the offices of professors from the Department of Rehabilitation Sciences. Our station displayed a promotional poster and flyers that describe the importance of maintaining a nutritious diet. Additionally, these promotional materials also included a QR code that linked to a Google Form survey with three questions to collect feedback. These questions identified student's experiences with our station. Through the course of our program, we distributed 136 bars. The majority of survey respondents felt that the snacks improved their nutritional health (90.9%), and improved their social/academic performance (69.7%). Furthermore, a feedback box placed on our table reveals positive written reviews from students. Overall, these main findings showcase the positive impact of our service-learning program, and feedback is continuously being accepted to improve our program and its sustainability. This service learning project was initially funded through The \$100 Solution and it will continue to be sustained by UTEP's Rehabilitation Sciences program. Our team hopes that Empowered Rehabilitation Station highlights the importance of supporting students nutritional health in educational settings to promote student well-being.

Abstract Name: "Motivations and Influences When Acquiring Tattoos"

This research project investigates the motivations and influences behind individuals' decisions to acquire tattoos, reflecting cultural shifts towards the acceptance and mainstream recognition of body art. Through our comprehensive literature review, the study identifies key factors that drive consumers to seek tattoos, including personal expression, social identity, and cultural significance. Employing a mixed-methods approach, the research utilizes surveys and interviews to gather qualitative and quantitative data from a diverse demographic. The findings reveal that motivations for getting tattoos are multifaceted, encompassing emotional, social, and aesthetic dimensions. Additionally, the study examines the impact of marketing strategies within the tattoo industry and how they resonate with consumer behavior. The conclusions drawn from this research not only contribute to the understanding of tattoo acquisition but also provide valuable insights for marketers aiming to engage effectively with this evolving market.

Abstract Name: Diet, Drinks, And Danger: Gender Gaps in Colorectal Cancer Risks Behaviors Among

African American Teenagers.

Colorectal cancer is a significant public health concern, and its incidence among African American adults highlights the importance of early prevention efforts. This study investigates gender differences in colorectal cancer risk behaviors—specifically diet, physical activity, alcohol consumption, and smoking—among African American teenagers aged 15 to 19. Using an intersectional theoretical framework, we explore how gender, race, and socio-economic factors intersect to shape health behaviors. Using data from the 2021 Adolescent Behaviors and Experiences Survey (ABES) -- which examined the dietary habits, physical activity, and substance use of high school students -- we analyzed high risk behaviors among African American adolescents. Bivariate analysis, conducted using SPSS, found significant gender differences in dietary and alcohol consumption behaviors. Male participants reported higher levels of alcohol consumption and unhealthy dietary choices compared to their female peers. These behaviors are associated with an increased risk of colorectal cancer later in life. Our findings underscore the need for targeted public health interventions focusing on reducing high-risk behaviors in African American youth, particularly in boys. Promoting healthier lifestyles at a younger age could mitigate colorectal cancer risk in adulthood.

Abstract Name: Generation of gRNA Expression Vectors for CRISPR-Cas9-Mediated Editing of SIN3 187

SIN3 is an important, co-transcriptional repressor that regulates gene transcription. SIN3 is the scaffold protein of the SIN3/HDAC complex, that removes acetyl groups from histone proteins. SIN3 is essential for progression through the cell cycle, cell viability, and supporting energy production in cells. Previous studies conducted in *Drosophila* used RNA interference (RNAi) mechanism to knock down Sin3A to examine regulated genes. This technique, however, has a few drawbacks, mainly that the reduction in protein expression is incomplete. We aim to develop a new tool to rapidly deplete SIN3 from the nucleus and export it to the cytoplasm. We will use CRISPR-Cas9-mediated homology directed repair to add the light-inducible nuclear export system (LEXY) at the C-terminus of one of the SIN3 isoforms in *Drosophila*, SIN3 187. *Drosophila* express different versions of SIN3, called isoforms, which have some unique functions. As a part of developing this tool, I created two guide RNA (gRNA) vectors using DNA cloning. These gRNA are intended to target the C-terminus of the SIN3 187-specific exon of the Sin3A gene. First, I annealed the top and bottom gRNA strands, which were ligated into the PU6-BbsI-chiRNA vector and then carried out transformation of chemically competent DH5 α cells. Colonies were isolated from selective media agar plates. A DNA mini-prep was done to isolate the plasmids with the gRNA vectors and the successful ligation was confirmed with DNA sequence analysis. Next, these vectors will be used with the repair template donor vector to develop the LEXY system for SIN3 187 isoform. Generation of this new tool will allow us to investigate the phenotypic consequences of removal of a critical SIN3 isoform while allowing other isoforms to retain function.

Abstract Name: Hospice Care: the last stage of cradle-to-grave

The central research question explores whether physician-assisted suicide (PAS) can ethically go along with hospice care. Hospice care is a form of medical care that provides comprehensive care for terminally ill patients to spend their last stage of life. The idea of hospice care was introduced in the United States in 1963 by Dame Cicely Saunders, and the first hospice was established in Bradford with the name of “Connecticut Hospice.” Hospice care evolved into four common forms: routine care, continuous care, inpatient care, and respite care. In terms of autonomy and end-of-life decisions, four principles of medical ethics, which are autonomy, beneficence, nonmaleficence, and justice, exist. Each principle puts emphasis on improving the quality of life and giving the best care for the patients. Amid these considerations, PAS is allowed in 10 states and is controversial among hospice associations. One who agrees to the PAS with hospice care argues that it helps terminally ill patients with intolerable pain to be prepared for their death with dignity. The research applied a qualitative research approach, analyzing the case studies and getting ethical guidelines from scholarly sources and professional medical associations. However, the research is expected to conclude that PAS cannot ethically partner with hospice care due to their conflicting goals. While PAS emphasizes autonomy by letting the individuals decide their timing of death, hospice care focuses on non-maleficence and physical and mental comfort at the final moment of life. Moreover, the palliative care that hospice care adopted was built on the foundation of neither hastening nor lengthening life expectancy, which goes against the PAS that intentionally ends the life.

Abstract Name: Teaching Data Literacy for All within Informal Learning Environment

As technologies and data increasingly shape daily life, fostering critical data literacy among children is essential. Critical data literacy enables learners to analyze and contextualize data, make informed decisions, and critically evaluate the power of data-driven systems. This is particularly significant for children from low socioeconomic status households, who often face limited access to formal education in this domain. Community-led efforts, embedded in local knowledge and context, offer valuable pathways for critical data literacy education. Informal learning environments, such as community centers and summer enrichment programs, support these efforts, though they come with challenges, including diverse learner backgrounds and maintaining engagement. This research presents reflections from a four-day critical data literacy session held in summer 2024 at a community center in Pittsburgh. Led by a community facilitator with support from the research team, the program engaged 12–15-year-old students in interactive, detective-themed activities to explore the data cycle: question, collect, analyze, interpret, and report. Observations highlighted the facilitator’s adaptability to fluctuating student attendance and varying skill levels, creating an inclusive learning environment. Contextual discussions, such as those about hacking and digital footprints, sustained engagement but occasionally overshadowed core data literacy practices. Activities like applying the CRAAP method to evaluate online information and analyzing timestamps enhanced students’ critical thinking and engagement with data. Findings underscore the importance of balancing contextually engaging content with foundational data literacy skills to ensure transferable learning outcomes. This work contributes to the growing field of informal critical data literacy education and offers insights for designing community-led programs that effectively support underserved populations. By leveraging community knowledge and

emphasizing adaptability, these initiatives can provide meaningful opportunities for students to develop as responsible digital citizens.

Abstract Name: Using Large-language Models for Performing Trial-and-Error Experiments for Autonomous Scientific Laboratories

A survey conducted by Nature revealed that about 70% of biological experiments are not reproducible. Autonomous scientific laboratories envision robots conducting cutting-edge experiments autonomously, reducing uncertainties introduced by humans and thus improving reproducibility. Argonne National Lab's Workflow Execution Interface (WEI) library facilitates the integration of multiple devices and sensors for complex scientific workflows required for autonomous labs. However, existing experiments rely on expensive robots and sensors for performing these experiments and are out of reach for most students and researchers. To improve the accessibility of these potentially revolutionary ideas, we design an experiment that utilize low- cost equipment, including Arduino robots and web cameras, in addition to large language models (LLMs) and object detection, to perform autonomous experiments. Specifically, we perform a pick-and-drop experiment using the Arduino Braccio robot and a web camera and control it using a locally fine-tuned Llama-3.1 LLM and YOLO-v3 object detection network. The positions of the pickup object and the drop position are obtained from the camera by using YOLO-v3. The variability in the output generated by the object detection network, coupled with low-cost robots that are not precise and have unwanted errors due to loose tolerance during manufacturing, makes the simple task of picking an object and putting it in another location challenging and error-prone. An interactive web application accesses our fine-tuned Llama-3.1 LLM and can be used to restart or adjust and potentially correct any error occurring during the experimentation. Overall, low-cost robots, cameras, YOLO-v3 object detection network, and Llama-3.1 LLM provide an accessible but varied learning experience for autonomous scientific laboratories for students and researchers.

Abstract Name: Bridging Clinical Expertise and Community Advocacy: Integrating Registered Dietitians and Promotores de Salud in Latinx Diabetes Education

Title: Bridging Clinical Expertise and Community Advocacy: Integrating Registered Dietitians and Promotores de Salud in Latinx Diabetes Education **Background:** Type 2 diabetes disproportionately affects the Latinx population in the United States, with a prevalence of 11.5% among Latinos, significantly higher than the 7.2% seen in non-Hispanic Whites. Given the growing importance of cultural competency in healthcare delivery, calls have been made for an integrated model employing both registered dietitian nutritionists (RDN) and promotores de salud (health advocates in Latinx communities). However, there is a lack of research focusing on the specific training needs of RDNs and promotores in the context of Latinx diabetes self-management. **Objective:** This study aims to explore what both RDNs and promotores know about each other's roles within the context of type 2 diabetes management among Latinx communities as well as potential barriers and facilitators for effective collaboration. **Methods:** This study employs data from an online survey (n=95) made up of RDNs (n=60) and promotores (n=35) to explore perspectives on the feasibility, perceived effectiveness, and practical challenges of integrating promotores into RDN-led diabetes education efforts. **Results:** This study will identify key factors affecting the successful integration of RDNs and promotores in delivering diabetes self-management education, along with the perceived efficacy of this model in enhancing diabetes outcomes. **Conclusion:** Findings may have the potential to provide insights for a scalable framework for addressing diet-related health disparities and improve diabetes self-management outcomes by integrating promotores into healthcare teams, thus extending the reach of RDNs to underserved Latinx communities.

Abstract Name: Impact of continuous, low-dose-rate neutron irradiation during gestation on fetal development

Background: It is unknown how space radiation impacts the maternal fetal system, specifically fetal skeletal development. We hypothesized that continuous, low-dose-rate neutron radiation exposure during gestation would lead to abnormalities in fetal skeletal development observed as alterations in external morphology. **Methods:** Female, C57Bl/6J mice (n=38; 8-12-week-old) were pair mated. Dams where mating was confirmed (plug positive) were randomized to irradiated or non-irradiated groups (~n=20/subgroup) and group housed (n=4/cage). Exposure to near-continuous, whole-body neutron radiation (1mGy/d) at the Colorado State University Neutron Radiation Facility began at gestation day 0.5. Non-irradiated animals were housed in a separate vivarium. All animals had ad libitum access to food and water. At 12.5 days of gestation, the dams were euthanized and whole fetal samples were collected. Samples were stored in 95% ethanol at +4C until analysis. Each fetus was examined under the dissecting scope for external malformations and morphometric measurements were taken using digital calipers. Nested-T Tests were used to compare measurements of irradiated and non-irradiated animals. **Results:** Litter sizes were not different between irradiated and non-irradiated groups (p=0.292). Irradiated animals had a shorter tail length (p=0.0075) and a longer left limb bud than right limb bud (forelimb asymmetry) (p=0.0075). Crown rump length, head width, head length, abdominal width, abdominal depth, width at the base of tail, left and right forelimb and hindlimb lengths, paw widths, and paw width symmetry were not statistically significant (p > 0.292). **Discussion:** By 12.5 days gestation, it is apparent that neutron radiation exposure may have caused some alterations in skeletal development. Further analysis of the samples using histology or micro-CT will assist in determining the extent to which external morphological changes are caused by skeletal deformations.

Abstract Name: Barriers to Sexual Assault Care in Rural Communities: A Scoping Literature Review

Purpose: Rural communities often rank lower than their urban counterparts on common public health indicators due to environment related barriers to healthcare. Sexual assault care is a specialty that is often missing from care in rural areas and a scoping review of existing literature is required to discover the specific barriers to sexual assault care access. **Methods:** I used the Pubmed database to conduct my literature review. The first search used key terms “Sexual Assault,” “Rural,” and “United States,” yielding 3 relevant results. The second search used “Barriers to care,” “Sexual Health,” and “Rural communities,” yielding 4 relevant articles. The third search was “Barriers to care,” “Sexual Assault,” and “Rural Communities,” resulting in 1 relevant result. Eligibility was determined by the involvement of adults (18+), published within 5 years, within the United States, and relevance to sexual assault care. A total of 8 articles were included. **Results:** Through evaluation of the articles, it is clear that rural communities have significant disparities in introducing and maintaining sexual assault care as well as community needs for such programs. Three of the 8 articles included the cost SANE licensure and lack of educational opportunities as barriers for healthcare professionals, and 3 of the 8 studies found geographic location, cultural ideologies, and mistrust to be barriers for patients seeking care. **Conclusion:** Due to the specific barriers that rural communities face when accessing sexual assault care, unique solutions are required. Before implementing programs, more research is needed to identify the driving forces behind why rural residents may not seek care and validate current research on why rural communities have a lack of SANE programs. Encouraging education and mentorship programs for nurses and outreach programs have shown to be a beneficial first step. Additionally telehealth programs present a promising solution, but require more data on effectiveness.

Abstract Name: Let's Make Online Learning More Effective

As educational institutions and workplaces adopt online learning platforms it is important to know what kinds of learning support online students may need. The purpose of this study is to identify the aspects of online learning that help students achieve the student learning outcomes for the course and to gain information about what can improve students' experience in online courses. Students enrolled in online courses completed a survey about their personal experiences with online learning. The survey included measures of online learning self-efficacy, learner-content interaction, learner-instructor interaction, learner-learner interaction, student satisfaction, and perceived learning (Alqurashi, 2019). Students were also asked about aspects of their online courses (Busch et al., 2022), their satisfaction with their online learning experiences, their need for accommodations, and what can improve their experience. Consistent with other research, we hypothesized that students will report difficulties communicating with the instructor, getting help when needed, and having

their accommodations met. Results provide suggestions for faculty who teach online courses to help students achieve the student learning outcomes and meet their learning needs. This research adds to our knowledge of effective online learning.

Abstract Name: Investigating Themes of Isolation and Despair in Edward Hopper's Ground Swell

The artist Edward Hopper's works deal with themes of isolation and loneliness during the early 20th century. Hopper has come to be best known for his rather austere depictions of urban life in the early twentieth century, which is often the sort of depictions that art historians investigate in relation to his work. The work of art Ground Swell, located in the National Gallery of Art in Washington, D.C., dates to 1939, and was produced during the modern period in the Realist style. Ground Swell deviates marginally from Hopper's other works with its more lighthearted subject of individuals on a boat during a warm day but it also hints at the impending turmoil of the period. The social dynamics of the 20th century led to a sense of imminent danger being a focus in this piece, primarily the lead up to WWII, with a sense of foreboding and distress. Ground Swell fits into the artist's greater body of work as a representation of both Hopper's past and his present, speaking to the anxiety of both the interwar period and the initial outbreak of WWII in his iconic style. While Ground Swell has been given less attention, aside from brief mentions of its place within Hopper's body of work, it merits deeper consideration for its connection to his larger themes.

Abstract Name: As American as Mickey Mouse? Reconsidering Euro Disneyland as a Means of American Cultural Imperialism

Americanization, or the spread of American culture and customs abroad, has been a topic of interest in many regards, especially when applied to the European context. The proliferation of American corporations, media, and consumer goods on the European continent has been studied, including the addition of American culture to the European built environment - through the construction of Euro Disneyland. Euro Disneyland (now known as Disneyland Paris) opened in 1992. As a physical representation of an American corporation and its American values, the French had a particular disdain for the park upon its opening. Such a representation of the process known as Americanization has garnered research from numerous academic circles, yet current research does not address the evolution of Americanization in France, namely through the lens of the Walt Disney Company. Looking into the evolution of sentiments provides an interpretation of French attitudes towards the United States, especially during the Cold War period. Historians have previously drawn conclusions relating to the idea of Euro Disneyland as the ultimate vector of Americanization (arguing that the overwhelming association with America was responsible for the park's initial lack of success), whereas this paper will argue that Euro Disneyland was not as wholly American upon opening as it may have seemed. Investigating the historical context of Euro Disneyland; interpreting the period in which it opened and was

designed; the climate of the Disney company in years prior; and the thought processes which were integral to the construction of the park as provided through primary source analysis and secondary rhetoric. This paper examines how Euro Disneyland has been argued as the most American enterprise Europe has ever seen and instead argues how it exists in a space beyond solely Americanization, instead speaking to corporatization and the globalization of popular culture.

Abstract Name: In Silico Analysis of the Flagella-Propelled Cell Swimming in Viscous Fluids

Flagella are whiplike subcellular organelles that bend actively to propel cells (algae, sperms etc.) or move fluids in airways or other passages. Flagellar motility is central to many biological and ecological phenomena, from cellular motility to enhanced biomixing and transport. These processes involve complex interactions between flagellar biomechanics and fluid dynamics. This project aims to create a computational fluid dynamics model of a green algae cell with two beating flagella moving through a viscous fluid. We utilize the AMReX- based fluctuating hydrodynamics solver, which features custom algorithms to simulate the flagella as an immersed chain of discretized force particles with specified motions. A key aspect of our approach involves leveraging Berkeley Lab's supercomputer, Perlmutter, by employing both CPU and GPU-compatible codes to enhance simulation performance. We have also improved the previously developed JupyterLab notebook with pyAMReX, a native Python API for AMReX codes, to streamline data importation, visualization, and analysis. The simulation, executed on Perlmutter, has allowed us to visualize and analyze fluid flow fields and forces on the beating flagella and the moving cell body. The results will improve our understanding on the hydrodynamic impacts of flagella-actuated cell swimming and biomixing, and provide a biophysical and mechanistic basis for development of novel microfluidic and biofuel devices that exploit these effects.

Abstract Name: UV-vis spectrophotometry for kinetic study of the Dushman reaction

The Dushman reaction describes the interaction between iodide and iodate ions in acidic solution: $5\text{I}^- + \text{IO}_3^- + 6\text{H}^+ \rightarrow 3\text{I}_2 + 3\text{H}_2\text{O}$. Under normal conditions, this reaction is in the fifth order overall, with a second-order rate law with respect to iodide (I^-). However, at micromolar I^- concentrations (approximately $5 \times 10^{-7} \text{ M}$), the reaction follows a different mechanism and becomes first order with respect to I^- . The aim of this study is

to use the UV-vis spectrophotometric method to measure the rate of the reaction at micromolar I⁻ concentrations, and to use that rate to measure the concentration at which the rate law of the reaction changes. Seven concentrations of I⁻ will be tested in triplicate: for each trial, aqueous KI, KIO₃, and HClO₄ will be combined in a cuvette, and the reaction will be allowed to run to completion inside a UV-vis spectrophotometer. The initial absorbance and the absorbance at 30 seconds will be used to determine the reaction rate, and a data set comparing the rate to the initial concentration of KI will be collected. Graphing the natural logarithm of the rate versus the natural logarithm of the initial KI concentration will reveal the order of the reaction with respect to KI: the slope of the linear graph will equal the order of the reaction, and the point on the graph at which the slope changes will represent the I⁻ concentration of interest (expected to be near 5×10^{-7} M). This research will serve to lend credibility to the spectrophotometric method of testing the rate of the Dushman reaction as it is used in chemical engineering (micromixing) applications, as well as providing data on which to base the usage of UV-vis spectrophotometry for other kinetic studies in a classroom or student lab setting.

Abstract Name: Optimizing Performances: Essential Physical Quantities for Track Runners from the Starting Line

This study explores the forces impacting track athlete's performance through an analysis of displacement, velocity, kinetic energy, and force. Using a timer, the track, and athlete data, the experiment focused on a runner weighing 150 pounds and standing at 5 feet 11 inches tall. Results indicate a displacement of 0.124 meters, a final velocity of 0.53 m/s, and an average velocity of 0.26 m/s. Kinetic energy was calculated at 9.02 joules, while the force exerted by the athlete measured 153.9 Newtons. These findings underscore the importance of understanding fundamental physics principles in athletic performance. Future research could explore additional variables to deepen insights into athletic dynamics, potentially informing training regimens and equipment designs to optimize athlete performance.

Abstract Name: Understanding the Degradation, Toxicity, and Environmental Impact of Macroplastics in Streams

Riverine systems have shown to be major contributors of macroplastics (>4mm in diameter) to the global ocean. Yet, few studies have evaluated the degradation and potential ecosystem impacts of macroplastics within these freshwater environments. Recent studies have suggested that biofilms which grow on the surface

of macroplastics bioaccumulate metals over time. In the mid-Atlantic region of the United States, the cumulative application of road salt has led to increased concentrations of metals in stream water via reverse cation exchange in soils. Therefore, biofilms could theoretically bioaccumulate higher concentrations of metals in streams with higher salinity, if controlling for geology and land cover. In this study, we deployed replicates of 4 common debris types (Non-Biosourced Dixie™ plastic forks (used at Villanova University); DASANI® polyethylene terephthalate (PET) plastic water bottles; Coca Cola™ aluminum cans; and Hefty® polyethylene plastic bags), suspended in three southeastern Pennsylvania streams for a total of 60 days. All three streams had the same underlying geology, yet varying salinity. Upon collection, biofilm metabolism was determined through the light/dark method; assessing gross primary production and community respiration to calculate the net primary production. Total metal concentrations on the surface of the debris were determined using x-ray fluorescence spectrometry. Select metal concentrations (Al, Ba, Cd, Cr, Cu, Pb, Sb, and Zn) were compared to the respective non-deployed material to determine the relative state of weathering. In addition, the bioavailability of metals was determined using an acetic acid extraction and inductively coupled plasma mass spectrometry. The study results provide valuable insights into the degradation and potential ecosystem impacts of macroplastics in riverine systems.

Abstract Name: Catalytic SABRE H Hyperpolarization of Pyridine in Aqueous Media by [Ir(Cl)(ITEG)(COD)]

Signal Amplification By Reversible Exchange (SABRE) is an emerging method to increase Nuclear Magnetic Resonance (NMR) signal by hyperpolarization of target substrates using an organometallic catalyst and parahydrogen. SABRE is also a promising technique for enhancing MRI sensitivity in vivo; however, the standard catalyst used, [Ir(Cl)(IMes)(COD)], is insoluble in water, and few potential catalysts have shown the ability to hyperpolarize substrates in a solely aqueous media. Here, we report the synthesis of a novel water-soluble iridium-based catalyst, [Ir(Cl)(ITEG)(COD)], which showcases the ability to hyperpolarize pyridine in both deuterated methanol and deuterium oxide. ¹H-NMR signal enhancement of pyridine was observed up to 83.5-fold higher than the thermal NMR signal in methanol-d₄ using a 60.0 MHz NMR spectrometer. Similarly, enhancement in D₂O was observed up to 1.6-fold. While research continues to work to improve [Ir(Cl)(ITEG)(COD)]'s efficiency in aqueous media, the ability to successfully hyperpolarize pyridine in both methanol and water provides a valuable step towards applications of SABRE hyperpolarization in vivo.

Abstract Name: Special Education in Appalachian Kentucky: Teacher Shortages and Health Factors Driving Rising Demand

The rising percentage of students with Individualized Education Plans (IEPs) in the United States reflects not only improvements in diagnostic tools but also broader systemic issues. In the "Disability Belt," a region spanning Appalachia, the mid-South, and the Mississippi Delta, socioeconomic challenges such as poverty, inadequate healthcare access, and limited educational resources contribute to disproportionately high disability rates. In Kentucky, Appalachian counties experience some of the most severe disparities in the state, with elevated poverty rates, lower educational attainment, and significant health challenges. Factors like smoking, low birth weights, and insufficient prenatal care often result in developmental issues that increase the demand for special education services. This rising demand coincides with a critical shortage of special education teachers, particularly in high-need areas like Letcher and Harlan county. These shortages directly impact schools' ability to comply with the Individuals with Disabilities Education Act (IDEA), which mandates appropriate educational services for students with disabilities. When schools lack the necessary staff, they struggle to provide the individualized instruction and support that students with IEPs require. To address these challenges, targeted policy interventions are essential. Expanding community programs such as KY-SPIN (Special Parent Involvement Network) can enhance family support systems, while initiatives like KY-Moms MATR (Maternal Assistance Towards Recovery) aim to improve maternal and child health. Additionally, increasing teacher salaries and offering retention incentives for special education staff could alleviate staffing shortages, ensuring that schools can meet IDEA requirements. These policy proposals are evaluated based on cost, feasibility, and long-term impact, with a focus on breaking cycles of disability and improving educational equity. By addressing both immediate needs and root causes, these initiatives aim to create sustainable improvements in special education services and overall community well-being in Appalachian Kentucky.

Abstract Name: The Influence of High-Fat Diet on Alcohol Preference in Male and Female Rats

Obesity's prevalence necessitates understanding and refining treatment. Surgical procedures such as Roux-en-Y gastric bypass (RYGB) are effective but, after surgery, people are more likely to develop alcohol use disorders; these behaviors can be modeled in rodents. However, research from our lab found that, while RYGB in "cafeteria" diet-fed female rats decreased body weight and rebalanced blood sugar homeostasis, it did not impact ethanol preference relative to sham surgery in similarly-fed rats. Chow-fed unoperated rats showed higher ethanol preference than either cafeteria-diet fed group. Here, we measure how diet impacts preference for low ethanol concentrations in male and female rats fed either a commercial high-fat diet (HFD) or standard chow (CHOW). HFD rats underwent sham surgery while CHOW rats remained unoperated. Ethanol preference testing consisted of 24 h free access to first 2% ethanol solution and water; after intake stabilization, ethanol concentrations will be increased to 4%, then 6% and 8%. We plan to assess group and sex differences across preference scores (intake of ethanol / total fluid intake) via 2-way repeated measures ANOVA. We hypothesize that, independent of sex, CHOW rats will prefer ethanol more than HFD rats, suggesting that higher body weight or a varied diet may be protective against alcohol consumption. We hope to assess the impact of RYGB-induced weight loss on alcohol preference in a later experiment.

Abstract Name: Agonistic behavior in plains zebra (*Equus quagga*) relative to distance to safari jeep, Ngorongoro Crater and Serengeti National Park, TZ.

Plains zebras (*Equus quagga*) are one of the many ungulates located in the Ngorongoro Crater and Serengeti National Park, Tanzania. They are a common prey among predators in these areas and they have multiple antipredator behaviors to increase probability of survival. We were interested in these antipredator behaviors (APB) – would we see a higher frequency when zebras were adjacent to the safari jeep. Are zebras viewing vehicles as a potential threat. We hypothesized that zebra proximity to jeeps would influence zebra antipredator behavior rates. Based on this hypothesis, we predicted that APB rates would increase the closer the animals were to the jeeps. Data was collected in the forementioned areas on May 28th to June 1st, 2024. APB data was collected relative to distance from jeep. Distances were determined using a rangefinder and categories were <25m, 25m-50m, 50m-75m, and 75m-100m. Antipredator behaviors observed (via binoculars) were herding, biting, kicking, ears pinned, and teeth barred. We observed a total of 512 individuals in 23 groups. Our results indicated that zebras closest to the jeep showed significantly more APB as compared to the other distance categories ($\chi^2 = 141.66$, $df = 3$, $p < 0.0001$). Our results supported our hypothesis. This research was important in understanding the way zebras may react to potential threats and greater vigilance should increase overall survival rates. This would help us understand how certain interactions and behaviors may increase their fitness and what we can do to further protect their role in the ecosystem.

Abstract Name: Effects of the Oral Microbiome on Generalized Anxiety Disorder

Generalized Anxiety Disorder (GAD) affects nearly one-third of adolescents and 31% of adults in the United States, and is accompanied by symptoms that severely impact daily functioning, such as irritability, difficulty concentrating, and physical manifestations like heart palpitations. Despite its prevalence, GAD's underlying causes remain poorly understood. Previous studies have explored the role of genetic predispositions and the role of the gut microbiome in anxiety regulation. These have shown that an individual's genotype may influence susceptibility, and that microorganisms in the gut interact with the brain and nervous system through the gut-brain axis. Links between the oral microbiome and anxiety, however, have received less research attention and may offer new insights into anxiety disorders. This study investigates the potential connection between GAD and the microbial composition of the oral microbiome, a topic that could have important implications for understanding mental health. To collect data for this IRB-approved study, a group of college age students from PennWest California were recruited and asked to complete the GAD-7 questionnaire, a validated tool to assess anxiety levels, as well as provide buccal swab samples. DNA will be extracted from each sample and quantified. Illumina MiSeq metabarcoding will then be performed to identify the microbial species present. Statistical analyses will be used to compare microbial profiles with self-reported anxiety levels from the GAD-7 questionnaire to identify potential correlations between the presence or abundance of specific microbial strains (e.g., *Treponema*, *Actinomyces*, *Fusobacterium*). We aim to reveal distinct microbial patterns associated with varying anxiety levels, which would implicate the oral microbiome as a potential contributor to GAD. This research seeks to enhance our understanding of GAD's biological

basis, offering a foundation for novel diagnostic and therapeutic strategies, which could pave the way for innovative approaches to managing anxiety by addressing microbial imbalances.

Abstract Name: Exploring the Synergistic Effects of Cisplatin and Curcumin in Osteosarcoma Cells

Osteosarcoma (OS) is a highly aggressive bone cancer characterized by rapid metastasis, which drastically reduces patient survival rates from 70% in localized cases to 30% upon metastasis. Current treatments combining chemotherapy with cisplatin and surgical intervention are often ineffective against metastatic OS and are associated with significant side effects. Cisplatin targets cancer cells by binding to DNA, disrupting transcription and replication, and inducing apoptosis. To address the challenges associated with current treatments, this study investigates the potential of combining cisplatin with curcumin, the bioactive compound derived from turmeric, as a novel therapeutic approach. Curcumin has shown anticancer properties through the induction of oxidative stress, mitochondrial damage, and increased reactive oxygen species, leading to cell death. We treated OS cells with cisplatin and curcumin, both individually and in combination, to assess their effects on cell proliferation, migration, and apoptosis. Our results demonstrate that the combination therapy significantly decreases cell viability compared to either agent alone while potentially mitigating the adverse effects associated with traditional chemotherapy. These findings suggest that the synergistic effects of cisplatin and curcumin offer a promising new therapeutic strategy for improving outcomes in patients with OS.

Abstract Name: Mapping the Binding Site of a Novel Paroxetine Analog on the Serotonin Transporter with Crosslinking and Mass Spectrometry

Serotonin transporter (SERT) dysfunction is implicated in psychiatric diseases such as depression and anxiety. SERT is an integral membrane protein in neurons that reuptakes serotonin into the presynaptic neuron. Selective Serotonin Reuptake Inhibitors (SSRIs), such as paroxetine, target and inhibit SERT, thereby increasing the concentration of serotonin in the synapse. SSRIs reduce levels of anxiety and are the most prescribed antidepressant in a clinical setting. For this work, we aimed to map the SERT-ligand binding site of a photoreactive analog of paroxetine to determine if the paroxetine ligand binds analogous to paroxetine on SERT. Paroxetine was derivatized with a photoreactive diazirine and a click chemistry terminal alkyne to

develop a SERT-selective clickable photoprobe. This novel ligand was subsequently incubated with purified rat SERT reconstituted into lipid vesicles. After photoactivation, mass spectrometry (MS) was utilized to identify sites of covalent crosslinking to this paroxetine ligand. Following in-gel proteolysis, analyses of bottom-up MS data identified mass-shifted peptides derivatized by the paroxetine analog. These peptides were then selected for further fragmentation (MS/MS). Our MS studies reproducibly showed that the analog specifically binds in the known paroxetine binding site within SERT. The crosslinking sites of the paroxetine ligand to SERT were refined within the peptide using MS/MS, further confirming our results. Therefore, this paroxetine analog can be utilized in subsequent physiological studies to exploit the utility of this SERT-selective probe. Future studies will include click chemistry applications, including attaching affinity ligands for the purification of paroxetine protein targets and fluorescent tags to visualize SERT. Overall, the goal of our research is to understand SSRI interactions within SERT better in working towards creating more novel and effective antidepressants.

Abstract Name: Dancing Off Center: How George Balanchine's Agon Paved the Way for Contemporary Ballet Choreographers

After being hired as a dancer and then ballet master at Ballet Russe by Sergei Diaghilev, George Balanchine is known for pioneering the dance technique of contemporary ballet. From his unique elongated movement aesthetic to his work, *Agon*, that kickstarted the contemporizing of ballet, Balanchine redefined this form by making dance and movement the emphasis of the performance, rather than depending on an elaborate plot or storyline. Contemporary ballet is separate from contemporary dance, for it remains deeply rooted in the ballet aesthetic, while contemporary dance is not. How has Balanchine's work in contemporary ballet inspired the work of future ballet choreographers? Are there similarities between Balanchine's work and current contemporary ballet artists such as William Forsyth and Wayne McGregor? I was interested in analyzing the development of movement aesthetics and trends throughout the brief history of this form. Through comparative viewing of videos of contemporary ballet works, one can notice trends and steps that have withstood the test of time, and what areas of the technique and movement have evolved. It is important to see the trajectory of choreographic trends stemming from Balanchine, and to see how the definition of contemporary ballet has changed drastically as time has progressed. With contemporary dance holding upmost popularity today, one can notice traditional ballet steps appearing in contemporary ballet works less and less, while the work still maintains its ballet validity through its aesthetics. In the spring of 2025, this research will be used as a foundation to create a twenty-minute work on ten or more dance students at Slippery Rock University and will be rooted in the contemporary ballet aesthetic. I envision the movement of the piece contemporizing as time progresses to represent the technique's modernization from the time of Balanchine to today.

Abstract Name: Affect, Empathy and Feminine Writing: An Comparative Reading of Kim Jiyoung, Born in 1982 and Convenience Store Woman

This essay offers a comparative analysis of affect, empathy and feminine writing as exemplified in two women authors' texts: Kim Jiyoung, Born in 1982 (2016) by Cho Nam-ju and Convenience Store Woman (2016) by Sayaka Murata. Cho Nam-ju's Kim Jiyoung, Born 1982 draws on affect to evoke empathy, highlight the emotional toll of patriarchal structures, and illustrate how cumulative emotional experiences shape identity and mental health. Through the protagonist's experiences, affect is shown through different stages of her life, demonstrating how societal pressures and discrimination erode her emotional well-being. Jiyoung's feelings of injustice and powerlessness as she witnesses everyday sexism result in the accumulation of small, daily emotional injuries, which build a sense of exhaustion and resignation. In Convenience Store Woman, Keiko ties her identity to the convenience store which provides Keiko with stability, purpose, and belonging. The store's hum of activity and routine mirrors her internal emotional rhythm. However, the societal expectations placed on Keiko create an atmosphere of tension and frustration and interrupts the calming affect of the precise sanctuary Keiko's convenient store provides. This emotional weight affects both Keiko and the reader, who feels her growing alienation. Both Kim Jiyoung, Born 1982 and Convenience Store Woman use affect as a powerful tool to explore the societal pressures placed on women. While Kim Jiyoung, Born 1982 elicits empathy through its emotionally charged narrative and portrayal of systemic injustices, Convenience Store Woman challenges traditional notions of empathy by presenting a protagonist who finds fulfillment outside societal expectations.

Abstract Name: Philadelphia Roadside and Subway Black Carbon Assessment

High levels of particulate matter (PM) in subway systems can pose health risks to commuters and workers. Subway systems, particularly those in urban areas, are especially vulnerable to elevated PM levels. This is due to inadequate ventilation and the friction created by the train's metal wheels breaking on the tracks, generating additional PM. This study focuses on measuring black carbon (BC) concentrations in an underground subway station during the summer of 2024 and comparing them to levels aboveground in Philadelphia and in a suburban location. Black carbon, essentially a form of soot, comes from the incomplete combustion of fossil fuels from vehicles, posing serious threats to human health and the environment through warming and contamination. The findings revealed that the highest BC concentrations were recorded in the subway environment, followed by the roadside location in Philadelphia, with the lowest concentrations observed at the suburban site. This study helps indicate that while trains do not emit BC inside the subway systems, external factors, such as outdoor traffic can also influence the underground BC levels. The findings underscore the need for improved ventilation and pollution control measures in subway systems to protect public health, given the high BC level observed in subway systems.

Abstract Name: The Role of Apoptosis and Mitochondrial Dysfunction in Hair Cell Loss in Zebrafish Cilia Mutants

Hair cells are the sensory cells of the auditory and vestibular systems and consist of densely-packed stereocilia and a single primary cilium, or kinocilium. Mutations in cilia intraflagellar transport (IFT) genes *ift88* and *dync2h1* result in the loss of the kinocilium. Mutations in *ift88* and *dync2h1* have also been found to cause decreased numbers of hair cells along the zebrafish lateral line, with some cells undergoing apoptosis, a form of cell death. Previous research has established a link between defective ciliogenesis in IFT mutants and increased susceptibility to mitochondrial-induced apoptosis in other cell types. However, the extent to which apoptosis accounts for the observed cell loss in zebrafish hair cells and the role of mitochondria in hair cell apoptosis has yet to be established. One main aim of this study is to assess the protective effects of apoptosis inhibition by comparing *ift88* and *dync2h1* mutant hair cell populations with wild-type fish following treatment with an apoptosis inhibitor. The second aim of this study is to evaluate if mitochondrial dysfunction in IFT mutant hair cells occurs independently of cell death. To achieve this aim, I will examine *ift88* and *dync2h1* hair cell mitochondria for network fragmentation, a marker of dysfunction associated with apoptosis, in early hair cell development before cell death. Next, to establish if mitochondrial dysfunction is a cause or consequence of apoptotic hair cell death, I will assess whether apoptosis inhibition attenuates mitochondrial network fragmentation. These findings would demonstrate that the observed hair cell loss in *ift88* and *dync2h1* zebrafish IFT mutants is primarily caused by mitochondria-induced apoptotic cell death. This study will provide insight into the mechanisms of cell death in hair cells lacking a primary cilium, further demonstrating the vital role of the primary cilium in sensory hair cell survival.

Abstract Name: The Blood Brain Barrier: The Role of NOTCH3

The Blood Brain Barrier (BBB) acts as a semi permeable layer around the blood vessels within the brain that regulates movement of molecules between the blood and the brain. Vascular smooth muscle cells and pericyte-like cells, also collectively called mural cells, regulate development of the BBB. The differentiation process of pericyte-like cells derived from NCSC is not well understood. Compared to in vivo samples, in vitro models of human brain mural cells show reduced expression in important mural cell genes, including NOTCH3. In this study, we explore if NOTCH3 signaling in hPSC derived neural crest stem cells (NCSC) can direct differentiation of brain mural pericyte-like cells. There are multiple methods to do this differentiation. Many use serum supplemented media, thus it can be said they are undefined methods. hPSC derived Neural Crest treated with Lentivirus that includes Notch3 intracellular domain (N3ICD) and GFP are seen to have differentiation of cells that have brain mural cell properties. N3ICD expression can be known by expression of green fluorescent protein (GFP) that is also in the Lentivirus. Our next steps include generating a dox-inducible line to have the ability to control the timing of N3ICD expression and levels of expression.

Abstract Name: Investigating the Impact of Inflammatory Mediators of Eosinophilic Esophagitis on Key Regulators of Mitochondrial Biology

Eosinophilic esophagitis (EoE) is a chronic, food-allergen mediated inflammatory disease of the esophagus characterized by the transmural infiltration of eosinophils and epithelial remodeling in the form of basal cell hyperplasia. Recent genetic evidence implicates a role for mitochondria in this disease. Preliminary immunohistochemistry (IHC) data revealed increased expression of mitochondrially encoded protein MTCO1 in the esophageal epithelium of active EoE patients compared to normal controls. qPCR analysis revealed increased levels of mitochondria DNA (mtDNA)-encoded genes, MTCO1 and ND6, in response to chronic exposure (7 days) to IL-13, a central regulator of EoE inflammation, in immortalized esophageal keratinocyte cell line, EPC2-hTERT. To understand if these phenomena are occurring due to Jak/STAT signaling, broad pharmacological inhibition was achieved with Ruxolitinib (Rux). Western blotting showed increased expression of phosphorylated nuclear STAT6 and STAT3705 as well as mitochondrial STAT3S727 in IL-13 treated cells and suppressed phospho-STAT expression in Rux treated cells in the presence and absence of IL-13. Furthermore, IL-13-mediated accumulation of mitochondria was suppressed in the presence of Rux. To further elucidate how the EoE inflammatory milieu impacts key mitochondrial regulators, EPC2-hTERT cells were treated with IL-13 and IL-4 across 7 days to analyze expression levels of genes associated with mitochondrial biogenesis, fission, fusion, and degradation. RNA was collected on days 0, 1, 3, 5, and 7. qPCR data revealed an upregulation of genes involved in mitochondrial biogenesis (TFAM) and degradation (Park2), downregulation in fission (DRP1), and overall steady levels of fusion (MFN1/MFN2), and genes related to mitochondrial stress protection (Pink1). Future studies will assess the expression levels of inflammatory signaling genes, and presence of mtDNA in the cell free media during this time course. These data will allow us to understand how regulators of mitochondrial biology are influenced by EoE inflammation as well as the involvement of novel mitochondria-related inflammatory signaling pathways.

Abstract Name: Searching for Dark Matter with LDMX

Dark Matter is extremely prevalent in our universe, making up 85% of the matter in the Universe. One theory about the origin of dark matter is that it exists as a thermal relic of the early universe. The Light Dark Matter Experiment (LDMX) was proposed with the intent to create Dark Matter particles from the interaction of energetic electrons with nuclei in a fixed target. A machine learning algorithm will be very important in

helping to discriminate between dark matter signals and known Standard Model (SM) interactions. In this work we utilized two different machine learning algorithms for signal vs background discrimination in LDMX: a boosted decision tree and a deep neural network (ParticleNet). The performance of both approaches is discussed and compared for future use in LDMX.

Abstract Name: Effects of Environmental Enrichment on Enhanced Nicotine-Seeking Behavior Following Exposure to Chronic Variable Stress

Drug addiction is a major public health and serious economic concern in the United States costing taxpayers billions of dollars annually. Chronic unpredictable stress increases the response to nicotine-rewarding properties in the conditioned place preference (CPP) test (Biala et al., 2018). Contrary to the effects observed following exposure to variable stress, both running and environmental enrichment (EE) reduce CPP for cocaine (Mustroph et al., 2016). Based on the interactions observed between EE and chronic stress on learning and memory (Wright & Conrad, 2008), it is reasonable to postulate similar interactions on the rewarding properties of nicotine. Only one study (Biala et al., 2018) has assessed the effects of chronic stress on the rewarding effects of nicotine in the CPP model and none have measured the potential of EE in attenuating this effect. Therefore, this study will investigate and determine whether EE can prevent, reverse, or abolish, the enhancement in the rewarding properties of nicotine following exposure to chronic variable stress in either adolescent or adult rats.

Abstract Name: An Efficient and Data-driven Learning Algorithm to Evaluate Facial Recognition

Facial recognition technology plays a crucial role in numerous fields, from national security to social media platforms. Convolutional Neural Networks (CNNs) stand out as the most prevalent technique for facial recognition due to their impressive accuracy and adaptability in various scenarios. However, CNN-based learning faces considerable challenges, including high computational demands, a dependence on large volumes of labeled data, and significant storage requirements, which all impede its overall efficiency. We aim to implement an innovative and efficient facial recognition approach utilizing structured neural networks grounded in Discrete Cosine Transforms (DCTs), achieving accuracy comparable to conventional CNNs. The extensive and varied facial dataset used for testing guarantees robustness against diverse features, expressions, and lighting conditions. Furthermore, we will conduct a comprehensive comparison between our proposed neural network and traditional methods such as Eigenfaces, emphasizing their performance in facial

recognition applications. Experimental implementation of DCTs show reduction in computational complexity while maintaining comparable accuracy to its traditional CNN model.

Abstract Name: Determinants of Psychological Safety in Higher Education: The determinant, uncomfortable comments, includes remarks unrelated to academic growth that cause another person distress

Psychological Safety (PS)—the degree of personal inclusion, contribution, and engagement one experiences in given situations—has become a popular issue in industrial settings. However, PS has not been studied in educational settings. This research examined students' perceptions of PS in various college courses with an innovative 51-question survey. A total of 124 students provided answers for this survey, each responding with reference to a university course taken within the past year. This questionnaire assesses PS with an eight-question "Psychological Safety in Education" scale, adapted from PS scales for industrial settings. It assesses students' perceived PS by asking them to respond to statements on a "strongly agree" to "strongly disagree" Likert Scale. Average Psychological Safety Scores (APSS) varied as a function of the specific class the student evaluated and were influenced by other factors. Specifically, a significant determinant of personal inclusion was a student's connection with classmates. Students who reported that they couldn't relate to other students in the class scored significantly lower on APSS (APSS=4.41) versus those who indicated they could relate to other students (APSS= 5.42). Additionally, it seems uncomfortable comments were another determinant of PS. Preliminary analysis revealed that APSS was lower (APSS=3.84) for students who reported uncomfortable comments toward them versus students who did not report uncomfortable comments toward them (APSS=5.05). While initial findings showed APSS to vary significantly as a function of relationships with peers in the class, additional factors are being analyzed, including the gender of the student versus the gender of the instructor, as well as the source of the uncomfortable comments toward them (e.g., from the instructor or from another student). This study is ongoing as we are exploring other determinants that potentially affect PS in the classroom along with students' connection with classmates and uncomfortable comments towards them.

Abstract Name: Injury Rates Among Collegiate Dancers: Developing an Optimistic Approach for Treatment and Prevention

Dance, a fusion of artistry and athleticism, is one of the most arduous forces that is exerted on the human body. This art form is taught at a young age, and dancers consider seriously training for their professional

careers while in college, whether in a pre-professional program or obtaining an undergraduate degree in the subject. As with other athletes, dancers exhibit their fair share of injuries. “Injuries are a problem for the dancer beginning at a young age, with 43.1 percent of dancers between the ages of 10 to 18 becoming injured. Collegiate dancers have self-reported injury rates ranging from 67 percent to 77 percent each semester” (Williams et al.). Given their unfortunate, repetitive nature and unpredictability, developing a strategy for treating and preventing injuries among collegiate dancers is critical. This presentation will discuss what types of injuries are the most frequent in a university population and how it has impacted their training. It will also include background on these injuries, the gathering of information in a student-driven survey, and the benefits of a plan to facilitate appropriate care and precaution.

Abstract Name: Medicaid Expansion and Lung Cancer in the US

Lung based cancers are historically and currently the most deadly cancers with predicted deaths in 2023, according to the American Cancer Society, being above 127,000 deaths with around 238,000 new cases estimated. Factors that damage lung tissues are significant as smoking tobacco is estimated to be responsible for 80 to 90 percent of lung cancer deaths. This study is centered around finding the impact of the medicaid expansion implemented in 2014 and its impact on access to prevent lung cancer deaths in the states that accepted the expansion versus those that declined. This state level policy study gathers data from federal sources to compile risk factors of lung cancer mortality rates across the states. The primary exposure variable that is focused on in this study is the states that expanded medicaid and those that did not expand it. The data is studied in a quasi experimental difference in difference format so the medicaid expansion policy exposure variable takes the form of an interaction term from the dummy variables for expansion states and policy periods. The results show that alongside risk factors like smoking and regions, the reduction of financial risks with the medicaid expansion by select states had no significant impact on reducing lung cancer mortality rates from the pre expansion period to the post expansion period. This implies that medicaid expansion policy does not correlate to lower mortality rates suggesting that it failed in providing preventative measures to uninsured individuals. The significance of the smoking variable shows that perhaps policy should also target smoking prevention as this study provides further evidence to a correlation between smoking and cancer. The regional dummy variables shows that there may also be unequal healthcare availability in the southern states, further investigation should be taken to deliver equitable care in all regions.

Abstract Name: Antibacterial Activity of *Artemisia ludoviciana* Associated Yeasts: Potential for Novel Antibiotic Development

Beyond their role in food production, yeasts play a vital ecological role. Plant-associated species represent an understudied potential source of novel antimicrobials to combat rising antibiotic resistance. The antimicrobial

activity of plant-associated yeast and their metabolites is largely understudied. These metabolites, having evolved to be effective against diverse microbial competitors, may also be effective against human pathogens. This study aimed to investigate whether wild yeasts from white sage (*Artemisia ludoviciana*) exhibit antimicrobial activity against high-priority multi-drug resistant bacteria. We hypothesized that plant associated yeasts produce secondary metabolites with antimicrobial activity as defense mechanisms due to their vital ecological role and interactions with other microorganisms. Bioinformatic analyses were used to predict secondary metabolite gene clusters in wild and model yeast genomes. These genomes contained regions encoding compounds with potential antimicrobial activities, including terpenes, beta-lactones, and non-ribosomal peptides. Yeasts were isolated from diverse parts of *A. ludoviciana* using direct plating and enrichment methods. The antimicrobial activity of seven isolates was tested against five relatives of pathogenic bacteria using disk diffusion and direct plating assays. The direct plating assay was most successful, with six out of seven isolates displaying antimicrobial activity against all five tester strains. The average zone of inhibition for the direct plating assay was 6.99 ± 6.77 mm. One of the isolated species was identified as *Wickerhamomyces anomalus*, a yeast recently noted for its strong antimicrobial activities. These findings support the potential of wild plant-associated yeasts as a source for developing novel antimicrobials, which is crucial in the face of increasing antibiotic resistance.

Abstract Name: Let's Get Physical: How We Can Redefine Queer Sexuality through BDSM

The LGBTQIA+ community has historically been, and presently is, a community with its own social dynamics, hierarchies, and structures in place. The correlation and relationship between the queer community and kink BDSM practices especially exemplifies the existence of power dynamics amongst LGBTQIA+ people. This presentation will examine how queer individuals in a post-modern state often identify with BDSM and kink. It will also examine how it has influenced their process of re-learning sexuality after growing up in a predominantly heteronormative educational system and media culture, where there were mostly cisgender and heterosexual examples of relationships. Through a surveying of individuals and exploration of the conversations from other researchers such as Muzacz, Bowling, and Montaro navigating the correlation between gender identity, sexual orientation, and identity exploration, this presentation will examine people's viewpoints on sexual freedom and power. Additionally, I will seek IRB approval to conduct anonymous and voluntary surveying of individuals over the age of 18 of how queerness and kink impacts their identity development. Several LGBTQIA+ documentaries will also be referenced to consider how the films represent people's interaction with queerness. Any approach to redefining queer culture and sexuality must also take into account factors of gender dysphoria, discrimination, and potential lack of physical spaces for queer people to comfortably exist and build community within. This presentation will also strive to provide solutions for how queer people can reimagine the impact BDSM and kink has on queer sexuality. Additionally, I will consider how different approaches to social dynamics in queer communities could be utilized to deconstruct and reconstruct more authenticity in ideas of human sexuality. In a predominantly online world, there should be an understanding of how queer and kink identities are inherently interlaced, and this presentation will make an effort to address those intersections.

Abstract Name: The Effectiveness of Culturally Relevant Breast Cancer Education Messages Tailored for Young Black Women

Background: Black women under the age of 50 have an excessively high breast cancer mortality rate. This disparity is due in part to the higher incidence of late-stage breast cancer diagnoses in this population. Previous studies have shown that young Black women have low awareness about breast cancer and breast cancer screening. Based on the results of our previous studies, we developed a series of brief breast cancer education messages that were tailored for young Black women and were designed to be disseminated via social media platforms. The purpose of this study was to assess the effectiveness of our breast cancer education intervention on the knowledge of young Black women. Methods: Black female college students ($n = 32$) were recruited to participate in the pilot test. The participants completed a breast cancer knowledge pre-test before watching 5 brief culturally relevant videos. After watching the videos, the participants completed a posttest. A paired samples T-test was conducted to determine if there was a significant difference between the pre-test and posttest scores. Results: The majority of the participants (78.2%) were upper-level students with a mean age of 20 years ± 1.524 . The breast cancer knowledge pre-test and posttest scores ranged from 1 to 7 and 2 to 8, respectively. The mean breast cancer knowledge posttest score (3.97 ± 1.38) was statistically significantly higher than that the mean pre-test score (6.47 ± 1.37) ($p < .001$). Conclusion: Breast cancer education messages that are targeted towards young Black women are highly effective at increasing breast cancer knowledge. Given the disproportionately high incidence of late-stage breast cancer among this population, more culturally relevant interventions are needed to increase awareness and decrease breast

Abstract Name: Investigating Seasonal Shifts in the Diet and Gut Microbiome of Madagascar's Red-Fronted Lemur

The gut microbiome (GM) is a dynamic community of microorganisms in the GI tract that aids in digestion and metabolism. The GM can respond to rapidly changing environmental pressures quicker than the host genome, suggesting it evolved as an adaptive mechanism for animal hosts. Seasonal changes in food availability are common ecological stressors that animals endure. However, while host diet is known to shape GM assembly, few studies have examined how the GM is affected by dietary changes between seasons. Here, we investigate how seasons drive rapid GM shifts using a species of brown lemur endemic to southeastern Madagascar. *Eulemur rufifrons*, the red-fronted lemur, occupies a montane rainforest that experiences heavy rain and extreme heat during the wet and dry seasons, respectively. Primarily frugivorous during the wet season, *E. rufifrons* resorts to consuming fallback foods (i.e., leaves, seeds, and flowers) when fruit is scarce during the dry season. We confirmed this with 160 hours of behavioral data from 2020, showing that *E.*

rufifrons consumed fruit for 88% of their feeding time during the wet season vs 61% during the dry season. To test whether the GM fluctuates with diet and season, we generated 16S rRNA metabarcoding data from 88 fecal samples spanning both seasons. Our results suggest *E. rufifrons* experiences seasonal shifts in gut microbial diversity and composition in response to different amounts of carbohydrates and fibrous foods. GMs had significantly higher microbial taxonomic richness during the dry season. Microbial community composition had the most variation explained by season relative to sex, location, and group. We conclude that GMs cycle throughout the year to buffer nutritional differences between seasons. By contributing to host plasticity, the GM may help primates cope with unprecedented changes in feeding ecologies caused by anthropogenic habitat disturbance and climate change.

Abstract Name: Utilizing Undergraduate Research in the K-12 Classroom Fosters Confidence in Both Populations

Scientific communication is a challenging skill to practice within the classroom setting. Therefore, it is essential that faculty provide opportunities for students to engage with the public in a low stakes environment. However, it is also important to find the proper population to work alongside. Middle school students are a strong group to work with, because many students decide in middle school that they aren't cut out for science. This is particularly true for middle school girls with most deciding to pursue other fields in the sixth grade. Previous studies demonstrated that exposure to hands on science, such as science fairs and interactive labs, improve middle school students' attitudes towards careers in STEM. However, most schools are underfunded, thereby decreasing availability to hands on labs, science fairs, and scientific clubs. Therefore, bringing undergraduate students with resources may be a potential avenue for improving retention in the sciences. In this study, undergraduate research students brought raw data to a middle school in Nashville, TN. Together, the research students taught middle schoolers how to use ImageJ software to analyze live cell microscopy data and generate a figure. Survey data demonstrated that middle school students had a higher chance of pursuing science after the semester long project, and undergraduate students felt a deeper connection to their work and its overall purpose.

Abstract Name: Mindfulness and Regret: Finding Peace in the Present

A. Problem or major purpose: Research has shown that regret is linked to anxiety, depression, and cognitive distortions (Markman et al., 2009; Markham & Miller, 2006). Painful experiences stemming from past actions and decisions can lead to negative rumination (Olatunji et al., 2013). However, by reducing this rumination, there is potential to gain valuable insights from previous decisions, even those that were distressing. This study examines the potential of mindfulness to alleviate the intensity of regret. It was hypothesized that participants would report lower levels of regret after practicing mindfulness meditation. B. Procedure: The study was conducted in two phases. In the first phase, participants were asked to recall a regrettable life event and rate the intensity of their emotional responses, including feelings of regret. After focusing on this memory, all participants took part in a guided mindfulness session. Following the session, they re-evaluated the recalled memory by completing post-session self-report measures, including a short 12-item version of the Five Facet Mindfulness Questionnaire (Baer et al., 2006) and the 12-item Self-

Compassion Scale (Neff, 2019). Participants were then instructed to practice the same meditation at least twice over the next week using an audio recording provided by the researchers. One week later, in the second phase of the study, phone interviews were conducted with the participants . C. Results: Thirty students will participate the study for a partial course credit. We expect to find that participants will report experiencing significantly less amount of regret following guided meditation. D. Conclusions or Implications: We expect that present study will demonstrate the mitigating effect of mindfulness on experience of regret. Future direction and implications will be discussed.

Abstract Name: Investigating Resveratrol and its Mechanisms on Drug Resistant Breast Cancer

Breast cancer will develop in about 1 in 8 women in their lifetime, and is responsible for more than 40,000 deaths per year. Currently, drug resistance is a major reason for poor prognosis which keeps mortality rates high each year. Resveratrol, a potential treatment option, is a natural occurring antioxidant found in the skin of grapes and various plants. In previous studies, resveratrol has shown promising anticarcinogenic effects in multiple cancers such as prostate, pancreatic, colorectal and others. Therefore, this study aims to investigate resveratrol's effects on both drug-resistant and drug-sensitive breast cancer using MDA-MB-231 and MCF-7 cells respectively. Preliminary research from this study has shown resveratrol to cause cell death in both MDA-MB-231 and MCF-7 cell lines. These results were produced via CyQUANT assay which measured cell viability at various resveratrol concentrations (100µM, 150µM, and 200 µM). As resveratrol concentration increased, a decrease in cell viability was observed indicating resveratrol's promising apoptotic effects. Previous results from this study demonstrate cells are not changing their metabolic growth strategy to oxidative growth. This was shown by no significance for oxygen plate and lipid peroxidase assays at various resveratrol concentrations (100µM, 150µM, and 200 µM). In an attempt to elucidate resveratrol's mechanism of induced apoptosis, this study will investigate the PI3K/Akt and NF-κB pathways.

Abstract Name: The Recovery of the North American Turkey: A Historical Approach to Successful Privatized Conservation Efforts.

Humans have long had a complex relationship with the landscape and the animals who call it home. The advent of game management and the conservation movement in the early 20th century reframed this relationship into a more fact driven, sophisticated science rather than an abusive theft of ecosystems. In turn, these changes gave rise to specialized advocacy groups that promoted conservation as a means to manage healthy animal population levels for multiple uses including hunting, fishing, and trapping. My research examines one of these groups, the National Wild Turkey Federation (NWTf), and its efforts to conserve and

rebuild the wild turkey population in North America during the twentieth century. In doing so, it shows how their achievements apply to not only the turkey but other game species. The NWTf's model of using involved sportsmen to aid in conservation efforts set a precedent for animal relocation, habitat management, and ethical standards of harvest. These strategies and more helped create a relationship between citizens and game agencies to repopulate a robust wild turkey population to the continental United States, Hawaii, Canada, and Mexico. The NWTf is one of many groups that pieced together small contributions by individual members to yield large dividends in the restoration of habitat for wild birds, fish, and other game animals. This sportsman-led model of conservation helped to provide a template for other interested parties to develop conservation plans for other game species. The intent of this research is to show the broader implications of sportsman-led conservation efforts and their effect on the greater ecosystem and, in doing so, it offers a different way to view the history of conservation in the United States.

Abstract Name: Barrier Effects on the Escape and Pursuit of an L1 Pursuer and L2 Target

In mathematical pursuit and escape games a pursuer (agent 1) tries to catch a target (agent 2) by closing the distance between them. Both pursuer and target can move as long as their movement is unobstructed. The distance in traditional pursuit and escape games is taken as the Euclidean distance given in terms of the so-called L2-norm where the Pythagorean Theorem holds true. During this project, the effects of limiting one of these -agents to movement measured in the L1 norm and the addition of a finite, straight-line barrier, or obstacle, were investigated, both analytically and numerically. The earliest time in which the pursuer and target -can meet defines their dominance regions. It was found that even with lower speed (up to a ratio of 50%), an L2 target -can escape from an L1 pursuer if the target takes the "optimal" path within its dominance region. Escape is defined when the target's dominance region becomes unbounded, meaning that it has freedom of movement in an infinite region. To define these (what is "these" referring to?), the dominance region functions were fitted to oblique asymptotes (probably would leave this sentence out entirely because you cannot explain briefly what these functions are and why you use fitting). When introducing the barrier, there are three cases for the L1 pursuer's path: one axis of movement (AoM) blocked, both AoM blocked, and no AoM blocked. The case with single AoM and both AoM being blocked results in global change of the dominance regions, whereas the case with no AoM blocked only results in local- change. Models of pursuit and escape are used to describe and explain real-world phenomena, including predator-prey interactions, and find applications in unmanned ground vehicle (UGV) to unmanned aerial vehicle (UAV) pursuit and target-tracking algorithms.

Abstract Name: Improving the quality of education of special needs students with intentional physical environments, adaptive devices, and family support.

In this session, we will explore how to create high-quality physical environments in special needs classrooms for students in 4th through 8th grade. The focus of our presentation will center around three adaptive devices currently being utilized in special education classrooms. We will focus on adaptive devices that benefit students and explore the challenges that some of those devices pose in daily and practical use. Family support and practical techniques will be shared in the session to help improve the utilization of adaptive devices. By creating intentional physical environments that meet the needs of each student in the special education classroom, the teachers are taking the first step in improving oral quality care and education. Through administrative support in the form of budget and prompt delivery to classrooms, teachers and students can familiarize themselves with adaptive devices and utilize them daily to enhance learning. Additionally, an important factor is family engagement and involvement. The suggestion shared in this session will bridge home and school and ensure a holistic approach to supporting the teacher, the family, and every unique student.

Abstract Name: The Impact of Social Determinants of Health on Nicaraguan Immigrants in Costa Rica

During Valparaiso University's annual service learning trip to Costa Rica in March 2024, five public health clinics were conducted in the communities of La Carpio, Boca Arenal, and San Gerardo, which held a combined population of approximately 69,000 at the time, most of which were Nicaraguan immigrants. These clinics were led by students and translators, small groups of which were sent out each day to conduct home visits within these neighborhoods to gather quantitative and qualitative data, including demographic information, details about the home environment, health insurance status, reasons for immigrating to Costa Rica, and perception of health threats in the community from their members. Participants' blood pressures were also collected. A total of seventy-nine families provided us with invaluable information, which helped us answer questions surrounding the impact of social determinants of health on Nicaraguan immigrants in Costa Rica in several areas, as well as gain insight into the perception and prevalence of preventable and chronic disease in these communities. Some findings of interest from this sample of participants were that the main reason for immigrating to Costa Rica was poor economic conditions in Nicaragua, the average blood pressure was 130/78, and that the two are potentially related. We were also able to obtain an understanding of the perception of Nicaraguan immigrants towards the Costa Rican public healthcare system. It is hoped that more data can be collected on how to assist the three above mentioned communities and better their health status in the future.

Abstract Name: History By The Bottle: Prohibition-era Beverage Bottles From The Gass Saloon, Hamtramck, Michigan

During Hamtramck's heyday, the city had more saloons per capita than any city in the United States. For residents of the industrial city, places like the Gass Saloon were at the heart of daily life during the 19th and early 20th centuries, providing spaces for business, entertainment, political discussions, and community development. The Gass Saloon operated between 1890 and 1927, including as an illegal bar during Prohibition in Michigan (1917-1933). In 2022, archaeologists excavated at least 181 beverage bottles from the Gass Saloon, including many bottles dating to the Prohibition era and labeled as containers for soda and other non-alcoholic beverages. Records from the 1920s confirm that the business continues to operate illegally as an alcohol-serving saloon during Prohibition. This paper analyzes glass beverage bottles during the Prohibition era and integrates historical and archaeological data to suggest the likelihood that the containers concealed alcohol.

Abstract Name: Effect of Low Dose Caffeine Consumption on Time-Based Academic Performance

In 2018, 92% of college students who were surveyed reported consuming caffeine in the past year (Mahoney et. al., 2018). Of that sample, 31% reported using caffeine to improve concentration. The average adult living in the U.S. consumes a moderate level of caffeine at 280 mg per day (Titchenal et al., 2020). Minimal research surrounding the effects of low dose caffeine (80mg) on academic performance has been conducted. This study aims to determine whether consumption of a low dose caffeinated drink has an effect on the accuracy of a timed multiplication assessment. Students from a small residential liberal arts college will be recruited via mass email. Independent variables will include a low-dose caffeine beverage trial, a no-caffeine beverage trial and a control trial. Participants will be asked to refrain from caffeine consumption prior to all data collection trials. During each trial, participants will be given a timed multiplication test. During the beverage trials, participants were required to wait 10 minutes after consuming one of the beverages to allow caffeine to enter the bloodstream. Research is being conducted in a double-blind manner as only one member of the research group and the faculty advisor will know who is receiving caffeine and when it will be administered to the participant. A repeated measures ANOVA ($p < .05$) statistics will be used to analyze the data. We anticipate caffeine consumption will cause an increase in accuracy on the multiplication assessment due to the effect of low-dose caffeine. To better understand caffeine and its effects on academic performance, future studies should examine different levels of caffeine through a double-blind study to determine what levels of caffeine are efficient and/or harmful. Data collection is in progress.

Abstract Name: Relationship between Affordable Care Act Medicaid Expansion and Diabetes

According to CDC, among chronic conditions, Diabetes is one of the leading causes of morbidity and mortality in the US. Access to health care is most essential to stay healthy for a diabetic person. With high cost of supplies, medication, education, and medical care to manage diabetes, affordable and adequate health insurance is imperative. Before the Affordable Care Act expansion in 2014, Medicaid program primarily covered pregnant women, low-income families with children, and elderly and disabled people with Supplemental Security Income (SSI). The expansion extended coverage to most of the adults up to 138% Federal Poverty Level (FPL), and it was adopted by 27 states in 2014 and by 2021, it increased to 39 states (including DC). Past literature provided evidence that this led to a significant increase in the total Medicaid coverage and consequently a decrease in the total number of the uninsured individuals in the expansion states. This paper examines the impact of the Affordable Care Act (ACA) Medicaid Expansion on diabetes diagnoses, and its management to prevent health complications caused by diabetes. Exploiting the differential timing of adoption of Medicaid expansion by different states, we employ a staggered difference-in-difference framework to compare the diabetes outcomes in the expansion states (treatment group) with the non-expansion states (control group).

Abstract Name: Unveiling the Relation between Art and Environment: Documentaries, Social Media, and Climate Change

Climate change has emerged as a paramount global issue over the past few decades, manifesting as long-term shifts in temperatures and weather patterns due to human activities, particularly fossil fuel burning, which has elevated greenhouse gas levels in the atmosphere. This research delves into the profound impact of climate change and explores how media channels, specifically documentary films and social media, play a crucial role in raising awareness and inspiring action to mitigate the effects of this pressing phenomenon. Despite extensive scientific discourse on climate change mitigation strategies, public comprehension of the issue remains limited. This gap underscores the necessity of leveraging media channels to demonstrate the gravity of climate change and mobilize societal engagement. Documentary films, characterized by their capacity to combine imagery, narrative, and music, have proven effective in emotionally engaging audiences and providing insightful information. Social media, on the other hand, has become a pivotal platform for disseminating information and fostering public discourse on climate-related issues. The research examines secondary data from 12 sources, analyzing documentaries like *An Inconvenient Truth* (2006) and *Climate Refugees* (2010) to identify storytelling techniques that enhance audience comprehension and motivation. Social media's role in spreading awareness, such as through viral moments like the 2019 Australian bushfires, is also explored. While the American film industry has significantly addressed climate communication, the Egyptian industry has yet to fully engage with this topic. In conclusion, findings suggest that integrating scientific information with engaging narratives in documentaries and using social media's immediacy can enhance public understanding of climate change. These channels serve as accessible platforms for education

and action, demonstrating their potential to mobilize collective efforts toward sustainability. This study highlights the intersection of media, art, and activism as a vital tool in addressing the climate crisis.

Abstract Name: Threaded Allegiances: Catherine de Medici's Valois Tapestries as Agents of Admiration and Devotion

This paper explores the role of art as diplomacy through an examination of Catherine de Medici's commissioning of the Valois Tapestries during the Renaissance. Amidst political and cultural exchange in 16th-century France, Catherine used these tapestries as agents of devotion and admiration for her children, their Valois heritage, and her own Medici lineage. My study investigates the context surrounding Catherine's patronage, her motivations, and the thematic elements embedded within the tapestries. Methodologically, this research combines contextual analysis with art historical inquiry to dissect the composition, symbolism, and stylistic influences of the Valois Tapestries. By contextualizing Catherine's commission within the broader framework of Renaissance diplomacy, this paper sheds light on the intersection of politics, art, and identity. It addresses gaps in existing scholarship by providing a nuanced understanding of Catherine's strategic use of artistic patronage to foster dynastic unity and promote her family's legitimacy. The thesis argues that the Valois Tapestries served as powerful tools for reinforcing loyalty and allegiance, while also facilitating the synthesis of Italian Renaissance and French artistic values. Ultimately, this study contributes to our understanding of the multifaceted role of art in shaping diplomatic relations and cultural identities during the Renaissance period.

Abstract Name: Microplastics in the Laurentian Great Lakes Watershed as a vector for toxicant transport and their capacity as environmental reactionary surfaces

In an economy dominated by petroleum-based plastic commodities that pose low front-end costs for production, there is growing concern and research into the scale and potential effects of plastic pollution, degradation, and environmental persistence. Plastic waste is difficult to contain absolutely with current waste infrastructure, which significantly varies by country, while plastic ubiquity continues to rise. There are myriad vectors by which plastic enters the environment, including, but not limited to; laundry effluent from washing clothes containing nylon or polyester, environmental degradation of plastic bags and bottles which often contain polypropylene or polyethylene terephthalate, or films used in shipping and packaging that often compose of low-density polyethylene. The behavior of microplastics (MPs) can often be generalized as many plastics are driven by non-polar interactions within their environments and many MPs share a resistance to degradation under natural conditions. The non-polar interactions of these MPs lead them to not only adsorb

non-polar toxicants, such as organochlorides, but also to sequester in fatty tissues of biological organisms and have even been shown in studies to complex with metals such as arsenic and exhibit phytotoxic effects. Photodegradation of plastics occurs in freshwater and marine environments by UV light along with mechanical wave action, leading to dispersal of micro- and nano-plastics (MP and NPs). The movement within these systems is dependent on individual plastic species density, which may be greater or less than water, as well as sorption of sediments, and biological accumulation in filter-feeding species. This study aims to characterize the compounds that are carried by MPs and understand the potential transport of persistent organic pollutants (POPs) within this watershed. By using standardized testing methods from current research and characterizing the compounds carried by MPs, we may be able to describe plastics as reactionary surfaces within freshwater environments and predict metabolites of interest.

Abstract Name: Students in Action: Fostering a K-12 School and University Partnership to Promote Community Engagement and Professional Development through Bi-Annual Conferences

Multiplying Good was a nonprofit organization partnering with communities to foster service engagement. Students in Action (SIA) is an initiative implemented in K-12 schools to provide students with the skills to lead service-learning projects. The dissolution of Multiplying Good due to financial difficulties resulted in the need for a charter to continue to serve as the liaison between K-12 schools across the community, such as through planning bi-annual conferences. We took on this role by fostering a connection between Purdue University and our local Greater Lafayette K-12 partner schools, serving as coaches working alongside the students and teachers, and taking over Multiplying Good's former role in planning the annual conferences. To do so, we coordinated all conference logistics, facilitated communication between attendees, and created engaging, personalized lesson plans for SIA students. The conference created a space to facilitate inter-school conversations, allowing students to deepen their understanding of their role in SIA and their community. Students and teachers viewed the conference positively, with multiple common themes emerging from narrative and observational data. The conference helped foster connections across schools through discussions and activities made possible through a collaborative environment. Additionally, our activities and lessons were beneficial for students regardless of experience in the program, ranging from those who were new to those who had participated in SIA for several years. Finally, the conference left students feeling empowered to take on service-learning projects in their respective schools, prepared with new skills that will help them further their endeavors within their respective SIA teams. We hope our work can serve as the foundation for other universities nationwide to support youth service-learning initiatives, such as the partnership created between Great Lafayette SIA teams and Purdue University.

Abstract Name: Advancing Undergraduate Research Through Systems of Shared Governance

Undergraduate research is a cornerstone of experiential education that fosters critical thinking, problem-solving skills, and professional development. At Montana State University, the Undergraduate Research Council (UGRC) has pioneered a model that leverages shared governance to enhance access, equity, and sustainability within undergraduate research programs. By engaging diverse stakeholders, the UGRC integrates the voices of undergraduates into decision-making processes that directly affect the research culture at Montana State. The UGRC serves as a formal student-led part of the shared governance framework at our university that elevates students voices to balance with other researchers. Initiatives the UGRC have tackled include standardizing the process for earning research credits, integrating peer research support, hosting an annual Research Fair, and publishing the student-run journal *Curiositas*. These efforts to create streamlined access have resulted in record-breaking participation in undergraduate research programs, increasing representation from historically marginalized groups. The UGRC's model highlights strategies for fostering collaboration across institutional silos by examining barriers to participation in undergraduate research. The Council addresses resistance to organizational change and gaps in communication through inclusive and transparent practices that promote interdisciplinary collaboration. By prioritizing student agency within governance frameworks, the UGRC aims to serve as a replicable model for other institutions seeking to advance undergraduate research on a systemic level. As higher education increasingly prioritizes equity and access, the UGRC's model offers a blueprint for embedding student voices into systemic change, ensuring the long-term sustainability of undergraduate research programs.

Abstract Name: Novel Socket Designs for Myoelectric Prostheses: Innovative Solutions for Enhanced Comfort and Fit

Rejection rates for upper limb myoelectric prostheses remain high at 35%. Among factors leading to abandonment, the comfort of the interface between the user and their device is a major point of concern. To address such concerns, this research outlines the development and improvement process of these interfaces for a customizable myoelectric prosthesis socket. This research laboratory's preliminary socket designs were

limited to diameter and length alone without consideration of irregular topologies that naturally occur with limb difference. The need for an improved approach capable of accommodating each participant's limb is evident and has now been implemented. Various photos and videos of the residual limb are taken to develop an accurate 3D model, from which a custom interface is generated. The 3D modeling process begins with Blender to create a limb model; Autodesk Fusion is then used to design the socket and its corresponding components for the final design. Features including surface electromyographic electrodes, a battery adapter, and an adjustable tension dial to accommodate fit are then added. To improve socket fit and comfort, the previously wired gel electrodes have been replaced with dry counterparts embedded into the socket for enhanced signal reading and ease of placement. The dry electrodes provide direct access to target muscles that may be inaccessible by the gel electrodes, improving the signal quality from the contracted muscle. Additional development methods are being explored for future implementation in the socket production process. For increased efficiency in designing the sockets, a 3D scanner and casting methods may offer improvements to accuracy while reconstructing the residual limb models. By integrating these findings into the user interface, this research seeks to improve comfort and lower the rejection rates of upper limb prostheses.

Abstract Name: Beaver Lodges Host Diverse Visitors in the D.C.-Baltimore Corridor

American beavers (*Castor canadensis*) are noted ecosystem engineers who transform landscapes when they fell trees and dam rivers and streams. However, relatively little research has focused on the impact of their lodges – 10 to 50-foot wide woody structures that can outlast beavers in many ponds and wetlands. Here, we characterize animal activity at seven beaver lodges in the largest green space of the D.C.-Baltimore corridor, including the Patuxent Research Refuge and Fran Uhler Natural Area. We recorded animal movements for >25 days using 13 trail cameras placed approximately 6-12 feet from beaver lodges on metal poles. In total, over 20 species used the lodges for activities such as basking (eastern painted turtles, *Chrysemys picta picta*), foraging (Great Blue Heron, *Ardea herodias*), and resting (Common Grackle, *Quiscalus quiscula*). Within species, we counted photos separated by at least 30 minutes as independent observations. We then quantified the frequency of observations and species richness in relationship to lodge location (island versus bank), time of day, temperature, and human presence. Overall, our data demonstrate commensalism between American beavers and a diverse assemblage of birds, mammals, and ectotherms. We also find evidence that animals divide their use of lodges by time and temperature, and we provide one of the first investigations of human, beaver, and beaver-predator interactions on lodges in a nationally important wildlife refuge.

Abstract Name: Macrophage-targeted nanomedicine reduces fibrosis in a mouse inflammation model by downregulating TGF-beta and other pro-fibrotic factors in a sex-dependent manner.

Fibrosis is abnormal tissue scarring seen in later stages of injuries, cancers, genetic disorders, and or following an infection. It is characterized by an increased amount of extracellular matrix (ECM) material or changes in the ECM degradation processes. Emerging research shows that macrophages and other immune cells play a key role in the development of fibrosis. We previously showed that macrophage-targeted COX-2 inhibition using theranostic nanomedicine reduces inflammation in both sexes. Connections between macrophage COX-2 and TGF-beta, one of the theorized supermolecules in fibrosis, have been shown in other studies. In this study, we aimed to investigate the impact of macrophage-specific COX-2 inhibition on fibrosis and unveil previously unknown sex differences. We induced inflammation in male and female mice by injecting CFA (Complete Freud's Adjuvant). Tissues collected on Day 21 were analyzed by immunofluorescence and immunohistochemistry, while tissues collected on Day 40 were stained with picrosirius for collagen. Images were processed with Pathfinder R for immune cell detection and with CT Fire to assess collagen characteristics. Pathway enrichment was performed using pathfindR and gene analysis was performed by Nanostring. Literature searches were performed on each significant gene to assess involvement in fibrosis. We found that treatment with macrophage-specific COX-2 inhibiting Nanoemulsions significantly downregulated TGF-beta and other theorized immune cell pro-fibrotic factors in both sexes. Both sexes also had a significant reduction in fibrotic collagen characteristics, with females showing more of a reduction compared to males. Additionally, we uncovered a possible non-canonical fibrotic pathway that is significantly upregulated in males even with treatment but is unaffected in females.

