Over the last few years, ChatGPT and AI have advanced tremendously in both academic spaces and the public. The misuse of these technological advancements in academic settings, such as on projects or papers, has been questioned. Previous studies have been conducted on how the influence of personality traits predicts the possibility of academic dishonesty. Some studies have used the trait models from the Five-Factor Model (FFM) of personality, which includes the five factors of Openness to Experience, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. Although the FFM has showed significant utility, recent research has revealed support for a six-factor alternative model of personality trait structure known as the HEXACO model (Ashton & Lee, 2007). This structure of personality contains the six factors of Honesty-Humility (H), Emotionality (E), Extraversion (X), Agreeableness (A), and Openness (O). The more impressive feature of this structure is the domain of Honesty-Humility or the so-called "H factor." This factor is unique to the HEXACO model and does not correspond directly to any factors of the FFM. The HEXACO model was used in a recent study by Greitemeyer & Kastemuller (2023), who explored the relationship between personality traits and the intention to use chatbot generated texts to commit academic dishonesty. However, sole use of the HEXACO model in this study is limiting. The purpose of this study, therefore, is to revisit the association between the intention to cheat and personality by relating intention to cheat using ChatGPT/AI to the six personality traits of the HEXACO model and the FFM. We expect the HEXACO model to account for more variance than the FFM in the prediction of academic dishonesty using these technological advancements.

Abstract Name: Unlocking Potential: Exploring the Question of Mental Freedom on Wellbeing

A. Problem: This study examines the effectiveness of the Mental Freedom coaching framework, designed to teach six cognitive heuristics with the intention of increased emotional resilience, coping skills, and personal autonomy (Olver, 2024). Mental Freedom centers around the application of William Glasser's Choice Theory to a proposed set of Basic Needs over six sessions (Olver, 2024; Marlatt, 2013; Wubbolding, 2011). Each session focuses on a different principle, beginning with an elaboration of Stephen Covey's writings on proactivity (Covey, 2004), reframed as Responsibility vs. Response-ability. The second principle introduces The Unconditional Trust Challenge, rooted in Choice Theory's assertion that behavior is purposeful (Christensen & Gray, 2002). The third principle explores the positive implications of selectively empowering self-talk, while the fourth poses the subjectivity of memory (Buchanan, 2007) as an opportunity re-write traumatic episodic memories (Wheeler, 1997). The next principle differentiates the discomfort of pain from its evolutionary purpose to prevent further harm. The final principal asks clients to recognize and appreciate life's gifts, lessons, opportunities, and wisdom (G.L.O.W.) (Demartini, 2002). B. Method: 23 Mental Freedom-certified counselors and life coaches will administer the Mental Freedom program to clients as the experimental condition, whereas clients in the control condition will attend six weeks of their pre-existing counseling. Each provider will administer the Scales of Psychological Wellbeing (Ryff, 1989) and Ways of Coping Questionnaire (Folkman & Lazarus, 1984) before and after the program. C. Results: We expect to find a significant difference between existing methods of coaching/counseling and Mental Freedom conditions upon comparing participant pre and post scores. D. Conclusions We expect that the present study will demonstrate a positive growth in self-acceptance and autonomy within the experimental condition, consistent with the Mental Freedom program's focus. Further research on the efficacy of Mental Freedom across levels of imminence for stress/trauma may shed light on its effectivity in various contexts.

Abstract Name: Collaboration in Process: Making the Dancer Visible

While creating my piece “Maximum Occupancy” for our conservatory’s Student Choreography Project, I chose to research ways in which a creative process in dance could be collaborative with the dancers so I could implement them more into my own choreographic process. The concept of my piece was heavily based on expression and individuality. I wanted to find a way to incorporate this concept not just in my choreography, but in how I worked with the dancers and included them in the space and the creation of the piece. In short, I wanted to find out how the dancers could be integrated into the work rather than just be a vessel for it. I reviewed multiple journal articles and found that tasking the dancers and utilizing improvisation would yield the desired results of giving the dancer autonomy in implementing their own perspectives on the concept of the piece, all while demanding engagement and presence from them. These methods will be demonstrated through videos of the process and performance during my presentation. After my process was over, I interviewed professional directors and choreographers who also facilitate collaborative processes to see how these compare to how I facilitated my own. I then interviewed dancers they have worked with, as well as the dancers I worked with, to gauge how effective these processes were at fostering collaboration. Overall, I will demonstrate how inciting collaboration is much more than the compositional methods used, but requires constant conversation with the dancers and the maintenance of an environment that encourages acceptance, exploration, discovery, and understanding.

Abstract Name: Ethanol Exposure Impacts Cardiac Development and Function in Zebrafish

Ethanol is commonly used for sterilization and disinfection in the clinical setting, and is present in alcoholic beverages when diluted. Chronic ethanol consumption has detrimental effects on organ systems such as the cardiovascular system, nervous system, and digestive system. This study focused on both the timing and concentration of exposure to experimental ethanol groups. We hypothesized that when compared to a control, higher ethanol exposure groups will show more extreme changes in cardiovascular morphology and have compromised cardiac function. Furthermore, we hypothesized that when zebrafish are exposed to ethanol early in their life cycle, they will be unable to overcome developmental and physiological deficits when compared to those exposed later in their life cycle. Zebrafish (*Danio rerio*) were placed at random into ethanol concentration groups (0.0%, 1.0%, 1.5%, 2.0%, and 2.5%) and timing groups (12-24hpf, 24-48 hpf, and 48-72 hpf). Development, morphology, and physiology of the cardiovascular system were assessed. Through observations over seven days, it was seen that ethanol causes concentration-dependent morphological abnormalities. It was determined that there was a significant difference in the average body length of embryos exposed during 12-24hpf and 24-48 hpf exposure periods. Pericardial diameter and heart rate were also significant across exposure periods at certain experimental concentrations. Further research will need to be conducted to properly analyze time as a variable to assess cardiac development during exposure to experimental ethanol concentrations.

Abstract Name: Exploring the versatility of viral evolution and immune evasion through selective pressure

Viruses are small subcellular agents categorized as strict intracellular parasites that can only multiply when inside of a susceptible host cell. Viruses use attachment proteins to gain access into the host cell, an event that can be blocked in presence of neutralizing antibodies generated by our immune system through natural exposure or immunization. The ability of viruses to quickly alter the composition of their attachment protein through mutations allows them to escape from antibodies—creating a major public health problem as oftentimes these mutations limit the effectiveness of immunizations over time. Notably, viral evolution has limitations as genetic flexibility is limited to biochemical constraints and, accordingly, certain genetic viral sequences remain relatively constant for viruses to maintain their fitness and thus represent ideal therapeutic targets. My research focuses on analyzing the genetic and protein sequences of mammalian Reoviruses that are or become insensitive to antibody-mediated neutralization. For this, we infected human cells grown in vitro with different reoviral strains in presence or absence of a neutralizing antibody and assessed their sensitivity to this antibody through immunofluorescence microscopy and immunoblotting approaches. We have successfully determined the sensitivity of some, but not all, strains to this antibody. In addition, we are promoting the emergence of novel Reovirus variants through serial passaging in presence of antibodies to identify novel acquired mutations that allow them to evade this selective pressure. These so-called “escape mutants” will soon be analyzed through genetic sequencing of their attachment protein to ultimately determine a consensus sequence amongst the mutant progeny. Our results will provide insights into the balance between flexibility versus constraints of viral evolution.

Abstract Name: Brushstrokes of Insight: Improving Patient Care Through the Lens of Art

There has been a growing interest in integrating art education into healthcare academic programs. This literature review analyzes scholarly articles on the relationship between art history and its integration with medical and scientific practices, examining how the integration of art creation and analysis can enhance the study of science. The hypothesis is that this integration will enhance researchers' and students' medical and scientific skills, ultimately leading to improved patient care. During the Renaissance period, the fields of medicine and art progressed together through methods centered on meticulous observation of the human body. Artists, anatomists, and doctors shared curiosity and passion that led to innovative advancements. A significant development in Renaissance art was the use of aerial perspective and realism, which inspired artists to engage in detailed observation and studies of the human body, often in collaboration with the pioneering anatomists of the time. This visual scrutiny in art was linked to medical breakthroughs during the Renaissance. Artists often portrayed physical conditions before medical science had identified the corresponding diseases, highlighting the important role of observation for clinicians. Research has shown that integrating art, both in analysis and creation, into the health sciences curriculum has been highly advantageous for clinicians, enhancing observation skills, critical thinking, and a more comprehensive understanding of the patient. These improvements are facilitated by the neural connectivity that develops through engaging with art and refining one's discerning eye. The frontal lobe, crucial for decision-making in patient care, has been shown to develop improved connectivity as a result of engaging with art. It becomes evident that engagement with art offers significant advantages to clinicians today. It is crucial to maintain the connection between art and medicine, as seen during the Renaissance.

Abstract Name: Minimal Forts of Cartesian Products of Graphs

Zero forcing is a color change game played on the vertices of a graph. It has applications in the study of quantum systems, power grids, linear algebra, and various other fields. Graph forts are an important subject in the study of zero forcing. A fort F of a graph G is defined to be a nonempty subset of the vertices of G such that no vertex not in F is adjacent to exactly one vertex in F . It has been shown that a fort of a graph is the complement of a failed zero forcing set, making it interesting to study the minimal forts of graphs. Previous research in this area has placed bounds on the cardinality of the minimum fort of a Cartesian product of graphs based on the Cartesian product's factors. This presentation will prove and demonstrate new techniques for constructing minimal forts of a Cartesian product of graphs using minimal forts of its factors. It will focus on how these techniques can be used to generate minimal forts of large hypercubes from minimal forts of smaller hypercubes.

Abstract Name: Control of Minimally Actuated Quasi-Passive Bipedal Walker

This research project aims to explore and enhance the control systems of quasi-passive dynamic bipedal walkers at different scales, focusing on improving their robustness and agility in varied terrains. At small scales, motor scaling laws and mechanical design constraints necessitate fewer actuators, which limits both torque output and controllability. Each actuator must consequently be precisely controlled by adaptable algorithms. We present a Proportional-Integral-Derivative (PID) control strategy for Mugatu, a single degree of freedom (DOF) hip-actuated bipedal robot, designed to achieve straight-line walking while maintaining stability and maximizing velocity. In our robot, the single DOF is an actuated joint at the hip, the only control input into the system. Our approach integrates proprioceptive joint feedback with an Inertial Measurement Unit (IMU) to measure body state and the robot's spatial awareness. The sensory integration enables real-time monitoring of the robot's orientation and acceleration, allowing adjustment during various phases of the gait cycle. The research aims to provide a comprehensive analysis of underactuated biped dynamics, examining how physical parameters such as mass distribution and spherical foot profile influence the system's behavior. This work explores gait optimization strategies maximizing walking stability and speed of quasi-passive dynamic walkers across different terrain types, including slippery surfaces and inclines. These findings have implications for applications requiring efficient bipedal locomotion in confined or intricate spaces, such as industrial inspection, and disaster recovery tasks. The developed control framework provides a foundation for designing more capable small-scale walking robots that can operate effectively in real-world environments while maintaining simplicity in mechanical design.

Abstract Name: Cross-Border Stem Education: Evaluating The Role Of Technology In Supporting Border-Residing Students In South Texas

Transborder students, also known as cross-border students, commute daily from Mexico to the United States to pursue higher education. This research examines the

unique challenges faced by transborder students commuting from Nuevo Laredo to colleges in South Texas, focusing on transportation issues, academic performance, and technological support. Surveys of both transborder and local students revealed significant commuting challenges, including long border wait times, unpredictable transportation schedules, and language barriers. A literature review was conducted to explore potential technological solutions to enhance academic support for all students. Transborder students reported longer commutes and higher stress levels compared to local students, with 35.8% always experiencing stress due to border delays and 31.3% occasionally feeling stressed. These challenges negatively impacted academic performance, with 47.7% reporting adverse effects. Additionally, 95.5% of transborder students felt disadvantaged compared to local peers, citing limited campus resource access, inflexible schedules, social integration difficulties, and insufficient academic support. The study underscores the need for institutions to provide targeted support for transborder students. Survey responses indicated that 26 students believed their college offered inadequate support, and 18 felt only partially supported. Suggested improvements include dedicated bus services, flexible schedules, and faculty accommodations for border delays. Technological solutions such as Cross-Cultural Intelligent Language Learning Systems (CILS), speech-enabled language translation, collaboration platforms, and video conferencing tools were identified as promising enhancements. These findings highlight the importance of implementing dedicated transportation, streamlined border-crossing procedures, and expanded academic resources to better support transborder students.

Abstract Name: Erasmus: The Radical Reformer in the Protestant Revolution

This paper hopes to better understand the place of Desiderus Erasmus in the Protestant Reformation by redefining many aspects of the Reformation and the Reformation itself. Drawing on current scholarship and analyzing the works of Erasmus, alongside those of prominent reformers such as Martin Luther, this paper will argue that Erasmus should be recognized as a radical reformer within the context of the Reformation. While differing in approach from Luther, Erasmus' critiques of the Catholic Church and advocacy for a return to the authentic teachings of Christianity demonstrate his significant impact on religious reform during this period. Furthermore, this paper will redefine reformers such as Calvin, Luther, and Zwingli as revolutionaries instead of reformers as well as the Protestant Reformation may be more aptly named as the Protestant Revolution due to the impact of the previously named individuals. This paper will analyze Erasmus' character as described by himself through his *Compendium Vitae* (1524). Coinciding with Erasmus' *Vitae* there are four of his main works that this paper will analyze, *The Handbook of the Militant Christian* (1503), *The Praise of Folly* (1511), and *On Mending the Peace of the Church* (1533). These works will express Erasmus' beliefs and his stance on the papacy while further expressing Erasmus' characteristics that are established in his *Vitae*. Furthermore, Erasmus' *On Free Will* in 1524 will be contrasted with Luther's *The Bondage of Will* 1525 to exemplify the differences between the two scholars and why Luther is a revolutionary and Erasmus is a radical reformer. Overall, the contrasting focus of Erasmus' works compared to revolutionary works like Luther's will show how Erasmus is a radical reformer not a revolutionary. Since Erasmus was a reformer during a revolution this hopes to discern Erasmus' impact during his time and his legacy on modern theology and education.

Abstract Name: Cloning, Overexpression, and Functional Analysis of a *Karenia brevis* Caspase 3-like Gene in *E. coli* using an Alternate Start Codon

Blooms of the toxic dinoflagellate *Karenia brevis* can persist in the Gulf of Mexico for months before their sudden termination. Although the mechanism remains unknown, programmed cell death (PCD) is one hypothesis for *K. brevis* bloom termination. Previous work has shown that *K. brevis* displays hallmarks of PCD, including DNA fragmentation and caspase activity. Caspases play a critical role in PCD by breaking down polypeptides and facilitating cell destruction. Recent work has identified a potential caspase candidate (Kb-cas3) that contains all functional components of a true caspase, including P10 and P20 domains, conserved active sites, and proteolytic cleavage sites. Previous work did not yield strong overexpression of Kb-cas3 in *E. coli* to determine gene function. This project aims to clone Kb-cas3 into a different expression vector to improve overexpression in *E. coli* for future functional characterization of this gene. Kb-cas3 was amplified using PCR, inserted into a pET46 Ek/LIC vector, and transformed into NovaBlue-competent *E. coli*. Plasmid DNA was isolated, and a restriction digest confirmed the inserts. BL21 competent *E. coli* cells with pLysS were transformed with the pET46/Kb-cas3 plasmid. Cultures were grown to mid-log phase at 37°C with shaking. Prior to induction, samples were taken, centrifuged, and pellets were stored at -80°C. Protein expression was induced with IPTG and cultures were incubated overnight at 20°C with shaking. Samples were taken again after the overnight incubation. Cells were lysed and proteins were visualized using SDS-PAGE. No bands of the expected protein sizes were observed in the induced samples. Currently, the expression protocol is being optimized and alternative hosts optimized for expressing eukaryotic genes are being tested. Results of this work will also be presented. Robust protein expression is the first step in characterizing Kb-cas3 function and understanding its potential role in bloom termination.

Abstract Name: Cultural Diplomacy: K-Pop Artists' Role in South Korea's Global Strategy

The country of South Korea has risen on the global stage due to its push for soft power. Soft power refers to a country's ability to persuade or attract others through its cultural and political values, rather than coercion or military power, which would be considered hard power. One aspect of South Korean soft power that has

gained international recognition is South Korean popular music, also known as K-Pop. Since its rise in the early-2010's, K-Pop has captured the hearts and minds of people world-wide, and it is because of this popularity that has led it to become a frequent subject of interest in the field of global studies and international relations. The globalization of K-Pop and its expansion of Korean culture to the entire world has had an impact on improvements in diplomatic relations between South Korea and other countries. The purpose of this study is to understand how K-Pop artists have contributed to helping South Korea create diplomatic relations with other countries by analyzing three case studies in which K-Pop artists have either performed in different countries to showcase their music and culture or have attended/spoken at international events to represent South Korea and speak on important issues. Through the analysis of these three case studies, we found that the Korean Wave defines South Korean soft power which is why South Korea's current diplomatic standing is at an all-time high. Furthermore, we found that all foreign engagements made by K-Pop idols will always be imbued with political significance. In conclusion, this study demonstrates how South Korea uses its cultural power, such as K-Pop artists, as a means of building positive international perceptions and strengthening its diplomatic relationships with other nations.

Abstract Name: Do Rewards Matter for Student Participation in Optional Laboratory Skills Assessments?

Students can come to an introductory General Chemistry course with little to no experience with hands-on laboratory skills. This difference in prior experience can be exacerbated when introductory laboratory experiments are done in pairs or groups where each student may not perform each hands-on skill for completion of the experiment. To probe student prior experience and assess their achievement of basic hands-on laboratory skills, we designed and modified authentic skills assessments. These assignments (with rubrics) require students to record and submit a narrated video of themselves properly performing that skill. Students were queried about their experience and confidence level with each skill prior to the course and following the video assignment. A pilot study with a small (n=11) summer section of General Chemistry 1 and 2 was used to develop and test these authentic skills assessments. Following the pilot study, four new laboratory skill assessment modules were deployed in a large (n=103) General Chemistry 1 course in the fall of 2024 to investigate student motivation for completing these assignments. Throughout the fall semester, students in each laboratory section of the course earned laboratory credit and some earned an additional reward for successful completion of each module. Additional rewards included a digital badge or a physical sticker. Upon completion of the fall semester, student data on participation, successful completion of modules, and pre/post survey responses will be analyzed. Changes in student confidence and experience with each laboratory skill will be presented, and any impact of rewards on student completion will be discussed.

Abstract Name: Investigating Nitinol Flow Diverters for Aneurysm Treatment Using Laser Precision Machining

Flow diverters have established themselves as a highly effective endovascular technique for treating brain aneurysms, traditionally employing braided designs made from materials like nitinol and chromium-cobalt alloys. However, the structural flexibility of these braided flow diverters (FDs) remains constrained. This study investigates the feasibility of fabricating finely meshed, non-braided nitinol FDs using precision laser machining, aiming to optimize laser parameters to enhance the fabrication quality and design versatility of these devices. A precision fiber laser machine was utilized to create fine pores, with systematic adjustments to laser power, focal distances, horizontal speed, passes, and cooling media (air and water). Post-fabrication, the FDs underwent polishing in a custom-built tumbler, and their surface quality was analyzed using a scanning electron microscope (SEM) and high-resolution imaging. Surface burning was quantitatively assessed on a 1-to-10 scale based on visual inspection. The findings revealed that laser power and focal distance were pivotal in minimizing surface burning and bulge formation. While water cooling provided additional flexibility, its frequent evaporation required continual refills, making air cooling—with carefully calibrated power and passes—a practical alternative for achieving burn-free, high-quality FDs. This investigation offers critical insights into the production of non-braided nitinol FDs, paving the way for advancements in aneurysm treatment by enabling greater design precision and control in the fabrication process.

Abstract Name: The Implications of Latent Toxoplasmosis

Background: *Toxoplasma Gondii* (TG) is a widespread protozoan parasite that remains dormant within its host for life, leading to asymptomatic presentation with a high seroprevalence. Infection with TG in an individual is called Toxoplasmosis (TP). Horizontal transmission commonly occurs through the fecal oral route via exposure to undercooked meat, unwashed produce, contact to contaminated soil or water, and consumption of unpasteurized milk. Additionally, cats are the definitive hosts where sexual reproduction of TG occurs and exposure to cat fecal matter can be infectious. It is estimated that worldwide infection is approximately 30%. Growing literature suggests that latent infection, which exists as tissue cysts particularly within the brain, can be linked to increased rates of numerous psychiatric conditions such as depression, anxiety, schizophrenia, Dementia, Parkinson's, epilepsy, bipolar disorder, and migraines. The parasite's effects on dopamine and serotonin are believed to exacerbate mental health conditions, depleting key nutrients. This points towards the benefits of supplementation with folic acid and vitamin B-12. Purpose: This project aims to provide an educational campaign to nurses and mid-level providers about latent TP and its association to psychiatric disorders and neurodegenerative diseases. Lifestyle interventions and the benefits of promoting supplementation of folic acid and B-12 will be included in the education. Methods: A seminar will be held for health care science professionals. A survey and knowledge check will be conducted afterwards. Conclusion: Evidence suggests a strong association between latent TG infection and various psychiatric disorders. Seroprevalence is high, and vulnerable populations are especially at risk. Public health interventions that promote education, hygiene, food safety, and supplementation are expected to improve health outcomes. Keywords: *Toxoplasma gondii*, Toxoplasmosis, Seroprevalence, Cognition, Folate

Abstract Name: Exploring the Relationships among Nicotine Use Expectancies and Disordered Eating Attitudes and Behaviors in College Students

Introduction: Nicotine use among young adults is a relevant health concern. Recent studies have shown an increase in alternative nicotine devices such as vapes and nicotine pouches. Also relevant in this population, are disordered eating behaviors such as bingeing, purging, and calorie restriction. The current study will examine the motives underlying nicotine use and the relationship to disordered eating attitudes and behaviors. Methods: Data collection is ongoing with over 300 college students at the University of Wisconsin – Whitewater. Participants completed a survey assessing frequency of nicotine use, four types of nicotine use expectancies such as negative smoking consequences, positive reinforcement, negative reinforcement, and appetite/weight control as measured by the Short Form Smoking Consequences Questionnaire and modified versions for vaping and nicotine pouches respectfully, and disordered eating attitudes and behaviors as measured by the Eating Pathology Symptoms Inventory. Results: Although results will not be available until the spring of 2025, it is expected that higher scores in subscales of disordered eating attitudes and behaviors related to cognitive restraint, binge eating, purging, and negative attitudes towards obesity will predict higher prevalence of nicotine use. It is also hypothesized that there will be a correlation between nicotine use as an effort of weight and appetite control and these aforementioned disordered eating attitudes and behaviors subscales. Results gathered from this study will help to understand potential motives for nicotine use within the population of young adults exhibiting disordered eating attitudes and behaviors. This research aims to provide insight into the relationship between these two health harming behaviors to inform potential prevention and intervention strategies.

Abstract Name: Law Enforcement Perceptions of Sexual Assault and Sex Trafficking.

Understanding law enforcement perceptions of sexual assault and sex trafficking victims is essential for improving victim advocacy and case outcomes. This study explores how Tennessee law enforcement officers assign blame, interpret victim and perpetrator demographics, and assess scenarios of sexual assault and trafficking. Misconceptions, such as rape myths and trafficking stereotypes, can undermine investigations, exacerbate victim trauma, and limit arrests and convictions. This research contributes to the growing body of literature on victim-centered approaches by addressing gaps in understanding how law enforcement biases impact case outcomes. The research seeks to identify these biases and their impact, offering insights to improve training and victim-centered approaches. This study utilizes a mixed-methods approach, by using a Qualtrics survey distributed to law enforcement agencies across all Tennessee counties. The survey includes vignettes varying by factors such as victim and perpetrator demographics, type of non-consent, and contextual circumstances of the incident. Respondents also provide demographic information and report whether they have received related training. Quantitative data will be analyzed using R to examine patterns in perceptions, while qualitative responses will be coded in NVIVO to identify themes reflecting acceptance or rejection of myths. The study hypothesizes that female officers will show lower rates of myth acceptance and that minority and low-income victims will receive differential treatment in responses. Results are expected to highlight the prevalence of misconceptions and areas for improvement in law enforcement training. Findings will be discussed in the context of enhancing training programs and shaping policies to mitigate misconceptions and promote equitable justice. By addressing these issues, the study aims to advance victim advocacy and inform policy changes that promote equitable and effective handling of sexual assault and trafficking cases.

Abstract Name: Co-abuse of Nicotine and Ethanol: Effects on Working and Long-Term Memory Driven by Appetitive vs Aversive Stimuli

Nicotine and ethanol are two of the most commonly used drugs in society and are often co-abused. Despite this common use, there is little information known about the combined interactions of nicotine and ethanol in the brain. Therefore, this current study analyzed the combined actions of nicotine and ethanol in the brain and how this use affects working and long-term memory in the presence of an appetitive versus aversive stimulus. Two commonly used measures of working and long-term memory in rodents are the radial arm maze (RAM) and passive avoidance. Rats were trained on the radial arm maze for 2 weeks to ensure their learning of the maze. Half of the arms were baited in the 8-arm RAM to serve as the appetitive stimulus. A working memory error was counted if the rat entered an arm that was already entered during that trial. Meanwhile, long-term memory errors were counted if the rat entered an arm that was not baited. The passive avoidance test occurred in a 3-compartment conditioning chamber in which one side was paired with a shock (aversive stimulus) and the amount of time the rats avoided the shock-paired chamber in the following session was recorded to test for long-term memory. The control group consisted of an injection of saline + saline. Meanwhile the experimental groups consisted of saline + nicotine, saline + ethanol, and nicotine + ethanol in a within-subject experimental design to account for any possible differences in the subjects. Both drugs act on the meso-dopaminergic system and nicotine is predicted to reduce the alcohol-induced memory impairments that occur during co-use. If nicotine can reduce the memory impairments caused from alcohol use through interactions in the reward system, then memory performance in the RAM will be enhanced and latency to enter the shock-paired chamber will be longer.

Abstract Name: Role of *klf17* in lateral line development of Zebrafish

How genes regulate pattern development during development is a fundamental question in biology. Our laboratory is researching the function of *klf17* during lateral line development in Zebrafish. The lateral line is a sensory organ, unique to fishes and amphibians, that allows individuals to sense vibrational movements in water. Proper development of the lateral line involves specifying individual sensory organs, known as neuromasts, at specific locations in the embryo. This highly stereotyped pattern is regulated by a lateral line primordium that migrates from anterior to posterior on the body depositing neuromasts as it moves. My undergraduate thesis work has shown that *klf17* mutations result in striking defects to neuromast patterning during embryogenesis. The first 3 neuromasts in *klf17* mutants are completely lost, however, more posterior neuromasts are variably present across embryos. Furthermore, I have shown that loss of *klf17* leads to fewer differentiated sensory hair cells and fewer stem cells within neuromasts suggesting *klf17* affects either deposition of neuromasts and/or stem cell differentiation and neuromast fate. To further explore the mechanisms of *klf17*, I used HCR to show that the lateral line primordium loses polarity and may exhibit migration and/or deposition defects. This would mechanistically explain why *klf17* mutants have fewer lateral line neuromast. Understanding the role of *klf17* in development of sensory organs will inform research in cancer biology, immune system functioning, and multiple diseases.

Abstract Name: Effects of Wim Hof's Breathing Technique on Aerobic Capacity

Traditionally, the sympathetic nervous system has been considered beyond conscious control. However, evidence suggests that certain individuals, through specialized training techniques and mental focus, can exert voluntary control over sympathetic responses (Cryer, et al., 1980). Research has primarily focused on meditation, biofeedback, and specific breathing techniques. The Wim Hof breathing technique claims to influence the sympathetic and parasympathetic branches (Kox, et al., 2014). Despite the growing interest in the potential health benefits of the Wim Hof Breathing Technique (WHBT), there is a lack of research examining its effects on aerobic performance as measured by VO2 max. The purpose of this study is to investigate the effects of WHBT on VO2 max in healthy adults. Participants will include men and women ages 19-23. A one-sample design will be used. A baseline Balkeware Submax treadmill test will be conducted using a gas analyzer mask to allow participants to gain comfort with procedures before any experimental treatments are applied. The independent variable will be the breathing method which includes box breathing and WHBT. The order of the breathing methods administered will be randomized. The dependent variables will be VO2 max estimation and heart rate recovery time. A Repeated Measures ANOVA analysis ($p < .05$) will be used to detect significant differences between each trial. It is hypothesized that WHBT will result in a significant increase in estimated VO2 max in healthy adults compared to the box breathing and control conditions. In conclusion, this study may suggest that utilization of the WHBT before engaging in aerobic exercise may improve performance. Future research might look at specific athletic applications of the WHBT as an ergogenic aid. Data is currently being collected. IRB Protocol Number: #471735

Abstract Name: Analysis of U.S. Colleges and Universities to Assess the Feasibility of Heating with Wood at Northern Michigan University

In the past few decades, there has been an emphasis on trying to mitigate the amount of greenhouse gas (GHG) emissions. At Northern Michigan University (NMU), the Ripley Heating Plant contributes about 60% of GHG altogether from burning natural gas. NMU has a sustainability goal of reducing their GHG emissions 25% by 2030 and 50% by 2040. There is consideration to make a switch from natural gas to wood chips. Natural gas is a cleaner fuel source when comparing to coal and petroleum, but it does not mean it is sustainable. A more sustainable resource is wood; this has been an important resource in cooking food, building homes, and heating homes for centuries. The goal of this project was to identify the benefits and challenges in using wood and reviewing journal articles on other universities that have switched to wood as biofuel. U.S. colleges and universities were found via Google, and the Sustainability Tracking Assessment and Rating System (STARS). Institutions were categorized into those who currently use wood, those that formerly used wood, and those who considered using wood. Interviews were set up, interview protocols were created, and information was analyzed into common themes and trends. Similarities and differences in wood implementations and document analyses were discussed. Collecting information on the use of local wood will allow future decision makers in choosing the most sustainable option for heating at NMU. This report aims to assist in research for conducting a feasibility study on wood-based heating systems.

Abstract Name: Misinformation and Public Health: A Framework to Address Issues and Challenges

Literacy is a vital skill necessary to successfully navigate healthcare systems and, more broadly, the new digital landscape we inhabit. Healthcare systems in place require advance digital literacies, yet many individuals lack a basic understanding of how to improve their literacies (digital, media, health, critical thinking, etc.). Compounding issues have arisen as a result of illiteracy and subsequent exacerbated inequities (e.g., mis/disinformation, the Loneliness Epidemic, challenges navigating healthcare systems). These issues threaten to destabilize core societal functions of institutions and social systems. Building on prior frameworks that connect digital literacies and eHealth, the research will build out a comprehensive framework conceptualizing new connections relevant to the modern digital age. An updated version of the eHealth Lily Model, a comprehensive, multifaceted overview of multiple literacies, will be developed under the guidance of experts in digital health literacy and epidemiology. A synthesis of the literature will lead to the creation of an adapted model that includes important concepts such as inclusion, equity, & accessibility. Next, a focus group of experts will be established via mentor-guided purposive sampling and their feedback will be used to make improvements throughout each iteration of the model. The resulting expanded framework will

demonstrate to researchers and experts of all fields the role that literacy plays in our growing understanding of how to address these challenges. In the process, this research may improve interventions, encourage educational efforts, and empower citizens with the literacy skills they need to resolve problems.

Abstract Name: A Microphysiological System to Quantify Astrocytes and Microglia Communication

Neuroinflammation plays a critical role in cognitive decline and the progression of neurodegenerative diseases, such as Alzheimer's disease. In the central nervous system (CNS), microglia and astrocytes regulate immune responses, mediating neuroinflammation. This study presents a microphysiological system designed to investigate astrocyte-microglia communication under inflammatory conditions. Using microfabrication techniques, such as photolithography and soft lithography, we developed a microfluidic device to quantify communication between immortalized human astrocyte and microglial cell lines. The microfluidic device was designed with a microglia cell chamber and an astrocyte cell chamber that were interconnected by a series of 10 micrometers by 10 micrometers migration channels. The system enabled real-time observation of cellular interactions under controlled inflammatory conditions, addressing the limitations of traditional cell culturing techniques. It reduced costs associated with culturing large quantities of human cells and reliance on animal models, while also improving experimental precision. Validation of the device demonstrated its ability to replicate the dynamic interactions between astrocytes and microglia under inflammatory conditions. Using time-lapse imaging with a Nikon TiE2 microscope and biochamber, we quantified migration velocities, acceleration, and directionality of both human astrocytes and microglia. The system allowed for precise observation of cellular migration, morphological changes, and responses to cytokine (IL-4) exposure in a controlled microenvironment, confirming its ability to model neuroinflammatory processes. Future applications include the use of digital droplet PCR (ddPCR) to quantify inflammatory markers and further explore signaling pathways involved in neuroimmune interactions. By bridging the gap between standard cell cultures and murine models and human clinical trials, this microphysiological system advances preclinical research in CNS diseases and offers a platform for identifying therapeutic targets to address neuroinflammatory processes.

Abstract Name: Aqueous Synthesis of Copper Nanoparticles for Lightweight Semiconductors

This research investigates a novel, aqueous synthesis procedure to create copper nanoparticles that can be

used in the development of lightweight semiconductors. The study explores how different variations of ligand type, ligand amount, and temperature affect the morphology and properties of synthesized nanoparticles. Previous research that follows a similar approach to copper synthesis has primarily relied on organic solvents, a comparatively more costly and unsustainable process when scaled up for commercial application. The synthesis employs a bottom-up methodology, starting with copper ions in aqueous solution and creating nanoparticles through a controlled experiment in a nitrogen environment. In order to optimize the procedure to produce pure copper as opposed to copper oxides, UV-Vis spectroscopy is utilized to systematically determine subsequent variations in the molecular weight and amount of the ligand polyvinylpyrrolidone (PVP). Samples are then prepared for more detailed characterization and analysis through centrifugation and sonication of the solution prior to vacuum filtration. Preliminary findings suggest that PVP of a higher molecular weight will produce pure copper, however it is anticipated that the longer ligand also inhibits conductivity. Thus, larger amounts of lower-weight PVP may be required to prevent oxidation while demonstrating other properties characteristic of copper. Pure copper nanoparticles can ultimately lead to the development of lightweight semiconductors that allow for the replacement of other materials. An optimized aqueous synthesis procedure can therefore enable eventual sustainable production and potential cost savings for a wide breadth of industries, including aerospace and automotive fields.