Abstract Name: "It was nice to know there was a backup plan": Investigating Student Perceptions and Final Grade Outcomes Across Multiple Non-Traditional Grading Schemes in Introductory Biology Courses

Nearly half of undergraduate students who pursue undergraduate degrees in STEM fields ultimately change their major, many after introductory gateway courses with high failure (D/F) and withdrawal (W) rates. Implementing non-traditional grading schemes has been proposed as one possible solution. Non-traditional grading schemes provide students more flexibility and opportunities to succeed, such as exam retakes or dropping lowest grades. Previous studies have found that non-traditional grading schemes lead to enhanced performance and less student anxiety compared to courses with traditional grading schemes, but little research has been done comparing non-traditional grading schemes to each other. This mixed method study begins to fill this gap by exploring how student perceptions and grade outcomes vary across three different non-traditional grading schemes in introductory biology courses at a large public university. The grading schemes in the three courses included an optional test retake (Introductory Biology I course), dropping of the lowest exam score (Introductory Biology II course), or the reduction in weight of the lowest exam score (Introduction to Genetics course). Survey data (n=114) indicate that students feel decreased anxiety and increased understanding of course content in each of the three courses. On average, students in the courses that offered an optional exam retake and dropped the lowest exam score were more likely to agree/strongly agree that their anxiety decreased and that they felt confident in their knowledge of the course material compared to the course where the weight of the lowest exam score was reduced. Semi-structured interviews with students helped explain and extend quantitative survey results. In the final stage of this ongoing study, we will determine the extent to which the different grading schemes improve final grade outcomes. These findings provide critical insight into how most effectively design introductory biology courses to maximize the benefits of non-traditional grading schemes.

Abstract Name: Demonstration of Hooke's Law: Laser diffraction imaging of helical structure

Diffraction imaging is an important topic that spans across multiple educational fields. Biologists use macromolecular crystallography – a diffraction-based technique similar to coherent diffraction imaging to obtain the structure of proteins and use phase retrieval programs to reconstruct the image [1]. In physics, diffraction imaging is used in x-ray crystallography [2]. Perhaps the most famous example of the application of these principles to a biological problem is the use of x-ray crystallography to study the structure of DNA. Since technical challenges make it impractical to study crystalline DNA in introductory physics, the helical structures can be approached by substituting an optical laser source for x-rays and a ballpoint pen spring for DNA molecules [3]. In this work, we introduce an advanced methodological strategy to demonstrate Hooke's Law by using helical structure through the benefit of a laser diffraction imaging technique.

Abstract Name: Exploration of the Molecular Controls of Secretory Mitophagy

Tumor metabolic reprogramming is a hallmark of cancer progression, survival, and therapeutic resistance. A targetable class of cancer metabolic adaptation exploits mitophagy, a specialized autophagy pathway known to be linked to the cancer phenotype. Mitophagy selectively eliminates dysfunctional mitochondria by targeting them, via autophagosome shuttling, to the lysosome for degradation. Cancer cell mitophagy is triggered by elevated oxidative stress and mitochondria DNA damage caused by hypoxia, radiotherapy, molecular therapy, and immunotherapy. A high mitophagy demand can overwhelm the lysosome capacity resulting in accumulated damaged mitochondria that is harmful to the cell. We hypothesize that the newly discovered process of secretory mitophagy exports damaged mitochondrial fission-released segments to reduce the overload pressure on the lysosomal system, and thereby sustains cancer cell survival in the face of therapeutic mitochondrial stress. We discovered a form of secretory mitophagy occurring in vivo in a growing solid tumor. Our molecular analysis of the full repertoire of extracellular vesicles (EV) shed into the resident tumor interstitial fluid (IF) in vivo yielded a rich set of information about the functional state of mitochondria within the tumor cells and host cells. Within tumor IF, and the culture media of cancer cells undergoing oxidative stress, we identified an EV-packaged full set of mitochondria molecules comprising the peripheral fission pinched-off segment of the mitochondrial organelle. It has recently been found that peripheral mitophagy fission, regulated by mitochondrial fission 1 protein (FIS1), is a key essential regulator of mitophagy, distinct from mid-zone mitochondria biogenesis. We also found that mitophagy inducer PTEN induced kinase 1 (PINK1) cleavage status is prominently reflected in the set of mitochondrial proteins exported within IF EVs. This may constitute a new quantitative measurement tool to monitor the real-time state of tumor intracellular mitophagy. Our findings raise important mechanistic questions regarding molecular controls of secretory mitophagy.

Abstract Name: Apoid Wasp Digitization Initiative: Argentine Species Checklist

Apoid wasps, a cosmopolitan group within the order Hymenoptera, encompass nearly 10,000 species across

four families, showcasing remarkable diversity in morphology, habitat, and behavior. Commonly referred to as hunting wasps, they play essential roles in ecosystems. Despite their fascinating life histories and ecological importance, apoid wasps remain understudied, with a limited number of experts researching them and scarce digitized museum collections. Consequently, global databases such as GBIF and iNaturalist exhibit a pronounced bias toward North American and European data, failing to accurately reflect the true biodiversity of this group, especially in regions such as Argentina. The main objective of our project is to address this gap by leveraging historical collection records from the American Museum of Natural History (AMNH), particularly utilizing the extensive work of the late entomologist Dr. Manfredo Fritz. We focus on the apoid wasps of Argentina, a region that harbors significant potential diversity, as Dr. Fritz conducted the vast majority of his collections within his home country. To measure the biodiversity of apoid wasps, we meticulously combed through the apoid wasp collection, sampling one male and one female representative of each species. This process includes recording identification data, taking photographs, and compiling the information into a comprehensive database, which will then be integrated into an open-source platform. Our efforts on this project have led to a tenfold increase in the AMNH's recorded data on Argentine apoid wasps, significantly enhancing the available information for this understudied group. Our study has stimulated further investigation into the ecological roles and conservation needs of these wasps, raising awareness of their biological importance. Our aim is to promote future collaboration among researchers and contribute to a better representation of these species, as well as to repatriate the wasp collection by making its data openly available worldwide.

Abstract Name: Mya's Tricycle: A Better Form of Mobility

Last year our group was hit with a challenge. A woman named Mya who had dyspraxia and her family in the local community were looking for a group of engineers to repair her push bike. The bike had been made specifically for her by a private company, but there were flaws with the bike and as the summers drew on, Mya eventually grew out of the bike. The bike not only allowed Mya to enjoy her time outside, it also was used by her therapist to continuously move the muscles in her legs by pedaling. Dyspraxia is a condition that affects a person's coordination. In Mya's case, she was also non-verbal. The question we were left with was how can we design and develop tools to assist someone with dyspraxia and is nonverbal to be able to ride a bike safely. Last year we were able to elongate the bike, 3D print new pedals to fit her shoe size, create calf and ankle support braces, 3D print a mount to keep front handlebars fixed axially, add a new brake cable, and add tricycle wheels to help with steering. This year after Mya was able to use the bike over the summer, our group was able to receive feedback from the family. We learned that the ankle brace that was 3D printed had broken and was uncomfortable and the pedals should be printed an inch thicker. We also were informed by the family of extra ideas to add to the bike to make it easier for Mya. This year we will be adding a sunshade, creating a button system for Mya, fixing the issues Mya's family previously brought up, adding a dead man's brake, and potentially motorizing the bike.

Abstract Name: Understanding the Effects of Alprazolam on Planarian Regeneration

Wound healing is an important and complex cellular and molecular process that can be influenced by a variety of extrinsic factors. These include age, underlying disease, infection, stress, and certain medications. To understand how one commonly prescribed medication, Alprazolam, a generic form of the benzodiazepine Xanax that is used to treat anxiety disorders, affects the wound healing process, we chose study its effects in planaria. As wound response mechanisms are widely conserved, planaria provide a simple model system for examining how Alprazolam affects wound healing. We first established that Alprazolam could influence anxiety-like responses in planaria, using a light/dark test. Next, we exposed regenerating planaria to various physiologically relevant doses of Alprazolam and compared the results to control regenerating planaria. These results suggested that Alprazolam causes regeneration to proceed more slowly. As some medications are known to cause epigenetic changes, we hypothesized that alprazolam might be exerting its effects on regeneration by epigenetically influencing transcription. One common epigenetic modification is DNA methylation. To test whether changes in DNA methylation are responsible for the slower regeneration, DNA was extracted from regenerating planaria after 1, 4, 6, 24, or 48 hours, and the amount of 5-methylcytosine present was quantified using a colorimetric ELISA assay. DNA methylation was also quantified from planaria that had been allowed to regenerate for two weeks. Preliminary results suggest that DNA methylation levels are higher in Alprazolam-exposed planaria than in controls during the initial stages of regeneration. As methylation is frequently associated with repression of transcription, this might indicate decreased gene expression is occurring during early stages of regeneration. As wound response mechanisms are widely conserved, this research could help us to understand how a commonly prescribed anxiety medication influences wound healing in humans.

Abstract Name: Hospice Ownership Type and Access to Quality Hospice Care

This study investigates the variation in hospice care quality across the United States by geography and hospice provider ownership type. Hospice is designed to provide palliative (symptom relieving) and supportive end of life care for terminally ill patients. Over the past few decades, the hospice system has become increasingly reliant on for-profit providers, often incentivized to enroll patients with less complicated diagnoses. Previous studies have shown a correlation between for-profit status and lower quality of care. This study is aimed at identifying how access to high quality hospice care has changed across the US in recent years, differentiating between for-profit and not-for-profit providers. The Provider Consumer Assessment of Healthcare Providers and Systems (CAHPS) Hospice Survey data contain quality information for each

hospice certified by Medicare meeting eligibility criteria (some do not have reported data due to small size). The star rating system used allows for comparison of care quality between hospice providers, with 1 being the lowest quality and 5 the highest. We define “high quality” hospices as those with a star rating of 4 or greater. We examine 9 waves of hospice survey data from 2022 to 2024, to assess changes in access to high quality care by region and ownership type. From 2022 to 2024, the mean star rating increased by almost 0.2 points. 60.3% of not-for-profit providers were rated high quality whereas only 42.2% of for-profit providers were high quality. Data from February 2024 showed high-quality hospices are predominantly concentrated in the East Coast, West Coast and Midwest. There are substantial gaps in access to high quality care in the Mountain West and the Northern Great Plains. This is critical in understanding what regions of the country still lack access to high quality hospice care and how this varies by ownership type.

Abstract Name: Optimizing Near-Infrared Fluorescent Proteins for Enhanced Noninvasive Deep-Tissue Imaging

Noninvasive, deep-tissue imaging techniques are critical for advancing our understanding of neural circuits across various areas of neuroscience. Among these, near-infrared (NIR) wavelengths have emerged as promising tools, offering deeper tissue penetration due to reduced light absorption and scattering, while minimizing tissue damage. However, the limited brightness of NIR fluorescent proteins remains a major challenge for their effective application in in vivo imaging. This study addresses this challenge by focusing on optimizing the brightness of NIR fluorescent proteins, while preserving their essential spectral properties. A key obstacle, the limited binding affinity of biliverdin (cofactor with NIR fluorescent proteins) in mammalian tissues, has further complicated the development of NIR sensors. To overcome this, we performed a quantitative analysis of several novel NIR fluorescent proteins, evaluating their fluorescence intensity and spectral characteristics. Through this analysis, we identified several top-performing candidates that demonstrated significant potential to enhance noninvasive deep-tissue imaging. These findings highlight the promise of NIR fluorescent proteins, especially when paired with selective labeling strategies, such as cell-type-specific promoters or organelle-targeting sequences. The improved brightness of these proteins paves the way for further refinement, potentially leading to more precise and efficient methods for deep-tissue imaging and related neurological research and beyond.

Abstract Name: Picture-perfect Success in Digital Photography Identification System for Crawfish Frog Individuals

Identification of individual animals is important to estimate population numbers, identify environmental threats, and study behavior; however, traditional marking methods for amphibians relied on marking the animal in invasive ways. The objective in this study is to determine if photographs can be used to identify individual crawfish frogs (*Lithobates areolatus*) through either their dorsal or tympanum patterns. The species has experienced a decline in its populations, and photographic identification would eliminate the need for any kind of marking. Improvements in the species' welfare through limiting use of invasive techniques as well as allowing them to be studied easier will be of benefit through this method. We monitored a population of crawfish frogs over its entire breeding season and photographed both the dorsal pattern and the tympanum of each frog captured on each night. We used the photo ID software, Wild-ID, to process the images and identify matches, which were confirmed manually. The software correctly identified individuals in almost all cases and the combination of software and user identification was 100% successful in correctly identifying matches for images of both the dorsum and the tympanum. Because photographic identification was highly accurate, this method could be used exclusively to identify individual crawfish frogs, which has important implications for monitoring populations of this species of conservation concern.

Abstract Name: Racial Bias in Education: A Case Study for African Americans

This study examines how African American adolescents experience gender and racial discrimination within the educational system. Critical Race Theory illuminates how race is a social construct and highlights the ways in which people are unfairly judged and marginalized based on their perceived internal and external characteristics. Laws and policies often perpetuate this oppression. This study hypothesizes that there would be a gender difference in the frequency with which African American female and male students reported experiencing racially motivated unfair treatment in school. Data from the CDC's 2021 Adolescent Behaviors and Experiences Survey (ABES) was analyzed ($n = 7,676$) using a t-test to assess statistical significance. Findings indicate that both genders rarely reported feeling mistreated due to their race. However, female respondents reported experiencing more discrimination than males. These results underscore the need for interventions such as ethnic-racial socialization, fostering ethnic pride, and restorative justice practices that promote inclusivity and positive learning environments.

Abstract Name: Reframing Abolitionism: Linguistic Reform in Mainstream and Academic Rhetoric Addressing Modern Sex Trafficking

Anti-trafficking nonprofits like End Slavery Tennessee and Operation Underground Railroad claim to combat "modern-day slavery." While "modern-day slavery" is often used interchangeably with "modern sex trafficking," progressive researchers in this field such as Lorelei Lee and Lyndsey P. Beutin suggest that present-day human trafficking deviates so significantly from the triangular trade, a system backed by

legislation that stripped masses of kidnapped African people in America of their human rights in the imperial and colonial eras, that the discourse in this movement needs to shift to reflect that distinction. Beginning with figures like Frederick Douglass and Harriet Jacobs, social activists with lived experience in organized oppression in America demonstrate a long history of pursuing accurate terms for their disenfranchising experiences. As Douglass said, "Education is emancipation." Therefore, those in the anti-trafficking field must better shape our terminology to inform others about the qualities that distinguish modern sex trafficking from the triangular trade and help current victims liberate themselves from the chains of silence. This presentation will compare firsthand accounts written by formerly enslaved people with present-day accounts written by those with lived experience in modern-day human trafficking. Through this comparison, I hope to answer the following questions: "What are the gaps in current discourse and research in the anti-trafficking movement? How has the rhetoric surrounding modern human trafficking in current discourse inaccurately represented the experiences of enslaved peoples of the past? How can that rhetoric be revised?" In this careful analysis, I hope to uncover the parallels between 18th- and 19th-century rhetoric on enslavement and current trends in the cultural conversation on human trafficking. Ultimately, these findings will demonstrate the necessity of utilizing primary sources to ensure accurate portrayals of trafficking-related issues in the humanities.

Abstract Name: Pricing Under Pressure: Student Comprehension of Fairness and Price Gouging

While standard economic theory posits that the priority of a firm is to maximize profits, behavioral economic theory suggests that firms will engage in behavior that limits profits to avoid being considered unfair. The purpose of our study is to determine when it is acceptable for firms to raise prices and to examine how violations of price fairness translate into legislation. Inflation and the rising cost of living continuously caused concern among the electorate and proved to be common topics in the 2024 election. Some explain the rising prices as leftover consequences of pandemic supply shocks while others claim firms exploit market power through price gouging and other unfair pricing practices. Research indicates that people have an inherent sense of fairness guided by implicit rules and are often willing to penalize those who act unfairly. As a result, anti-price-gouging legislation tends to be a popular response in inflationary times. To better understand undergraduate students' comprehension of price fairness, we conducted a survey of scenario-based questions regarding prices, inflation, and price gouging. Our findings reveal that business students and men respond differently to price fairness, adding complexity to the overall reaction to price gouging.

Abstract Name: Analysis of Antibiosis in Capsicum Annuum Varieties Against Thrips parvispinus

Thrips parvispinus is an invasive and polyphagous insect that feeds on many commercially important food and ornamental crops. This species of thrips is native to Southeast Asia and was introduced to Florida in 2020. In 2023, T. parvispinus caused total crop losses of pepper in southern Florida, with losses up to \$1 million. Due to its economic importance, an accurate understanding of T. parvispinus' relationship with host plants is needed. There is limited information regarding plant resistance in peppers to thrips infestation. Therefore, the goal of this research project is to assess the antibiotic properties of commercial Capsicum annuum varieties against T. parvispinus. Five pepper varieties will be evaluated based on the survival rate, reproductive rate, and feeding damage of T. parvispinus females on leaf samples of each pepper variety. Understanding the differences of susceptibility in C. Annuum varieties to T. parvispinus infestation will provide valuable insight into identifying varieties with plant resistance to thrips. Specifically, the results will provide local growers with information on varieties which are more tolerant of or resistant to T. parvispinus enabling informed pest management strategies and planting decisions.

Abstract Name: Reducing Antibiotic Necessity by Using Chlorine Based Agents on Resilient Bacteria and Endospores in Turkey Houses

Aggressive bacterial and endospore growth in industrial turkey houses causes heavy mortality in high-investment birds, driving farmers to choose between extraneous antibiotic use or crippling financial loss. Current treatments using dilute ammonia at industry standard practice wipe out the majority of bacterial loads to negligible levels but resilient volatile bacteria, like Clostridium difficile an endospore bacteria, remain. This grade of bacteria is inhabitable in the lab setting, but in industrial turkey houses with livestock, the only current solution is swathing each house in antibiotics. Turkeys require more antibiotics per kilogram of body mass than any other livestock and, as per USDA regulations, flocks must exceed 2% total flock mortality per week to qualify for antibiotic treatment. FDA-approved antibiotics are applied at the minimum dose and require a specified withdrawal period prior to shipping, to flush antibiotics from their systems. The use of an antibiotic is an expensive investment and broad application solution due to the potency required and nonspecific target. This reactive protocol is limited to moderating flock loss after bacteria levels have become intolerable. Targeting the source with a chlorine complex, entailing a chlorine-based product combined with an acid solution and bleach-based sprays that are tilled through layers of windrow litter, directly combats escalating levels of encapsulated endospores without harm to livestock birds. These more aggressive treatments remove the stores of resilient bacteria from infected turkey houses and prevent pathogen levels from reaching levels necessary for antibiotic intervention, keeping the birds healthier, protecting antibiotic stewardship and the turkey industry.

Abstract Name: Preliminary Validation of a Novel Survey to Measure Complicated Living Grief in Head and Neck Cancer Patients

Complicated living grief (CLG) is a persistent and distressing emotional response to non-bereavement-related loss, often characterized by maladaptive thoughts and behaviors. For head and neck cancer (HNC) patients, the disease's physical and emotional impacts—such as loss of speech, altered appearance, and diminished social functioning—make them especially vulnerable to CLG. Unlike anxiety and depression, no standardized screening tool exists to measure CLG, leaving this critical mental health challenge underdiagnosed and undertreated. This ongoing study aims to validate a novel screening tool, the CLG Assessment, specifically designed to measure CLG in HNC patients. The questionnaire builds on the Inventory of Complicated Grief, with modifications to capture losses associated with cancer diagnosis and treatment. Recruitment is underway at a tertiary care medical center, targeting adult HNC patients across the treatment spectrum to ensure diverse representation. To date, over 80 participants have completed the 16-item survey, which evaluates yearning, emotional response to loss, and daily life impact. Data analysis to establish reliability and validity is ongoing. This research addresses a significant gap in psychosocial oncology by developing a tool to identify HNC patients experiencing CLG. Although final results are pending, preliminary observations suggest CLG is prevalent among this population and correlates with poorer quality of life, increased anxiety, and depression. Once validated, this survey will enable clinicians to systematically assess CLG, guiding tailored interventions such as early palliative care and grief-directed therapies. By capturing the unique grief experiences of cancer patients, this study represents a critical step toward addressing the hidden psychological burdens of living grief. Its innovative approach equips clinicians with actionable insights to develop personalized interventions, ultimately empowering patients to navigate their cancer journey with greater resilience. This tool not only enhances survivorship care, but also lays the groundwork for broader applications in oncology and other chronic illnesses.

Abstract Name: DEVELOPMENTATION OF LOWER EXTREMITIES EXOSKELETON ATTACHED TO A WHEELCHAIR FOR REHABILITATION

Approximately 75 million people worldwide rely on wheelchairs due to lower limb disabilities, yet rehabilitation options promoting mobility and independence for seated individuals remain limited. Existing exoskeleton technologies focus on enabling upright walking, neglecting the needs of those who require assistance while seated. Addressing this critical gap, we are developing a lower-extremity exoskeleton attachment for wheelchairs designed to enhance rehabilitation and encourage regular movement for both permanently and temporarily disabled individuals. The proposed exoskeleton features a multi-jointed system

including the knee, ankle, and other joints, enabling controlled and safe movements while seated. Safety is a top priority in the design. By incorporating advanced actuation mechanisms and modern bracing techniques, the system provides stability and self-centering capabilities at the joints, ensuring user comfort and safety. Rigorous testing of mechanical design and software controls is conducted to prevent any risk of injury during operation, emphasizing the importance of precise control in the system's performance. Preliminary evaluations indicate that the exoskeleton can significantly improve muscle engagement and joint mobility, potentially accelerating rehabilitation outcomes. By facilitating dynamic lower-limb movement without standing, this innovation offers a transformative approach to rehabilitation for wheelchair users. The anticipated benefits include enhanced muscle strength, increased joint flexibility, and improved circulation, all contributing to a better quality of life and greater user independence. This research is a significant advancement in the field of assistive technologies. The novel exoskeleton attachment for seated rehabilitation fills a significant void in exoskeleton applications. By addressing the unique needs of wheelchair users, this exoskeleton has the potential to impact millions globally, redefining rehabilitation practices and supporting faster recovery for patients

Abstract Name: Investigating the Effectiveness of Visual Feedback in Mandarin Tone Acquisition for Second Language Learners

This study examines the potential of visual feedback to improve Mandarin tone acquisition among second language learners. It focuses on a custom-built mobile application designed to provide real-time feedback on pronunciation through pitch contour analysis. At the time of writing, the app includes a foundational module that introduces all four Chinese tones and enables users to visualize their pronunciation performance. Unlike popular language-learning platforms such as Duolingo or Rosetta Stone, which do not provide real-time pitch contour analysis or vowel feedback for tonal languages, this app fills a critical gap in existing tools by offering a novel approach to feedback. The study evaluates the effectiveness of visual feedback through A/B testing. Both experimental and control groups will use the app; however, the experimental group will receive both visual and textual feedback, while the control group will interact only with textual feedback. The key metric for evaluation include pronunciation accuracy, and I hypothesize that learners who use visual feedback will achieve better accuracy than learners who only have textual feedback. The app development will be completed in Fall 2024, and the study will be carried out in Spring 2025. By integrating linguistic theory with technology, this research contributes to the field of second language acquisition by incorporating advanced visual feedback mechanisms into the learning process. Additionally, it seeks to understand how interactive, feedback-driven approaches can address persistent challenges in learning tonal languages like Mandarin.

Abstract Name: Comparative genomic and antimicrobial susceptibility analysis of *Acinetobacter baumannii* clinical isolates in a large U.S. Deep South hospital system

Background: The U.S. Center for Diseases Control and the World Health Organization list *Acinetobacter baumannii* (Ab) as a critical-priority pathogen for urgent therapeutic development. However, as a species, Ab harbors diverse multidrug resistance (MDR) mechanisms. Previous studies have shown that an Ab isolate's phylogenetic lineage is linked to unique resistance phenotypes. We report an update to the investigation of lineage-dependent resistance features among clinical isolates obtained in the University of Alabama at Birmingham healthcare system. **Methods:** 21 Ab isolates identified from May 2024 to July 2024, were compared to previously characterized, contemporary isolates. All isolates underwent whole genome sequencing (WGS), comparative genomic analysis, and Kirby-Bauer antimicrobial susceptibility tests (AST).

Results: MDR isolates belonged to multiple, unrelated phylogenetic clonal groups (CGs). Antimicrobial resistance gene content was overall predictive of each isolate's AST results. The degree of non-susceptibility to beta-lactam antibiotics differed between prevailing MDR lineages, which correlated with lactamase and non-lactamase genetic determinants conserved among strains in each lineage. CG108 and CG499 isolates displayed lineage-exclusive heteroresistance to sulbactam or trimethoprim/sulfamethoxazole, respectively.

Conclusions: Various canonical and non-canonical determinants were responsible for MDR Ab isolate in our single region, highlighting the value of molecular surveillance in determining therapeutic challenges specific to the region. We must further investigate the factors that determine the different degrees of beta-lactam resistance and the drug-specific heteroresistance observed in these emergent lineages.

Abstract Name: An Exploration of Youth Community Mental Health and the Democratization of Mental Well-being in Chennai, Tamil Nadu

One in seven Indians, which is approximately 200 million people, experience a mental health disorder at any given time, and over 60% of these people go untreated. Despite the high prevalence of mental health challenges, less than 1% of India's national health budget is allocated to mental health services, and only 10% of individuals with mental health needs utilize available care. This study, which was carried out during a semester abroad through the School for International Training (SIT), aimed to explore the necessary steps to democratize mental health and well-being in India through an examination of youth community mental health. Fifteen semi-structured interviews were conducted with psychiatrists, psychologists, social workers, community health workers, and patients at two mental health non-governmental organizations in Chennai, Tamil Nadu: Schizophrenia Research Foundation (SCARF) and The Banyan. Key themes that emerged from the interviews included community engagement, collaboration, and ownership. The findings of this study emphasize the importance of promoting a holistic understanding of mental well-being across India. Youth community mental health practitioners highlighted the value young people place on agency and having a platform to voice their opinions. Collaboration with non-mental health organizations and sectors was identified as a means to expand access to mental health education and care. Empowering people with responsibility and autonomy over the mental well-being of themselves and their communities was found to be effective in increasing awareness, access to care, and the utilization of mental health services.

Abstract Name: Cognitive synchrony among dance spectators: Through a compositional lens

The article by Orgs et al. al titled “Movement synchrony among dance performers predicts brain synchrony among dance spectators”. After reading and presenting this article during lecture, I found myself very enamored and intrigued by not only the thesis behind this study, but the methodology used. Seeing that I was so fascinated with this study, I chose to pivot the direction of my honors project, and mimic this study on a much smaller scale. The movement used for observation for this study will be the compositional work I presented at the Fall Student Choreography Project titled ‘Kin’. I consulted the professor of my Critical Analysis of Literature for advice on forming a survey to analyze cognitive synchrony. Due to the lack of brain mapping, I chose to focus on cognitive rather than brain synchrony. We came to the conclusion that a self-completed questionnaire evaluating the spectator's enjoyment throughout the video performance would provide adequate data on the cognitive engagement experienced. The video was sectioned into segments ranging between 35-40 seconds, to allow insight as to what about each segment is correlated to the most cognitive engagement. As in the study, some questions were geared toward finding out what characteristics brought about cognitive engagement. The hypotheses posed for this study include: Hypothesis 1: That the highest measure of cognitive synchrony within a study group will be within the experienced dancers. and Hypothesis 2: Synchrony will provide the most cognitive engagement among all study groups. This data reinforced the data found in the original study, with small variance which is to be expected when working with a smaller sample group, as well as less advanced screening. Knowing what engages audiences of all dance experiences, and understanding which compositional tools work among different groups, is an invaluable asset to a choreographer.

Abstract Name: Optimizing EMG Sensor Locations on the Leg Muscles to Obtain an Optimum Signal to Activate a Rehabilitation Exoskeleton Device

A cost-effective rehabilitation technology is required that may help millions of patients who need rehab exercises to regain their mobility. Expensive traditional remedies, including surgeries and mechanical exoskeletons, often lack adaptability. The Assistive Bionic Joint (ABJ) has been developed at SJSU to address these issues. The leg rehabilitation device surpasses traditional exoskeletons by incorporating various sensors such as electromyography (EMG) sensors (DFRobot Gravity and Delsys Trigno sensors) and adaptive control systems for its fluidic muscles. EMG sensors are crucial to the ABJ's success, enabling precise tracking of muscle activity to initiate a human walking sequence. This is executed via a control system, consisting of an Enfield LS-V15S proportional directional valve, a D1 Bi-directional proportional PWM valve driver, and an Omega PX309 Transducer. Through further tuning, the ABJ will respond more precisely to EMG data initiation. After extensive trials, it is determined that the sensors placed on the Biceps Femoris, Gastrocnemius Lateralis, and Tibialis Anterior provide the muscle data most precisely. In this work, attempts are made to optimize the EMG sensors' signals, as they are placed along the leg muscle. This is achieved by

varying EMG triplets' locations along the leg that produce electrical signals as a function of the muscles' tension. After obtaining an optimized signal, a filtering system is employed through the Arduino microcontroller to eliminate noise from the signal, which is subsequently used to trigger the main controller. The EMG sensors are placed on a human leg, whereas the ABJ is mounted on a mannequin leg that moves via a control system activated by the EMG signal. Through the integration of these sensors with the ABJ's fluidic muscle system, the prototype is capable of providing users with effective knee rehabilitation. Full details of EMG and ABJ performance will be presented at the conference.

Abstract Name: Reclaiming Couture & Culture: Patrick Kelly and Willi Smith's Impact on Fashion, Blackness, and Queer Identity

In the fashion industry, it's no surprise that two equally visionaries achieve similar levels of influence and success. But what if both of these individuals were black and queer and tackled issues involving racial, sexual, and gender identity. Patrick Kelly and Willi Smith are exceptional figures who redefined the boundaries of race and design in 20th-century fashion, creating the foundations of modern streetwear culture. Through vibrant artistry, Kelly was an African American fashion designer who became the first Black designer inducted into the Chambre Syndicale de la Mode in Paris. Willi Smith was another trailblazing fashion designer who co-founded WilliWear Limited, a street couture brand that blended highly stylish fashion with streetwear made for everyone. Known for his bold designs and cultural collaborations, his legacy influences contemporary fashion. Sadly, both men passed away from AIDS, but the significance lives on through inclusive and exciting approaches to life and creativity. Blending narratives of black culture and queer identity ultimately creates bold artistic statements that design rarely gets a glimpse of. Through design, we see how sophisticated and playful groups of people are, especially when both groups are under fire and misrepresented. Their work challenged how we see stereotypes and what is considered design through storytelling and elevated concepts. By closely examining their groundbreaking achievements and tribulations, we can explore the fascinating and dynamic interactions between fashion and graphic design. The relationship between fashion and graphic design are equivalent disciplines that merge to convey powerful voices of social commentary, artistic innovation, and personality intersections.

Abstract Name: Effects of Climate Change on Genome Stability of *Saccharomyces cerevisiae*.

Climate change has been gradually deteriorating our environment. The Earth's rising temperature has profound implications for biodiversity, human health, and ecosystems. Most organisms have numerous pathways to maintain genome stability, however genome stability comes with the tradeoff of reduced evolutionary chances. Previous data in the Goellner lab shows that the heat shock protein 70 (Hsp70)

interacts with the genome stability protein, MLH1, and inhibition of Hsp70 in human cells prevents MLH1 degradation through lysosomal pathways. This suggests an interesting scenario in which increased temperature could lead to programmed downregulation of genome stability through increased Hsp70 and downregulation of MLH1. This could potentially provide a mechanism for tuning evolutionary ability in climate change scenarios. Heat shock proteins and mismatch repair systems have been well conserved through evolution. We used a budding yeast model system, *Saccharomyces cerevisiae* to test this hypothesis. Budding yeast grow optimally in the laboratory at 30C. We grew our cultures at various temperatures, either 30C, 34C, or 37C for two overnight periods (roughly 16 generations) then measured overall growth rate and DNA mismatch repair capacity using a frameshift reversion assay. Our preliminary data shows a roughly 10-fold reduction in growth rate at 34C and 1000-fold reduction in growth at 37C as measured through qualitative assay. Our preliminary data also suggests a qualitative increase in mutation rate in yeast that have grown at increased temperatures. We are now following this data with quantitative measurements of growth rate and quantitative mutation rate through fluctuation analysis. Together this data supports the hypothesis that increased ambient temperature during climate change could lead to increased genetic variability in lower organisms including fungi.

Abstract Name: Got God? When Spirituality Meets Behaviorism

Practitioners of Applied Behavior Analysis (ABA) identify and modify environmental events in order to increase or decrease target behaviors. Practitioners use the principles of classical conditioning, operant conditioning, and modeling as therapeutic interventions. However, ABA has recently come under increased scrutiny for dismissing the individuality and agency of its clients. For counselors who identify as spiritual or religious, these concerns may be especially unsettling because if the concerns are accurate, conducting ABA may violate the practitioner's values. How can integrating religious beliefs and practices into a theoretical framework of ABA aid practitioners in conducting therapeutic interventions consistent with their values? This literature review examines and critiques existing models of Christian integration in therapeutic intervention with particular emphasis on how Christian belief can inform the practice of ABA. Although existing models of Christian integration in psychotherapy are also theoretically integrative or evaluate theoretical frameworks based on Christian beliefs, this literature review is unique in providing practical suggestions on how to integrate Christian belief with practices in ABA. For example, Christian integration encourages practitioners to focus on increasing a client's range of adaptive behaviors and their agency to choose between those behaviors. In this way, Christian integration prioritizes cultivating behavioral freedom over enforcing compliance with a specific behavior. This is one example of how spiritual and religious integration can benefit practitioners of ABA who identify as spiritual or religious and provides an area for further study.

Abstract Name: Art and Identity in the Temple Beth Jacob

Identity is at the heart of Jewish art and architecture. Since the destruction of the Second Temple in 70 C.E under Roman rule, the characteristics of synagogal architecture have often conformed to the dominant culture the Jewish diaspora lived within. Preserving Jewish tradition through the principle of “living memory” is reflected in the structure of synagogues, from the act of praying towards the Holy Land to the inner mimesis of Temple features. However, despite the synagogue's constant function as a place of worship, the question of how to visually express the abstract in Judaism has been probed since antiquity. Scholars have historically characterized Judaism as an aniconic religion, implying a lack of concrete artistic expression. The reoccurring instance of architectural acquiescence did little to negate this notion. It is within this tension—between the pressures of cultural assimilation and the Jewish commitment to preservation—that my exploration lies. Using the Temple Beth Jacob in Miami as a specific case-study, I analyze these themes through its architecture and evolving purpose. The synagogue, comprised of two buildings constructed in 1929 and 1936, blended into the Art Deco aesthetic that would come to define Miami Beach. Due to a decline in Jewish population in the 70s and 80s, Beth Jacob was slated for demolition when it was rescued by MOSAIC, an organization dedicated to collecting Floridian Jewish history. Transformed into the Jewish Museum of Florida, the synagogue now embodies a revitalized purpose, exploring and renewing the use of traditional Jewish symbolism. This transformation highlights how Beth Jacob reflects Judaism's connection to memory, merging ancient tradition with modern adaptation and encapsulating the dynamic essence of the contemporary Jewish experience.

Abstract Name: Facility for Educating Children and Parents on the Importance of Nutrition and Physical Activity

Parents and children are increasingly concerned about physical and mental health due to the growing isolation caused by technology use. Many children lack physical fitness, outdoor activity, and proper nutrition, making it essential for parents to foster habits that promote lifelong wellness. This project aims to design a space where children can unplug from technology and learn key health and well-being skills. Findings from a one-on-one interview, case studies of elementary schools, and design theory reviews highlighted child obesity and its link to mental health issues. The interview provided insight from a mother's perspective on what safety measures would bring her comfort as well as how to create an environment that would engage her children. Therefore, creating an enjoyable environment can encourage children to adopt and sustain healthy habits. Programmatic design concepts tailored to the needs of children were integrated into the facility, such as visual access, safety, engagement, inclusivity, comfort, and flexibility. These principles are reflected in elements like material selection, adherence to WELL Standards, furniture placement, and floor plan design. For example, activity rooms include retreat spaces where children can decompress if overstimulated. This is based on prospect and refuge theory, which balances open, engaging spaces with private, calming areas to support emotional well-being. Color theory influences the facility's atmosphere, using calming blues and greens in spaces like the sensory room and library, and energizing reds, yellows, and oranges in active areas like the indoor playground. A sensory design approach is integrated to offer calming, interactive features that encourage exploration, creativity, and problem-solving. In conclusion, this project designs a space that promotes health and well-being for children, addressing issues like obesity and mental health. Through thoughtful design, the facility encourages healthy habits, sensory engagement, and emotional support, aiming to inspire lifelong wellness for children.

Abstract Name: Bars, Flyers, and Memory: Exploring Queer Technologies and Archival Silences in the Papers of Donny Thinnies

This research explores the ethics of archival extractiveness and the reconstruction of Pittsburgh's queer past through the papers of Donny Thinnies, a former local gay bar owner, which document the city's LGBTQ+ social atmosphere from the 1970s to the early 2000s. It aims to explore how archives can ethically preserve and represent queer histories while highlighting the social tools and technologies — such as bar flyers, organizational meeting minutes, and paraphernalia — that shaped and recorded community life. By focusing on the ways in which queer people communicated and identified, this research seeks to contribute to a more nuanced understanding of how queer pasts are remembered and represented. This research contributes to broader discussions in archival studies and queer theory by interrogating the ethics of archival interaction. It critiques the extractive tendencies of traditional archival practices, which often prioritize historical reconstruction over individual autonomy. By foregrounding the tools and spaces that structured queer life, this research reframes these materials as "queer technologies" that mediated identity, memory, and community cohesion. The methodology involves a close reading of Thinnies' archival materials, supported by comparative analysis of LGBTQ+ archives like those at Gerber/Hart in Chicago. This approach situates Pittsburgh's queer history within broader archival and cultural frameworks while highlighting the challenges of navigating archival silences and omissions. Preliminary findings underscore the ethical complexities of rebuilding queer pasts, particularly regarding the tension between historical preservation and respecting the wishes of those who sought privacy. These findings will be discussed within the context of evolving queer identities, the politics of inclusion and omission, and the ethical imperatives of archivists. This thesis seeks to contribute to archival and queer studies by proposing strategies for engaging archives in ways that honor the complexities and lived realities of queer communities while fostering a more inclusive historical record.

Abstract Name: Polylactic Acid (PLA): Chemical Breakdown of a Plant-Based Plastic to Enable More Effective Recycling Efforts

Plastics are an indispensable factor of daily living—toothbrushes, water bottles, etc. are only a few examples. While plastics ease everyday activities, they, in turn, cause environmental turmoil with regards to recycling. Scientists estimate that only around 9% of all plastics get recycled globally, while around 80% end up in landfills or the environment. This is a direct result of ineffective recycling methods such as the unsuccessful chemical breakdown of traditional plastics due to 99% of them being made from crude oil. Recycling centers then resort to other recycling methods such as, 'downcycling,' where plastic items are reused at a lower quality for other applications. To resolve these issues, one alternative is polymerizing plant-based lactic acid (LA) into polylactic acid (PLA), which is a renewable resource and not tied to petroleum reserves. In addition, PLA is more readily broken down into monomer units which could promote more effective

recycling efforts. PLA conversion occurs in a single step, followed by an experimentally optimized isolation process of the target LA from other reagents and byproducts. Infrared and NMR spectroscopy were used to determine that the sample was indeed LA based upon comparison to known samples. LA oligomers, or larger monomer units, may be present and hence will be further investigated. Another avenue of future research includes the conversion of LA to PLA. This reverse reaction would form a closed-loop system that will be advantageous for economical and industrial purposes due to minimization of waste and optimized resource efficiency; furthermore this reaction will allow for PLA to become more widely used in the plastics industry.

Abstract Name: Oxytocin Receptor Activation in the Nucleus Accumbens Differentially Mediates Phasic Dopamine Release

Oxytocin is being researched as a new treatment option for substance use disorder. Oxytocin likely alters the rewarding properties of stimuli by altering their effects on mesolimbic dopamine release. Our lab has previously shown that oxytocin infused directly into the nucleus accumbens (NAc) reduces stimulation-evoked phasic dopamine release. The current study expands on these findings using in vivo fixed potential amperometry with carbon fiber recording electrodes in the NAc of anesthetized C57Bl/6J mice. Given that oxytocin can act on multiple types of receptors, we infused the selective oxytocin receptor agonist [Thr4, Gly7]-oxytocin (TGOT) (25 ng in 1 μ l volume over 1 min) into the NAc during dopamine recordings. Dopamine release was elicited with electrical stimulations in parameters set to mimic phasic (20 pulses at 50Hz) and tonic (4 pulses at 5 Hz) activity patterns. We found that intra-NAc TGOT reduced dopamine release elicited by phasic stimulations (-22.5%) with no significant differences observed between males and females; however, intra-NAc TGOT infusions did not significantly alter dopamine release elicited by tonic stimulations (-3.5%). Phasic dopamine release in the NAc is classically thought to drive drug-related reward and learning, with phasic firing highlighting salient environmental stimuli. Oxytocin has previously shown to reduce the rewarding effects of drugs but promote the salience of social stimuli. Although more research is needed, the present findings lend support to the hypothesis that oxytocin's opposing influence on drug vs social reward may be related to its differential mediation of phasic vs tonic dopamine release.

Abstract Name: Congenital Prosopagnosia in a University Setting

Prosopagnosia is a neurodevelopmental condition where an individual has difficulties with recognizing faces

(Shah et al., 2015). Prosopagnosia is called developmental prosopagnosia (DP), or congenital prosopagnosia, when the condition is present at birth (Cook & Biotti, 2016). It is not widely known, so many do not know they even have this disorder. Because DP is a condition from birth, prosopagnosics tend to believe that everyone else struggles like they do (Yardley et al., 2008) or that they are just lazy and do not care enough. For those who do know about prosopagnosia, there is a lack of standardized self-report instruments which prevents comparison across samples and creates heterogeneous testing (Shah et al., 2015). This study aims to bring attention to developmental prosopagnosia as well as look at the sociobehavioral implications on lack of facial recognition. Participants will fill out four surveys online (General Belongingness Scale; Friendship Network Satisfaction Scale; Prosopagnosia Index Scale (PI20); SQ9) and then come in person to take a facial recognition test. The four surveys will be assessed on Qualtrics. The computer experiment will be run to assess an individual's ability to recognize faces without contextual information such as hair, eyebrows, background, and makeup. The first thing to be assessed is the validity of the computer program by looking at the correlation of the score with the score of the PI20. We hypothesize there will be a negative correlation- the lower the score of the facial recognition test, the higher the score of the PI20. We will also be looking at if lack of facial recognition negatively impacts relationship satisfaction and feelings of belongingness in communities. Third, we will assess if there is a positive correlation between uncomfortable experiences and poor facial recognition via the SQ9, a questionnaire that collects both quantitative and qualitative data.

Abstract Name: Investigating Reward-Related Neural Activity and Antisocial Behavior

Antisocial behavior, (ASB) is a broad term describing a range of behaviors, including rule-breaking, violence, aggression, risk-taking, and illegal actions. The persistence of ASB is partially related to differences in responding and learning from reward and loss, as individuals may continue a certain behavior even after receiving negative feedback or outcomes. Furthermore, past studies have also linked ASB to dysfunction in frontostriatal reward circuitry, which is involved in reward and goal-directed decision-making. This study aims to investigate neural activity in individuals who exhibit ASB. Participants were acquired through the Michigan Twin Neurogenetics Study, (MTwiNS) where data was collected through interviews, questionnaires, biological samples, and a functional magnetic resonance imaging (fMRI) session. During the fMRI session, participants would complete a card game task, measuring reward-seeking and responses. Expected results may show individuals who exhibit ASB may have differences in neural activity during the reward task when compared to individuals who do not exhibit ASB. The study aims to contribute to understanding of the neural processes underlying ASB and reward, as well as guide more specific interventions, such as those focused on reward-related decision-making and judgment, for individuals who are at risk or who exhibit ASB.

Abstract Name: Usage of Event Based Cameras in High Frequency Dynamic Systems

The primary purpose of this study was to understand the practical application of neuromorphic event-based cameras in various dynamic environments. Neuromorphic event-based cameras use a biology-inspired sensor to detect both movement and changes in light. The year-long project analyzed the abilities of the camera as well as the tracking methods used to recognize and trace events. Studying both egocentric and exocentric motion, the camera was put through a variety of tests to find its ideal use environment. The camera was tested in various light conditions, focuses, and temporal resolutions. Peak performance was seen when the camera was stationary, tightly focused, at a mid-to-high temporal resolution, and in an indirectly lit environment. Tests were run in a controlled environment using pendulum motion. The algorithms used to trace motion were based on a Kalman filter. Using the location and velocity of previous events, the algorithm predicted the location of future events. After new events occur, the algorithm uses the measured states from the camera to enhance its propagated state. The result is a frame-by-frame recap of actual events with an overlaid predicted state. The project concludes that neuromorphic event-based cameras are capable tools that work well in stationary, consistently lit environments. While they offer a dense data stream, use in dynamic applications is not practical. Dynamic systems drown out useful data with noise and egocentric events. Performance is at its peak when egocentric motion is minimized.

Abstract Name: THE EFFECT OF MULTITASKING ON REACTION TIME AND BALANCE IN DIFFERENT AGE POPULATION

As individuals age, how they process stimuli is affected (Hardwick, R. M. et al., 2022). According to Konard et al, 1999, aging reduces our ability to process motor commands and translate those into musculoskeletal function. When a multitasking piece is added to a motor skill, performance is decreased (Hemond et al., 2010). There is less knowledge on how cognitive function affects multitasking as age increases. PURPOSE: This study aims to investigate the effects of multitasking on reaction time and balance among different age populations. METHODS: This study will include males and females from a college population aged 18-75. Subjects will perform a ruler drop test to determine reaction time and the Romberg balance test to establish balance. Participants will be randomly assigned to either complete both tests with a multitasking component or without it. Participants completing the multitasking element will count even numbers backwards from seventy-four. Each test will be performed three times and averaged. The researchers will randomize the order of the assessments. A two-way ANOVA analysis will be used to decide if there is an interaction between age

groups and multitasking or no multitasking. Significance will be determined at the $p < .05$ level. Anticipated RESULTS may reveal that participants below the age of twenty-eight will have a quicker reaction time and fewer errors during the balance test whether multitasking or not. CONCLUSION: In conclusion, this study may show that multitasking has a greater effect on reaction time and balance in older populations but no differences are anticipated among a younger population. Future research might examine how music affects reaction time and balance rather than multitasking. Data is currently being collected. IRB # 464551

Abstract Name: Evaluating the effects of psilocybin on mental health disorder symptoms in recreational settings

Currently, there is a high frequency of mental health disorders; 19.86% of adults are suffering from mental illness in the United States. Of those who seek medication as treatment, between 20-60% show treatment resistance. Psilocybin has reemerged as a possible alternative treatment for psychological disorders. Recent clinical studies (employing trained therapists, in controlled environments, with screened participants) have shown exceptional promise. Psilocybin as a clinical treatment has led to 54% of participants meeting remission criteria for depression and an 80% anxiolytic response rate in participants with anxiety. The frequency and efficacy of psilocybin use for addressing psychological disorders outside clinical confines remains unknown, though public and professional awareness of its use for these purposes has been growing. The purpose of this study is to evaluate the self-reported use of psilocybin for self-treatment of depression, anxiety, and traumatic symptoms in recreational settings. One hundred fifty-seven reports were randomly selected from Erowid.org's vault of psilocybin experiences anonymously reported by users. Reports were evaluated through qualitative methods based on frequency of use for treatment of psychological disorders (depression, anxiety, and PTSD), frequency of individual symptoms, efficacy of treatment, length of efficacy, and other relevant variables. Results showed 15.3% of all randomly selected recreational user reports highlighted medical purpose as the reason for their use. All users who reported using psilocybin for depression, anxiety, and PTSD symptoms reported beneficial and often long-lasting effects. Results suggest the presence of a therapist in clinical settings may be valuable in limiting negative effects.

Abstract Name: Alibi Believability: Corroborator Cooperativeness with Police and Consistency of Corroborator Certainty

An alibi is a statement that places a defendant elsewhere at the time of a crime (Nolan & Nolan-Haley, 1990). Alibis are studied empirically due to the number of innocent people who had alibis but were wrongfully convicted (Heath et al., 2021). Person alibi evidence is evidence involving a corroborator, and it is frequently used in actual cases (Dysart & Strange, 2012). This study investigated two alibi corroborator

characteristics: certainty and cooperativeness. Only one study has empirically studied alibi corroborator cooperativeness, and the authors found that when a corroborator was cooperative with police (versus uncooperative) the alibi was more believable (Allison & Kollar, 2023). 320 participants recruited from CloudResearch read a description of a theft, police investigation, and trial. They were randomly assigned to one of eight conditions in a 2 x 4 between-subject design. Half of the participants read a police investigation in which the alibi corroborator was cooperative with police by returning their calls and half read one in which the corroborator was uncooperative with police. Participants then read that the corroborator was questioned twice about how certain he was about being with the defendant. The corroborator's certainty was maintained either high (100%-100%) or low (75%-75%), strengthened (75%-100%), or weakened (100%-75%). Next, participants completed a questionnaire where they rated the alibi's believability, the defendant's character, and the likelihood of guilt. Alibis were more believable when the corroborator cooperated with police than when he did not. Alibis also were more believable when the corroborator's certainty was maintained and high than when it was maintained and low. The defendant was seen as more likely to be guilty when the corroborator did not cooperate with police than when he did cooperate. Lastly, the defendant was viewed more positively when the corroborator cooperated versus when he did not.

Abstract Name: Hungry: Alternative to Touchscreens in Toys

This toy design project presents Hungry, an innovative toy nightstand, or desk clock designed for Kidrobot, reflecting the brand's playful, colorful, and minimalistic design language. In response to a paradigm shift among Generation Z—marked by increasing resistance to touchscreens—Hungry reimagines digital interaction through tactile, engaging design. Shaped like a friendly monster, Hungry features posable arms and horns, with an open mouth housing a screen. Users interact with the clock by placing collectible fruit- or vegetable-shaped figures on its tongue. Each figure, distinguished by its unique color, activates embedded recognition technology that dynamically alters the screen's display. This tactile interface bridges the physical and digital, introducing an intuitive way to engage with technology. Beyond its functional role as a clock, Hungry inspires exploration and imaginative play. Users can discover a variety of interactive features beyond the time, including photo of the day, fun facts, word of the day, date, and weather, displayed in full-screen or split-screen formats. While basic settings—such as location, language, and user age—are adjustable through a simple companion app, the device itself maintains a hands-on approach. Its durable design and playful features make it appealing to both children and young adults, while aligning with the vibrant, minimalist aesthetic appreciated by Kidrobot collectors. Hungry transforms everyday clocks into sources of play.

Abstract Name: The New American Mother and Coeducation: the Story of the Valparaiso Male and Female College

Against the backdrop of civil war threatening the United States and the rise of the Republican Party, a push for patriotism and virtue surged throughout the North. Educating Americans, especially Northern white women, became the ultimate solution for both the social and economic gain of the United States. Americans realized that a mother was a child's first teacher, so women needed to be educated themselves in order to pass on that learning to their children. This movement stemmed from the ideology of Republican Motherhood, the 18th century belief that motherhood was a civic virtue and responsible for creating the next generation of upstanding citizens. In the mid-to-late 19th century, this new kind of Republican Motherhood ushered white American women into the classroom, and collegiate institutions began to address this new need. The most innovative of these being coeducational colleges. Accordingly, the Northwest Indiana Conference of the Methodist-Episcopal Church formed a college that invited not only men but also women to take part in a complete, thorough educational and intellectual experience. Henceforth, the Valparaiso Male and Female College (1859-1871) came to fruition. Scholarship, however, fails to include the Midwestern coeducational institutions that made these radical strides in women's educational experience, focusing more on Northeastern women's colleges. This paper braves a new path into the study of women's education by uplifting the stories of Midwestern women in a coeducational institution. Moreover, this paper dissects the cultural context of women at the Valparaiso Male and Female College; and, in doing so, it explores how this new opportunity gave women a voice in the social and political machine. The late 19th century Republican Mother, educated at a coeducational college, was indeed a woman rearing children for their success, her own success, and the success of future women.

Abstract Name: Global Obesity Prediction: Worldwide Key Factors Identified Through IBM Watson Machine Learning Models

Obesity is a chronic disease that affects a significant portion of the population; in the United States, 4 in 10 adults suffer from this condition, with a high prevalence, particularly among Black, Hispanic, and caucasian communities. Similarly, countries like Mexico and Saudi Arabia face escalating obesity rates due to dietary shifts, while nations like Japan and South Korea report significantly lower rates. Environmental factors such as urbanization and industrialized agriculture exacerbate obesity rates by promoting unhealthy lifestyles and imbalanced diets. Obesity is also a precursor to numerous fatal diseases, including diabetes and cardiovascular diseases. Our hypothesis states that preemptive diagnostics can address obesity through early intervention by employing machine learning-based predictive models to identify health and environmental factors contributing to the condition. The obesity data was collected from 2,112 patients from Mexico, Columbia, and Peru, including key factors such as age, gender, alcohol consumption, smoking habits, dietary patterns, physical activity, and caloric intake. We used the IBM Watson platform to implement three algorithms (LGBM, Snap Random Forest, and Snap SVM classifier) with and without enhancements (HPO-1, FE, HPO-2). Notably, the model accuracies ranged from 90.9% to 96.9% in predicting outcomes. In order to incorporate factors of patients' environments on their obesity levels, a worldwide dataset related to individuals' demographics and lifestyle habits was also obtained in an attempt to compare these factors with the ones from data acquired from Mexico, Columbia, and Peru. While the inclusion of enhancements yielded marginal improvements, the significant features identified across algorithms were largely consistent, with only slight variations. This dataset analyzed key factors such as age, gender, height, weight, BMI, and physical activity levels. The confusion matrices generated by each algorithm indicate that these predictive models are robust and ready for future applications. Further details will be presented at the conference.

Abstract Name: Learning to generate realistic medical images to improve pancreatic cancer segmentation and detection

Pancreatic cancer is a disease with a high mortality rate due to a lack of early symptoms and data scarcity. Recent research has focused on improving AI models to produce more accurate diagnoses given medical images such as CT scans. Existing AI diagnosis models, trained on publicly available medical image datasets, often struggle with diagnosis because of limited training data. Our research provides an innovative approach to improving training data, which can be used to make existing diagnosis models better. We seek to train a model to generate realistic synthetic CT scans, which can then be used to improve the performance of pancreas segmentation and classification models. Our research investigates multiple generative models, including GAN (Generative Adversarial Network) and VAE (Variational Autoencoder). After training the generative models with real CT scans, the models generate synthetic CT scan datasets that mimic realistic pancreatic cancer CT scans; these realistic CT scans contain small tumors that doctors easily miss. To evaluate the performance of different synthetic datasets, multiple model training experiments combine various ratios of synthetic and real data. Two common metrics, Dice value and Binary Cross Entropy (BCE) are used to understand how realistic the synthetic images are, as well as their correlation with real pancreas annotations. Overall, our anticipated result is to generate realistic CT scans that can help train more accurate pancreatic cancer diagnosis models in the future.

Abstract Name: Scarcely A Stone Stands: Natural Disaster Resilience and the Impact of Post-Earthquake Housing Policies on Housing Affordability in 20th-Century San Francisco and Tokyo

This thesis examines how historic earthquakes have shaped urban planning and housing policies in San Francisco and Tokyo, with a focus on affordability, resilience, and sustainability. Beginning with the 1906 Earthquake in San Francisco and the 1923 Kanto earthquake in Tokyo, this study uses these seismic events as starting points for analyzing modern policy development and urban resilience, arguing that earthquakes have played a large role in shaping urban planning through the creation of reactionary resilience policies. However, these reactions have led to divergent outcomes. Tokyo's zoning flexibility and encouragement of high-density construction have allowed it to maintain a steady housing supply despite frequent rebuilding demands. In contrast, San Francisco's emphasis on preservation, combined with restrictive zoning regulations, has led to a shortage of affordable housing. By comparing these two global cities, this thesis explores how differing responses to earthquakes influences planning priorities and, subsequently, housing affordability. Using a comparative case study framework, this research draws from urban planning and housing policies, newspaper archives, and government housing data to assess the impacts of these historic seismic events on present-day realities. Diverging from existing scholarship, this project draws an explicit link between historic earthquakes and the subsequent policy to contemporary housing affordability issues. There is already scholarship that

discusses Tokyo's unique housing system compared to the United States, but this project provides a historic lens as to why these policies exist today and how they have been informed and forced from natural disasters. This thesis is significant because we live in an era where natural disasters are becoming increasingly common. Furthermore, both Tokyo and San Francisco are likely to experience a large earthquake within the next few decades.

Abstract Name: Butterfly World 3.0: Virtual Reality as a Tool for Exploring Imperiled Butterflies in the Florida Keys and Caribbean

Butterfly World 3.0 is an interactive, bilingual desktop and virtual reality (VR) serious game designed to immerse players in a coastal dry forest ecosystem. The game focuses on imperiled and common butterfly species, as well as native and invasive plant species, with particular emphasis on the federally endangered Schaus' swallowtail butterfly (*Heraclides aristodemus ponceanus*). This butterfly also has subspecies in the Lucayan Archipelago and the Caribbean (island biogeography). VR immersion offers several educational advantages, including access to diverse ecosystems, opportunities to interact with species that are difficult to encounter in real life, and fostering empathy for wildlife and the environment. To assess the cognitive impact of Butterfly World 3.0, we conducted an experiment with biology students, dividing them into two groups: one receiving VR-based lessons and the other engaging in traditional lessons. Both groups completed pre- and post-exams to evaluate knowledge gains. Afterward, the groups swapped lesson formats. Surveys comparing the two lesson types revealed that students in the VR-based lesson group showed significantly greater increases in content knowledge compared to the traditional lesson group. Most students expressed a preference for the VR lessons, although both groups identified the learning curve associated with VR technology as a major barrier without instructor assistance. These findings suggest that VR-based lessons can significantly enhance cognitive learning in subjects such as butterfly and plant ecology. By integrating VR gamification, Butterfly World 3.0 offers a novel approach to teaching complex ecological concepts. Conference attendees will have the opportunity to experience the latest version of our desktop and VR game firsthand.

Abstract Name: Genome Instability in Cancers

Cancer is a phenotype that occurs as a result of genomic instability in cells. Genomic instability increases the chances of advantageous mutations (which promotes cancer growth) which causes further genomic instability, creating a positive feedback loop. Genome instability can take many forms: this research focuses on

researching a type of genomic instability that results in aneuploid cells (cells with an abnormal number of chromosomes). Dr. Chinnayan's lab is working to artificially induce genomic instability in lung cancer cells by treating euploid cells (cells with the appropriate number of chromosomes) with drugs that induce aneuploidy. Preliminary research suggests that certain candidate biomarkers (such as IGF2BP3, IGFBP1, PYCR 1 and UCHL1) are positively correlated with genome instability in some cells; that is, some cancerous cells were found to have higher levels of these biomarkers when their genomes were relatively more unstable (Cho et al., 2024)¹. Thus, Dr. Chinnayan's lab is working to corroborate this hypothesis: drug-treated aneuploid cell lines are being tested for biomarker levels; one method for doing this is PCR. PCR is being used to amplify the genes that code for these biomarkers, which makes it possible to measure relative amounts of pre-existing mRNA within the cell via amplification curves and critical values/cycle thresholds. Correlation is to be tested further through knockdown experiments, in which candidate biomarker proteins are destroyed from cell lines and resulting genome stability is measured. Establishing a strong association between these biomarkers and genomic instability may allow for medical professionals to determine cancer aggressiveness and possible resistance to treatment. Cancers with excessively unstable genomes that survive treatment are likely to become treatment resistant; therefore, having markers indicative of increasing instability may prove to be important information for medical professionals when treating cancers.

Abstract Name: Patient response system using SNS

To reduce the burden on nurses and improve work efficiency, we developed a patient-response system that uses SNS. There are various issues in Japanese society, but the high overtime rate owing to a shortage of nurses is a serious problem. Although nurses are required to work 72 h less for night shifts, 34.3% of the nurses work more than 72 h. This shows the seriousness of labor shortages. Given this context, we developed a patient response system that uses LINE Bot to reduce the burden on nurses, improve work efficiency, and provide desirable responses to patients. The patient response system operates as follows: First, the patient sends a nurse call to an SNS. Thereafter, the LINE Bot receives a nurse call, and it sends a notification requesting the nurse to respond. When the nurse sees the message and completes the patient's response, the series of steps concludes with the nurse replying "OK." The original point is that the nurse receives a reminder message every three minutes, allowing her to respond to patient calls quickly and reliably. This reminder function prevents delayed and missed responses and supports nurses' work. To build the system, we used the SNS app "LINE," which is widely used in Japan. We developed a LINE Bot program by combining LINE's "Messaging API" with "ngrok," a tool for exposing local servers to the outside. The implementation method involved obtaining a LINE business ID, registering with LINE Developers, creating a channel to enable the Messaging API, and connecting to ngrok on a PC to run the Bot program created in Python. In this study, we built a chatbot that benefits both nurses and patients, reducing the workload on nurses and making it easier for them to contact nurses.

Abstract Name: The Blue Scare: How Cuban Voters Impact the Hispanic Electorate in Florida

The accuracy of forecasting models has been under increased scrutiny due to unpredictable outcomes in two out of the last three presidential election cycles. One potential cause of instability is the difficulty faced when trying to sample racial/ethnic minorities, populations that historically have given heavy support to the Democratic party but that are not always reliable. Understanding the variation in Hispanic voting behaviors has become especially important as Hispanics become a larger portion of the active electorate. Past analysis of Hispanic voting behavior has led scholars to observe that partisan differences in the Hispanic electorate are more tied to nationality than race. Cuban voters in Florida have historically been an example of a population that diverges from the trends in the voting behavior of their group. This project examines voting by the Floridian Cuban population in recent Florida elections and explores some of the mechanisms leading to divergence in their voting behavior, particularly in the Miami metro area. We will estimate Hispanic voting behavior in both Cuban and non-Cuban Census tracts to trace the growth in Hispanic Republican voting heading into the 2024 election.

Abstract Name: Vehicle Price Prediction using H2O-AutoML and Spark based on Feature Engineering

In the automotive industry, the estimation of vehicle prices is critical for dealerships, consumers and manufacturers. Traditional methods struggle to capture the complexity of pricing factors. This paper proposes a framework for vehicle price prediction using big data technologies (H2O AutoML and Spark) and machine learning (ML) models. H2O AutoML automates model selection and tuning, and Spark facilitates efficient processing of large datasets. The proposed framework consisted of phase 1: EDA and Preprocessing, phase 2: Modeling, phase 3: Evaluation. The selected ML models are linear regression, Adaboost, Gradient Boosted Regression (GBR), random forest, and XGBoost, and are evaluated based on R2, Mean Squared Error (MSE), and Mean Absolute Error (MAE). The results indicate that the models consistently achieved higher R-squared (R2) values compared to benchmark studies with the best performing model being GBR, achieving an R2 value of 98.1% and exceeding previously reported values of 90%. These results suggest that manufacturers can use this framework to set competitive prices. Dealerships can then optimize their pricing strategies, and consumers can make more informed purchasing decisions. Big data and machine learning techniques have the potential to revolutionize vehicle pricing strategies and enhance the car-buying experience.

Abstract Name: Gender and Social Media: Delving into Young Adults' Daily Participation on Facebook

With the prevalence of social networking platforms, it is crucial to study the role that gender plays in its use, for gender, which is continuously shaped by society, plays a critical role in our identities and daily lives. This paper explores how the social construction of gender affects and is affected by social media through discussing the usage of Facebook by young adults, especially Middle Eastern cisgender males and females, and women's limited freedom on this social networking site in the Arab countries. It is argued that despite individuals having some freedom online compared to offline, their choices, specifically that of women, is constrained within the borders set by societal gender norms. The main focus of this paper is on young adults since they are the dominant age group of users and on the use of Facebook due to its popularity and multi-functionality that allows an offering of tailored user experience. It is concluded that gender differences play a significant role in how social media is used since women tend to use social media for emotional interpersonal purposes while men use them in task-oriented individual manners alongside multiple other dissimilarities. Additionally, users tend to present an edited version of themselves online due to societal pressures and norms, and particularly women in the middle-east struggle to have complete liberty in their online behaviour.

Abstract Name: Preparation and Characterization of Polyhydroxybutyrate (PHB)/Polylactic acid Cellulose Nanocrystal (CNCs) Nanocomposites

The mass production of single-use synthetic polymers and their improper disposal have negatively impacted our environment. According to the U. S. EPA, of the approximately 35 million tons of plastic waste collected in 2018, 75% was dumped into landfills. The anaerobic degradation of this waste in landfills generates methane and other greenhouse gases, contributing to climate change. The plastic waste includes polyethylene terephthalate (PET), high-density polyethylene (HDPE), and low-density polyethylene (LDPE), which all have recyclable properties but 90% fail to be recycled. We aim to develop biobased biodegradable polymer blends and composites with thermomechanical properties that will allow them to replace petroleum-based polymers. We have prepared polylactic acid (PLA)/polyhydroxybutyrate (PHB) polymer blends incorporating lignin and cellulose nanocrystals (CNCs). Lignin/CNCs (0.3 wt.%, 0.6 wt.%) were incorporated into 50:50 and 70:30 PLA/PHB PLA/PHB polymer blends by high torque melt mixing. Differential Scanning Calorimetry (DSC), Thermogravimetric Analysis TGA, rheology, and optical microscopy were used to characterize these new materials. The lignin/CNCs were found to serve as nucleating agents and improved the thermomechanical properties of the polymer blends. The results of this research will be described.

Abstract Name: Bioremediation in the Chesapeake Bay: Anthropogenic Ocean Acidification Mitigation in an

Interactive Multi-Tropic Ecosystem

Zostera marina is a species of marine macrophyte that has been largely prioritized in past submerged aquatic vegetation (SAV) restoration initiatives within the Chesapeake Bay because of its 1) previous abundance, 2) demonstrated carbon burial abilities, and 3) observed ability for meadows of *Z. marina* to ameliorate low pH conditions. Due to the temperature variability and poor water quality in the Chesapeake Bay, *Z. Marina* beds have experienced several die-off events with limited capacity for regrowth. *Ruppia maritima*, an opportunistic species with tolerance to temperature shifts within the bay, may have the potential to maintain SAV coverage in areas experiencing *Z. marina* die-off. The potential benefits of calcium carbonate production via calcifying organisms such as *Thalassia testudinum* and *Crassostrea virginica* are also investigated. By considering the environmental needs of each organism in the location of SAV and bivalve restoration efforts, both species might experience an enhanced ability to perform essential biological functions including photosynthesis and calcification. This synergistic interaction benefits from the support provided by other organisms within the bay's ecosystem. Given the recent shifts in environmental qualities of the bay, this systematic review may have implications that could assist the formation of a more effective ocean acidification management strategy with a potential for increased longevity. Evidence from this review suggested that future SAV research initiatives in the Chesapeake Bay could investigate how biodiverse and traditional *Z. marina* beds compare in terms of pH modulation abilities, as well as how the strategic placement of calcifying organisms nearby restored SAV beds may impact the bed's ecosystem services.

Abstract Name: The Southwestern University Guitar Tutorials

The Southwestern Guitar Tutorials are a series of videos that serve the world-wide musical community through the creation of pedagogical videos that focus on best practices for instructional content in the medium. These works are deemed to be “green videos” as the content does not become outdated, and highlights works that are widely available and in the public domain. This on-going project represents critical next steps in thinking through the process of delivering instructional digital video as an aid to applied music studies. The strength and depth of the cohort of current student collaborators showcased their talents in performance and scholarship. The videos we created were comprised of sections that a.) demonstrate a slow tempo performance with close-up split screen shots of the player's hands and animated scores, b.) offer contextual pedagogical and/or historical information in the form of a lesson-demonstration, and c.) present a regular tempo performance of the selected repertoire. Student performer teachers Zachary Logan, Maeve McCarthy, Raul Najera, and Liberty Taylor acted as a collaborative team of researchers, writers, editors, and technicians. We aimed think critically and speak cogently about technical elements of video production and editing, audio engineering through the lens of guitar pedagogy and performance. We discussed the role that video resources currently occupy in instrumental music pedagogy, and sought to continue to create content that maximizes the potential of the medium. We reviewed and reflected on our previous works in initial production meetings. We gained an increased awareness of sound and video recording techniques, and refined our skills in guitar performance and pedagogy through this unique and deliberate process of creation, and enhanced our knowledge of and practical familiarity with the software programs that were used in the project's production. We look forward to presenting this work.

Authors:

Abstract Name: Flow and Stagnation: Integrating the Fluid Systems into Movement

Somatic practices are rooted in strengthening the mind-body connection, an aspect of deep awareness that all dancers and performers must have. Bartenieff FundamentalsSM emphasizes breath support, harmony, and efficient movement patterns, and facilitates expressive, functional movement (Bartenieff FundamentalsSM). As an extension of the world of Bartenieff FundamentalsSM, Bonnie Bainbridge Cohen's Body-Mind Centering is an "experimental study that provides body re-patterning and movement re-education" (Bainbridge Cohen). The topic being explored through Bainbridge Cohen's program is the fluid systems- blood, lymph, cerebrospinal fluid, and more. These fluids are essential to life because fluids carry nutrients and oxygen to cells, flush out waste products, regulate body temperature, and much more (Wergin). Each of these fluids has its rhythm to be examined. Inspired by Bonnie Bainbridge Cohen's work, I am developing warm-ups and improvisational prompts to get each specific fluid system flowing in their dancers' bodies. These prompts will explore how movement differs when we bring awareness to different parts of the body and we can sense a change when we focus on "moving from" the bones, muscles, organs, and fluid systems. During the creation of the piece I am choreographing, I am investigating ideas of flow and stagnation in relationship to our fluid systems. An example is using the contrast of interrupted and continuous movement phrases. The adaptability of fluid informs the dancer's formations and spatial patterns while the rhythms of each fluid inform the movement quality. For example, cerebrospinal fluid moves slowly versus lymph moving taut and directly. The purpose of this project is to create a visual representation of the human fluid systems through a collaborative choreographic process with dancers from my university. It is bringing the fields of dance, somatics, and anatomy together to guide the dancers and myself through a journey to strengthen the mind-body connection.

Authors:

Abstract Name: Political Spectacles: Royal Ceremonies in The Contemporary United Kingdom Versus The Qing Dynasty

This study compares and contrasts depictions of royal ceremonies in the contemporary United Kingdom and the Qing Dynasty. I will study art associated with royal coronations as a part of a royal spectacle which supports the royal ideology of power. I will demonstrate that while art produced in royal ceremonies were aesthetically different, the notion of coronation ceremonies shared certain characteristics: the sameness of place, time, spectacle, and objects. First, I will provide a brief introduction to the coronation as a political spectacle. Second, I will discuss the coronation of contemporary royals in the United Kingdom, followed by a discussion of the coronation of Yongzheng (1678-1735), the fifth emperor of the Qing Dynasty. A comparative conclusion will emphasize the similarities of their respective ceremonies, in likeness to their use of ceremonial clothing, processions of power, and use of religious ideology to support political power. This study is grounded in art historical research and primary sources, including formal and cultural meanings of artwork. The information provided within the study is vital because it emphasizes cross-cultural similarities as opposed to differences which are given the most attention in scholarship.

Abstract Name: The Perception of Tap Water Signals to Lack of Equity in the Water Sector Field

Despite popular belief that higher-income households produce higher bottled water consumption, research has shown that the opposite is true. Due to several varying factors, lower-income minority groups, specifically lower-income Latino groups, often reject their tap water and opt for bottled beverages instead. This has several negative impacts on these communities like increased spending, obesity, and inadequate fluoride access. This project aimed to determine if the perception of tap water amongst East Palo Alto residents, a majority low-income Latino community, signals issues with the quality of their tap water, creating tap water rejection. Using Python Pandas and Seaborn, we cleaned and analyzed survey data from 50 households to produce results about their tap water perception. Although the results signaled no correlation between their perception and tap water quality, they did signal the effects of an alarming lack of equity in the water sector field. To conclude, we proposed changes geared towards including equity in the water sector field, which we hope will encourage lower-income Latino groups and other marginalized groups to trust their tap water in the future.

Abstract Name: Convergence Guarantees for Particle Swarm Optimization

Particle swarm optimization (PSO) is a popular algorithm commonly used in state-of-the-art optimization toolboxes to tackle high-dimensional and non-convex problems, for which obtaining gradient information can be costly or infeasible. Meta-heuristics like PSO offer a powerful alternative to gradient-based methods and often converge to a global minimizer quite fast. However, since these meta-heuristics make very few assumptions on the function, they are difficult to prove convergence results for. In this work, we prove a novel convergence guarantee for PSO, enabling users to adaptively select optimal parameters in the algorithm. Systems involving ensembles of communicating agents, such as neurons in the brain or birds in a flock, are often modeled using differential equations that govern particle dynamics under mutual influences. For large numbers of particles, a mean-field approach is commonly employed to study average behaviors. While the standard PSO equations are not amenable to mean-field analysis, a related meta-heuristic, consensus-based optimization (CBO), allows for such an analysis and exhibits proven convergence. We present an equivalent convergence result for a modified PSO setting and demonstrate exponential convergence through numerical simulations, with tradeoffs in parameters of the initial distribution, the algorithm parameters, and the objective function itself. These results not only provide the first-ever

theoretical guarantees for PSO but also offer practical insights for parameter selection, supported by detailed numerical evidence for a variety of test functions.

Abstract Name: Managing Hospital-Acquired Infections in Older Adults: A Case Study Highlighting Nursing Interventions and Best Practices

IntroductionIn the United States, Hospital Acquired Infections (HAI) are a major cause of morbidity and mortality, leading to serious emotional, financial, and health repercussions. HAI are preventable infections that affect 1 in 31 patients with adults aged 65 years or older being at higher risk when compared to the general population.**Methods**This study employed a case study methodology to explore the dynamics and contextual conditions pertinent to HAI, nurse actions, and interventions. Using a case study involving an older adult who was discharged to home with three HAI and a narrative literature review, this paper describes and discusses the complexities associated with managing such infections in a vulnerable population. Literature from the past 14 years (2010 - 2024) from multidisciplinary databases was used and included studies focused on HAI and/or cross infections, older adults, and nurse(s) and/or nursing interventions.**Discussion**The use of a single case is not generalizable however, by employing this method, this study provides a nuanced understanding of HAI, nurse actions, and interventions specific to an older adult hospitalization.**Conclusion**HAIs are viewed as preventable patient events that stem from a variety of healthcare procedures that expose patients to infectious agents. In the case study, the HAI directly impacted the patient's discharge and led to admission at a long-term care facility. Nurses are distinctively positioned as providers of person-centered care to identify, assess, intervene with clear procedures, and outcomes monitoring to ensure that patients are protected from HAI. Promoting communication between all care providers, re-education on important prevention strategies, and following detailed care regimens are ways nurses may help lower the prevalence of HAI. Working together, nurses and healthcare staff can lead the way in the design and implementation of policies with procedures that allow for reduction and potential elimination of risk for HAI.

Abstract Name: Integrating Nutrition and Healthcare: Assessing the Implementation of Food as Medicine Programs

Chronic diseases, often exacerbated by poor nutrition and food insecurity, pose a growing public health challenge (Brown et al., 2019). Food as Medicine (FAM) programs address a patient's chronic health conditions and food needs through a holistic perspective of medicine. However, several research gaps remain in assessing the implementation of the FAM programs. This project evaluates the implementation of the FAM

programs, with a focus on participation retention, accessibility of medically tailored food packages through delivery services, and health-related outcomes. Program data, including clinical biometrics, participant testimonials, and feedback from healthcare partners and staff were collected on multiple cohorts. The project also reviewed key program components, including medically tailored groceries, mandatory medical nutrition therapy sessions, and weekly check-ins to assess their influence on participant engagement and retention. Preliminary observations suggest improved retention rates in recent cohorts, attributed to program modifications such as the introduction of in-person pickup experiences and enhanced communication strategies, suggesting that target modifications can improve effectiveness of the program. As chronic disease rates rise, integrating programs like FAM into healthcare can drive systemic change, highlighting the need for policy support and sustainable funding to expand nutrition-based healthcare interventions.

Abstract Name: Non-polar amino acids as cellular uptake moieties for peroxisome targeting fluorophores

Peroxisome Targeting Signals (PTS) are amino acid sequences that facilitate the import of molecules into peroxisomes. Given the inherently polar nature of PTSs, small molecule peroxisome fluorescent probes delivered to the peroxisome in live cells are limited to those which have nonpolar fluorophores. To address this issue, a less polar PTS is being synthesized to improve cell permeability. Presently, efforts are focused on modifying an amide with a medium length carbon chain. It is hypothesized that coupling the more hydrophobic amine to a PTS will improve enhance permeability while maintaining peroxisomal import. Current synthetic efforts to make these molecules will be presented including chemical characterization of products. Overall, this new approach should allow for the delivery of polar molecules into cells while maintaining the ability of the molecule to interact with biological targets.

Abstract Name: PREP for Transition: Evaluating a Transition Training with Ethiopian and Eritrean Parents of Children with IDD

As the diagnosis of special needs increases over time, so does the necessity for future planning. While many parents want to prepare for their child's future, a majority lack knowledge to navigate complex support systems. PREP for Transition was conducted to provide Ethiopian and Eritrean parents with information and resources their children need as they transition into adulthood by enhancing advocacy skills to develop

appropriate goals tailored to their child's specialized needs. This four-week culturally adapted intervention program was designed to increase parents' transition knowledge, advocacy skills, and social belonging for children with IDD. Partnering with a community organization, we created evaluation measures through recruitment procedures, curriculum adaptation, and interview protocols. Training sessions were conducted weekly for an hour, including the following topics: IEP goals in transition planning, postsecondary education opportunities, employment and living arrangements into adulthood, and reliable resources in the community. One month after completing PREP, parents were invited to share their experiences in hour-long interviews via Zoom. We will complete the interview analysis by March 2025 using grounded theory and thematic analysis. Of the 28 parents registered, an average of 21 parents attended each session with increasing attendance and registrations occurring. Post-session surveys indicate high levels of satisfaction with training on a week-to-week basis, reflecting an increased sense of "transition" community and strong advocacy skills to navigate the adult service system. PREP demonstrates the impact of mentor and peer support for parents of children with IDD. The feedback garnered provided insight into the persistent needs of the targeted communities through deep investigation that this research-practice partnership offered. Findings suggest while attendance and engagement were evident, more work needs to be done for parents to transition these skills into the educational systems for their children.