Abstract Name: Early Technology Exposure and Academic Performance in Generation Alpha: Reduced Attention Span and Impact on Handwriting

The increasing prevalence of handheld devices in the lives of young children inspired this research, particularly regarding their potential impact on attention spans and cognitive development in Generation Alpha. Early exposure to tablets and smartphones before the age of seven coincides with critical periods of neuroplasticity, during which the brain is highly receptive to environmental influences. This matters because attention and cognitive skills formed in childhood lay the foundation for academic success and long-term personal development, and the shift toward digital learning platforms in schools may have significant consequences. This study aimed to investigate whether early exposure to handheld devices influences attention spans and classroom engagement in young children. To explore this, I examined existing research on early childhood screen time, analyzed developmental studies on neuroplasticity, and reviewed educational trends highlighting the integration of digital platforms in learning environments. Preliminary findings suggest that excessive early exposure to handheld devices may be linked to shorter attention spans and challenges in maintaining focus during traditional classroom tasks. Conversely, moderate and purposeful use of digital tools can enhance cognitive skills like problem-solving and adaptability. These findings suggest a nuanced relationship between screen time and cognitive development that depends on factors such as the type and amount of digital interaction. As handheld devices continue to shape educational practices, it is essential to strike a balance that leverages the benefits of digital learning while mitigating its potential drawbacks. Future research should focus on developing guidelines for healthy digital engagement in early childhood and further exploring how technology can support, rather than disrupt, attention and learning processes.

Abstract Name: Asteroid Mining: The Next Big Thing or a Gimmick?

Asteroid mining, a sci-fi concept that is rapidly emerging as a potential cornerstone for humanity's expansion into space. This paper explores the economic, technological, and legal challenges of asteroid mining, by examining its feasibility, potential benefits, and other challenges that could hinder its development. Some argue that mining asteroids could provide essential resources and reduce dependency on Earth leading to sustainable space colonization, but critical challenges still remain. Through a review and rational comparison of recent advancements and setbacks, this paper presents an analysis of the potential of asteroid mining; findings suggest that while asteroid mining holds significant potential for the future of space exploration, it is hindered by unresolved challenges in technology, economics, and international law, which require further research and innovation.

Abstract Name: The Moderating Role of Coping Strategies Between Work-Family-School Conflict and Academic Stress in Latinx Students

A growing number of Latinx college students are reporting lower GPAs and higher dropout rates (Fernandez et al., 2023). Stressors, specifically academic stress, are associated with poor academic outcomes (Fernandez et al., 2023). Limited research has examined the impact of work-family-school conflict on academic outcomes. Latinx college students face unique challenges that exacerbate stress experienced at school (Burgos-Cienfuegos et al., 2015). For example, family obligation values, defined as attitudes toward respecting and assisting families, contradict individualistic academic expectations from schools (Burgos-Cienfuegos et al., 2015). Given the importance placed on family, Latinx college students deal with various roles and demands that conflict and heighten stress (Bellare et al., 2023). Additionally, work and school demands contribute to college students' work-school conflict (Wan et al., 2022). Role strain theory posits that individuals allocate finite resources, including time and energy, across roles; however, a lack of these resources may increase role strain (Goode, 1960). Role strain theory explains how individuals seek mechanisms to reduce role strain, like coping, to reduce stress. The current study aims to examine the association between work-family-school conflict and academic stress and whether adaptive and maladaptive coping methods exacerbate or buffer this association. Latinx college students (N=323) were recruited from a university in central California. Participants were primarily US-born (85.9%) and female (77.3%). Work-family-school conflict was separated into the following subscales: work-to-school conflict, school-to-work conflict, family-to-school conflict, and school-to-family conflict. Correlation and moderation analyses were conducted. All work-family-school conflict subscales were positively associated with academic stress. Only maladaptive coping moderated the association between work-to-school conflict and academic stress. Latinx college students often face work-family-school conflict and targeting maladaptive coping may inform interventions that aim to reduce academic stress. Considering Latinx college students report worse academic outcomes, understanding how work-family-school conflict impacts academic outcomes is necessary to address educational disparities.

Abstract Name: Hot Electron Chemistry on Bimetallic Gold Core-Shell Nanoparticles

With the rise of CO₂ emissions, a significant global climate challenge has emerged such as global warming, driving the need for innovative solutions. One approach to reducing CO pollution involves converting CO or CO₂ into methanol (CH₃OH) using catalysts, which lower the reaction barrier for the reaction and increase efficiency. Plasmonic photocatalysts offer a promising method for producing green fuels, including methanol, by enhancing light-driven reactions that convert CO₂ into valuable chemicals. Our plasmonic photocatalysts are composed of bimetallic transition metal core-shell nanoparticles, which have unique optical properties, such as enhanced light absorption and localized surface plasmon resonance (LSPR), as well as catalytic properties like increased reaction rates and stability. These properties potentially boost their photocatalytic efficiency compared to traditional catalysts. We focus on bimetallic core-shell nanoparticles with Gold (Au) as the core metal. As of current, rhodium (Rh) and Ruthenium (Ru) have been used as the shell metal, and within this upcoming year the goal is to also incorporate nickel (Ni). These shell metals were selected because of their catalytic properties. Both Au/Rh and Au/Ru nanoparticles are synthesized through reflux reactions, followed by washing via centrifugation, and characterized using Scanning Electron Microscopy (SEM), Energy-dispersive x-ray spectroscopy (EDS), and Ultraviolet Absorption Spectroscopy (UV-Vis). To assess their photocatalytic efficiency, we plan to perform CO oxidation, as well as hydrogenation reactions, as these processes are crucial for understanding the nanoparticles' potential in green fuel applications. By studying these bimetallic core-shell nanoparticles, we aim to gain insights into their catalytic properties and assess their effectiveness in advancing green fuel technology.

Abstract Name: Advanced Chemical Vapor Deposition System for Silicon Nanostructure Fabrication in Lithium-Ion Battery Anodes

Developing silicon-based anodes for lithium-ion batteries (LIBs) represents a promising pathway to significantly enhance energy storage performance. Silicon, with its high theoretical capacity, has the potential to store up to ten times more lithium ions compared to traditional graphite anodes. However, the inherent challenges associated with silicon's large volume expansions (up to 400%) during lithiation and delithiation, which lead to mechanical degradation and reduced cycle life, have hindered its widespread adoption. This

study presents the design and implementation of an innovative Chemical Vapor Deposition (CVD) process aimed at overcoming these challenges by synthesizing silicon nanostructures. The custom-built CVD system, 'Evil Octopus,' enables precise control over gas flow, temperature, and pressure, utilizing a fully automated programmable logic controller (PLC) and human-machine interface (HMI). The synthesis involves reducing silicon dioxide (SiO₂) using magnesium (Mg) at elevated temperatures, followed by a carbon deposition phase to create a protective layer. The resulting silicon nanostructures are incorporated into a porous and mechanically strong matrix, which helps mitigate the effects of volumetric expansion during battery operation. Characterization techniques, including X-ray diffraction (XRD), scanning electron microscopy (SEM), and energy-dispersive spectroscopy (EDS), were employed to validate the morphology and phase composition of the synthesized nanostructures. The CVD system's automation capabilities provided uniform nanoparticle coatings, optimizing first-cycle efficiency and reducing first-cycle losses. This approach contributes to the advancement of next-generation lithium-ion batteries by improving energy density, essential for the widespread adoption of electric vehicles (EVs) in addressing climate challenges. Future work will focus on scaling the CVD process for industrial applications, ensuring consistent quality and cost-effectiveness for advanced energy storage technologies. By addressing the limitations of current LIB technologies, this work aims to pave the way for more sustainable and high-performing energy solutions, which are crucial for the future of clean energy and the universal adoption of electric vehicles.

Abstract Name: The Developments and Outcomes of Childhood Trauma

Childhood trauma is a significant issue associated with adverse mental, physical, and life outcomes, highlighting the urgent need for effective interventions and a deeper understanding of resilient factors. Although research has established its connection to long-term health challenges and maladaptive behaviors, gaps remain in tailoring interventions to diverse cultural, socioeconomic, and developmental contexts for optimal recovery. This study examines the relationship between childhood trauma and subsequent life outcomes by analyzing archival data from the Texas Department of Family and Protective Services (DFPS), Texas Government Dataset, and Statista. These datasets provided comprehensive insights into child welfare, foster care, and Prevention and Early Intervention (PEI) programs. The methodology of this study included an extensive literature review of scholarly articles and an analysis of the Texas Government Datasets. According to the Texas Government Dataset, 41,409 youth and 24,692 families benefited through programs such as Community Youth Development, Healthy Outcomes through Prevention and Early Support, Texas Home Visiting, and Nurse-Family Partnerships. Findings indicate that children who experienced trauma and participated in PEI programs demonstrated improved mental and physical health outcomes compared to those who did not receive such interventions. These results have significant implications for mental health professionals, policymakers, and educators. For practitioners, understanding the nuanced effects of trauma can inform personalized therapeutic approaches. Policymakers can leverage these findings to design interventions to create supportive environments for at-risk children. Lastly, educators, through targeted training, can better identify and support traumatized children, fostering resilience and recovery. This underscores the critical role of targeted, trauma-informed interventions in improving long-term outcomes for children and addressing key gaps in care strategies.

Abstract Name: Complexities of Claiming Indigeneity as Chican*s and US-born Mexicans

Does being Chican* or a US-born Mexican mean you are inherently indigenous? These communities' unique histories are one of the reasons behind an assertive answer to this question. This literature review examines the different arguments surrounding the complexity of claiming indigeneity as Chican*s and US-born Mexicans. The argument is that claiming indigeneity as Chican*s and US-born Mexicans can unintentionally contribute to the neglect of Indigenous struggles and experiences. US-born Mexicans (commonly called Mexican Americans) were included due to their similarities with Chican*s. To critically analyze this issue, the literary focus was placed on the historical junctions of the analyzed literature and the general arguments relating to Chican* Indigeneity and Indigenism. The historical junctures chosen were the Spanish conquest, Modern Nation-State Mexico, the Anglo conquest, and the Chicano movement. Then, both supporting and critiquing stances were examined for two questions: are Chican*s Indigenous? And is a potential claim beneficial? The gap found was that the content surrounding this discussion, primarily written in English, restricts perspectives critical to this conversation. As the final point, the stance taken is that counterarguments about policing or validating identity fail to include Indigenous frameworks, which is when claimed indigeneity could perpetuate settler colonialism.

Abstract Name: Using AI to Quantitatively Analyze Extraocular Muscle Pulley Morphology from MRI

Strabismus is the misalignment of the eyes, which can be caused by abnormalities in the pulley connective tissues. Magnetic Resonance Imaging (MRI) is used to study the structural and biomechanical features of strabismus. Recently, artificial intelligence (AI) techniques, specifically deep learning, have been implemented in segmenting the images obtained by MRI. However, these techniques need improvements for more accurate depictions of the structures. MRI images from patients with strabismus containing the extraocular muscle pulley morphology were obtained. Deep learning techniques will be used to locate the muscles using pixel-based labeling. Then, segmentation masks will be created containing the muscles with various colors. These locations will be analyzed through two F-measure-based metrics. These metrics are the Intersection of Union (IoU) and the Dice coefficient. While results have not yet been determined, the techniques are expected to accurately show the location of each extraocular muscle through different colors representing each muscle. These techniques are also expected to obtain IoU and Dice scores of close to 1 to show a complete overlap between the original MRI image and the image of the predicted locations. These refinements in the segmentation process will significantly enhance the performance of AI segmentation used for studying strabismus in medical imaging.

Abstract Name: The Effects of Regular Physical Exercise Programs on Behavior and Cognition in Early Alzheimer's Disease

Background: Alzheimer's Disease (AD) is a debilitating neurodegenerative disorder that causes progressive cognitive decline, behavioral and executive function decline, and reduced independence in activities of daily living (ADLs), diminishing quality of life and imposing a heavy burden on caregivers. Research suggests that physical exercise can positively influence cognitive, behavioral, and executive function in individuals with AD. Purpose: This proposal will investigate the effectiveness of a structured physical exercise program in improving cognitive, executive, and behavioral functions and enhancing quality of life. Method: This project will evaluate a teaching program focused on the benefits of physical exercise programs on cognitive, behavioral, and quality of life in AD Standardized tools, including the Mini-Mental State Examination, Montreal Cognitive Assessment, Quality of Life in AD, Behavior Pathology in AD, Cornell Scale for Depression in AD, and Caregiver Strain Index, will be utilized. Conclusion: This project will provide valuable insight into the effectiveness of structured physical exercise as a non-pharmacological approach to slowing AD progression, promoting cognitive and behavioral resilience, and improving the quality of life. Keywords: Alzheimer's, exercise, behavior, and cognition.

Abstract Name: "Inside They Are Ravenous Wolves": Hypocrisy as a Moral Vice in Charles Dickens' Bleak House

In Charles Dickens' Bleak House, hypocrisy stands out as perhaps the greatest of all evils in Victorian society. A grown man calling himself a helpless infant to whom money is incomprehensible is revealed to be a calculating sell-out. A mother is so devoted to charity across the sea that she has no devotion to spare for her own miserable and neglected family. Lawyers purport to serve the best interests of their clients while feeding off of their protracted suffering like so many leeches. Much of the scholarship concerning the novel focuses on the legal system of the court of Chancery but, as McClure (2003) suggests, the work deals in no small part with individual moral failures. Ballenger (2008) sees elements of the Gothic in the novel, especially when considering how the characters practice a grotesque sort of hypocrisy within the legal system. Of all the societal faults highlighted by Charles Dickens in Bleak House, it is clear that he regards hypocrisy as the most reprehensible. The court of Chancery serves as a reflection of human moral failure rather than the cause of it. Indeed, Mota (1994) suggests that the work may be best understood in relation to the Christian community. This presentation attempts to reclaim the discussion of Bleak House as a book concerned primarily with human hypocrisy and immorality, for while the story itself is quite complex with its dual narration and discussion of the London legal system, like much of Dickens' work it is essentially a story about morality. While no small amount of suffering is perpetuated by the interminable deferment of the judicial system, Chancery is not itself the primary font of badness in Bleak House, but is rather a side effect of the true moral villain of society, hypocrisy.

Abstract Name: Investigating the Effects Electronic Dance Music Has on Heart Rate

Music elicits a parasympathetic response and activates multiple parts of the brain, decreasing heart rate and anxiety levels. Previous studies between music and heart rate showed many inconsistencies in researchers' findings, most likely due to the lack of a clear and reported methodology. As a result of these many variables, studies have not been consistent enough to make a proper conclusion. Random beat drops in music, which often occur in electronic dance music (EDM), activate one's stress response. Because of this, we hypothesize that electronic dance music increases the heart rate of individuals. 39 undergraduate students were randomly selected to participate in our experiment. Students sat in silence with their eyes closed for an initial heart rate. The song was then played for three minutes and the final heart rate was recorded after the song. From the data collected, a bar graph was created depicting the initial and final heart rates of the participants. The final heart rate after listening to EDM is higher than the initial heart rate ($p=0.04$). With our alpha value of 0.05, the null hypothesis is rejected, showing that there is a significant change in heart rate when listening to EDM. With this in mind, public locations, such as healthcare facilities, should avoid playing EDM music to avoid high-stress levels. For future studies, more participants should be tested to ensure a larger sample size and more diversity.

Abstract Name: Identifying ADAM9 and BHLHE40 gene expression in green anole lizards (*Anolis carolinensis*)

Green anole lizards (*Anolis carolinensis*) have distinct breeding and nonbreeding seasons in which they display different behaviors and morphological changes, such as changes in dewlap displays, pushup-like movements, territorial behaviors, and gonad size. Our question is to determine the role of gene expression in these seasonal changes. Implications of our research on gene expression could lead us to better understand the relationship between behavior changes and gene expression. We are examining genes ADAM9 and BHLHE40 for their expression level in the breeding and nonbreeding seasons between males and females. ADAM9 regulates angiogenesis/neurogenesis and cell-to-cell interactions. BHLHE40 regulates circadian rhythm and is a DNA-binding transcription factor. We predicted that ADAM9 would be upregulated in the nonbreeding season while BHLHE40 would be upregulated in the breeding season based on their functionalities. We designed three primers for each gene, testing each to determine the effectiveness in

amplifying the correct sequence. We chose one primer set each to move on with. We prepped samples through RNA isolation and cDNA synthesis to be used later in the experiments. We are currently working on qPCR to determine expression in breeding and non-breeding seasons between sexes. This study will help us to understand the impact of gene expression on behavioral changes, which could provide insight into the human genome and its influences on our behaviors.

Abstract Name: Developmental impact of neonicotinoid or nicotine exposure in chicken embryos

Imidacloprid is a neonicotinoid designed to target the nicotinic acetylcholine receptors of invertebrate insects but may affect the development of vertebrates. Nicotine is known to alter vertebrate development. Avian species may also be of particular risk of exposure to neonicotinoids from environmental pesticides and ingestion of contaminated insects and freshwater species. We evaluated the impact of environmentally relevant imidacloprid (10 µg/mL) exposure on vertebrate embryo development using a chicken egg assay and compared that with the effects of saline or nicotine exposure (0, 10 and 100 µg/mL). Research grade, specific-pathogen-free (SPF) eggs were injected on day 0 and harvested on day 14 of development. Egg weight, embryo weight and body morphometrics were compared between the treatment groups. Eggs treated with nicotine had an overall (10 - 20%) lower survival rate ($P < 0.05$). Embryos exposed to 10 µg/mL nicotine that remained viable at 14 days did not differ significantly from controls. Embryos exposed to 100 µg/mL exhibited reductions in limb development ($P < 0.01$) and altered head circumference ($P < 0.009$). Reductions in limb length were noted in imidacloprid exposed embryos although not significant ($P = 0.086$). Embryo weight was significantly reduced in the imidacloprid exposed embryos relative to controls ($P = 0.034$). Tissues were harvested to determine histological changes as a result of imidacloprid. Use of the chicken embryo assay highlights the potential effects of developmental neonicotinoid exposure in vertebrates.

Abstract Name: The Tenuous Relationship Between Psychology and Diversity

Diversity and psychology are closely related in a variety of ways. The purpose of this research was to assess the current state of the relationship between diversity and the field of psychology. Similarly to many scientific fields modern psychology has its roots in predominantly white and Eurocentric origins. This has caused many problems in how the field interacts with cultures and peoples that come from outside of the aforementioned group. From false diagnosis to mistreatment during research, diverse and especially marginalized communities have a history of being mistreated by the field. While there have been efforts to diversify the industry and improve treatments, issues still persist into the modern day. Examples can be seen in the largely white workforce and the still prevalent misdiagnosis. In order to gain an understanding of the field as it exists

currently I have conducted research into the statistics of the modern day industry related to the workforce, and I have examined a local psychological practice to see what measures they have in place to ensure fair and effective treatment. Finally, I have conducted interviews with current clinical psychologists to not only ask how they account for diversity in their careers, but also what their personal experience in the field has been like. The findings of my research were largely positive. They showed a field in the process of moving away from its homogenous past, however there is still improvement to be made. My presentation of the findings is not only meant to inform on the inner workings of an industry, but also call attention to the importance of striving to create a more diverse workforce and understanding in health fields.

Abstract Name: From Grand Strand to Center Stage: Myrtle Beach in the Rise of Rhythm and Blues Music

Beginning in the early twentieth century, American music scenes and audiences grew more inclusive and diverse. Specifically in urban centers like New York and Chicago, new popular styles attracted artists and listeners across demographic divides. Consequently, previous scholarship has tended to overlook the role that remote areas played. One example is Myrtle Beach, a resort town on South Carolina's coast. In the 1950s and 1960s, when African American musical innovations like rhythm and blues increasingly influenced mainstream culture, Myrtle Beach attracted visitors from different parts of the country. People from Southern states, where segregation shaped public and cultural life, as well as the Northeast, where traditional standards of propriety prevailed, first encountered rhythm and blues and other fresh styles in Myrtle Beach. Even big-name performers like Little Richard and Ray Charles played local music venues to the amazement of mixed audiences. Representing a student-led research undertaking at Coastal Carolina University's Center for Inclusive Excellence, this project investigates how the Grand Strand region catalyzed the rise of new popular music forms. Using oral histories provided by contemporary witnesses, news sources from media archives, and information gathered at historical sites, it examines what roles the relatively remote Grand Strand played in the evolution of American pop culture. Interviewees shared unique personal perspectives that offered valuable insights into the period's social, political, and cultural climates. The cast of witnesses included figures from the circuit of commercial entertainment, local residents who saw the area evolve into a hotspot of popular culture, and individuals who vacationed in Myrtle Beach as teenagers looking for new excitements. Aspiring to close a persistent gap in research on the dissemination of popular culture, this project explores how Myrtle Beach expedited the development of all-American musical and cultural experiences that reflect the nation's inclusive and diverse character.

Abstract Name: Optimizing Fab Production for Glycine Receptor Analysis

Glycine receptors (GlyRs) are a class of membrane ion channel receptors that inhibit neural excitation. They are mainly found in brain stem and spinal cord neurons. Their significant impact on motor coordination and sensory processing makes GlyRs a promising therapeutic target for pain, anxiety, drug addiction, and other neurological diseases. For this reason, there is substantial interest in understanding GlyR behavior at the single-molecule level, both in purified systems and in native cellular conditions. GlyRs belong to a large family of receptors called pentameric ligand-gated ion channels (pLGICs) that assemble as a pentamer of homologous subunits. There are multiple GlyR subtypes, each varying on the types of subunits that compose the pentamer. One subtype called homomeric GlyR α 1 is composed of five identical α 1 subunits. To help distinguish between GlyR subtypes, it is essential to characterize tools that can recognize specific subunits. One such tool is a Fragment Antigen Binding (Fab) region of an antibody that has been established as a biomarker in protein characterization. Structurally, the Fab consists of one heavy and one light chain, bound by a disulfide bond, with the chains each consisting of a constant and variable domain. With a relatively smaller molecular weight of 55 kDa, Fab adequately serves as a fiducial marker for larger proteins with homologous subunits, such as GlyR α 1. A GlyR α 1-Fab complex has previously been developed for this purpose, however, its effects on channel structure and function have not been fully characterized. Here, we present our protocol for purifying this Fab along with size-exclusion chromatography data of purified GlyR α 1-Fab complex. We plan to further experiment with this complex using cryo-electron microscopy.

Abstract Name: AMEFURU - A rainfall sensor useful for daily life -

To address accurate and flexible wake-up time adjustments, we have developed "Amefuru Alarm," an application that adjusts the alarm time according to the weather forecast. The purpose of this app is to provide users with an environment where they can adapt to weather changes by acquiring real-time weather data and automatically adjusting the alarm time based on accurate forecasts. This system is intended for use on iPhones and iPads and was developed on Playgrounds using the Swift language. This app acquires real-time weather data from the Japan Meteorological Agency for a designated area and sets an alarm for the usual wake-up time. Based on the probability of precipitation and rainfall amount, it determines the intensity of rain as a "rain level" and automatically advances the alarm time according to this "rain level." The alarm then sounds at the set time. For example, users can customize settings such as "wake up 20 minutes earlier than usual on rainy days" or "change the wake-up time only during heavy rain." Furthermore, even if the weather changes while the user is asleep, the app reflects the information in real-time and sets the optimal alarm time. To realize this system, we utilized the data provided by the Japan Meteorological Agency and built a mechanism to accurately acquire the probability of precipitation and rainfall amount simply by entering the name of a city or region. In particular, we incorporated logic that enables flexible alarm time adjustment according to rainfall conditions by analyzing precipitation data in detail. The advantages of this application are improved accuracy, simplified operation, and enhanced quality of life. By reflecting weather changes in real time, it helps prevent unnecessary early wake-ups and sudden schedule changes, and significantly improves convenience by eliminating the need for users to manually set alarms.

Abstract Name: Study of binding of triplex DNA with flavone derivatives using fluorescent intercalator displacement

Targeting duplex DNA using a triplex-forming oligonucleotide (TFO) in a sequence-specific manner is an attractive approach for antigene strategy. A TFO binds into the major groove of duplex DNA via Hoogsteen H-bonding. The formed non-canonical triplex structure can serve as a padlock on duplex DNA to regulate gene expression and replication and induce DNA damage and genomic instability. However, the triplex formation is thermodynamically unstable and kinetically unfavorable due to the repulsions between three negatively charged DNA strands. Antigene enhancers are small molecules that bind to triplex DNA specifically while having little effect on duplex DNA. Our lab has recently discovered and developed several classes of triplex binding ligands based on the flavone scaffold. These molecules bind to triplex DNA with high affinities via intercalation. In the present work, we investigated the relative binding specificity of these ligands with triplex DNA using a fluorescent intercalator displacement (FID). When thiazole orange (TO) binds to DNA, it fluoresces significantly. Adding a ligand into the TO-DNA solution can displace TO out of DNA and subsequently reduce the fluorescence of bound TO. Comparing the fluorescence signals as a function of ligand concentrations allows us to determine the relative binding strength of ligands. In this presentation, we will discuss the experimental setup and FID results.

Abstract Name: Real-Time Solar-Event Calculation Device

The aim of this project is to develop a silicon-labs microcontroller-based system that calculates sunrise and sunset times using geographical positioning data from a GPS module. This device is the assembly of a Silicon Labs EFR32BG22 development board and Interface Ublox Neo-6M GPS Module. It operates independently of internet connectivity and is programmed with C language, in Simplicity IDE, to retrieve GPS data through UART communication. Critical data such as time, latitude, longitude, direction indicator and date are received, parsed then converted into information that is useful to the system. This information is then used to find unix time, time zone, and apply Daylight Savings Time adjustments. A mathematical model with parameters like Julian Day, Solar Mean Anomaly, Local Apparent Time, Solar Declination, etc. is then used to calculate the solar events. The results are finally displayed, in a readable format for humans, on a Simplicity Studio terminal. Applications of this device include automating garage porch lights, integrating smart home systems to control blinds or shades and, in larger sectors, optimizing lighting and ventilation schedules in agricultural settings enhancing efficiency and reducing manual effort.

Abstract Name: I'm the "Alpha;" Negotiating Black Manhood Under the Aegis of Hosting Podcasts: A Systematic Media Analysis

Although podcasting has become a pervasive platform for expressing and constructing identities, podcasting as a tool for identity construction is understudied, particularly in the context of Alpha male identity and its intersection with the Black experience. Some popular podcast hosts advocate for an Alpha male ideology, where masculine dominance is framed as natural and necessary, and they present exaggerated gender performances to assert control. For Black men, systemic racial oppression reinforces the need for strict adherence to hegemonic masculinity as a way to gain the capital and privilege of manhood lost through their marginalization. These two social forces raise questions about how Black men negotiate their masculine identity (considering systemic oppression and stereotype) as "Alpha Male" podcast hosts and what then is the relationship between "Alpha male" identity and the effects of systemic oppression. In this study, I identified three video podcasts using the search terms "High-Value Black Man" and "Black Alpha male podcast." Utilizing thematic analysis, I examine verbal and visual cues to glean how the host's racialized experiences impact their self-presentation and the justifications of their identity. I expect that systemic oppression and stereotypes will shape/impact how Black male podcast hosts talk about and understand their masculinity, by aligning with white dominant hegemonic standards while paradoxically championing their Blackness. Understanding identity construction as both a reflection and a creation of societal/cultural norms is essential to dismantling oppressive systems that limit and restrict the human experience.

Abstract Name: Lipotoxicity Mediates Annexin A2 Enrichment in Extracellular Vesicles from Hepatocytes

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD), and its progressive subset metabolic dysfunction-associated steatohepatitis (MASH), are the most prevalent liver diseases globally; yet there is a lack of approved therapies for MASH. In the context of MASH, extracellular vesicles (EVs) have emerged as potential biomarkers and carriers of disease-related information. The damage associated molecular pattern (DAMP), S100A11, is enriched on EVs in MASH. However, the mechanisms underlying S100A11-EV enrichment remain unclear. Aim: Our aim is to elucidate the role of Annexin A2 (AnxA2) in mediating S100A11 enrichment on EVs from lipotoxic hepatocytes. Methods: Utilizing gain-of-function and loss-of-function genetic approaches, pharmacological inhibitors, human and mouse cell lines, and primary hepatocytes, we will investigate the regulation of AnxA2 by the endoplasmic reticulum stress-induced transcription factor XBP1. Additionally, we will explore the binding of AnxA2 to S100A11 in the endosomal

membrane compartment, demonstrating the necessity of AnxA2 for selecting S100A11 as EV cargo. Results: Preliminary data indicates the enrichment of AnxA2 and S100A11 on EVs from palmitate-treated hepatocytes. Co-immunoprecipitation experiments reveal the binding of AnxA2 to S100A11, with upregulated expression observed in human MASH livers and mouse models. Our study will provide detailed insights into the regulatory mechanisms governing these interactions. Conclusion: This research holds the potential to uncover novel therapeutic targets for MASH by understanding the intricate signaling processes involving AnxA2 and S100A11. Insights gained may lead to the identification of diagnostic and prognostic biomarkers, contributing to the development of interventions that alleviate or reverse metabolic dysfunction-associated steatohepatitis.

Abstract Name: The Three-Tab Keyguard: A Novel, Low-Cost Device to Help Special Needs Students Communicate

Autism affects approximately 1 in 36 children in the U.S., with 30% considered “minimally verbal.” Young students often use aids such as text-to-speech apps to communicate in schools, though this can be difficult when paired with motor control impairments like dyspraxia or cerebral palsy. Approximately 7% of U.S. children in special education are classified as having multiple disabilities, highlighting a need for accessible solutions for communication. The purpose of this project is to address this challenge by developing low-cost tactile aid devices for iPad text-to-speech apps to assist special needs students in communication. These devices, known as iPad keyguards, are physical plates with holes to guide users’ fingers to the correct text-to-speech buttons, which typically cost \$25 - \$100 and rely on attachment mechanisms such as velcro, suction cups, and magnets. Our team worked to lower this cost by employing a design-based research approach. We iterated five prototypes through CAD, laser cutting, and 3D printing, and testing each for durability and usability. Our final “three-tab keyguard” design features strategically placed tabs that leverage the iPad’s existing physical structure - including the headphone jack, power button, and charger port slots - for secure attachment. Unlike traditional attachment methods, this design eliminates reliance on external adhesives or magnetic attachments, enhancing durability and ease of use in classroom environments. By utilizing this simple approach, we reduced the production cost to \$3.30 per unit while enhancing stability. This work highlights the potential for collegiate design teams to address unmet needs in assistive technology by creating scalable, cost-effective solutions. Our three-tab keyguards are currently being tested in Virginia elementary schools. Feedback from these trials will guide adaptations for broader iPad case compatibility, making the device more accessible to students with disabilities and demonstrating the impact of student-driven innovations in creating inclusive educational environments.

Abstract Name: Exceptional Sounds: How Elementary Music Teachers Support Students with Exceptionalities & Their Impact

Music education has long been recognized as a powerful tool for fostering cognitive, social, and emotional development in typically developing children. However, its potential to positively impact students with exceptionalities, such as autism spectrum disorder, intellectual disabilities, learning disabilities, and giftedness, has only recently gained significant attention. This literature review explores two central research questions: (1) How do elementary music educators adapt their teaching strategies to support students with exceptionalities, and what impact does music education have on these students' engagement and learning in inclusive classrooms? (2) How does music education impact the development of a child with exceptionalities, and what can educators do to facilitate this? By synthesizing existing research, this review examines the specific ways in which music education enhances the cognitive, social, and emotional development of students with exceptionalities. It highlights strategies music educators use to adapt lessons, such as leveraging mnemonic devices for cognitive development, fostering social-emotional learning through collaborative musical activities, and using music to refine motor skills in students with physical disabilities. These findings underscore the profound impact music can have on engagement, emotional regulation, and interpersonal skills in inclusive classroom settings. This review also identifies significant gaps in the literature, calling for further research to inform best practices and strengthen the evidence base. By advocating for the integration of music education into special education programs, this study aims to highlight music's transformative potential to improve the quality of life for students with diverse needs, ensuring their holistic development and academic success.

Abstract Name: Enhancing Coarse Particle Flotation Efficiency on Metal Sulfides: A Comprehensive Adsorption Study on Novel Collectors

Coarse particle flotation has emerged as a breakthrough innovation in the mineral processing industry. Coarse particle flotation saves energy by reducing the need for extensive grinding, allowing for the recovery of valuable minerals at a larger particle size, which lowers overall energy consumption in the mineral processing cycle. A key factor in realizing its full potential lies in optimizing the chemical interactions involved in the flotation process, particularly the fundamental principles of adsorption, which directly influence recovery rates. As part of a comprehensive project aimed at refining the performance of coarse particle flotation, this study investigates the adsorption mechanisms and underlying principles for both novel and commercially available collectors, with a focus on dithiocarbonate (DTC) and dithiophosphate (DTP). These collectors are commonly used in sulfide mineral flotation, but their behavior in the context of coarse particle recovery remains an area of active research. Understanding their adsorption dynamics is essential for improving flotation efficiency. The experimental work was carried out on a range of particle size fractions with low surface area exposure of metal sulfides (less than 20%), including +850, -850, +600, -600+300, -300+212, and -212+150 microns, with varying collector dosages to investigate the adsorption behavior of the collectors. These measurements provided critical insights into how the collectors interact with coarse particles, helping to identify the optimal conditions for maximizing recovery and selectivity. The results of this research are

expected to contribute significantly to the understanding of collector adsorption in coarse particle flotation, offering a scientific basis for the development of more effective collector designs. By tailoring collector chemistry to specific particle sizes and conditions, this study aims to further enhance the capabilities of coarse particle flotation and push the limits of mineral recovery.

Abstract Name: Experimental Study of an Elastohydrodynamic Seal for Supercritical Carbon Dioxide Turbomachinery

Supercritical carbon dioxide (sCO₂) power cycle shows great promise to emerge as the next-level technology in power generation industries. Current sCO₂ turbomachinery experiences high leakage rates, which is a major obstruction for the full realization of sCO₂ power technology. The high leakage rates not only penalize the efficiencies but also create environmental concerns due to greenhouse effects caused by increased CO₂ discharge to the atmosphere. As a potential solution, we propose an elastohydrodynamic (EHD) shaft end seal. In this study, we experimentally carried out a proof-of-concept study for the proposed seal design and proved that the EHD seal restricts the leakage to minimal values at high pressures. A test rig was fabricated for a 2-in stainless steel static shaft. Three different test seals made of virgin PEEK and bearing grade PEEK were used for this study. The trials were run with an inlet pressure of up to 13.5 MPa and an initial clearance as low as 0.001-in. A total of 27 individual tests were conducted and investigated. The maximum leakage rates recorded for virgin PEEK and bearing PEEK seals were 3.6 g/s and 8.15 g/s at 5.5 MPa. Following then, leakage rates began to drop down to 0.96 g/s and 3.37 g/s as the pressure increased to 13.5 MPa. All three seals showed throttling effect by generating a bell-shaped mass flow rate. These preliminary findings suggest that the proposed EHD seal design can potentially be applied to sCO₂ turbomachinery.