Abstract Name: Caste-specific Gene Expression in Eusocial Shrimp with Comparative Insights from Honeybees

Eusociality is a highly specialized social system offering significant insights into the mechanisms of evolutionary biology. Snapping shrimps, including *Synalpheus elizabethae*, exhibit complex eusocial structures, making them an ideal model for studying the ecological and genetic factors underlying eusociality. Their relatively recent evolutionary divergence from other non-eusocial species provides a unique opportunity to investigate the genetic mechanisms of eusocial behavior in aquatic environments. Here, we aimed to explore potential genetic differences between queen and worker *Synalpheus elizabethae* to better understand the genomic basis of eusocial behavior. The experiment utilized Differential Expression (DE) analysis to compare gene expression profiles between queens and workers. A comparative analysis of the Gene Ontology (GO) terms was performed, comparing *S. elizabethae* to GO terms that are enriched in queens in a well-studied eusocial species, *Apis mellifera* (western honeybee). We found that *S. elizabethae* queens had a higher expression on a distinct set of genes linked to reproductive processes, suggesting a genetic specialization that supports their role in colony reproduction. Conversely, the *S. elizabethae* workers expressed a different gene set related to the maintenance and non-reproductive roles held within the colony structure. *S. elizabethae* and *A. mellifera* queens exhibited no significant overlap in GO terms between differentially expressed genes except for the decreased expression in normal cellular function. This suggests that while both species share the complex social structure characteristic of eusocial organisms, the genetic underpinnings of their social behavior differ significantly. This study highlights the potential for significant evolutionary divergence in the genetic mechanisms that support eusocial behavior across different taxa.

Abstract Name: Alternative use of Animals-The Effect of Rabbit Manure and Urine

Agricultural researchers are investigating agronomic practices that lessen waste and prevent chemical runoff and pollution through organic methods. This project expands on research into the alternative use of animals by adding to the possible significance of the non-meat uses of rabbits. This research project evaluates rabbit manure as a fertilizer and fermented rabbit urine as a pesticide. As the rabbit urine in particular demonstrated control of squash borers, an alternative to synthetic insecticides, I argue that more in depth research should be taken along with some improvements that would help further research into the ethics of animal use and organic food production.

Abstract Name: Examining how mosquito presence and abundance varies across an urban-rural gradient in Nashville, TN, USA

Mosquitoes pose a public health risk in many cities because they are important vectors of infectious disease. In addition, there are some mosquito species that benefit in urbanized areas from high human presence and alteration of land. Despite this awareness of the public health risk associated with mosquitoes, for many geographic areas there is often limited information about which species are present and how this variation in species presence may impact disease risk. In this study, we set out to examine how the presence and abundance of mosquito species varied in three city parks that span a rural to urban gradient in Nashville, TN, USA. This study is of particular importance because Nashville, TN is a city with more than 2 million residents in the greater metropolitan area. Using this approach, we identified more than 1,500 mosquitoes and determined that mosquito presence and abundance varied spatially across three parks. In addition, we also found that the highest levels of diversity were in the most urban park and that at all three of our parks mosquitoes that are disease vectors made up more than 75% of all individuals found. Collectively, our findings indicate that mosquito presence and abundance varies across an urban-rural gradient and that exposure to disease-carrying mosquito species also varies spatially across the city.

Abstract Name: Utilizing eDNA to survey the Powell River for presence of Blotchside Logperch (*Percina burtoni*) for endangered mussel conservation.

The Powell River has historically contained some of the highest freshwater mussel diversity in the United States. Over the last 100 years, anthropogenic impacts have negatively influenced many aquatic faunal groups including mussels. The Cumberlandian Combshell (*Epioblasma brevidens*) is a federally endangered mussel species that is being reintroduced at sites in the Powell River of southwestern Virginia and northeastern Tennessee by the Virginia Department of Game and Inland Fisheries (VDGIF). Like many other mussel species, the Cumberlandian Combshell depends on specific host fishes, such as the Blotchside Logperch, to complete their life cycle. The goal of this project is to collect water samples for eDNA analysis to confirm presence of the Blotchside Logperch at sites important for the establishment of populations of the Cumberlandian Combshell mussel. This knowledge will help VDGIF in their reintroduction efforts by focusing on sites that allow more reproductive success. The results of this study can provide insight on successful management of two aquatic faunal species in need of conservation focus.

Abstract Name: Analysis of Synthetic Biodegradable Polymers and Their Blends for Medical Device Applications

Synthetic biodegradable polymers are used to provide physical structure in medical devices, release drugs during healing, and disappear over time, thereby reducing possible long-term negative effects. There are many synthetic biodegradable polymers, each having different attributes and biocompatibility. The goal of evaluating these polymers and their copolymers is to be able to customize physical and degradation properties for a particular medical device application. Aliphatic polyesters such as polyglycolide (PGA) and polylactide (PLA) are commonly used in medical devices. PGA is highly crystalline but its hydrophilic nature causes it to lose its mechanical strength relatively quickly, typically around two to four weeks after implantation. PLA has a high molecular weight and is more hydrophobic and therefore maintains its mechanical strength for a longer period of time. In attempts to combine the positive attributes of these polymers, researchers have created poly(lactide-co-glycolide) (PLGA), a copolymer that combines PLA and PGA. Unfortunately, PLA and PGA structures don't combine well and cause PLGA to degrade very quickly. Studying these compatible or incompatible qualities can help create polymers and copolymers that could be combined with more desirable traits such as improved mechanical strength, less acidic degradation products, and prevent undesired biological responses. Peer-reviewed scientific studies and observations were compared and analyzed to create an organized reference of the structure, degradation products, rate of degradation, and attributes of biodegradable polymers. The most desirable polymers will have qualities of high mechanical strength, capability of drug delivery, degradation products that have low or no toxicity, and good biocompatibility.

Abstract Name: Under Pressure: The Impact of Game Score on Performance in Men's Collegiate Tennis

Tennis is a sport defined by its unique scoring system, introducing psychological and strategic complexities at different score intervals. This is especially relevant at the collegiate level, where player performance is more variable than in the pro circuit. This study explores how scoring conditions influence the performance of men's collegiate tennis players, focusing on variations in performance when players are ahead, behind, or tied during games. Professional players on the ATP tour have long had access to similar data. Collegiate players, however, haven't been studied this way, providing a potential tactical advantage. For example, a player's performance when trailing 0-30 may differ significantly from their performance when leading 40-0. From collegiate tennis matches, I collected data at each score interval and analyzed point outcomes at various game scores, evaluating factors such as first-serve success rates and break-point conversions. The results revealed notable trends: players trailing in the score often adopt a more aggressive and resilient style, while players in a leading position may display reduced focus or risk-averse strategies. These findings suggest that game score directly impacts players' mental and tactical approaches, ultimately shaping match dynamics. This research illuminates tennis's psychological and strategic components, offering valuable insights for players, coaches, and analysts aiming to optimize performance under different scoring pressures. Understanding these patterns could lead to developing targeted training strategies, helping players manage high-stakes moments more effectively.

Abstract Name: Rescuing sustained attention capability in aged rats using a combined therapy of nicotinic acetylcholine receptor allosteric modulation and environmental enrichment after experimental brain trauma

Traumatic brain injury (TBI) is a leading cause of death and poses significant challenges for elderly populations, often exacerbating existing cognitive decline. Empirical evidence suggests disruptions in cholinergic neurotransmission following TBI may contribute to cognitive deficits. We predicted that parietal injury in aged (15-16 months old) male rats will augment sustained attention deficits compared to young adults. We then hypothesized that chronic NS-1738, a novel positive allosteric modulator (PAM) of the $\alpha 7$ nicotinic ACh receptor ($\alpha 7$ -NACHR) will improve sustained attention post-TBI in aged rats, alone and in combination with environmental enrichment (EE). Aged male rats were trained in the 3-choice serial reaction time task (3-CSRT) prior to injury and required more sessions to reach criterion than young adults. Following

a controlled cortical impact (CCI) of moderate severity to the right parietal lobe or sham injury, rats were randomized to daily NS-1738 (5 mg/kg) or vehicle, as well as daily EE (24h) or standard housing starting post-injury day (PID) 1. 3-CSRT retrials occurred on PID 17-27. Anxiety-like behavior was assessed via the open field test (OFT) on PID 28. Cortical lesion volumes were assessed post-sacrifice. Statistical analysis utilized repeated measures ANOVAs with Newman-Keuls post hoc tests. TBI-induced cognitive deficits were pronounced in aged rats ($p < 0.05$) and were rescued by chronic NS-1738 ($p < 0.05$). NS-1738+EE rendered an additive effect on restoring accuracy and lowering omissions ($p < 0.05$). TBI reduced OFT center exploration without reductions in ambulation ($p < 0.05$). NS-1738 and EE housing individually restored center exploration ($p < 0.05$). While both NS-1738 and EE rendered trends in reducing the extent of cavitation, the combined therapy was ineffective at promoting tissue preservation. Our findings reflect the vulnerability of the elderly following TBI and support benefits of $\alpha 7$ -NACHR PAM and/or EE treatment after experimental brain trauma on sustained attention through cholinergic neurotransmission.

Abstract Name: Wealth, Well-being, and Crisis: The Impact of Income on Mental Health Before and During the COVID-19 Pandemic in the U.S.

This study analyzes the relationship between income and mental health in the United States before and during the COVID-19 pandemic, which was characterized as both a health and economic crisis. During the pandemic, real GDP contracted by 32.9% in Q2 of 2020 and unemployment surged from 3.6% in late 2019 to 13.0% in mid 2020. Non-essential workers were required to stay home, and many were unable to contribute due to the inability to work remotely. Financial instability and social isolation during the pandemic exacerbated stress levels, uncertainty, and loneliness, adversely impacting mental health. Utilizing data from the 2019 and 2021 Panel Study of Income Dynamics (PSID), this study examines the link between family income across quintiles and mental health diagnoses, controlling for individual and household demographics. Additionally, state-level data on pandemic stringency measures in 2021 were incorporated to account for lockdown effects, which may have influenced mental health outcomes related to the pandemic and isolation. Preliminary findings show an increase in the percentage of individuals with mental health diagnoses from 12% in 2019 to 14% in 2021. While average income generally increased, the lowest quintile did not experience this improvement. In the zero-order model, all income groups exhibited significantly lower rates of mental health diagnoses than those in the lowest quintile. However, in the full model, only individuals in the top two income quintiles had significantly lower mental health diagnoses than those in the lowest quintile. Additionally, factors such as being female, white, non-Hispanic, young, unmarried, unemployed, non-religious, having higher than a bachelor's degree, being in an interreligious marriage, and living in urban areas were associated with a higher likelihood of mental health diagnoses. These findings can inform policymakers and healthcare professionals in addressing disparities in mental health during times of health and economic crises.

Abstract Name: Role of chemical neurotransmission on post-embryonic neuronal maturation in *Caenorhabditis elegans*

During postnatal nervous system development, neuronal circuits are strengthened and further refined, leading to various molecular and functional processes that elicit diverse behavioral outputs. Disruptions to these molecular and functional changes during postnatal neuronal development can lead to neurodevelopmental disorders during early development and neurodegenerative disorders during adulthood. Even so, much is unknown regarding what regulates these temporal changes during critical periods of postnatal neuronal maturation. One potential mechanism of regulation is through neuron-neuron communication, specifically chemical neurotransmission. Previous research has indicated that chemical neurotransmission is involved in development and that disruption in early development leads to behavioral impairments. However, the manner in which chemical neurotransmission plays a role in regulating postnatal nervous system development remains unclear, as well as the critical time period during postnatal maturation in which it acts. Considering this, we aimed to further understand the regulation of post-embryonic nervous system maturation in *Caenorhabditis elegans* by examining the effects of neuron-neuron communication. We utilized spatiotemporal neurogenetic tools, such as the Auxin Inducible Degradation (AID), that allow us to impair and restore protein function. We specifically targeted the UNC-13 protein, which plays a key role in the process of chemical neurotransmission, allowing for vesicle docking and fusion at the synaptic membrane. Worms were then recovered by the adulthood stage, and assessed for locomotive impairments using an automated, high-resolution worm-tracking system. We expect that inhibition of UNC-13 during post-embryonic development will result in locomotive behavioral defects during adulthood, indicating an impairment of post-embryonic neuronal maturation. Future directions for this research include narrowing down the critical time period of altered neurotransmission to finer developmental time periods as well as identifying specific molecular pathways that are activated by altered neurotransmission due to environmental changes.

Abstract Name: Machine Learning for Early Detection of Parkinson's Disease: Combining Speech and Motor Data to Develop Accurate, Multimodal Diagnostic Tools for Enhanced Healthcare Outcomes and Advancements in Neurodegenerative Disease Research

Introduction: Parkinson's disease is a progressive neurodegenerative disorder often diagnosed at advanced stages, limiting treatment effectiveness. Early detection is critical for improving patient outcomes, as it enables timely therapeutic strategies and slows disease progression. This research addresses a significant gap in healthcare diagnostics by employing machine learning to develop accurate, early-stage detection tools, integrating speech and motor features as predictive indicators. Objective: The study aims to develop and validate ML models capable of detecting Parkinson's disease in its early stages. The central research question is: Can machine learning effectively combine multimodal data, including speech and motor assessments, to improve early detection of Parkinson's disease? Methodology: The research utilized a dataset containing speech metrics (e.g., pause intervals, respiratory patterns) and motor assessments (e.g., tremor severity). Exploratory Data Analysis identified significant predictors, such as pause intervals and loudness, with dimensionality reduction techniques refining features to enhance model performance. Various ML

classification algorithms were evaluated using metrics like accuracy, sensitivity and ROC-AUC. Results: Preliminary results indicate ML models achieved sensitivity and specificity rates exceeding 90%, highlighting their reliability for early detection. Speech features such as pause intervals and respiratory patterns were the strongest predictors, while motor assessments showed moderate correlations. Combining multimodal data significantly improved accuracy over single-modality approaches. Dimensionality reduction reduced noise, enhancing robustness and focus on key features. Additionally, dimensionality reduction through PCA reduced noise and improved robustness, highlighting the importance of key features. These findings suggest that ML-driven multimodal diagnostics can capture subtle early symptoms, enabling earlier and more precise detection. Conclusion: The study demonstrates the transformative potential of ML-driven multimodal diagnostics for early detection of Parkinson's disease. These findings provide actionable insights for clinical applications and establish a foundation for integrating personalized monitoring systems. This research contributes to predictive healthcare, offering opportunities for advancements in neurodegenerative disease diagnostics and treatment strategies.

Abstract Name: Drivers of Firm Financial Performance among U.S. Restaurant Chains: The Role of Business Experience and Marketing Inputs

Franchising is an important business form that accounts for an estimated 806,270 franchise outlets and, in 2024, is expected to employ about 8.9 million people. Franchising is very prominent in the restaurant industry, being represented by 132,687 franchise restaurant chains across the United States. The existing literature demonstrates that degree of franchising, measured as the proportion of franchised units to total units, is positively related to financial performance, where more franchising is better for firm financial performance (Madanoglu et al., 2011). However, there is a scarcity of studies that investigate factors that influence chain-level success in terms of profitability, strength in franchising network, customer, and employee satisfaction. To fill one of these gaps, this project aims to examine the relationship between chain-specific characteristics and chain financial performance. The sample of this study consists of 73 restaurant franchising chains listed in FRANDATA, a major franchising data source in the United States. The observation period encompasses the 4-year period between 2016 and 2019, which makes up 274 firm-year observations. Proprietary data on chains such as system size, profitability, franchise fees, revenue etc. is obtained from FRANDATA, through an exclusive agreement. The dependent variable in this study is 3-year sales growth. Potential predictors are marketing inputs per store (marketing expense to number of stores) and business experience (years of experience before launching franchising). Both factors are expected to have a positive relationship with chain financial performance. The study controls system size, franchising proportion, and geographic dispersion as common determinants of firm financial performance. Multiple regression will be used to analyze data. This research study expects to determine which chain-specific factors influence financial performance. Findings can offer some insights to franchising firm executives in their efforts to understand how some controllable factors such as marketing inputs can impact financial performance.

Abstract Name: The Analysis of Marshallese Perceptions of Health and Weight in Adolescents

Purpose: The purpose of the research is to analyze and understand the perceptions of Marshallese adolescents on the topic of health and weight, in order to provide guidance for interventions and public health efforts. The United States has the largest Marshallese population outside the Marshall Islands. Perceptions of weight and health is under researched for minority communities and from the insight of adolescents. Pacific Islanders such as the Marshallese are often categorized as part of the larger Asian American ethnic population, which is not always accurate in certain aspects where public health could provide support areas of concern. **Design:** Focus groups of adolescents who identified as Marshallese from the ages of 10-17 were arranged into 2 groups based on age, 10-13 and 14-17 respectively. Respective groups participated in focus group discussion interviews (n=32) and then completing a survey (n=32) based on questions regarding health and obesity. Focus group discussion interviews were recorded and analyzed for themes. The survey results were recorded and analyzed. The interview and survey themes were compared and examined for correlations. **Results:** Common themes for an individual considered healthy included balanced diet and physical activity. Majority of adolescents that participated in the survey concluded they believed they were healthy (66%). When asked to categorize themselves, most participants (59%) categorized themselves as “slightly overweight”. The participants contributed many of the same factors to why an individual would be considered unhealthy to why an individual would be overweight. **Discussion:** Adolescents in the Marshallese community view weight as a proponent of overall health. Overall health was recognized as fluid due to many proponents such as exercise, diet, and hygiene effect health outcomes. To understand at what value of the BMI scale constitutes as unhealthy would further promote education.

Abstract Name: Using stable isotopes to examine nutrient uptake in harmful algal blooms

Harmful algal blooms (HABs) populate 160 countries and nearly every continent, where they wreak havoc on aquatic ecosystems and pose serious threats to human populations. HABs are a particularly persistent issue in western Lake Erie, where they are dominated by a strain of cyanobacteria, *Microcystis*. *Microcystis* produces

the toxin microcystin, which is responsible for turning these algal blooms into HABs. Microcystin is a nitrogen molecule. Excess nitrogen is carried into Lake Erie by runoff along the Maumee River. The river runs through long stretches of farmland where it accumulates nitrogen from fertilizer. This project aims to determine which forms of nitrogen Microcystis takes up most efficiently, in order to better understand the impact of the fertilizers that farmers employ. To do this, our lab grew whole water communities, containing Microcystis, from Lake Erie with different concentrations of various forms of nitrogen, ammonia, nitrate, and urea. NanoSIMS is then used to reveal how much nitrogen of each form the community members took up. Preliminary results indicate that Microcystis may modify their uptake of nitrogen depending on the bloom stage.

Abstract Name: A Lyrical Analysis of Addiction and Recovery Narratives in Popular Music

Background: Music has been recognized as a powerful tool in addressing substance use disorders and facilitating addiction recovery. Music therapy and music-based interventions are gaining traction as complementary approaches to traditional treatment modalities, reflecting the potential of music to resonate deeply with individuals' emotional and social experiences. This study examines how the addiction and recovery processes are portrayed in the lyrics of popular songs about addiction, exploring their potential influence on both public perception and individual recovery journeys. Objective: To identify recurring themes, patterns, and emotional tones within the lyrics of popular songs purported to be about addiction and recovery. By analyzing these narratives, the study seeks to understand their messages and their implications for addiction treatment and recovery support. Methods: We compiled a list of the most commonly indicated songs about addiction and recovery, based on systematic web searches including eighty-seven relevant websites. The top song was listed on thirty sites and the 51st song was listed on six sites. 316 lower-ranking songs were excluded to ensure feasibility of analysis. Two raters conducted a lyrical analysis using a codebook inductively developed to guide the evaluation of recurring themes. Inter-rater reliability checks ensured consistency in analysis. Results: Among the identified songs, 82% referenced mental health symptoms, 80% addressed social issues, 65% alluded to a specific substance, and approximately half mentioned physical symptoms associated with use or withdrawal. Nineteen (37%) referenced recovery or reducing substance use. Conclusions: Popular music often portrays addiction through a biopsychosocial lens, highlighting commonly relatable mental health and social issues. However, a notable gap exists in the representation of recovery processes, which may limit the utility of these songs as recovery aids. These findings suggest potential areas for enhancing the role of music in addiction treatment, including increased emphasis on recovery themes in music therapy contexts.

Abstract Name: Exploring the Association between Race-Related Vigilance and Anxiety

A heightened sense of vigilance is common during periods of intense anxiety and stress, and an established symptom for anxiety disorders including acute and post-traumatic stress disorder. A growing literature has explored race-related vigilance, the stress response to anticipated racial encounters. However, little research has explored the overlap between RRV and broader anxiety symptoms. In the present study we examined the relationship between race-related vigilance assessed using a measure developed by David Williams and trait anxiety and physiological symptoms as measured by the Spielberger Trait Anxiety Inventory and Beck Anxiety Inventory (BAI), respectively. Utilizing archival data, descriptive statistics and Pearson correlations were computed to assess the initial associations among study variables in, $n=149$ self-identified African American college students (60% women, $Mage = 19.95$, $SD=3.182$) recruited across three distinct institutional types (Historically Black Colleges and Universities, PWI, MSI). Race-related vigilance was positively associated with physiological symptoms of anxiety ($r = .187$, $p = .022$), but not trait anxiety ($r = .083$, $p = .310$). Institution 1 had the highest Race-Related vigilance ($M= 20.140$, $SD=4.494$), Institution 2 had the highest trait anxiety ($M= 49.93$, $SD=9.104$), and Institution 3 had the highest physiological symptoms ($M= 13.31$, $SD=9.039$). Notably, there is a stronger association between physiological symptoms of anxiety and race-related vigilance. These findings underscore the complex interplay between race-related vigilance, anxiety, and physical activity, highlighting the need for further research in this understudied population, particularly as African Americans are more likely to underreport symptoms in national surveys.

Abstract Name: Numerical Simulation of Jellyfish Swimming

Jellyfish are considered the most energetically efficient swimmers to have ever existed, so their propulsion method can be researched to improve our own underwater vehicle designs. These unique animals need to be very efficient because of their untraditional bodily components, and because most consume limited food as they prey passively while swimming. Jellyfish accomplish their efficiency through vortex propulsion. The contraction of a jellyfish's bell generates a vortex ring as it swims, which due to its axial symmetry we will simplify into two dimensions using two point vortices. We model these vortices using a system of differential equations, for which parameters can be selected to adjust their strength, location, and direction of rotation. To numerically solve the system, we use the fourth order Runge-Kutta method in MATLAB. The first goal of the project is to examine the jellyfish's propulsion and maneuvering mechanism, which involves creating simulations for various parameter values in the system of differential equations. Secondly, we study the material transport in the vicinity of jellyfish and its implication on food acquisition. Massless particles are inserted into the fluid flow to observe how the jellyfish and particles around it move through the water as affected by the vortices. To work towards these goals, we have implemented bell shapes to represent moon jellyfish, Pacific sea nettles, cannonball jellyfish, and lion's mane jellyfish to provide a breadth of bell shapes and sizes. Each of these bell shapes serve as a barrier to material transport, so the jellyfish can capture

particles from the surrounding environment. These results have significant implications for fields such as biomimetic engineering, such as improvements to sub-aquatic vehicle efficiency and reliability, especially in cases when speed is not a priority.

Abstract Name: Polymorph Characterization of the Antisickling Compound ILX-002

Sickle cell disease (SCD) is a genetic disorder arising from a single point mutation of glutamic acid to valine in the oxygen-carrying protein hemoglobin (Hb), leading to the formation of sickle Hb (HbS). Upon release of oxygen to tissue, the deoxygenated HbS polymerizes, resulting in sickling and hemolysis of red blood cells (RBC), inflammation, vaso-occlusive crisis, and multiple organ damage. Only the FDA-approved drug, hydroxyurea appears to be effective for treating SCD. The recently approved gene therapies for SCD, Casgevy and Lyfgenia are costly and inaccessible. Dr. Safo's group is developing a promising drug, ILX-002, that could potentially lead to a "functional cure" of SCD. This study was undertaken to obtain the best polymorph of ILX-002 for the upcoming clinical studies. ILX-002 was crystallized at either room temperature or 0oC using dichloromethane (DCM), ethyl acetate (EtOAc), methanol (MetOH), ethanol (EtOH), tetrahydrofuran (THF), and acetone. The crystal structures and melting points of the crystals were determined. The DCM, EtOAc, MetOH, and EtOH crystals obtained in RT resulted in one polymorph having the same space group (P21/n), cell parameters, and crystal packings. The acetone and THF crystals, also obtained in RT resulted in a second polymorph having the same space group (P21/c), cell parameters, and crystal packings. The crystals obtained at 0oC with EtOAc and EtOH resulted in the same polymorph as the corresponding RT crystals. All crystals showed similar melting point values (123.5-124.5oC). Interestingly, the two polymorphs showed notable similarities in their crystal packings, explaining the similarities in their melting points. Our results indicate that ILX-002 likely exists in two polymorphs. Still, irrespective of the solvents or crystallization temperature, the polymorphs appear to have similar chemical and physical stabilities, suggesting that any of the solvents can be used to prepare the final drug for clinical studies.

Abstract Name: Investigating the Effect of pH on Alpha Acid Isomerization Rates in Beer: An Inquiry-Based Analytical Chemistry Approach

Inquiry-based projects in analytical chemistry courses at UW-Madison simulate the research experience. Fall 2024 semester's research project focused on determining the isomerization rate and order of alpha acids for controlling the bitterness of beer and understanding the brewing process. Using a recent literature article as reference, students developed a modified control procedure that accounted for the alpha acid source,

equipment available and proposed a variable to introduce or change to test a hypothesis. Our group hypothesized that a more basic pH (5.5 vs. 5.2) would increase the isomerization rate. Ultra-high-performance liquid chromatography (uHPLC) was used to determine the iso-alpha acid concentrations and monitor changes over time. A filtered (n=7) control data set (i.e., replicates from other groups completing the control procedure) was compared to data from the literature article for statistical analysis of alpha acids cohumulone and N-adhumulone. Cohumulone (0.098 ± 0.018 mg) and N-adhumulone (0.0064 ± 0.0020 mg) were both found to be statistically different from what was found in the literature (0.01141, $t_{calc} > t_{table}$ at 95% confidence level). The rate order for cohumulone was consistent with the literature (first-order), while N-adhumulone showed an inconsistent result, a zero-order rate constant. For the variable data, the cohumulone (0.09897 ± 0.01952 mg, first order) showed no statistical change in their rate constant, but N-adhumulone (0.005694 ± 0.003124 mg, zeroth order) was observed to be statistically different due to pH change. We concluded that the hypothesis that a more basic pH (5.5) increases the isomerization rate was supported for cohumulone but not N-adhumulone. This suggests that pH affects the isomerization rate for some, but not all, alpha acids. Future research could explore a broader range of pH values, and consider additional factors such as temperature and time, to determine optimal conditions for isomerization in beer.

Abstract Name: Comparison of Lactate Response to Perceived Stress

Lactate is an acid produced as a byproduct of anaerobic glycolysis, and is used as an energy source for metabolism in the oxidative system. Initially classified as a waste product of cellular metabolism and a primary source of fatigue during exercise, lactate has recently been shown to play a large role in a number of vital physiological processes. Clinically, lactate has now been shown to interact with autonomic nervous system (ANS), and may be a valuable measure in diagnosing severity of disease. Commonly measured during exercise testing, lactate levels can provide vital information into an individual's exercise capacity. Currently, no research has been conducted examining the relationship between resting blood lactate (BL) and ANS activity relating to exercise. The purpose of this study is to 1) determine the relationship between resting BL levels and ANS activity, and 2) investigate potential differences in resting BL measures between sedentary and well-trained individuals following a stressor. A minimum of twenty participants (10 sedentary and 10 well-trained) will complete 2 trials separated by a minimum of 24-hours. On the first visit participants will be informed they will not be performing exercise and will only be measured for resting values of heart rate variability (HRV) and BL. On the second trial participants will incur a stressor by being made to believe they will be performing a maximal graded exercise test. Following the perceived stressor, researchers will collect resting HRV and BL measures. Statistical analysis will be used to determine differences between the groups and trials. Data collection will be complete prior to the NCUR 2025. Results of this study may serve to inform researchers of the mechanism responsible for potential differences in resting BL levels as well as determine if resting BL may be able to serve as an accurate indicator of ANS activity.

Abstract Name: Optimization of Natural Fiber Prosthetic Socket Manufacturing Method for Sierra Leone

Less than 10% of patients globally have access to orthotic and prosthetic medical care, and thus have barriers to managing the effects of their disability and to maximizing their mobility. For prosthesis users, the prosthetic socket, the interface between the residual and prosthetic limb, is the most critical component of the device to maintain. The socket requires frequent adjustments and replacement to ensure the health of the residual limb and painless ambulation. Sockets are typically made from carbon-fiber mesh, supported by acrylic resins. Acquiring materials to fabricate carbon-fiber sockets— “the gold standard of care”—is logistically difficult and prohibitively expensive in locations like Sierra Leone, West Africa. Research studies by Nigerian scientists proved the feasibility of using natural fibers from locally-grown plants, like banana trees, as carbon-fiber alternatives to produce natural fiber prosthetic sockets for use in similar environments. However, data on clinical safety of these sockets and guides informing fabrication processes for clinicians are limited. Therefore, this project aims to optimize a step-by-step manufacturing method for fabricating natural fiber sockets including material testing, fabrication, and mechanical testing at MIT, in a simulated tropical environment, and in Sierra Leone, followed by clinical trials. Chemical and manual extraction methods were tested, with a combination of water retting and 5% NaOH solution providing the optimal result. Mechanical testing has ensured that the natural fibers equate to carbon fiber in terms of characteristics like tensile strength and bendability. The preliminary results are promising and indicate the potential for adoption in numerous limited resource environments, thus improving the prosthetic management of care post-amputation and enabling mobility for patients who benefit from this innovation.

Abstract Name: Comparing the Effects of Human Fitspiration, Anime-themed Fitspiration, and Body Image Flexibility Quotes on State Body Image, Mood, and Exercise Motivation in Young Adult Men

Social media is recognized as a risk factor for body image disturbances for women, while men remain understudied yet are increasingly recognized as impacted by body image concerns, particularly with growing research surrounding the muscular ideal. Beyond gender, body image is nuanced by sexuality, hence gay and bisexual men tend to have greater body image disturbances, including muscularity concerns relative to their heterosexual counterparts. Fitspiration has become a popular trend on social media, whose creators often claim to be promoting exercise motivation but has been empirically found to pose health risks in the context of body image. A primary mechanism for conferring this risk is appearance comparisons, especially to idealized bodies often seen in fitspiration. Within fitspiration, anime characters have recently emerged as contemporary mainstream media targets for comparison, often in the form of physical appearance goals. The proliferation of anime fitspiration content raises new public health concerns given characters are often portrayed with exaggerated, cartoonish physiques, performing impossible feats of strength. Alternatively, body image flexibility may represent a possible strategy to motivate exercise that does not simultaneously confer a detrimental impact on body image and mood relative to both traditional human fitspiration and modern anime fitspiration social media content. This is because body image flexibility encourages individuals to openly accept challenges to their body image, without trying to change the thoughts or feelings that arise in

the service of moving in valued life directions. The present study will expose young adult men to one of four image conditions: human-based fitspiration, anime fitspiration, body image flexibility quotes, or a control condition to examine the differential effects of viewing this content on body image satisfaction, mood, and exercise motivation. An exploratory aim is to provide a preliminary evaluation of whether sexual orientation further moderates the hypothesized effects.

Abstract Name: The Effects of Alcohol-Related Scenes on Driving Performance and Attention

PURPOSE: The combination of distracted driving and alcohol administration can dramatically impair one's driving performance (Van Dyke & Fillmore, 2015). These distractions can be greatly influenced by our attentional bias; alcoholic cues and stimuli capture more attention and can be an inhibitor of cognitive performance (Qureshi et. al, 2018; Weafer & Fillmore, 2012). The aim of the study is to investigate if alcohol-related scenes affect driving performance. **PROCEDURE:** Preliminary participants (ages 18-22, N=48; 54% male, 87.5% Caucasian) have completed the study. Self-reported measures of quantity and frequency of alcohol use, and problematic consumption (DDQ-R, Collins, Marks & Marlat, 1985, AUDIT-C, Suanders et al., 1993, SIP-R, Kiluk et al., 2013) were assessed. Participants completed a behavioral cued go/no-go task, and a driving simulator task which utilizes eye-tracking equipment.

RESULTS: Preliminary data analysis on self-report measures did show a positive relationship between SIP-R and AUDIT-C, N=48, $r=.295$, $p<.05$. Participants took 12 minutes to complete the driving simulator task and on average went under the given speed limit 6.86 times (SD=3.98, and range of 0-18) and over the given speed limit 4.28 times (SD=3.37, and range of 0-14). Further analysis on the preliminary data shows that there's no significant relationship between AUDIT-C and driving performance at $p=.68$. **IMPLICATIONS:** Preliminary findings of this ongoing study support the possibility of data collection during multi-method use of driving simulation and eye tracking. Further analyses of this ongoing study will further address the effects of self-reported alcohol use and driving performance in alcohol versus control scenes. Preference for alcohol related scenes via eye tracking and effect on driving performance will also be assessed.

Abstract Name: Sex Differences in Fixational Eye Movements following Concussion

Fixational eye movements (FEMS), small ($\leq 1^\circ$) motions of the eye that occur during periods of stable fixation, have shown promise for detecting ocular dysfunction post-concussion. However, the diagnostic and prognostic utility of FEMS for concussion has not been systematically investigated between males and females. Here, we investigated if FEMS differ between the sexes in a group of patients in the acute-to-subacute period following concussion (≤ 21 days) and age- and sex-matched healthy controls. Eye movements were recorded using a retinal image-based eye tracking device: a tracking scanning laser ophthalmoscope (TSLO). Participants performed two fixation tasks for 30s: 1) a center task in which they fixated on the center of the imaging raster and 2) a corner task in which they fixated on the corner of the raster. On the center task, concussion patients made significantly larger amplitude fixational saccades than controls, consistent with previous studies. However, we also found that females made significantly larger fixational saccades than males on this task. No significant difference in fixational saccade amplitude was found between concussion patients and controls or between males and females on the corner task. Finally, no significant between-group differences in fixational saccade direction were found on the center task. However, on the corner task, females made a higher proportion of oblique fixational saccades and a lower proportion of horizontal fixational saccades than males. Although these findings support previous work showing that FEMS may provide an objective measure of ocular dysfunction following concussion, they suggest that care needs to be taken to control for sex-specific differences. Future research is needed to investigate if the diagnostic and prognostic utility of FEMS can be improved by establishing pre-season FEMS measurements and allowing athletes to serve as their own controls.

Abstract Name: "I was able to see what science was": Assessing the Impact of Course-based Undergraduate Research Experiences on First-Generation and Low-Income Students

Undergraduate research is lauded as one of the most impactful experiences for students across different fields. Research indicates that undergraduate research participation increases retention within STEM, increases graduation rates, and decreases equity gaps. Unfortunately, students from various backgrounds and with different identities have unequal access to these educational experiences outside of the classroom. In the past 20 years, course-based undergraduate research experiences (CUREs) have emerged as one of the leading solutions to increase access to undergraduate research in the sciences. However, it is not well-known what impacts CUREs may have on first-generation and low-income (FGLI) students, though they are among the most impacted by financial and personal barriers to participation in traditional undergraduate research. This is due in part to the difficulty of ascertaining socioeconomic status for students. To address this gap, we have designed a pre- and post-survey to assess student gains in relation to their identities. In our analysis, we look at both the traditional measure of low-income status, Pell grant eligible students, as well as students working more than 20 hours per week during the academic year. Student gains are self-reported on Likert scales. Demographics were collected at the pre-survey and matched with post-survey responses ($n = 142$ paired responses). We use paired t-tests to assess within group gains and two-sample t-tests to assess between group

differences at the pre- and post-survey. We find that all students, regardless of demographic, reported significant gains across measures of cognitive and affective skills necessary for performing authentic, novel research. This suggests that CUREs are equally effective in promoting positive outcomes for FGLI students as they are for their non-FGLI peers, reaffirming the utility of CUREs in leveling the playing field in undergraduate research opportunities.

Abstract Name: Threads of Empowerment: Fashion Autonomy in Transforming Emotions and Social Dynamics Across Social Classes

Fashion autonomy plays a significant role in stimulating positive emotions across different social classes by serving as a powerful medium of self-expression, identity formation, and emotional resilience. Once primarily functional, clothing has evolved into a sophisticated tool for conveying individuality, beliefs, and emotional states. This transformation underscores the ways autonomy in fashion fosters positive emotions and shapes its role within the broader social scene, thus highlighting the deeper inquiry of how autonomy within fashion amongst different social classes stimulates positive emotions, and what role they essentially play across the social scene? The democratization of fashion—bolstered by the rise of social media—has granted people from various socioeconomic backgrounds greater access to trends and the freedom to assert their individuality. This shift challenges traditional class-based fashion norms, encouraging the creation of unique styles that transcend social hierarchies. Fashion autonomy is especially meaningful for women, who have historically been constrained by societal expectations surrounding appearance. By leveraging fashion as a means of self-expression, women across social classes were able to redefine boundaries, build confidence, and achieve emotional empowerment. Additionally, social media platforms have provided marginalized groups with opportunities to celebrate individuality, fostering inclusive digital spaces that recognize and support diverse identities. These platforms amplify the emotional rewards of fashion autonomy by enabling connection, style sharing, and solidarity, ultimately nurturing collective pride, hope, and resilience. Ultimately, the role of fashion autonomy in bridging social divides, promoting individual empowerment, and enhancing emotional well-being is essential in understanding how clothing choices shape identities, influence social dynamics, and contribute to the overall emotional landscape of society.

Abstract Name: High Fat Diet Alters Gut Microbiota Composition in Transgenic F344-AD Female Rats: Insights from Microbiome Analysis

Alzheimer's disease (AD) is a neurodegenerative disease that causes a progressive decline in memory, thought, language, and behavior in patients. The risk factors for AD include age, obesity, and diabetes which alter how AD progresses in the brain. Diet plays an important role in inducing obesity and generating diabetic effects that promote neuropathologies. Our lab explores the effects of High Fat Diet (HFD) on the microbiome of transgenic (Tg) rats that were co-injected with two human genes known to cause early-onset AD when mutated: amyloid precursor protein (APP) and presenilins 1 (PS1). The Western diet consists of approximately 40% fat from sources such as red meat and processed food which emphasize the significance of HFD related research on the progression of diseases like AD. The gut-brain axis, a network of nerves and

signals that allow the gut and brain to communicate bidirectionally, explains how diet might influence the microbiota in the gut and how that will impact cognitive health and motor function. Our lab used 16s rRNA sequencing data from the UAB Microbiome Resource as well as QIIME to measure metrics related to the microbiome: alpha and beta diversity. While there were no differences in the Alpha diversity between the samples, the Beta diversity was significantly different between them. ANCOM-BC analysis showed an enrichment of phylum Firmicutes, order RF32, and family Lachnospiraceae in Tg female rats. Tg rats had depleted levels of the bacteria order Clostridiales, family GZKB119, and family Alcaligenaceae. Through an analysis of the microbiome of wildtype (Wt) and Tg female rat models, we aim to define the role microbiome plays in the development of neuropathologies, particularly with regards to AD progression.

Abstract Name: The Correlation Between Perfectionism, Social Anxiety, and Fear of Failure in College Students

This study investigated the relationship between perfectionism, social anxiety, and fear of failure in college students. Previous literature revealed positive correlations between these three variables. For example, a significant relationship between perfectionism and social anxiety has been found; specifically a positive correlation between the two. Furthermore, perfectionism has been found to have a positive correlation between fear of failure. Previous literature has also revealed a positive correlation between fear of failure and social anxiety. Based on this previous literature, the following hypotheses were proposed. There is a positive correlation between perfectionism and social anxiety; there is a positive correlation between perfectionism and fear of failure; and there is a positive correlation between social anxiety and fear of failure. To test these hypotheses, the Frost Multidimensional Perfectionism Scale (FMPS), the Social Anxiety Scale for Adolescents (SAS-A), and the Performance Failure Appraisal Inventory – Revised (PFAI) were administered. Eighty-nine (N = 89) undergraduate students participated in this study. The participants were students of all classifications from fine arts, science, and psychology classes. Upon IRB approval and permission from the professor, instrument packets and consent forms were administered in classrooms. Participation was voluntary and confidential. The collected data was analyzed by a correlational analysis using SPSS software. It was found that perfectionism and social anxiety were positively correlated at a significant level ($r = .394, p \leq .001$ one-tailed), perfectionism and fear of failure were positively correlated at a significant level ($r = .549, p \leq .001$ one-tailed.), and fear of failure and social anxiety were positively correlated at a significant level ($r = .576, p \leq .001$ one-tailed). One limitation to the study was a lack of gender diversity.

Abstract Name: The Qualitative Study to Explore the Foundations of Teacher Self-Efficacy Reported by the Education Majors at a Mid-size Midwestern University

Self-efficacy is a sense of an individual's ability to complete a task proficiently and successfully. High self-efficacy also contributes to teachers' approaches to instruction, resulting in positive attitudes towards inclusion, better work attitudes, and more effective student-related decision-making. Studies show that higher self-efficacy among educators is associated with better student outcomes; however, quantitative studies on students' self-efficacy are subject to the criticism on their inconsistent measures of self-efficacy across the studies; as a result, such developmental mechanisms are often analyzed in silos, lacking the comprehensive thematic connections to synthesize on how individuals build their foundation in self-efficacy in education setting. This research project attempts to explore how graduate students within education majors foster their personal self-efficacy as it relates to their teaching career. The subjects will include graduate students who are enrolled in the graduate-level teacher licensure programs at Minnesota State University, Mankato. Qualtrics survey will be used to collect responses on open-ended questions which ask their foundation of self-efficacy relating to their teaching. The thematic analysis will be conducted through the steps including: familiarization with data, initial coding, theme generation, focused code creation, and data organization. The research will show roles of external and internal factors contributing to the development of self-efficacy among education graduate students, positively or negatively. The findings from this inductive research will inform professionals in the field on the significance of self-efficacy among teachers and suggest specific implementation of policies and plans to redesign the teacher education curriculum. After analysis, professionals can use the information given on how educators within the educational system fostered their self-efficacy to be able to recreate that for their students within the classroom. This may also allow professionals to reflect on their own self-efficacy and their journey on how their self-efficacy has been fostered.

Abstract Name: Enhancing Microneedle Drug Delivery Efficiency Through the Inclusion of Microchannels: A 3D-Printed Design Approach

Efficient and precise drug delivery is crucial for improving treatment outcomes in skin cancer and other localized therapies. Traditional methods often face challenges like imprecise dosing, uneven distribution, and patient discomfort. Advances in 3D printing offer a transformative solution, enabling intricate drug delivery system designs with precise control over features like size and geometry. Microneedle arrays have demonstrated success in drug delivery, but there is still a lack of data on how design modifications impact the efficiency and distribution of therapeutic agents. This study investigates the feasibility of 3D-printed microneedle array designs with integrated microchannels. By evaluating the fidelity of these designs and analyzing their impact on factors like release speed and drug mass loss, we aim to reveal how variations in features such as channel curvature and surface area affect drug uptake, release, and diffusivity. Microneedle array-based devices were fabricated using high-resolution stereolithography. Twelve designs were compared based on characteristics like connectivity and channel tortuosity. Drug delivery performance was tested in an in vitro model to validate administration efficiency. We hypothesize that the addition of microchannels and feature variations will improve drug release rates. However, we recognize that these features may introduce challenges, like unintended drug loss. Expected results will provide insights into whether microchannel incorporation optimizes localized drug delivery while identifying strategies to address any potential

drawbacks, offering a pathway for improvement. This study will help improve microneedle-based drug delivery systems for targeted medical treatments. Through design changes, we hope to improve the effectiveness and usability of the microneedle-based platforms. Furthermore, the study highlights 3D printing as a precise manufacturing method capable of producing intricate microfeatures, enabling complex designs that are otherwise difficult to achieve with traditional manufacturing methods.

Abstract Name: Weaponizing motherhood to further fascism: the Nazi party and modern far-right in Germany

This presentation analyzes propaganda from the National Socialist German Workers party (NSDAP), known as the Nazi party. Visual propaganda also is analyzed from the Alternative für Deutschland party (AfD). Specially, the purpose of this research is to compare the depictions of motherhood in the propaganda and how that further the beliefs of both parties. For this presentation, 25 resources were studied – which includes written articles and published propaganda from both parties. However, none of the resources focus on motherhood in propaganda, which this research does. The propaganda published by the NSDAP comes from illustrations in the party's magazine and mostly from the late 1930s. The propaganda for the modern far right AfD comes from campaign posters from the 2017 parliament election in Germany. To compare the propaganda, similar propaganda from both parties will be placed and compared visually. When looking at the illustrations published by the NSDAP, which was mostly viewed by members of the party, there is a specific picture of family. Every example of NSDAP propaganda depicts a healthy looking all white family with a mother and father. This is because of the Nazi belief that there should be one white German race. Also, the researched articles state motherhood was the highest role for women in Nazi Germany. The campaign posters published by the AfD, which in public have the same physical image of family as the NSDAP. Also, the AfD is known for having a fear of Germany becoming "more Muslim". This demonstrates how both parties fear demographic change which is rooted in white supremacy. This presentation argues that when looking at propaganda, motherhood is important concept to look for, this can be demonstrated by the Nazi party and AfD having similar depictions of motherhood to further white nationalism by valuing the childbearing of white women.

Abstract Name: Effects of Opioid Antagonist, Naloxone, on GnRH Release in Prepubertal and Pubertal Monkeys

Gonadotropin-releasing hormone (GnRH) in the hypothalamus plays a crucial role in reproductive function by regulating the release of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) from the anterior pituitary gland. In adult animals, the removal of the gonads (gonadectomy) leads to an increase in GnRH, LH, and FSH, as gonadal steroid hormones suppress the release of these hormones. However, in

prepubertal animals which are known to have the capability of GnRH, LH, and FSH release, gonadectomy does not cause an increase in GnRH, LH, and FSH release. This suggests the presence of an inhibitory mechanism in the hypothalamus at the prepubertal stage of animals. In the study, we investigated the possible role of opioid neurons in regulation of GnRH release during the prepubertal period by performing in vivo microdialysis experiments. To block the activity of opioid neurons, we infused naloxone, an opioid antagonist, at 10nM concentration, to the median eminence of the hypothalamus every 3 hours, while microdialysates were continuously collected for 12 hours at 20 minute intervals. GnRH levels in microdialysate samples were measured by radioimmunoassay. Results indicated that the prepubertal monkeys had a baseline level of 2.5 ± 1.6 pg/mL (Mean $\pm$ SEM, n=4) GnRH concentration, significantly increased to 8.0 ± 3.1 pg/mL after naloxone infusion ($p < 0.05$), and returning to 2.1 ± 1.2 pg/mL during recovery after challenge. In contrast, the pubertal primates had baseline levels of 7.3 ± 3.3 pg/mL (n=7) GnRH concentration, decreased to 5.8 ± 2.3 pg/mL after naloxone, and then returned to 4.2 ± 1.9 pg/mL during recovery. These results indicate naloxone significantly stimulated GnRH release in prepubertal monkeys, but not in pubertal monkeys, suggesting that opioid neurotransmitters may contribute to the suppression of GnRH release before puberty.

Abstract Name: A polymorphic dinucleotide repeat in the human relaxin (RLN2) promoter affects transcription levels in vitro

One in ten infants born in the United States is affected by preterm birth, which is also the leading cause of infant mortality and morbidity worldwide. Several factors contribute to susceptibility, but higher levels of the relaxin peptide hormone later in pregnancy may contribute to the premature rupture of the membrane that occurs prior to preterm birth. Relaxin's primary function is to loosen ligaments in the pelvis and soften cervical tissue in preparation for labor. Previous studies identified an association between alleles at a single nucleotide polymorphism in the promoter region of the relaxin gene (RLN2) and serum levels of relaxin. We hypothesize that variation in the length/composition of a (CT) n (GT) m compound microsatellite within the RLN2 promoter will affect levels of relaxin. To test our hypothesis, we amplified the ~1kb upstream promoter region from four different genotyped human DNA samples, ligated the products into a luciferase reporter vector, and transfected them into a human placental cell line and an ovarian cell line to quantify transcription in vitro. DNA sequencing confirmed the promoter alleles contained 23, 28, 33, and 36 dinucleotide repeat units. Additional controls included a promoterless luciferase reporter vector and the RLN2 promoter with the dinucleotide repeats excised by site-directed mutagenesis. Luciferase reporter assays indicated that all human alleles drove transcription greater than the promoterless control. One-way ANOVA testing identified significant differences in transcription levels among human alleles, with the 33-repeat allele consistently showing the lowest expression levels in both cell lines. These results will be discussed in light of human genetic variation at RLN2 and susceptibility to preterm birth.

Abstract Name: Modulating Neutrophil JAK/STAT Pathways: Impacts on Brain Anatomy in a 3xTg Alzheimer's Disease Model

Alzheimer's disease (AD) is a progressive neurodegenerative disorder affecting approximately seven million Americans. It is marked by hyperphosphorylated-Tau, amyloid-beta aggregation, and cognitive decline. As the disease progresses, changes are observed in the brain, including brain volume, cortical thickness reduction, and ventricular enlargement. Recent evidence has implicated the role of the peripheral immune system in AD pathology. Neutrophils are the most abundant peripheral immune cell. In this project, various studies show that neutrophils infiltration in AD leads to poor cognitive performance. In our lab, we are interested in understanding how neutrophil activity and recruitment, through JAK/STAT activation, contribute to this pathology. Our preliminary data show that JAK2 activation plays a role in neutrophil migration. Therefore, we hypothesize that changing JAK2 activity, upregulation and downregulation, in neutrophils will change (increase and decrease, respectively) brain morphological changes associated with AD pathology. To test this hypothesis, we generated AD mice with overactive JAK2 or non-functional STAT3 (intracellular effector of JAK2) in neutrophils. Monthly whole brain, cortex, and ventricle volume were assessed using a small animal MRI. Preliminary findings show that JAK2 overactivation in neutrophils alters brain anatomy in a sex-specific manner. AD female mice with either overactive JAK2 or deficient STAT3 neutrophils maintain their whole brain volumes through disease progression. Specifically, volumes stay similar to wildtype controls and never decrease as observed in AD controls. These results suggest neutrophil activation, through JAK2 signaling, influences AD pathology in a sex-dependent manner.

Abstract Name: Effects of Tributyltin Exposure on Expression of Insulin-Degrading Enzyme and Amyloid Precursor Protein in a Transgenerational Mouse Model

Type 2 diabetes, which is linked to a downregulation in insulin-degrading enzyme (Ide), and Alzheimer's disease, which is characterized by increased expression of amyloid precursor protein (App) in the brain, have increased significantly over the last few decades and have become some of the most salient diseases worldwide. This project attempts to answer the question "Is there an association between TBT exposure and expression of Ide and amyloid precursor protein?", by first assessing beta-amyloid plaque formation in the brains of transgenerational mice with chronically decreased levels of Ide in their livers due to long-term consumption of a high-fat diet. The brains of these transgenerational mice were stained with an anti-amyloid beta antibody and with Thioflavin S to visualize amyloid beta plaques, both of which resulted in no visible signal. qPCR was performed on these brains and showed no significance in gene expression of Ide between male control and TBT mice as well as an increase in App expression in TBT mice. There was no significant difference in Ide or App between female DMSO and female TBT mice or for App in male mice between diet conditions. This project suggests that TBT exposure is associated with the upregulation of App in the brains of transgenerationally exposed mice, although a possible mechanism for this upregulation, downregulation of Ide, cannot be argued.

Abstract Name: Conserved domains in promoters of differentially expressed genes: How to find them and what can they tell us?

The complex process of regulating gene expression involves a large number of cis- and trans-acting components. The cis elements also referred to as cis regulatory elements (CREs) are highly conserved across species, and are often referred to as conserved domains mainly located in the promoters of genes. The trans acting sequences such as enhancers, moderators and insulators are also crucial in the regulation of gene expression. With an increased influx of genomic and transcriptomic data, study of differentially expressed genes (DEGs) is highly effective in understanding genes that are either up- or down-regulated in response to a given treatment or stress condition as compared to the controls. In this case, a key step in understanding gene regulation involves identification of CREs in promoters of differentially expressed genes (DEGs) and examine shared patterns among those genes. In this paper, we will discuss the use of probing promoter regions of DEGs for conserved domains and their use in regulation of gene expression.

Abstract Name: Identification of Regulatory Roles for Stress Responsive Transposable Elements in Rice

Transposable elements (TEs) are widely known for their structural and functional roles in the rice genome. They can be activated in response to various biotic and abiotic stresses. As the global temperatures rise, heat stress threatens crop production worldwide by affecting grain quality and yield. Concern for food security amidst a growing population warrants development of novel methods to study regulation of gene expression in response to heat stress. Two japonica rice varieties, Cypress and LaGrue, perform well and poorly, respectively, under high night temperatures (HNT) based on their ability to withstand heat stress during growth and development. Using these contrasting genotypes and their varied response to HNT conditions, we designed this study with an objective to understand how transcriptionally active TEs affect gene expression. Total RNA was sequenced from caryopsis tissues at R6 stage under HNT ($82.4 \pm 1^\circ\text{F}$) and control ($72 \pm 1^\circ\text{F}$) conditions. The data was analyzed to identify Differentially Expressed Transposable Elements (DETs) at $\log_2\text{FC} \geq 1$ and $\text{padj} \leq 0.05$. We identified 139 transposons that are differentially expressed (up- or down-regulated) between the HNT and control conditions in Cypress and LaGrue, of which 77 were differentially expressed in a Genotype x Environment manner, suggesting a genotype-dependent response to

stress. Additionally, we identified 91 GaTEs (Genes Associated with Transposable Elements) based on their genomic locations. A comprehensive genomic analysis is underway to determine the regulatory roles of DETs in gene function, and to explore the epigenetic regulation of TEs and its effect on neighboring genes.

Abstract Name: Domain knowledge synthesis for AI-based predictive modeling in rice cultivation

As the population increases and global temperatures are on the rise, farmers are facing an agricultural crisis. It is, therefore, critical that today's agricultural practices are efficient, reliable, and sustainable. Rice, the foundation of the international diet, is negatively impacted by heat stress resulting in poor grain quality and declined yield. Research has pointed to Artificial Intelligence (AI) as a plausible solution to lessen the threat of food insecurity by implementing AI-based predictive modeling in the cultivation of rice. Precision Agriculture is the practice of agriculture using AI such as automation and predictive analytics to increase crop production and facilitate disease detection and diagnostics. This study compiles and curates a comprehensive and exhaustive list of features that will synthesize domain knowledge to facilitate predictive model development. These features include but are not limited to the availability of heterogeneous datasets such as phenotypic and genotypic data, data on agronomic practices, multi-omics data integration, epigenetic modifications, regulatory elements, Gene Regulatory Networks (GRNs) etc. This will help in feature engineering, data transformation and guide questions on the cost-benefit assessment of each added feature, with the objective to develop predictive algorithms with enhanced accuracy and applicability in agriculture. Additionally, AI coupled with the state-of-the-art genomics and sequencing technologies enables a well-informed choice of algorithm for predictive modeling of agricultural data. This allows the models to make informed and effective decisions about agricultural processes, such as gene regulation, yield prediction, forecasting of pest infestation, irrigation needs, and disease detection.

Abstract Name: Determining the Effects of Ankle Fatigue on Gymnasts with Varying Levels of Chronic Ankle Instability

Ankle sprains in gymnasts are an extremely common injury, given the extreme load placed on them during various movements. Up to seventy percent of gymnasts who have experienced prior ankle sprains have developed chronic ankle instability (CAI). The objective of this study was to assess how gymnasts with varying levels of CAI react to fatigue. The study participants consisted of fifteen female Division III gymnasts at Hamline University in St. Paul, Minnesota. Participants engaged in an ankle fatigue protocol that

involved multiple rounds of running, shuffling, lateral hopping and landing from various heights. Fatigue responses were evaluated through the use of electromyography (EMG) sensors on the medial gastrocnemius, peroneal longus, and tibialis anterior muscles. Center of pressure (COP) measurements were assessed through the use of a force plate. Pre and Post fatigue tests were conducted that included single leg hopping and landing. CAI was self-reported using the Cumberland Ankle Instability Tool (CAIT). Results: Single leg hopping and drop landing produced significantly lower muscle activation in all three tested muscles post-fatigue. Postural sway, measured by COP area, significantly increased post fatigue. Participants with higher levels of CAI had higher activation of peroneal longus during pre-fatigue single leg hopping. These findings demonstrate a relationship between CAI and gymnast's muscle activation. We also observed that gymnasts responded to fatigue with lower muscle activation. Findings from this study can help inform and design gymnast-specific ankle rehabilitation protocols.

Abstract Name: Imaginaries of Happiness in Medellín: Distant Reading of 65,000 Short Stories About the Aburrá Valley

This research aims to identify, using tools from the digital humanities, the social imaginaries of happiness and unhappiness present in the short stories submitted to the Medellín en 100 Palabras contest between 2018 and 2023. The corpus consists of approximately 65,000 micro-stories focused on life in the Metropolitan Area of the Aburrá Valley. Given the size of the dataset, this study will employ distant reading methods and tools, such as Orange Data Mining, to extract, analyze, and interpret the statistically significant literary representations of the region's inhabitants regarding the good life and its opposites. The research seeks to address questions such as: Which themes are associated to positive and negative experiences? Which places are connected to fortune and misfortune? What differences can be observed in the representations across different age groups? These social imaginaries offer a way to understand the subjective universe of individuals and provide insights into society as a whole. Beyond their value as new knowledge, this information can be operationalized to support a wide range of initiatives (political, cultural, pedagogical, etc.) aimed at promoting collective well-being. As outcomes, we will develop a protocol for tracing social imaginaries in literary databases, a scientific paper where we will present our theoretical and methodological findings, and a series of digital visualizations designed to communicate the results in different scenarios.

Abstract Name: Discovery of a Functional Nuclear Localization Sequence in the N-Terminus of Satb2

All cells possess the ability to regulate their genes. Eukaryotic cells do so in a number of ways including the reorganization of their DNA into regions of hetero- and euchromatin. Heterochromatin is tightly condensed and contains silent genes, while euchromatin is loosely arranged and contains active genes. These structures are created by chromatin architectural proteins such as Satb2, which plays an essential role in osteogenesis by activating the RUNX2 transcription factor gene. Mutation of Satb2 can lead to Satb2-associated syndrome, which is characterized by craniofacial bone defects in humans. Satb2 is located in the nucleus, and the protein contains a predicted Nuclear Localization Sequence between amino acids 613-616. However, the functionality of this region has not been tested. Here, we use truncation analysis and fluorescence microscopy to demonstrate that this region is not functional. Instead, we show that the N-terminus of Satb2 is necessary for nuclear import, and amino acids 21-40 are sufficient to direct the nuclear import of cytoplasmic cargo proteins.

Abstract Name: Framing the Narrative: Analysis of How Intersectional Impacts of Racialized Language Affects Downstream Attitudes and Healthcare Inequities

Socio-political narratives play a critical role in the American healthcare system, both in determining who has the ability to access care and how it is delivered. Awareness of the ongoing issues affecting various minority communities across New York City highlights the interplay of social, economic, and environmental injustices, alongside disparities in accessible healthcare. These intersecting elements shape the lives of many, forcing them to navigate inequitable systemic barriers that restrict accessibility to essential quality care and resources. The language used in healthcare discourse, specifically in racial or genetic narratives, influences the perception of women and minority groups, leading to institutionalized inequalities that may contribute to profound physical and psychological consequences. In NYC, these narratives fuel distrust in healthcare professionals and worsen health outcomes for marginalized populations, addressing these issues is crucial in fostering equity in healthcare and enhancing community well-being. My project investigates how the framing of language and racialized narratives shape downstream attitudes, perpetuating systemic inequities in healthcare accessibility and patient outcomes. With a particular focus on the experiences of women of color, the study aims to understand how the dissemination of racialized narratives exacerbates biases in healthcare and medical language used in institutions. To examine these dynamics, this research will draw on narratives rooted in historical perceptions of race and gender, media representations, and statistical findings from psychological experimental surveys. By analyzing how such language plays a critical role in the psychological and physical health of minority women, this research will analyze the impact of these biases in the perception and treatment of women of color in clinical settings. This biased framing of language, reinforced by the media and medical education, contributes to both physical and psychological harm, as it often leads to the dehumanization or dismissal of minority patients' concerns.

Abstract Name: Observing effects in longer lived worms when supplemented with serine

Serine, a non-essential amino acid, plays critical roles in cellular metabolism, protein synthesis, and stress response. Deficiency in serine can impair various physiological processes, including cellular function, growth, reproduction, and sensory nerve functions. Previous studies have shown that serine supplementation promotes longevity, but little is known if this same effect is observed in long lived models. Using aging models provide information related to genes and pathways that could help organisms delay disease progression or atrophy. To determine if serine supplementation during adulthood affects lifespan in other long lived models we, and physiology, we used the nematode model *Caenorhabditis elegans* (*C. elegans*) *daf-2* mutant to determine the effects (Kenyon et al 1993). This model is also used to study insulin signaling which is critical to the normal development, and homeostasis of animals. Wild-type and the long-lived model *daf-2* were supplemented with various concentrations of serine (0mM, 1mM, 10mM, and 15mM), which were incorporated into nematode growth media. Lifespan analysis revealed a dose-dependent effect, with higher concentrations of serine significantly extending mean and maximum lifespans. Other assays were used as well to measure physiological aspects of the worm via (egg-laying, locomotion, and muscle strength). This extension is likely attributed to serine's involvement in metabolic pathways, including protein synthesis and cellular repair, which help mitigate oxidative stress and support cellular homeostasis. These findings suggest that serine modulates metabolic pathways, offering insight into its potential as a dietary intervention for aging and health maintenance in *C. elegans*. Further investigations may clarify conserved mechanisms of serine's role in longevity and reproduction across species.

Abstract Name: Visualizing Futures: Aphantasia and Vocational Outcomes

Aphantasia, or the inability to form mental images, has primarily been studied for its effects on perception, memory, and cognition. Aside from a study at the University of Exeter, the impact of sensory imagery on educational and career pathways, particularly in fields that rely heavily on visual imagery, remains largely unexplored. This study investigates the likelihood of individuals with aphantasia pursuing degrees in visual arts disciplines such as architecture and design. Using convenience sampling, the study assessed 329 students from five fields (architecture, design, music, STEM, and humanities) with the Vividness of Visual Imagery Questionnaire (VVIQ). Participants were categorized into one of three groups based on their total score: aphantasic, low-intermediate visual imagery, or high-intermediate visual imagery. Among 127 architecture students, 1 reported aphantasia and 7 exhibited low-intermediate imagery. None of the 10 design students reported aphantasia or reduced vividness. Of 64 music students, 1 reported aphantasia and 4 had low-intermediate vividness. Among 95 STEM students, 6 exhibited aphantasia and 14 showed low-intermediate vividness. Of 33 humanities students, 1 experienced aphantasia and 5 had low-intermediate vividness. Chi-square analysis revealed significant underrepresentation of aphantasic students in visual arts fields (architecture and design) compared to non-visual fields, $\chi^2 (1, N = 329) = 7.17, p = 0.007$. Further, a one-way ANOVA revealed a significant difference in VVIQ scores based on degree choice (visual vs. non-visual), $F(1,327) = 23.75, p \leq 0.001$. These findings suggest that differences in mental imagery capabilities influence career choices, with students lacking strong visual imagery more likely to gravitate toward non-visual disciplines. This research contributes to our understanding of how differences in visual imagery ability

shape educational and professional pathways and warrants further study. With a deeper understanding of how sensory imagery shapes our decisions, we may better establish its role in human development, creativity, and perception.

Abstract Name: Assessment of Student Achievement in Chemistry: Driving Academic Innovation Through Quality Matters Implementation

In an effort toward continuous improvement of the chemistry program, this research project focused on the assessment of student achievement in Principles of Chemistry I Laboratory (CHEM 101L). The selected Program Student Learning Outcomes (PSLOs) were using critical thinking to solve problems and demonstrating knowledge in core laboratory skills. Student achievement was evaluated for two labs: Sodium on a Pretzel and Volumetric Analysis of Vinegar. Assessment data, based on a 3-point scale, indicated that students (N=47) were meeting or exceeding the standard of 2.0. A total of 376 artifacts were evaluated in this study and revealed the mean values for the pretzel lab (2.11) and vinegar lab (2.18). Results indicated that the majority of students were meeting or exceeding the standard (2.0-3.0) for explaining the processes of sodium analysis and titration techniques. Conversely, some responses showed that learners were not quite meeting the standard of 2.0. Some examples included chemical measurement, explaining the purpose of an indicator, and writing formulas. Therefore, a plan was created to enhance learning in these areas including adding new instructional materials into the lesson such as video content for visual learners. This content was analyzed for accuracy, effectiveness, and accessibility and then implemented into the course in alignment with Quality Matters (QM) standards. These efforts will enhance the learning experience for future CHEM 101L students. Furthermore, this project allowed for student partnership in chemistry assessment and connected to the institution's mission by developing student leadership as the first student to pioneer QM initiatives. Another unique result of this project was student leadership in quality assurance, an institutional strategic goal for ensuring the quality of program offerings.

Abstract Name: Julius Caesar and His Exploitation of Britain: Research Concerning the Accuracy of Caesar's View of Britain in the 50s B.C.E.

My research explores the extent to which Julius Caesar's written account in the Gallic Wars accurately observed Britain during his invasions of 55 and 54 B.C.E. In addition to his primary text, I observe modern secondary sources by experts on Romano-British history and archaeological records to observe the validity of Caesar's depiction of Britain, both the events that occurred and customs of local tribes. My exploration of this

time period also accounts for Caesar's dynamic aspiration to attain absolute power in Rome as the Roman Republic decayed. Furthermore, my analysis concludes that the narrative Caesar presented established his status as a Roman conqueror to enforce a vision of dominance in Rome by distorting the Roman perspective of the Britons. The propagandistic narrative Caesar told emphasized the military triumphs he won over foreign peoples. However, despite their importance, his invasions of Britain are rarely observed as important factors in his quest for dictatorial authority, ignoring both the events and legacy of such ambition instead for developments in Rome. Events on mainland Europe are thought to be more significant and contributing to Caesar's ascension to doctoral rule. The contemporary mythical status of Britain and Caesar's ambition are both just as significant as Roman affairs in continental Europe. As I argue, the depiction of Caesar in his invasions of Britain greatly contributed to his later legacy and influence. Through my historical analysis, Caesar's perspective of Britain can be emphasized within the larger historical context of this transformative era.

Abstract Name: Laser-Targeted Bacterial Inhibition: Exploring Light-Based Therapies for Acne Management

This study explores the potential of light-based therapies to inhibit bacterial growth, with potential implications in acne treatment. Laser treatments are widely recognized for their ability to promote cellular turnover and reduce sebum production, both of which assist in acne management. This research aimed to directly examine the effects of various laser therapies on bacterial colonies. The experiment focused on two bacterial species, *Serratia marcescens* (Sma), Gram-negative, and *Kocuria rhizophila* (Krh), Gram-positive. Cultures (~70 CFU) were suspended on membranes and treated using three laser types. The PiQo laser, wavelengths of 1064 nm and 532 nm, is a picosecond laser used for pigment correction and resurfacing. The Vbeam laser, at 595 nm, is a pulse dye laser designed for vascular lesions. Lastly, the CO2 laser, at 10,600 nm, is an ablative laser known for its resurfacing capabilities. Following laser application, samples were incubated, and colony numbers were quantified and compared to untreated controls. The study determined these laser therapies could effectively reduce bacterial growth and may have the same potential in skin layers where bacteria thrive. This preliminary research provides insight into the direct effects of lasers on bacteria, laying the groundwork for future acne treatment innovations.

Abstract Name: Sudden reductions and pulsations in solar radio emission: May 11th, 2001, major flare

Radio emission from solar flares offer a powerful diagnostic tool to address long-standing questions about different energy storage and release mechanisms, plasma heating, particle acceleration, and particle transport

in magnetized plasmas as well as a physical picture of the associated active region at different levels of the solar atmosphere. The present work describes the radio emission associated with the May 11th, 2001, major flare at 237 MHz. The data was recorded with the solar radio polarimeter at the Basovizza Observing Station-Trieste Astronomical Observatory. Specifically, we analyze the evolution of radio emission during its maximum stage. Contrary to expectations, this major event appears to have no other counterparts associated with it, which is unusual for an event of such magnitude. Some possible generating mechanisms are discussed.

Cheyenne Torres

WV - West Virginia University

Discipline: Gender, Ethnicity, Diversity, or Cultural Studies

Authors:

Abstract Name: Children's Toys and the Idea of a Women

Historically children's toys have been the main targets for lining up with specific gender roles children eventually grow to uphold. When young girls are told that they need to play with dolls and kitchen sets because it's "what a girl does," it gives them a narrow idea of what choices they have in life, leading them to feel stuck in an endless cycle. This enforced stigma has allowed for the strict gender roles to continue to be confirmed through media advertisements that tell young kids "This is what you're meant to be." The purpose of my study is to see if children's toys and the idea of what it means to be a woman are in fact, correlated. To achieve this answer, some important questions that I came up with were, how does advertising on packaging differ between toys for girls, boys, and gender neutral? What are some of the words being put on these packages? How are the aisles labeled in toy store layouts? What types of toys are in each section? Finally these all go to answering the important question of, what do the toys promote? My goal is to show that the kinds of products being put on display will affect children's cognitive habits. After figuring out those habits and creating tables of data, it led me to the conclusion that the traditional idea of what a women's role should be is not dead, even in 2024, and children are picking up what that means for them.

Abstract Name: Health Literacy and Its Influence on Healthcare Access and Medication Adherence in African Children and Caregivers

Under-5 mortality remains high in many resource-limited settings, with an estimated 4.9 million deaths among children under five in 2022 alone, many of which are preventable; one contributing factor is suboptimal health literacy in many continents, and Africa is no different. Health literacy may be especially problematic for children who are more vulnerable and often require more complex drug treatments while having to rely on their parents to get the care they need. Our research focuses on health literacy, including medication literacy for children under the age of 15 and their caregivers, exploring impacts on health care access, treatment adherence, and health outcomes. We will undertake a scoping review to identify currently

available evidence on how health literacy, including medication literacy, affects children under 15 years and their caregivers in Africa, including the impact on healthcare access, medication adherence, and health outcomes. Through this systematic assessment of the literature on health and medication literacy among African children and their caregivers, we will identify critical evidence gaps that can be addressed in future research. We aim to bring attention to the importance of health and medication literacy to improve the health and well-being of children in Africa.

Abstract Name: Coyote and red fox competition in a southeastern Wisconsin forest

Food web complexity and stability in an ecosystem is determined by various factors, including the number of predators and their interactions. Coyotes (*Canis latrans*) and red foxes (*Vulpes vulpes*) are two prominent and key predators of many North American forests. We will test if there is resource partitioning or competition occurring between coyotes and red foxes by combining fieldwork and previous data from the University of Wisconsin-Whitewater's Nature Preserve. We will set out 10 trail cameras to collect data for 2024 in the Nature Preserve and use five previous years of data from this area to assess resource partitioning by comparing the proportion and timing of fox and coyote sightings each year. Our expected results are that there will be fewer fox captures in areas and years where there are more coyote captures, because of their size difference. This information will give us insight into the types of communities present in the Nature Preserve and help us make decisions about its management.

Abstract Name: Influence of Phytochemicals Present in Mint Extract in Preventing Oxidative Stress in Human Serum Albumin

Human beings are continuously exposed to harmful pollutants which can be damaging in absence of antioxidants. Phytochemicals are plant products which are known to have antioxidant properties by reducing oxidative stress in the physiological system. They have important therapeutic applications against a wide spectrum of diseases including cancer, neurodegenerative disorders, cardiovascular disease, hypertension and diabetes. In this study, the antioxidant effects of phytochemicals found in *Mentha piperita* (mint) were examined on human serum albumin (HSA) protein before and after inducing oxidative stress with damaging hydroxyl radicals. HSA is the primary natural carrier of drugs in the human body, transporting various medications throughout the bloodstream due to its high abundance in plasma and ability to bind to a wide range of molecules including drugs. Phytochemicals from mint leaves were extracted in water and ethanol

solvents. High-performance liquid chromatography (HPLC) on mint extracts indicated presence of various phytochemicals which belong to mostly plant flavonoid and phenolic acid families. Native HSA protein under oxidative stress displayed significant structural damage as observed in the studies conducted by UV-Vis, fluorescence, circular dichroism (CD) spectroscopy, HPLC and SDS polyacrylamide gel electrophoresis. In the presence of mint extracts and under similar oxidative stress conditions, however, the protein retained its native structural conformation to a significant extent. Comparable effects but to a lesser extent were also observed when the protein was bound with the individual flavonoids and phenolic acids. Molecular docking studies using AutoDock Vina indicated the binding sites of the flavonoids and phenolic acids in the protein HSA to be close to the single tryptophan 214 amino acid. Our ongoing studies include exploration of the synergistic effects of *Mentha piperita* extract with flavonoids and phenolic acids against oxidative stress in HSA using both experimental and computational approaches.

Abstract Name: Evaluating Growth Responses and Nutrient Sufficiency Ranges in Lettuce Cultivators

This research was conducted to determine the growth rate and nutrient sufficiency ranges of three lettuce (*Lactuca sativa* L.) cultivars. The main goal is to determine the target concentration and mixture of minerals and fertilizers needed to maximize absorption, growth, and production with the least impact on the surrounding environment. This information will also be used to generate a SAP report. SAP reports are vital for future time management, product selection, treatments and adjustments, and management. The Random Complete Block Design (RCBD) was used to control variation and reduce biases in results. In the (RCBD), each treatment must occur in every block to obtain reliable results. In this design: we placed three rows of nine trays each, nine plants in each tray, eighty-one plants in each row with a total number of 243 plants. Twenty-seven units of nitrogen were applied in three different concentrations (50, 100, and 200 mg/L). The pH was kept between 5.5 and 6.5, and pH and Electrical Current (EC) was recorded three times a week. After harvesting; measured parameters including leaf area, fresh and dry weight, leaf count, chlorophyll, light absorption, and anthocyanin count were recorded for analysis. Two-way ANOVA indicated significant cultivar effects on leaf area ($p=0.0375$) and anthocyanin content ($p<0.001$), with no significant impact from fertilizer concentration. Turkey's HSD test identified significant leaf area differences between Chicarita and Cherokee, and anthocyanin content differences among all cultivars. These findings highlight the importance of cultivator selection in the optimization of lettuce growth. Based on the data analysis, the maximum absorption, usage, and production target was achieved at 140-150 mg/L of nitrogen.

Abstract Name: Ready For Success? Exploring the Academic Preparedness of First Year HBCU Students

This quantitative study examines the academic preparedness of first-year students at historically Black colleges and universities (HBCUs), focusing on whether they feel equipped with the skills necessary for college success. Academic preparedness is defined as possessing foundational skills, such as writing, time management, and mathematics, critical for higher education. The research seeks to answer: What do HBCU second-semester students report about their academic preparation for college? Prior studies highlight that many HBCU students feel underprepared due to deficiencies in essential academic skills, often stemming from inadequate high school preparation and systemic inequities (Lamidi et al., 2019; Harper et al., 2020). Challenges in writing, critical thinking, and time management are frequently reported, with effective support programs shown to improve outcomes (Gearns et al., 2022). This study aims to gather direct feedback on students' perceptions of preparedness and the impact of high school and first-year programs on their college readiness. Participants will include 100 male and female first-year students, aged 18-20, from Clark Atlanta University. Data will be collected through a 38-question survey combining scales for Academic Support, College Readiness, Academic Self-Efficacy, and Growth Mindset. The survey includes yes/no questions (e.g., "Do you have a system for taking notes?") and open-ended responses (e.g., "What academic task gives you the most difficulty?"). Insights from this study will inform interventions to better support first-year HBCU students in developing essential academic skills.

Abstract Name: Determinants of Gratitude Expression at Dining Facilities: A naturalistic behavioral observation study

Interpersonal gratitude refers to expressions of thankfulness and appreciation toward another person. Research has demonstrated that expressions of interpersonal gratitude increase the overall wellbeing of those who express and receive that gratitude. With advancements in technology over the past decade, the use of headphones has increased dramatically, leading to a decrease in interpersonal conversations. This decline in sociability could decrease instances when interpersonal gratitude is expressed, leading to an overall reduction in individual wellbeing and life satisfaction. This naturalistic field study of behavior was designed to observe the potential impact of headphone use on interpersonal expressions of gratitude. At two university dining facilities, trained research students systematically observed and recorded whether customers thanked their cashier when checking out, and whether the customer was wearing headphones. More specifically, the observers recorded whether the customer had none, one, or two headphones/earbuds covering/in their ears. The two specific Virginia Tech dining halls were chosen for data collection because they provided the opportunity for customers to express gratitude towards their cashiers. Frequencies of wearing no headphones (55% of 6,173 customers) on expressions of gratitude were substantially larger than the one headphone (8% of 6,173 customers) and two headphones (12% of 6,173 customers) conditions. This suggests that the use of headphones influenced fewer expressions of gratitude. The two different locations also revealed substantial differences in expressions of gratitude, suggesting the impact of environmental conditions on gratitude expression. At the first location, which is a "Student Center," 49% of 6,173 customers expressed gratitude, while at the second location, located on the academic side of campus, only 25% of 6,173 customers expressed gratitude when paying for their food. The low percentage of gratitude expression at the academic location was likely because customers, in a hurry, viewed it as an inconvenience to remove their headphones.

Abstract Name: Identifying Transposable Elements Across Different Ages and Cellular Reprogramming Timepoints

Aging is a fundamental biological process marked by increasing vulnerability to disease and declining physiological function. At the molecular level, this decline manifests through distinct cellular hallmarks. However, a groundbreaking discovery has shown that these aging markers can be reversed: when somatic cells are reprogrammed towards induced pluripotent stem cells (iPSCs) using specific transcription factors, they exhibit remarkable cellular rejuvenation. Through analysis of molecular markers, including γ H2AX and H3K9me2/3, we observed age-related changes in DNA damage response pathways and heterochromatin status. To investigate the complex causal role of reprogramming-mediated cellular rejuvenation, we performed single-cell multiome sequencing of mouse fibroblasts at various ages and reprogramming stages. We then utilized a computational pipeline to track the expression dynamics of transposable elements (TEs) and their neighboring genes. This study profiles aging-associated markers across multiple cellular ages, combining both molecular and computational approaches to evaluate their potential rejuvenation during cellular reprogramming to provide insights into the mechanisms of aging.

Abstract Name: Presence of the Fungus that Causes White-nose Syndrome in Aboveground Rock Formations Used by Bats in Virginia.