Abstract Name: The Role of Neuropeptide Y Signaling in the Auditory Thalamus

The auditory thalamus, or medial geniculate body (MGB), is a critical relay center for auditory information before it reaches the auditory cortex. Dysfunction in neuronal circuits in the MGB are associated with hearing loss and tinnitus. Most neurons in the MGB are glutamatergic (excitatory), and ascending inhibitory inputs, including a significant projection from the inferior colliculus, primarily modulate their activity. A previous study from our group showed that a class of inhibitory neurons in the inferior colliculus that express neuropeptide Y (NPY) projects to the MGB. NPY is an evolutionarily ancient signaling molecule that has been shown to modulate fear responses, feeding behavior, and epilepsy. Since NPY neurons produce NPY,

and neuropeptides can act over longer distances, we hypothesized that NPY signaling might affect the activity of MGB neurons. To test this hypothesis, we performed in situ hybridization using probes against the NPY Y1 receptor (Npy1r), NPY Y2 receptor (Npy2r), and synaptophysin in MGB slices. Next, we performed whole-cell current clamp recordings targeted to MGB neurons and exogenously applied NPY to test how NPY signaling alters the activity of MGB neurons. Our data shows that nearly all neurons in the MGB express the Npy1r, positing NPY as a significant regulator of the activity of MGB neurons. Surprisingly, Npy2r was not present in the MGB. Our electrophysiology data show that applying NPY in a whole-cell current clamp decreases the activity of MGB neurons, suggesting an inhibitory effect. Together, our data indicates that NPY plays a significant role in regulating the excitability of MGB neurons. In our next steps, we will perform intracranial injections using retrograde tracing in the NPY-hrGFP mouse to determine the sources of NPY to the MGB and combine electrophysiology and pharmacology to determine the signaling pathway by which NPY modulates the activity of MGB neurons.

Abstract Name: Gendered Pathways to Smoking Initiation Among African Americans

This research investigates the relationship between age and smoking initiation among African American males and females. Utilizing an intersectionality theory framework, this study hypothesizes that Black males are more likely to initiate smoking at an earlier age compared to Black females. Leveraging the CDC 2021 Adolescent Behaviors and Experiences Survey and employing SPSS software for statistical analysis, this research project examines disparities in smoking initiation among Black Americans, with a particular emphasis on the distinct experiences of gender. Preliminary findings challenge prevailing cultural assumptions and social norms, suggesting that Black males do not initiate smoking at earlier ages than their female counterparts. These results underscore the necessity of re-evaluating our understanding of the complex interplay of factors, including racial inequality and cultural norms, that contribute to tobacco use among African American adolescents. This study highlights how deeply ingrained cultural assumptions can obscure the realities of adolescent behavior and hinder effective tobacco prevention and cessation efforts within the Black community.

Abstract Name: Family stories: A light in the darkness

Family narratives play a critical role in processing experiences, fostering meaning-making, and offering hope during crises. Storytelling, a universal practice across cultures, serves as a means of sharing struggles, beliefs, and healing processes. This research investigates the role of family stories in coping with difficult life events through qualitative narratives, informed by narrative theory, which suggests that storytelling helps individuals make sense of their experiences and environments. A systematic review of literature (2015–2025) on the use

of family narratives in understanding trauma and stress reveals a gap in research specifically focused on family processes during crises. This cross-sectional qualitative study explores how families narrate their experiences of overcoming challenges and adapting to adversity. Through inductive reasoning, the study analyzes thematic patterns in family stories and evaluates the therapeutic impact of shared narratives. Sociodemographic data are collected to provide a comprehensive view of the participants' backgrounds, ensuring diverse representation across various family structures, life stages, and crises. The study recruits 50+ families through undergraduate and graduate courses, as well as social media, with participants completing a survey on their family's story. Findings are expected to provide new insights into family resilience and contribute to the academic understanding of therapeutic storytelling. This research has implications for enhancing family-centered care and supporting resilience-building strategies within clinical settings, offering valuable knowledge for future studies and practical applications in the field of family life education.

Abstract Name: Characterizing Critical Micelle Concentrations in Mixed Peptoid Oligomer Systems: Insights into Composition-Dependent Self-Assembly for Nano-medicine

Electrostatic interactions play a crucial role in biological systems, influencing processes like protein folding, cellular signaling, and molecular recognition. Although the significance of electrostatics in biological systems is well understood, their impact in synthetic systems remains less clear. Mixed micelle systems may be difficult to study because there is much difficulty in modeling and understanding the formation and solute partitioning in such systems. Composition-dependent behaviors of mixed micelles and the deviations from ideal mixing models complicates their characterization and application as nanoscale drug carriers. Recent advancements in polymer design have made progress, but studies focusing on mixed micelle systems are less reported due to their complex behavior and interactions. Mixed micelle systems offer several advantages over homogeneous systems, including enhanced stability, tunable properties, and improved functionality for specific applications. Determining the critical micelle concentration (CMC) is vital in designing mixed micelle systems, as it provides insights into their self-assembly and stability. In this study, we characterized the CMC of various binary mixtures of sequence-defined peptoid oligomers. Our findings revealed that the CMC values of the binary micelles varied significantly depending on the composition and sequence of the peptoid mixtures. By demonstrating that the CMC can be fine-tuned through composition control, this study opens up a wide range of potential applications in calorimetric analysis of mixed micelle and mixed copolymer micelles for Nanomedicine.

Abstract Name: Voices of #MeToo: Analyzing a New Genre

This undergraduate Honors thesis identifies a genre of literature, film, television series, and other forms of

media that emerged after the #MeToo movement in October 2017. The first chapter briefly discusses the #MeToo movement and the resulting discourse, which includes many new works that deal with rape and sexual abuse. The following sections analyze three pieces of media that I attribute to the "#MeToo genre" to identify perspectives on sexual assault or the #MeToo movement itself, including how these works understand sexual assault as a gendered cultural issue. The media that I analyze include the film *Cuties* (2020), the novel *My Dark Vanessa* (2020), and the Netflix docuseries *American Nightmare* (2024). I try to understand the opinions of the writers/directors by close reading and bringing in relevant outside sources, including *Down Girl* (2017) and *The Lolita Effect* (2008). Lastly, the final chapter discusses takeaways from my analysis and suggests applications from this research, such as using the #MeToo genre in secondary and postsecondary education to teach about systems of misogyny and rape culture.

Abstract Name: Hear Our Stories: Research in Native American Rhetoric and Storytelling

“Let us form one body, one heart, and defend to the last warrior our country, our liberty, and the graves of our fathers.” -Tecumseh In his speech to the Choctaws and the Chickasaws in 1811, Tecumseh rallied his people together with his words (Fixico 13). According to scholar Donald Fixico, stories are a powerful component of many Native American cultures, affecting both the speaker and listener emotionally and spiritually. My research explores creation stories, oral histories, Native American philosophy, and environmental values, all discussed by Donald Fixico, Robin Wall Kimmerer, and other prominent Native American scholars. For the second portion of my paper, I use Native American rhetorical strategies identified by Karen Redfield to create my own story about a granddaughter and her garden. My story's theme is Indigenous food sovereignty, which is a hot topic in tribal politics right now. In my proposed presentation, I will discuss the significance of storytelling and oral tradition to Native American cultures, giving a brief overview of my research. I will then attempt to tell my story, practicing the methods of oral storytelling I have learned. Lastly, I will end with a reflection on challenges and learning curves while creating my story, and what this has taught me about Native American rhetorical strategies, oral tradition, and cultures.

Abstract Name: Griefbots and the Digital Afterlife: Ethical and Cultural Implications of AI in Mourning

The Digital Afterlife Industry (DAI) has evolved significantly since its early roots in the mid-2000s, when platforms like Facebook began memorializing deceased users' accounts instead of deleting them. This marked a shift in how death and digital presence interact. With the advent of Artificial Intelligence (AI) and Large Language Models (LLMs), currently, the DAI extends beyond static memorialization into dynamic, interactive recreations of deceased individuals. Known as AI griefbots or deathbots, these LLMs, similar to other AI chatbots look to build a “personality” of a deceased loved one, while continuing to learn from user

interaction to become increasingly more adept at revitalizing the deceased. This project explores the intersection of LLMs and the DAI, focusing on the ethical, social, and cultural implications of these technologies in two avenues. Firstly, we aim to examine the concerns surrounding the newest avenue for profit-driven and exploitative grieving strategies as a personal data concern. We additionally look to the hyper-individualizing and isolating processes of grief that these griefbots promote. Through an in-depth theory-driven analysis, the aim is to provide a nuanced understanding of how AI-driven tools are reshaping the deeply personal and cultural experience of grief, contributing to broader discussions in digital ethics and the future of AI in human-centered domains.

Abstract Name: Exploring the Mechanical and Physical Properties of Ultra-Soft Colloidal Microgels

Soft colloidal particles have garnered significant attention due to their broad range of applications in material science and bioengineering. Among these, ultra-low cross-linked (ULC) microgels form a distinct category defined by their exceptional softness. These particles display unique characteristics, such as high compressibility and sensitivity to external stimuli like temperature and ion concentration. Our study focuses on the highly packed colloidal assemblies of ULC microgels in the form of microgel pastes, where the microgels are significantly compressed, leading to unique mechanical behaviors. Through detailed investigations into their rheological properties, dissolution stability, and internal structure—utilizing techniques such as rheometry, optical and atomic force microscopy, and dynamic light scattering—we have discovered that the mechanical and swelling/dissolution behaviors of these pastes are closely linked to the softness of the microgel particles and their interactions, which are influenced by charge-compensating counterions. Understanding these physical and mechanical properties is vital for optimizing the material's potential in various biological applications.

Abstract Name: MOSFET: P-typed...Silicon

The current research study will dive deeper into understanding the inner workings of logic circuits as well as their packaging. The project is expected to show the mechanical and electrical makeup of the MOSFET transistor. Specifically, I will discuss information regarding its materials' conductivity, oxidation and its other aspects that prove its effectiveness. I will be researching by using the traditional method of reading articles and textbooks to gather knowledge as well as observing the transistor itself. I will be able to demonstrate

these findings by recording them as I observe the usage of the transistor within a circuit in two different ways: one including the AND gate and one utilizing the OR-gate; which both are made with the MOSFET transistors from the CMOS family. The results and the investigative observations discovered during this project will explain how the components and materials used to produce the MOSFET transistors affect its functionality and effectiveness. This project will go in depth about the reasons why this type of transistor is so commonly used and more specifically, how these transistors are manufactured. The significance of this project goes beyond this generation's prototypes and inventions. Alas, by using the concepts and technical information found in this study, future generations will be able to enhance the smart grid, improving the quality and speed of electrical tools and resources. Understanding the proper materials and methods of utilization, future engineers and others who work in the industry will be able to produce better transistors in the future, furthering the advancement of modern technology.

Abstract Name: Synthesis of isatin-linked 4,4-dimethyl-5-methylene-4,5-dihydrothiazole-2-thiols (IT2Ts) and determination of their cholinesterase inhibition activity.

Alzheimer's Disease (AD) is one of the most prominently known neurodegenerative diseases for its relatively high frequency and severe affliction to cognitive processes mainly seen in older demographics. A primary mode of treatment for AD has been and continues to be acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) inhibitors with high potency and safe biological activity. Previous investigation in our lab has been concerned with synthesizing isatin and indole dimers, as well as N-alkyl isatins, and determining AChE and BChE inhibition. Recent study into the synthesis of isatin-linked 4,4-dimethyl-5-methylene-4,5-dihydrothiazole-2-thiols (IT2Ts) has shown promising AChE inhibition activity for the trimethylene-linked IT2T, whereas BChE inhibition was preferred with octamethylene-linked IT2Ts. In this study, a series of trimethylene-linked IT2Ts with aromatic substituents, ranging from halogens to simple alkyl groups, was prepared and tested to expand the structure-activity relationship (SAR) for AChE inhibition. Furthermore, two additional IT2Ts with nonamethylene and decamethylene linkers were synthesized and tested for AChE and BChE inhibition to explore the effect of longer linkers on BChE inhibition. Preliminary results suggest the aromatic substituents enhanced AChE inhibition with IC₅₀ values in the low micromolar range. Additionally, the nonamethylene-linked IT2T seemed to improve BChE inhibition, but the effect was diminished with the decamethylene linker. Full results of these ongoing investigation will be presented. Confirmation of the optimal IT2T aromatic substituent and alkyl linker length for AChE and BChE inhibition allows for further investigation of SAR of these compounds that have the potential to increase inhibitor viability for potential AD treatment.

Abstract Name: A Novel Method to Investigate the Association Between Maternal Oral Health Status During Pregnancy and Bacteria Identified in Dental Caries of their Children's Exfoliated Primary Teeth.

Research has suggested that birth order or environmental factors affect siblings' oral health status during childhood. However, more recent research indicates that the strongest predictor of children's oral health status is the mother's oral health status. This project investigated the association between the oral health status of the mother during pregnancy and bacteria (biofilms) identified in cavitated lesions (dental caries) of their children's exfoliated primary teeth. Five consenting maternal participants anonymously donated their children's primary teeth and completed a questionnaire about their oral health status during each pregnancy. After visually identifying the exfoliated teeth with dental caries, the biofilms were disrupted using a novel method of vortexing, sonicating, and vortexing before culturing and biochemically identifying the isolated bacteria. Six different bacteria species were isolated from the siblings' exfoliated teeth with dental caries, including one predominant genus/species. However, no direct association between maternal oral health status and the bacteria identified could be drawn because of the small sample size. Here, we establish a new method to recover bacteria (biofilm) in dental caries; however, this research requires additional maternal participants/donors to understand an association between maternal oral health status and bacteria isolated in children's dental caries.

Abstract Name: Impact of the opt-in and opt-out organ donation policies on recovery of organ transplantation after the decline during the COVID-19 pandemic

Background: About 90% of the global annual demand for donor organs is left unmet, causing a long wait and significant morbidity and mortality. The opt-in (formally consented to post-brain-death organ donation) and opt-out (consent implied if not formally rejected post-brain-death organ donation) policies of a country may affect the procurement of organs of brain-dead donors. The COVID-19 pandemic (C19P) exacerbated the donor organ shortage. This study investigates the effects of consent policies on the average transplantation rate (ATR) per million population (PMP) before, during, and after the C19P. Methods: Transplantation data (2015-2023) of ten solid organs in 64 countries was obtained from GODT and IRODaT databases. The countries were divided into four clusters based on WHO/World Bank data on six key health/economic variables. The ATR for the pre-C19P (2015-2019), during C19P (2020), and post-C19P (2021-2023) were analyzed to find the adjusted effect of consent policies using longitudinal multilevel modeling. Results: Of the 66 countries, 39 implemented the opt-in, and 27 implemented the opt-out system. Opt-out countries had higher ATRs in all periods: pre-pandemic (52.7 vs. 35.9 PMP), during the pandemic (43.0 vs. 29.7 PMP), and post-pandemic (49.5 vs. 34.8 PMP). The opt-out countries had a significantly higher ATR in six of the ten transplant types. Deceased donor kidney transplantations were 10.60 PMP higher in opt-out countries (p -value= <0.01 , 95%CI: 4.57 to 16.63), while live donor kidney transplantations were 5.48 PMP higher in opt-in countries (p -value= <0.01 , 95% CI: -8.88 to -2.07). Adjusted analyses showed opt-out countries performed 12.95 PMP more transplants overall ($p = 0.04$, 95% CI: 1.11 to 24.79). Conclusions: Opt-out

policies were associated with higher transplant rates before, during, and after the pandemic, with smaller pandemic-related declines, suggesting universal transitioning to the opt-out policy.

Abstract Name: From Umm Al Dunya's Bench: The Pitfall of Judicial Attitudes in Egyptian Investment Treaty Arbitration and Foreign Direct Investment

In 2023, Egypt secured its position as Africa's leading foreign direct investment (FDI) destination, attracting \$13.46 billion. However, the success of "Egypt 2030," a national agenda aimed at doubling FDI's GDP contribution to \$100 billion within five years, is hindered by inconsistent state adherence to bilateral investment treaties (BITs)—a cornerstone of investor confidence. Treaty interpretation falls to Egypt's national courts, yet judicial inconsistencies in recognizing foreign judgments and the absence of a formal precedent system generate significant uncertainty. Institutional lapses in transparency further obscure mechanisms intended to uphold agreed-upon human rights protections, including property rights enshrined in BITs, and contribute to delays, exposing the state to claims of fair and equitable treatment clause violations. This study employs a mixed-methods approach to explore relationships between Egypt's domestic judicial practices, compliance with in-force BITs, adjudication timelines, FDI inflow percentages, and rule of law indices across countries. The methodology combines analysis of BIT texts, statistical evaluations of judicial terms, stakeholder insights on investor-state dispute settlement (ISDS) bottlenecks, and reviews of landmark ISDS cases involving Egypt as the respondent state. This integrated approach identifies patterns and connects judicial practices, treaty compliance, and investment outcomes. Findings reveal domestic judicial inconsistencies, exacerbated by executive actions compromising the rule of law, deny justice, jeopardize investor confidence, and deter FDI inflows. The lack of an established precedent system erodes fair and equitable treatment, impeding national economic development while neglecting broader human rights safeguards embedded within BITs as *lex specialis*. Governance challenges to achieving uniformity are not exclusive to Egypt but underscore critical gaps, raising external concerns about the MENA region's commitment to customary international law. Judicial and institutional reforms aligning domestic practices with international legal obligations are crucial to restoring Egypt's position as a dependable ally in sustainable business partnerships founded in mutual dignity.

Abstract Name: A High School Design for Social Sustainability

Classen High School: A High School Design Rooted in Connection and Growth explores adaptive reuse as a sustainable solution for creating a high school designed around social sustainability. This thesis reimagines the abandoned Oklahoma City Public School Administration Building, inspired by the concept of mycelium, which is a natural network symbolizing collaboration, resilience, and regeneration. This metaphor shapes a

design focused on fostering meaningful connections among students, staff, and the broader community. The project is informed by research conducted through a focus group with high school students from across Oklahoma. Participants shared their views on how schools can better support students, emphasizing the need for improved mental health resources, safe outdoor spaces, and greater access to essential support systems. These insights are directly reflected in the design's priorities, ensuring a supportive and inclusive environment. Incorporating WELL and LEED standards, the project emphasizes environmental sustainability alongside occupant health. Biophilic elements, efficient resource use, and adaptable spaces create an environment that mirrors nature's interconnectedness and adaptability. Flexible learning zones cater to diverse needs, providing collaborative spaces for engagement and quiet areas for focus. The design extends beyond academics, integrating communal hubs and multipurpose spaces to encourage interaction and community involvement. Outdoor green spaces provide safe, welcoming environments for recreation and connection, addressing students' calls for spaces that nurture both physical and mental well-being. By weaving together focus group research, sustainable practices, and innovative design inspired by mycelium, this thesis reimagines a neglected structure as a thriving educational environment. Classen High School embodies connection, growth, and resilience, empowering students and the surrounding community to embrace sustainability and thrive together.

Abstract Name: Ozark Region: the difference in varying oaks in the same environment based on proline quantification and leaf area.

The ecosystem of the Ozark region in North America has a large, diverse population of varying oak species all while being located within a close region. While the species richness of oaks present in the Ozarks is large, it is unknown how many different species can all occur and thrive within the same ecological niche. Examining different stress tolerance and morphological adaptations was done by measuring 8 different species within the Ozarks. We further examined the relationship between leaf areas and proline concentration in the differing species to see how each species has adapted to living in the same ecological niche. Because all 8 species live in the same area, we hypothesize that they will have different leaf area and proline concentration levels to better differentiate competition against surrounding species. To test this hypothesis, we took 8 species leaf samples (3 leaves from each specimen) and measured their leaf area index and their proline concentration values. We expect that the smaller the leaf area, the higher the proline concentration will be as the results will correlate to drought tolerance. This research enhances our understanding of the relationship between leaf area index and proline quantification levels, further enhancing our knowledge of plants adaptations to high stress levels. RISEbio has given us the opportunity to better understand plant stress and adaptations through allowing us to pursue this research and gain research method knowledge. Six keywords: Ozark region, oaks, proline quantification, leaf area index, plant competition, morphological adaptations

Abstract Name: Development of Cell Permeable Peptide-Based PROTACS to Study Peroxisomal Biochemistry

Peroxisomes are organelles with various metabolic functions that have significant roles in eukaryotes due to its role in cellular metabolism, redox balance, and other essential processes. The dysregulation of peroxisomal function has been involved in neurodegenerative diseases, metabolic disorders, and cancer, making them interesting targets for therapeutic development and further exploration. Here, we report efforts to develop a Proteolysis Targeting Chimera (PROTAC) that degrades, Pex5, the key receptor controlling import of proteins into the peroxisomes, based on the natural substrate trimer peptide for Pex5, Peroxisome Targeting Signal 1 (PTS-1). PTS-1 sequences tend to be quite polar preventing efficient passive cellular uptake. To overcome this, we are working on incorporating a medium-chain lipid to increase cell permeability while maintaining the natural amino acid sequence. This medium-chain lipid is then attached to a natural PTS-1 sequence and combined with a peptide-based E3 ligase cereblon (CRBN) recruiting moiety to create a cell permeable and completely peptide-based Pex5 PROTAC. The ability of this PROTAC to enter cells and degrade Pex5 will be determined by Western blotting and fluorescence microscopy. Overall, our efforts will produce new chemical tools to study peroxisomes enabling a better understanding of their function in cellular metabolism.

Abstract Name: The Unsung Heroes of the Underground Railroad: The Role of Free Black Communities and Leaders

The Underground Railroad (UGRR) has long been celebrated as the bravest example of resistance against slavery. Unfortunately, the contributions of Black communities and their leaders have long been overshadowed by white liberal narratives. My research demonstrates the significant role of Black communities in Ohio's Underground Railroad. By analyzing census data from the years 1820-1860, this research finds counties where Black populations grew significantly over the decades of high UGRR activity. Displaying the migration patterns of Black persons as they joined the communities within Ohio. A formidable force of resistance against slavery came from within the Black churches, which would create associations and conventions to join the flight publicly as well as be the center of change in the background within the UGRR. Black communities provided critical support for freedom seekers, giving them shelter, education, and providing them with what they needed to live a free and fulfilled life. Cincinnati's "Little Africa" provided food, shelter, and education to freedom seekers as they crossed the Ohio border. Similar settlements like the Gist and Greenville communities also welcomed and provided resources for freedom seekers in Ohio risking their freedom and lives to help others. One strong example of this bravery is Joshua McCarter Simpson. He was active in Zanesville and within the church he helped create. Simpson also authored multiple works of anti-slavery songs and speeches dedicating his whole life to helping achieve freedom for all American citizens. The contributions of Black communities and their leaders must not be forgotten as they were the bravest example of American heroes.

Abstract Name: Identifying Key Facilitators and Barriers for Urban Native American Families' Use of Traditional Foods to Support Nutrition-Based, Community Interventions

The traditional diet of Native Americans is nutrient dense and sourced from foods naturally abundant in local environments. Centuries of colonization and forced assimilation have led to a decrease in knowledge of Indigenous foodways. Concurrently, urban Native Americans face a significant burden of food insecurity, which is a well documented contributor to chronic disease risk. Rates of cardiometabolic diseases are more frequent for Native Americans which coincides with the highest mortality rates from diabetes in the United States. The objective of this research is to comprehend the state of urban Native American food sovereignty within the context of identifying barriers and facilitators to the use of culturally relevant foods for cardiometabolic health. A team of three researchers reviewed the existing literature using keywords: urban Native American nutrition, Indigenous food sovereignty, and Indigenous foodways. Articles in Pubmed, Academic Search Premier, and Google Scholar were reviewed for content related to our objective. Twenty-two articles were selected, reviewed, then common themes and admissible data were discussed. Key findings suggest the following facilitators to increased consumption of Indigenous foods are: ensuring the intergenerational sharing of traditions; establishing strong connections with tribal members within the community; promoting sustainable practices; expressing reciprocity with Creation. Barriers identified are: limited access to cultural networks; lack of physical space for communal gardens and gathering spaces; decline in generational knowledge of traditional practices; disproportionate rates of poverty. With these key findings we are able to further support community-based initiatives to reduce health inequities in Native American populations. A paucity in the research was observed with regard to nutrition-related health disparities in urban Native American communities along with effective interventions in order to advance health equity. More work is needed to identify and advocate for future interventions that are effective at reducing health disparities in urban Native American communities in Minnesota.

Abstract Name: CEO Verbal Behavior on Earnings Calls Using Natural Language Techniques

CEOs are central to corporate decision-making and the primary voices in earnings calls—critical moments that shape investor sentiment and market reactions. These calls are more than routine updates; they are strategic performances where language, tone, and clarity can signal confidence or caution. This research applies advanced natural language processing (NLP) techniques to analyze thousands of earnings call transcripts, aiming to uncover how the linguistic choices of CEOs and CFOs influence market behavior. We focus on key textual measures—such as tone, fog (based on the Gunning Fog Index) and words—capturing the sentiment, complexity, and verbosity of leadership communication. Do CEOs who maintain a positive tone generate better market reactions? Does the complexity of language signal competence or equivocation? How does the length of responses in Q&A sessions affect investor confidence? These are the questions

driving our exploration. By analyzing communication patterns across a dataset comprising thousands of earnings calls, we seek to illuminate the relationship between what is said—or unsaid—and how the market responds. More specifically, are subtle shifts in tone enough to sway investor sentiment, or do investors still seek more clarity and precision? Does the density of word usage convey expertise, or does it obscure key insights? Beyond seeking definitive answers, this research elucidates key patterns in how financial markets digest and respond to language, assess leadership, and evaluate corporate performance. Further, this study offers a fresh perspective and framework for examining the intricate nuance between corporate communication and market perception, with implications for investors, analysts, and academics alike. By decoding the language of earnings calls, we aim to provide a richer understanding of how corporate leaders wield words to navigate market expectations—an endeavor as complex and dynamic as the markets themselves.

Abstract Name: A Changing Tide Shifts Only Some Boats: Examining Political and Ideological Trends In Liberal Democracies After Major Economic Dislocations

This project aims to discover whether there were any trends in the politics of five subject countries—the United States, United Kingdom, Canada, Australia, and New Zealand—during elections that took place after periods of economic dislocation that challenged dominant economic orthodoxies at the time, the two periods being the Great Depression and the “Stagflation Crisis”. This trend would be a change in ideology, not just in terms of political party. To complete this study, I conducted a large review of literature not only about certain elections, but about the individuals those elections elevated, and the proper way of studying shifts in politics during economic events. I also read literature related to certain key terms that would help me in my studies, like those of ideology (modern liberalism, neoliberalism) and of political history (the history of all major parties in studied countries). After conducting this research, I found that following the Great Depression, there was only a slight shift to the left across the five countries, as while the United States and New Zealand elected strong “modern liberal” governments, Australia and the United Kingdom did not (although the United Kingdom did join the leftward shift in the Depression-focused 1945 election), and Canada was restrained from doing so by a leader who only took limited steps towards modern liberalism. In the case of the Stagflation Crisis, there was a more definitive shift to the right, as the United States, United Kingdom, and New Zealand all elected neoliberal governments following the crisis. Australia and Canada, meanwhile, ended up with modern liberal governments, although ones that were beginning to embrace some tenets of neoliberalism as well. However, governments were less stable during this crisis, and government shifts came late, after less reactionary alternatives had been attempted, a hesitancy not found in the post-Depression electoral period.

Abstract Name: Exploring the Neurolinguistic Processing of Nonbinary Pronouns in First vs Second Languages

The present study sought to investigate potential differences in how people process nonbinary pronoun constructions (NBPCs, e.g. singular ‘they’) in their first versus second language (L1 vs L2). Research on NBPC processing to date has primarily only focused on L1 with only some literature investigating L2 English processing. Participants (right-handed, native English speakers) were first taught a limited set of French vocabulary and grammar. They then completed an acceptability judgement task (AJT) while undergoing electroencephalography (EEG) recording. During the AJT, participants determined the acceptability of sentences in French and English containing a variety of pronoun constructions. From the EEG recording, event-related brain potentials (ERPs) were extracted to probe the neurocognitive processes active when encountering the NBPCs. The ERPs were compared across conditions within and across languages to understand the effects of a second language on processing. Participants also completed behavioral tasks to measure their political attitudes, implicit biases against transgender people, and their working memory updating ability. ERP effects are predicted to be observed in the P600 component, consistent with L1 literature, suggesting grammatical processing difficulty. N400 effects, suggesting semantic processing difficulty, will also be tested for as these are more common in early L2 learners. Finally, the Nref component will be probed, which indicates referential processing failure in pronouns. It is hypothesized that individual differences in ERP response will be observed that may correlate with the behavioral metrics. Statistics from linear mixed effects models and significant differences in ERP waveforms will be reported. Implications of the results may elucidate deeper reasoning for reported NBPC interpretation and processing difficulty and suggest ways for overcoming this sociolinguistic issue from a second language acquisition standpoint.

Abstract Name: Sowing the Seeds of Pollution: How Agricultural Plastics are Shaping Soil Chemistry

Plastic mulching has become commonplace in both large- and small-scale agriculture. Despite this widespread use, the practice is of concern to human health as it may be introducing metals into soil. The metals contained within plastics are potentially leaching into soil, destabilizing the environment and leaving humans vulnerable to metal contamination exposure, often without their knowledge. This exposure can have severe health effects including, anemia, organ damage, and increased cancer risk. It is due to these exposure effects that plastics with a thickness of 20-50 μm have been banned in several countries, yet the practice of plastic mulching continues to spread. This study assesses four types of weed suppressant materials for metal leaching potential and physical degradation: polyethylene plastic sheeting, a blue all-purpose tarp, coconut husk, and burlap. Materials were placed in mason jar microcosms consisting of 4 cm of small rocks, overlain with 5 cm of planting soil with the weed suppressant placed on top to imitate agricultural conditions. All microcosms were deployed in the Villanova University's greenhouse with 5 samples of each material collected at the 30- and 90-day time intervals. Each microcosm was watered weekly with 40 mL of deionized water to replicate a 1-inch rainfall event further emulating field conditions. Before deployment and following collection, materials were measured for total and exchangeable heavy metal concentrations using the x-ray fluorescence spectrometer and the inductively coupled plasma mass spectrometer. The physical degradation of samples was evaluated through measurements of weight change. The hypothesized results are that plastic mulching materials will exhibit higher metal leaching and lower physical degradation under field conditions than nature-based alternatives. With these results, this study aims to offer potential alternatives to the widespread use of agricultural plastics and therefore minimize the impact of such plastics on human health.

Abstract Name: Censorship within the Change from Manga to Anime, its Effects in Society, and what it Represents About Japanese Society

In this paper I will be discussing the relation between Japanese manga and anime, and the changes from the transition from manga to anime due to censorship laws within the contemporary period. Continuing, I will discuss what these laws and changes within Japan are meant to accomplish and what their application/results could have on their media as a whole. Next, I will be discussing what changes are made to media when exported to other countries to adhere to their censorship, rating, etc laws. The definition of censorship that I will be using for this paper is: "Places where media that has been changed to limit the themes, concepts, or actions that are deemed unsensible or unwanted by a large (usually government) body." This definition is meant to include things that are commonplace such as blurring, using black boxes or similar, or even censorship that's more transformative via cutting out parts of original material completely. This research will

make people aware of how media can be changed to convey a certain culture's beliefs on what is “appropriate” for a certain group of people. To take it to a more extreme level, this research will also convey how strict/effective censorship can be at a non-concerning level (not censoring certain content to prevent learning about certain information). And how potentially concerning censorship could be put in place with similar laws.

Abstract Name: Does Time of Administration Matter? Effects of Exenatide, a GLP-1 Receptor Agonist, on Clock Gene Expression in the Brain of Type 2 Diabetic Mice

Objective: Type 2 diabetes is one of the most prevalent chronic diseases worldwide, and diabetic vascular complication is a major cause of morbidity and mortality in diabetic patients. Our labs have shown that exenatide, the first glucagon-like peptide-1 receptor agonist (GLP-1RA) drug approved by the FDA for treating diabetes, restored normal daily rhythm of blood pressure, sleep, and feeding behavior in type 2 diabetic db/db mice when administered at ZT0 (zeitgeber time 0 = light on) but not ZT12 (light off). However, the underlying mechanism is unknown. This study aims to explore whether clock genes are involved in the timing effect of exenatide in db/b mice. Approach & Results: Thirty-two 14-week-old male diabetic db/db and nondiabetic control (db/+) mice were split into four groups (4-6 mice/group): db/+ control, db/db control, ZT0 db/db, and ZT12 db/db. The mice were injected with normal saline or exenatide (20 µg/kg, IP) at ZT0 or ZT12. The mice were sacrificed at either ZT5 or ZT17 five days later. The brain cortex, hypothalamus, and hippocampus were collected and processed for total RNA extraction, reverse transcription, and real-time PCR to determine clock gene (Bmal1, Clock, Per1, Per2, Cry1, Cry2, Rev-erba, and Rorc) mRNA expression. Compared to db/+ control mice, the clock gene was disrupted in db/db mice. Interestingly, exenatide administration at ZT0 but not ZT12 restored the normal daily clock gene expression pattern in the brain cortex but not the hypothalamus and hippocampus of diabetic db/db mice. Significance: Our results demonstrate that administering the same dose of exenatide to diabetic db/db mice at different times has different effects on clock gene expression in the brain in a tissue-dependent manner and suggest that exenatide can potentially be used as a chronomedicine against type 2 diabetes and its complications.