North American bat populations are being impacted by the introduced disease white-nose syndrome (WNS), caused by the fungus *Pseudogymnoascus destructans* (Pd). The impacts of WNS have primarily been studied on bats hibernating in belowground sites such as caves and mines, where conditions are known to be suitable for Pd growth. We studied prevalence of Pd in aboveground rock formations used by Eastern Small-footed bats (*Myotis leibii*) and Big Brown Bats (*Eptesicus fuscus*) to investigate the potential role they play in the spread of WNS. We sampled for Pd genetic material in talus slopes and cliff formations used by bats in summer and winter, respectively. From 2020-2024, we sampled genetic material from surfaces of rock-roosts and nearby random crevices, guano found in roosts, and from bat skin surfaces. Presence of Pd DNA was assessed using Polymerase Chain Reaction followed by gel electrophoresis, with positive and negative controls. We detected Pd in roosts of both bat species including at cliffs used for overwintering and in talus used during summer. Pd was most prevalent in winter crevices, with 8.14% of cliff crevices testing positive. At talus slopes, Pd was detected in only 0.5% of crevices tested but was found in 6.4% of guano samples in summer. Our data suggests that aboveground rock formations could play a role in the spread of WNS. This

possibility is especially relevant in western North America, where many species of bats roost in rocks, and should be further investigated.

Abstract Name: The Power of Nostalgia: An Analysis of Companies Advertising Techniques to Maintain Customer Loyalty

Using the tool of nostalgia can be powerful and beneficial in building relationships with customers in Public Relations. Companies using nostalgic references in their advertisements attract both consistent and new customers. This can only be accomplished if a company can execute the nostalgic ad correctly by appealing to target audiences. The researcher frequently uses Chili's as the main example of achieving customer loyalty through nostalgia by appealing to older generations while at the same time recognizing Generation Z's particular needs. Social media can play a big role in creating the narrative of nostalgia for today's audiences. When companies are able to touch on emotions that a person is familiar with, they will comment, share it, like it, or save it. Posts that generate high engagement from all demographics of customers make marketing efforts successful, and nostalgia is an important tool used to make customers feel connected with that brand.

Abstract Name: Humanizing AI: The Impact of Anthropomorphic Chatbots on User Experience in Hospitality

The development of advanced technology to improve users' experience across various industries saw the adoption of artificial intelligence (AI) and AI-based tools, such as chatbots. In customer service, particularly within the hospitality field, there has been a growing trend toward humanizing chatbots through anthropomorphic features. These anthropomorphic features include visual cues like avatars or appearances, as well as communication styles that implement gendered pronouns, personalized names, and message interactivity. In order to examine the impact of anthropomorphic chatbot features on customer perceptions and behavioral outcomes, a comprehensive literature review was conducted, including both empirical studies (both quantitative and qualitative) and theoretical groundwork. These studies mostly investigated restaurants, hotels, and retail context. Based on cross-cultural and global approaches, there were observations of positive impact from integrating anthropomorphic features in chatbots on users' behaviors. When being introduced to more human-like chatbots which had names, gender, pronouns or being interacted with in a more interactive and conversational way such as including small talk or emoticons, there were generally more positive perceptions from customers, regarding both psychological and behavioral outcomes. These positive responses were found in increased customer satisfaction, trust, loyalty, and likelihood of recommendation. In addition, this research highlighted customer demographics with a diverse range of studies on not only university students, millennials, but also older adults and even hospitality employees. Collectively, the studies' findings offered valuable insights into both the bright and dark sides of AI-based chatbots. As businesses increasingly adopt AI-based solutions, understanding factors that impact consumer behaviors could contribute to user-

centered approaches. These findings not only widen understanding of how chatbots function but also provide practical guidance for better chatbot designing in order to improve user experience over the long term.

Abstract Name: Monolith: The Agency of Landscape in Literature

This research explores the concepts of agency and personification of nature in literature, arguing that these elements actively participate in narrative development and character interactions. By examining literary and artistic works from 1800 to the early 20th century, this study aims to highlight how nature and landscape influence human emotions, relationships, and decisions, asserting agency within their respective plots. The first chapter analyzes James Fenimore Cooper's *The Last of the Mohicans* and *The Deerslayer*, alongside Thomas Cole's artwork for *The Last of the Mohicans*. The section will explore how Cooper personifies the American wilderness as a powerful force, impacting the character's identities and moral choices, reflecting early American ideals and the complex relationship between settlers and indigenous landscapes. The second chapter will focus on German Romantic literature and Nathaniel Hawthorne's *The Scarlet Letter*. Human emotions and natural elements will be highlighted, showcasing how Romantic tradition personifies nature as a mirror to the human experience. Themes of guilt, the sublime, and redemption illustrate nature's role as an active participant in the character's journeys. The third chapter will explore Emily Dickinson's poetry and Henry David Thoreau's journals, emphasizing their intimate relationships with nature. This section will investigate how Dickinson's imagery and Thoreau's sketches personify the natural world, suggesting that these interactions demonstrate a deeper understanding of the self and existence. Finally, the fourth chapter will examine John Muir's Yosemite diary and Eadweard Muybridge's photography of Yosemite, analyzing how Muir's writings and Muybridge's visuals convey the grandeur and agency of the natural landscape, emphasizing environmental consciousness. Through these analyses, the project seeks to establish nature as an influential force within literary narratives, encouraging a reevaluation of human connections with the natural world.

Discipline: Film/Photography Studies

Authors:

Abstract Name: "Awesome Mix, Vol. 2 Cassette": A Study on Soundtrack Dissonance

The perfect film score has the unique capability to accompany an image and heighten the viewing experience, activating neural regions associated with pleasant emotional states. When synchronized and punctuated alongside the climax, tension, visual rhythm, leitmotifs, or on-screen action, the brain is able to combine the auditory and visual inputs of the film into a neurologically calming and satisfactory experience, but not a particularly memorable one. However, with the initiation of the 20th century, experimentation with contrapuntal music arose. This method of presenting music contrary to the mood of a scene proves as a psychological technique that inflicts upon audiences a type of mental shock- creating a more memorable and

infuriating dissonance between auditory and visual processing centers; therefore proving Eisenstein's "thesis-antithesis-synthesis" montage method as indeed more beneficial in terms of viewership recollection than simple coherent soundtracking.

Abstract Name: Rehabilitation Center for Girls Healing from Human Sex Trafficking

The purpose of this research is to regain the patient's psychological well-being and confidence after experiencing the dreadful and daunting consequences associated with human sex trafficking. The design of the rehabilitation center is intended to cater to the psychological needs of these young girls and women ages 12-22 who have experienced these types of traumas without causing more harm or making them feel uncomfortable through the use of natural elements to enhance and communicate the beauty and delicacy of a female. This facility will incorporate the appropriate safety, security, and healing measures and resources for every single girl and woman who steps into the rehabilitation center with the desperate need to heal and overcome their current unimaginable situation. Therefore, the rehabilitation center is intended to help these young girls and women regain a "sense of self" that they once had but was secretly ripped from them without their consent. Most importantly, it is imperative to conduct a thorough and rigorous evaluation of current rehabilitation facilities through literature review, case studies, interviews, and field study, working with human sex trafficking patients to ensure that they are executing their responsibilities with utmost efficiency, making necessary improvements, and augmenting their capacities. It is important to empower these girls and women with the essential tools and resources to successfully transition from living in a trapped mindset to transitioning back into the world without fear of the future. Therefore, the design of the rehabilitation center integrates natural elements, calming colors, and personalized spaces to promote healing and security for survivors of human sex trafficking. It includes therapeutic areas, community zones, and sustainable materials, focusing on cultural sensitivity and safety to empower residents and help them regain self-confidence.

Abstract Name: Endurance through History: Examining Resilience and Grit

Historical trauma theory proposes that individuals belonging to minority populations that have endured systemic oppression—such as war, slavery, and colonialism—are more susceptible to physical and psychological illnesses. While this theory has been extensively studied in Native American and African American communities, there is a notable gap in research exploring its relevance to Hispanic populations, who have also faced significant historical trauma. This research focuses on the prevalence of trauma susceptibility and comparisons of resilience and grit within the Hispanic population relative to other groups. Upon IRB approval, I collected data from 100 Hispanic students to examine the link between historical trauma and trauma susceptibility in rural U.S. Hispanic communities. Additionally, as I am still collecting

data, I plan to utilize a sample of 300 diverse students to investigate the relationship between resilience and grit, comparing these traits across a sample of Hispanic (n = 100), Native American (100), and White (non-Hispanic; 100) low-income college students. This study employs a mixed-methods approach, integrating qualitative and quantitative data collection through validated survey instruments such as the Scale of Protective Factors, the Life Stressor Checklist-Revised, and the Grit Scale. It is hypothesized that Hispanic students will exhibit significantly higher susceptibility to trauma as measured by the Life Stressor Checklist-Revised. This will correspond with lower levels of grit and resilience, by the Grit Scale and the Scale of Protective Factors compared to White (non-Hispanic) students. Furthermore, among Hispanic students, those demonstrating a greater stage of acculturation, based on the United States Acculturation Scale, are expected to display lower grit scores but higher resilience ratings on the Grit Scale and Scale of Protective Factors. The findings aim to expand research on the Hispanic population, highlighting the impact of trauma and informing strategies to strengthen resilience in vulnerable populations.

Abstract Name: Purification and Isolation of Potential Antimicrobial Compounds in *Janthinobacterium lividum* CO

The discovery of penicillin in 1928 revolutionized medicine, dramatically reducing mortality from bacterial infections. However, bacteria continue to evolve resistance to antibiotics, threatening to outpace the development of new treatments. *Janthinobacterium lividum*, a gram-negative bacterium with distinctive purple pigmentation, produces several organic compounds with promising antimicrobial activity. Commonly found in soil, glaciers, and freshwater, this bacterium's potential for novel therapeutics remains underexplored. Our research aims to isolate and purify the antimicrobial compounds produced by *Janthinobacterium lividum* as a step toward addressing the growing antibiotic resistance crisis. The isolation of organic compounds started with a liquid-liquid extraction. The organic material went through several rounds of chromatography, followed by a paper-disc assay to detect antibiotic activity. Samples that were active against a lawn of *Bacillus subtilis* were characterized using nuclear magnetic resonance and mass spectroscopy. As a preliminary step, we applied our isolation and purification techniques to *Lysobacter antibioticus*, which is known to produce the antibiotic 4-hydroxyphenylacetic acid, to refine our methods. The results determined that *Janthinobacterium lividum* contains antibiotic compounds that can be isolated and characterized. These antibiotic compounds have the potential to contribute to future research aimed at combating antibiotic resistance.

Abstract Name: Effects of Transcutaneous Vagal Nerve Stimulation on Objective and Subjective Sleep: Insights from an Overnight Laboratory Study

Americans are sleepy. A recent 2023 Gallup poll suggested that 73% of American adults report getting less than the recommended eight hours of sleep per night. Non-invasive interventions that can improve sleep are needed. Transcutaneous vagal nerve stimulation (tVNS) can improve subjective and objective sleep for healthy adults when administered before sleep. We examined the impact of administering tVNS during sleep on objective and subjective sleep measures in a sample of healthy adults. The University of Kentucky Institutional Review Board approved all testing procedures. Fifty-one healthy participants [Age=18-65 [Mean $\pm$ SD = 23.16 $\pm$ 4.70, 26 Males] were included in the study. Each participant completed two nights of polysomnographic recordings with active tVNS and sham stimulation – which were counterbalanced across participants' visits. Each participant was titrated to a stimulation frequency and amplitude (i.e., intensity) during orientation. On visit nights, active or sham stimulation began once participants entered non-rapid eye movement Stage 2 sleep and continued for the first 90 minutes of the 8-hour sleep period. Morning subjective sleepiness ratings were obtained using the Karolinska Sleepiness Scale (9-point Likert scale with 1 = extremely alert and 9 = extremely sleepy). Paired t-tests were used to examine differences between objective and subjective sleep outcomes on stimulation and sham nights. Bivariate correlations examined the relationship between objective and subjective sleep outcomes within sham and stimulation nights. No differences in sleep architecture were detected on sham vs stimulation nights ($p>0.30$). KSS scores also did not differ the morning after sham or stimulation ($p=0.37$). On stimulation nights, higher stimulation intensities were associated with lower KSS scores or greater feelings of restoration in the morning ($r = -0.306$, $p=0.03$). These data suggest that tVNS administered during sleep may reduce next-day feelings of sleepiness.

Abstract Name: Rethinking the rise of the Revolutionary Union Movements in Detroit through the effects of anti-communist sentiment in the UAW

This paper seeks to historicize the rise of anti-communist sentiment in the UAW to isolate significant correlations between the UAW's reactionary shift towards anti-communism, and the rise of Revolutionary Union Movements in Detroit with reference to the League of Revolutionary Black Workers. To answer the question, did the UAW's move towards prioritizing reform over revolution play a role in the formation of the Revolutionary Union Movements of the late 1960s? A thorough investigation into multiple archival sources such as the Dodge Revolutionary Union Movement Records and the Black Workers in the Labor Movement Oral History Project both found in the Walter P. Reuther Library, Archives of Labor and Urban Affairs, located on the campus of Wayne State University in Detroit, Michigan. This paper argues that while this perception of the events of 1967 being a catalyst to the foundation of the Revolutionary Union Movements is true, it remains limited. Identifying that long-standing problems within the UAW and the labor movement originating with the UAW's shift towards reformist policymaking play a more significant role when recognizing the shift in attitudes within workers that precipitated the formation of Revolutionary Union Movements. Historians have, for many decades debated the environment in which revolutionary ideas occur, this paper seeks to provide a unique perspective through the lens of labor history. Historians should look to apply these findings to other examples of revolutionary movements in history to further contextualize what conditions have to be met in society for the people to turn to revolution.

Abstract Name: Analysis of Pre-Screening Techniques for PCOS Using Data from MIRA (a fertility app)

Hormone fluctuations over the course of the menstrual cycle are critical predictors of ovulation and indicators of cycle regularity and fertility. Our research aims to better understand these patterns, deepening our understanding of the menstrual cycle and its relationship to reproductive disorders, and building tools to help individuals manage their own reproductive health. Our study uses data from the MIRA fertility app, a digital health tool designed to empower individuals in managing their reproductive health. The app logs quantitative urine hormone data collected through the MIRA Fertility Tracker, a device that provides precise hormone measurements. MIRA's primary goal is to help users predict ovulation and gain insights into their menstrual cycles. For this study, we focus on individuals with Polycystic Ovary Syndrome (PCOS), a condition characterized by irregular, infrequent, or prolonged menstrual cycles and difficulties in ovulation, which can impair fertility. To model individual menstrual cycles, we employ a Hidden Markov Model (HMM). This statistical approach maps cycle days to corresponding phases based on hormone levels, particularly estrogen, progesterone, and LH. The HMM allows us to capture the temporal dynamics of hormonal changes and classify phases with precision, even in irregular cycles. Our analysis includes an evaluation of cycle consistency within individuals and correlations between hormone fluctuations and observed cycle irregularities. By comparing these patterns across the subgroups, we aim to identify distinctive features of PCOS cycles relative to healthy cycles. The insights gained from this research will contribute to a more nuanced understanding of the diversity in menstrual cycle patterns. This knowledge could ultimately enhance personalized healthcare approaches, empowering individuals with PCOS and other reproductive challenges with insights about their health and fertility.

Abstract Name: Birdsong in the Machine: An Auditory Re-Imagination and Realization in Spreading Wildlife Awareness and Technological Advancement

Birdsong in the Machine is a soundscape composition that explores the evolving relationship between natural and artificial worlds through the story of the Streaked Horned Lark (*Eremophila alpestris strigata*), a threatened coastal songbird native to the Pacific Northwest. The central research question is: How can artificial intelligence (AI) and machine learning (ML) enhance environmental storytelling to amplify the voices of endangered species and reimagine human-nature-technology relations? By integrating AI-generated audio, wildlife recordings, and digital sound processing, this project critically examines the paradoxical role of technology as both a disruptor and preserver of ecological systems. Inspired by my lifelong connection to technology and deep appreciation for the natural world, Birdsong in the Machine reflects on the impacts of technological progress on the Streaked Horned Lark. The project draws from Donna Haraway's *A Cyborg Manifesto* and the works of Bernie Krause and Thom van Dooren, challenging the perceived divide between

the natural and artificial. It envisions a future where these realms coexist harmoniously, fostering collaboration rather than conflict. This composition combines recordings of the lark's song and habitat with AI-generated audio, using machine learning models to emulate and predict natural soundscapes. Digital audio processing techniques integrate these elements into a cohesive narrative. Bibliographic, archival, and ethnographic research reinforce the ecological and artistic focus of the composition. Through its juxtaposition of organic and AI-generated sounds, *Birdsong in the Machine* illuminates the paradox of technology's role in ecological degradation and preservation. The soundscape fosters empathy and awareness for endangered species while reimagining relationships between humans, nature, and technology. Future directions will explore the ethical implications of using AI in ecological art and expand collaborations with scientists and digital artists. Ultimately, this piece stands as both environmental advocacy and an artistic experiment, challenging audiences to rethink their place in the interconnected natural and artificial worlds.

Abstract Name: Assessing Developmental and Behavioral Changes in Larval Zebrafish (*Danio rerio*) Exposed to Microplastic Leachates

Commercial microplastics (MPs) end up in aquatic environments and contain additives such as heavy metals and disinfection byproducts. These additives leach into the surrounding environment, raising concerns about their potential toxicity to developing organisms. Currently, many studies on MP leachates rely on either one type of commercial MP or pure polymers, which lack additives, both of which may provide unrepresentative assessments of leachate effects. This study investigates the impacts of early exposure to leachates from various commercial MPs on the development and behavior of larval zebrafish. Plastics, acrylonitrile butadiene styrene (ABS), polyethylene terephthalate (PET), polyamide 66 (PA66), polystyrene (PS), and reinforced glass fiber (MIX), were collected from a recycling facility, frozen in liquid nitrogen, and crushed to form MPs. Leachates were made by suspending 2 g of MPs in 50 mL of zebrafish embryo-rearing media and exposed to UV-C light, heat, and agitation for 24 hours to simulate environmental weathering before filtering out the MPs. Fluorescence and UV spectroscopy were used to identify dissolved organic matter content in MP leachates. Zebrafish embryos were exposed to leachates between 6- and 120-hours post-fertilization (hpf). At 120-hpf, effects on larval survival, overall development, prevalence of developmental defects, background activity, and motor responses to acute stressors and peripheral irritants were evaluated. Spectroscopic investigations indicated the presence of DOM in the collected leachates. Our findings indicated that exposure to MIX resulted in an increase in mortality. Exposure to the leachates did not alter the prevalence of developmental defects. However, overall larval growth was reduced in zebrafish exposed to PET. Larval baseline activity and behavioral response to acute stressors were significantly altered in ABS, PA66, and PET exposures. This study provides valuable insight with significant translational relevance into the potential adverse effects of developmental exposure to various commercial MP leachates on development and behavior.

Abstract Name: Bacteriophages found in Rochester, MN

Bacteriophages (phages) are a type of virus that infects bacteria. Like human viruses, phages use their host cells for replication and reassembly. Phages are present where there is bacterial contamination, so one can determine and quantify bacterial presence by analyzing environments for phages, whether in water or soil. Harmful bacteria in water and soil can be present because of fecal contamination from animals in the region. These fecal-borne bacteria can be pathogenic to humans, like *E. coli*. The natural replication of phages allows testing to determine the presence of these fecal-borne bacteria in bodies of water. Previous investigations into finding and extracting bacteriophage from Zumbro River and Silver Lake have shown inconclusive results, producing uncertainty in whether we have bacteriophage in our waterways. Zumbro River and Silver Lake were chosen due to signs of fecal contamination populating the water with bacteria that serve as a host cell for bacteriophage replication. Chloroform was used to isolate the phage from water and soil samples from both locations. To ensure we only have bacteriophage, a filter allowed the phage to travel to a sterile microcentrifuge tube before inoculating it with an *E. coli* broth. Our results showed positive for bacteriophage within soil surrounding fecal-contaminated waterways using Silver Lake samples. Zumbro River samples produced negative results for bacteriophage prevalence. Due to the widespread presence of fecal contamination in Rochester waterways, further analysis of bacteriophage presence using these methods is warranted to further understand our overall water quality.

Abstract Name: Growth and experimental measurements on superconducting thin films and heterostructures

Our research delves into the growth, experimental measurements, and analysis of high-temperature superconductor YBCO-based thin film-heterostructures for their integration into a wide array of superconducting electronic devices. These devices include sandwich-type Josephson junction devices, superconductor quantum interference device (SQUID) magnetometers, rapid single flux quantum (RSFQ) circuits, and terahertz (THz) frequency devices. The structural and electrical transport properties of the heterostructures were investigated through Raman Scattering and various types of x-ray diffraction techniques such as x-ray profile, x-ray reflectivity, pole figure, and reciprocal mapping. The structural investigations showed (110)-oriented epitaxial growth with a preferred c-axis-in-plane orientation, while the electrical resistivity measurements showed superconducting critical temperature (T_c) above 77 K and a minimal proximity effect due to the interfacial contact of the YBCO superconducting layers with the middle insulating layer of the heterostructure. Here we present our recent results that demonstrated the possibility of integrating these heterostructures into various types of superconducting electronic devices to provide them with a higher performance and efficiency.

Abstract Name: In Vitro Model of the Human Circle of Willis to Investigate Drug Delivery in the Brain

Stroke is one of the leading causes of death world-wide and ischemic stroke accounts for 87% of these cases, occurring when an artery leading to the brain is occluded. Intravenous drug delivery of tissue plasminogen activator can be used to break up clotting but only has a 50% success rate in reperfusion. In order to improve this drug delivery process, a better understanding of the underlying flow physics in cerebral arteries is required. The main arterial network in the brain is the Circle of Willis (CoW), which includes a proximal connection of supplying vessels, and distal collateral vessels that are important for rerouting flow in the event of an occlusion. Cerebral hemodynamics are difficult to study using in vivo and clinical imaging because of the small vessel size, and complex network structure. Our project presents an in vitro method to investigate flow through cerebrovascular networks. The setup includes a 3D-printed planar phantom model of the CoW in series with a peristaltic pump that drives distilled water through the system. Our procedure includes injecting a set concentration of dye into the network and measuring the volume of fluid and concentration of dye at each outlet. We also use a high-speed camera and image subtraction to track intensity profiles of CoW vessels over time. We conducted a set of experiments with a 3D-printed occlusion introduced in the RMCA vessel to represent a stroke case with varying distal collateral configurations and compare flow and concentration for cases without stroke. By comparing these cases we can investigate how cerebral flow physics change in the event of a clot as well as the role of the distal collaterals in rerouting flow around the occluded vessel. Ultimately, we plan to use these findings to help illuminate the mechanics of drug delivery in stroke patients.

Abstract Name: Impact of Dietary Sodium Benzoate on Gut Microbiome and Behavior in Mice: Exploring the Gut-Brain Axis Over 9 Months Feeding Trial

Sodium benzoate (SB) is a widely used preservative in various food and beverage products such as sodas, condiments, fruit juices, and more. While the FDA approved rate of consumption of SB is at 0.1% of food weight, many food products have been found to exceed this level. There is strong evidence in the literature establishing the dietary influence on the gut microbiome and the gut-brain axis mediating metabolic, immune, and neurological functions, however not much is known about the chronic effects SB has on these functions. This study aims to investigate the potential implications of prolonged exposure to SB, particularly focusing on its impact on the gut microbiome and associated behavioral changes in mice. Our previous studies showed morphological changes in the gut wall, decreased mucus production, and inflammatory changes in response

to long-term SB consumption in mice. In this study, female C57BL/6 mice after weaning were maintained on a standard rodent chow with or without 1% SB diet for nine months. Behavioral data were collected using the BORIS software for home cage test, open-field test, novel object test, as well as forced swim test for assessing overall activity, social interaction, and short-term memory. Gut microbiome from fecal and cecal samples were analyzed by 16S Illumina sequencing. The differences in microbial population between treatment groups were determined by QIIME2 metabarcoding bioinformatics analysis. Unique to the SB-treated mice were higher amounts of Firmicutes and Proteobacteria while the control group had higher amounts of Bacteroidetes. There was no difference in behavior between treatment groups for the small data set we analyzed thus far. Our data suggests that long-term SB consumption could alter the gut microbiome and hence potentially impact gut health and communication through the gut-brain axis.

Abstract Name: Reading Between the Lines: An Eye-Tracking Experiment of Design Effects on Data Privacy Policy Comprehension

This study investigates how the use of icons affects user engagement and comprehension of online data privacy policies through a between-subjects experiment. Leveraging eye-tracking technology, the research compares how data privacy policies with and without icons (i.e., text only vs. text + icons) influence users' information processing as demonstrated through gaze patterns and fixation durations. In addition to eye-tracking metrics, memory of policy information and self-reported attention allocation are also measured. The results revealed that on average, the data privacy policy with icons received 41% more fixations and led to 43% longer fixation duration than the text-only data privacy policy without icons. Additionally, the participants interacting with the data privacy policy with icons demonstrated a higher level of memory of policy information than those who interacted with the text-only version without icons. This research also uncovered variations in individual reading behaviors, suggesting that personal habits and prior familiarity with digital interfaces could contribute to participants' engagement with the data privacy policy. These findings highlight the potential for user-centered design to improve the accessibility and effectiveness of data privacy policy. By integrating thoughtful visual elements, organizations can enhance user comprehension while maintaining the necessary legal integrity of data privacy policy documents. As digital agreements continue to play a critical role in online interactions, this study provides actionable insights into how design strategies can make these essential yet often overlooked documents more user-friendly, helping bridge the gap between legal content and user understanding.

Abstract Name: The Rise and Fall of C.I.A. Support for Operation Condor

Operation Condor (Condor) was a transnational terror network set up by six military dictatorships in South America with the support of the United States' Central Intelligence Agency (CIA) in order to kill and silence dissidents in the nineteen seventies. Condor involved surveillance of dissidents, coups, and assassinations across international borders. While research on Operation Condor tends to focus on the individual dictatorships involved, the relationship between those dictatorships and the United States has been comparatively understudied. The human rights violations committed by the Operation Condor dictatorships eventually resulted in Congress investigating the CIA and tying human rights requirements to U.S. foreign assistance to the nations involved. Unlike in many Cold War battlegrounds, human rights violations in South America resulted in a reshaping of United States foreign policy towards the region. The relationship between the United States and the Conder dictatorships broke down as U.S. foreign policymakers began to criticize the increasingly brazen and brutal tactics of Condor. In the 1980s, international pressure and internal activism forced Argentina's military government to hold elections, and the other Condor nations followed.

Abstract Name: AI Innovation for Biological Research: Creating a Strategic Model for Researchers

In alignment with the institution's mission to develop leaders in service, this project explored the possibilities of student leadership in AI innovation for biological research. A student team analyzed the effectiveness of AI that led to a successful strategic model for applying AI to real-life applications and also served as a learning tool for fellow student researchers. Through the analysis of several trials, key insights were identified related to the use of AI technologies. Data revealed several trends including AI navigation (12.5%), visual representation of information (12.5%), application with collaboration (37.5%), experience level (25.0%), and focus on future application (12.5%). Further trials showed more depth to the ability of AI such as success rates (100%) in usage for the realistic applications for medical research, personalization of AI-generated content, and the importance and application of AI ethics in scientific content. Additional trials indicated that AI served as a starting point for biological research project design, while other experiments showed its usefulness as a comprehensive tool to support the entire research process. Overall, this work demonstrated that Gemini and ResearchRabbit were the most effective followed by ChatGPT and Connected Papers. Therefore, these findings served as the framework of the model for utilizing AI in biological research. Special features of the model included its usefulness in successfully creating student projects with realistic biological applications including healthcare, but it can also be applied to any discipline across campus. Interestingly, student researchers benefited from the project through high-impact practices such as collaboration in undergraduate research and the investigation of AI through a common intellectual experience. Overall, this model showcased student-driven AI innovation in biological research, thereby highlighting the students' leadership in serving the common good.

Abstract Name: Discovery of Novel 2D Materials from High-throughput Computational Etching of Experimentally Known Compounds

There is a great need for 2D materials and their extraordinary properties. Most of these materials discovered so far are synthesized from 3D Van Der Waals crystals. However, the small number of such parenting structures limits the discovery of novel ones. Another option is the selective electrochemical etching of 3D layered structures with intercalated atoms. Thus, this project seeks to find, among existing stable crystal structures, the ones that are layered and contain weakly bonded atoms that can be etched selectively. This was inspired by the work of Jonas Bjork et al in a paper published in the Science academic journal and that of

Goowon Cheon et al. in a paper published in the ACS journal. First, 144,191 stable material structures are drawn from the Materials Project database with the MPRester Python library. Next, the resulting data was screened for their dimensionalities with different tolerance factors. This was done by implementing the open-source algorithm developed by Cheon G. et al, that was modified to return the types of intercalated atoms between the layers. The resulting structures were analyzed to determine the proportion of layered 3D structures present that are suitable candidates for selective electrochemical etching. We also provide statistics about the interlayer atomic species to suggest etching agents for 2D material creation. This dataset can be next used for Density Functional Theory calculations to evaluate exfoliation energies and define 3D structures that can be etched, that will lead to the creation of a database with prospective parenting materials for novel 2D materials. Calculations were conducted utilizing AU Easley high-performance computer accessed through a Linux-based terminal.

Abstract Name: The Mentor-Mentee Dynamics: Increasing Research Curiosity Through Collaboration, Guidance, and Support

Mentoring takes many forms and can significantly impact individual matriculation, career choices, and professional trajectories. In STEM contexts, particularly for underrepresented students, mentoring is an integral component of the socialization process. Mentoring offers students access to social and cultural capital while increasing their likelihood of continuing in STEM fields after graduation. This qualitative research study aims to advocate for more research on mentoring relationships in postsecondary milieus that encourage implementing new mentoring experiences. Using an anti-deficit and socialization framework, the authors show how undergraduate students from different disciplines conduct interdisciplinary research and provide varying forms of mentorship. The researchers employed Interpretative Phenomenological Analysis (IPA) to critically evaluate the impact of mentoring on eradicating the Impostor Phenomenon among undergraduate researchers at an HBCU. This study explored the structure and essence of the experiences of student researchers who engage with the Impostor Phenomenon and how mentoring serves as a ready tool for eradicating the phony feeling. Personal interviews were conducted to explore the perceptions of the same respondents regarding impostor feelings and the impact of mentoring on their self-esteem development and eradication of the impostor phenomenon. For many undergraduate researchers, especially those at an HBCU, the impostor phenomenon is prevalent, especially when conducting research, writing, and publishing. The findings show that the academic demands on students require a higher level of mentoring to ensure persistence, completion, and research exposure. The findings will help inform current research on the routes and processes necessary to succeed against all odds while navigating their degree programs and research experiences. The study will also inform higher education administration and faculty of the unique needs and attention required of undergraduate researchers and how these needs can be adequately met through mentoring to foster retention, persistence, and scholarly activities such as publishing, conference presentations, and teaching.

Abstract Name: Analyzing Transcriptional Control of IL-10 in Macrophages using CRISPR-Cas9

Macrophages are known to have a plastic nature as they can change from M1 to M2 states and vice versa. M1 and M2 states are partially characterized by their pro-inflammatory and anti-inflammatory cytokines, respectively. Notable examples of anti-inflammatory cytokines that can be efficiently used for regenerative medicine include IL-10 and IL-4. This study focuses on the possibilities of manipulating macrophages to optimize immune responses. IL-10 promotes healing by preventing uncontrolled immune responses. In diseases such as diabetes, this process gets dysregulated and macrophages struggle to induce the M2 state. The catalytically inactive CRISPR-Cas9 system, known as dCas9, can help to upregulate or downregulate cytokines to promote an anti-inflammatory phenotype. In this study, we aim to promote the upregulation of IL-10 in RAW 264.7 macrophage lines. Previously, using VP64, a virally derived transcriptional activator, we were able to induce IL-10 activation. In this study, we will compare P300, a human-derived histone acetyltransferase, against VP64 to analyze if one has a higher efficiency. The RAW 264.7 cells will be transduced with lentiviruses encoding dCas9-P300 and undergo antibiotic selection. We will transduce CRISPR guide RNAs targeting IL-10 in each macrophage line- RAW 264.7 with dCas9-VP64 and RAW 264.7 with dCas9-P300 and perform a second selection using cell sorting. RT-qPCR will be done to confirm both the presence of dCas9-P300 and IL-10 gRNAs. Then IL-10 expression will be analyzed using RT-qPCR. We will normalize against GAPDH, a constitutive gene, and compare the IL-10 levels to when RAW264.7 cells are in a pro-inflammatory and unstimulated state. These results will show which transcriptional activator, VP64 or P300, is more likely to induce an anti-inflammatory state through IL-10 activation. This technology can then be analyzed in the context of wound healing and immunotherapy to improve patient outcomes.

Abstract Name: How New Orleans Became a Sound: An Exploration of the Birthplace of Jazz

As a jazz musician it is not uncommon to be told to “sound like New Orleans,” in order to develop an authentic replication of early jazz charts. No other U.S. city shares a similarly distinctive musical identity. How, then, did New Orleans develop a musical culture distinct from the rest of the United States? As a port city, New Orleans stands out as historically culturally diverse, bringing together European, Caribbean, and African cultures through migration and the transatlantic slave trade. To understand the debated question of how jazz developed during its formative years in New Orleans, I have studied the development of jazz, New Orleans history, and examined the pioneering musicians “Papa” Jack Laine (1873-1966) and Joseph “King” Oliver (1881-1938). My research has been guided by a combination of academic publications, travel to New Orleans, and primary sources collected through collaboration with the New Orleans Jazz Museum curators and archival work at Tulane University. While many scholars place their conclusions purely on Congo Square, brass band traditions, or set jazz aside as purely unique, I have concluded that New Orleans formed a unique musical culture through the intersection of the American brass band tradition and diverse African musical traditions shared at Congo Square. In my presentation, I will provide evidence that intersecting musical traditions led to the genesis of jazz through musical examples to present the “sound of New Orleans”

as defined by pioneers of New Orleans jazz, historical accounts, and the contextual history that combines Congo Square and the American brass band into a united musical culture.

Abstract Name: Applying Machine Learning to Find Pricing Patterns in Chemicals

The cost of chemicals is an important factor for every chemistry research laboratory. Machine learning has been crucial in understanding chemical datasets and analyzing complex chemical structures. This study focuses on using Principal Component Analysis (PCA), an unsupervised machine learning algorithm, to analyze the structures of molecules and help determine what components of chemical structure significantly affect price. The algorithm takes a textual representation of the 3-dimensional chemical structure of a molecule as input. It organizes the dataset based on the chemical structures and determines the pricing and organizational patterns within the PCA. The research focuses on three main datasets which are primary cluster (the largest dataset), "Ring" cluster, and "Cef" cluster. PCA evaluated the chemical structures of 226 points in my dataset and I personally analyzed 20 points in the primary cluster and 5 points in the other two smaller clusters. Since the experimental dataset is small, future work will be extended to a larger data set to potentially produce clearer patterns data. The experiment will also be improved by using a clustering algorithm instead of manually clustering the PCA. I believe that unsupervised machine learning algorithms will create an effective organization based on structure and will demonstrate a correlation between more complex chemical structures and higher prices. It will have a significant impact on research laboratories as scientists can make informed decisions on buying chemicals and find alternatives to replace expensive ones.

Abstract Name: Co-option of Two N-alkanes as a Brood Pheromone Modulating Foraging Preferences in *Temnothorax* Ant Workers

In social insects, specialized foragers fulfill the nutritional needs of all colony members. This study investigates the chemical cues used by *Temnothorax longispinosus* ant larvae to increase protein-foraging in foragers. Based on previous chemical analyses, we tested whether two larva-biased n-alkanes function as brood pheromones. Colonies lacking brood were exposed to synthetic versions of n-C27 and n-C29, which are more abundant in larvae than in workers. A combination of n-C27 and n-C29 increased protein-foraging to the same level as full larval Cuticular hydrocarbon extracts, while n-C27 and n-C29 individually did not elicit the same response. n-alkanes can be found across insects and are involved in waterproofing the cuticle. Our findings provide the first evidence that a combination of two specific n-alkanes has been co-opted to

additionally function as a brood pheromone in ants, influencing worker behavior to meet larval nutritional needs. This suggests a quantitative mechanism where the relative abundance of these compounds plays a key role. Understanding these chemical communications offers insights into colony homeostasis and social behavior evolution in ants. Our findings contribute to a broader understanding of how chemical signals mediate complex social interactions in eusocial organisms, providing a foundation for future studies on chemical communication.

Abstract Name: Comparing the 3D chromatin organization of breast cancer subtypes through Hi-C analysis

With breast cancer affecting a large portion of the population, finding effective methods of treatment is an increasingly strong demand. Cancer is a result of incorrect gene expression resulting from abnormal 3D chromatin organization. Through breast cancer research, specific targets have been identified to strengthen prognosis and efficacy of treatment. This project aims to find differences between breast cancer subtypes to aid in identification of specific genetic structures and expression for cancer treatments. Through Hi-C analysis, comparisons can be made between the different subtypes to find unique features of genome organization in each subtype. Hi-C is an experiment that identifies interactions between regions of DNA, allowing us to analyze 3D structures and chromatin organization. This data can be used to make contact maps that show where the chromatin interactions are occurring. This can show unique structural elements in the subtypes such as TADs and chromatin loops. This research will identify and explore how the chromatin interactions are similar and different in 2 breast cancer subtypes (ER-positive and TNBC). Contact heat maps will be used to visualize contact frequency from Hi-C datasets and find chromatin loops and interactions. Then, combining this data with RNA-seq data, we can see the expression of genes and what the structure looks like at those areas. Both breast cancer subtypes will be compared against each other to find similarities and differences. The expected results will suggest that TNBC has the most variability compared to normal-like cells. Based on previous results in the lab, we expect that 3D organization of ER+ and TNBC samples will be the most different, contributing to the vast differences in gene expression profiles. Investigating breast cancer subtypes will provide insights for more effective precision medicine therapies for breast cancer patients.

Abstract Name: Integrating Hydrodynamics and Socioeconomic Data to Address Flood Vulnerability and Environmental Justice in Arkansas

In Arkansas, flooding is a frequent hazard that affects both urban and agricultural areas. In this study, a geospatial cyberinfrastructure (GCI) framework is developed to analyze flood hazards and socioeconomic

vulnerability throughout the state. We simulate flood depths and quantify how it intersects with land use, infrastructure, and socioeconomic characteristics using remote sensing-based terrain data and demographic markers. The study results show notable disparities, with minority and low-income populations, particularly in the Mississippi Alluvial Plain, at higher risk of flooding. Clusters of vulnerability are spatially identified using high-resolution mapping and Bivariate Local Moran's I analysis, indicating the intersection of economic and racial inequality with flood risk. When used with Google Earth Engine, the GCI combines several datasets to provide detailed and easily navigable interactive maps and visualizations. Stakeholders, including legislators and urban planners, are empowered by these tools to assess flood risks and develop focused, well-informed mitigation plans. The study reveals the value of integrating geospatial technologies to address environmental justice challenges and the importance of equitable flood management policy. Its ultimate goal is to enhance flood preparedness decision-making in Arkansas and add to the larger discussion on socio-environmental justice.

Abstract Name: Sex Differences in Mitochondrial Protein Expression Following a Traumatic Brain Injury

Traumatic brain injuries (TBI) disrupt normal brain function and cognitive impairments ranging from mild to severe. Primarily, TBI studies focus on males as the research subject, but recent reviews observed females have better outcomes following TBI. Mitochondrial dysfunction is a key driver of secondary injury after TBI and has been well-established in male animal models of injury. However, research in females has found little to no mitochondrial impairment after TBI. Synaptic mitochondria within the neuronal synapse are more susceptible to dysfunction due to heightened bioenergetic demand following TBI than non-synaptic mitochondria. A recent study has shown that both synaptic and non-synaptic mitochondria from male mice were bioenergetically impaired following severe controlled cortical impact (CCI) while only synaptic mitochondria from female mice were impaired. To investigate potential causes for this apparent sex difference, we measured expression of proteins involved in the Oxidative Phosphorylation (OXPHOS) system in the total, synaptic, and non-synaptic mitochondrial populations. We hypothesized mitochondrial OXPHOS protein expression in females will be greater than in males. Age-matched male and female mice received sham or severe CCI followed by mitochondrial isolation 24h post-injury. OXPHOS protein expression was measured using western blot analysis. Results showcased a significant increase in OXPHOS expression in both total and non-synaptic mitochondria from sham females compared to sham males. Synaptic mitochondria from males and females showed decreases in protein expression following injury. Previous functional bioenergetic analysis observed a similar injury pattern, suggesting spared non-synaptic mitochondrial function in females is masking impaired synaptic function through increased protein expression. These studies highlight the importance of assessing both sexes and mitochondrial fractions following a severe TBI-induced injury to prevent spared functioning of one fraction from masking impaired dysfunction of the other fraction. Ongoing experiments are exploring sex differences in glial cell expression following severe CCI.

Abstract Name: Helping Out the Hollers: Exploring Homelessness in Eastern Kentucky

Prior to the 1970s, homelessness in America rose and fell according to the financial markets. Later governmental policies allowed homelessness to increase and become entrenched in society. Today, over 4,000 Kentuckians face homelessness. The Appalachian areas of eastern Kentucky hold some of the poorest counties in the U.S. with up to 36% living below the poverty line. This research aims to look back at the root causes of homelessness and how they were addressed in the 1970s to the 1980s. Using the collection of Tenant Services and Organization Assistance, Inc. records, 1970-1981, at the University of Kentucky Special Collections Research Center, this research will explore how Kentucky service organizations, governmental policies, and other social services worked to combat homelessness in the era when it was becoming entrenched in society. The collection contains newspapers, meeting minutes, and photographs from the time when Kentucky experienced a rise in homelessness and established programs to relieve the problem. Research will compare how initiatives differed in urban Kentucky areas versus rural eastern Kentucky areas of Appalachia, and also how these programs evolved over the past 50 years. Today's homelessness crisis is being met with extreme measures, such as cities like Lexington banning outdoor sleeping and homeless encampments. Looking into the history of homelessness in Kentucky—and the efforts to combat it—will hopefully shine light on those who are often left behind by society.

Abstract Name: Presence of Hemoglobin-Acrylamide Adducts in Smokers and Non-Smokers

Background Acrylamide is a reactive organic compound and a carcinogen produced in cigarette smoke. It can also be produced in food through the Maillard Reaction. All humans, but especially smokers are exposed to acrylamide. When the body is exposed to this compound, it binds to different biomolecules and creates a covalent adduct, which in turn can interfere with their function. A highly abundant biomolecule that forms these adducts is Hemoglobin which demonstrates a dose-dependent response of adduct formation to blood-acrylamide concentration. We propose to analyze smokers and non-smokers hemoglobin-acrylamide adducts. In order to do this, the Globin must be separated from the whole blood, and then the Globin must be digested with the use of a protease—Trypsin. Purpose To observe differences in hemoglobin-acrylamide adducts between smokers and non-smokers. Methods Whole blood from both smokers and nonsmokers (n=25) was taken, and the globin was isolated. Then it was digested using immobilized Trypsin. Finally, the digested samples were analyzed by a Q-Exactive, to evaluate the amount of the adducts on both smokers and non-smokers. Results A t-test was performed on the difference of the percentage of acrylamide-hemoglobin adducts for both smokers and non-smokers ($p < 0.0001$). Discussion There is a significant difference between the percentage of acrylamide-hemoglobin adducts between smokers and non-smokers. Demonstrating that the excessive consumption of acrylamide can lead to more adducts. Additionally, this also shows that the method developed could be used to find other adducts.

Abstract Name: Perception of Knowledge and Comfort Level When Discussing Controversial Topics in the Classroom

Previous studies have examined the relationship between students' perception of knowledge and their classroom participation, suggesting that students are more likely to engage in discussions when they perceive themselves as knowledgeable about the topic. To explore how this dynamic applies to controversial topics related to politics, gender, and religion. The Campus Expression Heterodox Academy survey was distributed to students enrolled in an Introduction to Psychology course. Two survey questions were analyzed: one asking students to rate their knowledge on these topics and another assessing their comfort level in expressing their views during discussions on controversial issues. A Chi-squared test showed a connection indicating that students who reported most-to full understanding about gender, politics, and religion felt more comfortable sharing their opinions when it came to controversial topics related to the previous categories compared to those who reported little to no understanding. Future research could investigate how demographic factors influence perceived knowledge and comfort levels in voicing opinions during classroom discussions.

Abstract Name: Monetary Incentives in Public Health

The U.S. is facing a growing health crisis and struggling to deal with it effectively. Most attention is on treating the different health issues that arise from obesity, less has been done to address the root cause: unhealthy lifestyle habits. Economics could show us how to deal with this issue effectively. Monetary incentives could promote healthier behaviors in people and bring down the obesity rate. The purpose of my research is to investigate public opinion on offering monetary incentives to improve public health. I wrote a 20 question survey, distributed it through Amazon MTurk, and received 164 completed surveys. The data was analyzed using IBM's SPSS to assess public opinion on the effectiveness of monetary incentives for leading a healthier life. Specifically I'm testing to see if there is a statistically significant difference in opinions of men and women on these incentives being offered. Most notably, there was a statistically significant gender difference in opinions of the government providing positive monetary benefits for participating in fitness challenges. All surveyed women answered yes on this question while only 88.6% of men believed this to be a good idea. These results were statistically significant at the 1% level of significance. By incorporating gender differences into health policies, there may be new approaches to improve public health, especially when utilizing monetary incentives to create change.

Abstract Name: The Role of Midkine in Pancreatic Cancer Liver Metastasis

Pancreatic cancer is the third leading cause of cancer deaths in the United States, with metastasis, the spread of cancer cells beyond the original tumor, being the primary cause of mortality. Patients with advanced metastatic disease have a 5-year survival rate below 5%. Studies show that the metastatic tumor microenvironment, which includes surrounding non-cancerous cells, blood vessels, immune cells, and signaling molecules, plays a key role in the progression of metastasis. Midkine (MDK) is a protein involved in various cellular processes and has been studied for its potential involvement in cancer progression. Our lab demonstrated that in a mouse model with accelerated pancreatic metastasis in the liver, MDK expression is increased in liver cells. It remains unknown if MDK contributes to pancreatic cancer metastasis. To address this gap, we aimed to determine whether liver-derived MDK influences tumor cell behavior. Since MDK can bind to several receptors, we assessed which receptors are expressed by human and mouse pancreatic cancer cell lines, as well as whether the cancer cells themselves express MDK. We show that pancreatic cancer cells express and secrete MDK and also express its associated receptors SDC1 and PRKCZ. Further, analysis of publicly available datasets from pancreatic cancer patients reveals that high MDK expression is associated with more aggressive pancreatic cancer, and MDK levels are elevated in liver metastases compared to primary cancer sites. These findings suggest a potential pathway for therapeutic intervention, as we aim to test whether targeting MDK may effectively prevent metastatic progression and improve patient outcomes.

Abstract Name: Impact of Art & Crafts on Social Interaction Amongst the Elderly

Social isolation represents a persistent and critical public health challenge among the elderly populations, frequently showcasing declines in mental and physical well-being. This service-learning intervention explored the transformative potential of arts and crafts as a strategic mechanism for mitigating social isolation and enhancing community engagement. Over a meticulously structured five-week period, weekly 2.5-hour creative sessions were implemented at the Bartlett Assisted Living Center, encompassing activities such as polymer clay molding, sculpture painting, pinecone birdfeeder construction, wood canvas painting, and snowflake canvas painting. These interventions were designed to create different craft opportunities outside of their consistent routine for meaningful connection, storytelling, and skill exchange. Impact evaluation surveys were provided to the director and caregivers during the period to assess mood, connections, and the program's success in reducing isolation. Notably, the program showed to have challenged preconceived notions about aging and creative potential, demonstrating that artistic engagement is not confined by chronological age or perceived limitations. Residents, including those with mobility challenges, who were initially reluctant to participate, showed significant increases in engagement. Survey responses indicated

notable improvements in emotional well-being, with many residents expressing feelings of joy and fulfillment, alongside visible improvements in social interactions. The project demonstrated that creative, collaborative approaches represent a powerful and replicable model for combating loneliness, offering valuable insights into innovative strategies for promoting social connectedness and psychological resilience in aging populations. Underscores the importance of different creative and inclusive interventions in promoting connection and well-being in the elderly community.

Abstract Name: Sharky: An Interactive Robot for Campus Sustainability

This research focuses on developing an autonomous robot designed to promote recycling on campus by interacting with individuals and navigating its environment. Inspired by the MDC shark, the robot integrates hardware and software technologies to raise awareness about environmental issues. Powered by 12W DC motors and controlled by an Arduino R4 Wi-Fi module, the robot uses ultrasonic sensors to detect obstacles and walls. An OpenMV H7 microcontroller camera, programmed in Python, enables visual recognition of obstacles and human presence, allowing for autonomous navigation and effective interaction. The chassis, 3D-printed with PLA material and designed in Fusion 360, ensures structural integrity and lightweight mobility. Calculations of weight, wheel resistance, and movement dynamics were conducted to optimize performance. The robot's free-roaming capability allows it to autonomously traverse campus spaces, avoid obstacles, and engage individuals through a speaker system that delivers messages about recycling and environmental conservation. By integrating robotics with community engagement, this project offers an innovative approach to sustainability and environmental education. The robot combines autonomous navigation with meaningful interactions to inspire action and promote sustainable practices on campus. The anticipated outcome is heightened awareness of recycling and sustainability within the campus community, showcasing the potential of robotics to advance educational and environmental objectives. This research also contributes to the broader field of robotics by demonstrating its application in addressing environmental challenges through interactive and impactful solutions.

Abstract Name: Role of Mast Cells in Stress-Induced Increase in Intestinal Permeability

This research explored what chemical mediators are released by the intestinal mast cells under stress situation

and whether they influence epithelial permeability in the mouse colon. Mast cells are a type of immune cell that release chemical granules that contain histamine, proteases, cytokines, etc. when stimulated by neuronal, hormonal, or paracrine signals. It has been demonstrated that mast cell deficient animals show no increased intestinal permeability after exposure to stress, suggesting that mast cells may play a crucial role in stress-induced disruption of the intestinal epithelial barrier. There is little research on the specific chemical mediators released by mast cells during stress and their roles in intestinal barrier function. Mice were divided into four groups (5/group): control male, control female, stress male, stress female. Stress animals were restrained for one hour/day for five consecutive days. Control animals were kept in their home cages and did not experience restraint. Following the final restraint/control session, the proximal colon was removed and dissected. The mucosa/submucosa of each preparation was mounted to an Ussing Chamber. Corticotropin-releasing factor (CRF) was added to the basolateral side of the chamber to stimulate mast cell degranulation and samples were taken before and 30-min after adding CRF. The levels of mast cell mediators (histamine, mast cell tryptase, tumor necrosis factor- α) were measured using enzyme-linked immunoassay (ELISA). The results for histamine release showed no significant difference in either the baseline histamine release or CRF-induced histamine release between control and stressed mice. Release of mast cell tryptase and tumor necrosis factor- α will be analyzed in the next few months. Our research has the potential to identify the key chemical mediators released by mast cells during stress. This could lead to further research to identify treatments that selectively target the mast mediators that increase intestinal permeability.

Abstract Name: Identification of cyclic-di-GMP regulated biofilm matrix genes in *Pseudomonas fluorescens* by transposon mutagenesis

Cyclic-di-GMP (cGMP) is a ubiquitous second messenger in bacteria that regulates biofilm formation primarily by activating extracellular matrix genes. Biofilms are responsible for most chronic human infections due to their extracellular matrix conferring resistance against chemical and immunological interventions. Therefore, understanding extracellular matrix components' spatial function and organization is crucial for developing new therapeutic strategies. In *Pseudomonas fluorescens*, increased cGMP levels result in a dry-wrinkly colony morphology and non-motile behavior. These phenotypes likely manifest through increased production of matrix components that collectively act as extracellular glue to hold individual cells together and turn off motility genes. This study aimed to identify the matrix genes responsible for the dry-wrinkly morphology by mutagenizing a high-cGMP-producing *P. fluorescens* strain with a Tn5 transposon containing a kanamycin resistance gene from *Escherichia coli*. This transposon randomly inserts into the host genome, disrupting gene function while conferring kanamycin resistance. To target genes responsible for producing extracellular matrix components, kanamycin-resistant colonies that no longer produce the dry-wrinkly phenotype were isolated and screened for positive motility to filter out mutations that reduce cGMP production. The genomes of selected mutants were analyzed to identify specific biosynthetic genes associated with the extracellular matrix components.

Abstract Name: Diverse bacteria from the skin of the Eastern Red-backed Salamander

Amphibians are facing a significant biodiversity crisis. In the last few decades, these animals have been decimated by two fungal pathogens, *Batrachochytrium dendrobatidis* (Bd), and *Batrachochytrium salamandrivorans* (Bsal). Curiously, the most common amphibian species in the northeastern United States, the Eastern Red-backed Salamander, (*Plethodon cinereus*), appears to be largely resistant to Bd infections and also does not appear to be greatly affected by Bsal. The factors that contribute to this resistance are not fully understood. In this study, we collected *P. cinereus* skin swab samples from a total of three locations (Caesars Creek, Hills and Dales, and Taylorsville) surrounding Dayton, Ohio. Suspensions from the swab samples were plated to isolate bacteria. From a total of 27 skin swab samples, we obtained a total of 107 bacterial isolates. Many of the isolates are identified as bacteria commonly found in soil. Interestingly, some isolates are closely related to environmental clones where no cultivation of the organisms has been reported. In a preliminary test, the antimicrobial activity of the bacterial isolates was tested against *Listeria monocytogenes*, *E. coli*, *Salmonella enterica*, and *Saccharomyces cerevisiae*. Findings from this study will help elucidate the role of skin microbes in the protection against pathogens for *P. cinereus* and ultimately provide insight into amphibian conservation.

Abstract Name: Tattoos and Fear Factors: Perceptions and Presentations of Tattoos of the College Students

Tattoos due to a long association with deviant individuals, gangsters, and prisoners, had long been perceived as scary presentations. However, the popularity of tattoos among the general public in recent decades has changed the perceptions as well as the presentations of tattoos. Instead of having tattoos of high-fear designs (such as skulls and guns), many had elected to have tattoos with low-fear designs (such as hearts and stars). The purpose of this study is to examine (1) how high-fear tattoos, and low-fear tattoos are perceived respectively, (2) if having tattoos changes that view, and (3) how gender plays a role in the selection of high-fear tattoos or low-fear tattoos, as well as in the placements of the tattoos, by the college students. This study utilizes the study of the presentation of self in symbolic interactionism as a theoretical framework. More specifically, Mindy Fenske's work, *Tattoos in American Visual Culture*, as well as Clinton Sanders and D. Angus Vail's *Customizing the Body: The Art and Culture of Tattooing*, provide the theoretical foundation for this study. Margo DeMello's work, "The Convict Body: Tattooing Among Male American Prisoners," in *Anthropology Today* also informs the research questions in this study. The researcher hypothesizes that (1) high-fear tattoos and low-fear tattoos would generate different perceptions among the college students, and (2) gender would impact on the selection of high-fear or low-fear tattoo designs, as well as the placements of tattoos on one's body, by the college students in this study. A survey, designed to ascertain the perceptions of high-fear tattoos and low-fear tattoos, as well as the selections and the placements of tattoos, was administered to students in a midwestern university who served as volunteers in this study. The data collection is underway, with the research findings to become available in the near future.

Abstract Name: A New Method of DNA Extraction for Fieldwork Application

Noninvasive genetic sampling is a method for collecting genetic data from wildlife without capturing, handling, or physically restraining animals. This approach is especially valuable for obtaining genetic information while minimizing disruption to the animals and their habitats. One common noninvasive sample is scat, which often contains low DNA quantities, making extraction challenging. Traditional DNA extraction kits, like those used for scat, typically require centrifugation, significant time, and are limited in their ability to process multiple samples simultaneously, making them impractical for field use. The aim of this study was to develop an efficient, field-friendly DNA extraction protocol for scat samples that could be applied across various species, require minimal supplies, and be completed quickly while processing multiple samples at once. The protocol developed utilizes Axygen paramagnetic beads to successfully bind DNA from scat. Samples, collected between 2018 and 2024 from species including snow leopards, deer, and wolves, were dissolved in either Tris HCl or water, with both yielding comparable results. The resulting protocol proves to be highly effective and efficient for field use. It requires only the chemical Tris HCl, eliminates the need for centrifugation, and can process multiple samples within an hour. This method offers significant advantages over traditional kits in terms of time, cost, and practicality. It is ideal for wildlife genetic studies, especially in conservation efforts that involve large-scale, noninvasive sampling. This protocol represents a substantial improvement in DNA extraction for scat samples, making it an excellent tool for researchers and wildlife managers working in the field.

Abstract Name: The War of Liberation in Britain's First and Last Colony

The Troubles of Northern Ireland was a complex and multifaceted conflict which is typically thought of as being between the Protestant Unionists and Catholic Nationalists. This simplistic categorization of the clashing sides deprives the Troubles of their complicated nature and intricate socio-political issue rooted in centuries of British imperial policies and cultural suppression. The traditional timeline of events points to a thirty-year conflict but based on political violence and the loss of children, the timeline is closer to forty years ending in 2007. The Troubles were marked by military raids, political violence, and significant human rights violations. The project further explores the impact on families, especially children, and underscores the ongoing struggles for peace and reconciliation in the aftermath of the Good Friday Agreement. My research drew from newly declassified documents from the British government which are held in the British National Archives in Kew. I completed this archival research in March 2024 and these military and governmental documents provided the basis for the project. I supplemented the use of primary sources with secondary sources pertaining to the loss of children and political violence seen in Northern Ireland.

Abstract Name: Children: Humans or Threats?

Children: Humans or Threats? Can children be both human and threats? For the 732 children that were deemed as threats by the Nazi government and survived the Holocaust, the answer is yes. These children survived the Holocaust and were sent to England in an effort to become rehumanized. To their childhood governments, they were threats to the racial, nationalist, and antisemitic ideas. At the heart of the Nazi ideology lay the mass killing of 'undesirable' children. They survived the horrible six years of the Holocaust, where they were repeatedly dehumanized and degraded. When they were sent to England, they were taken pity on and were rehumanized by largely the Jewish community. This project pulls stories from a few of the children's lives to show what it was like to be children of genocide... to be children labeled as threats. My research drew from the oral histories from the children as well as the few secondary sources produced on the subject. As children tend to be underrepresented in the literature surrounding the Holocaust and genocide in general, this project aims to put children into the narrative and fill the holes in the field of study. This project not only adds to the field of Holocaust study, but also challenges the reader to think critically about conflict and genocide in both the past and into today.

Abstract Name: Golf Putter Design Optimization

This research investigates the influence of varying insert materials, infill densities, and patterns on the performance of golf putters, emphasizing the role of additive manufacturing (3D printing) in enhancing customization for individual golfers. While traditional putter designs typically feature metal or polyurethane inserts, additive manufacturing enables precise control over the internal structure, allowing for the optimization of weight distribution, feel, and acoustics. This study explores different infill densities (low, medium, and high) and patterns to evaluate their effects on critical performance metrics such as putting accuracy, consistency, and player preference. Prototypes are produced using 3D printing, and their performance is benchmarked against conventional putters in both simulation modules and field trials. Results indicate that custom-designed internal structures significantly influence a putter's responsiveness, providing a more personalized and refined experience tailored to individual golfers. The ability to manipulate these internal characteristics allows for more precise adjustments in feel, sound, and overall performance. This research highlights the potential of additive manufacturing to revolutionize golf club design by offering unparalleled customization, paving the way for a new generation of putters that better suit the unique needs of

each golfer. Ultimately, this approach could lead to improved putting performance and a more individualized, player-centric product.

Abstract Name: Navigating Difficult Conversations in Healthcare: The Use of AI Chatbots in Training Undergraduate and Graduate Nursing Students

Nursing students at both undergraduate and graduate levels require practical opportunities to develop their skills in managing difficult conversations with patients and families—a critical component of patient care that is often challenging to simulate adequately in traditional educational settings. To address this gap, we are developing a tiered experiential learning approach that incorporates an AI-based communication tool leveraging Dante-AI, which utilizes Retrieval-Augmented Generation (RAG) to build custom large language models (LLMs). By adapting and piloting this tool, we aim to enable approximately 80 nursing students to practice difficult conversations in a controlled, yet realistic environment before interacting with real-life standardized patients matched to their competency levels. Using Dante-AI's platform, we have fine-tuned a custom LLM with domain-specific data, integrating nursing communication protocols, ethical guidelines, and patient scenarios into its knowledge base. The RAG framework enhances the model's ability to retrieve relevant information during interactions, ensuring contextually appropriate and pedagogically valuable responses. Students will engage with the AI chatbot to simulate challenging dialogues, after which they will be evaluated using established rubrics aligned with course outcomes. A post-activity survey will assess their perceptions of the tool's usability and efficacy in enhancing their communication skills. By focusing on building a custom LLM using Dante-AI and RAG, this initiative not only provides a scalable and personalized learning platform but also enriches the educational experience by offering context-rich simulations that prepare nursing students more effectively for real-world patient interactions. The anticipated outcomes include improved communication competencies among nursing students and valuable insights into the integration of advanced AI technologies like Dante-AI in nursing education.

Abstract Name: Reception of Video Games over the Past Forty Years

In just forty years, video games have quickly grown from a niche hobby into a multibillion-dollar industry and a major shaping force in Western culture. Previous research into the evolution of the gaming industry has

shown interesting relationships between big publishers and indie developers, differences between genres, and more. However, this has become somewhat outdated considering how rapidly the market evolves with the emergence of new technologies and shifts in consumer demands. This research investigates how the current state of the gaming industry compares to previous findings and expands upon previous research by focusing on review scores and critical reception to different types of games. This was done using a dataset containing information on video games from the 1980s through 2023, created by scraping the video game collection website Backloggd. Using python, the dataset was processed, split into an exploration and testing set, and explored using linear regression and clustering algorithms, and statistical tests. Findings revealed that in addition to an exponential increase in game releases over time, game reviews are also increasing. Genre-specific analysis showed that Multiplayer Online Battle Arena (MOBA) games attract the largest player bases but receive the most unfavorable reviews, while Indie games are part of a recent and swiftly growing genre that is well-reviewed but reaches smaller audiences. Lastly, Nintendo's significant influence in the industry was highlighted through its connections with many of the largest game development teams. This data both confirms results of previous research and expands upon it to provide a better understanding of critical reception to different games and to the industry across time.

Abstract Name: Italianità and the Italian Response to Migration from 2014 to 2024

As unprecedented waves of irregular migration came to the shores of Italy from Africa in 2014 the EU and Italy had to respond to what was then a crisis. Ten years later, this crisis has turned into a new reality, and migration policy has changed in response to be more hostile towards asylum seekers. It is not only important to examine this issue from a political lens, but also a cultural one. Today's Italy is still affected by the narratives created by the Fascist government to unite the peninsula under a common identity of Good People, or in Italian – Brava Gente, and to legitimize Italy's colonial desires. This shared national memory hinders Italy's ability to critically reflect on its history and current migration policy. The myth of the Italian Brava Gente molds xenophobic policy and state violence against minority groups. The right to seek asylum has been protected internationally since 1951 with the Refugee Convention, but since then there have been numerous ways in which its safe guards have been circumvented. In 2017, Italy struck a deal with Libya to provide their 'so-called coast guard' with technical and financial support. The Libyan Coast Guard is actively intercepting migrants crossing the Mediterranean in hopes of reaching Europe, and returning them to deadly, and abusive environments, that the UN finds may constitute crimes against humanity. Italy has outsourced its efforts to block "undesirable" asylum seekers to Libya, aiming to keep its hands clean and uphold the moral superiority associated with the Brava Gente narrative.

Abstract Name: Subordination or State Socialism: A Marxian Interpretation of the Russian Revolution

This paper will argue that Russia's 1917-28 economic policies affirm the conclusions of the Marxian theory of history. To do this, it will first interpret the war communism of 1918-21 and the New Economic Policy (NEP) of 1921-28 through the paradigm of so-called "dependency theory," which argues that countries peripheral to global capitalism are systemically economically de-developed by those countries core to it. Through this argument, I will provide an understanding of war communism and NEP as attempts to avoid "de-development" of the Russian economy by advanced capitalist nations of Western Europe and the United States. This understanding will disrupt narratives of the Russian Revolution as subverting global capitalism which would have otherwise encroached upon it, reframing it as a project to develop capitalistic conditions competitive with the global economy--albeit, under the title of state socialism. My paper will, secondly, define the Marxian theory of history with reference to the necessity that it accords to the predating of socialism by capitalism. With these two interpretations established--first, of the Russian Revolution, and second, of the Marxian theory of history--my paper will argue that the conditions within which peripheral impulses for socialism are formed are necessarily exclusive from those within which those efforts would succeed. That is, peripheral impulsions towards socialism presuppose the entrenchment of global capitalism, and this entrenchment necessitates the essentially capitalistic nature of any socialism achieved by the peripheral. Correspondently, I will claim not that capitalism is unconditionally necessary for socialism, but that the dynamics of global capitalism reduce the possibilities through which socialism might be achieved without an antecedent stage of capitalism. In this way, empirical reality has produced conditions that are unlikely to disprove the Marxian theory of history. This reality, specifically, causes the socialist aspirations of the periphery to necessarily stem from and resolve in capitalism.

Abstract Name: Quantification of neurons in Macaque A1 region

Quantitative studies of brain anatomy are crucial for elucidating the relationship between neural function and structure. Our research, of significant importance, aims to determine neuronal density in the macaque primary auditory cortex (A1), spanning from layer 1 to the white matter region. A1, which receives direct input from the thalamus, serves as a key area for initial auditory processing. The difference in total neuronal density between A1 and V1 may contribute to variations in information processing capacities. The consistent proportion of PV cells across these primary sensory areas suggests preservation of the excitation/inhibition ratio. Our meticulous approach, employing large-scale confocal imaging combined with automated segmentation methods, has emerged as an effective approach for accurately quantifying neuronal density across diverse brain regions. We employed confocal imaging and automated neuronal quantification analysis. Neurons were labeled with: 1. NeuN (pan-neuronal marker) 2. Parvalbumin (PV) to identify a subpopulation of inhibitory neurons 3. DAPI (counterstain for later sections) Our current dataset, derived from two columns of two macaques' A1 region, revealed: - Average total neuronal density: 115,680 neurons/mm³ - Parvalbumin (PV) neuron density: 6,941 neurons/mm³ - PV neurons constitute 6% of the overall neuronal population Comparative Analysis Compared to previous data from macaque primary visual cortex (V1): - A1 neuronal density is approximately half that of V1 - The percentage of PV cells is comparable between A1 and V1 Implications. We are preparing to administer additional staining, specifically calretinin, for cross-referencing and further characterization of neuronal subtypes. This study, with its potential to provide valuable insights into the neuronal architecture of macaque A1, is eagerly anticipated for its contribution to our understanding of auditory processing and sensory cortex organization. The comparative analysis with V1 highlights both

similarities and differences in primary sensory cortices, opening avenues for further investigation into sensory information processing.

Abstract Name: Monitoring Radon Washout/Rainout Events with Modified CosmicWatch Radiation Detectors

Gamma-ray intensity variations were monitored for precipitation events over several months, including the remnants of two tropical cyclones, using a set of modified CosmicWatch radiation detectors. Clear signatures of radon washout/rainout were recorded for each event with > 1 mm of precipitation, with gamma-ray count rates in excess of 50% above normal in some cases. All of the washout/rainout events were verified by measurements from an on-site rain gauge. The results demonstrate that low-cost CosmicWatch systems can be used for sensitive atmospheric radon monitoring.

Abstract Name: Genetically Engineering *Vibrio campbellii* with Chromoproteins for Multispecies Assays

Chromoproteins are proteins that produce bright, distinguishable pigments under the visible light spectrum when expressed by organisms, and have the potential to serve as novel reporters for studying gene expression in bacteria. *Escherichia coli* has previously been engineered to express a palette of chromoproteins encoded on plasmids as an alternative to using fluorophores in research, which require sophisticated equipment to excite and detect expression. However, limited work has been done to use these chromoproteins in other bacterial species, or in the use of studying multispecies bacterial behaviors such as bacterial motility, biofilm formation, and type VI secretion competition. In this project, we sought to engineer a chromoprotein-producing strain of *Vibrio campbellii*, a Gram-negative marine pathogen. We cloned the gene encoding the yellow chromoprotein gene (DasherGFP) from *E. coli* into a *V. campbellii*-compatible plasmid vector and introduced it to *V. campbellii* through conjugation, successfully producing visible yellow pigment in *V. campbellii* colonies distinguishable from the wild type. Using this plasmid backbone, we aim to expand our library of pigmented *V. campbellii* to construct strains corresponding to other colors in the rainbow for use in future multi-species studies. We plan to use these strains in competition assay between *V. campbellii* and *E. coli*, comparing *V. campbellii* mutants deficient in motility, biofilm formation, and type VI toxin secretion and their effect on each species when grown together. This project ultimately explores the potential for using

chromoproteins as a new genetic tool to expand existing microbiological assays for studying multi-species competition.

Abstract Name: Effect of EDOT-Py Nanoparticles in the Viability of Brain Tissue Scaffolds

Organic bioelectric devices like scaffolds have recently made many breakthroughs in tissue engineering but a critical issue in modern medicine, brain tissue regeneration, remains relatively untouched. Scaffolds function to generate a tissue with a particular form but are limited by being too rigid to support various cell types. Since tissue cells should ideally be in a scaffold similar to the environment the tissue experiences in vivo, most scaffolds are not conducive to mimicking a brain environment for brain tissue regeneration. The creation of a new scaffold device with similar properties to the brain would allow for more exploration of brain tissue regeneration treatments. Biocompatible materials for brain tissue scaffolds would need to be soft and conductive. This may be achieved through using hydrogels functionalized with polymers with these properties. EDOT-Pyrrole nanoparticles (NPs) were selected due to their high sensitivity to bioelectrical signals while fibronectin was chosen for its pre-existing use in wound healing. A hydrogel with both materials could help encourage tissue regeneration. ND7/23 cells were cultured in the hydrogels then analyzed through fluorescent imaging. The implications of the results could allow functionalized hydrogels to be adapted into current bioelectric devices and create a new and safe method to regenerate brain tissue in patients that may need it. In doing so, this research works to further add to health literacy and understanding of neurological processes and provides a basis for future exploration of innovative medical treatments for tissue regeneration, be it in brain, skin, or heart tissue.

Abstract Name: Investigating the Genetic Architecture of Ion Intake in Plants

Climate change has become a complex series of issues in our world, impacting our ecosystems and vegetation land, including rising soil salinity due to increased evaporation. The elevation of salinity in our soils due to unsustainable agricultural practices such as excessive fertilizer use, improper irrigation, poor-quality water, and deforestation. These practices have negatively affected crop growth and yield by spiking soil salinity which disrupts water uptake and causes nutritional imbalances. Like many organisms, plants are able to resist and regulate their system during dire times such as droughts, floods and high salt levels due to runoffs. Plants have a limited capacity to endure extreme conditions, but identifying regulatory functions can help develop

salt-tolerant plants. The development of salt-tolerant crops is essential for combating climate change and harmful agricultural practices. Some *Arabidopsis thaliana* mutants have been shown to exhibit higher salt tolerance than their wild-type counterparts, suggesting that certain genetic factors may regulate ion uptake and metabolism. In our research, we conducted a lab which focused on three different gene mutations in the *Arabidopsis thaliana* plant predicted to be able to change the gene expression in response to changes in soil ion concentration. We evaluated the different gene mutations based on their phenotypic features such as seed size, root length and leaf size. Larger seed sizes have been shown in some case studies with salt-tolerant mutant plants to be more effective at regulating ion intake. In addition to this, longer root length has shown to be more tolerant to high salinity. The measurement of leaf sizes will be used to determine how well the mutant plants grow in comparison to the wild type. By understanding the mechanism behind how plants regulate ion intake and tolerance to high salinity soil, we can maintain agricultural productivity and food security.

Abstract Name: The Robot: From Dance Craze to Dance Partner

What is the state of artificial intelligence (AI) and machine learning in the performing arts today? How will such programs integrate into dance spheres, and at what level should that integration be? These questions arise when viewing the imminence of AI machinery in nearly every aspect of everyday life, with little restriction on its development. By comparing the origins of AI in dance to what it is currently capable of achieving, as well as examining current forerunners in the field, there may finally be answers. There will also be analysis of notable works partially created using AI by notable choreographers such as Merce Cunningham in order to better understand its contribution to an overall piece. Using this information, as well as the findings of engineers and artists Catie Cuan and Ken Goldberg, we can predict what it may be capable of in the future, allowing us to have more healthy and intelligent discussion about its trajectory. I have found a comfortable spot personally at the use of dance as a choreographic tool. Much like one would call upon choreographic techniques from composition classes to create unique movement, artificial intelligence would become an alternative methodology of creating inspiration or framework that the choreographer would be able to adjust and personalize. It is notable that this approach is not without flaws. It may be impossible to draw a definitive line, free of criticism, but opening this topic for discussion and inspection is likely one of the most important ideas for dance spaces to explore.

Abstract Name: Isolation of Antifungal Compounds Deoxyviolacein and Violacein from *Janthinobacterium lividum* VT36D and CO Strains

Antibiotic resistance in various microbes is a growing problem. Throughout the last century, many antibiotics have been discovered and used for the treatment of infectious diseases. Unfortunately, the increased use of antibiotics leads to the microbes responsible for these infections developing drug resistance. In this context, finding novel antibiotics has become a research area of significant interest. Many microbes produce their own antibiotics. *Janthinobacterium lividum* bacteria is known to display antifungal activity, specifically inhibiting the growth of the *Batrachochytrium dendrobatidis* (Bd) fungus. This fungus is threatening global amphibian populations with an epidemic of the disease chytridiomycosis. Cutaneous amphibian bacteria such as *J. lividum* can aid in defense against fungal infections by producing compounds with antifungal properties. In collaboration with UMass Boston's CURE Microbiome course, we set out to test the effect of *J. lividum* bacteria cultured from frog skin on the Bd fungus. Our research focuses on isolating the organic compounds produced by two strains of *J. lividum* bacteria, *J. lividum* VT36D and *J. lividum* CO. We collected a similar purple crude extract from both of our strains, and using paper disk assays with Bd fungus, we observed significant growth inhibition. Using liquid-liquid extraction, high-performance liquid chromatography (HPLC), H-NMR, and mass spectroscopy, we isolated and identified the key antimicrobial compounds in these strains of bacteria. We detected deoxyviolacein from *J. lividum* VT36D, a visibly purple compound with antifungal properties. We also detected violacein from *J. lividum* CO, another purple antifungal compound with a similar molecular structure. During the isolation process, we used thin-layer chromatography (TLC) and found that Methanol-D4 was an effective solvent to dissolve these specific compounds. Finally, we used a new solvent, DMSO, to investigate the effects of the solvent on our structural analysis of these antimicrobial compounds, and we were able to further support the identity of violacein.

Authors:

Abstract Name: High Literature, Low Literature, and its Impact On Social Systems and Functions

My project examines the relationship between high and low literature, a classification that reflects themes of race, gender, and especially class. The explanation for this concept has proven itself through a myriad of changes to its supposed stagnant system. Renowned writers such as Daniel Defoe and William Shakespeare exemplify this evolution. Their works are now in academic spaces, studied by scholars and deemed the blueprint of high literature. However, in their time, they were deemed as low literature, their popularity seemingly proving their lack of highbrow status. This nature could refer to topics or themes discussed in their writing that were considered trash, cheap or taboo. Like in Defoe's *Roxana*, where the protagonist is a woman who indulges in affairs to attain status and wealth while abandoning the role of a mother, or Shakespeare's *Othello*, in terms of race, where *Othello* was depicted in blackface by male actors. My methodology focuses on the variety of high literature novels taught in English courses at the Brooklyn College campus, observing which novels or writers are known by the public and which are not. Aside from investigating what works are considered high literature or low literature, I look at the specific factors that ultimately play the role in determining this status, factors that include accessibility, level of literacy and mobility. High literature is essentially exclusive and can mostly be found in academic spaces where it is discussed in scholarly discourse, whereas low literature is popular and highly inclusive and features many voices in its discourse, though often with far less scholarly emphasis. Are these disparities between classifying high and low literature products of social issues and if so, can by solving or at least understanding that system help then, solve conflicts reflected in society?

Abstract Name: Rapid Changes in Coloration in Adult Field Crickets in Response to Climate Change

The animal kingdom displays a diverse array of colors. The ability to express different types of melanin-based coloration may be crucial for animals' adaptation to climate change. For example, insects can adopt lighter coloration to limit heat absorption from solar radiation ('thermal melanism hypothesis'). Other environmental factors, such as water availability and predation risk, may also affect melanism or dark coloration. Cuticular melanin plays a role in many adaptive responses in insects, such as reducing water permeability, so darker insects can exhibit reduced rates of water loss during drought ('water conservation hypothesis'). Insects also rely on crypsis or camouflage to reduce predation risk, with dark environments potentially increasing melanization and light environments reducing it ('crypsis hypothesis'). Here, we used a factorial design to manipulate temperature (20°C or 30°C), water availability (with or without drinking water), and environmental color (white or black background) during early adulthood in the variable field cricket (*Gryllus lineaticeps*), which naturally exhibits a range of coloration, from pale tan to red to black. We measured melanization in the crickets' wing pads to test the relative importance of temperature, water availability, and crypsis in the plasticity of coloration, as well as potential interactive effects between these factors. Preliminary results indicate strong support for the thermal melanin hypothesis, no support for the crypsis hypothesis, and contradictory support for the water conservation hypothesis. Our research will clarify how plasticity in coloration may respond to ongoing climate change and urbanization, which continue to alter temperature, water availability, and predation risk worldwide.

Abstract Name: Using *C. Elegans* to elucidate the cellular mechanisms of Exercise-Induced Recovery from Methamphetamine Addiction

Methamphetamine (METH) is a highly addictive stimulant that inflicts detrimental effects on the central nervous system (CNS), leading to addiction and various neurotoxic consequences. Excessive dopamine and glutamate production caused by METH can contribute to oxidative stress and toxicity. These changes in neurotransmitter levels have been associated with decreased learning, cognition, and dopaminergic terminal neurodegeneration. Despite extensive research, the precise molecular and cellular mechanisms underlying METH's toxicity remain elusive. To address this, we employed *Caenorhabditis elegans* (*C. elegans*) as a model organism to gain valuable insights into the drug's impact on the CNS. Through behavioral assays and neurobiological investigations, we examined the effects of METH exposure on *C. elegans*, aiming to uncover the pathways responsible for behavioral and neurobiological alterations. Our results revealed that METH exposure induced a dose-dependent increase in nose touch behavior, indicating reduced learning ability in this model. Additionally, we observed a significant dose-dependent decrease in DAT expression, demonstrating

dopaminergic terminal neurodegeneration. Moreover, our investigation into oxidative stress via glutathione transferase expression highlighted potential targets for therapeutic intervention in METH-induced neurotoxicity. Overall, our study contributes valuable insights into the mechanisms through which METH affects the CNS in *C. elegans*. The conservation of key neurobiological pathways between *C. elegans* and mammals suggests that these findings may have implications for understanding the impact of METH on humans. This knowledge could potentially guide the development of targeted therapies to combat METH addiction and its associated neurological complications.