Abstract Name: Searching for Pathways Responsible for Hydrostatic Pressure Resistance in Deep Sea Extremophiles

A piezophile is a classification of organisms that thrive under high hydrostatic pressure. They are found in the deepest seafloors and oceanic trenches and have evolved many adaptation mechanisms to grow in hydrostatic pressures exceeding tens of megapascals. These adaptations helped them to overcome cellular stress, including an increased rate of protein misfolding, increased cytoplasmic viscosity, and cellular membrane deformation. To investigate possible genetic adaptations responsible for their pressure resistance, we utilized a shallow dwelling from *Xenopus laevis*. By submitting frog embryos to high hydrostatic pressure, we identified genes whose transcriptional profiles had been altered. By expressing and knocking down these genes, We aim to recreate similar pressure resistance properties in frog embryos. So far, my project is centered on the AP1 complex, whose central genes are Jun and Fos. Both of these genes are induced under high environmental pressure. Jun and Fos are transcription factors that can interact with each other upon activation and regulate a diverse array of cellular activities, including cellular differentiation, proliferation, and apoptosis. Our next step is to overexpress these genes in *Xenopus* embryos via microinjection and test their effects on granting embryos resistance to high pressures.

Abstract Name: Translation and Literacy as Resistance

Translating a novel from one language to another does not create text exactly the same as the original but instead involves an intricate rewriting process that places the translator's influences and perspectives at the forefront of the viewer's reading. This research intends to explore the context, phrasing choices, and possible intentions behind the French translation of *The life and most surprising adventures of Robinson Crusoe of York Mariner* by Daniel Defoe, which was translated by Duchesse de Luynes during the French Revolution. The Duchesse not only translated 16 additional novels, but also printed them on her private printing press, ostensibly to teach her son English. With a sharper eye, one might look at the novels she selected and her choices in translation to determine if she had other motives. Research will first explore Robinson Crusoe through an abolitionist lens of potential reading that contextualizes it as anti-slavery. The Duchess translating and publishing a text such as Robinson Crusoe is thought-provoking when considering why she translated this specific text. She benefits from the French's forcible enslavement, a tool for French imperialism, but is translating a novel satirizing and critiquing slavery to teach her son English during the French Revolution and then following Napoleon Bonaparte's reign. Her translation could be a form of resistance against the French authority, and her translation for the literacy of her child could also be resistance in itself as Napoleon bans private printing presses. This research is significant to the argument that literacy is powerful and influential; without literacy, knowledge is not imparted, resistance then has no soil to take root in and change cannot happen.

Abstract Name: The Correlation between Helicopter Parenting, Academic Motivation and Fear of Failure

This study sought to identify how helicopter parenting correlates to fear of failure and academic motivation in undergraduate students. Excessive involvement in decision-making, conflict resolution, and deficits in knowing when to withdraw are all factors discovered as important in determining overparenting behaviors seen in children. Regarding fear of failure, several studies defined it in terms of motive disposition to avoid failure. Academic motivation has been shown to influence one's goals, past experiences, cultural background, and opinions of teachers and peers. With consideration of the previous literature, the following hypotheses were proposed. Overparenting scores will be positively correlated with fear of failure scores and overparenting scores will be positively correlated with academic performance scores. The Helicopter Parenting Instrument (HPI) was used in this study to assess the excessive involvement, direction, control, monitoring, and support of an overparenting style. To test these hypotheses, the Helicopter Parenting Instrument (HPI), Performance Failure Appraisal Inventory (PFAI), and Academic Motivation Scale (AMS) were administered. Seventy-seven ($N = 77$) undergraduate students participated in this study. The participants consisted of students from a science class and three psychology classes. Upon IRB approval, consent forms and instrument packets were administered in classrooms with the permission of the professor. Participation was voluntary and confidential. The collected data was analyzed by a correlational analysis using SPSS software. It was found that both fear of failure and academic motivation scores were predictors of helicopter parenting. There was a significant relationship between helicopter parenting and fear of failure; specifically, a weak, positive correlation was found between both variables, $r = .269$, $p = .009$ one-tailed. Additionally, helicopter parenting was shown to have a weak, positive correlation with academic motivation, $r = .295$, $p = .005$ one-tailed. Limitations included the homogeneity of the sample, and future research was advised to include more sample diversity.

Abstract Name: APP-GUIDED COLONOSCOPY PREPARATION INSTRUCTIONS COMPARED TO TRADITIONAL PAPER HANDOUTS: A RANDOMIZED CONTROLLED TRIAL

Colorectal cancer is one of the leading causes of cancer-related deaths worldwide, and colonoscopy plays a vital role in its prevention and early detection. The success of a colonoscopy heavily depends on the quality of bowel preparation, yet adherence to preparation protocols remains a significant challenge, with non-compliance rates as high as 25%. This study aims to evaluate the effectiveness of a mobile application designed to guide patients through the colonoscopy preparation process compared to traditional paper-based instructions. The mobile app integrates step-by-step guidance, automated reminders, and visual aids to enhance patient engagement and understanding of preparation protocols. Participants will be randomly assigned to two groups: one using the mobile app and the other receiving standard paper instructions. The study will measure adherence to dietary and medication instructions, bowel preparation quality (using the Boston Bowel Preparation Scale), and patient satisfaction through surveys. Additionally, app usage data, such as task completion rates and login frequency, will be analyzed to assess engagement. It is anticipated that patients using the mobile app will demonstrate higher adherence to preparation protocols, resulting in improved bowel cleanliness scores and fewer incomplete procedures. The app is also expected to enhance patient satisfaction by providing real-time guidance and reducing confusion associated with traditional handouts. These findings could have a transformative impact on clinical practices by supporting the integration of digital health tools to improve patient compliance, reduce procedural inefficiencies, and

enhance overall healthcare outcomes. This study will provide evidence for the feasibility and potential benefits of app-guided colonoscopy preparation, paving the way for broader adoption of mobile technology in patient care.

Abstract Name: Livia Drusilla: Perception, Power, and Biases

In most ancient sources, there is a common theme of strong women being demonized. Livia Drusilla, wife of Rome's first emperor Augustus, is no exception. I looked beyond that and dived deeper into who she was. Through a comprehensive study of primary and secondary sources, I believe I continued an ongoing discussion about the misogyny surrounding strong women in ancient times. By diving into these sources, I've uncovered the biases that may have influenced historical accounts and have highlighted the extent of her influence and power. I used several primary sources, such as Cassius Dio, Suetonius, Plutarch, and many more. This exploration will show her agency and its impact on her portrayal. I demonstrate her significance to Rome and her vital role in the Principate. This discussion is essential as it challenges and fights misogynistic interpretations of powerful women, allowing us to appreciate and understand the nature of feminine power in ancient civilizations. Through this deeper examination, we can better understand the historical treatment of strong women and the societal structures that shaped these narratives.

Abstract Name: Examining Conversations on Diet and Nutrition between Obstetric Care Providers and their Patients at Initial Prenatal Care Visits

The ACOG emphasizes eating well and maintaining nutritional goals during pregnancy to promote healthy maternal and fetal weight outcomes. Few studies have examined the frequency and way obstetric (OB) providers speak with pregnant patients about eating, food, and nutrition. This study aims to characterize how often OB clinicians address food and eating with their pregnant patients and the focus during these discussions. We examined data from an IRB approved observational study that recorded initial prenatal care visits with patient and provider consent. 180 randomly selected, transcribed audio recordings were thematically analyzed for discussions surrounding diet, nutrition, and weight. Out of 180 qualitatively analyzed initial prenatal care visits, 111 visits (62%) included a mention of prenatal diet/nutrition. Of these 111 visits, 104 (94%) included some form of counselling regarding eating from the provider (e.g. "we want to keep it as healthy as possible, so not a whole lot of fats but you want to keep it balanced between like healthy grains and cereals"). Forty of the 111 visits (36%) that mentioned prenatal diet included specific, numeric weight gain and/or caloric intake recommendations from the provider. Sixty-four of the 111 visits (58%) mentioned foods to eat while 69 of the 111 visits (62%) mentioned foods to avoid. Water intake was

mentioned at 64 of the 180 total visits (38%). Sixty-eight of the 104 visits (65%) with diet counseling included a discussion on weight. Discussions regarding food and eating were inconsistent in our observed obstetric visit conversations. The importance of prenatal nutrition warrants more research to investigate the specifics behind how providers address diet and nutrition at initial care visits.

Abstract Name: The Integral is the Area: A Study on Students' Conceptions of Integration

Students pursuing science, technology, engineering, and mathematics (STEM) degrees require some proficiency in Calculus. However, the Calculus sequence has historically been a roadblock for students intending on pursuing STEM. The Fundamental Theorem of Calculus (FTC) is arguably the most important theorem taught in a Calculus I course, yet it is not covered until the last weeks of the semester. As a result, students tend to not hold deep conceptual understandings around integrals, and the conceptions that they do hold are very procedural based. Prior research on student conceptions on integration reveal that students cling to procedural methods for working integrals. In addition students primarily conceptualize integration as two different ideas; a process for finding the area under the curve or finding an antiderivative. In this project, we engage Calculus III students in cognitive interviews around traditional, yet diverse, integral tasks in order to determine whether the conceptions they developed in Calculus I persist through Calculus III. Our focusing research question is, what is the nature of student conceptions around integration? Our preliminary findings confirm prior research, suggesting that students have concept images of integrals that involve procedures such as integration by parts, the substitution rule, and the evaluation theorem. Students were able to apply these anti-derivative procedures, but appeared unconfident in their explanations. The predominant conception was that definite integrals coincide with computing the area under the curve. Findings from this work can inform instructors at our institution (and potentially other postsecondary institutions) about student conceptions and misconceptions. This work can support the development of mathematical tasks to help prevent unproductive ways of interpreting integrals and to instill confidence.

Abstract Name: Examining a Farmers' Market Match Incentive Program - Using Administrative Transaction Data from 2018-2024

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of chronic disease. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity in America. It is particularly challenging for low-income households to purchase/eat the

recommended amount of FV. Farmers' markets (FM) offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at FM. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the ECDFM. This presentation uses administrative transaction data to tell the story and describe trends in both utilization and spending by SNAP shoppers using ECDFM MMP from 2018 – 2024. Our findings show that program utilization increased significantly over the two years during COVID, and then subsequently fell coming out of COVID, with the level of utilization stabilizing at a higher level than pre-COVID. Our data also reveal the average SNAP shopper visits the market 2.5 to 3 times per season representing 9% to 10% of SNAP Households in Eau Claire County. However, it is also the case, that nearly 70% of SNAP shoppers visit the market only one to two times per season. This presentation flows into an analysis of 2023 - 2024 survey data from SNAP shoppers using the ECDFM MMP (same community partner, same mentors).

Abstract Name: "The Beating of His Hideous Heart": The Incessant Draw of Horror Fiction

The cultural obsession with horror has always been a paradox. Telling ghost stories and creating monsters disturbs and frightens us while simultaneously bringing joy and pleasure. This contradiction raises many questions as to why certain audiences cannot get enough. Our research asks: What about horror makes it so captivating? How does literary theory contribute to our understanding of the psychological factors involved in the enjoyment of horror? We first present perspectives from motivational and evolutionary psychology. Horror media activates an addictive pattern of arousal and relief via excitation transfer. This experience is then appraised by the individual as pleasant or unpleasant and subsequently sought out or avoided. Even though this facet of the human psyche has been manipulated for centuries, horror media truly gained notoriety with the first Gothic revival. Edgar Allen Poe, a pioneer of the Southern Gothic genre, reveals why horror is so captivating. A close reading of "The Raven" and "The Tell-Tale Heart," shows how Poe contributes to affect theory. While this theory is not acknowledged extensively amongst Gothic literature scholars, we argue that the purpose of horror is to produce an effect, which is then used to spur the emotions we seek out in horror media. This effect permeates all aspects of horror, from older texts like Frankenstein and Dracula, to more modern films and video games such as The Ring (2002) and the Five Nights at Freddy's franchise (2014-2024). These depictions experiment with point of view, jumpscars, and existentialism to unsettle and fascinate audiences. By examining both the psychological effect of horror and how it impacts audiences, our research exposes the interdependence of these fields, proving exactly why this genre is so prolific.

Abstract Name: Examining the Effects of Visual Feedback on Gait Adaptation in Young Adults with Runway Model Training

Gait adaptation represents our ability to adjust walking patterns to safely navigate environment demands. For example, our ability to walk on a slippery surface by taking shorter, controlled steps or shifting our bodies to avoid obstacles reflects the remarkable adaptability of human gait. Traditional research has used split-belt treadmill walking (SBT) to study how different brain regions respond to novel walking patterns, revealing age-related differences in adaptation strategies. Similarly, runway models develop a deliberate mastery over their walking patterns, implementing adaptations for aesthetic precision, spatial awareness, and temporal control. Current research suggests that with aging, people shift from using spatial adjustments (where they step) to temporal adjustments (when they step) when learning novel walking pattern, revealing age-related differences in adaptation strategies. The controlled movement in runway walking training (RWT) could enhance older adults' gait adaptability, offering structured practice in spatial and temporal control that may help them better navigate challenging environments despite age-related changes. Therefore, this study examines the impact of visual feedback on gait adaptation in young adults with RWT compared to young adults without training. Fourteen age and sex-matched participants between 18 - 27 were recruited for this study. Participants in the RWT group had more than one year of runway walk training. A 17-camera motion capture system tracked our lower-body marker set that measured participants as they walked overground (pre/post-SBT) and during SBT. Participants received external visual feedback during SBT with the coupled (each belt moving at the same speed) and decoupled (belts moving at different speeds). We hypothesize that participants with RWT can adapt faster to a novel walking pattern with visual feedback and greater accuracy. By examining the role of RWT in gait adaptation with external visual feedback, we may identify a new method of gait training for adaptability in older adults.

Abstract Name: Efficient Palladium-Catalyzed Buchwald-Hartwig Amination of Brominated Heterocycles using Pd₂(dba)₃ and Xphos Ligand

Palladium catalyzed reactions have become prominent reactions for creating C-N bonds and are widely used in the synthesis of pharmaceuticals. The reaction progress is substrate specific and supported using specific phosphine ligands with unique electronic and steric properties. In this study, multiple phosphine ligands were investigated in the palladium catalyzed coupling of aliphatic and aromatic amines to a bromine containing benzodiazepine. Our results showed of 5% Pd₂(dba)₃ in conjunction with 10% Xphos was the best catalytic system when carried out in toluene. Full conversion with aniline was observed within 2 h at 90°C. The addition of THF increased the solubility of some products and improved their yields. In general, yields ranged from 26% to 89%. For ortho substituted aromatic amines, we did not observe reduced product formation due to steric hinderance. All products were analyzed and characterized using liquid chromatography-mass spectrometry and NMR spectroscopy.

Abstract Name: Quality of Life Impacts in Young Adult Prosthetic Users: Assessing Mental Health, Financial Challenges, and Sexual Well-Being by Literary Analysis

In the United States, millions of people live with limb loss (LL) or limb difference (LD). There are several documented studies focusing on the quality of life (QoL) issues in many age demographics of the amputee community, yet no research solely centralizes on young adults 18- to 25-years-old. As well, young adults are congregated with the adolescent or adult age groups in the majority of the studies being done. This paper focuses on QoL aspects specifically in these three areas: mental health, financial challenges, and sexual well-being to emphasize the young adult population as they are impacted the most by these realms. A call for research will be made specifically on 18- to 25-year-olds using an artificial limb as their prosthesis to identify areas of need and improve QoL for this age group.

Abstract Name: Exploration of the Psychosocial Consequences Due to Parental Loss .pdf

This exploratory study investigates the lived experiences of parental loss among adolescents, examining the psychosocial consequences of loss through death, divorce, or separation abandonment. Recognizing past research that African American children experience parental loss disproportionately in early life stages, this research acknowledges the unique experiences based on the nature of loss and seeks to answer: How do adolescents experience parental loss, and how do the psychological impacts differ based on the type of loss? Using diversity purposive sampling, nine participants were recruited from a historically black university, representing varied demographics and loss types (three through death, five through divorce, and one through separation/abandonment). Data collection involved semi-structured interviews exploring behavioral, emotional, and social impacts, analyzed through phenomenological coding. A total of seven open-ended questions were posed during interviews. Sample questions include, "How has the loss of your parent impacted you in terms of (a) behaviors, (b) thoughts, and (c) emotions?" and "Has this loss affected your social and interpersonal relationships?" Preliminary results indicate that the type of loss influences psychosocial consequences. Coded interview data were expressed as Grief and Loss, Resilience, Family legacy, Emotional support, Community support, Social Relationships, Education and Career, Growth and Reflection, Identity Formation, Coping Mechanisms, Comparison, and Aspiration. Codes were further themed by individual impact, external sources for paternal loss, and mitigating loss. Results indicated that loss was uniformly oriented to an 'unfilled void.' Implications of the results for future studies include having more knowledge on how to treat the differences in grief and understanding that the void due to parental loss would not be filled. Additionally, results can contribute to the field of counseling, specifically childhood trauma and grief, and help initiate positive change for individuals, families, and communities to heal and move on in life amidst the void of a missing parent.

Abstract Name: Assessing the Impacts of Historic Redlining In The United States On Lichen Species

Historic redlining, a prejudicial loan practice that began in the 1930s, greatly impacted human health and the environment. However, we are just now beginning to understand the full extent of these impacts. In this study, we examined how lichens, which are commonly used as bioindicators to assess pollution impacts and environmental change, have been impacted by historic redlining. To assess this question, we overlaid research grade observations of 2,327 lichens from iNaturalist, the largest citizen science biodiversity database, on to 10,151 maps of Home Owners' Loan Corporation (HOLC) graded areas across the United States. We then assessed whether lichen presence, abundance varied in redlined versus non-redlined areas. Using this approach, we found that there were significant variation in lichen presence in different HOLC areas. In addition, we did find that lichen functional groups that are thought to be most sensitive to pollution (i.e., fruticose lichens) were less commonly found in redlined areas. Collectively, our findings suggest that historic redlining has had lasting impacts on biodiversity and that more research is needed to continue to address this issue.