Abstract Name: Bridging the Gap: Students Translators and Interpreters within the Community

This presentation analyzes translation and interpretation projects carried out by university students. By taking real “clients” in the legal, medical, social services, and education fields, students enrolled in a Community Translation and Interpretation course delve into the complexities of providing language services with cultural awareness to diverse communities to guarantee their access to services in crucial areas such as housing, immigration, specialized medical attention, domestic and gender violence, food and education. In this presentation, as the Professor of the course and as a mentor for students conducting independent research in translation and interpretation, I will discuss aspects such as the use of Spanish inclusive language and the linguistic variations in translation, and ethical and cultural dilemmas student interpreters face, particularly in health care settings. As I have students who have submitted proposals to the NCUR to present their research on translation and interpretation, I foresee this as an opportunity to engage the audience in discussing the theory and praxis of translation and interpretation for the community and the impact of these types of courses in the language curriculum in higher education.

Abstract Name: Resort and Marina with Biophilic Elements

The goal of this themed resort was to evoke curiosity in guests by creating a themed environment for them to enjoy. The research conducted was survey questions about what any age group or demographic looks for in a resort, a field visit was also conducted. These themes will be El Dorado, which in myth is known as the city of gold. Taking inspiration from ancient Colombian culture and legends can cause people to be more curious about the resort and its aspects. A ceremony that was told was of precious jewels thrown into the lake to appease a god that lived underwater. By taking inspiration from some of these parts of the legends and the culture that was told they were in space, the resort uses some of these aspects in some detail, like bodies of water that may be placed in the resort. Plato told Atlantis that this land was half god and half human. Their homes were also concentric islands separated by wide moats and linked by canals. These lush islands contained gold, silver, and other precious metals, supporting abundant rare, exotic wildlife. This space can be

transitioned to the water, leading to the different themed legends in the common areas. The Hanging Gardens of Babylon are thought to be located near the royal palace in Babylon. However, some research says they might have been constructed in Nineveh, Assyrian. Research purposed that these gardens were rooftops created by Sennacherib, king of Assyria. By taking inspiration from the Hanging Gardens of Babylon and the rooftop gardens in the interior, guests feel a botanical paradise when visiting this resort.

Abstract Name: Leveraging Machine Learning for Rapid Response in Wildfire Management

A wildfire is described as an unwanted and uncontrolled burning of a natural area, such as forests or grasslands. Throughout history, various methods have been utilized to detect and prevent wildfires in a timely manner. However, with the rise in global warming, wildfires have become more frequent, highlighting the need for new and innovative solutions. Research from the Center for Climate and Energy Solutions indicates that a 1-degree Celsius rise in temperature could result in a median annual burned area increase of up to 600%. The goal of this research is to show how machine learning can help with the detection of wildfires through the use of developing technology. The research will implement machine learning through the use of convolutional neural networks (CNNs), long short-term memory networks (LSTMs), and the Random Forests algorithm. By leveraging the power of CNNs, LSTMs, and Random Forests, this research aims to improve the early detection of wildfires, ultimately providing faster response times and reducing the devastating impact of these disasters on both human life and the environment. Two datasets were used and combined into one dataset containing 500 images. The images were divided into training, testing, and validation sets. The training set had 200 images, and the test and validation sets had 50 images each. Each set was split evenly into 'fire' and 'no fire' labels. In addition to the image data, temporal information, such as weather patterns over time, was incorporated using LSTMs to analyze the progression of environmental changes. Furthermore, environmental factors such as temperature and wind speed were included in the model. As technology continues to evolve, integrating machine learning models with real-time data could significantly enhance early detection and response systems. The research aims to enhance wildfire prediction strategies, advancing the potential of machine learning in environmental monitoring.

Abstract Name: Calvarial biopsy using augmented reality technology: a video case report and technical note

Background: Calvarial lesions are uncommonly encountered and are often slow, progressive processes. Biopsies of calvarial lesions can be uniquely challenging due to its proximity to critical structures. Augmented reality (AR) offers a potential alternative to CT guidance that reduces radiation exposure and provides hands-free intraoperative guidance through complex and challenging surgical approaches. Methods: Our patient is an 86-year-old female with significant past medical history of coronary heart disease. The patient underwent imaging which demonstrated a left parietal lytic skull lesion with extracranial extension. Using Surgical AR (Medivis, New York, NY), a trajectory was planned centered on the lesion. Surgical AR was registered using point-to-point registration reliant on four anatomic fiducials. We used a ground truth, which is a bi-faced adhesive tag that measures 2cm x 1cm, with a QR code on each side that the Surgical AR system recognizes. This ground truth was placed on the patient's forehead which linked to the registered holographic overlay. A small incision was made and after removal of a small portion of the overlying skull, multiple pieces of the lytic skull lesion were sampled. Results: A specimen was obtained for frozen sectioning. Intra-operative pathology was consistent with metastatic carcinoma. Total surgical time was 35 minutes from incision to closure. Conclusion: The frameless AR navigation system successfully allowed accurate location, visualization, and biopsy of a calvarial lesion that had minimal surface landmarks. More so, this was completed without obscuring the surgical field or requiring time-consuming setup or registration.

Abstract Name: Visuospatial Reasoning Does Not Predict Ability in Mixed-Reality

Background: Existing literature has indicated a strong correlation between visuospatial abilities and video game experience with the performance in robotic surgery techniques. However, this performance ability is often attributed to the innate aptitude – not progressive skill improvement – of participants. We hypothesize that participants with greater visuospatial abilities and video game experience will perform Mixed-Reality (MR) tasks with improved speed, accuracy, and demonstrate more task improvement when compared to individuals with lower spatial reasoning skills and video game experience. Methods: Twenty-one participants with limited MR experience were selected. Visuospatial abilities were measured with a series of mental rotation tasks (MRT). Next, all participants were trained to perform a series of clinical and non-clinical tasks

in MR using Medivis SurgicalAR. Following testing, participants completed a survey evaluating mental demand. The data will undergo quantitative coding for accuracy, measured by slips, time for completion, and perceived difficulty. Normality is assessed by a Shapiro-Wilk test, and Pearson correlations assess whether MRT score predicts task completion time and accuracy. Additionally, a two-tailed paired t-test assesses if practice improved performance. A learning curve analysis is used to identify whether variations in MRT score and video game experience correlate with differences in learning ability. Early Results: Early analysis indicates that MRT score predicts clinically relevant placement time for the last of four physical landmarks, ($p=0.024$). There was also a statistical improvement in completion time and accuracy of non-clinically relevant MR tasks with time decreasing between trial 1 and 2 ($p=0.024$), trial 1 and 3 ($p=0.018$), and number of slips decreasing between trial 1 to 2 ($p=0.018$), and trial 2 and 3 ($p=0.002$). Conclusion: Early analysis of data indicates that the results observed with robotic-surgery techniques extend into MR. The presence of learning among participants also indicates that performance is highly susceptible to learning.

Abstract Name: Environmental and Anthropogenic Effects on Terrestrial Mammal in the Oklahoma City Metro Area

Urbanization is growing world-wide, particularly in North America, posing challenges for wildlife. In this study, we investigated factors that affect wildlife distribution in the highly urbanized Oklahoma City (OKC) Metro area to understand the relative importance of habitat quality, presence of domestic animals, and human activity intensity on wildlife, using medium-large terrestrial mammals as a model taxon. Here we report preliminary data on 21 camera trap sites (active for ~78 days during Summer of 2022 and 2023) combined with site covariates (summer and winter NDVI, road intensity and number of domestic records) collected in a 250 m radius buffer around the camera locations. We used Poisson Linear models (GLM) to test the effect of site covariates on mammal species richness. Except for larger predators (i.e., black bear, cougar), we detected most mammal species expected to occur in the region. Sites varied greatly in species richness (3-9), with the white-tailed deer and the skunk being the most and least detected species, respectively. The summer NDVI model was the top ranked, followed by the winter NDVI model, suggesting that habitat quality, expressed in higher vegetation cover, positively influences mammal distribution in the study area. Data collection in the 2024 summer and the inclusion of other covariates (e.g. habitat connectivity and human population density) will help us further understand the factors that influence mammal distribution in urban environments.

Abstract Name: Helium DBD Plasma Power and Gas Temperatures Measurement

Dielectric Barrier Discharge (DBD) due to its non-thermal nature is attractive for applications in the medical field. Research now supports the fact that DBD plasma exposure on a wound can accelerate the healing process. Another important feature is about the plasma ability to mitigate bacteria that may assist the wound to heal quickly. Traditionally, the plasma DBD plasma jet needs a dielectric material that holds two electrodes across which an ac voltage (5–10kV/30-50kHz) is applied to ionize the working gas. Due to their ionization potential helium or argon is used as the working gas that passes through the dielectric tube at moderate flow rates (10-15slpm). One drawback of using the plasma jet on the wound surface is its higher gas temperature that may damage the cells. The plasma gas temperatures heavily depend on the input power that we intend to measure in this work. In addition, Plasma vibrational and rotational temperatures are also measured at identical operating conditions. The plasma input power was measured by measuring the current and the applied ac voltage (5kV-10kV at 30-50kHz) voltage before and after the plasma discharge. The V/I signals were measured across 100 Kohm Bellet resistor and were displayed on the oscilloscope before and after the plasma. Due to capacitive nature of the plasma, there was a phase lag around between the signals across the plasma that was used to estimate the input plasma power. Our result show that plasma input power varies between 20 W to 43 W for our operating conditions. Plasma gas temperatures were measured using a k-type thermocouple that was scanned along the plasma jet. The plasma jet tip temperatures were found around 25 C. The details of the electrical circuit, hardware, experimental set up, and the relevant calculations will be detailed in the coming presentation.

Abstract Name: Deconvolution of Partitioning Delays from Time-Resolved Trace Gas Measurements

Time-resolved measurements of low-volatility gases are limited by the partitioning of analyte to instrument surfaces, resulting in what are known as partitioning delays. These delays slow instrument responses and affect the accuracy of subsequent analyses. In this work, a deconvolution algorithm is introduced for the purpose of correcting measurements affected by partitioning delays. The performance of the algorithm was evaluated using synthetic data and its success in correcting for partitioning delays was demonstrated in airborne nitric acid measurements. The effectiveness of deconvolution was compared to frequent subtraction of instrument background, which is the current best practice for correcting partitioning delays. Frequent background measurements are outperformed by the deconvolution algorithm when sample concentrations are changing rapidly. The deconvolution algorithm can be applied to time series that include frequent measurement of instrument backgrounds, enabling reanalysis of past data. Furthermore, the algorithm does not rely on any coincident data; it is effective without any external information about the true time series of an analyte. When applied to nitric acid measurements from a wildfire smoke plume, deconvolution increased the calculated normalized excess mixing ratio ($\Delta\text{HNO}_3/\Delta\text{CO}$) by 72%. This work demonstrates that the deconvolution algorithm is applicable to ground, airborne, and eddy flux covariance measurements of ‘sticky’ compounds.

Abstract Name: Navigation System for Snowplow in Low Visibility

This research presents an advanced navigation system designed to support snowplow operators during low-visibility conditions in winter, addressing safety and efficiency challenges. Developed at the Real-Time Analytics of Transportation Data (REACTOR) Lab, Iowa State University, the system integrates GPS, radar, and lane departure algorithms to guide operators and prevent accidents caused by poor visibility. The system employs high-precision DURO GPS to accurately locate vehicles, detect lane positions, and calculate deviations from road boundaries. A Delphi ESR radar with a configurable 45° field of view identifies objects up to 60 meters ahead, categorizing hazards into green (50–100 feet) and red (0–50 feet) zones. These data streams feed into a lane departure algorithm that calculates a deviation threshold (2.5–3.5 feet) and alerts drivers via a user-friendly tablet interface. A key innovation is the generation of detailed road maps using GPS and Linear Referencing System (LRS) data. Maps were created for 70 miles of roads near Ames and Tama, Iowa, enabling precise navigation. Deployed at the Iowa Department of Transportation's Tama Garage, the system was tested on a snowplow for over 200 hours in real-world conditions, successfully detecting obstacles and ensuring road clearance. Integrating radar object detection, lane departure algorithms, and real-time GPS mapping, the system provides actionable insights to operators, enabling safer navigation in challenging winter conditions. This research enhances safety, mitigates risks, and ensures uninterrupted road maintenance during extreme weather events. It aligns with the broader mission of the Institute for Transportation at Iowa State University while fostering collaboration with the Iowa DOT.

Abstract Name: The Role of Newspapers in U.S. History's Only Successful Coup D'etat: The Wilmington Insurrection of 1898

November 10, 1898, was one of the most harrowing days for Black citizens in North Carolina's history. The first and only successful coup d'état in United States history, the violent Wilmington Insurrection is perhaps one of the most overlooked racially motivated events following the Civil War and Reconstruction. In part started by a newspaper editorial and misreported in newspapers until memory became faulty, this event's history has largely been defined by newspapers from beginning to end, and still is today. At the time, Wilmington was the largest city in North Carolina, with a population of roughly 10,000 that was over 50% Black. Following the events of the day, dozens had been killed and over 2,000 Black citizens had been displaced from their homes in Wilmington. Launched due to a combination of the November 8 election results and tensions over a local newspaper editorial written by the Wilmington Daily Record's Black editor Alexander Manly, the local White Democrat party was able to force various Fusionist political leaders of Wilmington into resignation. Throughout the day, local and state papers rushed to report information, often publishing incorrect or politically biased editorials on the events, creating a cacophony of contradictory knowledge. Over time, memory and understanding of the events that took place have become no less

disorganized. The government made no effort to begin an investigation or issue an official report until 2006, 108 years after the event, leaving the narrative up to the newspapers who had published on it. Due to the long-term lack of official information, these newspapers were a key part of the way the Wilmington Insurrection is viewed publicly, even today. Viewed as a chaotic riot rather than a racially motivated coup d'état, newspapers play a key role in the distorted memory of the Wilmington Insurrection of 1898.

Abstract Name: Growing The Garden Of Change: Sharing The Stories Of Those Affected By Alzheimer's And Dementia

I was inspired to research the impact of Alzheimer's and Dementia on families after a car accident left my grandma in the hospital, and my grandpa Jack with Dementia in the care of my family. Seeing the work and emotional toll it took on my family to care for him, I wanted to learn more about the disease and find support from those in the community with similar experiences. I connected with the local Alzheimer's Association Chapters to attend events as a volunteer photographer so I could take photos for my project while giving back to the organization and community members. It was inspiring to meet and talk to people who share similar experiences as my family and gain new perspectives from those who currently live with the disease or have lost someone to the disease. Being able to connect so deeply with members of my community encouraged me to put my all into this project as I wanted to share their stories candidly and bring awareness to Alzheimer's and Dementia in hopes to find a cure. This project helped me realize my passion for sharing stories and encouraged me to pursue journalism post graduation. Additionally, I received recognition from the community, the Alzheimer's Association, and in academia for my work. I made professional prints of my book and shared it with members of the local chapter and with the families of those I featured. Those families reached out to share how meaningful it was to have a physical reminder of their loved ones. My book was shared throughout the organization, making it all the way to their Chief Marketing Officer, Michael Reich, who was impressed with the depth of my research. I was chosen as an Honorable Mention for the 2024 CAHS Outstanding Undergraduate Researcher award.

Abstract Name: Analyzing Energy Transference in the γ Subunit of Escherichia coli ATP Synthase through Terminus Extension

Adenosine Triphosphate (ATP) is recognized as the cell's energy resource that is primarily synthesized by the enzyme ATP synthase. This enzyme is composed of two multisubunit subcomplexes which form a rotating component and a stationary element. Energy transmission between these components is vital for the function of ATP synthase. As one of the rotary elements the γ subunit is the core component for energy conversion and the main focus of our research. Our research aims to determine whether addition of 4, 8, 12 or 14 alanines to the N or C terminus in the γ subunit would affect the enzyme's function and its energy conversion efficiency. We hypothesize that significant alterations, in this case, addition of alanine to the N and C terminus will reduce the enzyme's energy yield. This is hypothesized based on previous studies of the importance of the length of the γ subunit. We aim to evaluate the exact number of amino acid additions the γ subunit can tolerate without causing complete functional disruption.

Abstract Name: Effects of photoinhibition on material thickness using in-situ ultrasonic monitoring

Vat Photopolymerization (VPP) is an Additive Manufacturing (AM) process that applies light to cure a photopolymer resin in sequential layers. While common VPP methods utilize a single light source, our approach employs a dual light projector (DLP) that merges blue and Ultraviolet (UV) light for printing. In this system, the blue light initiates the photopolymerization curing reaction, while UV light acts as an inhibitor. This phenomenon is known as photoinhibition, where the ratio of blue light to UV light intensity is the inhibition ratio. Photoinhibition enables better control during the printing process, providing better print results and structural integrity. Past studies have explored photoinhibitions overall effects but lack focus on its effects on layer thickness and quality. To discover photoinhibition's effects on layer thickness we conducted three experiments printing samples with different inhibition ratios. We used In-situ ultrasonic monitoring (IUM) to collect data during printing and analyzed the data by looking at the time of flight (ToF) of each sample. The data from the ToF graphs and the quality of the three printed samples pointed towards a correlation between photoinhibition levels and material thickness.

Abstract Name: DISMANTLING MYTHS ABOUT LATINX IMMIGRATION AND THE U.S. ECONOMY

Abstract For centuries, immigrants from all different parts of the world have come to the United States looking for a better life. As seen through the Bracero Program and the use of Asian labor to construct railroad systems, the United States itself has exploited immigrants for its benefit and needed them to build this country. Despite this reality, there are many misconceptions about immigrants—as many American citizens tend to view them as a burden. Whether they are viewed as a burden because they “take jobs” or have difficulty assimilating—immigrants have always faced discrimination. In this research, I will analyze the realities that Latinx immigrants face in the United States and debunk the myths surrounding their role in the economy of modern-day America. Keywords: history, immigrants, jobs, assimilation, Latinx

Abstract Name: What Do Americans Think About The Death Penalty?

The death penalty has long been a controversial topic and a major theme in ethical dilemmas. Because of its contentious nature, I decided to conduct a survey to better understand the American perspective on the death penalty as a form of legal punishment. Additionally, I believed there would be a difference in the levels of support for this form of legal punishment between men and women. To test this, I designed a questionnaire with 17 questions, collected data via Amazon Mechanical Turk, and received 147 completed surveys, which were analyzed using IBM's SPSS. My interest in this disparity was inspired by Hofstede's study of cultural dimensions. According to his theory, men tend to be more assertive and tough, whereas women are generally more nurturing and relationship oriented. Based on these assumptions, I hypothesized that women would be more likely than men to support the death penalty as a punishment for sexual crimes against children and rape crimes. Surprisingly, my research results showed that 14.7% of women opposed the death penalty for sexual crimes against children whereas 4.2% of male respondents opposed the death penalty in this instance. Furthermore, 43.7% of males supported the death penalty as a punishment for rape crimes, while 33.3% of women expressed support. These results were statistically significant differences at the 5% level and contradicted my initial prediction, for they showed that more men than women support the death penalty as a form of legal punishment for rape crimes and sexual crimes against children.

Abstract Name: Molecular Investigation of A2B Subtype, Partial c Antigen, And GATA-1 Mutation in an Individual of Egyptian Ancestry

A 21-year-old individual of Egyptian ancestry with a history of microcytic anemia due to iron deficiency demonstrated an ABO typing discrepancy, suggestive of a rare subtype. Serological, lectin, and genotype tests, including ABO subtyping and targeted next-generation sequencing (NGS), revealed the presence of the A2B subtype, unexpected anti-A1 antibodies, and partial c antigen expression. Genotyping confirmed ABOA2.01 / B.01 alleles and heterozygous FY01 / FY*02N.01. Further, we plan on identifying the isotype of the unexpected anti-A1 antibodies. These findings suggest implications for transfusion safety and alloimmunization risks. Blood group typing discrepancies, often due to rare subtypes or variant antigens, can complicate transfusion medicine. Individuals with the A2B subtype may produce anti-A1 antibodies, which pose clinical challenges. Additionally, partial c antigen increases alloimmunization risk, particularly in populations with limited allele frequency data. This study focuses on molecularly characterizing the A2B subtype and partial c antigen in an individual of Egyptian ancestry, where such variants are understudied. Combining serological methods and next-generation sequencing, this investigation explores the clinical significance of these findings.

Abstract Name: Comparative Genomic Analysis of Colorectal Cancer Microbiome Bacteria to Discover Novel Relationships

The National Cancer Institute (NIH) highlights the importance of microbiome research, offering grants to advance this critical field of research. Our work aligns with this mission, as the purpose of our research is to study the microorganisms/bacteria in the gut microbiome that are influential to the progression of colorectal cancer (CRC), which is uncontrolled tumor growth originating in the colon. Lifestyles, environments, and genetics, among other influences, affect the development of CRC. Our central research question focuses on finding differences in pathways/enzymes between cancerous and non-cancerous associated bacteria in the gut microbiome, as outlined by a recent cancer microbiome review. Our research methodology began with utilizing the Bacterial and Viral Bioinformatics Resource Center (BV-BRC), where we compiled our bacteria's genetic information into genome groups and used the comparative systems service to identify target pathways and construct phylogenetic trees. After focusing on genomes, we delved deeper into the enzymes.

The programming language R was used to narrow down four specific enzymes from the set of genomes: two from the pathways in non-cancerous bacteria and two in cancerous-associated bacteria. Our results were confirmed with a Multiple Sequence Alignment (MSA) run at the genome level, which identified the range of lowest entropy among the genes in the four enzymes — one of which had the lowest range of 30-40. Currently, we are using NCBI Blast and other bioinformatics methods to characterize/validate the four enzymes in our respective target bacteria with gene expression meta analysis. In conclusion, our end goal is to target/screen the unique pathways and enzymes (like enzyme 5.4.3.2) of the cancer-associated and non-cancerous associated bacteria to decrease the metastasis of CRC tumors. Our future steps include wet lab manipulation of these genes, which help create enzymes, in order to create a probiotic drink targeting CRC.

Abstract Name: Development of a Rapid, Temporal, Cartilage Assay to Screen Novel Arthritis Therapeutics

Arthritis is costly (\$65 billion per year) and traumatic. Current therapies for arthritis primarily address symptoms rather than the underlying causes of disease progression. Therefore, identifying novel drugs that target the underlying mechanisms driving this disease is crucial. Traditional 2D adherent cell line based screens fail to recapitulate the 3D architecture of cartilage. High-throughput 3D cell-based drug screening offers an efficient and rapid method to screen potential compounds. However, a challenge in creating these assays is the loss of cell aggregates during testing due to their small size. To address this issue, we are investigating the optimization of cartilage aggregates to 384-well plates, compared to traditional 96-well plates, for compound screening. In this study, lubricin promoter-driven bioluminescent primary human chondrocyte reporter cells will be cultured, trypsinized, counted, and seeded into 384-well plates to form cell aggregates of 5,000 cells each. The bioluminescent reporter cells enable easy, non-destructive, cost-effective assessment of lubricin production - a key component of articular cartilage that reduces friction and damage. The Opentrons pipetting robot will test aggregates (16 per condition) with variations in pipette type (P20 vs. P300), flow rate (2 μ L/s to 50 μ L/s), and aspiration height (2mm to 3mm). The aggregates will be fed every other day over 14 days under physioxia (5% oxygen) conditions, simulating oxygen tension in the human joint. Plates will be imaged every feeding day to track aggregate growth and calculate the proportion of lost aggregates to determine the optimal protocol for compound screening. Ultimately, the goal is to discover a lubricin-stimulating drug that can prevent osteoarthritis progression, enabling individuals affected by sedentary lifestyles to return to active, healthy living. Achieving this requires optimizing the 3D high-throughput screening assay to minimize aggregate loss and improve overall screening efficiency.

Abstract Name: Virtual Reality for Enhancing Spatial Visualization Skills

This work introduces a Virtual Reality application still under development, designed to enhance spatial visualization skills—an essential cognitive ability in STEM education. These skills, which involve mentally comprehending and manipulating 2D and 3D shapes, are closely linked to success in various STEM fields. However, many students struggle to develop these skills through traditional methods. The VR application immerses students in a 3D environment where they interact with virtual objects. The current version includes two core modes: a "free view" mode, which allows users to freely manipulate 3D objects and see their corresponding 2D projections, and an "orthographic view" mode, which presents multiple tasks aimed at reinforcing spatial concepts through structured activities and orthographic representation of 3D objects. This work showcases the development process, which utilizes the new XR toolkit to ensure compatibility across various VR headsets, although the application is currently being used with Oculus Quest. The use of the XR toolkit allows for future scalability and deployment on a wider range of devices, ensuring flexibility in educational settings. This presentation focuses on the work completed so far, detailing how these interactive features have been developed to enhance spatial visualization. Future developments will include more advanced features, such as the integration of reinforcement learning to provide adaptive challenges based on user performance, further refining the personalized learning experience. This ongoing work aims to create an innovative tool for improving spatial skills and expanding immersive educational experiences in STEM.

Abstract Name: Exploring Cannabigerol as an Agonist for PPAR γ in Metabolic Dysfunction-Associated Steatotic Liver Disease in Mice

Metabolic-Dysfunction Associated Steatotic Liver Disease (MASLD) is the leading chronic liver disease in America. MASLD progresses through a gradual build up of lipids in the hepatocytes (>5% of lipids). If not treated, MASLD can lead to more serious conditions, such as metabolic dysfunction steatohepatitis and cirrhosis. Obesity and metabolic syndrome are related to MASLD, with insulin resistance (IR) being a major risk factor associated with MASLD. Peroxisome proliferator-activated receptor gamma (PPAR γ) is a nuclear receptor with primary function in adipose tissue in the liver. PPAR γ has many biological effects, such as regulating adipogenesis and lipid metabolism. In the liver, PPAR γ promotes the expression adiponectin (ADN), a hormone that plays a role in increasing insulin sensitivity and inhibiting lipid accumulation. Cannabigerol (CBG) is a non-psychoactive minor constituent of the cannabis plant. CBG has been shown to have anti-inflammatory effects and a potential PPAR γ agonist. This project aims to investigate the effects of CBG, as the PPAR γ agonist, in modulating the progression of MASLD via PPAR γ -ADN axis. Male and female mice were fed a high-fat, high-sucrose diet for 16 weeks. From week 8 to week 16, mice were supplemented in the presence or absence of CBG. Liver tissues were harvested and proteins were extracted. Western blot protocol was used to detect the expression of PPAR γ . ELISA was employed to evaluate the serum level of ADN. The results showed that the expression of PPAR γ was increased in both male and female mice. Meanwhile, the ADN in serum increased during treatment of CBG in males but not females. Our results suggest that CBG could activate the expression of PPAR γ , but a gender differential response exists in regulating the ADN levels. With MASLD cases continuing to rise, it is vital to explore underlying mechanisms that are associated with MASLD in efforts to explore alleviating treatments.

Abstract Name: Random Tn5 Mutagenesis of *hns* has Different Effect on Motility in *Paraburkholderia unamae* and Expression of *flhDC*

Paraburkholderia unamae, a diazotrophic gram negative bacterium endemic to the American Southwest and Mexico, is a plant growth-promoting bacterium with multiple copies of the flagella master regulator *FlhDC*. To identify genes that affect motility in *P. unamae*, a genetic screen using Tn5 mutagenesis was used. Mutations within and surrounding the histone-like nucleoid-structuring (*hns*) gene were frequently identified and mutants showed different degrees of effect on motility. Mutations upstream of *hns* resulted in significant reduction in motility, suggesting potential regulatory regions. Two other mutations within *hns* also resulted in significant reduction in motility. H-NS protein is known to be involved in the positive regulation of the *flhDC* operon in other gram negative bacteria, such as *E. coli*. To determine if H-NS also has a positive regulatory effect on *flhDC* in *P. unamae*, RT-qPCR was performed on wildtype *P. unamae* and an *hns* mutant, TR3.50, to compare the relative transcription of *flhD1C1*. *flhD1C1* expression was reduced in TR3.50 relative to wildtype. In addition, in a motility assay, the TR3.50 mutant, showed a significant reduction in motility relative to wildtype, an 82% to 93% reduction. These findings show a positive regulatory relationship between *hns* and the *flhD1C1* operon in *P. unamae*. Additional studies are needed to determine the regulatory mechanism of H-NS on *flhD1C1*.

Abstract Name: The Impact of Different Management Strategies for Invasive Honeysuckle on Nesting Success of a Common Songbird

Human activities such as climate change, fragmentation, and urbanization have led to the proliferation of invasive Amur Honeysuckle (*Lonicera maackii*) in urban areas. The management practices carried out to control this vegetation are important in determining the success of urban-adapted wildlife like the Northern Cardinal (*Cardinalis cardinalis*). Our study aimed to determine how management for honeysuckle affected nesting success demonstrated by nestling growth rates, fledging success, predation, and clutch size. We surveyed 3 sites differing in management practices and hence in abundance of honeysuckle as well as the diversity of other bushes and trees. We searched for Cardinal nests from early-May to early-August, finding a total of 235 nests. We recorded GPS coordinates, approximate nest height, and its contents (eggs or nestlings) and then revisited nests every other day. Eggs were weighed upon initial presence and nestlings were individually marked and weighed every other day. We found no difference between sites in clutch size, hatching success, or fledging success, as predation appeared similar across all three sites in contrast to our initial expectations based on the literature. Additionally, nestling growth rates were lower at the honeysuckle-dominated site than at the most similar site lacking honeysuckle, contradicting the expectation that higher insect abundance associated with honeysuckle would promote faster growth. We propose that differences in food supply for adults (seeds) versus nestlings (large insects) may explain these differences, with diverse woody vegetation supporting more of the latter. Given the feeding diversity of songbirds, how honeysuckle-dominated environments affect insect communities may affect the growth of nestlings of other species

differently. Future research should explore how management for invasive species affects the nesting success of different songbird species and further investigate invertebrate abundance and nestling diet.

Abstract Name: A Mixoplankton's Response to Low Light and Missing Prey

Mixoplankton are protists capable of two trophic modes, photoautotrophy and phagotrophy. They play a crucial role in marine ecosystems and have been observed to switch between trophic modes in response to differences in environmental resource availabilities. The factors influencing their switching capabilities remain poorly understood. We investigated the impact of resource availability on *Cymbomonas tetramitiformis*, a model mixoplankton species. Four treatment groups were established: (1) control (regular light, regular prey), (2) regular light and low prey, (3) low light and regular prey, and (4) low light and low prey. Growth was measured via cell counts using flow cytometry over five weeks. As expected, the control group exhibited the highest growth rate. Interestingly, the low light and low prey group displayed faster rates of growth and larger cell counts compared to the low light regular prey group, a result that warrants further investigation. These findings suggest that *C. tetramitiformis* may employ complex strategies to optimize resource utilization under different environmental conditions. Further research is needed to evaluate the underlying mechanisms driving these responses, including possible metabolic shifts and behavioral adaptations. Work will be continued in the development of fluorescently labelled bacteria (FLB) to observe the phagotrophic mechanism in hopes to understand why the low light and low prey treatment of *C. tetramitiformis* grew so well.

Abstract Name: Living with Age

Medical science has enabled longer but not necessarily better lives. Aging can be a demoralizing process as elders become increasingly dependent on others to perform activities of daily living (ADL). ADLs are rituals that define daily life, including bathing, walking, dressing, toileting, transferring, and eating. Dependence on others interrupts rituals that have been built over a lifetime. Without the proper resources to maintain ADLs, elders become unable to adjust to new rituals, and caregivers become overwhelmed with responsibility, resulting in families turning to care communities. According to the Center for Disease Control and Prevention (CDC), more than one million individuals live in residential care communities on any given day in the United States. 88% of residents need assistance performing ADLs, bathing being the most common, with 75% needing assistance. Why has bathing, a private ritual critical for physical and emotional health, been pushed out of the home? The physiological and psychological consequences of poor hygiene make it imperative that caregivers provide proper care. Homes are not currently built to accommodate the changes in bathing rituals.

Through primary research of elders, immediate caregivers, and professional caregivers as well as analysis of the product landscape for Durable Medical Equipment (DME) and Assistive Technologies (AT) I aim to develop a design innovation that enables caregivers to support elders' hygiene rituals in their homes.

Abstract Name: Investigating the Impact of Vaccine Metaphors on Vaccine Attitudes in College Students

According to the World Health Organization, vaccine hesitancy, defined as an individual's delay or refusal to become vaccinated, is a top ten global health threat. College students are a particular category of interest because of their role as superspreaders during the COVID-19 pandemic and their relatively higher rates of vaccine hesitancy. Common reasons for vaccine hesitancy include mistrust in the scientific and medical community and low levels of health literacy. Both of these issues can be mitigated through effective scientific communication. One previous study demonstrated that culturally relevant metaphors are an effective way to explain clinical trials to women in rural areas, and another study tested the effect of vaccine metaphors on the general population. However, the effect of using culturally relevant vaccine metaphors when communicating vaccine information to college students has not yet been discerned. Participants in our study read either a passage presenting information about vaccines as college student-focused culturally relevant metaphors or as literal information. Participants completed the vaccine attitude measurement (VAM) questionnaire and accompanying questions about trust in scientists before and after reading one of the two passages. Our study recruited undergraduate college student participants which we randomly assigned to read one of the two passage types. Science confidence increased in both conditions as did VAM scores, indicating a more favorable attitude towards vaccines as a result of the intervention, though no additional impact of the metaphor passage was found to influence overall science confidence or VAM scores. VAM subscales including personal attitudes towards vaccines and speed of vaccine development, were increased in the metaphor and literal groups, respectively. Taken together, this intervention demonstrated that health messaging positively impacts vaccine attitudes and trust in science in college students, highlighting the importance of effective science communication in transforming public attitudes towards vaccines.

Abstract Name: Polymorphic Phase Transformation of Artemisinin in Polymer-Based Formulation Development for Pharmaceutical Applications

Hot-melt extrusion (HME) and additive manufacturing have gained recognition as innovative processing technologies for formulating crystalline solid dispersions in pharmaceuticals. These methods offer distinct

advantages over conventional techniques, including reduced unit operations, cost efficiency, solvent-free processing, and compatibility with continuous manufacturing. However, their broader application has been hindered by concerns about potential polymorphic phase transformations (PPT) of active pharmaceutical ingredients (APIs) during processing. To enhance their viability as alternative strategies for solid dosage formulations, it is essential to understand how critical process parameters (CPPs) such as temperature, pressure, and shear stress influence PPT. The solvent-mediated polymorphic phase transformation of artemisinin (ART) was employed to optimize the formulation and stability of its metastable state. ART, known for treating malaria, is an active pharmaceutical ingredient with two known polymorphic forms that influence its physicochemical properties. The metastable form, ART II, possesses higher bioavailability and solubility than the commercial form, ART I. However, ART II tends to transform into ART I due to the thermodynamic stability favoring the stable form. Incorporating a dispersant, specifically polyethylene glycol 4000, within the ART matrix optimized the favorability for the formation of the metastable state. Coupling these critical processing parameters accelerated the time required for the transformation from ART I to ART II. Temperature-stimulated extrusion (TS-E), temperature-pressure-stimulated extrusion (TPS-E), and temperature-pressure-shear stress-stimulated extrusion (TPSS-E) were performed with in situ polarized optical hot-stage microscopy and time-resolved powder X-ray diffraction to monitor the nucleation induction time and complete transformation. This approach effectively facilitated the transformation from the stable to the metastable state of ART. By controlling the selectivity of ART II through novel polymer-based formulations, there is potential for more effective and controlled production of solid dispersions on a large scale, ultimately improving drug stability and efficacy.

Abstract Name: Goya's Black Paintings: Perpetuating the "Tortured Artist" Theory and the Romanticization of Mental Illness

This study examines Goya's Black Paintings within the context of the Tortured Artist theory to study the romanticization of mental illness within today's society. Artists today are notorious for perpetuating their struggle in order to justify their artistry and create 'authentic' work. Holistically, this research aims to explain how and why artists will emphasize their turmoil to create more emotional work, as it feeds into a negative mindset that can be observed and applied to famous artists from hundreds of years ago. This research synthesizes psychology studies, deep dives into artworks and their documentation, and experiments that seek answers from response time. It can be concluded that the Tortured Artist theory contributes to a heavily toxic mindset which can lead to a further unhealthy relationship with art, as well as a detrimental link between suffering and profits.

Abstract Name: Exploring the Dual Role of *Beauveria bassiana* as a Biofertilizer and Bioinsecticide for

Spotted Lanternfly Control

The spotted lanternfly (*Lycorma delicatula*), native to China, threatens U.S. plant health by feeding on the sap of over 70 plant species, including black walnuts, causing reduced crop yields, plant stress, and even death. With limited control mechanisms, this devastates agricultural and forestry industries, leading to this investigation of using a microbial inoculant on plants to inhibit spotted lanternfly activity. The objective of this study is to inoculate black walnut saplings (*Juglans nigra*), a plant species commonly targeted by the spotted lanternfly, with *Beauveria bassiana*. This entomopathogenic arthropod-pathogenic fungus grows naturally in soils. We hypothesize that *B. bassiana* will positively impact plant growth while killing the spotted lanternfly. Wisconsin fast plants (*Brassica rapa*) and black walnut saplings inoculated with *B. bassiana* had increased plant height and number of leaves compared to control groups. Additionally, *B. bassiana* was lethal to nymph and adult spotted lanternflies directly inoculated with the fungus. There is a current gap in knowledge about how *B. bassiana* influences insect-plant interactions, which this research also aimed to address by exploring the potential of *B. bassiana* to mediate these interactions and contribute to pest management strategies. To investigate whether *B. bassiana* inoculation would limit plant-insect interactions, black walnut saplings were inoculated with *B. bassiana* for 24 weeks. Plant-insect interaction trials presented spotted lanternflies with inoculated and control plants to observe insect behavior, including initial choice, interaction frequency with saplings, type of interaction, and duration of interaction. Across the 12 trials, results indicate that *B. bassiana* treatment does not alter plant choice by spotted lanternflies but is lethal to the spotted lanternfly while enhancing plant health. This suggests *B. bassiana* could serve as both a biofertilizer and bioinsecticide, offering a promising strategy to control spotted lanternfly populations while promoting plant vitality.

Abstract Name: An Analysis of How James Monroe's Communication and Mannerisms on His National Tour Affected the Era of Good Feelings

This paper explores how President James Monroe's personality and communication style shaped the Era of Good Feelings (1817–1824), a period in U.S. history often associated with national unity and reduced political conflict. While this era is typically attributed to postwar nationalism following the War of 1812 and the decline of the Federalist Party, this study highlights Monroe's active role in fostering cohesion through his unprecedented national tours. Monroe's tours allowed him to connect directly with citizens, presenting himself as approachable and inclusive. These interactions, along with his adaptable leadership style, fostered a sense of shared purpose and reduced political tensions. Unlike his predecessors, who often maintained formal and rigid approaches to governance, Monroe's willingness to engage with citizens of differing political views positioned him as a "common man." This quality, along with his tolerance and affability, helped bridge ideological divides. Contemporary accounts, including speeches, newspaper articles, and citizens' reflections, reveal the widespread respect Monroe earned, even from political opponents. The study introduces the concept of the "formality-commonality complex," which contrasts Monroe's balance of personal connection and statesmanship with the more formal styles of Jefferson and Madison. The paper also addresses historical debates, challenging critiques that downplay Monroe's contributions to the era. By analyzing novel primary sources from historical archives - such as Monroe's speeches, newspaper articles, and firsthand accounts from citizens - it argues that Monroe's tours and personal interactions were crucial in defining the Era of Good Feelings as a reality rather than merely a retrospective label. Ultimately, this research highlights how individual leadership can shape broader social and political dynamics. Monroe's ability to foster unity through empathy, flexibility, and engagement provides valuable lessons for understanding leadership's role in reducing polarization and creating a cohesive national identity.

Abstract Name: Diet Impact on Knee Osteoarthritis Pain, Mental And Physical Health: A Holistic Approach to Medicine

Knee osteoarthritis (KOA) is a chronic pain condition that leads to a decrease in quality of life (QOL). The traditional treatments for KOA pain are pharmaceutical-based and focus on symptom management rather than finding a long-term solution. Previous research has shown that a low carbohydrate (LCD) diet can be effective at reducing pain in those with KOA. As an alternative to medication, this study is observing the impact of the LCD and the standard United States Department of Agriculture (USDA) diet on KOA pain as well as mental and physical health. Participants were between the ages of 45 and 85 and were enrolled in the study for 7 weeks. Six of those weeks consisted of the randomly assigned diet intervention. Participants returned five times during the course of the study to undergo mechanical and movement-evoked pain testing, and to complete questionnaires regarding mental health, physical health, and pain. DEXA scans and blood samples were obtained at baseline and the end of the diet. Preliminary results indicate significant reductions in pain severity and intensity after completion of both diets. A significant decrease in PHQ-9 scores as well as participant's weight in both diet groups suggests an improvement in mental and physical health. As further research is conducted, it is expected that this dietary intervention has the potential to start improving upon various facets of health and continue yielding significant results for the questionnaires and tests that are being conducted. The results of this study indicate that diet can affect the different aspects of health: mental, physical, and pain. Changes in diet pave the path to offering a holistic treatment to disorders rather than pure symptom management through medication; this method will hopefully have longer-lasting benefits.

Abstract Name: Effect on pH After Room Temperature Storage of E-liquids

Electronic cigarettes, often known as vapes, are now the most popular nicotine product among American youth. The most common vapes used by college students from brands like JUUL and Vuse utilize the form nicotine salt. Differing from the free-base form prevalent in previous generations of vapes, protonated salt has acid added to a nicotine base. While free-base e-liquid has a higher pH than nicotine salt e-liquid initially,

nicotine concentration and flavor may affect these values. To determine the pH of various e-liquids containing free base nicotine and nicotine salt at various concentrations, as well as flavoring chemicals, at two time points test whether storage at room temperature has an effect on e-liquid pH.

Abstract Name: Comparison of the Shape Memory Properties of 3D/4D Printing Materials

3D printing has many industrial applications due to its low cost and accessibility but is limited by durability, time, and rigid post-printing shapes. To address this, 4D printing has emerged, enabling printed objects to react to external stimuli and change shape. This is achieved using materials like TPU, which have shape-memory properties due to their glass transition temperature, allowing them to become soft and return to their original shape when heated. Interestingly, some common 3D printing materials, such as PLA, also exhibit glass transition temperatures, suggesting potential shape-memory properties. Our investigation explores whether PLA and other widely used filaments can serve as cost-effective alternatives to specialized materials like TPU for 4D printing. We hypothesized that many 3D materials possess limited shape-memory properties, but their effectiveness would vary based on factors like infill density and durability over multiple deformation cycles. To test this, we printed PLA, ABS, and TPU ASTM-D638-Type-1 standard dogbones at 20%, 60%, and 100% infill densities. We measured the time each sample took to return to its original shape and the number of cycles it could undergo before losing its shape-memory properties. Results for TPU showed a positive correlation between infill density and recovery time, with 100% infill samples taking 1.5 times longer to return to their original shape compared to 20% infill. Furthermore, lower-infill samples lost their shape-memory properties more quickly than higher-infill ones. A full analysis of and comparison will be presented at the conference.

Abstract Name: Perceptions of Health Risks of Nicotine Usage in Adolescents

In adolescents, nicotine use impairs brain development, for example, damaging the prefrontal cortex and the reward pathway. To educate adolescents about the health risks associated with nicotine use, it is important that web sources, such as the CDC website on nicotine effects, present information in a way that promotes understanding. Currently many sources do not present information in an evidence-based way. Past research

shows a combination of numeric, verbal, and visual is most effective (Lipkus, 2007). This study aims to establish the best way to communicate health risks to adolescents by testing their understanding of nicotine-related health statistics. Participants in introductory psychology classes at UK were randomly assigned to four visual aid conditions (text, graph, table, or picture) and reported on their beliefs and experiences with nicotine via Qualtrics. Participants viewed health information for 10 minutes in their assigned condition and answered interpretation questions. We also measured subjective numeracy and graph literacy. A logistic regression revealed a significant interaction effect between subjective numeracy and condition on redundant information accuracy. Among participants with high or average subjective numeracy, viewing information in a graph was more helpful than any other type of presentation. However, among participants with low subjective numeracy, there was no effect of condition. Furthermore, when information was presented in the text only, participants in the graph condition were less likely to accurately remember as compared to the text-only condition. These findings establish the need for health information presented by health sources to adjust and use a combination of visuals and texts to promote understanding of health risks in adolescents leading to the number of adolescents using nicotine to decrease.

Abstract Name: MATLAB-based Modeling to Predict the Performance of Heat Sink for Passive Cooling of a High-power LED Panel

High-power UV-LED panels are increasingly used for indoor plant growth, with immediate applications in space agriculture. UV light has shown potential to accelerate seed germination. However, a significant challenge in UV-LED operation is the heat generated during use, which necessitates effective thermal management. Both passive and active cooling techniques are commonly employed to mitigate panel surface temperatures. In this study, an aluminum heat sink with dimensions of 4"×6"×0.25" was used to investigate thermal performance. The fins had a fixed height of 4" and a thickness of 0.02", with the number of fins varied to optimize surface temperatures and heat transfer rates ($Q_{t-Q_{\dot{t}}}$) of the heat sink. Heat generation in the base plate was assumed to be 200 W. Conduction and convection heat transfer equations were applied to model the heat sink's performance and the base temperature as a function of fin count. MATLAB was employed for the analysis. As a first step, air properties—including density, Nusselt number, and Prandtl number—were calculated at an ambient temperature of 20 °C. Elenbaas's equations were then used to determine the Nusselt number, linear thermal transmittance (Ψ), and Rayleigh number as functions of fin count and spacing. These parameters enabled the estimation of convective heat transfer coefficients, fin efficiency, and heat sink efficiency. Preliminary results indicate that the heat sink's thermal conductance increased with fin count, reaching an optimized value of approximately 8 W/K with 28 fins. Optimal fin spacing was found to be around 0.8 inches. At a base plate temperature of approximately 100 °C, the addition of fins reduced the temperature to an optimized value of around 65 °C with 28 fins. Detailed results on heat transfer ($Q_{t-Q_{\dot{t}}}$), fin efficiency, and effectiveness will be presented in the final study.

Abstract Name: A Framework for Bias Detection and Mitigation in Machine Learning

As AI systems increasingly influence critical decisions in domains like hiring, salary prediction, and criminal justice, the lack of transparency in their predictions raises significant fairness concerns. This research addresses these challenges through a framework that combines Explainable AI (XAI) techniques—such as SHAP, LIME, and fairness metrics—with mitigation strategies like reweighing and adversarial adjustments to detect and reduce bias in machine learning models. The framework is applied to real-world datasets, including the COMPAS dataset for predicting criminal recidivism, the UCI Adult dataset for income classification, and a resume screening dataset focused on gender bias. Results demonstrate effective bias mitigation with minimal impact on model accuracy, as evaluated using fairness and performance metrics. This research contributes to responsible and transparent AI adoption by providing a practical, reusable toolkit for bias detection and mitigation.

Abstract Name: Human Impacts on the Water Quality of Lake Yojoa, Honduras through Time

Lake Yojoa is the largest tropical lake in Honduras and is a staple in the country for consumable fish exports. The lake has suffered from serious water quality degradation due to several human activities that have altered the hydrological flow. Influences such as hydrological changes, new mining operations, and intensive tilapia aquaculture have increased nutrient levels, heavy metal contamination, and changes in sedimentation processes that promote the growth of harmful algal blooms (HABs). These HABs threaten the ecological health of the lake which harms the fish in the farm as well as the water supply to local tourism. Lack of historical data on these tropical lake systems has inhibited the identification of the primary cause of degradation. This research attempts to fill this gap by reconstructing the historical impacts of human activities on the water quality of Lake Yojoa with the use of paleolimnological methods. Our sediment core that was collected in January 2023 will be analyzed for key nutrients (carbon, nitrogen, phosphorus), heavy metals (mercury, arsenic, lead), and photosynthetic pigments (chlorophylls, carotenoids) to track changes in primary productivity and pollutant levels over time. By linking these results to historical human influences, my research intends to point out the specific roles of aquaculture and mining in nutrient enrichment and heavy metal contamination. It will investigate if these inputs have served as the reason for the influx of HABs that are harming the nearby environments. The findings are expected to inform management strategies to mitigate further degradation, not only for Lake Yojoa but also for the conservation of lakes and waterways globally, providing insights that can help address similar environmental challenges worldwide.

Abstract Name: Intercellular Stress Generation During 1D Collective Migration of Cancer Cells

Physical forces drive many cellular processes such as migration and proliferation. A metastatic tumor will have invasive strands/chains that extend from the main tumor. These chains of cells collectively migrate away from the main tumor to establish new colonies elsewhere in the body. However, how physical forces drive this collective invasion and the required energy for this process is not well understood. Invasion of a metastatic tumor to surrounding tissues leads to a majority of cancer-associated death and is often a collective effort among cells, it is therefore important to fully understand the process behind collective cancer invasion. The goal of this project is to determine the forces that drive collective cell migration in a one-dimensional system of cells. Analyzing a single strand of migrating cells allows for an in vitro analysis of metastatic chains developed by a tumor. To confine migrating cells to a one-dimensional chain we engineered the extracellular environment via micropatterning such that cells only migrated along a thin line of extracellular matrix proteins patterned onto an elastic substrate. Once contained on a patterned elastic substrate with known physical properties, cell-matrix, and cell-cell forces were quantified via Traction Force Microscopy (TFM) by tracking substrate deformations. To connect these forces with cellular bioenergetics, we will quantify the energy level of these migrating cell chains by measuring the cellular ATP:ADP ratio with a genetically encoded molecular probe. Current results suggest that cells leading the collective migration experience greater forces, implying that these cells have greater bioenergetic needs. We predict that migrating cell chains experiencing higher forces will face additional strain and need to increase their energy output and therefore ATP:ADP ratio.

Abstract Name: Exploring Eco-Friendly Deposition of Bismuth Thin Films for Lead Detection

The presence of heavy metals, such as lead, in drinking water is a growing concern in the United States. Traditional lead ion detection methods often involve toxic substances and complex techniques. This research aims to develop a simple and environmentally friendly method for preparing bismuth thin films to enhance lead ion detection in drinking water. We focused on the electrochemical deposition of bismuth onto a copper base using a non-toxic bismuth nitrate solution, as opposed to the more hazardous nitric acid and acetate buffer solutions commonly used. Bismuth was chosen for its accessibility and non-toxic properties. Our experiments explored various parameters, including voltage, concentration, and deposition time, resulting in a range of bismuth deposits with distinct nanoscale structures. Our results revealed three types of deposit morphologies: microscopic bismuth particles, shard-like deposits, and speckled textures. Deposits made with a concentration of ≥ 1.0 mM yielded bismuth nanoparticle clusters and nanowires. The optimal conditions for producing speckled morphology were found to be a concentration of 0.75 mM, a deposition time of 30 seconds, and a voltage of -1.4 V. This morphology was also observed at 0.16 mM under similar conditions. Time primarily affected the amount of bismuth deposited, often leading to overgrowth rather than desirable structures. These findings contribute to a better understanding of electrochemical deposition techniques and their application in preparing bismuth thin films for effective lead ion detection.

Abstract Name: Deep Learning Models for Predicting Flight Rules using Weather Data

In aviation, weather is an important hazard factor with a potentially drastic impact on the safety of aircraft. One of the leading causes of fatal weather-related accidents was low cloud ceilings and/or visibility between 2008 and 2022, resulting in 41% of all fatal weather-related accidents for general aviation and 49% for Part 135 aviation. To reduce the weather-related accident rate, the FAA limits aircraft flight in instrument meteorological conditions (IMC) to instrument flight rule (IFR) certified pilots. Still, pilots who are only visual flight rule (VFR) certified or are on a VFR flight plan occasionally fly into IMC, known as "VFR into IMC" events. VFR into IMC events are the major cause of both weather-related accidents and fatal weather-related accidents. Available statistics validate the need to predict flight rules and flight categories (FCATs) in areas where VFR into IMC events are possible. In this study, a deep learning architecture is implemented for time series analysis of flight data for predicting flight rules. A long short-term memory (LSTM) architecture is utilized, and the predicted flight rules are compared with the outcomes obtained using a recurrence neural network (RNN) and a gated recurrent unit (GRU). These three models were trained using weather data from four equidistant airports and their known FCAT at the time of data recording. These models obtained comparable results for predicting flight rules, but the LSTM and GRU models performed slightly better than the RNN model for predicting FCATs. The results demonstrate that the proposed models have sufficient accuracy for predicting common-occurring FCATs, usually VFR and Marginal VFR (MVFR). However, they had poor performance in predicting rare-occurring FCATs, usually IFR and Low IFR (LIFR). The future research focuses on improving the accuracy of the models for prediction of IFR and LIFR.

Abstract Name: Natural and Anthropogenic Ecosystem Loss Following Establishment of Percy Priest Lake in Middle Tennessee

Worldwide, the construction of dams has provided large-scale hydroelectric power and flood control but is also responsible for extensive environmental disruption. One example was the damming of the Stones River in middle Tennessee in 1967, which produced the 5,747-hectare Percy Priest Lake. The objective of this study was to evaluate the extent of natural and anthropogenic ecosystems lost due to the formation of this lake. Using pre-lake aerial photographs, ecosystems that were covered by the lake were identified, mapped, and their area quantified using ArcGIS. The largest ecosystem lost was non-forested areas, which were mostly crop lands in the Stones River floodplain, and woodlands were the next highest ecosystem lost. Forests, the Stones River and its tributaries, and cedar glades represented <13% of area lost. In addition, at least 188 structures and four bridges were destroyed. The damming of Stones River represented an economic loss to farmers, which included their agricultural land and buildings, and a loss in important natural ecosystems, such as cedar glades and riverine environments. Similar losses likely occurred throughout the southeastern United States in the 20th Century as the Tennessee Valley Authority built many dams in the region.

Abstract Name: Gratitude's Effect on Acute Stress and Cardiovascular Response

Gratitude has been described as the quintessential positive psychological trait. It has been linked with numerous aspects of physical and mental well-being, such as improved sleep, personal growth, higher quality relationships, optimism, and reduced rates of depression. Recent research suggests that gratitude can also mitigate the effects of acute stress on the cardiovascular response. The purpose of the present study was to test this relationship experimentally. Specifically, we hypothesized that individuals would show a diminished cardiovascular response to an acute stressor following a gratitude manipulation relative to a control manipulation. Using a within-subjects design, 21 undergraduate university students completed two sessions in consecutive weeks that included either a control prompt (asked participant to write about personal values) or gratitude prompt (asked participant to reflect on areas in their life they experience gratefulness). Immediately after the five-minute writing task, participants underwent two minutes of immersing their arm in ice water and two minutes of difficult mental math. Both these tasks have been shown to increase acute stress. Blood pressure, heart rate, and self-reported stress levels were measured. Consistent with expectations, participants' heart rate was less elevated in response to stress in the gratitude condition. Participants also reported lower stress following the gratitude writing task. However, no significant differences between blood pressure and self-rated stress were found after the stress induction. These results provide partial support for the idea that psychological factors such as gratitude can influence cardiovascular response to stress. Given the link between physical health and psychological health, further research is warranted to clearly support these results.

Abstract Name: Investigating Interconnectedness of Water Quality and Social Equity in a Metropolitan Urban Stream Watershed

Reducing disparities in stream water quality is a state-level priority in Georgia, USA, yet targeting communities for assistance is hindered by the lack of empirical evidence regarding populations disproportionately affected. This study addresses this gap by analyzing stream water quality and social equity by identifying the types of communities disproportionately burdened by water contaminants. We hypothesized that watersheds with a majority of low-income communities and minority groups (Hispanics and non-Whites) face greater likelihood of poor water quality contamination. The study focused on an urban stream network of two creeks—Proctor Creek at Burbank Drive (AW-BB), Proctor Creek at Grove Park (AW-GP), and one River—the Chattahoochee River (AW-CHR) —representing communities with diverse socioeconomic backgrounds. Physicochemical water quality parameters were measured using a Horiba U-50 portable meter and microbial indicator testing following the IDEXX standard methods were conducted to assess water quality. Windshield survey observations explored visible differences in pollution levels among the creek environments, with affluent areas exhibiting cleaner environments compared to economically

disadvantaged neighborhoods. Laboratory microbial analysis revealed varying levels of microbial contamination, with higher counts of microbes observed in samples from low-income areas, particularly AW-GP. Interpretation of the results underscores the complex interplay between socioeconomic disparities and contemporary water quality challenges. The findings suggest a need for targeted interventions to address environmental justice concerns and ensure equitable access to clean water for all communities in Georgia. This research contributes to a broader understanding of the socio-environmental dynamics shaping water quality disparities, highlighting the importance of impact in addressing contemporary environmental challenges. By elucidating the connection between sociodemographic and environmental inequities, this study underscores the imperative for inclusive and equitable water management strategies to promote environmental justice and safeguards for public health.

Abstract Name: Probing Membrane Binding of Alpha-synuclein Using Double Histidine Cu(II) Labeling And Electron Spin Resonance Spectroscopy

Alpha-synuclein (α S) is a heavily expressed protein in the nervous system specifically in the presynaptic terminals and exhibits a natively unfolded state (intrinsically disordered) under normal physiological conditions. α S is responsible for synaptic transmission between neurons, assisting in signals within the brain, through its ability to bind to phospholipids and the surface of synaptic vesicles. Upon binding, α S undergoes structural reorganization from a dynamic and disordered state to a conformation consisting of a long-extended helix. Conditions can cause α S to form insoluble aggregates known as Lewy bodies, often associated with Parkinson's Disease and other synucleinopathies. This study attempts to mutate specific sites on α S to form a double histidine mutation, which will serve as an attachment point for a copper spin label and allow for electron spin resonance (ESR) analysis of protein dynamics. The experiments will improve understanding of α S binding affinity to membranes of differing curvature. Mutants of α S will be generated through site-directed mutagenesis on chosen sites. The DNA will be transformed in *E. coli* and sequenced to confirm successful mutagenesis. Up to this point, a successful double histidine has been confirmed, expressed, and purified. Attempts to attach the copper spin label can begin to perform an ESR analysis.

Abstract Name: The Impact of Henry VI's Mental Illness on Politics and Religion in England

This paper examines the life of Henry VI of England (1421-1471) who suffered from catatonic schizophrenia, which is diagnosed by medical experts in a modern medical analysis of symptoms noted during his lifetime, and analyzes its impact on the political and religious life of fifteenth-century England. The life of Henry VI was filled with turmoil and instability. His reign saw defeat in France at the end of the Hundred Years' War,

and the beginning of a civil war in England known as the "Wars of the Roses." Henry suffered from a mental disability that contributed to the ineffective leadership he displayed, allowing rivals to seize power from him. Henry's physical and mental state was devastated by his battle with catatonic schizophrenia which forced him to be absent from the throne. As a result, this created a power vacuum within the kingdom and allowed many of his political rivals, such as Richard the Duke of York, to take advantage of Henry's suffering seize control of the kingdom, and start a civil war. Henry's disability drastically affected not only the political history of early modern England but its religious history as well; Henry became the subject of a religious cult after his death and was said to work miracles for believers.

Abstract Name: Cardiorespiratory Exercise Intensity and Perceived Stress Among College Students

The purpose of this study is to dive deeper into research on different intensities of cardiovascular activity and how it affects stress in the population of college students. Further, this study will examine if a single workout can impact perceived stress. Pursuing higher education may build up stress comprising multiple components, whether it is financials, time commitments, assignments, or external factors. The primary hypothesis is that exercise intensity will impact stress among college students. The secondary hypothesis is that a single workout will (increase, decrease, or not change) perceived stress. A convenience sample of college students attending a midwestern university were recruited by email and social media ($n = 7$). Participants completed a physical activity readiness questionnaire (PARQ+), a short demographic survey, an interview of qualitative questions, and then completed the perceived stress scale test. After the PSS they completed a 35-minute physical activity intervention including a five-minute warm up, three five-minute bouts at light, moderate, and vigorous intensity in random order with 5 minutes of cooldown in between, and then a five-minute recovery. During the fifth minute of each bout, participants were asked to rate their perceived stress and exertion on a scale from one to ten. The results indicate a significant difference in stress between the three intensities, $F(2,12) = 5.77$, $p = .02$. Stress was significantly higher during vigorous intensity exercise ($M = 4.14$) when compared to moderate intensity ($M = 2.86$) and light intensity ($M = 2.14$). Although perceived stress was lower following one workout, this change was not statistically significant, $t(6) = 0.72$, $p = .25$. The conclusions from this study are that stress is impacted by exercise intensity, with stress being higher at vigorous intensity than at moderate or light intensity, and that perceived stress is not changed significantly by a single workout.

Abstract Name: Project InSight: The Privacy Risks of AI Enhanced AR

We are experiencing the simultaneous rise of augmented reality (AR) and AI technologies, which are enabling promising new interactive experiences across domains such as education and healthcare. Advancements in large language models (LLMs) enhance daily activities by enabling personalized AR experiences, like task-specific guidance or context-aware reminders. However, as AI-enhanced AR devices become incorporated in daily life, they will collect extensive data, such as gaze patterns, spatial environments, and biometric details such as muscle movements and stress levels, consolidating this data into single repositories. This raises significant risks to users' privacy and autonomy, including inferences on biometric data that could reveal health conditions, manipulative visuals that exploit gaze tracking to influence purchasing decisions, and behavioral profiling used to create addictive experiences or target users with emotionally exploitative content. To address these concerns, this research develops and evaluates an AR Privacy Educational Assistant designed to raise end-users' awareness about privacy risks and encourage privacy-preserving behaviors. By processing AR sensor data, the Assistant generates inferences about users' physical surroundings and usage context, presenting users with clear explanations and depictions of potential privacy threats, from subtle to severe. To evaluate its effectiveness, end-users will participate in simulated AR usage scenarios, such as AR demo apps like Stadium360, which lets users watch live games from home in an immersive stadium. Their responses will be analyzed before and after showing the data the app collects and its uses to assess whether awareness impacts their willingness to adopt privacy measures. Ultimately, our work aims to contribute to the development of awareness and educational mechanisms for end-users and bystanders, informing future AR systems that prioritize privacy and security while enabling innovative applications. By fostering transparency and user empowerment, we hope to mitigate the risks posed by the growing convergence of AR and AI technologies.

Abstract Name: Caring for Vanua: Exploring Community-Led Solutions for Plastic Waste Management in Waitabu, Fiji

Plastic pollution poses a serious threat globally, with an estimated 8.3 billion tonnes of plastic produced since the beginning of its industrial production (Horton & Blissett, 2021). This overproduction creates staggering waste levels, underscoring the urgent need for effective waste management strategies, especially in vulnerable regions like low-lying communities in small island developing states (SIDS). In remote villages that lack centralized waste management, plastic waste is often burned or buried. These methods of disposal not only harm the environment but also pose serious health risks to local populations and local ecosystems. This transdisciplinary qualitative case study research project explored the role of art, upcycling, and eco-brick-making in diverting plastic waste from entering the ocean and atmosphere in Waitabu village on Taveuni Island, Fiji. Carried out from September to November 2024, the study utilized a participatory action research framework that involved collaborating with community members to reconceptualize plastic waste collection, use, and reuse, especially through innovative, low-tech solutions such as making eco-bricks. Focusing initially on women, the research also encouraged children and other Waitabu community members to engage in the process of making eco-bricks. The teaching of this process was then further extended to some surrounding villages and the local state-run elementary school. Surveys, interviews, and group interviews were then utilized to ascertain the impacts of the project on the Waitabu community. The study found that the process of making eco-bricks was easy to teach and a time-efficient way to significantly reduce the amount of plastic waste entering the environment and provide a usable building resource. Participants reported increased awareness of plastic pollution and expressed a commitment to sustainable practices. The main finding was that eco-bricks and other upcycling techniques were simple and effective to teach and implement, with significant engagement from the community.

Abstract Name: Progress Toward the Synthesis of a Color-Changing Molecular Sensor for Phthalate Esters

Phthalate esters are endocrine disrupting chemicals (EDCs), which are often used as plasticizers with both home and medical applications. Recent data show an association between phthalate esters and hypothyroidism, a deficiency in thyroid hormones, with broad neurological, cardiovascular, and developmental implications. Our research addresses this by developing a color-changing molecular sensor for detecting phthalates in aqueous solutions. Previous research has reported a sensor for carboxylate dianions, including phthalates, with moderate success. However, their synthetic approach uses harsh reagents and limits the sensor's potential applications. Using more accessible and safer techniques, we are exploring two synthetic routes to our target molecular sensor. Following the synthesis of our target, we plan to use it for the detection of hydrolyzed phthalate esters in aqueous solutions. This research can help develop reliable, safe sensors for a wide range of environmental and biological applications.

Abstract Name: Artistic Response to the Demonization of Working Families in Contemporary US and Poland

By the people, for the people...is that right? Societies are built by workers, serviced by workers, and defended by workers. However, worker families are mostly excluded from the opportunity of social and economic advancement, especially in capitalist societies, due to the deregulation of the market, labor, and unions. This study demonstrates this exclusion and demonization of workers in the twenty-first-century US and Poland, by examining a photo-series, "The Notion of Family", and a sculpture "Janusz, Grażyna, and Sebik," respectively. First, the introduction to neo-liberal capitalism, supported by Christianity, and its notion of working class is provided. Second, the formal and cultural analysis of the photo series is provided, followed by the formal and cultural analysis of the sculpture. A comparative conclusion demonstrates egregious demonization of workers in both societies, although in Catholic Poland, neoliberal capitalism has been recently introduced while in Christian US, neoliberal capitalism emerged in the early 1980s. This study takes a qualitative approach to the analysis of neoliberal capitalism and working-class families through historical and secondary research while evaluating economic and social policies that target working groups, including minorities in both countries. This research was conducted by reviewing official government data and examining articles and books by European and American scholars who provide context on post socialist Poland, the advancement of neoliberalism, and the struggles of the working-class family. Keywords: America, Poland, neoliberal capitalism, working class, working-class families

Abstract Name: Impact of Salient SCOTUS Case Decisions on American Voter Turnout

The Supreme Court is a powerful institution with remarkable influence over American governance, yet little research has investigated its impact on electoral behavior. This study seeks to address this gap by examining the relationship between the release of salient SCOTUS decisions and voter turnout. Utilizing 2012 data on the landmark healthcare ruling *National Federation of Independent Business v. Sebelius* (2012) from the American Panel Survey (TAPS), we employ a logistic regression model to assess the correlation between the release of a salient SCOTUS decision and an individual's intent to vote and actual voter turnout. We examine whether salient SCOTUS cases positively influence American voters' intent to participate in upcoming elections, and whether the release of these decisions effectively drive American voters to the polls. Through this analysis, we reveal important implications for the social influence wielded by the Supreme Court and the numerous facets of civic engagement within the American electoral process.

Abstract Name: An Examination of the Relationships between Pain Catastrophizing, Pain Modulation, and Cognitive Function in Older Adults with Knee Osteoarthritis

Knee osteoarthritis (KOA) affects nearly one-third of Americans over 60, contributing to chronic pain, fatigue, and reduced physical function, with both physical and psychological factors impacting pain perception. This study explored how cognitive function influences the relationship between pain catastrophizing and endogenous pain modulation in adults with KOA. In a sample of 190 adults, pain catastrophizing was measured using the Pain Catastrophizing Scale (PCS), and cognitive function was assessed with the Montreal Cognitive Assessment (MoCA). Pain sensitivity was evaluated through Quantitative Sensory Testing (QST), including temporal summation (TS) and conditioned pain modulation (CPM). Results showed significant associations between PCS and both TS and CPM, with lower cognitive scores correlating with higher pain sensitivity. However, cognitive function did not significantly moderate the relationship between PCS and endogenous pain modulation. Despite this, the data indicated a trend suggesting that decreased cognitive function may strengthen the association between pain catastrophizing and pain facilitation, warranting further research. These findings suggest that cognitive function could indirectly influence pain modulation and should be considered in future studies. Clinically, incorporating cognitive and psychological evaluations may improve personalized treatment approaches for KOA-related pain.

Abstract Name: Is Prospective Aging Self-efficacy Predicted by Rurality and Income?

Age-related physical and mental health outcomes often differ between people in relation to factors like socioeconomic status, health care access, nutritional intake, socialization, environmental urbanization, etc. (e.g., Skoufalos et al., 2017). Additionally, an individual's endorsement of Western stereotypes regarding aging (that are both pervasive and, generally, negative, Hummert, 2011) may also relate to both expectations they have about their own aging and the eventual aging outcomes they experience. For example, one who believes that physical health declines during adulthood might be less likely to engage in activities intended to lessen any such declines. The current mixed methods study investigated aging self-efficacy, which is the belief that one has control over the way(s) in which they age, across a variety of domains, and this presentation will focus on cognitive and social components of aging. Self-efficacy has been studied in various adult populations, but generally in the sense of their current circumstances (e.g., Tovel, et al., 2017). Some longitudinal studies do exist, but these examinations usually pertain to relatively brief periods (e.g., McAvay et al., 1996, for a span of 3 years). Although this study is not longitudinal, we collected data about participants' beliefs about their current level of functioning in each domain as well as estimates of future functioning as they age. We collected quantitative data regarding perceptions of function along with qualitative data pertaining to the reasons people hold these beliefs. Key hypotheses include that aging self-efficacy will relate to (1) the degree of urbanization such that those from more rural environments will feel less able to age healthily compared to those from more urban environments and (2) the income level of participants such that those with higher current familial income and higher expected personal income at age 50 will expect to age more healthily than those with lower income.

Abstract Name: Calmodulinopathy Disease Mutations at D131 and their Effect on Protein Stability and Folding

Calmodulinopathies are life-threatening syndromes that affect various parts of the heart rhythm and occur when there is a genetic mutation in various CALM genes that code for protein calmodulin. Calmodulin, abbreviated as CaM, is a calcium binding protein that interacts with many other proteins, ion transporters, and enzymes serving as the major intracellular calcium regulator in eukaryotic species. My research project focuses on genetic mutations that change an aspartic acid amino acid residue in calmodulin's primary amino acid sequence at position 131 to either a glutamic acid (D131E), valine (D131V), or histidine (D131H). CaM has 148 amino acids in its sequence with two distinct lobes termed the N-lobe and the C-lobe. Both lobes contain two calcium ion binding sites, called EF-hand motifs, allowing for CaM to bind up to four calcium ions at once. The D131 amino acid is in the C-lobe of CaM and directly binds to a calcium ion in EF hand IV motif, which in turn stabilizes the protein and allows for calcium transportation. These mutations have been shown to cause various cardiac arrhythmias including Long QT Syndrome (LQTS) and Catecholaminergic

polymorphic ventricular tachycardia (CPVT) in patients. Previous data has shown that these mutations have a significant effect on calcium binding affinity in calmodulin, but the mechanism and subsequent protein actions are not fully understood. Results of my research indicated that this mutation, both with and without calcium being present, affects the thermal stability and refolding capabilities of calmodulin, which could help explain at the molecular level why these disease mutations lead various different cardiac arrhythmias.

Abstract Name: Cultural Influences on the Impact of Parental Divorce: A Comparison of Chinese-American and Non-Chinese-American Children

This paper investigates cultural influences in the differences of negative impacts on the wellbeing of Chinese-American and Non-Chinese-American Children. This paper utilizes a simplified model of Amatto (2000)'s Divorce Stress Adjustment Perspective model that analyzes the effects of Chinese-American cultural moderation upon the effects of divorce on children's psychological and behavioral problems. Through a comprehensive quantitative survey analysis with test of significance, this paper presents with the following findings: 1) There is significant evidence ($p=0.02299$) that Chinese-American children experience more negative impacts on mental-well being than Non-Chinese-American children; 2) There is not significant evidence that there is significant difference in cultural influence between Chinese-American children and non-Chinese-American children; 3) There is not significant difference in negative academic impact between Chinese-American children and non-Chinese-American children; and 4) There is not significant difference in negative impacts on peer interaction between Chinese-American children and non-Chinese-American children. These findings highlight the complex interplay of culture and individual well-being in the context of parental divorce.

Abstract Name: Sexual Harassment and Public Transit

Since the COVID-19 pandemic, over 4,000 incidents of harassment against Asian Americans have been reported nationwide, predominantly in public spaces like transit systems. Women and marginalized communities are disproportionately harassed but remain underreported and poorly understood. Based on existing data, incidents at bus stops are likely overrepresented in harassment events, especially among women, young adults, and people of color. Using Los Angeles Metro ridership experience data from 2014–2019 and 2022–2023, we analyze harassment rates by race to establish pre- and post-COVID baselines. We will also conduct qualitative interviews of residents who frequently ride the bus and metro, specifically from Asian ethnic hubs in Los Angeles. In early 2025, LA Metro will conduct its first survey on sexual harassment (the result of tireless efforts Asian American community organizers). This project will provide route-specific insights, filling gaps in understanding the racialized and gendered dynamics of harassment on public transit

and contributing to policy advocacy for safer transit environments. We will also discuss the need to protect Asian ethnic hubs and address systemic hate through community-centered solutions, advancing both local and national efforts to combat harassment and promote inclusivity in public spaces.

Abstract Name: Resource Guides: Connecting Kentucky's Communities

Background: Resources within communities often hold barriers regarding accessibility, knowledge of resources, and stigmatization. Many communities lack a comprehensive report of all major resources available within and around their county. By targeting the base knowledge within the individual, it can increase participation of these resources and in turn can improve overall health outcomes in a specific area. Objective: Create a list of comprehensive resources within each Kentucky County that can be distributed via pamphlet handout or website linkage. These resource guides have the ability to serve as a crucial connecting point between academia and local health departments. Methods: Scan the internet, social media, and contact community resources to get a holistic understanding of resources. The standard operating procedure provides points such as logistic availability, requirements, contact information, and process of attainment within each guide. Resources are pulled from each county or if not applicable to a specific county, the nearest resource to that respective location. Within each resource guide, the following categories are included: behavioral health centers, domestic violence resources, food assistance, harm reduction/syringe program, health services, housing services, legal services, medication for opioid use disorder, meetings, naloxone location, social support services, support and treatment locators, and transportation services. Guides are provided to different partners such as county officials, local health departments (LHD's), or various non-profit organizations within the counties. Results: 52% of all Kentucky counties have been completed and are awaiting review/approval for distribution, with the remainder of counties to be completed in the future. Numerous guides have been used as a point of first connection between LHD and the University, along with being part of various community health improvement plans.

Abstract Name: Evaluating the Combine Effects of Ginger and EGCG on Human HCT-116 Colon Cancer Cell Lines

In 2024, over 2 million new cases of cancer will be diagnosed in the United States, and over 600,000 people will die from the disease. Among these, 106,590 people will be diagnosed with colon cancer, resulting in 53,010 deaths. Currently, colon cancer is treated by surgical removal of cancerous tumors or by

chemotherapy. However, surgery is expensive and can lead to complications like bowel leakage, while chemotherapy targets healthy cells, leading to side effects such as hair loss and chronic fatigue. Natural therapeutics, such as ginger and EGCG, have been found to have individual anticancer properties, such as inducing apoptosis and inhibiting cell growth. This makes them candidates for less toxic and less invasive therapeutic approaches. This study aims to determine whether EGCG and ginger, when combined, have synergistic or antagonistic effects on cancer proliferation. HCT-116 colorectal cancer cells were plated at 8,000 cells/well and treated with various concentrations of ginger and EGCG, both individually and in combination. Cell viability was determined using an MTS assay. The preliminary results indicate that EGCG alone causes a dose-dependent increase in cancer cell metabolic activity, while ginger extract alone decreases metabolic activity at high concentrations. Interestingly, the combination of ginger and EGCG did not result in a dose-dependent decrease in cancer cell metabolic activity, but rather a dose-dependent increase in cell metabolic activity, which suggests that EGCG interferes with ginger's anti-cancer activity when the compounds are used together.

Abstract Name: Effects of Different Blood Flow Restriction Cuffs on Performance and Perceptual Responses

The aim of this study was to investigate the effects of wall squats with single- and multi-chambered blood flow restriction cuff bladders on performance and perceptual responses. Twenty-seven physically active and otherwise healthy participants (11 females; age: 22.6 ± 5.7) underwent three randomized testing sessions (single-chamber, Delfi Personalized Tourniquet Device; multi-chamber, BStrong Cuffs; and no blood flow restriction cuffs, no cuffs), one week apart. Testing sessions consisted of 4 sets of wall squats using 20% of the 1-repetition maximum (1RM) with repetitions to failure and 1-minute rest intervals. Cuffs were simultaneously placed on the proximal portion of both thighs and inflated to 60% of limb occlusion pressure for single-chamber cuffs and 300 mmHg for the multi-chamber cuffs for the entire exercise duration including the rest period. Performance metrics including total repetitions and training volume, and perceptual responses including rating of perceived exertion (RPE), rating of perceived discomfort (RPD), and likelihood of performing the exercise again were assessed for all sessions. A higher RPD was reported during the single-chamber (7.6 ± 1.8 , $p < 0.001$) and multi-chamber (6.3 ± 2.1 , $p = 0.035$) compared to no cuffs (4.9 ± 2.3) testing sessions. No significant differences in RPE were reported between the single-chamber (8.8 ± 1.1), multi-chamber (8.6 ± 1.2), and no cuffs (8.6 ± 1.0) exercise sessions ($p = 0.176$). A lower number of total repetitions occurred in single-chamber compared to multi-chamber cuffs (60 ± 24 vs. 83 ± 41 , $p = 0.043$), respectively, and in single-chamber compared to no cuffs (60 ± 24 vs. 126 ± 53 , $p < 0.001$), respectively. Furthermore, a lower number of total repetitions was achieved in multi-chamber compared to no cuffs (83 ± 41 vs. 126 ± 53 , $p = 0.005$). The use of blood flow restriction cuffs appears to increase discomfort regardless of bladder design, while the single-chamber cuffs may reduce training volume more than multi-chamber cuffs.

Abstract Name: Mother and Daughter (M-D) Behavioral Randomize Control Trial to Reduce Risks of Gestational Diabetes (GDM) among Female American Indian/Alaska Native (AI/AN) Adolescents: Importance of Institutional Review Boards

Background/Purpose: Research requires Institutional Review Board (IRB) approval. Studies with AI/AN-communities usually require Indian Health Service (IHS) and/or Tribal IRB approvals. Federalwide Assurance (FWA) are principles governing insitutional responsibilities of protecting the rights/welfare of research subjects. Tribal IRBs without FWA, require both IHS and Tribal IRB approvals. These IRBs protect/promote the interests/health/safety of AI/AN-communities, while conducting ethically/culturally-appropriate research to prevent exploitation/misconduct. The Stopping-GDM Study required approval from five sites, two Tribal and two IHS IRBs. This methodological-abstract describes IHS/Tribal IRB process in obtaining approvals for our study. Methods: University, Tribal, and IHS IRBs were obtained prior to the study. As part of the IRB process, participants provided informed consents or assents (<18yrs). We recruited 149 AI/AN dyads: female adolescents/young adults (AYA) 12-24yrs at risk for GDM and their mothers; and randomized to an intervention to reduce AYA GDM risk or usual care. IHS/Tribal and academic institutional IRB approvals were renewed annually. Results: The frequency of IRB reports depends on individual IHS/Tribal IRB Councils, ranging from quarterly to yearly, including updates on findings/dissemination and monitoring participants' wellbeing/safety. Data and conclusions drawn from the study are required in reports and approved before researchers disseminate this information. Approvals must be obtained from IHS/Tribal IRBs prior to submitting: abstracts to conferences, manuscripts to journals, posters/PowerPoints to conferences. Tribes may require electronic and/or hard copies prior to meetings. Some Councils require investigator's attendance and presentation of the posters/presentation. The Stopping-GDM study had the following submitted/approved: abstracts (n=15), posters/presentations (n=15), and manuscripts (n=6). Implications & Conclusions: The IHS/Tribal IRB process protects research participants in AI/AN communities. It is the responsibility of researchers to abide by their regulations to assure the safety and rights of all study participants.

Abstract Name: TCER-1 and its Target Lysosomal Lipid Coordinate Immunity and Reproduction Maintenance through Egg Integrity

The intricate balance between fertility and immune function is a well-documented phenomenon across various organisms. However, the mechanisms connecting these two crucial and energy-intensive processes remain poorly understood, particularly in complex, slow-reproducing animals. Our lab previously discovered that TCER-1, the homologue to the human Transcription Elongation & Splicing Factor 1 (TCERG1), links reproductive fitness to innate immunity in the nematode *Caenorhabditis elegans*. TCER-1 mutants show

reduced fertility but enhanced innate immunity against the human opportunistic pathogen *Pseudomonas aeruginosa* strain PA14 (PA14). This study aims to investigate the epigenetic modifications of TCER-1 and how its downstream lysosomal lipolysis pathway influences reproductive health, specifically egg integrity. Our preliminary studies suggest that TCER-1 modulates lipid metabolism to repress immunity and enhance reproductive health. Gas chromatography-mass spectrometry revealed that the absence of TCER-1, especially during maternal infection, leads to a deficiency in essential fatty acids in the embryos. These fatty acids are crucial for developing the permeability barrier of the eggshell. Using BODIPY dye exposure, we observed that eggshell defects predominantly occur in TCER-1-deficient mothers. This indicates that TCER-1 is vital for ensuring that essential fatty acids are available for eggshell development, particularly under stress conditions.

Abstract Name: Suburbanization Biodiversity

The suburbanization of the United States in both urban and rural areas has depleted resources needed to support the biodiversity of native plant and animal life through habitat loss, air pollution, and disruption of the natural ecosystem in the area. The purpose of this research is to correlate the negative externalities of suburban sprawl to the diminishing biodiversity observed within these areas. To understand the impact of suburban growth, I use data on housing subsidies provided by the government, which led to the development of new single-family homes, and measure population decline and endangerment of pollinating species responsible for the fertilization of plant life in these affected areas. I find that there is a direct correlation between the horizontal expansion of suburban communities and the loss and migration of pollinating species that have, in turn, created an unsustainable environment for native plant life.

Abstract Name: What are the determining factors that cause Black students to leave Universities?

Student attrition, while often discussed in the context of higher education retention efforts, remains underexplored when it comes to understanding the specific causes that drive students to leave their academic programs—particularly for students from marginalized communities. This research focuses on the issue of Black student attrition at a mid-sized Western university, where, during the 2022-2023 academic year, 9% of Black students did not continue their studies. Given the distinct stressors and barriers faced by Black students, this study seeks to understand the unique experiences contributing to the attrition of students who have attended the university within the last five years. This project adopts a qualitative action research approach, using narrative analysis to explore the lived experiences of former Black students. Through semi-structured, one-hour interviews with 10 participants, this study explores their reasons for leaving the university, focusing on how intersecting identities (e.g., race, class, gender) and a perceived lack of institutional support may shape their decisions. The core of the inquiry is rooted in understanding the specific barriers that hinder Black students' persistence and retention, moving beyond general attrition studies to address race-specific factors. The action-oriented nature of this research is designed to lead to a practical agenda for institutional change. The findings aim to identify key factors that deter Black students from completing their degree programs, with the ultimate goal of creating recommendations for policies and practices that foster an environment of support and inclusion. By centering the voices of Black students who have experienced attrition, this study will provide the university with critical insights that can guide future efforts toward improving retention, promoting persistence, and ensuring an equitable educational experience for all students.

Abstract Name: Efficacy of EMDR Therapy in Adolescents with PTSD: A Meta-Analysis

Eye Movement Desensitization and Reprocessing (EMDR) therapy is a relatively new psychological treatment with mechanisms of action that remain partially understood. While most EMDR research focuses on adults, evidence suggests it could benefit adolescents as well. This meta-analysis investigates the efficacy of EMDR in treating post-traumatic stress disorder (PTSD) symptoms in adolescents aged 12 to 18, addressing a significant gap in the existing literature. To frame the research, the PICO approach was employed: the Population is adolescents; the Intervention is EMDR therapy; there is no direct Comparison group; and the Outcome is the improvement of PTSD symptoms. Although EMDR research has predominantly targeted PTSD, emerging evidence suggests broader applications, including the treatment of test anxiety and phobias. A comprehensive meta-analysis conducted four years ago demonstrated the potential versatility of EMDR across various mental health conditions and age groups. However, that analysis revealed issues of bias, raising concerns about its influence on clinical decision-making. This study synthesizes existing data on EMDR for adolescents with PTSD, critically analyzing methodological quality to ensure robust conclusions. Results are expected to clarify whether EMDR is an effective treatment option for adolescent

PTSD and identify areas for improvement in study design. In the short term, this meta-analysis aims to assist mental health providers in making informed decisions about the use of EMDR therapy for adolescents. Long-term, it seeks to guide future research toward evaluating EMDR's potential applications for other mental health conditions in this population. By addressing existing research gaps and minimizing bias, this study will contribute to a clearer understanding of EMDR's role in adolescent mental health treatment and its broader implications.

Abstract Name: How Exclusionary Nationalist Rhetoric Shapes Danish Immigration and Integration Policy

Denmark is broadly recognized for its restrictive immigration and refugee intake policies, as well as its harsh, government-enforced integration measures. This project examines how 'exclusionary nationalist' political rhetoric by the New Right style, Danish People's Party (DPP), shaped the current immigration and integration approach. This 'exclusionary nationalist' framework explains and examines a style of elite-crafted rhetoric where state actors conjure 'threats' around, and place 'problems' on, outsiders, or non-Western and Muslim immigrants in the Danish context. This fosters public support for strict policies, generates electoral success for New-Right politicians, and excludes individuals who do not meet the rigid, cultural criteria constructed through this rhetoric. This analysis challenges the assumption that increased immigration inflows strain Danish culture and the welfare state, which, as these New Right politicians posit, requires a strict approach. Moreover, these findings challenge the notion that these increased numbers lead to xenophobia and, subsequently, strict policies. Instead, this project asserts that Denmark's descent into a neo-fascistic immigration regime has emanated from an elite-crafted process wherein state actors rhetorically create 'threats' around welfare, security, crime, terrorism, and cultural differences. This rhetoric necessitates policy 'solutions' such as oppressive, unhumanitarian, and ultimately, temporary, asylum, immigration, and integration practices. This project utilizes a sentiment analysis, tracing the language of the Danish People's Party (DPP), the Venstre Party (V), and the Social Democratic Party (SDP) from 2001 onward, illustrating how the center-left, SDP, co-opted the platform of the DPP and became the face of the anti-asylum-seeker and anti-immigration front. This project also compares this rhetoric to relevant policy developments, demonstrating how far-right ideas have entered Denmark's political mainstream and how the current unhumanitarian temporary protection and repatriation-focused approach was actualized. This offers a valuable explanation for the global rise of the New Right and the normalization of anti-immigrant and exclusionary policy and messaging.

Abstract Name: On the Edge of Whiteness: A Historical Analysis of the Evolution of Italians' Relationship with Race from the 1900s to Contemporary Italy

This project examines Italians' relationship with race, tracing its evolution from the mass migration of Italians

to the United States in the late 19th and early 20th centuries through the post-war period to contemporary racial perceptions in Italy. This exploration is significant because it reveals how historical experiences shape the current realities faced by Black Italians and African migrants in Italy. Through a historical analysis, personal accounts, and surveys of Italians, I investigate the connections and parallels between the Italian immigrant experience in the U.S. and the Afro-Italian experience today. While Italians have been victimized by white supremacy, they have also, at times, weaponized this racial hierarchy for their own acceptance. I argue that Italians exist on the edge of whiteness; although their phenotype grants them access to this racial category, they have not always been fully accepted into it, particularly within the context of American whiteness. The Italian immigrant experience in the United States heightened Italians' awareness of race and racism, leading Italians to navigate these complexities to protect their identity as a white nation.

Abstract Name: Arrested Development: Comparing the Impact of Colonial Heritage on the Development of Former Western European and Soviet Union Colonies

Why are some former colonies more developed than others? Is there a difference between Soviet colonization and Western Colonization? In today's age it is easy to forget that colonial efforts still have a massive impact on the development of former colonies, and that many colonies have completely different patterns of development based on their colonial heritage. But what is not known is exactly what factors lead to better development in a post-colonial nation. This paper will argue that the way in which the Soviet Union colonized was different from the way Western powers colonized and that the tenants of Soviet colonization led to a divergence in development outcomes once these colonies were independent. This research ultimately finds through the use of linear regressions and mean comparison analysis, as well as a small case study, that there is statistical significance to support the observation that former Soviet colonies are at the very least more politically developed than former western colonies due to the fact that the Soviet Union practiced indirect rule colonization, which led to the formation of stronger independent governments.

Abstract Name: Comparative Analysis of the Depiction of Saints in the 12th Century in Sicily and Southern India

The concept of "saint" exists in many cultures globally, but under this blanket term, the portrayal of saints is culturally specific. This cultural specificity is demonstrated through the comparison of two sculptures: Saint Clement Seated, by the Abruzzi School, made in Sicily, Italy in the 12th century, and Saint Sambandar, created in South India during the Chola Period, also in the 12th century. The former is a saint of Sicilian Catholicism compared, while the latter reflects South Indian Hinduism. The comparative examination is

supported by historical articles written by scholars on the context and events of both 12th-century Sicily and South India. First, I will provide a comparison of the defined meaning of saint within the two cultures. Second, the notion of Saint Clement Seated in Catholic Italy will be discussed, considering formal analysis within a historical framework, followed by a formal and historical analysis of Saint Sambandar. The comparative conclusion will establish the similarities and differences between the expectations, appearances, and behaviors of the two saints, emphasizing a higher value placed on dynamic motion, and bodily autonomy in Hindu saints. At the same time, stoicism, modesty, and minimal attention to the human figure characterized Catholic Sicily. Despite the contrasting elements, comparatively, both pieces reflect an emphasis on poignant facial features, detail in drapery, and dynamic hand positions relaying a gestural form of nonverbal communication.

Abstract Name: Trapped by Design: Redlining, Government Aid, and the Cycle of Poverty

Government aid has played a critical role in supporting low-income communities by providing essential resources such as food, housing, and medical care. These programs have benefited Black communities, as families have been lifted from poverty and these programs promote social mobility. Institutions such as the American Rescue Plan and the Minority Business Development Agency have done much to alleviate economic inequality, and the Inflation Reduction Act is intended to make housing more affordable for low-income families. Yet, alongside these advantages, government support has also had inadvertently harmful effects on upward mobility for many beneficiaries. This study compares the history of redlining with the institutional issues of government assistance. Redlining, an unjust act that effectively excluded minority communities from financial services, imposed long-term socioeconomic disadvantage. Likewise, government assistance, while providing short-term comforts, can prevent citizens in poverty from being able to escape their situation. Other big problems are dependence on aid, program inefficiencies, and incentives to work. The prospect of unemployment benefits or housing vouchers could be more attractive than finding low-wage work. Furthermore, stigmas surrounding government aid discourage beneficiaries from seeking to escape the reliance on aid. A significant challenge lies in the "welfare cliff" where little increases in income can mean instant loss of benefits and families can't even pay for their basic needs. This leads to a paradoxical situation where poverty seems more manageable than aspired mobility. Second, the poverty level doesn't reflect the regional cost of living or economic complexity and thus could be an inaccurate measurement of the extent of US poverty. While aid from governments can be essential short-term relief, their long-term architecture is likely to put recipients into a state of dependence. This research argues for solutions to these structural deficiencies that would bring economic self-sufficiency and justice to low-income and minority communities.

Abstract Name: Examining the Psychological Impact of Parental Substance Use on College Students in 2024

Background: Substance use disorders have lasting, significant effects on a family unit, especially children. The prevalence of substance use disorders (SUD) has been increasing since the 1990s, with 8.7 million children under the age of 17 residing at home with a parent who is diagnosed with a SUD. There is limited research conducted on the college undergraduate population concerning the effects of parental substance use. It is imperative to understand these effects in order to better grasp how parental substance use may have life-long effects on children, especially when they are entering a period of young adulthood. Study purpose: The purpose of this research is to determine whether a correlation exists between parental SUD and college student mental health and resilience. Methods: A cross-sectional study was conducted with 325 students at a small Mid-Atlantic liberal arts college. A 48-item e-survey that included the PHQ-2, GAD7, CD-RISC-10, and Ryff Psychological Well-Being Scale was used. The prevalence of parental substance use was calculated using participant reports of current and past substance use by parents. Using bivariate analyses, differences in scale scores between participants with and without parental substance use were examined. Results: Preliminary analyses indicate that 12% of college students have a parent with current substance use, and 10% indicate previous parental SUD. Among all participants, 21% are at risk of a major depressive disorder. Additionally, 21% of participants scored within the range suggesting moderate anxiety, while 17% scored within the range suggestive of severe anxiety. Additional analyses will be conducted to determine the correlation between the two populations on the variables of interest. Conclusion: It is anticipated that these results can be utilized to better understand the long-term effects of parental substance use on an understudied group - undergraduate students.

Abstract Name: The Structure of Male Tail Sensory Cilia and CEM Cilia in the Absence of *tbb-4* in the Model C. elegans

Cilia are cellular cytoplasmic extensions made up of a microtubule based axoneme. The axoneme is composed of a ring of microtubules in either a 9+0 formation for stationary cilia or 9+2 for motile cilia. C. elegans has 60 ciliated sensory neurons and 16 genes that encode for tubulins. To understand the structure of cilia we are using tubulin mutations and tubulin fluorescent protein reporters. Our results show that one of the nine alpha-tubulin proteins, TBA-6, is exclusively expressed in ray neurons. TBA-6 is found in the dendrites at the end of the cilia. The beta-tubulin, TBB-4 has a sequence motif located in the ciliary beta-tubulins. Currently we are investigating the role of TBB-4 using the localization of TBA-6.

Abstract Name: From Gaze to Belief: The Role of Eye-Tracking in Understanding Climate Messaging

Understanding attitudes and beliefs surrounding climate change is crucial for addressing today's increasing social and environmental challenges. This study explores the effects of message framing on visual attention and its ability to predict attitudes toward climate change and political beliefs. Employing a multidisciplinary approach, the research combines eye-tracking with a survey. Participants completed an online survey assessing participants' perceptions, political ideologies, and demographic information. Then, they were exposed to climate-related messages framed either positively (e.g., recycling decreases landfill mass) or negatively (e.g., non-reusable plastics end up in landfills), and their gaze location and fixation duration were monitored through eye-tracking. Results from the eye-tracking data revealed that negatively and positively framed messages elicit longer fixation times compared to neutral messaging, highlighting the influence of message valence on visual engagement. Survey results demonstrated a nuanced relationship between implicit visual attention patterns and explicit attitudes moderated by social desirability bias and political ideology. Liberal participants showed greater fixation durations for all message frames than conservative participants, who preferred positively framed messages over negatively framed ones. These findings underscore the value of integrating implicit and explicit measures to understand public attitudes toward climate messaging. By bridging psychological and political science perspectives, this study provides valuable insights for researchers and practitioners seeking to enhance the effectiveness of climate-related communication and foster greater environmental awareness.

Abstract Name: Age Determination of Imperiled Fishes in the Red River of Texas and Oklahoma

Knowing how and where fishes obtain their energy is critical for understanding their ecology. Currently, it is unknown whether native fishes in the Red River of Texas and Oklahoma obtain their primary energy from allochthonous or autochthonous inputs, and how those inputs may change with respect to factors such as age, season, salinity, discharge, etc. The goal of my project is to determine the overall age structure of four target species: Red River shiner (*Notropis bairdi*), Red River pupfish (*Cyprinodon rubrofluviatilis*), plains minnow (*Hybognathus placitus*), and prairie chub (*Macrhybopsis australis*), to better inform a larger ongoing study of the diet habits of the study species. Sampling was conducted at six sites spanning 320 river kilometers during spring, summer, and fall of 2023. The lapillar otoliths were removed and annual growth rings deposited on these as they grow were enumerated. A total of 571 otoliths were analyzed for this study. Preliminary data indicates that individuals live a maximum of three years, with less than 3% reaching age 3. Age 1 and 2 individuals make up the remainder of the population in roughly equal proportions. Fall samples trended higher in Age 1 individuals, presumably because ages 2 and 3 individuals reached the end of their life cycle and senesced out of the population. Once all age data are fully analyzed, they can be integrated into the larger data set to get a broader picture of how age may influence diet and energy patterns for these species. The age data can also be used to compare age and growth data of similar species in adjacent river systems that is collected by other scientists. Gaining a better understanding of prairie stream fishes in the Red River of Texas and Oklahoma will better inform conservation and management of these and other imperiled prairie stream fishes.

Abstract Name: Cyclic vinyl polymers prepared in ionic liquids

A radical ring expansion polymerization of vinyl monomers to form cyclic polymers was recently reported by our group. Cyclic polymers were best produced when the polymerization was conducted at high reaction concentrations in a relatively viscous solvent under mild reaction conditions. Due to degenerative chain transfer during polymerization, cyclic multimers that varied in size were found in the final material. The goal of this work is to prepare cyclic unimers via light-driven ring expansion polymerization in highly viscous solvents known as ionic liquids. High viscosity solvents will limit polymer chain diffusion and therefore the oligomerization which formed multimers caused by chain transfer. Results detailing the control of molar mass and polymer architecture will be discussed.

Abstract Name: The Experiences of Neurodivergent Individuals: Guidelines for Effective Neuro-Inclusive Patient Care

Within humanity, there are various ways of thinking that influence how people communicate with others. 'Neurodivergence' refers to the variation from what is considered typical. Examples include autism, ADHD, dyslexia, and various other conditions. In healthcare settings, earlier studies show that neurodivergent individuals may experience barriers because of the lack of understanding among healthcare providers. The gap in the knowledge among healthcare providers and underdeveloped practices are concerning; in fact, it is reported that major disparities between neurodivergent and neurotypical individuals continue in access to care and outcomes across populations. Furthermore, neurodivergent individuals often feel excluded in research environments designed for neurotypical individuals, and many neurotypical researchers are uncertain about how to engage with neurodivergent individuals. This inductive project aimed to discover the experiences of neurodivergent individuals in patient care. The studied population consisted of neurodivergent individuals over the age of 18, recruited from the campus of Minnesota State University, Mankato. The participants provided their consent to take part in an hour-long semi-structured interview. Topics covered within these interviews included participants' healthcare experiences, perceived barriers, and suggestions for improvement. The qualitative analysis was employed to analyze the interview transcripts, and the small sample size allowed us to explore the in-depth experiences of neurodivergent individuals. The findings highlight the necessity for enhanced resources and support within the healthcare system to better assist neurodivergent individuals. With the insights of the public, the findings also contribute to more neuro-inclusive practices that significantly help the wellbeing of neurodivergent individuals across the state.

Abstract Name: Characterization of New Molecular Tools to Detect Branched Ubiquitin Chains

Ubiquitin chains are key regulatory signals that control the stability, activity, and location of proteins in various ways. Recent studies have shown that ubiquitin chains can be branched and that branched chains regulate proteins through diverse mechanisms. Despite mounting evidence that branched chains have important biological functions, our understanding of these signals has been limited by a lack of accessible methods to detect them. In this study, we explored the effectiveness of two newly developed tools designed to detect branched K48/K63 chains. An engineered nanobody reported to bind branched K48/K63 chains with high affinity and specificity (Lange et al., 2024) was purified from *E. coli* and assayed for binding to ubiquitinated proteins containing branch points. Under the conditions tested, the nanobody did not show specificity for branched K48/K63 chains in complex mixtures of ubiquitinated proteins. We also tested the deubiquitinase, MINDY1, which has been reported to preferentially cleave K48 linkages within K48/K63 branch points, in addition to the K48 and K63-specific deubiquitinases, OTUB1* and AMSH*, for their ability to cleave branched K48/K63 chains attached to substrates. As expected based on the topology of the chains, MINDY1 and OTUB1* effectively removed distal K48 linkages from K48/K63 branch points, whereas AMSH* cleaved K63 linkages proximal to the branch points. We conclude that the nanobody may not be an effective tool for detecting branched K48/K63 chains in certain contexts. However, MINDY1, and potentially other deubiquitinases that have recently been shown to specifically target branch points, hold promise as new diagnostic tools to detect branched K48/K63 chains.

Abstract Name: Investigating the role of host LSD1 during Herpes simplex virus type 1 infection

Herpes simplex virus type 1 (HSV-1) infects most of the global population, causing a variety of diseases including cold sores, encephalitis, and keratitis. Previous studies in our lab have identified that host lysine-specific demethylase 1 (LSD1) associates with HSV-1 replication forks and replicated viral DNA. In the absence of infection, LSD1 acts as a transcriptional repressor or activator to regulate host cellular gene expression. Previous studies found that LSD1 inhibition reduces HSV-1 DNA replication, late gene expression, and viral yield. However, the mechanism by which LSD1 is recruited to the viral genome and how LSD1 inhibition blocks infection is unknown. For this reason, we performed LSD1 immunoprecipitations to determine which cellular and viral proteins associate with LSD1 during HSV-1 infection. This revealed which host and viral factors interact with LSD1 and how LSD1 could be recruited to the viral genome. By western blotting, we confirmed that LSD1 immunoprecipitation was successful by identifying an association with histone deacetylase 2, a known interactor of LSD1. Mass spectrometry revealed novel interactions between LSD1 with both host and viral proteins, including viral protein UL54, an mRNA export factor essential for HSV-1 infection, and host tumor protein p53 binding protein 1 (TP53BP1). To determine whether an LSD1 knockdown would result in reduced viral yield, we performed an siRNA transfection, which resulted in reduced viral yield. In the future, we plan to further optimize these protocols and repeat for biological replicates.

Abstract Name: The Effects of Blue Light on the Eyes and if Blue Light Filtering Lenses can Relieve Digital Eye Strain Symptoms

The constant use of digital devices like phones and laptops has caused excessive exposure to blue light. The blue light emitted by devices affects the health of the eyes and can cause symptoms such as eye strain, fatigue, and overall discomfort. With the growing awareness of the effects of blue light, new technology has been created, such as blue light filtering glasses. With new technology being created, more studies are being done on the effectiveness of blue light glasses and if they can relieve eye strain symptoms. While there are currently multiple studies on the effectiveness of blue light glasses, there is very little research done on the undergraduate population. This is important since university students are using computers, laptops, and phones for several hours every day, and experiencing digital eye strain symptoms daily. The goal of this research is to determine if blue light glasses can relieve digital eye strain symptoms among university students. The requirements for participants of the study include current undergraduate students who wear contacts or do not wear glasses. Participants will fill out a survey about their eye symptoms before and after using blue light glasses, and statistical analysis will be applied to the data. Each participant will wear either blue light filtering lenses or placebo clear lenses for a week, while using digital devices. The hypothesis of this study is that blue light glasses will relieve digital eye strain symptoms. Key terms: Blue light, Digital Eye Strain, Blue light filtering lenses/glasses

Abstract Name: Cancer Care Decision-making Preferences of Black Patients with Advanced Lung Cancer

Background Patients who take an active role in their healthcare decisions often experience benefits, such as higher satisfaction and better physical and psychological health. Black patients are less involved in shared decision-making (SDM) during appointments, which could contribute to health disparities. Yet, little is known about Black cancer patients' decision-making preferences. We sought to describe preferences among

Black patients with advanced lung cancer, and examine if preferences varied according to sociodemographic and clinical factors. **Methods**We analyzed data from Black patients with advanced lung cancer (N=29) who reported sociodemographic characteristics, clinical characteristics, and their preferred healthcare decision-making role on the Control Preferences Scale (CPS). Responses were categorized as active (prefer to make final treatment decisions), passive (prefer their doctor to make final treatment decisions), or collaborative. We used Chi-square and ANOVA tests to analyze relationships between characteristics and preferences. **Results**Participants were primarily female (62%), high-school level educated (38%), and were aged 48 to 81 years. On the CPS, most participants preferred collaborative (n=12, 41%) or passive (n=12, 41%) roles in cancer care decision-making; fewer (n=5, 17%) preferred an active role. Gender was associated with preferences (p=0.095), such that more women preferred a passive role than men (50% vs 27%). Patients receiving immunotherapy preferred a passive role (78%), whereas those not receiving immunotherapy preferred a collaborative role (55%, p=0.002). Age, education level, income, religion, marital status, and time since diagnosis were not associated with decision-making preferences (all p-values $\geq$ 0.40). **Conclusions**In this small sample, Black patients with advanced lung cancer preferred a collaborative or passive role in their cancer treatment. Preferences varied by treatment. To support patient-centered cancer care, further research with larger samples is needed to understand Black patients' preferences, factors influencing them, and ways to align communication with preferences.

Abstract Name: Investigating mrp and pha Gene Expression in *Marinobacter adhaerens*

Studies in our lab focus on *Marinobacter adhaerens*, a marine bacteria that was isolated from laboratory cultures of the red-tide-causing dinoflagellate, *Karenia brevis*. *M. adhaerens* is a gram-negative aquatic bacterium that has been found in association with several harmful algal bloom-producing dinoflagellates. A previous bioinformatic study in our lab indicated a unique adjacent placement of two homologous multigene cation/proton antiporter clusters in the *M. adhaerens* genome: an mrp (Multiple Resistance and pH) gene cluster adjacent to a pha gene cluster. The mrp/pha family of cation/proton antiporters couple proton export with cation import and have been found to play roles in pH homeostasis, cation resistance, biofilm formation, and pathogenesis in other bacteria. This study uses Real Time qPCR and β -Galactosidase assays to investigate the relationship of mrp and pha gene cluster expression in varied external pH, [NaCl], and [KCl] conditions. RT-qPCR and β -Galactosidase assays provide complementary information regarding potential transcriptional and translational regulatory mechanisms for expression of these two antiporters. We found that the mrp expression and transcription profiles did not show parallel changes in increased [KCl] and pH. This indicates that post-transcriptional regulation may be used in these conditions. Further studies will be conducted to explore potential regulatory mechanisms.

Abstract Name: Drivers of State Solar Electricity Generation

Solar energy is radiation from the sun that is capable of producing heat and generating electricity. There are environmental benefits to generating electricity using solar energy. It is a renewable resource, and if used for electricity generation, it reduces greenhouse gas emissions and pollutants associated with the electric power sector. Some states have been working towards implementing the use of solar energy. States evaluate their geographic, economic, and environmental conditions to achieve this. Previous research indicates that state unemployment rates, political ideology, and educational levels affect solar energy adoption. We are interested in understanding drivers of state solar electricity generation. Our analysis considers state population, state gross domestic product (SGDP), governor and state house political affiliation, educational attainment, state size, state unemployment rate, state incentives related to solar energy, and measures for sunshine. We measure state sunshine two ways – first, we utilize the average annual percent of time between sunrise and sunset that sunshine reaches the ground within a state (percent of sun); second, we use the average annual number of days when cloud covers at most thirty percent of the sky during daylight hours (clear days). To answer our research question, we use publicly available data and multiple linear regression analysis. We specifically look at which variables impact the amount of electricity generated by solar within a state. There are two main specifications, one for each variable that measures sunshine. Results indicate that SGDP, state size measured in square miles, number of state solar incentives, and percent of sun significantly increase state solar electricity generation. If a state has one additional state incentive for solar energy, state solar generation increases by 158 thousand megawatt hours on average, holding all other variables constant. Other results show increases in SGDP, percent of sun, and state size raise state solar generation.

Abstract Name: The impact of disturbance on the growth of *Morella cerifera* at different life stages

The barrier islands off the coast of Virginia act as essential shields to mainland cities and ecosystems during major storm events. *Morella cerifera*, hereafter *Morella*, is a native shrub on these islands. Warmer winter temperatures have caused *Morella* to encroach into neighboring grasslands, resulting in a reduced ability of the island sediment to shift and rollover with the tides and wind, a feature known as island plasticity. Dunes can shield *Morella* from overwash events that deposit sediment and introduce salt spray. However, if dunes are destroyed by storms before they can be rebuilt, *Morella* may experience increased burial from storms and increased salinity from salt spray. The impact of the frequency of burial and salinity on *Morella* is currently unknown; however, seedling age may impact the tolerance to burial and salinity. The experiment aimed to investigate the extent to which the growth of *Morella* seedlings (7 week old and 1 year old) are differentially impacted by salinity only, burial only, and burial and salinity on the growth of *Morella*. The combination treatment is reflective of overwash events in the field. In order to simulate the natural microenvironment, each pot contained a single *Morella* surrounded by three *Sporobolus pumilus* grasses, and they were buried in sand from Hog Island, Virginia. Preliminary data shows that the seedlings treated with salinity and burial were the least successful, with three out of four replicates dying and the fourth growing by zero percent. The treatment group with the highest percent change (111 ± 1.4) was the year-old group treated with burial and salinity. These results suggest that the resilience of *Morella* to overwash stress conditions is partially dependent on the age of the seedling. Therefore, *Morella* must have time to establish and grow before it is able to withstand stress from overwash events.

Abstract Name: A Dynamic Framework for Standardized AI IQ Assessment

The rapid advancement of artificial intelligence (AI) has underscored an urgent necessity for standardized metrics capable of accurately measuring AI cognitive capacities. Existing AI performance assessments, such as the GSM8K benchmark, offer valuable insights into specific domains like mathematical reasoning. However, they fall short in providing a holistic evaluation of AI intelligence, lacking the breadth and consistency required to parallel human IQ standards. This limitation hinders the ability to comprehensively assess and compare AI systems across diverse cognitive functions. This research proposes the design and implementation of a comprehensive IQ test framework specifically tailored for AI systems. Unlike current benchmarks that rely on fixed datasets and often exhibit significant performance variability with minor input alterations, the proposed framework aims to establish a robust and standardized metric. It will encompass a wide range of cognitive abilities, including logical reasoning, verbal comprehension, memory retention, and complex problem-solving. To achieve this, the framework will utilize dynamically generated question sets that adapt in complexity and diversity, ensuring a more consistent and reliable assessment of AI capabilities. Additionally, the integration of symbolic templates and multi-domain tasks will enhance the framework's ability to evaluate AI reasoning processes and adaptability across different contexts. The expected outcome of this research is the development of a stable and objective metric for quantifying AI intelligence, facilitating more accurate comparisons between AI models and aligning AI assessment methodologies with established human intelligence standards. By addressing the shortcomings of current benchmarks, this framework will provide deeper insights into the cognitive strengths and weaknesses of AI systems, promoting the creation of more robust and versatile AI models. Ultimately, this standardized IQ test framework will serve as a pivotal tool in advancing AI research, guiding the development of intelligent systems that better mimic and complement human cognitive abilities.

Abstract Name: Mental Imagery, Emotional Valence, and Item vs. Associative Effects on Memory

Mental imagery is involved in many functions, including being an important encoding tool for several forms of memory. Stimuli are also better remembered when they are emotional, especially negative stimuli. Memory can also differ when it is tested for items versus associative pairs. Mental imagery, emotional valence of stimuli, and item/associative memory have all been independently researched as having effects on memory. The present study set out to test the relationship of all three factors and their combined effects on memory in a single study. It was hypothesized that memory would be greatest in the negative-imagery-

associative condition. 22 undergraduate participants (aged 18-22) took part in a within-subjects, single session word-pair research design. Participants were exposed to 180 word pairs across two encoding conditions. In the semantic encoding condition, participants wrote a sentence using both words in the pair. In the imagery encoding condition, participants were asked to form a mental image involving both words and rate vividness. Memory was tested in a recognition memory task. For half the trials, memory was tested for a single word (item condition) and for half it was tested for a word pair (associative condition). A 2 (Emotion: neutral, negative) x 2 (Encoding: semantic, imagery) x 2 (Memory test: item, associative) ANOVA was used to test for effects on the memory metrics of hit rate, d' (memory discriminability), and criterion (response bias). Results suggested that memory was better for semantic encoding than imagery encoding and for associative memory vs. item memory. In addition, a marginally significant effect suggested that when associative memory was tested, pairs with a negative word were remembered better than neutral-neutral pairs in the imagery encoding condition. The reverse effect was seen in the semantic encoding condition, suggesting that imagery encoding might be particularly beneficial for associative memory with negative items.

Abstract Name: EMMADAZEY

This project is an exploration of memory, decay, and personal introspection through an audio-reactive visual composition built entirely in TouchDesigner. The centerpiece of the project is a guitar performance where the live input generates real-time particle-based visualizations, projected onto the exterior of a deeply personal and symbolic site: my great-grandmother's vacant home, untouched for nearly eight years. The house, with its weathered surfaces and storied past, mirrors the themes of the song I chose to cover—a track by Narrow Head that delves into struggles with addiction, decay, and a bittersweet nostalgia for places and moments long gone. By integrating the performance with the space, the work transforms both the visuals and the setting into extensions of the song's emotional depth. The decision to forego more overt flame effects for subtle particle systems was deliberate, aligning the visual language with understated representations of age, decay, and memory's erosion. The act of projecting onto my great-grandmother's house not only contextualizes these themes but also serves as a metaphor for revisiting formative sites and uncovering new dimensions of self-understanding through creative interaction. The lyrics of the song—centered on themes of clinging to past highs despite a pervasive numbness—are echoed in the comforting yet haunting visuals. This interplay between place, sound, and light invites viewers into a synesthetic experience, fostering reflection on how our physical and emotional landscapes intertwine. The project represents a confluence of art, technology, and personal narrative, demonstrating how digital tools can deepen our engagement with universal themes of loss, memory, and transformation. The development of this work will continue to be something I think about often to find out how to expand on these ideas and eventually make more pieces centered around this medium.

Abstract Name: Does Lactic Acid Bacteria Inhibit Biofilm Formation of Methicillin-Resistant *Staphylococcus aureus*?

Methicillin-resistant *Staphylococcus aureus* is a major cause of healthcare-associated infections, in part due to its ability to form resilient biofilms on medical devices such as catheters and implants. These biofilms help to protect the bacteria from the external environment and reduce antibiotic efficacy. This study investigates the potential of lactic acid bacteria, in particular, *Lactobacillus rhamnosus* and whether it can inhibit *S. aureus* biofilm formation. *L. rhamnosus* is a common probiotic found in dairy products and has been shown to exhibit antimicrobial activity against pathogens such as *Escherichia coli* and some strains of *Salmonella*. Using plating techniques and spectrophotometric analysis, we assessed the ability of *L. rhamnosus* to reduce *S. aureus* growth. Our results indicate that a co-culture with *L. rhamnosus* as well as a supernatant wash can reduce biofilm growth compared to sterile saline and sterile MRS controls.

Abstract Name: Hyperaccumulator *Salicornia* and The Current State of Mercury at the Great Salt Lake

Salicornia Utahensis and *Salicornia Pacifica* are halophiles, or salt loving, succulents that could help purify the land around the Great Salt Lake in Utah through the accumulation of dangerous compounds much like how these plants draw salt from their environment. Plants instinctive accumulation of compounds present in soil could help us understand possible solutions to mercury, its effects on the native plantlife, and ways to identify heavy metal sediments at Utah's Great Salt Lake. This project's main goal is to find whether or not *Salicornia*, otherwise known as Pickleweed, is absorbing mercury from shoreline and topsoil at Great Salt Lake. With the help of my mentor Doctor David Parrott at Westminister University, there has been sampling pickleweed at three separate Great Salt Lake locations and the consecutive use of a lab freeze dryer and a Direct Mercury Analyzer (DMA-80) to quantify the present mercury. It is currently hypothesized that trace amounts of mercury will be found, but not a significant amount as mercury is more common in deeper substrates than the shoreline soil. This project is currently underway with strong suggestions that there is a negligible amount of mercury in the surrounding shoreline soils, but more research is needed and underway. If there's mercury in the shoreline soil it tells us that it will be present in dust storms that would affect the populations across Utah, causing degenerative issues such as neural damage as well as harming lung tissue. This project will address environmental science issues and implications for future public health issues depending on results.

Abstract Name: What's Food Got to Do with It? An Exploration of Food Insecurity and Health Factors in College Students

The goal of this study is to identify how stress relates to an individual's sleep patterns and food insecurity (consistent lack of access to healthy food options). Studies have shown a complex interplay between stress, coping skills, and poor mental health outcomes (i.e., sleep disturbances and poor eating habits). Depending on an individual's coping skills, declines in mental health have shown to lower emotional well-being, increase emotional strain, and increase maladaptive behaviors (e.g., insomnia). One particular group of individuals who experience high levels of stress, changes in sleep patterns, and food insecurity are college students. In college, students experience numerous stressors related to classes and tend to have lower income. Limited time and lower income tend to lead to increases in stress and poor coping skills. College students report having chronic stress and it has an impact on their quality of life. In this study, we aimed to examine factors that can become impacted by increased stress. We predicted that increases in stress will lead to increased sleep disturbances and greater food insecurity. Participants will complete the Short Form of the Food Security Survey Model (USDA ERS), Food Insecurity Experience Scale model (FIES), Pittsburgh Sleep Quality Index Survey (PSQI), and the Perceived Stress Scale (PSS). The USDA ERS survey and FIES model was used to measure food insecurities among individuals to measure their eating habits. Sleep will be measured with the PSQI survey. The PSS was used to measure stress levels in individuals. We expect to find a significant relationship between all with stress predicting increased sleep disturbances and greater food insecurity to demonstrate the complex interplay between mental health and behavioral outcomes.

Abstract Name: Galactosylceramidase Deficiency in Adult Oligodendrocytes Exacerbates Demyelination in Experimental Autoimmune Encephalomyelitis

The lysosomal enzyme galactosylceramidase (GALC) is essential for the proper myelination of the mammalian nervous system throughout early developmental stages. However, the effects of GALC deficiency in the adult brain are still unclear. This study found that mice with GALC enzyme selectively removed from mature oligodendrocytes have worsened pathology following the administration chronic experimental allergic encephalomyelitis (EAE), which ultimately leads to fatal sensitization. In contrast, mice not treated with EAE and who have GALC ablated from their oligodendrocytes only exhibit non-lethal demyelination. Within the doubly challenged experimental group, we have identified severe inflammatory demyelination with a lack of remyelination, as well as increased gliosis and a disrupted fusion of lysosomes and autophagosomes. Our findings highlight that the physiological impact of GALC deficiency depends strongly on factors such as the time when it occurs, the cell type (i.e. oligodendroglial vs. global expression), and the presence of inflammation. Thus, this study concludes that GALC expression in adult

oligodendrocytes is critical for maintaining myelin within the adult central nervous system and reducing susceptibility to demyelinating injury.

Abstract Name: “‘We are at War!’: The New Afrikan Independence Movement and the Internationalist Struggle to Free PoWS”

In the early 1970’s, the New Afrikan Independence Movement (NAIM), a coalition of Black nationalist organizations aspiring to create a Black nation within the United States, organized for the release of Black Liberation Army (BLA) members. The BLA engaged in military actions against police officers, banks, and drug dealers often in self-defense of what they deemed the Black nation. Once imprisoned, the NAIM declared BLA members Prisoners of War. This research analyzes the NAIM’s citation of international law in their argument for BLA members status as a PoW, which reframed their domestic criminalization and positioned them alongside anti-colonial guerrillas from a variety of national liberation movements. “We are At War!: The New Afrikan Independence Movement and the Internationalist Struggle to Free PoWS” illuminates how the evocation of PoW status facilitated a politics of solidarity with other national liberation movements on the basis of their universal right as colonized people to use armed struggle to “Free the land!”

Abstract Name: Synthesis of Europium (III) Thenoyltrifluoroacetate Terpyridine Complexes and the Influence of Electron Donors and Acceptors on Fluorescent Efficiency.

In this project europium (III) complexes were synthesized to probe the effect of electron-donating and withdrawing ligands on the quantum yield of Eu(III) fluorescence. The fluorescent spectra of europium(III) complexes have large Stokes shifts and long emission lifetimes which make them potentially useful in fluorescent bioassays, labeling experiments, and as dyes in confocal microscopy. A simple definition of quantum yield Φ is the ratio of photons emitted to the number of photons absorbed. Europium(III) fluorescence is enhanced when coordinated with Thenoyl Trifluoroacetate (TTA) which acts as an antennae that increases the number of photons absorbed (UV-Vis). Adding ligands such as terpyridine to the EuTTA3 center influences the efficiency of the emission of photons (Fluorescence). This study used 4-methylphenyl terpyridine (CH₃-terpy) as an electron-donating ligand and 4-trifluoromethylphenyl terpyridine (CF₃-terpy) as an electron-withdrawing ligand. The structure and properties of the ligands and europium complexes are being determined by FT-IR, ¹H-NMR, UV-Vis, and fluorescence spectroscopy along with the influence of each ligand on the europium fluorescence and quantum yield.

Abstract Name: A Study on Negative Self-Perception and Academic Self-Efficacy in Neurodivergent College Students

The objective of this study is to assess the association between negative self-stigma and academic self-efficacy among neurodivergent college students. Negative self-stigma, characterized by internalized negative beliefs and attitudes about one's neurodivergence, can significantly influence students' perceptions of their academic capabilities and performance. Neurodivergence – which includes ADHD, autism spectrum disorder, and learning disabilities – encompasses individuals whose brain process, learn, and/or function differently from what is considered typical. The difference between neurodivergent and neurotypical thinking and interpreting information can be crucial when learning in an environment suited for the typical population. When these differences are noticed by an individual with neurodivergence, they may begin to think poorly of themselves since stereotypes about neurodiversity say that neurodiverse persons are “stupid,” “lazy,” “needy” given the academic or occupational accommodations they may receive. Drawing on the previous literature, this study will examine how self-stigma manifests in neurodivergent students, and how it affects is associated with their academic self-efficacy, the perception of their ability to be academically successful. With this, it can be surmised that neurodivergent college students that perceive negative stereotypes or have internalized negative self-stigma about neurodivergence will report lower academic self-efficacy scores. Participants enrolled at least part time in a post-secondary education, and those with and without neurodivergent identities will be needed. Self-stigmatization, academic self-efficacy, and level of neurodivergent traits will be asked in a self-report survey.

Abstract Name: There's No Place Like (Someone Else's) Home: The Wizard of Oz as American Settler Folklore

Over a century after the publication of L. Frank Baum's *The Wonderful Wizard of Oz* (1900), the beloved story, with hundreds of adaptations across mediums, has transcended from its origins as a simple children's novel into a multifaceted cultural phenomenon embedded into popular culture as a vital, yet nearly undefinable, component of American folklore. It is important to understand the folklore of any given society as not only cultural archive but also a dynamic space for deliberation on collective identity and ideology, and in the case of the American settler state, our folklore has often been used as an arena to widely rationalize colonial violences. With this in mind, I evaluate the role of *The Wizard of Oz* within American folklore. I do this first by determining the lore's foundation through analysis of both the 1900 novel and the 1939 film adaptation as settler colonial narratives which reflect the collective anxieties of their respective eras and

depict Dorothy as the idealized, benevolent American settler. I expand upon this analysis by engaging each iteration of *Wicked* — Gregory Maguire’s revisionist novel, the Broadway musical, and the 2024 film adaptation — all of which effectively exonerate the Wicked Witch of the West and bring Oz into the contemporary age by attempting, but perhaps failing, to view the story through a postcolonial lens. My project examines *The Wizard of Oz* not as some static artifact but rather as a dynamic cultural text which constantly evolves to reflect shifts in societal values and political ideologies, yet always retains the settler colonial underpinnings embedded in the tale from its conception. Ultimately, I inspect both the evolving Land of Oz and the society which keeps reinventing it in order to determine how narratives adapt over time to continually justify the existence of the American settler state.

Abstract Name: "Raising our awareness is a suicide prevention strategy": Personal impact of an undergraduate suicidology course

Despite repeated calls for improved suicide prevention strategies (United States Surgeon General’s Office, 2021), provisional data shows suicide continues to be a public health crisis (CDC, 2024). Integrating suicide prevention education has shown promise as a way to improve direct care (Cramer, 2018) and motivate advocacy (Muehlenkamp et al., 2019). Most suicidology courses are introduced at the graduate level for clinical training, limiting prevention knowledge and potential for broader public health impacts within the general public. The current study evaluates the effects of a semester-long undergraduate course in suicidology. Participants included (n =102) undergraduate students from a variety of majors who enrolled in an undergraduate suicidology course. Students completed an end of semester reflection prompt inquiring about the personal impact of the course. Four investigators inductively analyzed the responses to generate themes. Each response was coded twice by different authors to ensure inter-rater reliability. Five major themes emerged: 1) empowerment (e.g. "this class has taught me that I have the capability of creating change in a positive way."), 2) knowledge (e.g. "I learned a lot about the complexities surrounding mental health crises and suicide and it has deepened my understanding of human struggle"), 3) application (e.g. "from this class I can better talk to my loved ones about suicide and if I am noticing changes in them."), 4) general personal/lived experiences (e.g. "I was able to learn more about the thinking of an individual that I lost to suicide"), and 5) reflection upon value/experience of class. Additional sub themes were identified and will be expanded upon. This research emphasizes the value of undergraduate education on suicidology. Undergraduate suicidology courses may help facilitate understanding, advocacy, and strengthen support for public health interventions to prevent suicide.

Abstract Name: Market Dynamics and Competitive Strategies in Airline industry

The airline industry is dynamic, being affected by economic changes, altering consumer preferences, and continuous technological changes. The main critical question that the study explores is: What are the market dynamics and competitive strategies in the business aviation sector? This study investigates how airlines respond to these emerging challenges in the environment: increased fuel and labor operational costs, demands of sustainability, and competition coming from low-cost carriers. The following paper points out ways in which airlines use their business model to gain a competitive edge through a combination of influencing factors-operational cost trends, revenue trends, consumer preference, and regulatory environment. This research focuses on an oligopolistic market structure dominated by a few companies, with high entry barriers increasing the competition. It will also investigate new emerging markets' opportunities, sustainability innovation, and the effects of digital transformation. The research will adopt a quantitative approach using historical data for 2019-2023 on cost structures, revenue patterns, and passenger traffic. Major airlines will be studied through case studies, which would qualitatively assess their strategic choices and operational challenges. Comparisons would be made in operational performance and customer satisfaction between full-service and low-cost carriers. Preliminary findings show the airline industry is resilient post-pandemic, with passenger traffic and revenues close to pre-2020 levels. However, challenges like rising fuel prices, labor shortages, and strict environmental regulations remain. Yet, opportunities exist in emergent markets, sustainable aviation technologies, and digital innovations that boost efficiency and customer experience. This study will discuss how the long-term sustainability and growth of the airline industry can be promoted. The adaptive strategies to attain cost efficiency, environmental duties, and changing consumer demand need to be balanced by an airlines competitive advantage through complex settings globally. This study provides key insights for stakeholders, including industry leaders, investors, and policymakers, as they navigate the airline sector.

Abstract Name: Echoes from Galang to Calgary: Tracing the Vietnamese Refugee Journey

Cultural preservation, identity formation, and integration within the cultural fabric of Canada are critical challenges that define the experiences of Vietnamese refugees and their descendants. This research explores the nuanced, personal journeys of Vietnamese refugees who resettled in Calgary, Alberta and examines how these individuals navigate the pressures of cultural retention, assimilation, and survival in a multicultural society. This study employs a qualitative methodology grounded in 15 in-depth, semi-structured interviews with first- and second-generation Vietnamese refugees and their loved ones to contribute to refugee studies and cultural preservation literature. Open-ended questions guided these interviews, allowing participants to reflect on how they maintained cultural ties to their Vietnamese heritage while adapting to Canadian societal norms. Thematic analysis, enriched by historical context and supported by relevant literature, reveals the tension between preserving cultural traditions and the societal demands of adaptation. First-generation refugees often prioritize economic stability and their children's success in Canadian society over cultural retention, reflecting the trauma of displacement and survival. Conversely, second-generation individuals frequently strive to reconnect with their Vietnamese roots, showcasing a renewed emphasis on cultural identity reclamation. This study emphasizes the critical role of Calgary's Vietnamese community in bridging generational gaps. Community institutions, including language schools, religious centers, and cultural events, emerge as necessary resources for fostering cultural continuity and identity exploration. Despite the enduring

impact of trauma and integration challenges, families demonstrate resilience through efforts to honour their heritage via language, cuisine, and traditional celebrations. By examining these dynamics, the study provides valuable insights into the Vietnamese refugee understanding and contributes to broader discourses on refugee integration and cultural heritage preservation in Western multicultural societies. Ultimately, this study underscores the significance of community-driven efforts to promote cultural preservation and support the well-being of refugee populations.

Abstract Name: Timing of Consonant and Vowel Articulation When Reading Aloud Primed Words

The objective of this study is to tease apart the timing of lip movements associated with initial consonants and tongue movements associated with vowels. It is usually assumed that all tongue and lip movements within a spoken syllable are planned and coordinated in advance, and that physical articulation of initial consonants and nuclear vowels is started simultaneously. However, emerging evidence suggests that at least some movements can be controlled independently in real-time (Kawamoto et al., 1998; Krause & Kawamoto, 2020). The key research question is how this timing is affected by giving a speaker advanced knowledge of consonants or vowels before giving them the whole word to say. In this in-process study, participants wear the Micro Speech Research Ultrasound headset that has an ultrasound probe to capture tongue movements, a camera to track lip movements, and a microphone to record their auditory responses. Participants read aloud monosyllabic consonant-vowel-consonant words, preceded by overt unmasked primes. Primes are neutral (e.g., “_ _ _”) or signal the initial consonant (e.g., “P _ _”) or vowel (e.g., “_ A _”). Preliminary data will be reported. If speakers can independently control these movements inside the same syllable, assumptions common to most theories of motor speech will require re-evaluation.

Abstract Name: The Power of Attention: Simone Weil's Antidote to the Collective Ego

Philosopher, mystic and activist are all terms associated with Simone Weil. Her works emerged during the profound upheaval of the Second World War, standing at the crossroads of spiritual, political, and ethical philosophy. Though dismissed by some for their mystical undertones, her writings—such as *The Need for Roots* (*L'Enracinement*)—profoundly influenced figures like Albert Camus. This was particularly evident in their shared concern for justice and the intrinsic value of the individual. Simone de Beauvoir once remarked that Weil had “a heart that could beat right across the world,” reflecting the deep connection between her life of activism and work as an academic. Weil's critiques of Marxism, her reflections on oppression and affliction (*malheur*), and her mysticism are well-documented. Simone Weil's attention has been

underexplored as an antidote to totalitarianism and the collective ego. Weil described attention as a radical openness to reality, requiring the suspension of ego and the courage to confront truth. Attention as an ethical and spiritual discipline challenges the dehumanizing abstractions of totalitarian regimes by affirming individual dignity and intrinsic human value over blind allegiance to ideological constructs. Current scholarship largely examines totalitarianism through systemic and ideological lenses, yet Simone Weil's notion of attention offers a distinct psychological and spiritual perspective. By addressing how individuals can resist authoritarian power through an understanding of human suffering and the structures that perpetuate it, her work provides a valuable framework for countering the collective ego that fuels totalitarianism. This project, engaging with her writings in their original French, seeks to underline the relevance of her work in modernity. It advocates for a deeper study of her thought as a guide for transforming how we perceive and interact with the world today.

Abstract Name: Public Policy and the Human Condition: A Study of Poverty, Crime, and Mental Health in Rural Pennsylvania

This interdisciplinary study investigates the intricate, multidimensional impact of poverty on crime, drug use, and mental health in Lawrence County, Pennsylvania. Serving as an exemplary microcosm of rural socio-economic challenges, Lawrence County highlights the complex interplay between individual well-being and community structures shaped by economic hardship. Employing a mixed-methods approach, this study integrates quantitative data from national crime and health databases with qualitative insights obtained through ethnographic observations and participant interviews conducted during an internship with local social services. Ethical considerations, including IRB approval, participant consent, and cultural sensitivity, were meticulously observed to protect participants' confidentiality and dignity. Findings underscore the need for targeted policy interventions and additional research in similar communities to address these interwoven socio-economic challenges. The study ultimately contributes to a broader understanding of poverty's impact on community dynamics and mental health, emphasizing the necessity of holistic approaches in policy and support frameworks for rural populations facing economic adversity.

Abstract Name: Investigating The Relationship Among CRP Levels, Executive Functioning, and Self-Reported Mood Disturbances

Over 20 million individuals in America have had at least one major depressive episode and 18.6% are young

adults (SAMHSA, 2023). Depression is just one of the mental health disorders that is leading to the estimated 5 trillion USD associated with the global mental health burden (Arias et al., 2022). C-reactive protein (CRP), a measure of systemic and neuroinflammation, is an emerging biomarker for mood disorders. Higher CRP levels have been associated with bipolar disorder (Chang et al., 2017), manic symptoms in individuals who have major depressive disorder (Becking et al., 2013), and may predict stress disorders like PTSD (Friend et al., 2022). Along with mood disorders, CRP is also a potential predictor for diminished executive functions like burnout (Toker et al., 2005) and impaired memory (Noble et al., 2010). This study investigates the relationship among CRP levels, executive functioning, and self-reported mood disturbances (i.e., depression and stress). Participants completed a series of questionnaires including demographics, the adverse childhood events checklist (ACES), the alcohol use disorders identification test (AUDIT), and the Depression, Anxiety, and Stress Scale (DASS). Saliva samples were collected and will be measured to quantify CRP using enzyme-linked immunosorbent assays (ELISAs; Salimetrics, State College, PA). Participants also completed a series of computerized tasks, including a number-letter switching task (NLT), to measure cognitive flexibility (millisecond.com). We anticipate that neural inflammation, as indicated by CRP levels, will moderate the effects of adverse childhood experiences and substance use on cognitive flexibility. Our hope is that integrating self-report, cognitive, and biological perspectives will yield insights into the psychological basis of various mental health disturbances. If so, CRP may offer a useful biomarker for monitoring and evaluating treatment progress in mood disorders by helping to link inflammation with symptom changes.

Abstract Name: Understanding Stress During Microgravity Using a Tail Traction Hindlimb Unloading Model

Space flight presents numerous psychological effects, including space noise, periods of prolonged confinement, irradiation, loneliness, and microgravity. Microgravity seems to be a significant stressor during spaceflight, which can be studied through the hypothalamic-pituitary-adrenal (HPA) axis, the neuronal and hormonal stress responder. Elevated stress-hormone levels are typically found in microgravity experiments, but this is the first exploration of regulatory hormonal stress circuitry and cells in microgravity. However, we aim to study how microgravity acutely and chronically changes activity in the paraventricular nucleus of the hypothalamus (PVN), where corticotropin-releasing hormone (CRH) is released due to the presence of stressful stimuli activating the HPA axis. Tail traction is the current National Aeronautics and Space Administration standard for microgravity stimulation with hindlimb unloading (HU), reducing impacted body weight by 50%. To observe stress, CRH cells of the PVN will be recorded in vivo fiber photometry to test neuronal reaction, and corticosterone, a hormone released from activation of the HPA axis, will be tested through CORT ELISA from fecal boli. Heterozygous CRH-Ires-Cre mice will have Cre-dependent unihemispheric GCaMP8m AAV injections into the PVN, with a fiber optic cannula implanted above the PVN. Our tail traction HU housing system is single-hinged with a chain that allows the mouse to rotate without twisting the photometry cord for continuous recording with access to essentials and nest changings. The fiber optic cannula observation of the in-vivo CRH activation will be for three longitudinal time points: 7, 14, and 21 days. We hypothesize that the peak neuronal activity of CRH-positive neurons within the PVN will occur on day 14 and activity acclimation to microgravity conditions day 21; alternatively, PVN-CRH neuronal activity may continuously increase through observation. By learning the in-vivo and hormonal stress response in the PVN with HU conditions, we can better understand plasticity in typical to atypical stress responses.

Abstract Name: Japanese Ink Painting

Abstract This project explores the intersection of traditional Japanese art forms, particularly ukiyo-e woodblock prints and sumi-e ink painting, with contemporary artistic interpretation. Drawing from the Edo period's rich history and folklore, I created a narrative series inspired by Japanese yokai, focusing on themes of fear, connection, and transformation. The work blends historical techniques and personal innovation, reflecting a deep respect for Japanese artistic traditions while contributing a modern perspective. Early inspirations stemmed from exposure to Japanese media, evolving into a fascination with the precision and storytelling in ukiyo-e prints. Through research using public domain resources and published art books, I studied the technical and cultural significance of these works. This informed my decision to use traditional materials such as sumi ink, rice paper, and calligraphy brushes to maintain authenticity. Material experimentation posed challenges, particularly with the absorbency and fragility of rice paper, which required adaptation and pre-mounting for display. The resulting pieces balance traditional aesthetics with a contemporary graphic style, drawing on the wabi-sabi philosophy to embrace imperfections. The narrative follows human characters interacting with yokai, highlighting both the mythical creatures' cultural symbolism and their emotional resonance. This work deepened my understanding of Japanese art history, folklore, and technique while pushing my creative boundaries. Future works will expand on this project by integrating pop-art influences and acrylic paint to create bold, modern reinterpretations of ukiyo-e. This exploration contributes to my portfolio by showcasing technical versatility, thoughtful engagement with cultural storytelling, and a commitment to bridging historical and contemporary art forms. This series celebrates the enduring relevance of Japanese art and its potential to inspire meaningful connections across time and cultures.

Abstract Name: The Role of Psychological Distress between Cognition and Life Satisfaction in People with Multiple Sclerosis

Multiple sclerosis (MS) is an autoimmune condition that significantly affects individuals' cognitive abilities, emotional well-being, and overall life satisfaction. This study investigates whether mental distress mediates the relationship between cognitive functioning and life satisfaction in individuals with MS. A total of 373 participants, recruited through the National MS Society, completed surveys assessing cognition, mental distress, and life satisfaction. Correlational and mediation analyses were conducted to explore the interactions among these factors. Findings revealed that cognitive difficulties were positively correlated with mental distress and negatively correlated with life satisfaction. Mental distress was inversely associated with life satisfaction. Mediation results suggested that mental distress partially mediated the relationship between cognitive functioning and life satisfaction. Reducing mental distress may help mitigate the negative impact of

cognitive impairments on life satisfaction. Given the substantial role of mental distress, it is crucial for care plans to address mental wellness in MS patients, with a collaborative approach involving rehabilitation professionals to support the individual's challenges and goals.

Abstract Name: Persistent Anger and Mental Health: Evidence from WisconSays

Anger is a common emotional response frequently linked to stress, but its long-term effects on overall health remain less understood. This study explores the relationship between the frequency of anger and its impact on health outcomes, using data from the WisconSays survey. By controlling for key demographic variables such as age and gender, the study seeks to test the hypothesis that individuals who experience anger frequently report more days of mental health struggles. The preliminary findings reveal that individuals who report feeling angry "very often" or "extremely often" are significantly more likely to experience mental health problems. Up to eighty percent of those in this high-anger group reported experiencing at least one or more days of poor mental health. Interestingly, the data show minimal gender differences in how often people experience anger. However, an age-related trend is evident, with younger adults reporting anger more frequently than older adults. This difference suggests that younger adults may be more vulnerable to experiencing worse mental health outcomes due to anger, compared to their older counterparts. These findings underscore the potential role of anger in amplifying stress-related health issues. When demographic factors such as age and gender are controlled for, anger appears to exacerbate mental health problems, contributing to more frequent episodes of mental distress. By understanding the connection between anger and health outcomes, this research highlights the importance of addressing anger management in mental health interventions, especially for younger individuals, to reduce the negative health impacts of anger.

Abstract Name: Heatwave: A Game-Based Learning Experience Bridging Climate and Health

Human-caused climate change is a pressing issue for the world's population. However, some populations face disproportionate impacts from the heat. According to the Washington Post, heat is impacting the health of vulnerable populations worldwide, such as those with preexisting health conditions and less financial or social capital. For example, imagine suffering from heat exhaustion without air conditioning or neighborhood tree cover. To raise awareness of these important issues, we ask: How do we educate and engage people in learning about heatwaves and health? Raising awareness of the health effects of heat can be done using games, which increase engagement and enjoyment of learning about a topic. Game-based learning allows

players to become engaged in a learning objective via games that leverage design principles such as motivation caused by a challenge, socialization, and an emotional experience. Through its simulated environment, games have the potential to motivate players to learn with challenges and get students to practice critical thinking skills. This study designed and tested a game-based learning experience teaching the health implications of heatwaves and the populations most affected. Using a role-playing game called “Heatwave,” players take on the perspectives of members of vulnerable communities during a heatwave, answer climate-related trivia questions, and encounter random heat-related events that influence the players' health points. Two focus groups were assembled to investigate the relationship between the game, the topic, and student interest and engagement. They were then interviewed in a semi-structured interview format, with anonymous qualitative data being coded, to determine the primary learning outcomes of gameplay and inform future revisions to the game. Future revisions to Heatwave based on the coding of the focus groups will likely include increasing the game difficulty overall, adding more interactivity, and making character decisions more unique to their demographics.

Abstract Name: Development of a Novel Chronic Traumatic Encephalopathy Mouse Model via Retro-Orbital AAV Delivery to Examine the Impact of Chronic Alcohol Exposure

Background: Chronic Traumatic Encephalopathy (CTE) is a frontotemporal dementia resulting from repeated concussive brain injuries incurred throughout the course of a lifetime. CTE, though commonly observed in professional athletes and military personnel, remains frequently undiagnosed due to a lack of biological markers and inconsistent diagnostic symptoms. It is also well-documented that individuals with CTE are diagnosed with alcohol use disorders at higher rates than the general population. Objective: The current experiments introduce a novel preclinical model of CTE that incorporates human Tau (huTau) in non-transgenic mice. We will 1) validate the model and 2) explore the behavioral changes that result from a retro-orbital injection of huTau adeno-associated viral (AAV) vector followed by repeated cycles of repetitive mild traumatic brain injuries (rmTBI) and alcohol exposure. Methods: huTau was introduced to mice via retro-orbital injection of a systematic AAV vector (AAV-PHP.eB-CBA-eGFP-2A-Tau, 5E10 vg/mouse). After 4 weeks of incubation, the mice were assigned experimental conditions and then repeatedly exposed to sham or rmTBI weight drop procedure (conducted under anesthesia) and, 4 hours later, exposed to air or vaporized ethanol for 16 hours overnight. The rmTBI + ethanol exposure procedures occurred 4x/week for 3 consecutive weeks. Finally, mice were tested in a cognitive behavioral battery to assess sensory motor gating, locomotor activity, and spatial memory. To examine CTE-related pathology, immunohistochemistry of fixed tissue samples was examined using antibodies for gliosis, tauopathy and inflammation. Results & Conclusions: This pre-clinical model of CTE and chronic intermittent ethanol exposure is a useful model to study the neural mechanisms involved in CTE. Significant trends and interactions were observed for open field locomotion, sensorimotor gating, and spatial memory. These findings suggest potential behavioral symptoms associated with CTE and ethanol exposure in mouse models expressing huTau.

Abstract Name: Type of Treatment, Length of Treatment, and Length of Stay for Infants of Mothers with a Self-Reported Prenatal Opioid Use

Appalachia has a high incidence of opioid use especially in women of child-bearing age. Infants born with opioid dependency require long-term care. There is limited information regarding the type of prenatal substance abuse and exposure with resultant birth history. The purpose of this non-experimental quantitative study is to examine the relationship between self-reported opioid use during pregnancy and infant withdrawal length of treatment, length of stay, and need for secondary medication for treatment of withdrawal symptoms. Data analysis is ongoing.

Abstract Name: Flora of Candler's Mountain: Documenting Natural Communities and Establishing an Herbarium

Herbaria are natural history collections containing dried plant material and function as the working tool of taxonomists to support understanding plant identification, nomenclature, classification, distribution, ecology, and further consideration of the societal implications of plants (Bridson & Forman, 2013). By providing an accessible system of primary data centralized in one location, these plant collections are essential in investigating plant types and biodiversity of ecoregions. Teaching Herbariums are typically small-scale, limited collections housed at a university to illustrate representative populations of the local area and provide an educational resource on plant morphology and taxonomy (Bridson & Forman, 2013). The collection conducted on Candler's Mountain would compile data on the species present, biodiversity, and microclimatic conditions of the collected specimens. The project aims to perform field surveys of Candler's Mountain for (1) the documentation of flora in distinct natural communities and (2) the establishment of a botanical collection to be used as an educational and research resource. The project aims to establish a local herbarium focused on the >1200 vascular plants documented in Campbell County, VA, and identify flora within distinct natural communities on Candler's Mountain, located outside of Lynchburg, VA.

Abstract Name: Interrogating Novel Tubulin Inhibitors on the A375 Melanoma Cancer Cell Line

Cancer is defined as an uncontrolled growth of abnormal cells capable of spreading either locally to surrounding tissues or throughout the body. Cancer remains one of the leading causes of death globally, with millions of new cases reported annually. Chemotherapy is one of the most effective treatments against this disease and is typically used to target fast-growing cells or cells that are in various phases of the cell cycle. One such chemical used in chemotherapy treatments targets the formation of microtubules, which are important structures critical for proper cell division and aid in the process of mitosis. Because cancer cells rely on cell division, blocking tubulin incorporation into microtubules can prevent mitosis, leading to cancer cell death. Unfortunately, current tubulin inhibitors show high toxicity against normal cells. To overcome issues with toxicity, a new way to inhibit tubulin polymerization has emerged that focuses on binding small molecules to the colchicine site of tubulin to destabilize polymerization. Potential tubulin inhibitors have been synthesized to target the alpha and beta subunits of tubulin at the colchicine site. This study sought to determine the preliminary effects of these compounds on the melanoma cancer cell line A375, and their potential to function as inhibitors of tubulin polymerization. Initial screenings of these compounds used Western blotting techniques and immunofluorescent staining to determine the presence of proteins specific to the Sub-G1 and G2/M phases of the cell cycle and the structures of cells after incubation with potential inhibitors, respectively. Results from this study indicate that these compounds do have the potential to inhibit polymerization and provide the foundation for future studies. Further development of variations to these initially tested compounds may provide a novel way to reduce toxicity and overcome issues in current chemotherapy treatments.

Abstract Name: Taking Turns: A Color Analysis

MK Czerwiec's graphic novel *Taking Turns* was a heart-wrenching yet informative glimpse into the HIV/AIDS Care Unit 371. Throughout reading, it became clear that Czerwiec's goal was to use the color of these backgrounds to establish settings and tone throughout this novel. Color, viewed through the lens of graphic novels, often has a level of iconography associated with it. According to Scott McCloud, author of *Understanding Comics*, colors in comics could be used to establish mood, depth, or sensations within their readers. The primary research question for this project is: How do the colors in the novel *Taking Turns* by MK Czerwiec influence how the story is told and how the novel's settings are expressed? I believe this research is important because graphic novels are intrinsically artistic and a large part of art is color, so understanding how Czerwiec uses color can help us better understand this novel's overall implications. I created a spreadsheet to keep track of all the pages and box numbers in *Taking Turns*. I then went through the novel using the eyedropper tool to get the exact color associated with that page. Using my judgment, I then classified each color from the page with its word associate. For a final time, I went through the novel and determined if the page was establishing setting, and what that setting was, to see if there was a correlation between color and setting. In my results, I am looking to see the correlation between colors, setting, and themes.

Abstract Name: Induction of Remission through diet for Crohn's Disease

Crohn's disease is a chronic & destructive disorder that belongs to the group of inflammatory bowel diseases that can affect any area in the gastrointestinal tract. Crohn's disease treatment is multidisciplinary and complex depending on the patient's disease severity, subtype, behavior, mucosal healing, and deep remission, and location. Studies have shown that there is a strong link with dietary shifts towards a Westernized diet leading to intestinal dysbiosis and a disturbance in intestinal immunity. Management of this disease is multifaceted and usually involves only medication and surgery depending on the severity of the disease. Dietary therapy is often overlooked by clinicians due to patient adherence. Although studies have shown that dietary intervention could be the start of correcting a patient's intestinal dysbiosis. The implementation of dietary intervention with EEN and PEN shows the most effective at inducing remission. EEN and PEN diets have been comparable to pharmacological intervention in inducing remission. Although the results have been effective, patient adherence is low due to the lack of whole food. Whole food diets have shown promising results for inducing remission such as SCD, low-FODMAP, MD diets. These diets tend to be more palatable and adherence is higher. Keywords: Dietary therapy, Crohn's Disease, Whole Food diets, dysbiosis

Abstract Name: Influenza A Virus Alters Iron Homeostasis in the Microenvironment of Human Bronchial Epithelial Cells within Air Liquid Interface Cultures

Influenza A Virus (IAV) causes severe lung inflammation, leading to pneumonia and ARDS. Importantly, secondary bacterial infections following influenza increase the mortality and morbidity of IAV. Here, we identify potential mechanisms through which IAV facilitates secondary bacterial infection with *Streptococcus pneumoniae* (Spn) with a focus on the effects of iron binding and distribution within the cellular microenvironment. Iron is a critical nutrient for both host and microorganisms, and mechanisms for sequestration of iron are highly orchestrated. Iron homeostasis functions, including acquisition, sequestration, and metabolism, are crucial for bacterial host defense, and are involved in antimicrobial properties of immunological phagocytic cells and mucosal membrane proteins. Iron depletion in the microenvironment is hypothesized to enhance the ability for bacteria to infect differentiated human bronchial epithelial cells (HBEC) - ciliated, secretory, basal, and rare cell types. The host limits the capability for iron to be attained by pathogen (nutritional immunity), while bacteria have evolved scavenging mechanisms. We hypothesize that IAV infection promotes increased susceptibility to secondary infections by disrupting host iron regulation. Single cell transcriptomics analysis has identified key regulatory genes in iron pathways that are altered by

IAV infection. Key regulator genes, such as the Solute Carrier (SLC) gene family are required for the transport of iron across the plasma membrane, impacting the differences of iron presence in the apical surface liquid of the Air Liquid Interface (ALI) cultures. Thus, the regulation of SLC genes within differentiated cells introduces alterations in genomic pathways, producing a disruption in the homeostatic iron relationship. From this analysis, iron acquisition and sequestration are likely important changes leading to susceptibility to secondary bacterial infection. In this study, the parts per billion (ppb) concentration of iron in the apical surface liquid (ASL) of the ALI cultures proceeded through experimentation with Inductively Coupled Plasma Optical Emission Spectroscopy (ICP-OES).

Abstract Name: Increasing Nursing Knowledge and Interventions Related to Childhood Obesity

Childhood obesity impacts a child's psychological and physiological health. The rate of childhood obesity continues to increase annually with nearly 20% of children in the United States being diagnosed as obese. Although nurses can provide education and early interventions, many do not. Nurses cite various rationales for their lack of intervention, including complex communication with parents and a lack of in-depth understanding of the topic. This study's purpose is to identify if providing education on communication strategies and care plans related to prevention and management of childhood obesity will increase nursing knowledge, confidence, and patient-centered interventions. The theoretical framework of this study is based on Humanistic Nursing Theory. This theory emphasizes the therapeutic relationship between a nurse and patient and the importance of a patient's self-actualization. Nurses in a pediatric primary care office, specializing in the treatment of obese children, will complete a pre and post survey evaluating their level of knowledge, confidence, and active interventions. Between the pre and post survey, nurses will be provided with education on the prevention and management of childhood obesity and strategies to mitigate communication barriers. The research's outcomes will determine the effectiveness of education on nursing intervention and provide information to assist with future research on enhancing interventions to care for children with obesity. Keywords: Childhood Obesity, Nursing Interventions, Nursing Confidence, Communication Strategies, Education, Nursing

Abstract Name: "The Sexualization and Traumatization of Black Women"

My research delves into the harrowing impact of sexual assault/ trauma upon black women and connects their experiences of thriving in motherhood, sisterhood, and caretaking while dealing with the trauma and navigating healing. Looking at cases between the 1940s up to the 21st century, specifically in and around the deep south. The main purpose for this research is to shed light on the history of sexual assault upon black women and give way to different avenues of healing. I wish to display how the justice system has also created multiple generations of black women that have been silenced and forgotten about by not taking a stance in our defense sooner. My contribution to this aspect of research will focus on different types of sexual assault such as rape, sexual assault and sexual abuse. It will pose and answer the questions, "Why have Black women been targeted?", "Is there a lack of protection amongst black women?", "Why is there a gap in the research?" and "What does healing look like for the modern black woman?". It will also include the shift of conversation as to what healing looks like as it pertains to socioeconomic statuses, age, location, and even relation to the abuser. For this research, I will lay out how black women are the least protected in America using historical novels, interviews, and poetry. There will be an analyzation of statistics and how they have changed over the past seventy to eighty years. It will include data of what the crime of sexual assault does to the human body and how it changes the brain chemistry forever. Most importantly, it includes real life testimonies and

interviews of sexual assault survivors. I conclude my research by examining social movements, changes in policies, and healing journeys. Aiming to push the conversation forward.

Abstract Name: Isolation of Endophytes from Nodules of Native Plants for Sustainable Agriculture

Plants have an intimate relationship with microbes; a fascinating aspect of this relationship is their ability to attract beneficial bacteria and fungi depending on their current needs and nutrient deficiencies. Among the many beneficial microbes used in the agricultural community, *Rhizobium* is among the most notable and well-studied. This nodule-forming, nitrogen-fixing bacteria is extremely important, primarily when using legumes in crop rotation systems, and plays a significant role in crop production. However, legumes are not the only plants that form beneficial relationships with rhizobacteria and endophytes. Actinorhizal plants play an essential role in the global nitrogen cycle by forming nodules with actinobacteria *Frankia*. *Ceanothus velutinus* and *Shepherdia* sp. are two native plants in the Intermountain West region that attract beneficial microbes and can form nodules with bacteria, such as *Frankia*. *Frankia* not only fixes nitrogen by inducing nodules but also fixes nitrogen while living freely in the soil. This quality makes it a perfect candidate as a biofertilizer in agricultural systems. We performed two isolation screenings for endophyte bacteria and *Frankia* from the nodules of *C. velutinus* and a *Shepherdia* Hybrid. The first approach isolated the microbes from nodules by filtering nodule extract through 40 μ M and 20 μ M filters. The second approach was done by ultra-centrifuging the nodule extract in a sucrose gradient and collecting the fraction. We used two *Frankia* and endophyte-specific media, QMOD and *Frankia* basal media (FBM), to isolate bacteria. We isolated 16 unique bacteria from the nodules of *C. velutinus* using the filtration method and 15 via the gradient method. We are characterizing these microbes and will then identify them using 16S rRNA sequencing. We are still in the process of purifying isolates from the *Shepherdia* Hybrid using both methods.

Abstract Name: What We Can Learn from University Student Experiences Reading Non-English Code

Prior work has studied barriers for non-native English speakers learning computer programming. To discover what resources inside and outside the classroom can address such barriers, many studies have focused on quantitative assessment of beginner programmers working in programs like Scratch, and few have studied university-aged students. While improving translations and tools for non-English speaking beginners is important, most programmers are eventually expected to use English-based, text-based programming languages. This requires that students transfer their early experiences into the less scaffolded syntaxes of widely used programming languages. This paper contributes a qualitative case study of linguistically diverse students at a top computer science university in the United States to understand what skills and resources are

important when reading code not based in English. To investigate this, I conducted a survey and five interviews that involved live code tracing activities of code in various human languages. Results show that students' familiarity with a variety of programming languages helped them identify patterns and make confident guesses to read code that used a human language they did not know. This suggests that adaptability to unfamiliar syntax is an important skill that can be developed through explicit language-conscious instruction and practice reading code in a variety of syntaxes.

Abstract Name: EXPOSURE TO AN ENVIRONMENTALLY RELEVANT PHTHALATE MIXTURE INHIBITS OVULATION BY IMPAIRING PROSTAGLANDIN FUNCTION IN THE MOUSE OVARY

Phthalates are solvents and plasticizers found in cosmetics, food/beverage containers, and medical supplies; therefore, human exposure is ubiquitous. Phthalates are known endocrine disruptors that target the ovary, meaning exposure could disrupt ovarian processes like ovulation. Prostaglandins (PGs) are vital mediators of ovulation due to their involvement in angiogenesis and cumulus-oocyte complex (COC) expansion. PGs are synthesized by various cell types within the ovulating follicle (granulosa and cumulus cells) and bind to their receptors on endothelial and cumulus cells to facilitate angiogenesis and COC expansion, respectively. Levels of active PGs, inactive PG metabolites, expression of PG synthases, expression of PG receptors, and ovulation rates were measured via various ovulatory experimental mouse models using cultured whole ovarian follicles (WF), COCs, and ovarian endothelial cells. Culture media contained vehicle control (dimethylsulfoxide, DMSO) $\pm$ a mixture of 6 phthalates (MPTmix, 1-500 μ g/mL) derived from urinary phthalate levels in pregnant women to best mimic human exposure. In WFs, exposure to MPTmix decreased active PG levels (PGE2 and PGF2 α) and increased PG metabolite levels. The levels of PGE2 were also decreased in COCs exposed to MPTmix. These decreases were largely attributed to decreased expression of PG synthase (Ptgs2) in WFs and COCs exposed to MPTmix. MPTmix exposure increased expression of PGE2 receptor 4 in ovarian endothelial cells and altered expression of PGE2 receptor 1 and 3 in WFs. Most notably, exposure to MPTmix in WF cultures decreased ovulation rates. Across these ovulatory models, MPTmix exposure likely disrupted the function of PGs by decreasing PG levels and synthases, increasing metabolite levels, and altering PG receptor levels. These MPTmix-induced changes may be why ovulation was inhibited in the WFs. Thus, exposure to phthalates may disrupt the ovulatory process and may ultimately contribute to the prevalence of infertility in women. Supported by R01ES033767.

Abstract Name: Across Time and Space: Queer Love and the Influence of History, Age, and Media

The average age gap observed in same-sex relationships is three times larger than that of heterosexual relationships, raising questions about power dynamics and age of consent. Queer Time Theory offers an explanation for why these age disparities exist and the nuances that come along with them through a historical and social analysis of queer relationships and culture. By using a combination of literature and primary sources this presentation adds to the discourse surrounding Queer Time Theory by analyzing how age gap relationships have been intertwined with queer culture and the way power dynamics impact relationships of all kinds. Age gaps in queer relationships can be expected considering the climate that they had to develop in throughout history. Still, this subject has been minimally researched or often simplified into the common harmful "groomer" stereotype. Often, gay romantic connections could not grow past being a short sexual connection. If a long-term relationship did occur, individuals were signing up for a life of danger and ridicule. Age gap relationships can be observed in queer history most notably in the trials of Oscar Wilde where Wilde, a gay man, faced charges of "gross indecency" for being in relationships with younger men. Historical sources display age gaps within personal advertisements where younger gay men are looking for a "daddy" to "show them the ropes", as well as in gay cruising culture. Age gaps are often sensationalized in media today such as in films like Call Me By Your Name. This research presentation analyzes the way queer lives have been directly impacted by the oppression their community has faced throughout history and the ways that those effects have been perpetuated and interwoven into queer lives today. Presenting this research will equip queer people with an improved understanding of themselves resulting in healthier more fulfilling relationships.

Abstract Name: Rhizobacteria from Native Plants Promote Growth and Induce Drought Tolerance in Arabidopsis

Climate-induced environmental stresses increasingly threaten food production across the Intermountain West and, ultimately, the world. This issue is exacerbated due to the overuse and overreliance on chemical fertilizers, which can significantly deteriorate soil health. This is becoming particularly impactful in large-scale agricultural settings. In natural soils, microbes perform the vital function of protecting the health of the soil and assisting in native plants' growth. The Intermountain West region is home to many drought-tolerant native plants that are able to thrive in the high desert climate and nutritionally poor soils. *Shepherdia argentea*, also known as Silverleaf Buffaloberry, and *Shepherdia rotundifolia*, Roundleaf Buffaloberry, are two such native plants. Because these native plants can flourish in such adverse conditions, we hypothesized that they attract potent microbes in native soils that provide them with the resources and stress tolerance needed to survive. We harvested the roots and isolated plant growth-promoting rhizobacteria (PGPR) from both plants. We characterized seven potential Plant Growth Promoting traits, including Catalase activity, Protease activity, ACC-deaminase activity, Nitrogen fixation, Siderophore production, Phosphate solubility, and Indole-Acetic Acid production. We then tested the four most potent bacteria from each plant on *Arabidopsis thaliana*, the model plant, to determine growth promotion and drought tolerance. Ultimately, we found that four microbial treatments showed increased plant leaf surface area, one increased the fresh weight, and three microbes significantly increased dry weight. Additionally, we found that two of the bacteria helped the drought-stressed plants recover after rewatering.

Abstract Name: Advance Care Planning in the Appalachian Rural Region: A Qualitative Study

In the medical care setting, decision-making is hugely important in the patients' lives and their families. Advance care planning (ACP) is a way of deciding how someone would like to be treated in crucial times and serious illnesses (Owen, L et .2019). This process is critical for the patient's decision to be respected. In some areas of the United States [especially the rural areas as the Appalachian States] can be quite a challenge to apply the Advance Care Planning due to some political or religious beliefs, healthcare access, and socioeconomic issues. It is important to understand decision-making in the medical setting because it appreciates the patients' future wishes and it's important to know how this will impact the rural communities where usually medical care and decision-making are scarce and chronic illnesses abundant.

Abstract Name: Using Behavioral Tests and Immunohistochemistry to Gauge the Role of Cholesterol Dysregulation in Alzheimer's Disease

Alzheimer's disease (AD) is a chronic and lethal disease remains incurable and thus imposes an enormous economic and social burden worldwide. One of the major challenges in fighting AD is finding the cause. The popular amyloid hypothesis is questionable in case of sporadic AD (sAD), consisting of more than 95% cases. Evidence has pointed to the dysregulation of lipids in the brain, especially cholesterol (Chol), during aging. It is well known that certain types of brain cells and brain regions are vulnerable to sAD and exhibit neurodegeneration earlier than other parts. New tissue-clearing methods like iDISCO and volume imaging (i.e., light-sheet microscopy, LSM) allow the study of molecular and cellular changes in large samples like whole mouse brains. Immunofluorescence labeling was used to distinguish two types of brain cells, neurons and astrocytes, and gauge their cellular Chol regulation by measuring the amount and subcellular distribution of SREBP212, a Chol regulator in the brain. A set of tests for memory, learning, and locomotion were conducted to gauge the cognitive and sensorimotor functions of male and female hApoE4/4 mice and compare them with age-matched male and female C57B6/J mice as a wildtype control. The transgenic and wildtype mice were tested side-by-side for a fair comparison and the results of the control allowed for the set up of the baseline and identification of performance differences from ApoE4's effect on neurodevelopment. The outcomes of all tests provided a reference to normalize any differences due to gene or age-associated changes in locomotion, muscle strength, and coordination. For each age group, male and female mice were subgrouped to analyze any sex-associated change. All data was statistically analyzed plotted with GraphPad Prism and RStudio. ANOVA, followed by post-hoc comparison tests, were used to identify statistically significant differences across different groups.

Abstract Name: Visualizing the News: The Role of Graphics in Effective Information Sharing

In today's modern media landscape, we continually witness a rapid flow of information that overloads our senses, which can skew our ability to consume material in a way that is digestible and impactful. In this era of news media, graphic design is no longer just a creative tool to catch the viewer's eye but a powerful communicator. This presentation will not only address methods for gaining attention in our attention-scarce world, but also how we as an audience value credibility when it comes to deciphering true information through design. In our time of civic unrest where attention is fickle and information is weaponized, these skills are crucial for students and viewers to develop. This presentation will focus on the chronological process of curating motion and still graphics for U-View Television's 2024 Presidential Election Newscast at Point Park University, including background research, design, animation, finalization, and reception of said graphics through the live newscast. The presentation will examine the process with narration on each step and a demonstration of how well-designed graphics can transform data into core messages in seconds. After executing the project, we found that design was an essential element for our audience's comprehension of multilayered information, as newscasts must include quick 1-2 minute summaries of topics that viewers may struggle to understand due to the format. Through motion graphics and concise, striking visuals designed to engage even the most inattentive viewer, we ensured that our audience was able to decipher what candidate won, what the reporters were discussing, and maintain overall interest. We also discovered that it aided brand identity to convey to viewers the trustworthiness of the newscast and the reporters themselves. Above all, our work on this project demonstrates that cohesive design can uplift visual polish, clarity, and attention to detail to project authority and competence.

Abstract Name: Gait Analysis using Multivariate Extended Kalman Filter to Improve Patient Care

Gait analysis is a critical component of physical therapy, aiding clinicians in diagnosing and treating movement disorders by examining an individual's walking patterns. Key parameters such as step length, stride length, walking speed, step symmetry, step height, and foot clearance provide valuable insights into potential leg impairments. Traditionally, gait analysis relies on 3D camera-based motion capture systems, which are time consuming, expensive and may require elaborate, stationary setups limiting their accessibility in clinical settings. This study explores the feasibility of using wearable Inertial Measurement Units (IMUs) to measure joint angles and perform gait analysis as an accessible alternative to traditional systems. By attaching IMUs to the thigh, calf and foot joint, we can determine leg angles and replicate the side-by-side imagery that physicians utilize in assessments. The data from the IMUs allows for the calculation of leg positioning relative to the ground, enabling gait analysis to be conducted in any environment without the constraints of fixed equipment. Furthermore, we utilize the data collected through the IMUs (position and

angle) to develop a Multivariate Extended Kalman Filter (MEKF) algorithm, that is used to monitor and analyze the gait movements for possible anomalies. The biggest advantage of MEKF is that it is an online algorithm and can be performed on-board to provide instant feedback to the patients. We hypothesize that our proposed approach, relying solely on IMU data in addition to the MEKF algorithm, can provide accurate gait analysis while being more accessible and cost-effective, thus broadening the scope of clinical applications and benefiting a larger patient population.

Abstract Name: Analyzing the Effect of Alkylamine Length on CsPbBr₃ Nanocrystal Storage Longevity

Cesium lead bromide nanocrystals have garnered significant interest in the chemistry and physics communities due to their potential applications in renewable energy. The surfaces of these nanocrystals are covered in ligands that protect the nanocrystal from degradation and preserve their electronic properties. There are typically two ligand species used in CsPbBr₃ nanocrystal syntheses, an alkylamine and oleic acid. This study focuses on the effect of the length of the alkylamine ligands on the shelf-life of CsPbBr₃ nanocrystals. Oleic acid interacts with long-chain amines primarily through van der Waals forces and binds to the surface of these CsPbBr₃ nanoparticles. To investigate how varying the ligand identity affects the stability of the nanocrystals, the study will examine how the alkylamine carbon chain affects the stability and storage life of CsPbBr₃ nanocrystals. We monitored the stability by measuring fluorescence spectra at various time intervals for each nanocrystal sample. Future research could contribute to improved renewable energy technologies.

Abstract Name: Effects of Hydrothermal Vents on Chemistry and Mineralogy of 2021 Fagradalsfjall Eruption

Beginning with the first eruption at Fagradalsfjall in 2021, the Reykjanes peninsula of Iceland has been undergoing an intense period of volcanic activity. Recent studies done by Francesco Sauro indicate rare minerals and signs of extremophile life have been found in lava tubes created during the 2021 Fagradalsfjall eruption. Rock discoloration near the vents indicates chemical changes. These changes could be similar to those within the lava tubes. Our goal is to understand the effect of hydrothermal vents on nearby basalts. We collected and analyzed samples of altered and unaltered basalt. We are using powder X-Ray Diffraction (pXRD) for mineralogical analyses. Preliminary results from unaltered samples showcase magnesium-rich olivine and calcium-rich plagioclase. From vent altered samples we found zeolites such as Hydromagnesite,

Hydroxyl Clinohumite, Mordenite, and Laumontite and other layered silicates that are not present in unaltered samples. We are also using Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES) for chemical analysis. We did two separate closed vessel digestions, one in 70% v/v nitric acid and one in 70% v/v hydrofluoric acid in order to get a complete chemical signature of the sample. Changes in basalt chemistry and mineralogy due to hydrothermal reactions can provide important information about conditions of early life formation and can also create new and rare minerals. Therefore it is important to conduct detailed chemical and mineralogical analyses of samples altered by reactions with fresh lava. Overall, this study aims to find any existing relationship between reactions taking place around the vents found on the surface of the lava field and the lava tubes created during the eruption. This presentation will cover our analytical methods, data, and implications of our findings.

Abstract Name: Is there a difference in female and male affectionate interactions within prides of African lions (*Panthera leo*) in the Ngorongoro Crater and Serengeti National Park, Tanzania?

Most wild felids exhibit solitary social behavior. African lions are the exception, living in social groups of two to eighteen related females, their dependent offspring, and unrelated males. Within prides, affectionate behavior reduces tension and increases social bonding. In this study, we looked at the affectionate behavior shown by lions concerning their gender. We hypothesized that there was a relationship between gender and the rate of affectionate behavior. Based on this hypothesis, we expected to see more affectionate behavior in females because of their greater role in cub caretaking and reliance on the social group. The lions studied were in Serengeti National Park and the Ngorongoro Crater, Tanzania (May/June 2024). Ten groups of lions were observed, and our data reflects a combination of all lions. We took note of how many lions were seen in the same area, the gender of the lions, and if lions were exhibiting head-butting, rubbing, cuddling, mating, or licking with another lion. We found that female lions were more affectionate than male lions, with 80% of affectionate behavior observed conducted by females (the sample size was too small for statistical analysis). We also found that 50% of lions observed showed no affectionate behavior, either sitting near but not interacting with other lions, or sitting alone apart from their pride. Confounding factors included the time of day that lions were observed (mid-morning to afternoon) as lions are most active during dawn and dusk. Lions tended to be observed close to the road, where safari vehicles have easy observational access. Our hypothesis was supported - female lions are more likely to exhibit affection than their male counterparts and we conclude that this is due to their roles as cooperative hunters and communal cub carers.

Abstract Name: A Novel Magnetically Actuated Insulin Delivery Device

An estimated 8.7 million individuals worldwide live with Type 1 Diabetes (T1D), a condition affecting the pancreas' ability to make insulin. Automated Insulin Delivery systems, also known as Hybrid Closed Loop systems or Artificial Pancreas (AP) systems, are used to monitor and control unstable blood glucose levels. Left untreated, such blood glucose levels could have serious health problems for people with T1D, including damages to the heart, kidneys, eyes, and nerves. Studies from the Type 1 Diabetes Index suggest greater adoption of artificial pancreas systems as treatment for T1D could save 673,000 lives by 2040. However, many patients avoid these systems due to the inconvenience of carrying cumbersome on-body pancreas systems, which include an insulin pump and a glucose monitoring device. As a result, there is a growing demand for artificial pancreas systems with reduced size and improved user-centric features to enhance user adoption. This study introduces a magnetorheological peristaltic micropump designed to deliver insulin in a compact, lightweight, portable, and energy-efficient manner— combating common issues with modern artificial pancreas systems. The pump is wirelessly controllable and built for durability, catering to the specific needs of T1D patients. A physics-based 3D simulation using COMSOL Multiphysics software and the Magneto-Solid-Fluid Interaction model were employed to evaluate its performance. Results show that the micropump achieves a flow rate of 3.08 μL per pumping cycle within 0.41 seconds under a magnetic field strength of 125 mT. While primarily developed for insulin delivery, the micropump's versatility extends to applications in micro-cooling systems, cell sorting, and various other fields requiring precise fluid control. This innovative approach addresses critical barriers to adopting artificial pancreas systems by offering a promising pathway to improve health outcomes for T1D patients while also enabling advancements in related technological domains.

Abstract Name: Rapid Detection of ATRX (Alpha-Thalassemia X-Linked Retardation) truncation for Glioma utilizing Loop Mediated Isothermal Amplification (LAMP)

Glioma is a fast-growing central nervous system cancer found in the brain or spinal cord tissue that forms from supportive tissue called glial cells. The 2021 WHO (World Health Organization) recommendations for diagnosis of glioma places added emphasis on molecular characterization of tumors with approximately 80% of IDH (isocitrate dehydrogenase) gliomas harboring ATRX mutations as well. The key molecular distinction differentiating IDH mutant oligodendroglioma from IDH mutant astrocytoma is the presence of a truncated ATRX gene product in astrocytoma. The presence of the ATRX truncation leads to a worse prognosis and different treatment regimen, making identification of the mutation more clinically significant. However, identification of the ATRX mutation is typically performed over days utilizing next generation sequencing. Here, we provide proof of principle for the nucleic acid amplification technique, LAMP (Loop Mediated Isothermal Amplification), as a viable option for detection of the ATRX mutation. Utilizing synthetic DNA, we have demonstrated that LAMP can detect the truncated mutant ATRX with discrimination from the wild

type (WT) sequence in 45 minutes. With this molecular technique, we can quickly identify the ATRX mutation resulting in a more rapid and personalized treatment for the patient.

Abstract Name: The Ampullae of Lorenzini and its Role in Environmental Health

The ongoing problem with global warming has a direct impact on these creatures beyond just the literal warming of the ocean. For instance, the ice caps melting reduces ocean salinity which changes the electrical conductivity of the water. This academic panel presentation will analyze a lesser-known organ found in cartilaginous and basal bony fish; an extension of the lateral line system called the ampullae of Lorenzini. This is a sensory organ that fish such as sharks and rays use to detect electrical fields in water. Great White Sharks are so sensitive to electric fields that they are known to react to charges of one millionth of a volt in water. With that kind of sensitivity to small changes and the environmental damage being done on a macro scale, it could lead to ecological ruin. In this sense, humanity has reached a global crossroads in terms of how it proceeds with scientific findings of this nature. This presentation, part of the Natural and Physical Sciences discipline area, will pose the question: Can a better understanding of the ampullae of Lorenzini, how it's affected and how it's used, show us the state of marine and freshwater environmental health? I will briefly discuss its evolutionary place in our oceans and its discovery by Italian ichthyologist, Stefano Lorenzini. Then, the role of the ampullae of Lorenzini in hunting and mating will be discussed. Overall, this research encourages us to consider a seemingly minor finding within the context of environmental sustainability, with the goal of safeguarding our fragile ecosystem for future generations.

Abstract Name: Generation 2 Generation: Conversing with Kindred Technologies

Generation 2 Generation: Conversing with Kindred Technologies explores how humans and technology have always evolved together. This immersive, traveling art exhibition blends the past, present, and future of technology and language through physical, digital, and written media. Inviting viewers to consider their relationships and attitudes towards current and emerging technologies, this show and catalog act as both an action and a call to action. Generation 2 Generation provokes a reflection on how technology both enhances and evolves our understandings of politics and society, matter and nature, our world and ourselves. New technologies - with Artificial Intelligence being the latest and most rapid form - should induce neither blind optimism, nor crippling fear. AI, for example, continues to rapidly progress and improve, and Generation 2

Generation encourages discourse about its place in our personal lives, relationships, and broader society. The unifying element of a font created by AI, creates an aesthetic that challenges technology itself. Asking and answering these questions has seen the production of a monumental, poetic landscape of reclaimed electronic waste; an interactive mirror that “reads” human movement and translates it into dynamic code; a print- and image-based installation, featuring a custom AI font that evolves past human understanding, beyond the limits of the screen or page; play-based installation of stencils, coloring books, and paint; concrete poetry made of precious metals recovered from mining slag and computer waste — alchemized artifacts of digital communication; and, media-rich (generative/oral/aural/digital) performances of AI-powered poetry, updating an ancient art form for the approaching posthuman age. Neural Networks, as well as novel understandings of natural networks – are enabling and enhancing unique forms of creative exploration in and with various matter and materials, life and non-life. Generation to Generation hopes to open up those spaces for even greater exploration.

Abstract Name: Uncertainty and Wickedness in Creative Research

This presentation explores scaffolding techniques for adapting undergraduate research into hands-on, creativity-based courses aimed at solving novel, often wicked problems. Wicked problems, characterized by their complexity and lack of clear solutions, challenge students to embrace inquiry, navigate uncertainty, and trust in the process of discovery. Through a series of projects in placemaking and environmental graphic design, this session will demonstrate how students learn to set aside preconceived solutions, overcome fears of failure, and engage deeply in creative problem-solving. These methods not only foster innovative thinking but also prepare students for real-world challenges, highlighting the transformative power of research-driven, experiential learning in graphic design education.

Abstract Name: Early Internet Exposure and Personality Traits in Relation to Social Media Use and Anxiety and Depression Symptoms

The purpose of this study is to investigate how early internet exposure and personality traits relate to excessive social media use later in life which, in turn, relates to increased reported anxiety and depression symptoms. There have been many studies regarding social media. However, the factors being examined in this new study have never been examined together. There have been separate studies detailing how social media use can lead to increased anxiety and depression symptoms, how social media use is related to specific personality traits, and how early internet use may lead to increased social media use in adulthood. This study makes a unique contribution to this area of inquiry because it is incorporating the different factors of early internet use and personality traits to excessive social media use which has been correlated to higher anxiety

and depression symptoms. This new study also investigates an undergraduate student population while other studies have either focused on adulthood or adolescence. The methodology consists of using an online questionnaire. While the study is anonymous, there is a demographics questionnaire consisting of knowing the participant's age, gender, and academic standing. There is also an internet use questionnaire consisting of the participant's screentime, what age they first had access to the internet, and what their first internet connected device was used for. The study utilizes the HEXACO-60 for examining personality traits, PHQ-9 for depression symptoms, and the GAD-7 for anxiety symptoms. The expected result is that the earlier an individual was exposed to the internet, the higher their social media use later in life. For personality traits, high openness, emotionality, and extraversion are expected to relate to social media use in adulthood. It is anticipated that the combination of these factors, including increased social media use, will be significantly related to anxiety and depression symptomology.

Abstract Name: Assessing Community Needs Through a Community Engaged Lens

Rotterdam is a town in Schenectady County, New York. Organizations in the area, such as the Rotterdam Community Center, are assets within the community, yet unaddressed needs still exist within the town. It is important to understand the needs of towns like Rotterdam because many other communities across the country are similar and may have similar needs and assets. What do Rotterdam residents identify as the needs in their community, and how can the Rotterdam Community Center address those needs? Additionally, can this study provide information for other local agencies to address the needs that the Rotterdam Community Center cannot address alone? Needs assessments allow for organizations to understand the awareness, availability, accessibility, and acceptability of services in the community and the interventions that they can implement toward their targeted populations. We partnered with the Rotterdam Community Center through the Nonprofit Excellence and Transformation program at Siena College to create this survey-based needs assessment as well as an analysis of that data. The study was a convenience survey of 229 Rotterdam residents over the age of 18, with 37 quantitative questions to understand their feelings regarding safety, job security and opportunity, inclusion, healthcare needs, comfortability within the community, as well as participants' ability to have their needs met within their community. The survey also included 4 qualitative questions that allowed participants to express additional needs. The conclusions of the study have found that many residents' needs are more expansive, such as infrastructure improvements, that are unable to be addressed by the community center alone. We provided suggestions for the Rotterdam Community Center to address these needs through a report which will also be disseminated to other organizations for more expansive needs.

Abstract Name: Zebrafish endogenous retrovirus (ZFERV) potential phosphodiesterase predicted to disrupt the Innate Immune System.

Endogenous retroviruses (ERVs) are ancestral viruses that have integrated into host DNA and are inherited through the germline. Zebrafish models offer a simple framework for evaluating viral pathogenesis due to their well-characterized immune system that shares similarities with humans. Zebrafish endogenous retrovirus (ZFERV) is selectively expressed in the thymus and random insertions of ZFERV have been tied to T-cell leukemia in zebrafish. ZFERV contains a gene similar in sequence to cellular viral phosphodiesterases (PDEs). Viral PDEs have been shown to interfere with production of interferons that the host uses to defend against viral infection. In this study, we propose characterization of the ZFERV-predicted PDE using cell culture, transfection, and fluorescence microscopy. We hypothesize that the expression of ZFERV putative PDE will disrupt the oligoadenylate synthetase (OAS) - RNase L response to viral RNAs by cleaving the effector molecule 2-5A. Our research provides insight into the interplay between ERVs and the host immune response and would represent the first characterization of a PDE in a retrovirus.

Abstract Name: Abundance of *Azolla filiculoides* on Dissolved Oxygen Concentration

Mosquito fern, or *Azolla filiculoides*, is an abundant native aquatic species at Big Break Regional Shoreline, where it is found forming dense floating mats at the surface. It is a unique species due to its symbiotic relationship with cyanobacteria, allowing it to fix atmospheric nitrogen and double its entire mass in just 1.9 days. Historically, *Azolla* is also associated with major paleoclimatology shifts due to its ability to draw down carbon dioxide and regulate climate. This study aims to build on previous research on the ability of *Azolla* in lowering dissolved oxygen (DO) levels and further investigate its complex ecological role in the Sacramento-San Joaquin Delta. We grew varying masses of *Azolla filiculoides* (2g, 6g, 10g, 14g) in Delta water over a 20-day period and monitored DO levels regularly. The highest mass of *Azolla* yielded the lowest mean concentration of DO (6.206mg/L), whereas the lowest mass yielded the highest concentration (6.592mg/L). This negative correlation is likely due to the dense covering of *Azolla* on the surface, inhibiting oxygen diffusion into the water. While *Azolla* functions as a carbon sink, this plant genus clearly exhibits some ecological duality in lowering dissolved oxygen and potentially decreasing biodiversity in the Delta.

Abstract Name: Anterior Cruciate Ligament (ACL) Injury Prediction and Prevention in Athletes: Analysis and Experimental Design

Anterior cruciate ligament (ACL) injuries are prevalent in athletes during high-acceleration movement. This particularly affects female athletes due to a combination of biomechanical, anatomical, and external factors including hormone fluctuations, quadricep dominance, and differences in neuromuscular activation patterns. This study aims to develop a computational model to better understand the biomechanics of knee loading. The focus is on analyzing biometric data and neuromuscular activation patterns during dynamic movements using a sensory system comprised of electromyography (EMG) sensors, pressure insoles, and a motion capture system. EMG sensors will provide insight into the internal mechanisms of knee loading by capturing muscle contraction intensity and timing. Pressure insoles will record the location and magnitude of the forces being exerted. The motion capture system will measure key data including joint angles, acceleration, and deceleration speeds, and tracking knee valgus for an in-depth evaluation of knee loading patterns. Trials will be performed by male and female collegiate athletes and include kinematic and soccer-specific agility drills, with the aim of replicating high intensity and game-like movements. Using comparisons of knee loading patterns, joint angles, and acceleration data, this study aims to identify differences in injury risk between the sexes. This will allow for the identification of safe loading patterns and high-risk movements. With these insights, increased risk for ACL injuries, particularly for female athletes, can be predicted and would lead to injury prevention programs.

Abstract Name: The Battle of Kwajalein: A Critical Conflict for U.S. Amphibious Operations in World War II

Kwajalein, a tiny atoll in the Central Pacific, became a critical battleground in World War II. This paper examines Operation Flintlock, the U.S. attack on Kwajalein in February 1944, and its impact on future U.S. amphibious operations in the Central Pacific. It incorporates research from a variety of primary sources, such as official military reports, newspaper articles, and personal accounts, as well as secondary articles and books that examine parts of the invasion of the Kwajalein Atoll, to create a fuller account of the operation. This research was conducted by searching databases, analyzing peer-reviewed articles, as well as studying a variety of primary sources from individuals present at the invasion to materials from 1944 with information about the operation and its outcome. This paper considers the individuals responsible for the attack plan, the equipment utilized to carry it out, and the factors influencing the plan's development, leading to the final result. It then evaluates the invasion of Kwajalein Atoll, at both Kwajalein Island proper and at Roi-Namur. I used personal accounts, newspaper stories, and official reports to describe the experience of the American soldiers during this invasion. I further evaluate the impact on future U.S. operations by examining the results of this operation for both the Americans and the Japanese. It demonstrates the devastating impact this operation had on the Japanese, as well as concludes that it was critical to the future success of the Americans in the Central Pacific as it served as an example for future amphibious assault, advanced the United States position in the Pacific, and significantly weakened the Japanese in World War II.

Abstract Name: Enhanced Linear Algebra Learning Through Interactive Virtual Reality.

Virtual reality (VR) can improve learners' spatial abilities with its interactive and immersive features. This may facilitate affective learning as students experience positive emotions like curiosity and fun. VR has the potential to accentuate abstract mathematical concepts and cultivate higher-order thinking and problem-solving skills. Hence, learners can be motivated to investigate abstract mathematical concepts with enhanced engagement in VR. Linear algebra is essential for many fields, such as computer science, engineering, and physics, yet many students struggle to grasp and visualize the concept fully. The materials educators can use for visual demonstrations often limit linear algebra instruction. Learners have limited opportunities for interactive explorations. This project uses VR to better relay linear algebra concepts in a more understandable and interactive environment, allowing students to explore concepts, such as vector operations, projections, norms, dot products, and cross products, while enjoying the experience of VR. The application provides tools to spawn and select vectors, giving freedom to perform operations like addition, subtraction, dot product, cross product, norms, and projections, with interactive updates. VR creates a dynamic and scalable learning platform to provide unlimited educational cases and problem-solving experiences. By providing a VR platform for "hands-on" practice of linear algebra concepts, students can apply mathematical concepts more effectively and build stronger connections between concepts to support their learning. Playful explorations of mathematical concepts can make students better prepared to embrace underlying challenges. Investigating different operations in real-time helps visualization of abstract concepts while keeping the learning journey engaging. This project aims to incorporate immersive VR technology to help understand linear algebra concepts and show the potential to expand learning within VR. VR can facilitate effective pedagogical strategies, significantly improving instructors' teaching capabilities and maximizing student learning outcomes in linear algebra concepts.

Abstract Name: Oxidation of Chlorophenols Using Hypervalent Iodine Compounds as a Potential Route Towards Their Indirect Detection

Chlorophenols (CPs) are organic compounds that are often used as insecticides, pesticides and/or herbicides due to their antimicrobial properties. However, these compounds are toxic to the environment and can potentially bioaccumulate; causing them to be problematic for human health. This results in a number of them being placed on the EPA's list of Priority Pollutants. Contamination of CPs into the environment is widespread as many of the proposed hazardous sites to be included in the EPA National Priority List (NPL) contain CPs. This leads to a need for simple on-site monitoring of these compounds. Electrochemistry is an attractive means to accomplish this due to its simplicity, high sensitivity, and portability. Unfortunately, the

electrochemical oxidation of CPs tends to foul the electrode, causing material accumulation on the surface. This results in a significant decrease in the performance and hinders the long-term monitoring ability of the compounds. This project focused on a new way of detecting CPs by using hypervalent iodine (HVI) compounds to initially chemically oxidize the CPs, then electrochemically reduce the product formed. HVIs are known to chemically oxidize phenols, but little to no electrochemical studies have been conducted on the forming products. This presentation will show a preliminary study applying a specific HVI compound, Hydroxy(tosyloxy)iodobenzene (HTIB), to oxidize the CPs to quinone compounds, which can be electrochemically reduced. This allows for the indirect detection of CPs and would overcome the issue of electrode fouling. Specifically, we will present spectroscopic and electrochemical studies using HTIB to chemically oxidize 2-chlorophenol (2-CP) and 4-chlorophenol (4-CP) into products as an explorative experiment to determine the viability of this procedure for chlorophenol detection.

Abstract Name: Optimizing Students' Problem-Solving in Biochemistry Through Theory-Driven Instructional Strategies

Undergraduate science education aims to equip students with coherent knowledge of concepts and the ability to transfer that knowledge to novel problems. However, evidence shows that many science undergraduates complete their degrees without a strong grasp of foundational concepts and have difficulty applying their learning in new contexts. Metabolic pathway dynamics and regulation (MPDR), a core concept in biochemistry, is consistently challenging for undergraduates. Instructional shortcomings likely contribute to these outcomes. Research from educational psychology suggests two promising instructional approaches for addressing these instructional limitations: explicit instruction followed by problem-solving (I-PS) and problem-solving followed by explicit instruction (PS-I). These approaches are grounded in cognitive load theory and the productive failure hypothesis, respectively. Despite substantial support for both approaches, it remains unclear if one is inherently more effective or if their effectiveness depends on learners' prior knowledge. Few studies have compared these approaches across different knowledge levels in the life sciences. To address this gap, we developed MPDR instructional materials and conducted a randomized controlled study with 284 upper-level biochemistry students (advanced learners) and 295 introductory biology students (novice learners). This abstract focuses on data from the advanced learners. We hypothesized, based on our guiding theories, that advanced learners instructed with the PS-I approach would demonstrate better near transfer and far transfer performance in MPDR compared to I-PS students. Upper-level biochemistry students' problem-solving data are being scored qualitatively using an analytic scoring rubric. Scored data will be quantitatively analyzed using ANCOVA with prior knowledge as a covariate. We will compare the efficacy of I-PS versus PS-I for these learners. Our findings should provide insights into optimal instructional sequencing for problem-solving skill development and guide the design of improved support for learners at different stages of knowledge acquisition.

Abstract Name: Exploring the Intersection of Sense of Place and Belonging Among Minoritized STEM Students

Underrepresented groups in Science, Technology, Engineering, and Mathematics (STEM) often experience a lower sense of belonging, which is linked to reduced career retention rates (Dancy et al., 2018). Sense of belonging is not only derived from interpersonal interactions but is also linked to individuals' experiences and perceptions of specific geographical spaces, aligning with the focus of the theory of sense of place (Pearsall et al., 2015). Sense of place has been defined as the emotional connection that individuals or groups develop toward a specific place (Relph, 1976). Subsequent research has further elaborated on how this emotional connection can be eroded by places devoid of meaningful interactions or, conversely, fostered through positive spatial engagement (Pearsall et al., 2015; Ramkissoon, 2016; Relph, 1976). Based on this theory, exploring the interaction between campus environments and STEM students, and how it influences their sense of belonging, offers new perspectives to enhance STEM students' campus experience. A PhD investigator and a masters level student interviewed nine STEM students using a semi-structured set of questions regarding their sense of belonging on campus. Two research team members independently coded the interview transcripts in Dedoose, using pre-set codes related to sense of belonging and several descriptions of space. Results showed students felt a greater sense of belonging when they were in spaces where there's a positive communal environment involving the people inside the space, the positive interactions occurring there, and its academic or social functionality. This suggests that minoritized students feel a greater sense of belonging when they are in a space where they feel supported. In addition, some visual elements of the space (e.g., size/vastness, peacefulness) contributed to how students felt in the space. The findings will be discussed in terms of their implications for the design of spaces that encourage functionality plus positive interactions.

Abstract Name: Blooming Possibilities: Using Research to Enhance Career Perspectives

Extracurricular research in undergraduate education is a high impact practice supported by many institutions and a valuable way for students to learn and set themselves apart. Starting out in a new institution without senior faculty or on-going projects limited the view students had of career options available and left a void for students with aspirations of graduate programs. With the need for opportunities the next several years were spent building an undergraduate research laboratory where both existing and new projects could be shaped along with a culture of mentor and peer support. Research programs were built around applied topics students were motivated to learn with and develop their own lines of interest and build sub-projects into the larger work which are tied to future interests. Expected and unexpected factors have led to this endeavor growing to a group of about a dozen current students. Over the course of the presentation, we will discuss the growth of students from early introduction in projects to the self-led capstone projects they have been able to

accomplish. A look at how to recruit and retain students within the lab and even the importance of letting them leave to explore other areas. Ultimately, more students are finding they have opportunities in the mental health field with and without graduate school as they find success in research.

Abstract Name: The Role of Venom in Releasing the Constraint on Vertebrae Counts in Snakes (Serpentes)

The constraint-release hypothesis is a critical hypothesis in the field of evolution, which states that there are constraints on certain adaptations that can be released by other adaptations or by environmental change. In this study, we test the constraint-release hypothesis by looking at snake vertebrae. Snakes that rely on constriction to catch prey are limited to having a certain number range of vertebrae that is ideal for constriction. When a snake uses venom, there is a lower evolutionary pressure to maintain a certain number of vertebrae. Thus, the restriction on vertebrae counts would be released in venomous snakes, giving them higher variability in vertebrae counts. By investigating the number of vertebrae in constricting and non-constricting snakes, we hoped to find evidence supporting or not supporting this hypothesis. Our hypothesis based on the constraint-release hypothesis states that there will be more variation in the number of vertebrae of venomous snakes than constricting snakes. To investigate this, we conducted a literature review to find the vertebrae counts of a representative species for all snake families. We calculated the standard deviation among vertebrae counts in individuals of each species. Then we separated the data into two groups: constricting and non-constricting snakes. We then ran an ANOVA analysis comparing the standard deviations of each species in each of the two groups. It was found that non-constricting snake species did not have lower standard deviations in vertebrae count than constricting snake species.

Abstract Name: Short Interval Bright Light Therapy and Well-Being of College Students

Prior research has found that 30-minute Bright Light Therapy sessions can have anxiolytic effects, decrease feelings of depression, lower sleepiness ratings, increase alertness, and be an effective treatment for Seasonal Affective Disorder. As the majority of studies focus on repetitive exposure of working adults, it is unclear if singular short-interval exposure carries the same results, especially in college-aged students. This study aims to explore the effect of one 15-minute session of 10,000 lux lamp exposure on college students' mood, fatigue, anxiety, and concentration. Participants are randomly assigned to an experimental or control group. First, all participants complete a visual analog scale, Stanford Sleepiness Scale, and State-Trait Anxiety Inventory. Next, participants are given 15 minutes to complete a word-search task while being exposed to either: 1.) a 10,000 lux lamp 24 inches away at eye level (experimental group) or 2.) dim (2,000 lux) ceiling light 9 feet overhead (control group). After exposure, participants completed the visual analog mood scale,

Stanford Sleepiness Scale, and State-Trait Anxiety Inventory again. A between-groups comparison of pre- and post-score means will be analyzed. Additionally, the average number of words found within each condition will be analyzed. Based on prior research, it is hypothesized that students exposed to a bright 10,000 lux light will have improved mood, fatigue, and anxiety scores, and a higher number of words found compared to those exposed to the dim ceiling light.

Abstract Name: Low CO₂eq Ultra-High Performance Concrete for Use in Highway Infrastructure

Ultra-High Performance Concrete (UHPC) is a type of concrete with many beneficial traits, such as a discontinuous pore structure, chloride penetration resistance, and high compressive strength. Due to these benefits, UHPC garners increasing interest and usage for highway infrastructure. However, traditional UHPC mixtures require an elevated cement content, increasing the material's carbon footprint due to greenhouse gas (GHG) emissions from cement production. In efforts to reduce the carbon footprint of UHPC, this study developed an economical, non-proprietary, low CO₂eq UHPC mixture; it is anticipated that this mixture will be used by the Oregon Department of Transportation. A total of twelve UHPC mixtures were fabricated incorporating variables of differing cement content, cement type, fine aggregate size, various supplementary cementitious materials (SCMs) usage, and the quality of supplementary cementitious materials and the curing time before mechanical compression testing. Evaluations of the UHPC mixtures stemmed from compressive strength, a static flow test, free water evaporation, the mixture density, and the mixture's carbon footprint. Furthermore, the carbon footprint of each mixture was assessed by using a life cycle inventory program that calculated the greenhouse gas emissions when upscaling mixture sizes for Oregon Department of Transportation usage. SCM usage in the UHPC mixtures was effective at reducing carbon footprint without being detrimental to the compressive strength. Subsequently, the UHPC mixture using the SCMs of fly ash class C and metakaolin has the most promise after current evaluations, but further experimentation and evaluations are needed before the Oregon Department of Transportation selects an economical, non-proprietary, low CO₂eq UHPC mixture.

Abstract Name: Escape Room for Health Assessment

This project was aimed at developing an educational escape room for junior nursing students enrolled in a health assessment course as a means to enhance their critical thinking, clinical decision-making and active learning in an interactive, high-fidelity experience. The escape room had two clinical scenarios, one for

hypoglycemia and one for pneumonia; two patient conditions the students have already studied. Students collaborated as they solved clues and challenges related to their course objective; mirroring actual clinical situations designed to develop students' health assessment skills. The project was inspired by the increasing use of escape rooms for education as a pedagogical approach. The use of escape rooms is a developing method in many areas such as health care education. The aim of this work was to meet the current demand for more innovative teaching methods which promote engagement through active problem-solving and collaborative learning in difficult contexts, namely high-stakes clinical settings. Methods included challenges based on principles of health assessment and utilized a simulated patient experience through real-world clinical cases. Students solved clues to history, symptoms, diagnostics and treatment plans. This included patient scenarios and implementation of innovation. For example, students assessed the simulated patients using glucometers and vital sign monitors. The learning outcome of the escape room was to demonstrate competencies such as identification of symptoms and management of medication. The goal was to demonstrate that the escape room is an effective tool in facilitating engagement and increase retention of clinical knowledge for students. The immersive, hands-on experience received excellent feedback from students who reported it as engaging and an effective delivery method for key concepts. Future versions will optimize the escape room scenarios, incorporate more varied clinical cases, and investigate further how this mode of learning influences student performance in practice.

Abstract Name: In Vitro Stage II Pressure Ulcers: An Evaluation of Wound Healing Behavior in Cutaneous Models

Pressure ulcers, or injuries caused by prolonged pressure on localized areas, specifically bony prominences, remain a significant challenge in healthcare institutions. These wounds can extend deep within the cutaneous tissue, categorized from stages I-IV based on wound depth and exposed tissue. This experiment simulates in vitro cutaneous tissue by culturing seeded keratinocyte and fibroblast layers, supported by a gelatin scaffold to represent the four epidermal layers and the underlying dermal layer. A stage II pressure ulcer will be created within the cutaneous tissue model, characterized by an injury that penetrates both the epidermal and dermal layers. These wounds appear as shallow craters within the cutaneous tissue, varying in depth depending on anatomical location. This experiment aims to replicate the depth characteristics of a sacral wound. To create the pressure injuries, several custom 3D-printed apparatuses with extruded structures will be constructed. These will press into the keratinocyte-gelatin matrix at a consistent pressure to produce crater-like wounds that extend to the dermal layer. Variations in the wound apparatus dimensions will allow for representation of partial-thickness injuries of different sizes, diameters, and morphologies, including both spherical and amorphous forms. The primary focus will be the observation of wound healing and regeneration in terms of cellular behavior. Microscopy will measure keratinocyte confluence and migration along the wound borders, while clinical techniques will assess the length, width, and depth of each wound, as well as macroscopic features. Fibroblast behavior will be monitored to assess the efficacy of the model in the reconstruction of the scaffold. It is anticipated that keratinocyte and fibroblast activity will vary depending on the characteristics of the pressure ulcer applied, providing insight into cutaneous tissue regeneration in wound healing.

Abstract Name: Characterization of the Incomplete N-Terminus of the Glycine Receptor with Crosslinking Mass Spectrometry

The human $\alpha 1$ glycine receptor (GlyR) is an inhibitory ion-gated channel mostly residing in the spinal cord and brainstem. GlyR is involved in various functions like pain perception/regulation and motor control. However, the N-terminus of GlyR is unresolved in all known high-resolution structures. By introducing a single cysteine-point mutation at the K6C location in the terminus, the mutated GlyR was overexpressed in Sf9 insect cells. Overexpressed GlyR was purified and reconstituted into lipid vesicle for subsequent analysis using crosslinking mass spectrometry (CXMS) to identify sites of covalent crosslinking from the site of attachment at Cys6. Sites with covalent crosslinking were further fragmented (MS/MS) to refine these sites to obtain a more accurate structure of the region, which can be used as a blueprint for designing drugs targeting GlyR.

Abstract Name: Flood Prediction with Sentinel-1 Synthetic Aperture Radar from Hurricane Helene

Floods are the most common type of natural disaster worldwide, causing thousands of deaths every year. Timely and accurate flood forecasts are crucial for evacuation plans and mitigation strategies. Hydrological models used in forecasting depend on high-resolution, spatially continuous soil moisture data. However, existing remote sensing-based techniques for soil moisture estimation lack the spatial resolution needed for accurate flood modeling. In this study, we present an approach for soil moisture estimation using Sentinel-1 C-band synthetic aperture radar (SAR) data. SAR offers high spatial resolution, day/night operation, and operation in adverse weather conditions, making it advantageous for flood mapping. Furthermore, Sentinel-1's frequent revisit cycle allows for relatively continuous monitoring of soil moisture, which is essential for flash flood modeling. Analyses are performed for flooding following Hurricane Helene in North Carolina and Tennessee from September 25 to 30th of 2024. We gathered Sentinel-1 data using the Alaska Satellite Facility's Vertex Data Search and streamflow data using the USGS National Water Information System (NWIS) Mapper. Three backscatter parameters --- VV reflectance, VH reflectance, and the VV/VH ratio --- are selected for analysis. An initial soil moisture model is obtained by analyzing the relationship between the selected backscatter parameters and streamflow. Then, flood extent is mapped using thresholding of Sentinel-1 data and verified using NDWI calculated from Sentinel-2 multispectral data. Using the generated flood maps and ancillary data such as precipitation, soil type, and vegetation cover, we create a predictive soil moisture-based flood model. We verify the model using streamflow data gathered using the NWIS Mapper. This approach is promising for improving the accuracy and temporal range of flood prediction, especially in areas with limited ground-based soil moisture monitoring networks.

Abstract Name: Children's Awareness in their Forgetting in Massed vs. Spaced Learning

Generalization is the ability to transfer knowledge from one context to another and plays an important role in children's learning and cognitive development. Research has found that spacing out learning across time leads to more effective learning in long-term generalization than other methods, such as massed learning schedules. Researchers have suggested that the forgetting between learning events and retrieval practice across learning events are the mechanisms that lead to the efficacy of spaced learning schedules. The present study will determine whether children are aware that they forget and engage in more difficult retrieval during spaced schedules relative to massed schedules. This study will also examine whether this awareness contributes to their perception of the efficacy of spaced learning. We predict that when children start to be aware of their forgetting and retrieval difficulties, they will start to think that spaced learning is less efficient for learning. To test our hypothesis, we will present preschool children with an experiment where they learn new words; they will learn a total of 16 science nouns via massed or spaced presentation. Researchers will administer a post-test that will evaluate children's word learning. The children will also participate in tasks to assess their metamemory, such as by asking questions about whether participants believed they successfully learned the science words and if they felt like they had forgotten them. Caregivers will complete questionnaires about their children's vocabulary. The results of this study will have implications for early instructional methods on the effective use of learning strategies. That is, this work will identify the time period and mechanisms by which children start to believe that spaced learning is ineffective, supporting parents and teachers to successfully correct this misconception. Key Terms: generalization, science learning, spaced learning, forgetting, metacognition

Abstract Name: Bringing EEG Out of the Lab: Evaluating Portable EEG Technology With Naturalistic Stimuli

Electroencephalography (EEG) plays a critical role in cognitive neuroscience research, allowing scientists to study brain activity in response to various stimuli. However, lab-based EEG systems are expensive and lack the flexibility needed in real-world environments. Portable EEG devices offer an affordable and accessible alternative, but their effectiveness in capturing reliable data for complex, and continuous natural stimuli remains largely unvalidated. Yet we know this study is feasible due to previous studies validating the EEG devices for short-duration natural stimuli that are not ecologically valid. This study aims to assess the validity of using a portable EEG device by comparing its temporal response functions (TRFs) to natural speech stimuli with those of a lab-based EEG system during a divided attention task involving simultaneous audiobook narratives. We hypothesize that the portable EEG device provides TRFs comparable to a lab-based

EEG system. While lab-based EEG systems are widely considered for their precision in recording and measuring brain responses, portable EEG devices provide an affordable and accessible option for portable EEG recording. If our hypothesis is confirmed, it would suggest that research-grade EEG data can be captured with portable EEG devices in a real-world setting. Our findings will have significant implications for cognitive neuroscience, particularly for applications that require mobility and adaptability to obtain data in the real world. By enabling research in dynamic, real-world environments, the portable EEG device will help democratize studies, making it feasible for a wider range of researchers to explore brain responses to complex, real-life stimuli to obtain more ecologically valid and generalizable neuroscience data.

Abstract Name: Process Over Prizes: Goal Orientations and Team Evaluations in Global Virtual Teams The result may joke with you, but the process won't.- Marcel Proust

This study examines the impact of goal orientations (results-oriented vs. process-oriented) on team dynamics and performance evaluations within global virtual teams, challenging traditional assumptions about team efficiency. Drawing on Herzberg's Two Factor Theory(1959), Locke's Goal-setting Theory(1967), and intrinsic motivation frameworks, we analyzed data from the X-Culture Project, encompassing 3,660 undergraduate business students in 925 global virtual teams during Fall 2020. Our research specifically investigates how different approaches to incentive mechanisms and goal orientations influence team member perceptions and evaluations. Through multivariate regression analysis, we found that while both results-oriented (focused on monetary rewards and certificates) and process-oriented (valuing collaborative experiences and relationships) team members reported similar levels of subjective satisfaction, their peer evaluations differed significantly. Results-oriented members received lower peer evaluations, being perceived as less creative, less effortful, and less task-compliant. Conversely, process-oriented members were evaluated more positively, demonstrating stronger leadership qualities, active thinking, and perceived work ethic. This favorable evaluation of process-oriented members may be attributed to their stronger focus on team relationships, communication, and collaborative learning, which are particularly crucial in virtual environments where building trust and maintaining engagement require extra effort. Their emphasis on the journey rather than just the destination likely leads to more consistent participation, better communication patterns, and stronger relationship building - all qualities highly valued by peers in virtual collaborative settings. These findings challenge conventional wisdom about incentive structures in global virtual teams and suggest that process orientation may offer a competitive advantage in virtual collaborative environments. The study contributes to our understanding of team dynamics and has important implications for designing effective incentive mechanisms and managing diverse goal orientations in virtual team settings.

Abstract Name: Novel Finding of Type I Muscle Fiber Contribution to Running Economy in Recreational Runners

The contribution of different muscles toward stretch-shortening cycle potentiation (SSCP) and performance measures dictated by SSCP is an area of active research. The long head of the biceps femoris (BF_{lh}) may be important for hip extension. We present a secondary analysis from our cross-sectional study conducted on 19 male recreational runners that examined the relationship between SSCP (via jump and leg press throw) and running economy (@188 meters/min) with muscle and fiber type cross-sectional area (CSA) assessed via magnetic resonance imaging. We obtained a significant correlation between the muscle CSA of the BF_{lh} and running net VO₂ ($r = -0.55$; $p < 0.05$). However, there was no significant correlation between BF_{lh} cross-sectional area and SSCP is also not significantly related to running economy. We infer that BF_{lh}'s relationship with running economy may be driven by biochemical rather than biomechanical processes. We posit that a larger/stronger BF_{lh} muscle could utilize more efficient type I fibers to a greater extent because of preferential activation of type I vs type II muscle fibers. Our results yield preliminary evidence of the role of hip extensors for efficient running. Our results also indirectly indicate that biochemical and biomechanical mechanisms of SSCP could be muscle-specific.

Abstract Name: Analysis of the Impact of Notable Texts Referencing Gender Roles on American Contemporary Gender Norms

Christianity and its subjects have been a significant sociocultural influence on American culture – specifically in the way it has viewed men's and women's gender roles. According to Amy M. Blackstone, "gender roles are based on the different expectations that individuals, groups, and societies have of individuals based on their sex and based on each society's values and beliefs about gender." There have been plenty of written and spoken works discussing the idea of Christianity and gender roles. However, there is no overall consensus across those that I have read on what the role of gender is in both the historic and contemporary church. To better map this range of gender roles advocated in Christian cultural commentaries over time, I am building an overview of what commonplace Christian scriptures and commentaries say about gender roles. My ultimate aim is better tracing how Christian thought has contributed to gender roles in historical and contemporary America. To this end, I have analyzed texts in three categories—texts from early Christianity, texts from contemporary Christianity, and texts from popular culture that advocate certain gender roles—using a code created from said texts. This analysis allows me to study gender roles present in Christianity in order to explain common-day American gendered norms and place a more specific definition of the role of sex in the history of the Christian church.

Abstract Name: Accessing Neuromuscular Fatigue in Childhood Cancer Survivors

Vincristine is a chemotherapeutic drug commonly used to treat blood cancers such as leukemia and lymphoma, which is especially prevalent in young children. With significant advances in new cancer treatments, it is expected that over 80% of diagnosed children will become long-term survivors. However, its side effects include peripheral neuropathy causing acute damage to the motor, sensory, and autonomic functions of the body. The goal of this study is to understand the effects of chemotherapy on neuromuscular fatigue in childhood cancer survivors. We hypothesized that survivors would fatigue faster than an age and sex-matched control group. For the study, we gathered participants between the ages of 12 to 21 who have or have not received chemotherapy. Both groups completed fatigue-related surveys and other clinical tests to observe sensory loss. Participants also completed hand grip fatigue tests (50% max hold and 40 reps), a 6-minute walk test, and a Biodex test (40 reps of plantar/dorsiflexion). Cancer survivors showed decreased sensibility in their hands and feet, shorter walking distances, and less power and work while doing the 40 reps of dorsiflexion. Unexpectedly, the percent difference in the first and last repetitions of dorsiflexion revealed that the control group experienced greater fatigue, even when body weight was factored in. This could be because survivors generally used less power and work, leading to a smaller degree of fatigue. Regardless, adolescents who have been off vincristine for extended periods still show signs of decreased neuromuscular function. Considering this allows for possible preventive measures that stop further decline in neuromuscular functions.

Abstract Name: Role of Perineuronal Nets in Androgen-Induced Masculinization of Female Vocal Pathways of African Clawed Frogs

African clawed frogs (*Xenopus laevis*) use sex-specific vocalizations—fast clicks by males and slow clicks by females—to facilitate reproduction. A previous study showed that administering testosterone to adult female frogs masculinizes their calls, suggesting androgen-induced reconfiguration in the vocal pathways. This inspired exploration into how hormones can reorganize the mature nervous system, with potentially high relevance for neurodegenerative disease reversal. Neural plasticity is partly regulated by perineuronal nets (PNNs), a specialized extracellular matrix that stabilizes neural networks by limiting synaptic plasticity after development. Disrupting PNNs can modify otherwise stable synaptic connections. Interestingly, PNNs surround neurons that express parvalbumin (PV), a calcium-binding protein enabling fast spiking. This suggests androgen may modulate synaptic formation on PV neurons surrounded by PNNs in female *X. laevis*. We hypothesized that androgen-induced vocal masculinization is mediated by the loss of PNNs around PV neurons in the vocal pathways. Testing this required effective staining protocols for PV neurons and PNNs in *X. laevis* brains—a challenging endeavor. We successfully stained PV neurons, revealing numerous fast-spiking neurons in female *X. laevis* vocal nuclei. However, PNN staining posed difficulties. The standard approach using *Wisteria floribunda* agglutinin (WFA) yielded variable results, likely due to species-specific

efficacy. I tested four additional methods targeting different PNN components: antibodies for chondroitin sulfate proteoglycan (CSPG), glycosaminoglycan (GAG), and Cat-301, in addition to a biotinylated hyaluronic acid binding protein (HABP). None of the antibodies produced consistent results, and HABP showed no specific binding. As an alternative, we are focusing on staining effector proteins bound to PNNs, such as Semaphorin 3A, which stabilizes neural circuits by repelling axon growth away from PV neurons and preventing new synaptic formation. Preliminary trials successfully labeled Semaphorin 3A overlapping PNN structures in control female and male *X. laevis* brains. Progress on Semaphorin 3A labeling in testosterone-treated female *X. laevis* will be discussed.

Abstract Name: FDI Under Pressure: How Cultural Distance and Political Risk Shape Investment Decisions

This study examines the impact of cultural distance on foreign direct investment (FDI) flows and the moderating role of political risk in this relationship through a dyadic analysis of 96 countries spanning North America, South America, Europe, Asia, Africa, and Oceania. While existing research has explored cultural influences on international investment, the complex interaction between cultural distance, political risk, and FDI across different economic contexts remains understudied. Our methodology employs a dyadic approach, analyzing country-pair relationships where cultural distance serves as the independent variable and FDI flows as the dependent variable. Using panel data from our sample countries, we measure cultural distance through Hofstede's cultural dimensions framework and incorporate political risk measures from the International Country Risk Guide (ICRG). The analysis combines World Bank FDI data with these cultural distance metrics in a regression model to examine bilateral investment patterns. The findings confirm that greater cultural distance between country pairs negatively affects FDI flows, with this effect amplified under conditions of high political risk. These results suggest that multinational enterprises face compounded challenges when investing in culturally distant countries with political instability, though the magnitude of these effects may vary across different economies. Our research contributes to the understanding of cross-border investment barriers and provides valuable insights for policymakers and international business strategists working to enhance global economic cooperation.

Abstract Name: Recruitment and Retention of Asian American Women in Health Research: A Feasibility Study Collecting Multiple Forms of Data

The underrepresentation of minority populations in biospecimen research exacerbates health disparities. This

study aimed to describe and identify strategies for recruiting and retaining Asian American (AsA) women in a study collecting multiple forms of data. The recruitment and retention strategies are guided by Kimberlé Crenshaw's Intersectionality framework, which acknowledges sociodemographic identities can interplay and influence individual experiences. In this study, we used racially concordant team members to arrange personalized study visits. Descriptive statistics were calculated for recruitment and retention rates, and participant feedback was collected. We recruited English-speaking AsA women residing within 30 miles of the study site. Participants self-collected saliva samples four times/day for two days, wore an accelerometer for ten days, and completed a survey. Recruitment strategies included mass emails through a Midwest university, community organizations, social media, word of mouth, and information sessions. This ongoing study aims to recruit 20 participants. Of 424 individuals screened, 65.33% were eligible. Among these strategies, mass emails generated the highest response rate at 71.23%, followed by community outreach (3.30%), and social media (2.59%). The recruitment rate was 4.67 participants/month (14 participants), with a 100% retention rate and 92.96% completion rate. The average time from initial contact to study completion was 33.23 ± 12.80 days. Additionally, most participants expressed appreciation for conducting the study and willingness to support future studies. These results suggest that mass emails were the most effective method for reaching AsA women. The study's success was enhanced by the inclusion of racially concordant team members, flexible scheduling, and personalized study visits, offering a model for engaging underrepresented populations in health research.

Abstract Name: Healthy longevity in individuals with serious mental illness: A quality improvement approach

Individuals with serious mental illnesses (SMI), such as schizophrenia, bipolar disorder, or major depressive disorder, face significant challenges in accessing and managing physical and mental health care, contributing to a reduced life expectancy of 15–20 years compared to the general population. While advancements in treatment have helped patients manage their health more effectively, healthcare professionals often overlook a crucial aspect of healthy longevity: patients' limited awareness of how to manage their health for long-term well-being. The purpose of this quality improvement project aims to assess the current understanding of health longevity among individuals with SMI. This project will employ a cross-sectional design and collect data through a survey distributed to adults with SMI in outpatient settings, ensuring anonymity and confidentiality. The survey will include semi-structured open-ended questions to capture the diverse experiences and perspectives of participants. Thematic analysis will be conducted to analyze the data, providing detailed insights into patients' understanding of their health and longevity. We expect individuals with serious mental illness to have limited awareness of their longevity and may not be adequately prepared to live a healthy, long life. The findings from this study will highlight the need for clinicians to provide targeted patient education aimed at promoting healthy longevity. Additionally, the results will guide clinicians on how to better prepare patients for managing chronic physical and mental health conditions, prevent disability, and promote long-term well-being, while emphasizing the importance of integrated care models. This study will contribute valuable insight to inform clinical, healthcare policy, and patient empowerment strategies, ultimately improving the healthy longevity of individuals with SMI.

Abstract Name: Comprehensive Evaluation of Large Language Models for Multi-Dimensional User Productivity and Satisfaction

The exponential growth in developing and deploying Large Language Models (LLMs) has transformed productivity and user satisfaction across various applications. This study presents a comprehensive evaluation framework for assessing the performance of 14 state-of-the-art LLMs across four critical domains: Content Creation, Programming Assistance, Data Analysis, and Customer Service & Q&A. Each task encompasses multiple subtasks designed to evaluate specific aspects of user experience, including accuracy, efficiency, creativity, and structural logic. The framework utilizes a combination of manual assessments and automated tools to ensure precision and reliability in scoring. The methodology includes designing domain-specific subtasks with predefined scoring rubrics and benchmarks to test the LLMs. For instance, Content Creation tasks are assessed for theme relevance, linguistic fluency, and originality using tools such as Grammarly, Hemingway, and Turnitin. Programming Assistance tasks evaluate functionality, error handling, and code readability, employing cognitive complexity metrics and cyclomatic complexity analysis. Data Analysis tasks require LLMs to tackle statistical problems and regression analyses, with scoring based on accuracy and solution completeness. Customer Service tasks involve real-world scenarios, scored for key point coverage, politeness, and readability using manual extraction and automated tools. This structured approach ensures a detailed and multi-dimensional assessment of model capabilities. The results reveal that GPT-4o mini leads overall performance with a score of 85.37, excelling in Programming Assistance and Customer Service while displaying limitations in Data Analysis. GPT-4o (85.07) and Llama 3.1 70B (84.68) demonstrate balanced capabilities across all domains, notably in customer interactions and statistical inference tasks. The study emphasizes the strengths and weaknesses of each model, and its findings underscore the need for advancements in areas such as data-heavy computation, contextual creativity, and adaptability across varied domains. This research establishes a robust methodological foundation for evaluating and improving LLMs, offering a benchmark for future innovations in AI-driven productivity and satisfaction metrics.

Abstract Name: Investigating Parvalbumin Interneurons in the Prefrontal Cortex and Visual Cortex

Schizophrenia, a chronic psychiatric disorder, affects 24 million people and causes working memory deficits. Working memory is proposed to emerge from synchronized neural activity at γ -frequencies, creating transient γ -oscillations in the primary visual cortex (V1) and sustained γ -oscillations in the prefrontal cortex (PFC).

These oscillations emerge from a microcircuit created by excitatory pyramidal neurons and inhibitory parvalbumin-expressing interneurons (PVI). Schizophrenic patients show a deficit of PV firing at gamma frequencies in these regions, which correlates to working memory deficits. Our preliminary computational data found different levels of excitatory drive to PVIs create distinct types of γ -oscillations. This study proposes that different levels of excitatory drive to PVIs are required to generate different types of γ -oscillations in different regions. This involves both expansion and confocal microscopy of control postmortem human brain tissues to measure the synaptic and subsynaptic level of excitatory drive to PVIs in PFC and V1. The results are expected to show a greater amount of excitatory input in the V1 region compared to the PFC, thus resulting in transient γ -oscillations in V1 and sustained γ -oscillations in PFC. This aims to understand the neural mechanisms of working memory in control patients to ultimately provide insights for future therapeutic approaches of schizophrenia.

Abstract Name: Diagnosing Rhesus Alloimmunization in Low-Resource Settings Using A Lateral Flow Immunoassay

Hemolytic Disease of the Fetus and Newborn is a condition that occurs when a pregnant individual's immune system attacks the red blood cells of their fetus, potentially leading to severe complications including anemia, hydrops, and fetal death if not identified early in pregnancy. The most common cause of this disease is the development of maternal anti-D antibodies (Rhesus alloimmunization) which is preventable with the prophylactic administration of Rhesus immunoglobulin. Unfortunately, the absence of affordable point-of-care diagnostic tools for detecting Rhesus alloimmunization in low-resource settings leaves many individuals at risk for preventable outcomes. To address this critical need, we are developing a lateral flow-based diagnostic test to detect anti-D antibodies in maternal blood. Our system employs a lateral flow assay utilizing a biotinylated RhD antigen and a universal human IgG dipstick to identify the presence of anti-D antibodies. If anti-D antibodies are present, the biotinylated RhD antigen binds to the antibody, forming a complex with a streptavidin gold tag at the sample well. This complex migrates up the dipstick and is captured by the IgG test line, producing a red line. Preliminary tests of this system have demonstrated rudimentary detection of pure proteins. These early results suggest further optimization is warranted. This will include increasing the sensitivity, testing the specificity, and ensuring the system works with whole blood as an input. By providing a timely diagnosis of Rhesus alloimmunization, this tool may help resource-limited clinics refer patients for more advanced care of their pregnancies. In cases where no antibody is detected, patients who will benefit from the timely administration of prophylactic Rhesus immune globulin to prevent the formation of anti-D antibodies can be identified. The long-term impact of this tool will be a more efficient use of limited healthcare resources, saving time and costs for providers and patients alike.

Abstract Name: Using Bacteria to Trigger the Innate Immune Response in *Drosophila* to Examine the Potential Role of Dynactin in Toll Signaling

The innate immune response is the body's initial non-specific defense against invading pathogens. It is initiated through the cellular Toll signaling pathway by bacteria and injury which leads to the production of certain antimicrobial peptides. These responses have been found in vertebrates, invertebrates, and plants, where the basic mechanisms that regulate them are conserved. In *Drosophila*, the Toll Signaling pathway is involved in both dorsal/ventral axis specification as well as innate immunity. Dorsal, an NF- κ B related protein, a component of the Toll signaling pathway, is found to be expressed in both larval and adult fat body, an organ that functions like a vertebrate's liver. After larval injury, the Toll signaling pathway is activated, which results in a rapid translocation of Dorsal from the cytoplasm to the nucleus. Once in the nucleus, Dorsal activates the transcription of various defense genes. The transport of essential biological materials throughout the cell requires the molecular motors, Dynein and Kinesin. Dynein associates with the protein complex Dynactin, and it is known to promote Dynein function by serving as an adaptor for cargo and enhancing processivity. It was hypothesized that Dynactin could be involved in the transport of Dorsal from the cytoplasm to the nuclear envelope. To test this, *Drosophila* dynactin mutant larvae were challenged by feeding with bacteria in order to stimulate an innate immune response and the fat body was examined under a fluorescent microscope to compare the amount of Dorsal protein found in the nucleus in the unchallenged vs. challenged larvae. Fluorescent intensity analysis indicates that Dynactin is involved in the nuclear translocation of Dorsal. This reveals the pivotal role of Dynactin in regulating the nuclear translocation of Dorsal, shedding light on a key mechanism of Toll signaling with implications for understanding conserved pathways in innate immunity.

Abstract Name: A Segmentation-Free R(2+1)T Deep Learning Model for Automated End-Diastolic and End-Systolic Frame Detection in Echocardiography

Introduction: Accurate assessment of left ventricular (LV) ejection fraction is critical for detecting cardiac abnormalities in echocardiography. This is achieved by measuring LV volumes at the end-diastolic (ED) and

end-systolic (ES) phases. Current methods for ED and ES detection rely predominantly on deep learning models that segment LV volumes across all frames in echocardiographic sequences. However, these multi-frame segmentation approaches are computationally intensive, memory-demanding, and prone to errors inherent to the segmentation process, posing significant challenges to scalability in clinical and research applications. **Methods:** To address these limitations, we propose a novel approach utilizing an R(2+1)T model to identify ED and ES phases. Each cardiac cycle is classified into one of three categories: ED frame, ES frame, or non-ED/ES frame. This approach effectively captures both spatial features and temporal dynamics by employing 2D convolutions for spatial processing and 1D convolutions for temporal processing. The study dataset comprised echocardiographic studies from 407 patients focusing on the LV view, with an 80:20 split for training and testing. **Results and Conclusion:** The proposed model achieved an Area Under the Curve (AUC) of 97.79%, surpassing the performance of existing methods. In conclusion, the proposed approach enables accurate detection of ED and ES phases without relying on additional deep learning models, allowing direct utilization of detected ED and ES frames for ejection fraction calculation. Future work will focus on integration into automated echocardiography systems in clinical settings.

Abstract Name: EduVerse: Revolutionizing Career Guidance Through AI-Powered Mentorship

How can AI mentorship systems, like EduVerse's "Edura," be effectively integrated into academic and professional workflows to simplify learning, enhance skill development, and improve collaborative efficiency for students and professionals? This research explores the potential of AI-driven mentorship systems in transforming the way students and professionals approach education, skill acquisition, and teamwork. By leveraging personalized insights and actionable recommendations, AI mentorship can bridge existing gaps between traditional learning systems and modern professional demands. EduVerse aims to demonstrate how integrating such systems can create an accessible, inclusive, and efficient ecosystem for academic and career growth. Despite advancements in educational technologies, most platforms focus solely on either skill development or networking, failing to provide a comprehensive solution. EduVerse addresses this gap by integrating adaptive learning, project collaboration, and real-time skill assessments. By exploring these capabilities, the project contributes a novel perspective on leveraging AI to create a more accessible and inclusive academic and professional environment. The study employs a mixed-methods approach, combining user interviews, prototype testing, and algorithm analysis. Data on user engagement, learning outcomes, and collaborative efficiency will be collected to evaluate the effectiveness of Edura's personalized recommendations and project-matching features. The research anticipates that AI mentorship can simplify learning, enhance collaboration, and improve employability. Users are expected to benefit from tailored learning pathways, skill-matching, and dynamic platform features that encourage active engagement. These findings will provide insights into the role of AI in shaping future educational technologies and workforce development strategies, positioning EduVerse as a pioneering solution in the field.

Abstract Name: Our Model Ally China: How America Recast Chinese Stereotypes During World War II

Throughout the Second Sino-Japanese War (1937-1945), Chinese Americans engaged in various domestic and militaristic war efforts including fundraising parades, enlisting in the U.S. army, and boycotting Japanese goods. This activism developed increasingly “positive” American perceptions of Chinese people as patriotic and civilized, especially following Imperial Japan’s attack on Pearl Harbor. Consequently, Sino-American relations briefly improved throughout the 1940s and Chinese Americans earned an elevated status in American society through realistic media representations that defied Orientalist misconceptions. However, current research on this stereotype transition contains little analysis of the U.S. Government aiding said efforts. To fully understand the impact that American WWII efforts had on changing perceptions of Chinese people, this paper presents an examination of pro-Chinese WWII propaganda disseminated and influenced by the U.S. Government. An analysis of primary sources ranging from Department of Defense pamphlets, newspapers, and newsreels from various digital archives will be used. The contextualization of their motivations and content within shifting stereotypes of Chinese people reveals how American domestic WWII efforts combined with Chinese American war efforts. Together, they eradicated prior ideas of inferiority and foreshadowed the modern “Model Minority Myth.” Despite the central role that Chinese American campaigns for social acceptance and war relief played in this process, the concept of the model minority serves to instill American minority disunity. Therefore, its precedent cannot be attributed to just a side effect of Chinese American advocacy. Instead, it is required to look at the U.S. government and mainstream America’s agency in the creation of a myth beneficial to White America.

Abstract Name: Building Resilience in the Dialysis Population: Using Life Cycle Thinking to Inform Dialysis Technology Development, Deployment, and Selection for a Range of Patients and Extreme Events

Patients experiencing end-stage kidney disease need continuous dialysis treatments multiple times a week. The treatment requires large amounts of energy and water, relies on public infrastructure, and is vulnerable to extreme weather events. For example, Hurricane Helene in 2024 disabled production centers vital to dialysis supply. Hurricane Katrina in 2005 caused extended closures of 94 dialysis centers, affecting over 6,000 patients. Despite increasing extreme weather threats, there is a need to make dialysis treatment more resilient so that patients retain access to their almost daily treatments, including during extreme events. To this end, this study will use quantitative sustainable design, including life cycle assessment (LCA), to identify the most resilient dialysis modality (in-center hemodialysis, home hemodialysis, or peritoneal dialysis). We are quantifying life cycle energy and water use to reduce the reliance on these increasingly expensive and scarce resources and calculating carbon footprints (i.e., equivalent carbon dioxide emissions due to greenhouse gasses based on ecoinvent databases and TRACI impact method) to minimize the positive feedback loop between carbon emissions and the intensity and frequency of extreme events. These three metrics will be quantified by generating life cycle inventories of all the amounts and types of materials, energy, chemicals, and water required over a dialysis machine’s life cycle (e.g., production, disposal) and patient’s treatment sessions (e.g., transportation, medication). A range of representative patients will each have a digital twin to evaluate patient health as a fourth metric. With each digital twin, we will evaluate all four metrics, for each modality, over a range of extreme events (e.g., flooding, power loss, supply chain failure) to identify the most resilient modality based on patient type and extreme event. This data can be used to build resilience in the dialysis population, especially by informing dialysis technology development, deployment, and selection.

Abstract Name: Understanding the Effects of Ketone Diester Supplementation on Reducing Neuroinflammation and Neuropathology in TgF344 AD Rat Model of Alzheimer's Disease across the Lifespan

Alzheimer's disease (AD) is characterized by progressive neuropathology and neuroinflammation that causes impaired cognitive functions, but the mechanism and its relationship to aging is not fully understood. This study aims to explore the differences of pathology and neuroinflammation between normative aging and AD across the lifespan of a transgenic rat model, focusing on the basal lateral amygdala which is involved with emotion processing. We are additionally investigating the effects of ketone diester supplementation on neuropathology and fear behavior in these rats. The experiment uses staining techniques such as immunohistochemistry and simple Western blots to visualize and quantify biomarkers related to AD including amyloid-beta, microglia, astrocytes, and tau neurofibrillary tangles. Preliminary results suggest that ketone diester supplementation may modulate neuroinflammatory responses and protein buildup, with rescued fear extinction behavior in AD rats. The results will allow us to better understand the differential progression of AD pathology compared to normative aging, and the potential for dietary interventions in reducing neuroinflammation and neuropathological changes in the BLA and addressing fear extinction impairments associated with BLA dysfunction in AD.

Abstract Name: Design and Analysis of a High Gain, Low Power 60 GHz CMOS Low-Noise Amplifier for mmWave Applications

Millimeter-wave (mmWave) technology, operating in the 30–100 GHz range, is integral to next-generation systems such as 5G networks, automotive radar, satellite communications, and IoT devices. By offering abundant bandwidth, mmWave enables high-speed data transmission and precise sensing. However, the design of circuits for mmWave frequencies is challenging due to increased signal losses, parasitics, and the need for low noise and power efficiency. This research presents the design and simulation of a 60 GHz low-noise amplifier (LNA) in 65-nm CMOS technology, addressing these challenges with a current-reused cascode topology and integrated noise-canceling techniques. The LNA achieves high gain, low noise, and efficient power usage, critical for energy-constrained and high-frequency applications. Inductive degeneration ensures wideband input matching, achieving an S11 parameter of -17.6 dB for effective power transfer. Using

Cadence Virtuoso, the design was rigorously simulated and optimized, yielding a peak gain of 30.4 dB, a noise figure (NF) of 5.4 dB, and power consumption of just 12.06 mW from a 1 V supply. A figure-of-merit (FoM) combining gain, noise, and power efficiency was used to benchmark its performance, with an FoM of 31.8 dB demonstrating its competitiveness with state-of-the-art designs. These results highlight the potential of CMOS technology to meet the stringent requirements of mmWave systems through innovative design and optimization. The proposed LNA offers a scalable solution for integrating mmWave technology into advanced communication and sensing platforms, paving the way for broader adoption in future wireless and IoT applications.

Abstract Name: Post 9/11: The Legislative Impact of the USA Patriot Act

This research investigates the link between the terrorist attacks of 9/11 and subsequent legislation like the USA Patriot Act on the curtailment of civil liberties by granting agencies more power to monitor, gather information, and screen for potential terrorists. Even though this legislation was passed to safeguard the country, one can argue that by doing so, the people's civil liberties were compromised. This raises a question that the research seeks to address by providing historical context: How can the U.S. government achieve a balance between national security and civil liberties? The Patriot Act's primary goal was to enhance national security by giving law enforcement and intelligence agencies expanded powers to detect and prevent terrorism. This newly acquired power was used by agencies to access personal records, private emails, and tap phones. The Patriot Act's provisions allowed the government to have access to medical records, privacy emails, and monitoring individuals without their knowledge or consent and all of this in the name of national security. Critics claim that this access to private information violates the Constitution, such as its Fourth Amendment's protection against unreasonable searches and seizures. Understanding this balance between safety and privacy after a terror attack matters because it raises critical questions about the obligations of government and the rights of citizens. By studying the Patriot Act, my research highlights this intertwined relationship between security and civil liberties, especially in distressed times. The goal of the analysis is to show how U.S. legislation continues to evolve in an effort to uphold the intricate equilibrium between national security and civil rights.

Abstract Name: Presence and Abundance of Arbuscular Mycorrhizal Fungi in Florida Mangroves that are Encroaching into Salt Marshes

Subtropical mangroves are encroaching into temperate salt marshes in the southeastern United States because of reduced freeze events. Mycorrhizal fungi serve as important mutualists for tree species globally but are

often thought to be less abundant in wetland soil, where flooded, anoxic conditions render their chemoheterotrophic strategy difficult. We investigated the presence and abundance of arbuscular mycorrhizal fungi (AMF) on black mangroves (*Avicennia germinans*) that are increasingly present in salt marsh ecosystems in northeast Florida. Using plots from the WETFEET project in a marsh-mangrove ecotone, soils were sampled from two contrasting zones: a more frequently inundated creekside zone and a rarely flooded interior zone. We sampled 10 plots (2 hydrological environments x 5 replicates) and collected cores at a depth of 1-15 cm to analyze AMF abundance using microscopy. We hypothesized that AMF abundance is higher in less waterlogged soils. We stained root fragments (1 cm in length) and examined them under a light microscope to quantify AMF. We counted the number of arbuscules and hyphal branches at 20 randomly selected observation points per root fragment. Our results revealed that the mean percentage of fungal colonization in roots from plots in the interior zone was approximately 25% higher than that of the creekside zone, suggesting that zones with rarely flooded soils support higher AMF colonization. Although AMF have been documented in other coastal wetlands globally, this is the first study to investigate their presence in Florida's black mangrove ecosystems. Preliminary findings may suggest that AMF could play a role in supporting mangrove resilience and northward migration, though further research is needed to explore these potential links. This study contributes to understanding AMF's role in mangrove ecology and paves the way for future investigations.

Abstract Name: Remembering Stereotypes: The Influence of Implicit Biases On Sexual Minorities

This Honors Project investigates the interaction between implicit biases and false memory formation, specifically targeting stereotypes related to sexual orientation. Using a modified Deese-Roediger-McDermott (DRM) false memory paradigm, participants were presented with seven distinct word lists. Four lists, drawn from the original DRM paradigm, served as controls, while three experimental lists were created to evoke stereotypes regarding gender, scientists, and sexual minorities. Participants completed a memory recall task following the exposure to each list, during which false memories were measured by their tendency to recall non-presented but stereotype-consistent words. Although false recall is anticipated across all seven of the word lists, the experimental lists are expected to elicit higher rates of false recall in comparison to the control lists. Among the three experimental lists, the sexual orientation list is hypothesized to result in greater false recall than the gender and scientist lists, reflecting the influence of stereotypes associated with out-group identities. This research aims to deepen the understanding of how implicit biases impact memory, with broader implications for the ways that stereotype-driven information might alter perceptions and judgments in social contexts. This study is the first to use the DRM paradigm to explore biases toward sexual minorities and scientists, contributing novel insights to the field.

Abstract Name: Tattoos as a Risk Factor for B-cell Lymphomas

Tattooed individuals have been shown to have an approximately 21% higher risk of developing lymphoma than those without tattoos. Lymphoma is a malignancy characterized by uncontrolled proliferation of lymphocytes, specifically B-cells. These B-cells can have mutated or abnormal expressions of their cluster of differentiation (CD) markers that lead to this uncontrolled proliferation. While the cause behind the uncontrolled proliferation in lymphoma is unclear, tattoo exposure may participate in triggering this abnormal B-cell proliferation. The goal of this study is to identify atypical and precancerous B-cells that are associated with tattoo exposure from CD marker phenotyping. Using flow cytometry, we will phenotype B-cells from 50 people (25 with tattoos, 25 without) in search for CD marker expressions that are associated with atypical cells, activated B-cells, and possible lymphoma cells. Atypical Memory cells will be identified by the expression CD45+/CD19+/CD27-/CD21- and Activated B-cells will be identified when expressed as CD45+/CD19+/CD27+/CD21-. Possible lymphoma-associated cells will be identified with the expression CD45+/CD19+/CD10+/CD43-. These CD expressions show abnormalities in B-cells and will be used to find a possible link with tattoo exposure. If successful, the study will demonstrate an increase in atypical and precancerous cells in people with tattoos compared to those without. This would provide insight into how B-cells express markers differently when exposed to tattoo ink and could provide information for future studies on the immune response to tattoos.

Abstract Name: Policing Local Communities: A Thematic Analysis of Tonality Trends and Perceptions of Media Coverage (2017-2023)

In 2003, Ashcroft, Daniels, and Hart penned the report Factors that Influence Public Opinion of the Police and stated (as one of the four main findings) that media did not affect residents' perception of the police. Some 20 years later, Succar et al. (2024) have noted that public sentiment towards the police can be greatly influenced by both mass and social media. With these two conflicting positions posited, this study seeks to investigate how national, regional, and local media coverage in the United States interacts with public knowledge and perception. By analyzing patterns in media portrayals, the research examines how reporting at different levels informs individuals and community perspectives, shedding light on how local communities understand the police and policing. Given the significant influence of news media on perceptions of policing, the study adopts a thematic analysis as outlined by Braun and Clarke (2006), stating that thematic analysis identifies, analyzes, and reports patterns in the data. Thereby offering the greatest example of how people learn about, experience, and make decisions about policing in their local community. In order to explore the topic area from the broadest perspective, the analysis made use of two databases: (1) Newsbank and (2) U.S. Major Dailies, and examined media coverage from 2017-2023. Initial findings taken during the Fall of 2024 revealed that national media often presented law enforcement in neutral or critical tones, with supportive portrayals notably absent, especially in response to high-profile incidents. Regional and local contexts suggested a potential shift toward more nuanced perspectives. It is expected that by expanding the dataset and scope, the study would be able to provide a deeper understanding of how media coverage influences public perceptions of policing across varying levels of reporting.

Abstract Name: Students' Use of ChatGPT as a Writing Tool

Over the past decade, educational technology has drastically evolved. Generative artificial intelligence, commonly known as AI, chatbots such as ChatGPT developed by OpenAI, have recently become popular resources for students seeking help with assignments. These tools offer valuable support, making them widely used in academic settings. While articles discuss whether students should use generative AI, little research exists on how students engage with it in academic settings. Understanding how students interact with chatbots like ChatGPT can help us understand the implications of their use for academic performance. This study analyzes student interactions with ChatGPT, where participants enrolled in College English were tasked with writing a one-page essay. The selection of the College English course is aimed at providing a diverse range of students from different disciplines and skill sets, rather than a large group of English majors in a higher-level course. Without guidance on using ChatGPT, researchers instructed students to use AI to assist in essay development. Students' interactions with ChatGPT and their final essays are collected and analyzed across multiple dimensions, including the total number of prompts and types of requests, such as brainstorming, outlining, and information research. The essays will be evaluated using Natural Language Processing for grammar, organization, and vocabulary level. Finally, we will examine whether ChatGPT interactions reliably impacted essay quality. Understanding how ChatGPT can assist students in developing writing skills and comprehending generative artificial assistance will support further education regarding chatbots like ChatGPT and promote further curiosity about how generative artificial intelligence can be used morally and correctly. The findings of this research will also shed light on students' prior knowledge of artificial intelligence, showing how, without instruction, students interact with ChatGPT and use the resources to the fullest extent they know, such as outline development, language enhancement, sentence structuring, and source searching.

Abstract Name: Elizabethan Protestants, Catholic Persecution, and the Popularity of Hamlet

Queen Elizabeth I reigned in the late sixteenth century during a period when Catholicism was outlawed, and Protestantism was enforced. Today's modern perception of and academic teachings about Elizabeth I's reign promote the stereotype that the commoners in Elizabethan Protestant society shunned people who adhered to the Catholic religion. Scholars like Hervé Picton write that England had successfully stamped out religious minorities and become a Protestant nation by the end of the century; 250 Catholics were executed during Elizabeth I's reign. Despite these perceptions, teachings, and executions, my research suggests that Elizabethan society did not necessarily adhere to the religious laws of the monarchy or agree with the monarchy's actions. This paper explores historical accounts of Elizabethan London society, specifically

applying these studies to William Shakespeare's Hamlet. It argues that despite the monarchy's influence, Protestant society did not necessarily shun people who adhered to the Catholic religion. Hamlet was considered one of Shakespeare's most popular plays despite several Catholic remnants, such as Hamlet's father appearing as a ghost. This presentation draws upon scholars such as Isabelle Gatt and Peter Zhang who discuss the kind of community that theatre creates where audiences believe the actors, formulating a theatrical agreement, a point of connection grounded in a mutual understanding of societal truths. Even though Catholicism was outlawed, even though Protestants were told by their monarchy to despise Catholics, and even though Protestants denounced ghosts and other Catholic beliefs, they had no issue accepting the Catholic representation within the theatrical performances of their beloved Hamlet. For common Elizabethan Protestant society to love Hamlet as much as they did, they had to go against the monarchy's influence and be at least civil with the Catholics in their midst.

Abstract Name: Hidden in Plain Sight: The French Influence in Texas

When considering the contributions to Texan culture, beliefs, and identity, much of the focus is placed on the influences of Mexico and the United States, with communities such as Tex-Mex serving as a notable example of cultural hybridization. These influences are often celebrated for shaping Texas's bold and dynamic character. However, the French impact on Texas has been largely overlooked, despite its significant historical presence. Many view the connection between Texas and France as a relic of the past or a mere myth, overshadowed by the more visible legacies of the United States, Spain, and Mexico. This view ignores a rich and persistent French heritage that remains hidden in plain sight. While the involvement of France in Texas's path to independence is often acknowledged (Barker, 1967), French contributions to Texas identity are scarcely discussed in primary and secondary education (Davidson, 1973). Texas's pride in its cultural, historical, and moral diversity rarely extends to its ties with France, even though French-speaking communities, such as the Cajuns of East Texas, have left an indelible mark on the region (Louder & Leblanc, 1979). This research seeks to address this gap by investigating the ongoing presence of Franco-Texan cultural hybridization, particularly how varying designations—such as Tex-French and Franco-Texan—reflect regional identities and linguistic variations. Moreover, this study will explore the factors that led to the decline of the French language and its cultural influence in Texas, and whether any efforts have been made to preserve this heritage (Jordan, 1986). Through archival research and oral histories, the project will uncover the French presence in Texas and its enduring legacy, fostering a more comprehensive understanding of the state's diverse cultural roots. By recognizing these overlooked contributions, this research aims to ensure the preservation and appreciation of Franco-Texan heritage as a vital part of Texas's multifaceted identity.

Abstract Name: Caregivers' Perspectives of a Museum Based Early Learning Program for Children

Purpose: The purpose of this research is to investigate how children and caregivers are influenced by participating in museum-based early learning classes. Museums can be a place for early learning opportunities, but it is crucial to include children's caregivers in these activities because it supports children's learning and positively influences caregiver-child interactions and relationships. There may be a variety of reasons why caregivers attend this type of programming: socialization, supporting the child developmentally, and supporting themselves as caregivers. **Methodology:** Our research took place at a regional cultural and natural history museum. We invited children's caregivers who attended early learning classes to participate in a survey that included questions about demographics, the caregiver, and the child(ren) who attends classes. The survey included questions about the reasons caregivers choose to attend classes, how they feel that the classes influence their child(ren) and their interactions with their child(ren). **Results:** Caregivers reported that early learning classes are a great way to spend quality time with their child(ren). Caregivers' perception about quality time positively predicts that they felt that the classes are meaningful to their relationship and that they have learned new ways of interacting with their child(ren) by attending. However, quality time is not a predictor of caregivers talking to their child(ren) about what they learned or did in classes. We will now analyze if the age of the child(ren) affects these correlations. Caregivers' experiences and expectations may differ based on the age of the child(ren) or based on the type of caregiver who is attending class (ex: parent, grandparent, nanny). When comparing caregiver types, we found that parents and nannies view these classes as a way to socialize and connect with other adults, but grandparents did not. This information could be used to inform museum-based programming for different ages or caregiver types.

Abstract Name: Histotripsy Ablation of Pancreatic Tumors Modifies Tumor Microenvironment and Improves Systemic Anti-Tumor Immunity

Histotripsy is a novel treatment modality utilizing focused ultrasound and acoustic cavitation to ablate tumor cells and generate acellular homogenates. The non-ionizing, non-thermal, non-invasive, and real time imaging properties make it a promising treatment for historically resistant malignancies such as pancreatic cancer. Our hypothesis is that the generation of acellular homogenates will activate the immune system and improve systemic anti-tumor immunity, causing the recognition of metastasized sites and produce abscopal like effects. This study was conducted using C57BL/6 mice with contralateral Pan02 tumors developed in their flanks. One tumor on each mouse was treated with histotripsy and tumor diameter and immune cell populations were measured for both tumors at 0-, 1-, 7-, 14-, and 21-days post treatment. Our data suggests that histotripsy generates an acute abscopal like effect in the treatment of pancreatic tumors through the reduction in tumor diameter and change in tumor microenvironments in both the treated and untreated contralateral pancreatic tumors. Moving forward, we aim to evaluate the mechanisms of immune cell activation including the potential presentation of neoantigens with the hope that these could be modified to create stronger abscopal like effects and offer a greater chance at remission.

Abstract Name: Vascular Endothelial Growth Factor Receptor Phage-Mediated Cancer Control

The purpose of this project is to successfully identify a bacteriophage binding partner for VEGF (Vascular Endothelial Growth Factor) and observe inhibitory effects, supporting a new immunotherapy for various cancers. VEGF contributes to the growth of solid tumors by encouraging tumor blood vessel formation and plays a role in the onset of several other diseases associated with abnormal blood vessel development. VEGF is frequently overproduced in tumors, along with its receptors VEGFR1 and VEGFR2. These tumors have been detected throughout the body, promoting the rapid formation of blood vessels, which accelerates their growth and leads to faster tumor expansion. In this study, bacteriophages will be investigated as a possible inhibitor of VEGF RTKs (receptor tyrosine kinases). Bacteriophages, also known as phages, are viruses with remarkable specificity for bacterial receptors, enabling them to invade bacterial cells and reproduce inside them. We aim to exploit the targeting nature of phages and apply them to the overexpressed VEGF model in HEK-293 cells (Human Embryonic Kidney). Our process includes transfecting a VEGF plasmid tagged with Red Fluorescent Protein (RFP) and G418 resistance into HEK-293 cells to establish a stable cell line. This cell line, maintained in G418-treated media, will be tested with agonists, antagonists, and fluorescently tagged antibodies to confirm overexpression of VEGF RTKs before panning multiple bacteriophage libraries. Successful identification of bacteriophage binding partners to VEGF RTKs will lead to repeated panning to confirm binding, and further application of the identified bacteriophages is expected to show inhibitory effects. If the bacteriophage binding partners to VEGF RTKs exhibit the expected response, further research may support the use of bacteriophages as an immunotherapy in cancer related to angiogenesis.

Abstract Name: CHARACTERIZING THE EPIDEMIOLOGY OF HUMAN PARECHOVIRUS IN NEONATAL SEPSIS AT UPMC CHILDREN'S HOSPITAL OF PITTSBURGH

Human parechovirus (hPeV) is a non-enveloped, single-stranded, positive-sense RNA virus in Picornaviridae family. Transmitted through fecal-oral and respiratory routes, hPeV leads to near-universal infection by the age of 5. While most children older than 6 months are asymptomatic or experience mild symptoms, hPeV is more severe in children 3 months or younger leading to neonatal sepsis, meningoencephalitis, and/or death.

Nationally, hPeV is not included in routine testing for neonatal sepsis. As a result, the contribution of this pathogen to neonatal sepsis is incompletely understood. To improve the treatment of hPeV in children, a better understanding of the epidemiology and clinical presentation of hPeV is crucial. We aim to characterize the clinical presentation and epidemiology of hPeV at UPMC Children's Hospital of Pittsburgh through remnant cerebrospinal fluid (CSF) analysis and a clinical chart review. CSF samples from febrile infants under 3 months of age presenting between April to December 2024 were analyzed for the presence of hPeV genomic material using RT-PCR using panPeVF1 and panPeVR1 primers and the panPeVprobe1 as previously described. To assess differences in the clinical presentation of febrile infants with hPeV as compared to other viral or bacterial causes, we created a database of clinical information that included patient diagnoses, blood test results, CSF test results, bacterial culture results, hospitalization duration and course, and any abnormal findings such as rashes or seizures. Analysis of the data will create a better understanding of the hPeV clinical disease and the extent of similarities and differences between neonates with hPeV and those with other febrile illnesses in the first three months of life. Future work includes genotyping hPeV-positive samples to determine the prevalence of specific genotypes and their associations with clinical presentations¹. Nix, W. A. et al. Detection of All Known Parechoviruses by Real-Time PCR. *Journal of Clinical Microbiology* 46, 2519 (2008).

Abstract Name: Innovative DC to DC Buck Boost Power Converters for high efficiency, low load Applications, and Producing a Scalable Design

The DC-DC buck-boost converter is a commonly used voltage regulator, found in any electrical systems requiring a constant voltage. Despite high-voltage DC-DC Buck-Boost regulators being a well-studied field at high-loads, application for low-load is underdeveloped and often faces poor power efficiency characteristics, oftentimes having only about 20% or lower power efficiency. This DC-DC buck-boost converter aims to implement multiple modulation schemes dependent on the load, allowing for more efficient voltage conversion for items such as portable medical devices, mobile devices such as smartwatches, and any other device which implements and requires low current draw for extended periods of time. This paper aims to implement pulse width modulation (PWM), pulse frequency modulation (PFM), and pulse skip modulation (PSM) to meet target specs, as well as a mode control system to autonomously switch between these modulation schemes at optimal operating points. This paper will implement a DC-DC buck-boost converter at the low-load range which feature higher power efficiencies than most commercial DC-DC buck converters available today. For this design, the buck-boost converter will achieve at least 80% power efficiency at all ranges of current, and a physical printed circuit board implementation of the circuit will be designed, ordered, and tested. In addition, a layout of an on-chip design will be carried out to prove the scalability of this implementation, verifying that such a design can potentially be implemented in miniature portable devices where system form factors and its size are mainly concerned.

Abstract Name: Generating Bi-Directional Conversion of iEEG Data and Auditory Data

Bidirectional conversion between audio (human voice) and iEEG data requires a collaborative effort. Audio processing requires extraction of features such as pitch, intensity, formants, etc. They are later organized into a matrix where columns represent audio features and rows represent data points from the same time intervals. This matrix can then be input into a classifier to build a preliminary speaker classification model. Since individuals exhibit distinct preferences in pitch and intensity, this approach allows the creation of a rough classification model of speaker polarization. However, dealing with the overlap in audio features between different speakers requires manual labeling, employing supervised learning to assist the machine learning model in achieving more accurate speaker voice polarization. One significant challenge arises from the varying extraction frequencies of features such as pitch, intensity, and formants when using software like Praat. Instead of using Python's `scipy.signal` module for resampling, which involves Fourier transform that may produce ripple effects due to NaN or zero values in the input data, we opted for a simpler approach. Specifically, scaling the feature values based on the least common multiple of the different sampling rates for pitch and intensity. Additionally, applying a masking tool to filter out more non-voice segments from the audio, ensuring cleaner data for analysis. For processing starting from iEEG data, our laboratory already possesses a substantial dataset collected through UPMC. During data collection, not only were brain signals recorded, but eye-tracking glasses were also used to capture the objects of the patient's gaze, with a microphone nearby to record ambient audio. processed iEEG data can be associated with the faces observed and voices heard by the patient. This enables us to investigate how humans respond to external signals (auditory and visual) in real-life scenarios.

Abstract Name: The Evolution of Phishing: Types, Threats, and Machine Learning Mitigation Strategies

This paper explores the growing threat of phishing, which continues to target individuals and organizations using increasingly sophisticated tactics. The primary focus is on understanding how phishing has evolved over time, the various forms it takes, and how developing machine learning technologies might assist in detecting and preventing these attacks. Understanding the early strategies of phishing, which began in the mid-1990s, helps explain its progression into the diverse approaches found today, from basic false emails to sophisticated spear phishing, smishing, and deepfake-based vishing. The study provides a historical overview of phishing, categorizes its different types, and explains the motivations behind these attacks, which often exploit human trust and fear. Both technical and psychological factors that lead to phishing 'success' are discussed, emphasizing the importance of combining technological defenses with user education. Detection strategies are explored, such as machine learning-based email filtering and advanced URL analysis, which are essential tools for mitigating phishing risks. Additionally, machine learning models are evaluated, such as supervised and unsupervised algorithms, which are also effective at phishing detection by analyzing email content, sender behavior, and link credibility. The conclusions stress that while technological solutions are

vital, user education is an irreplaceable component of an effective defense strategy. The paper also examines how global events, such as the COVID-19 pandemic, have influenced phishing, with attackers taking advantage of public uncertainty to boost their chances of success. By investigating current trends, such as the use of AI and behavioral analytics in phishing detection, this study underscores the need for continuous adaptation in cybersecurity to counter increasingly sophisticated attacks. The goal is to provide clear knowledge of phishing's development and evolution and urge proactive defenses to minimize its impact, protecting both individuals and organizations from this ongoing threat.

Abstract Name: Assessing Health Literacy in an Adolescent Oral Health Education Curriculum to Prevent Oral Diseases

Prevalent oral diseases in adolescents include cavities, gum disease, and forms of oral cancer. Adolescent use of nicotine, including vaping, and exposure to the Human Papillomavirus (HPV) increase risks for these prevalent oral diseases. Educating students about the significance of these oral diseases and prevention strategies can improve oral health among this population. However, barriers to health education, such as readability, comprehension, and accessibility, can limit an individual's understanding of oral health. This study assessed an educational curriculum focused on vaping provided by an oral health community partner, Ready, Set, Smile (RSS), for 6th - 8th-grade students, aiming to expand the existing curriculum and improve health literacy for adolescents based on needs identified by RSS. An interprofessional student research team utilized three health literacy tools, the Center for Disease Control (CDC) Clear Communication Index, the Patient Education Materials Assessment Tool (PEMAT), and the SMOG Index, to evaluate the existing and revised educational material. Scores of 90% or above on the CDC Clear Communication Index and 70% or above the PEMAT are considered good, and a SMOG index at the 4th to 6th-grade level is recommended for health education materials. The existing curriculum received a CDC Clear Communication score of 73%, PEMAT scores of 68% (Understandability) and 42% (Actionability), and an SMOG index of 10th-grade level. The revised curriculum performed better with a CDC Clear Communication score of 93.75%, PEMAT scores of 100% (Understandability) and 80% (Actionability), and a SMOG index of 7th-grade level. The revised educational material demonstrates improved health literacy and readability scores at or near recommended levels and is being implemented to increase student engagement during teaching sessions with RSS. With improved engagement, there is hope that fewer middle schoolers will start using nicotine products and caregivers will consider HPV vaccination for their adolescents.

Abstract Name: Scalable Thermal Control Framework for Quantum Photonic Integrated Circuits Using

This research establishes a scalable framework for thermal control in quantum photonic integrated circuits (PICs), which are critical for quantum-enhanced communication, sensing, and computing. Precise resonance and phase stabilization are achieved using microheater-based systems integrated with components of the Pound-Drever-Hall (PDH) technique, including proportional-integral-derivative (PID) control and multi-channel programmable current sources. The methodology combines data acquisition systems (DAQs) with programmable current sources to independently manage multiple thermal control channels. PID feedback, implemented through field-programmable gate arrays (FPGAs), ensures exceptional temperature stability crucial for quantum photonic operation. Automated Python and LabVIEW interfaces streamline real-time data collection, enabling robust system evaluation and scalability. The PDH process further enhances resonance stabilization, serving as a backbone for integrating multiple quantum photonic components. This work introduces a novel approach to scalable thermal control, allowing for the independent regulation of multiple components within a single PIC. Preliminary results demonstrate precise stabilization of resonance and phase across multiple channels, achieving a level of scalability and precision that surpasses conventional methods. These advancements reduce energy consumption, operational costs, and the complexity of scaling quantum photonic systems. The broader implications extend beyond quantum communication and sensing to applications such as environmental monitoring, precision medical diagnostics, and autonomous navigation. By improving the thermal efficiency and scalability of quantum devices, this research contributes to a sustainable, quantum-driven future. It addresses critical global challenges in energy efficiency, secure communication networks, and precision measurement, while paving the way for breakthroughs in transformative technologies like quantum networks, advanced sensors, and energy-efficient computing systems.

Abstract Name: The Role of the Amyloid Precursor Protein (APP) on Tau Pathogenesis in Alzheimer's Disease

Background: Alzheimer's Disease (AD) is characterized by accumulation of amyloid- β (A β) plaques and neurofibrillary tangles (NFTs). NFTs form through the progressive, pathological accumulation and aggregation of tau in degenerating neurons. The amyloid precursor protein (APP), cleaved to generate A β , is specifically upregulated in NFT-bearing neurons. Moreover, familial mutations in APP, but not the tau gene MAPT, play a causal role in AD development. Although APP pathobiology is undoubtedly involved in AD progression, the lack of appropriate models has hindered our understanding of whether APP directly impacts tau aggregation and overall AD pathogenesis. **Method:** We investigated APP involvement in tau phosphorylation and aggregation using HEK293 cells overexpressing full-length APP and a novel, blue light-activated optogenetic system (optoTAU). We utilized biochemical and immunocytochemical analysis of total tau, phosphorylated tau (pTau), and APP to establish a causal role and investigate the putative mechanisms through which APP influences tau pathogenesis. **Result:** First, we show that APP overexpression in optoTAU expressing cells increases tau aggregation and phosphorylation at several AD relevant sites. Despite correlational evidence for an A β generation and tau pathogenesis relationship, our treatments with A β monomers, oligomer, and fibrils did not affect APP-mediated tau aggregation. As such, we investigated A β -independent mechanisms through which APP may influence tau aggregation. We further determined that tau and APP directly interact and that there is a trend toward increased tau-APP colocalization in cells undergoing tau aggregation. Lastly, we show that APP overexpression enhances cytotoxicity regardless of tau aggregation, implicating APP as the putative

trigger for neurodegeneration in AD brains. Conclusion: Our results elucidate a direct role for APP on tau aggregation and provide evidence to support a putative synergism between APP and tau on AD pathogenesis. Future studies aimed at dissecting this relationship in patient-derived neurons will identify APP-dependent mechanisms upstream and/or downstream of tau pathogenesis.

Abstract Name: Development of the Face-Saving Lies Scale: Examining Self-Esteem and Shame as Predictors

Lies and deception, though often frowned upon, are ubiquitous in human behavior. Among the various types of lies people tell, face-saving lies are particularly prevalent in everyday interactions. These lies may be told when individuals feel uncomfortable revealing something about themselves or their behavior, perhaps out of embarrassment, shame, or fear of how they may be perceived. As no existing scale specifically measures the tendency to tell face-saving lies, we developed a novel, 15-item scale. An exploratory factor analysis (EFA) using maximum likelihood extraction and varimax rotation revealed a single factor (eigenvalue = 8.48), explaining 56.52% of the total variance, with excellent reliability ($\alpha = .94$). Multiple regression analysis indicated that self-esteem ($\beta = -.38$, $p < .001$), shame negative self-evaluation ($\beta = .22$, $p < .001$), and shame withdrawal ($\beta = .17$, $p = .004$) significantly predicted the tendency to tell face-saving lies, accounting for 31.8% of the variance, $F(3, 214) = 33.20$, $p < .001$, $R^2 = .318$. Further research aims to replicate these findings and explore additional psychological factors, including social anxiety, attachment style, and narcissism.

Abstract Name: Impact of hibernation on endogenous carbon monoxide concentrations and heme oxygenase activity in thirteen lined ground squirrels (*Ictidomys tridecemlineatus*)

The thirteen-lined ground squirrel (*Ictidomys tridecemlineatus*) experiences periods of torpor in winter months that are associated with reduced body temperature, metabolism, and a significant decrease in heart rate that leads to blood flow reduction [ischemia (I)] to certain tissues. Between torpor events, brief arousals are shown by increased body temperature, metabolic rate, and reperfusion (R) to tissues. These I/R events cause damage in most mammalian tissues, but low to moderate levels of carbon monoxide (CO) have been shown to alleviate injuries in tissues exposed to frequent I/R events. High concentrations of endogenously produced CO have also been reported in blood and tissues of deep-diving mammals that routinely experience I/R in their tissues. Heme oxygenase (HO) enzymes break down heme, producing CO as a byproduct. We

examined CO concentrations and HO activity in tissues from 15 squirrels experiencing consecutive torpor for 1, 3, 4, or 10 days. Lung CO concentrations after 1 day of torpor (8.2 ± 2.3 pmol/mg) increased after 10 days in torpor (14.9 ± 5.2 pmol/mg). Conversely, HO activity in the lung on day 1 of torpor (10.2 ± 2.6 nmol/hr/g) decreased after 10 days in torpor (3.6 ± 1.2 nmol/hr/g). The spleen, an organ involved in erythrocyte turnover, had the highest average CO content among tissues (29.9 ± 7.0 pmol/mg), though values decreased with increased time in torpor. Similarly, HO activity was highest in day 1 of torpor (13.5 ± 4.4 nmol/hr/g) and decreased with increased time spent in torpor (11.6 ± 3.7 nmol/hr/g). These findings are the first to report variations in CO and corresponding HO activity in hibernating mammals, providing insight into the physiological significance of this cytoprotective gas during hibernation.

Abstract Name: Analyzing landslide recurrence in Pittsburgh, PA and Northern Panhandle of West Virginia through historical data and Light Detection and Ranging spatial comparison

Every year landslides kill thousands of people and cause roughly \$1 billion in damages globally. Thus, landslides are both destructive and dangerous to surrounding infrastructure, environmental systems, and human populations. Historically, landslide research has been challenged by records of historical landslides. When evaluating locations of landslides or other hillslope failures, examining patterns of remobilization or reoccurrence can provide insight for mitigation of future events. This research examines whether landslides are recurring in areas where historical landslides occurred, or in new areas where landslides have not been previously recorded. The work analyzes spatial patterns of landslide occurrence in two cases: Pittsburgh, Pennsylvania and the northern panhandle of West Virginia. In the Pittsburgh case, modern landslide data derived from citizen reporting (i.e., the 311 system) are compared with records of existing city wall infrastructure to quantify associations between modern landslides and historical landslide repair efforts. Similarly, West Virginia landslides derived from Light Detection and Ranging (LiDAR) data are compared with historical landslide mapping from the 1970s. These comparisons reveal that a majority of recent landslides occur in areas where historical landslides are not recorded. Our findings clarify where recent landslides are occurring, and thus reveal regions where remobilization should be central to assessments of future landslide events. Further, this work documents potential causation patterns in recent landslides, allowing development of safer and more sustainable risk mitigation practices in landslide prone areas.

Abstract Name: The Structuration of the 108th Nebraska Legislature

As the only Unicameral in our nation, Nebraska stands as a unique laboratory for the policy process, warranting critical study. Without the same procedures used in bicameralism, some may argue that there is limited public input and accountability in unicameralism. Through my analysis of the 108th Nebraska Legislature, I outline the reproduction of the structure of the session based on the changes in agency and

rules. The polarization of the nonpartisan body is at an all-time high and with heightened spotlights on the national level. The introduced socially charged policies of focus, rooted in national policy playbooks, include (a) LB574 the “Let Them Grow Act” a bill restricting gender-affirming care for minors, (b) LB575 the “Sports and Spaces Act” a bill restricting access to restrooms and school athletic teams for trans minors, and (c) LB626 the “Heartbeat Act” a bill restricting abortion. By utilizing structuration theory, I was able to define the regulation of the unicameral system by the rules and norms set by the actors. I have defined structural interactions as the micro-, meso-, and macrolevels. Primary internal and external agents interact within the microlevel. Primary internal agents adapted structural roles within the Unicameral to reproduce the structure to pass polarizing bills. External agents experienced increased barriers to engaging with the policy making process. Primary themes of personal freedoms, such as parental rights and bodily autonomy, have been highlighted through the exploration of the policies of focus within the mesolevel. Those mesolevel policy themes have reproduced macrolevel structures. The structural changes in all three levels due to agents, rules, and norms identified within the 108th Nebraska Legislature have produced unprecedented changes that caused the passing of socially charged health policies within the Unicameral.

Abstract Name: Measuring DBD Plasma Jet Gas Temperatures for its Applications in Wound Healing

Reactive oxygen and nitrogen species (RONS) generated by low-temperature Dielectric Barrier Discharge (DBD) plasma jets have demonstrated the ability to accelerate wound healing. A critical challenge, however, is maintaining plasma gas temperatures at safe levels to avoid damaging wound tissues. Developing an automated system to monitor plasma jet temperatures during wound exposure would be highly beneficial. This project is divided into three key phases. First, a DBD plasma jet torch was designed to generate a helium plasma jet (~10–15 slpm) with a length of approximately 50 mm. This was achieved using a quartz tube with two electrodes across which an AC voltage (~5–10 kV, 30–50 kHz) was applied. Plasma gas temperatures were measured using a K-type thermocouple. Second, a plasma sheet generator (50 mm wide, 50 mm high, and 2 mm thick) designed at SJSU was employed for two-dimensional (2D) temperature measurements across and along the plasma sheet. The third phase facilitated automated temperature monitoring for which a 2D scanning mechanism was developed. The scanning system incorporates stepper motors, ball screws, gears, and motor drivers. Torque and maximum speed calculations were performed to ensure the system's functionality. An Arduino microprocessor was used to control the traversing stage, enabling precise movement of the thermocouple across the plasma. Experimental results revealed that plasma gas temperatures were highest near the exit of the plasma torch (~60°C) and decreased progressively with distance, with the jet tip temperatures measuring approximately 30–35°C, depending on operating conditions. Plasma sheet experiments showed uniform temperature distribution across various locations on the sheet. In general, plasma temperatures decreased by 10–20% along the jet due to mixing with the surrounding air. Full design calculations and temperature results will be included in the final presentation.

Abstract Name: Hot Electron Chemistry on Bimetallic Au Core-Shell Nanoparticles

With the evolution of carbon emissions, carbon dioxide pollution levels have grown immensely. This issue can be combated by the conversion of either carbon monoxide or carbon dioxide into methanol through plasmonic photocatalysis. These novel catalysts convert pollutants into environmentally friendly products. Specifically, we synthesize and characterize bimetallic transition metal core-shell nanoparticles as plasmonic photocatalysts. Due to their unique properties, these nanoparticles can facilitate photocatalytic reactions as the plasmon core absorbs the light generating the hot electrons. The focus of the project involves the use of a gold (Au) core metal in the bimetallic core-shell nanoparticles. The gold core nanoparticles are then synthesized and paired with either rhodium, ruthenium, or nickel shells. Characterization techniques include Ultraviolet Absorption Spectroscopy (UV-Vis), Scanning Electron Microscopy (SEM), Transmission Electron Microscopy (TEM), and Energy-Dispersive X-ray Spectroscopy (EDS). Characterization of every synthesized sample reveals the dispersivity, size, shape, and distribution of elements. After characterization, the bimetallic core-shell nanoparticles are tested in the photoreactor chamber with mass spectrometry. In this process, the oxidation of carbon monoxide, hydrogenation, and combustion of oxygen can assess the photocatalytic efficiency of the core-shell nanoparticles. This work aims to provide more knowledge of eliminating previously mentioned pollutants and instead creating renewable fossil fuel alternatives.

Abstract Name: Small-Scale Composting Provides Sustainable Decomposition of Polylactic Acid (PLA) Bioplastic

The recycling process for plastic materials is woefully ineffective, which leads to most plastics being used one time and then ending up in a landfill. Only 9% of all the plastic waste generated globally is recycled. Alternative processes and polymer materials are needed to address the growing problem of single-use plastics. One promising alternative is polylactic acid or polylactide (PLA), a biodegradable polyester made from renewable biomass, typically fermented plant starch. Existing research on PLA supports the use of industrial composting facilities for decomposition, however our current infrastructure is insufficient and unable to support the widespread use of PLA. As a result, PLA often ends up in landfills with the majority of plastics. To make PLA a more sustainable option, my research focuses on small-scale composting, such as that found in community gardens and backyards, as a potential solution that addresses the lack of industrial composting facilities. In prior work, various plastics and their impact on the environment and human health were investigated. My current research explores the reversible conversion of lactic acid to polylactic acid polymer with known methods. Additionally, different solute isolation techniques (water, ethanol, or propanol) were assessed to determine which is most efficient at extracting lactic acid from soil. Finally, small-scale composting experiments of PLA were conducted to identify optimal conditions for its decomposition. Initial results suggest that ethanol is the most efficient solvent for extracting lactic acid from soil. PLA was observed to decompose in the presence of *Amycolatopsis* genus bacteria in a carefully monitored compost bin.

Abstract Name: Identifying Which Tissues Regulate Lifespan in Response to Death Perception

This study examines how the perception of death in *Drosophila melanogaster* (fruit flies) is triggered by the sight of deceased conspecifics and influences lifespan through insulin signaling. Sensory experiences have been shown to impact organismal aging across taxa. In particular, the perception of dead individuals significantly affects both the health and lifespan of animals that depend on insulin signaling. By exploring the role of insulin receptors in different tissues, this research aims to provide novel insights into aging mechanisms and strategies to promote healthy aging. The research focuses on identifying which tissues—including the gut, muscle, and fat bodies—mediate lifespan-shortening effects through insulin signaling. Specifically, it asks: Where are insulin receptors required to mediate the effects of death perception on lifespan? To investigate this, *Drosophila* were genetically modified to express a disruptable insulin receptor in specific tissues. This dominant negative insulin receptor was expressed to decrease insulin signaling in the gut, muscle, and fat bodies. Using a drug-induced expression in vivo system, we compared lifespan outcomes in flies with altered insulin signaling to those exposed to death perception. This process aims to identify tissues involved in lifespan alterations triggered by exposure to dead conspecifics. This research advances our understanding of insulin signaling and its role in aging. By identifying the tissues that mediate the effects of death perception, this study aims to clarify how sensory cues influence aging. The findings may lead to new strategies for promoting healthy aging and preventing age-related diseases, opening the door to innovative approaches for reducing the risk of such diseases and enhancing longevity.

Abstract Name: Klf4 sensitizes Mouse Embryonic Fibroblasts to FIN56 induced Ferroptosis

Krüppel-like factor 4 (KLF4) is a zinc-finger transcription factor involved in embryonic development, cell cycle regulation, autophagy, and DNA damage repair. Ferroptosis is a recently discovered form of cell death independent of apoptosis and is characterized by iron catalyzed lipid peroxidation. It has been hypothesized that Klf4 regulates ferroptosis-related genes. However, the molecular mechanism of how Klf4 regulates ferroptosis is yet unknown. In this study, mouse embryonic fibroblasts (MEFs) wild type for Klf4 (Klf4+/+) or null for Klf4 (Klf4-/-) were used to investigate the role of Klf4 in ferroptosis regulation. FIN56 is a drug that induces ferroptosis in cells via the degradation of GPX4, and thus reducing cellular protection against excess lipid peroxidation. MEFs both Klf4+/+ and Klf4-/- were treated with FIN56 to test the effect of Klf4 on sensitivity to FIN56 mediated cell death. In addition, trypan blue cell death assays were performed on MEFs untreated and treated with FIN56 to quantify the effects of the drug on cell death. Our findings revealed that Klf4+/+ MEFs responded to FIN56 treatment with a significant increase in cell death, while Klf4-/- MEFs showed resistance to the treatment. Furthermore, treatment of FIN56 with ferroptosis inhibitor (Fer-1) reduced Klf4+/+ MEFs' sensitivity to cell death, which further supports the hypothesis that Klf4 is positively regulating ferroptosis cell death. Finally, western blotting with primary antibodies for proteins

involved in ferroptosis regulation revealed that Klf4+/+ MEFs have higher levels of iron regulation proteins DMT1 and NCOA4, while the levels of iron storage protein FTH1 is reduced in response to FIN56 treatment. These results suggest that Klf4 is contributing to an increase of intracellular iron which could be sensitizing the MEFs to ferroptosis programmed cell death. Understanding this mechanism may illuminate possible targets for directed or combination therapy for cancer treatments.

Abstract Name: Music and Intimacy: A Study on Older Adults with Dementia

This research investigates the impact of music on memory for individuals with dementia, aiming to find non-pharmaceutical therapeutic techniques. This study focuses on the potential of using music, specifically songs they enjoyed in their youth, memories that were believed to be forgotten would be triggered back into short term memory. In addition, this could be specifically significant to adults in a relationship. If an individual were to listen to a song that was meaningful in their relationship (first dance song,) this will help the individual diagnosed with dementia remember their partner, and possibly signal for an intimate moment, like holding hands or kissing. The ultimate goal is to enact music in a care note as a therapeutic technique to de-escalate individuals with dementia. With the retrieval of memory, individuals would be less confused and would calm their emotional states. This investigation will take place starting January 2025, and will be conducted as a pre-test/post-test survey and qualitative interview. Individuals will be given a basic memory test, followed by listening to their favorite songs in youth, and then the test will be given again. However, researchers are mainly looking for observational intimacy data. Results are impending, but based on literature search conducted, it is believed that results will be very impactful. This study is inspired by the documentary *Alive Inside: A Story of Music and Memory* (Rossato-Bennett). This video discusses the benefits of music therapy, with personal stories from individuals with dementia and caregivers with the intervention of songs. Music as an intervention could increase the quality of life for residents and provide a multitude of therapeutic techniques. In addition, it can increase the quality of life for families as we hypothesize that music could bring memories back.

Abstract Name: Working Memory, Music, and the Sentence Generation Method: A Novel Approach to Second Language Vocabulary Acquisition

Learning vocabulary is a fundamental part of second language (L2) learning and communication. One approach to learning L2 vocabulary is through rote memorization of word pairs of first language (L1) and L2 translations. Another approach involves generating sentences using new L2 vocabulary words, emphasizing meaning of words and fostering deeper processing and long-term retention by creating a meaningful link

between the vocabulary and context. By learners generating their own information, they show a generation effect, indicating that there are more memory benefits for actively self-generating information than for passively reading information. Additionally, individual differences such as working memory and musical ability and training are also factors that are related to learning L2 vocabulary. Therefore, this study examines the efficiency of sentence generation on L2 vocabulary learning and investigates the relationship between working memory and musical ability and training and L2 vocabulary learning when trained using sentence generation. 30 native English speakers are trained on English-German word pairs using four strategies: reading a provided definition, reading an English sentence containing the target German word, generating their own definition, or generating their own sentence. Learning is assessed through a free recall task, a translation task, and a semantic relatedness task. We hypothesize that sentence generation will contribute to the best learning outcomes, and that working memory and musical ability and training will show a positive relationship with L2 vocabulary learning. We will also explore possible interactions between the training method and working memory and musical ability and training.

Abstract Name: Evolutionary Optimization of Biologically Inspired Mechanistic Input-Output Neural Circuit Models in the Auditory Pathway

Understanding how to compute specific functions from neural architecture is a fundamental challenge in neuroscience, with profound implications for artificial intelligence, neuromorphic computing, and neurological health. This study employs evolutionary meta-heuristic algorithms to optimize a mechanistic input-output spiking neural network (SNN) model of the cochlear nucleus, a key circuit in the auditory pathway. The research integrates biologically inspired initialization, iterative optimization, and data-driven validation to explore how connectivity and topology influence input-output relationships in neural circuits. Synthetic input-output spike train pairs for spiral ganglion and bushy cells are generated using a computational model of the cochlear nucleus. SNNs are initialized with biologically plausible parameters, and their synaptic weights and delays are refined using spike-timing dependent plasticity (STDP) while connectivity and distribution of cellular properties are evolved over generations. Fitness is evaluated based on the accuracy of replicating experimentally observed input-output patterns. The optimization is performed in parallel across a population of networks to enhance computational efficiency, with characteristic motifs in the optimized architectures analyzed to uncover their functional significance. This approach not only seeks to replicate the computations of biological circuits with high fidelity but also provides insights into the principles underlying neural circuit architecture. Preliminary findings are expected to demonstrate that SNNs can accurately mimic biological computations, offering a scalable methodology for computational neuroscience. SNNs are particularly promising for designing energy efficient models which are capable of reducing the carbon footprint of machine learning, by mimicking the sparse, event driven nature of biological neural activity. This work also has the potential to reduce the computational and time demands of traditional connectomic reconstruction by learning circuit architectures directly from empirical input-output data. Additionally, these results could inform the design of energy efficient neuromorphic hardware, test hypotheses about auditory processing, and guide neural architecture search (NAS) methods for artificial neural networks.

Abstract Name: Revealing the History of PFAS Contamination from Seepage Lake Sediment Cores

Increasing concerns over large-scale contamination of water, food, commercial and consumer products, and waste from polyfluoroalkyl substances (PFAS) have led to growing global pressure to assess the scope, magnitude, and impacts of PFAS contamination of the environment. To improve the understanding of the environmental sources and cycling of PFAS, we initiated a research project to look at the historical deposition of PFAS in water body sediments. Lake sediments, as demonstrated with other legacy and emerging contaminants, provide an accurate archive of historical contaminant deposition which can be useful to establish a deposition history of PFAS. This study focused on characterizing and constraining poorly understood atmospheric cycling and deposition of PFAS using seepage lakes whose inputs are dominated by atmospheric deposition. Sediment cores were extracted from the two seepage lakes in southern Wisconsin - reaching back to the early 1900's, well before PFAS was first produced. The cores were sectioned at 1 cm intervals and age dated using 210-Lead and 137-Caesium, to establish timelines for PFAS deposition history. This research aims to gain a better understanding of the distribution of historical inputs of PFAS, ultimately contributing to strategies that will control future inputs of PFAS compounds to protect the environment and improve public health.

Abstract Name: PAVE: Pervasive Analysis of Vibration for Enhanced home care

The need for elderly care continues to grow as the world's older (people aged 65 and over) population is projected to double by the year 2050. Caretaking requires significant advancements to ensure the safety and well-being of senior residents, particularly when caregivers cannot be physically present. This study explores the potential of autonomous vibration sensors as a non-invasive alternative to traditional monitoring methods such as microphones and cameras, which may infringe on residents' privacy. By analyzing and grading various sensor models, our research aims to optimize the efficiency of these sensors when deployed in a network, thereby enhancing the accuracy of activity detection. A key focus of this investigation is the minimization of noise interference, allowing for the precise identification of relevant events and movements through vibration sensing. Our findings will contribute to the development of improved monitoring systems that safeguard both the safety and privacy of residents in assisted living environments .

Abstract Name: A Multi-Perspective Case Study on Implementing a Novel College Student Coach Role in a Service-Learning Club: Oakland Academy Students in Action Team

Students in Action (SIA) is a nationwide initiative designed to empower K-12 students to lead service-learning projects that address the needs of their local communities. We are currently evaluating the implementation of a novel near-peer college student coach role to work alongside students and their advisors, typically teachers, within Greater Lafayette SIA teams local to Purdue University. This role seeks to increase K-12 student engagement with their community, provide access to university resources, and foster a meaningful partnership between the university and K-12 schools. I evaluated the implementation of this novel coach role at Oakland Academy, a local alternative high school. I analyzed skill growth from perspectives on hosting a student-led family mental health night, drawing insights from my observations, the advisor's perspectives, and the students' reflections on the event. Across all perspectives, several common themes emerged reflecting the benefits of this partnership, including increased access to resources to host larger-scale events, more opportunities for students to transform their passions into practical service projects, and growth in students' presentation, writing, collaboration, and project management skills. Implementing a near-peer mentor role can enhance students' service-learning experience by deepening their community impact and fostering professional development opportunities. Engaging students and advisors in collaborative reflection provides invaluable first-hand accounts that could not be obtained from observation alone. Furthermore, this case study examining a smaller, non-traditional school illustrates that the benefits of service-learning opportunities extend beyond financial barriers. Likewise, a university partnership can enhance opportunities through grants and mentorship. In conclusion, this case study highlights the benefits of implementing a near-peer mentor role and collaboration between an academic institution and K-12 schools in creating more impactful service-learning opportunities. We hope our work can serve as the framework for other universities to implement similar near-peer roles to develop more impactful youth service-learning opportunities.

Abstract Name: Prognostic Significance of Platelet Factor 4 (PF4) in Pediatric Respiratory Failure: Linking Inflammation, Coagulation Biomarkers, and Clinical Outcomes in a Multi-Institutional Study.

Platelet factor 4 (PF4) is a chemokine released from α granules of activated platelets and may play a role in disseminated intravascular coagulation (DIC). Platelets and PF4 play crucial roles in respiratory failure via inflammation and coagulation pathways. The release of PF4 leads to downstream stimulation of alveolar macrophages and production of chemokines promoting neutrophil recruitment and edema formation. PF4 also accelerates generation of activated protein C, which can counteract the increasing procoagulant state during sepsis. This study

aims to identify the significance and reliability of PF4 as a prognostic marker for clinical outcomes in respiratory failure. We assessed PF4 levels using Luminex assays in 295 mechanically ventilated pediatric patients from a multi-institutional pediatric insulin titration trial with heart or lung failure. We then tested the relationship of PF4 levels to clinical outcomes and systemic inflammation and immune dysregulation biomarkers. It was found that elevated PF4 levels were significantly correlated with longer mechanical ventilation (Spearman's $\rho = -0.146$, $p < 0.012$) and extended ICU stay (Spearman's $\rho = -0.144$, $p < 0.013$). Furthermore, PF4 levels were significantly lower in non-survivors (4,040 IQR 1,730-10,284) compared to survivors (7,963 IQR 2,437-16,835; $p < 0.03$), underscoring its potential as a negative prognostic marker. PF4 was also positively correlated with PAI1, P-Selectin, and platelets, while showing negative correlations with inflammatory biomarkers such as IL-6, IL-8, ANG2, TM, TREM1, ICAM1, and TNFR1. Overall, PF4 levels are significantly lower among non-survivors and patients requiring prolonged mechanical ventilation or extended ICU hospitalization. The strength of correlations between PF4 and other biomarkers suggests that it plays an integral role in the inflammatory and coagulation cascades associated with severe illness. Identifying biomarkers that reflect the complex pathophysiology of pediatric respiratory failure is crucial in improving prognostic accuracy and therapeutic strategies for this vulnerable population.

Abstract Name: Evaluating Cartilage Degeneration And Glenohumeral Joint Alterations After Brachial Plexus Birth Injury

Brachial plexus birth injury (BPBI), occurring in 1-3 of every 1,000 births, is a neuromuscular injury caused during childbirth, leading to muscle paralysis, shoulder contracture, and deformities in the scapula and humerus. Previous rodent studies have documented changes in glenoid development after BPBI (both nerve rupture and avulsion), but the timing of alterations, particularly cartilage degeneration and glenohumeral joint macrostructure, remains unclear. This study aims to characterize these changes over time, focusing on cartilage degeneration and structural alterations in the glenohumeral joint. We hypothesize that the postganglionic injury group will have the largest macrostructural changes, detectable as early as 4 weeks post-surgery. Sprague Dawley rats ($n = 245$) underwent surgery at 3-6 days postnatally, with postganglionic neurectomy (mimicking nerve rupture), preganglionic neurectomy (mimicking nerve avulsion), sham injury, or elbow disarticulation (limb disuse). Rats were euthanized at 2, 3, 4, 8, and 16 weeks post-surgery, and the humeri and scapulae from both injured and uninjured limbs were harvested. Micro-computed tomography scans of the scapula and humeral head were reconstructed, and macrostructural parameters, including curvature and angle measurements, were analyzed using Materialise Mimics. Statistical comparisons between groups were performed using a Kruskal-Wallis test (GraphPad Prism, $\alpha = 0.05$). Preliminary findings reveal that the disarticulation group's injured limb showed a significant decrease in the glenoid inclination angle—a

key macrostructure joint measurement—compared to a healthy shoulder at all time points, followed by preganglionic, postganglionic, and sham groups. Increased glenoid inclination angle reduces joint stability and increases the likelihood of additional shoulder dysfunction. Alterations in glenoid macrostructure and early cartilage degeneration were detectable as early as 4 weeks following disarticulation injury. These findings provide critical insight into the timing and mechanisms underlying cartilage degeneration and joint alterations, informing optimal clinical intervention timing in BPBI to improve outcomes for affected individuals.

Abstract Name: Destructive E-Graph Rewrites

Traditional program optimization suffer from the phase ordering problem: Optimization performance is dependent upon the order of program rewrites. Once a rewrite occurs, the initial program cannot be easily recovered. E-graphs can efficiently represent many different, equivalent programs—enabling non-destructive rewrites, where the initial term is retained in the e-graph, in a process known as equality saturation. However, e-graph size tends to explode with certain rewrite rules. For example, associativity and commutativity can result in an exponentially growing e-graph. This limits the practicality of e-graph driven optimization because the time complexity of equality saturation is linearly dependent on e-graph size. The compiler backend Canelift uses a modified version of e-graphs termed "acyclic e-graphs," where production-grade performance is achieved at the cost of acyclicity and limit the expressivity of rewrites. We introduce destructive e-graph rewrites, where the e-graph size can be reduced during equality saturation by undoing rewrites. Given a rewrite $L \rightarrow R$, undoing it involves finding all programs matching R and removing them from the e-graph. In the egg e-graph library, destructive rewrites speed up some benchmarks by 5x and improve with larger e-graphs. We are currently applying destructive rewrites in Herbie, a project to optimize floating point expressions that uses e-graphs during its optimization workflow. Destructive rewrites remove intermediate programs from the e-graph—an optimal program may be reached through multiple intermediate rewrites that produce intermediate programs. Once the optimal program is added to the e-graph, the intermediate programs can be removed.

Abstract Name: Empowering Export Growth: Cross-Border E-Commerce for SMEs in Developing Countries

This study aims to examine how small and medium-sized enterprises (SMEs) in developing countries can leverage cross-border e-commerce to enhance their export performance, with particular attention to the roles

of internet infrastructure, government policy environment, and competitive advantages. While existing research has extensively explored e-commerce's impact on large enterprises in developed economies, limited attention has been paid to SMEs in developing countries and the external factors affecting their e-commerce success. Drawing from the Resource-Based View (RBV) theory, we propose a conceptual model investigating the relationship between cross-border e-commerce participation and export growth, moderated by government policies and mediated by customer coverage rate. The study will collect data from SMEs engaged in cross-border e-commerce across multiple developing countries through surveys and secondary data sources. Our research methodology will employ structural equation modeling to test four hypotheses: (1) higher e-commerce participation leads to increased export growth, (2) better internet infrastructure enhances export performance, (3) improved customer coverage through e-commerce drives export growth, and (4) favorable government policies positively moderate the e-commerce-export relationship. The expected findings will contribute to both theory and practice by illuminating how developing country SMEs can effectively utilize cross-border e-commerce platforms and external resources to overcome traditional trade barriers. This research will provide valuable insights for policymakers developing e-commerce infrastructure and regulatory frameworks, while offering practical guidance for SMEs seeking to expand their international market presence.

Machine translation (MT) systems—computational systems for translating text from one language to another—are essential tools for communication, yet they often perpetuate cultural and linguistic biases in their training data. These biases undermine fairness, lead to misinterpretations, and weaken trust in AI systems. In this project, I investigate the root causes of translation biases in AI-based MT systems and assess methods for mitigating these biases, focusing on the effectiveness of two specific approaches: domain adaptation and data debiasing. Through a review of academic literature, I identified key sources of bias in MT systems, including limited diversity in datasets, lack of cultural and contextual understanding, and algorithmic biases from training data. I compared two primary debiasing approaches for these issues: data debiasing, which modifies datasets to reduce bias before training, and domain adaptation, which fine-tunes models post-training. While both approaches have their benefits, my analysis suggests domain adaptation is more advantageous for MT systems because it efficiently reuses existing biased datasets and offers scalable solutions for improving fairness without the need for retraining models from scratch. These findings suggest a path forward for developing more equitable AI-based MT systems. Future research will delve into refining domain adaptation techniques and exploring the adaptability of MT systems compared to human translators in unlearning biases. By addressing these challenges, I aim to advance AI's capacity for accurate, culturally sensitive, and ethical translation practices.

Abstract Name: Assessing Urban Walkability Using Deep Learning Approaches: Large Language Models and Contrastive-Language Image Pretraining

Existing assessments of walkability in urban areas often lack efficiency and accuracy. This research introduces an automated framework that combines deep learning techniques with geographic data to evaluate walkability and recommend optimal pedestrian routes. OpenAI's Contrastive-Language Image Pretraining (CLIP) and GPT-4o models were trained on 21,097 Google Street View Images (SVIs) of Seattle. These images, paired with descriptive prompts on sidewalks, intersections, traffic conditions, accessibility, comfort, and points of interest, were used to generate walkability scores. A survey of respondents rating 100 SVIs demonstrated that GPT-4o scores aligned more closely with human evaluations than CLIP scores. Walkability scores were mapped to Seattle's road networks, comprising of 11,659 nodes and 37,796 segments, using OpenStreetMap Network API. Road segment scores were calculated as the average walkability of associated SVIs, and path scores were determined by aggregating segment scores between specified origin and destination points. An enhanced Dijkstra's algorithm incorporating a shortest loopless path method identified the best walkable routes. Two penalty functions, accounting for altitude changes and slope degrees, refined path rankings to prioritize pedestrian accessibility and comfort. Future work includes integrating construction data from Seattle to penalize obstructed paths, employing a multi-objective A* algorithm to optimize paths based on distance, elevation, and accessibility, and generalizing the framework across diverse urban settings. Our research raises awareness of street quality for pedestrians, which supports safer navigation and fosters greater community engagement.

Abstract Name: Microglia and Oligodendrocyte-specific Genes are Significantly Associated with Alzheimer's Disease by Gene-based Polygenic Risk Score Analysis

Alzheimer's Disease (AD) is a progressive neurodegenerative disorder with a high heritability, but the exact genetic risk factors are not fully understood, especially at a cell-type-specific level. Recently, glial cells in the brain—microglia, astrocytes, and oligodendrocytes—are shown to be involved in AD development. This study aims to identify any glial cell-specific genes associated with AD. Lists of genes across three glial cells were obtained from a previous study. Gene-based polygenic risk scores (PRS) were constructed by PRSet software in AD cases/controls for each gene within three glial cell types, based on a previous GWAS study. Next, gene-based PRSs were evaluated in discovery data adjusted by the top two principal components (Model 1). A replication was followed in independent data for those genes with p -value ≤ 0.05 in the discovery data. Then, a meta-analysis was performed when the signals in both datasets were consistent. The association was further evaluated by adjusting with additional covariates, including age, sex, and APOE $\epsilon 4$ count (Model 2). Significance was determined by Bonferroni corrections (at $\alpha = 0.05$). Two microglia-specific genes (BCL-3 and RELB) were significantly associated with AD in Model 1, OR = 1.145[1.090-1.202], p -value = 5.26×10^{-8} for BCL-3, and OR = 1.149[1.094-1.206], p -value = 2.84×10^{-8} for RELB. However, neither reached significance in Model 2. One oligodendrocyte-specific gene (BIN1) was

significantly associated with AD in both models with similar results as $OR = 1.103[1.051-1.157]$, $p\text{-value} = 6.84 \times 10^{-8}$ in Model 1. None of the astrocyte-specific genes were significantly associated with AD. Two microglia-specific genes (BCL-3 and RELB) and one oligodendrocyte-specific gene (BIN1) are significantly associated with AD, inferring the distinct roles of glial cells in AD. Further study of those genes has the potential to provide more insights into the complex biological mechanisms and targets for the disease.

Abstract Name: SteMy-AI : Advancing Stem Cell and Regenerative Medicine with AI-Driven Lab Assistant Robots

Artificial intelligence and robotics are increasingly employed across various fields, yet their application in laboratories, particularly in the cultivation of stem cells, remains underexplored. Significant advances have been made in generating diverse cell types from human pluripotent stem cells (hPSCs), offering a potentially limitless supply for research and therapeutic applications. However, these differentiation processes are time-sensitive, inflexible, and challenging to manage. The SteMy project seeks to introduce an innovative AI-powered robotic companion designed to assist in stem cell culture, with the goal of accelerating research outcomes, improving culture quality, and streamlining cell line management. The project team engaged with expert investigators in stem cell biology, differentiation, and human-robot interactions to identify key challenges, define essential functionalities, and methods of implementation through co-design, workshops and interviews. During the initial phase, critical design guidelines were established, including cell line scheduling assistance, maintenance support, and improvements in lab communication. AI-prompt engineering was initiated to design effective AI-human interactions that address these challenges. Future work will focus on finalizing the design guidelines, prototyping the SteMy robot, and optimizing and testing its functionalities to enhance its application in stem cell research.

Abstract Name: Exploring the Metabolic Flexibility of Stem-Cell-Derived Squamous Cell Carcinomas via Pharmacological Inhibitors

Squamous cell carcinomas (SCCs) are a common form of non-melanoma skin cancer, posing a significant health burden due to their invasive nature and metastatic potential. SCCs originating in the head and neck regions are particularly associated with increased morbidity and mortality following surgery. Understanding SCC tumor evolution is critical for advancing preventative and therapeutic strategies. The Lowry Lab identified hair follicle stem cells (HFSCs) as the cell of origin for SCCs, revealing their metabolic flexibility in utilizing alternative carbon sources for growth. Although SCCs predominantly rely on the Warburg effect for lactate production via anaerobic glycolysis, deleting lactate dehydrogenase (LDHA) in HFSCs does not impede tumor progression. Instead, SCCs adapt by activating glutaminolysis, where glutamine is metabolized via glutaminase (GLS) to fuel the TCA cycle, implicating glutamine metabolism as a compensatory pathway. This study investigates whether dual inhibition of glycolysis and glutaminolysis suppresses SCC initiation and progression. Using K15CrePR mice, GLS and LDHA were genetically deleted in HFSCs (GLSKO/LDHAKO), and tumorigenesis was induced through DMBA/TPA chemical carcinogenesis. While single knockouts of GLS or LDHA led to SCC formation via compensatory pathways, dual knockout (GLSKO/LDHAKO) prevented SCC development. Elevated nutrient uptake in single knockouts prompted the exploration of nutrient transporters as additional therapeutic targets. To pharmacologically recapitulate these findings, small-molecule inhibitors of GLS (Telaglenastat, CB839), LDHA (GSK2837808A), glutamine transporters (V-9302), and lactate transporters (AZD0095) were evaluated. Early studies confirmed their effectiveness in penetrating the skin and inhibiting their targets. Preliminary results from combined GLS and LDHA pharmacological inhibition demonstrated delayed SCC formation and progression. This work provides insight into SCC tumorigenesis and offers a translational framework for developing combinatorial metabolic therapies to treat SCCs and other cancers.

Abstract Name: Glypican levels effects on temozolomide (TMZ) treatment in Glioblastoma Multiforme

Glioblastoma multiforme (GBM), is a form of brain cancer characterized by its aggressive tumor growth and low patient survival rate. GBM patients have limited treatment options and typical treatments like radiation and surgical removal are challenging due to the unique aggressiveness of GBM tumors. Chemotherapy regimens mainly consist of utilizing the drug temozolomide (TMZ) in combination with radiation and or surgical invention. Currently, TMZ is the standard of care chemotherapeutic treatment for GBM patients. Once TMZ is delivered into the tumor cell, the drug targets DNA and causes DNA damage that results in cell death and prevents cell division. Though initially effective, GBM tumor cells can develop resistance and even, in some cases, have minimal response to TMZ treatment. In this research project, we investigate the impact of extracellular proteins attached to the cellular membrane known as glypicans on GBM tumors treated with or without TMZ. We hypothesized that the high levels of glypicans on GBM cell surfaces could increase TMZ resistance in tumor cells. Understanding glypicans and their role in TMZ resistance is important for improving GBM survival rates and treatment options.

Abstract Name: Entangled timelines: Memories and Futures of the More-than-human-world

Human concepts of time are malleable and everchanging. Neither visible nor tangible, yet time can dictate our behaviours and thinking so strongly. Sometimes referred to as “time’s arrow”, and other times, a “cycle”. If it's already so complicated for humans, what about all the other bits of the world-- everything else that exists together with us? What do concepts of time look like in the more-than-human world? Timelines crash, as interconnected lives have unlike flowing of time. How will differing perceptions of time direct life by impacting priorities, desires, and experiences through a lifespan? My project aims to look at this question through imaginative exercise by short film animation. From mountains, to mosquitos and bodies of water, it is important to explore how memories of pasts and futures are perceived in the more-than-human world. To recognize that all the life around us experiences temporality and grief, is to recognize ethical and political accountability and responsibility. Everything that touches is connected (not just physical touch, but the other senses as well, like sight and smell). Although our human clocks are loud in the face of urgency and looming deadlines, if we begin to consider the perspectives of the more-than-human world that is an entangled mix of differing timelines, then we might just view our relationship with not only time, but also with the more-than-human-world in a new light. For instance, a mountain's life in comparison to that of a human's is colossal. To become a mountain--just for a moment in imagination--will require a shift in temporality from decades to millennia. Perhaps changing our definitions and scope of time will allow for new connections in human thinking.

Abstract Name: Mentoring Business Students in Research: An Immersive Approach

This research summarizes our immersive approach to mentoring undergraduate business students in conducting research, an area where opportunities are often limited compared to disciplines like nursing or the sciences. As business faculty members, we have successfully guided students through the research process by fostering an environment that emphasizes engagement, mentorship, and real-world applications. Our approach immerses students in research through four key steps. First, we establish strong connections with students through an open and supportive classroom atmosphere, complemented by career-related mentorship programs. For instance, one co-author leads a program that connects students with local professionals, creating an enriching network that helps students feel confident in facing challenges with faculty support. Second, in the classroom, we incorporate timely and relevant topics, such as generative AI and the Silicon Valley Bank collapse, to stimulate students' interest and encourage exploration beyond the syllabus. Third, we provide tailored guidance through a Call for Papers, offering potential research topics related to course material, and carefully select students or groups for research projects. Given that many business students have

little or no prior research experience, we organize regular meetings to ensure students remain on track with their research design and implementation plans. Fourth, we motivate students to present their findings at on-campus undergraduate research symposiums and regional conferences, fostering both professional growth and academic confidence. Our approach has resulted in increased student engagement with research, improved critical thinking skills, and greater academic opportunities for business undergraduates. In addition, we discuss the obstacles and lessons learned in our experiences, offering insights for other business faculty members interested in fostering research opportunities within their own programs.

Abstract Name: Mathematical Modeling of Micromagnetics

This research project investigates micromagnetics -- a theoretical framework developed by W.F. Brown, to describe the macroscopic behaviour of magnetic materials. A central concept in micromagnetics is the minimization of the magnetic energy within a material. The primary concepts used in this research were that of Absolutely Continuous Functions, Sobolev Spaces, and Gamma Convergence, as well as other ideas from analysis and measure theory such as Taylor's formulas. In this project we looked at the one dimensional variant of the energy equation developed by Brown. We analyzed several cases of the energy equation with different parameters and we constructed a sequence of functions which minimized the energy equation for each case. We studied this equation using gamma convergence and constructions of sequences of functions. We then analyzed the second order gamma limit of this energy equation. For two specific instances of the energy function we were able to explicitly solve for this gamma limit in terms of a differential equation. We were able to construct the sequence of functions which minimize the energy equation for both a specific potential energy function and a generalized potential energy function. Furthermore we characterized the speed at which these functions converge. The constructions we found could be applied to future analysis of magnetic materials and provide a framework for investigating the energy equation in higher dimensions.

Abstract Name: Temperature influence on the efficacy of RNAi in Colorado potato beetle

In recent years, RNA interference (RNAi), an innate antiviral immune response in most eukaryotes, has emerged as a transformative technology in therapeutics and agriculture. As extreme weather events and rising

global temperatures become more frequent, it is increasingly relevant to explore how temperature affects RNAi-based pest control strategies. In this study, we focus on the impact of temperature on RNAi efficacy in the Colorado potato beetle, *Leptinotarsa decemlineata*, one of the most devastating insect pests in the world. Through feeding assays, we found that the uptake of dsRNA was reduced at lower temperatures. To ensure a precise and direct delivery of double-stranded RNA (dsRNA) into the target insect, we elected injection rather than ingestion for the oral delivery. Based on our preliminary data and existing literature, we hypothesized that RNAi is more effective at physiologically relevant elevated temperatures. To test this hypothesis, we undertook the following steps: 1) identified temperature-sensitive gene candidates, 2) injected dsRNAs synthesized in vitro from the gene candidates into *L. decemlineata* larvae, 3) subjected the treated larvae to a temperature gradient and monitored their survival, and finally, 4) evaluated the influence of temperature on RNAi efficacy. The combined results support our overarching hypothesis. A better understanding of the temperature dependency of RNAi will not only facilitate the development of more resilient RNAi-based biopesticides, but also help optimize its application across different climates and seasons, ensuring reliable pest management under varying environmental conditions and sustainable implementation of RNAi in agriculture.

Abstract Name: Bridging the Cybersecurity Gap for Non-Profits in Pennsylvania: Student Reflections on Website Development for Sharing Research Findings

Cybersecurity has become a growing concern for organizations of all sizes and sectors. Smaller non-profits, especially in rural communities, often face distinct challenges addressing these concerns due to limited budgets, minimal technical expertise, and restricted access to advanced security infrastructure which can leave them vulnerable to cyberattacks. Faculty and student researchers at several Penn State campuses will conduct a formal assessment of the cybersecurity posture of non-profits in Pennsylvania to help bridge this cybersecurity gap using a comprehensive assessment tool. We will recommend core “best practices” to enhance the security posture of non-profits who lack the necessary resources. A website will also be published to serve as a focal point for sharing our research results and practical resources. It will include an About page that outlines our mission to help non-profits safeguard their operations. The Interest Form page offers a QR code to invite them to participate in our cybersecurity assessment. The Methodology page explains the assessment process and its benefits. The Research Team Profiles page highlights the dedicated professors and student researchers leading this initiative. Finally, the Contact page provides an avenue for non-profits to connect with the research team for additional information. Despite having no prior experience in web development, the team built the website through faculty guidance, self-taught methods, and persistent trial-and-error. Not only has this process equipped the team with new technical skills, but it has also ensured the creation of an impactful resource for this initiative. This website will expand beyond the current initiative to support ongoing research beyond Pennsylvania non-profits. By making these resources available online, our goal is to empower nonprofits across Pennsylvania to take informed steps toward better cybersecurity readiness and to safeguard their operations.

Abstract Name: Evaluation of Simultaneous Localization and Mapping (SLAM) for Static and Dynamic Environments: Establishing a Benchmark in Autonomous Mobile Robotics Research

The Simultaneous Localization and Mapping (SLAM) problem within the robotics industry poses a causality dilemma because of SLAM's objective of "simultaneously" localizing and mapping a given environment. Modern mobile robots equipped with Robot Operating System (ROS) can easily autonomously navigate using SLAM and path planning. Current SLAM development has proved effective in static environments; however, SLAM's performance in dynamic environments presents a challenge and requires further enhancement. A TurtleBot4 mobile robot running SLAM Toolbox on ROS 2 outfitted with a Light Detection and Ranging (LiDAR) device was used to conduct mapping and autonomous navigation trials. Testbeds for a dynamic environment were developed, and the behavior of a TurtleBot4 using SLAM and an embedded autonomous navigation algorithm, Nav2, was analyzed. The dynamic environments were built by implementing a VEX robot and an ArcBotics Sparki Bot to serve as repeatable dynamic obstacles. These experimental results provided valuable insight into the decision-making process of the Nav2 autonomous navigation algorithm when exposed to dynamic obstacles, showcasing the accuracy and efficiency of the TurtleBot4's autonomous navigation. The TurtleBot4's behavior can be refined for a given dynamic environment by tuning the Nav2 parameters. Nav2's inflation and velocity sample parameters were tuned to test the limits of the TurtleBot4's dynamic obstacle avoidance. Looking ahead, we plan on implementing essential performance improvements to the Nav2 algorithm to refine its path planning and obstacle avoidance capabilities in dynamic environments.

Abstract Name: Mirror-Touch Synesthesia: Do You Feel What I Feel?

Mirror-touch synesthesia (MTS) occurs when a person experiences the sensation of touch on their own body when observing another person being touched. Researchers estimate that approximately 1.6% of the population has MTS, making it one of the more common types of synesthesia (Banissy et al., 2009). The motivation for this project is to explore the relationship between MTS, empathy, and the ability to identify facial expressions. Individuals with MTS may have heightened abilities in both of these domains, but research evidence is mixed (e.g., Banissy & Ward, 2007; Baron-Cohen et al., 2016). We will use validated measures of MTS (Ward et al., 2018), empathy (Muncer & Ling, 2006), and facial expression recognition (Passarelli et al., 2018) to clarify the relationship between these variables, while also expanding to the unexplored area of animal touch. It is not yet known whether observing touch to animals elicits the mirror-touch phenomenon, as prior work on MTS has been limited to observing touch to humans and inanimate objects. Participants will complete an online survey in which they will be asked to identify any vicariously felt tactile experiences while viewing videos of touch to humans, animals, and inanimate objects (Ward et al., 2018). They will also complete the Empathy Quotient (Muncer & Ling, 2006) and Facial Expression Recognition Test (Passarelli et al., 2018). Consistent with prior research, we expect to find positive correlations between the degree of MTS, empathy, and facial expression recognition ability. We

predict that the novel domain of animal touch will elicit MTS experiences that fall between those felt when observing touch to humans versus inanimate objects.

Abstract Name: Flowers and Femininity: Sex, Women, and the Botanical Sciences

This paper explores the discovery and developmental understanding of plant sexuality, sex, and gender roles during the 17th, 18th, and 19th centuries, emphasizing key botanical works and their social implications. It highlights the importance of scientific botanical works including that of the so-called “Father of Botany” is Theophrastus of Eressus, Nehemiah Grew’s *The Anatomy of Plants* (1676), Carl Linneaus’ *Systema Naturae* (1758), and Charles Darwin’s *The Descent of Man, and Selection Related to Sex* (1871). Additionally, the roles of Enlightenment thinking, female education, and changing perceptions of gender roles both in the public and private spheres. The role of female botanical illustrators has been well documented and gained more appreciation and recognition for their contributions to the field of the botanical sciences. However, the botanical sciences’ effects on human understandings of sexuality and the gender roles and societal changes which came from these revelations is not so often studied. In this paper I cover the change in modes of speaking about sexuality, effects on the education of women and children, gender roles and choosing of life and reproductive partners, the ways in which women used these new concepts in floriculture such as the Victorian Language of the flowers, and the representational nature of plants by women and society: art, literature, poetry, botanical illustration. The evolving discourse on human and plant sexuality illustrates both the challenging and reinforcing of gender norms, contributing to a broader understanding of gender and sexuality in society.

Abstract Name: Integrated Digital Workflows for Efficient Prosthetic Manufacturing

Background: While additive manufacturing has advanced prosthetic development capabilities, current methodologies lack systematic integration across the development pipeline. This fragmented approach leads to unnecessary iterations, material waste, and inconsistent outcomes, particularly when incorporating electronic components. Clinical workflows often involve redundant steps between measurement and final

fitting, creating inefficiencies that impact both practitioners and patients. Methods: This research proposes a unified digital workflow integrating high-resolution scanning (Artec Leo, $\pm 0.1\text{mm}$), AR-guided design modification, and standardized hardware configurations with Arduino integration. The methodology employs a Unity-based visualization system with modular socket design templates that adapt to custom scanned limb data. The framework streamlines the process from initial scanning through design modification to additive manufacturing. System validation will assess technical efficiency through scanning-to-print time and iteration reduction compared to traditional processes. Results: The integrated workflow aims to demonstrate feasibility of a streamlined process linking scanning directly to fabrication through standardized base models and modification procedures. By unifying previously disconnected processes, this approach seeks to establish a systematic methodology for reducing iterations between scanning, design, and final production. Conclusion: This research addresses fundamental workflow inefficiencies in prosthetic development by establishing and validating a standardized digital pipeline. The framework provides a technical foundation for advancing prosthetic manufacturing while maintaining necessary customization capabilities.

Abstract Name: Development and Demo of "Talking with My Classmates": An Interactive Social Story for Students with Autism

Middle/high-school students with autism spectrum disorder, specifically levels one and two, exhibit social communication deficits that impede their ability to build interpersonal relationships in classroom settings. Such students may hesitate to apply those skills because they may fear the negative effects of unintentionally poor social choices. A safe and playful alternative is socialization through an interactive social story (ISS). The presentation will overview my ISS's development, from script with narration and dialogue, to a wireframe diagram, to coding with the JavaScript library p5.js and the text-to-image AI service Midjourney. The presentation will focus on a demonstration of a working prototype. The prototype will encourage socialization through teaching four social skills: identifying appropriate conversation topics, choosing appropriate responses, conversing, and staying on topic. The prototype is set in a special education classroom. The narrator initiates the first social skill simply: "Pick a classroom topic to discuss with your classmate." The player engages in a brief simulated dialogue about the skill with a classmate character. Then the narrator poses a multiple-choice question. If in response the player chooses the correct answer, the narrator and classmate provide positive reinforcement. Otherwise, the narrator encourages the player to try again until the player chooses the correct answer. This process repeats for the three other skills. We hypothesize that after playing the prototype, players will improve in all four classroom social skills in direct proportion to the number of skills and number of times they play.

Abstract Name: Understanding and Predicting Conversational Toxicity on GitHub

Open-source software projects thrive on the involvement and contributions of individuals from different backgrounds. However, toxic language and negative interactions can hinder the participation and retention of contributors and alienate newcomers. This study aims to understand and predict conversational derailment leading to toxicity on GitHub. By analyzing issues and pull requests that contain toxicity, we explore the characteristics of toxic conversations, including tone-bearing discussion features, discourse elements, and the timing and participation of developers vs. users. We focus on derailment points in GitHub conversations, which are critical moments in discussions where they begin to turn unproductive and toxic. Among other findings from our study, we observe that derailment point comments often contain discourse elements like second person pronouns, negation terms, and tones of Bitter Frustration and Impatience. Based on these empirical observations, we propose a proactive moderation approach to automatically detect and address potentially harmful conversations before escalation. By using LLMs (large language models) via prompting, we develop a conversation trajectory summary technique that captures the evolution of discussions and identifies early signs of derailment. Our experiments demonstrate that prompts tailored to provide summaries of GitHub conversations achieve 76.67% accuracy in predicting conversational derailment, strongly improving over a set of baseline approaches. This method of generating conversation summaries provides an important advancement in LLM-based proactive moderation of open-source software platforms.

Abstract Name: Non-genotoxic anthracyclines as a promising strategy in osteosarcoma treatment

Osteosarcoma is the most common type of bone cancer in adolescents and young adults. All patients are treated with anthracycline-containing chemotherapy regimens, and treatment response dictates prognosis. Though genotoxic agents are a mainstay of treatment, addition of highly DNA-damaging agents such as etoposide or radiation to current regimens has failed to improve outcomes. This suggests that DNA damage response-independent mechanisms may mediate the effects of doxorubicin. Here we explore in vitro efficacy of anthracycline variants that lack genotoxicity and instead perturb epigenomic phenomena, dimethyl-doxorubicin and aclarubicin, as possible alternatives for doxorubicin in osteosarcoma treatment. In patient derived cell lines, we found that cell viability at 2hr and 72hr with these two agents was similar to doxorubicin. We evaluated levels of DNA damage via amount of H2A.x, and apoptosis with cleaved PARP demonstrating that dimethyl-doxorubicin induces lower levels of DNA damage than doxorubicin at each time point. Murine studies show that dimethyl-doxorubicin can be dosed much higher than doxorubicin without incurring toxicity. We conclude that non-genotoxic anthracyclines are a promising strategy in osteosarcoma.

Abstract Name: Their Story: Unveiling the Truth

In recent decades, the United States education system has shown favoritism for white students over black, indigenous, and people of color (BIPOC) students, particularly in history lessons for grades k-2. Despite public school populations becoming more diverse, BIPOC students have not, or were less likely to, see their race in history lessons due to some lawmakers thinking implementing BIPOC history will take away white people's history in lessons. The purpose of this research was to create a website that gave teachers access to positive and manageable ways to implement more racial perspectives into their history lessons without taking away the white perspective. This research utilized the evidence-based practices from books and online resources, which all promoted implementing more races into our history lessons. The knowledge gained from that went to writing the literature review portion of the project, which guided the lesson plans and resources for the website. The results of this work demonstrated that implementing more races into history lessons can be positive and add to the history stories that children learn about. Results also showed that all teachers can benefit from this work because of learning more about their students' backgrounds, which can help them be better teachers.

Abstract Name: The Pitfalls of Global Sensitivity Analysis: Exploring Local Variability Using Active Subspaces

Complex mathematical models provide a comprehensive representation of real-world phenomena but may present challenges for model calibration, identifiability analysis, and sensitivity analysis due to their high-dimensional parameter spaces and computational complexity. The use of active subspaces—a dimension reduction technique—enables us to bridge the gap between limited resources and model complexity by identifying the linear combinations of key parameters that most significantly impact model behavior. As such, active subspaces may be used for sensitivity analysis, which attempts to quantify the impact of each input parameter on the model output. However, this study reveals that global sensitivity metrics derived from active subspaces can be misleading, particularly when local sensitivities vary significantly across the parameter space. To quantify the discrepancies, we use two different metrics representing subspace- and subset-based approaches. For the subspace-based approach, we measure the distances between globally and locally determined active subspaces. On the contrary, for the subset-based approach, we calculate activity scores on both global and local scales, which can be used to rank the original parameters in terms of their influence on the model output. Our results demonstrate that local sensitivity metrics often provide active subspaces and parameter rankings that differ from the ones computed globally, capturing regionally distinctive behaviors that global metrics may overlook. This study offers a cautionary perspective on relying solely on global metrics for conducting sensitivity analysis that may have downstream impacts on tasks such as model calibration. Additionally, we propose guidelines for a more accurate parameter space exploration and ensuing sensitivity analysis.

Abstract Name: X-Ray Crystallographic Characterization of Non-Heme Diiron Enzymes

Enzymes are catalytic proteins that perform a wide range of biological functions. Non-heme diiron enzymes are a subset containing two iron ions in the active site, that are not bound to a porphyrin ring. Within the “non-heme diiron” classification, enzyme ‘families’ exist, and two such families are the Ferritin Diiron Oxygenases (FDOs) and the Heme-Oxygenase-Like Diiron Oxygenases (HDOs). The protein structures of these two families differ notably in their binding of the diiron co-factor: the FDO architecture consists of eight alpha-helices, of which four contribute amino acid ligands that coordinate the irons. In contrast, the HDO architecture consists of seven alpha-helices, of which three contribute ligands to coordinate the irons. While the general motifs are known, specific protein structures for many FDOs and HDOs remain uncharacterized. Here, we explore the structures of the N-oxygenase HrmI, an HDO, and the hydrazone N-oxidoreductase Dob3, an FDO, using X-ray crystallography. We have successfully obtained structural data for apo, mono-iron, reduced diiron, oxidized diiron, and substrate-bound states for HrmI. These structures show that the HrmI active site is highly dynamic and undergoes conformational changes that depend on the nuclearity and oxidation state of the cofactor. Dob3 is in the optimization phase with promising crystals, diffracting to around 7-10 Å. By solving the structures of HrmI and Dob3, we will compare the distinct protein structures of an HDO and FDO that both perform N-oxidation reactions. We expect these results to aid in understanding how conformational changes affect the mechanisms and biological function of HrmI and Dob3.