Abstract Name: Comparative Analysis of Radiation Emissions: Apple Products v. Major Competitor

This study investigates the electromagnetic radiation emitted by various electronic devices, including cell phones (both iPhone and Android), laptops, tablets, and earbuds, with a primary focus on radiofrequency (RF) radiation—a type of non-ionizing radiation. RF radiation is commonly emitted by these devices during usage, and this study specifically examines how different scenarios of device operation contribute to exposure levels. Using RF meters to measure average power density (in $\mu\text{W}/\text{m}^2$), the experiment analyzed radiation levels across different usage patterns, such as making phone calls, texting, browsing, and streaming media. The measurement process varied the distance between the device and the participant, ranging from 3 cm to 20 cm, to understand how proximity impacts radiation exposure. To ensure accurate/reliable results, background RF levels in the testing environment were recorded, and variables such as device type, model, and usage location were controlled, minimizing external factors that might influence radiation readings. In addition, measurements were taken across multiple devices, providing a comprehensive understanding of how different electronic gadgets emit RF radiation under normal usage conditions. The findings of this study aim to assess the potential health risks associated with RF exposure, particularly in relation to long-term effects such as the development of brain cancer. Both children and adults are included in the analysis, with an emphasis on how younger individuals may be more vulnerable to radiation due to factors such as thinner skulls and developing tissue. By evaluating the effects of different usage scenarios and distances, the study underscores the importance of maintaining safe distances from electronic devices, particularly during extended use, to minimize RF radiation exposure. This research serves as a reminder of the need for greater awareness and precautionary measures when using electronic devices, especially for prolonged periods, in order to reduce potential health risks associated with RF radiation.

Abstract Name: Understanding Consumer Response to Polarizing Promotions: An Eye-Tracking Analysis

In this research, I use neuromarketing techniques to study how consumers respond to polarizing, and often controversial, topics and figures referenced in marketing promotions and advertisements. This study utilizes eye-tracking to see how consumers visually react to controversial advertisements conspicuously embedded in an article by tracking participants' eye movements and fixations. After reading the article with these advertisements, participants were asked questions about the article, the advertisements, and their viewpoints on particular (polarizing) topics and figures, such as gun ownership, drag as an art form, Colin Kaepernick, and Joe Rogan, all of which are referenced within the controversial advertisements. I hypothesized that if participants agreed with the advertisement's content, they would look at the ad for longer than if they disagreed. However, I found the reverse effect. Using a correlation analysis, correlation coefficients were slightly negative for all four advertisements (ranging from -0.12 to -0.36), indicating that people are likelier to look at a controversial ad for longer if they disagree with the content than if they agree with it. While these results signal to marketers that highly disliked topics and figures could benefit advertisers who seek attention

and recall amongst consumers, their use is limited because they are more likely to capture the attention of those who disagree with the particular topic or figure and likely have a negative perception of the use. Further research is needed to show how this tactic would impact a company's overall sales in both the short and long run.

Abstract Name: The Taxonomy of Evidence-Based Practices for United States History Education

Teaching the next generation of leaders, thinkers, and American citizens is the role of Social Studies teachers. This is especially true for those instructors who teach United States history. To help in this endeavor, this study has done a systematic review of the literature on Evidence-Based Practices used in teaching United States history. After an exhaustive search, 17 articles were compiled showing practices that have been proven beneficial in various history classes across the United States. A taxonomy was created with arms related to (1) effective technology use, (2) place-based learning, (3) primary document sourcing, and (4) culturally relevant teaching practices. This paper will discuss this taxonomy in-depth and discuss how social studies teachers can improve their teaching using these necessary evidence-based practices.

Abstract Name: Probing the Formation of [HSA-MnIIIPPIX-N(ligand)] Intermediates in Solution and Silica Sol-Gel Using Optical Spectroscopy

Manganese(III) porphyrins ([MnIII(PPIX)]) catalysts are capable of removing sulfur impurities from molecules that mimic compounds present in petroleum, using a relatively mild process called oxidative desulfurization (ODS). In ODS, the sulfur compound is converted to sulfur oxides in the presence of the catalyst and an oxidant such as meta-chloroperoxybenzoic acid (mCPBA). [MnIII(PPIX)] are more effective in the presence of co-catalysts, such as nitrogen-donating ligands (N-ligand). In this work, an artificial [MnIII(PPIX)-N(ligand)] complex encapsulated in a protein matrix, human serum albumin (HSA), is constructed to generate [HSA-MnIIIPPIX-N(ligand)]. The N-ligands that were tested for the formation and stability of the [HSA-MnIIIPPIX-N(ligand)] intermediate are amines (methylamine (MeAm), ethylamine (EtAm), and trimethylamine (TEtAm)), imidazoles (imidazole (Im), 1-methylimidazole (1-MeIm), 2-methylimidazole (2-MeIm), and 4-methylimidazole (4-MeIm)), pyridines (pyridine (Pyr), and 2-methylpyridine (2-MePyr)), and pyrrolidine (Pyr). UV-vis absorption spectroscopy shows that in solution, [HSA-MnIIIPPIX-N(amines)] generate the most stable Mn=O intermediate in the presence of mCPBA, causing the peak at 370 nm to red-shift. Imidazoles are also promising ligands, but the intermediate is not as stable. Pyridines and pyrrolidine have yielded little to no evidence of clear and stable [HSA-MnPPIX-

N(ligand)] oxo intermediates. The [HSA-MnIIIPPIX-N(ligand)] complexes are currently being tested for their stability in silica sol-gel, a matrix that might potentially extend the lifetime of the catalyst, therefore contributing to a more sustainable and efficient process for ODS reactions.

Abstract Name: Dynamic interference effects in reflected light from cone photoreceptors in the living human eye

Cone photoreceptor cells in the retina, responsible for light capture, are dynamic structures that undergo dimensional changes at the micron level when visually stimulated. These changes can alter the position between reflective surfaces within cones, potentially modulating how much light they reflect during retinal imaging. With multiple reflective surfaces, there can be interference effects if the surfaces move relative to each other when visual stimuli are delivered, resulting in increased or decreased reflected light intensity depending on whether constructive or destructive interference occurs. These phase-dependent interactions will shift cyclically as the distance changes, oscillating between bright and dark states to create different reflected intensities. Using a novel optoretinography technique, we investigated whether such interference effects can be seen in the human living eye. Differential coherence imaging at 840 nm was used to image cone reflectivity following stimulation with 543 or 710 nm light flashes. Cone reflectivity was tracked with an adaptive optics ophthalmoscope, measured at 30 Hz. Average reflectivity values were quantified for 243 stimulated cones and 210 unstimulated control cones. For each condition, we determined the frame at which the reflective signal exceeded a standard deviation threshold, the frame where the signal reached its maximum or minimum (depending on if the reflectivity increased or decreased), and the amplitude of the reflectivity change. Among stimulated cones, ~40% had measureable responses (both increasing or decreasing reflectivity) while ~25% of the unstimulated cones also registered responses, but these were 40% lower in amplitude. The response latency for the stimulated cones varied from 0.58 to 2.2 sec to reach the largest interference effects. Our results suggest that visual stimuli can drive reflectivity changes in cones that can be measured in the interference domain, which enables objective testing of cone photoreceptor function, with potential implications for a new diagnostic tool for retinal disorders.

Abstract Name: PINK-1-Associated Extracellular Vesicle Export of Tumor Suppressors in Cancer Cells Undergoing Oxidative Stress

Mitochondrial dysfunction is associated with many life-threatening illnesses, from Parkinson's disease to

malignant cancers. Cells remove damaged, aged, or stressed mitochondria through a process called mitophagy. Our team is investigating a potential pro-tumor survival mechanism cancer cells enact with the help of mitophagy initiation and subsequent export. Mitophagy initiation is sensed by the molecule PINK1, triggering the isolation and packaging of the damaged mitochondrial segment for degradation through the lysosome. Cancer cell mitophagy is triggered by elevated oxidative stress and mitochondrial DNA damage caused by hypoxia, chemotherapy, radiotherapy, and immunotherapy. In our recent study, we discovered a secretory form of mitophagy in which damaged mitochondrial segments are packaged and exported outside of the cell within PINK1+ extracellular vesicles (EV). Additionally, we found that these PINK1+ EVs export tumor suppressors (TS) phospho-P53 and Merlin along with mitochondrial segments outside the tumor cell. It has been discovered that p53 is phosphorylated by PINK1, ultimately enhancing mitophagy. We also found that Merlin, an unappreciated TS associated with neurofibromatosis, interacts with p53 through the MDM2 mediator. We hypothesize that secretory mitophagy export of TS and other mitophagy-related proteins is an adaptive mechanism of cancer cells to withstand oxidative stress and avoid apoptosis. The export of TS p53 and Merlin were analyzed in 4T1 & IOMM-Lee cells. We isolated EVs via differential ultracentrifugation, followed by immunoprecipitation of purified EV samples with PINK1 and phospho-p53 to identify protein-protein interactions. Western blotting and mass spectrometry were performed to validate immunoprecipitation results and PINK1 and p53 association. Understanding the role of EV-mediated export of TS in secretory mitophagy can reveal novel mechanisms aiding cancer cells' survival under oxidative stress caused by chemotherapy or other treatments, offering potential therapeutic targets for various cancers.

Abstract Name: Pre- and Post-Intervention Blood Pressure Analysis: A Statistical Approach

Hypertension remains a critical global health concern, necessitating effective interventions to manage and reduce blood pressure. This study seeks to evaluate the effectiveness of a specified intervention in reducing systolic and diastolic blood pressure. The central research question is: "Does the intervention significantly reduce blood pressure among participants?" To address this question, data will be obtained from the SPRINT database, an established source of high-quality clinical trial data. Pre- and post-intervention blood pressure readings will be downloaded in CSV format for analysis. The dataset includes paired measurements for participants before and after the intervention, enabling a robust within-subject comparison. The methodological framework involves organizing the data into two columns representing pre- and post-intervention blood pressure readings. The normality of the differences will be assessed using the Shapiro-Wilk test. If the differences are normally distributed, a Paired Sample t-test will be conducted to compare the means. If normality is violated, the Wilcoxon Signed-Rank test will be used as a non-parametric alternative. Statistical outputs, including t-values and p-values, will determine the significance of the findings. The anticipated results will include a comparison of mean blood pressure before and after the intervention, with a focus on the effectiveness of the intervention in achieving statistically and clinically significant reductions. These findings will be discussed in the context of their implications for hypertension management and future research. This study aims to contribute to the growing body of evidence on blood pressure interventions by employing rigorous statistical analysis to evaluate efficacy. The results are expected to provide valuable insights for healthcare practitioners and researchers in the field of cardiovascular health.

Abstract Name: A Thorough Comprehension of the Chemical Properties of *Salvadora Persica*

One main risk factor for unpredictable diseases that limit the lives of many individuals is the lack of proper oral hygiene. The most common treatment for oral infections is antibiotics and it was found that around 142,155 antibiotics were prescribed per 1,000 dentists per year. While antibiotics do a great job of treating infections overall, there are also many other associated risks, such as treating chronic periodontitis with antibiotics, which can lead to tooth loss and microbial resistance. The increasing use of antibiotics calls for understanding other preferable alternatives to preventing oral infections. A potential practice for dental care that has been around for ages is using herbal products such as cloves as an analgesic, rosemary oil as an antitoxin, and miswak, *Salvadora Persica*, as an antimicrobial agent [8]. Miswak has been shown to reduce bacterial count by 80% after 45 seconds of washing the mouth with miswak. Common compounds extracted include alkaloids, flavonoids, glycosides, vitamins, essential oils, minerals, sterols, and terpenes. Nevertheless, the chemical properties of miswak have yet to be investigated throughout. It is essential to understand the chemical properties of miswak to allow further investigation of its potential use as a widely known product or to comprehend any side effects or risks associated with it. In this study we aim to 1) extract compounds from miswak to investigate its chemical composition and 2) comprehend the importance of the chemical composition of Miswak and its critical role. To conduct this study, I extracted miswak in methanol and performed Thin Layer Chromatography and Column Chromatography. I hypothesize that the chemical composition of Miswak will contain diverse compounds beneficial for dental and overall health.

Abstract Name: Immunophenotyping of Circulating CD4 T cells in murine Steatohepatitis

Metabolic dysfunction-associated steatohepatitis (MASH) is a growing concern affecting about 6% of the US population. MASH is associated with an accumulation of fat in the liver which can lead to inflammation and fibrosis. It is gradually becoming evident that T lymphocytes contribute to the pathogenic immune response in MASH. Our unpublished data reveals heterogeneity within the liver CD4 T cell compartment when comparing healthy and MASH mice. Previously, we identified that there is a distinction among the CD4 T cell populations, particularly, the pro-inflammatory Th1 subtype of CD4 T cell was upregulated in the MASH liver. It is essential to understand whether the changes in the CD4 T cell landscape are systemic or localized just to the liver. Therefore, we sought to investigate the CD4 T cell landscape in the blood using a murine MASH model. Wild-type mice were fed either a MASH-inducing diet high in Fat, Fructose, and Cholesterol (FFC) or chow for 24 weeks. Thereafter, CD4 T cells were isolated from the peripheral blood and were subjected to mass cytometry by time-of-flight (CyTOF). An unsupervised clustering algorithm identified 18 unique CD4 T cell clusters. We observed that MASH peripheral CD4 T cells had a lower frequency of clusters of central memory T cells, and naïve T cells when compared to chow-fed mice. Additionally, Th1 and Treg subtypes were more abundant in clusters only in FFC-fed mice. Here, we demonstrate that the changes in CD4 T cell homeostasis in MASH mouse livers are replicated in the blood, and we speculate that the changes in CD4 T cells are systematic.

Abstract Name: The Influence of Practice Effects during Neuropsychological Testing of Cancer-Related Cognitive Impairment

As the cancer survival rate continues to increase, a larger number of patients are experiencing changes in cognition associated with cancer treatment, referred to as Cancer-Related Cognitive Impairment (CRCI). We recently conducted a longitudinal CRCI study which employed a battery of neuropsychological tests given both pre-chemotherapy and post-chemotherapy. Study results showed an unexpected trend: patients self-reported worsening experiences of CRCI after receiving chemotherapy, but their neuropsychological test scores improved across this same period. Here, we aim to determine whether this unexpected trend was an artifact of the methods being susceptible to artificial score improvement over time: a practice effect. To achieve this, we calculated Reliable Change Indices (RCIs) to determine how many patients displayed meaningful score changes across timepoints. We then corrected for any practice effect using a Standard Regression-Based Change model (SRB). After applying the SRB, we calculated another RCI for the corrected data. We found that prior to correcting for practice effects, 15% of our sample displayed a reliable score change; however, after correcting for practice effects, the proportion of patients displaying reliable score change decreased to 9%. This decrease in the number of patients displaying reliable change indicates that some amount of the score improvement observed was the result of practice effects rather than true cognitive improvement in the patients. Currently, we are using the same methods on a sample of healthy subjects whose scores we plan to compare to our preliminary data. We expect the healthy individuals to show improvement on the neuropsychological tests over time, but to a significantly greater degree than the CRCI patients. We expect that the difference obtained from subtracting the healthy volunteer improvement from the CRCI patient improvement will indicate the true amount of underlying cognitive decline experienced by the CRCI patients that may have been masked by practice effects.

Abstract Name: Synthetic vs Real-World Data: A Study in Data Poisoning and its Effects

As new Artificial Intelligence (AI) models are released seemingly every day, cybersecurity experts are growing increasingly concerned with the data used to train these models. As the pace to develop new models quickens, many are turning to AI-generated, synthetic data to increase efficiency. The use of synthetic data significantly reduces the time spent on data collection and cleaning, allowing for faster creation of new models. However, emerging research suggests that these techniques may be creating insecure, unstable models. To address this growing concern, we created two separate AI models, one trained on synthetic data, the other trained using real-world data, and conducted data poisoning campaigns against each model. Our real-world data collection process focused on movie reviews published in newspapers from 1970-1999. The

use of movie reviews allowed us to establish a baseline of truth from which to develop our poisoning campaign, and the period helped ensure each article was written by a human. The synthetic data was generated using GPT-3.5. By training two models trained on the same topic, we were able to directly compare the results of data poisoning in synthetic and real-world data. We anticipate our findings will show that the synthetic model was more susceptible to data poisoning than the real-world model. Further research can examine the stability of hybrid models as well as determine the long-term effects of using synthetic data.

Abstract Name: Failed Maternal Healthcare Within Prison Systems in Latin America

Between 2000 and 2017, the female incarceration rate worldwide increased by 53.3%, whereas the male incarceration rate increased by only 19.6%. Thus showing a rapid incline of maternal inmates, but a lack of resources for them. Latin America has among the highest female prison population rates in the world, relative to the national population (Walmsley, 2017). Maternal healthcare in Latin American prisons face significant issues due to overcrowding, unsanitary facilities, and limited access to medical care. Female inmates construct a minority group in prison, while discrimination within the system is frequent as they do not cater to their vulnerability. Their own special needs and characteristics are not taken into account, and there are unfavorable differences in terms of structure, treatment, and maternal health care (Esteban-Febres S et. Al, 2019). This study primarily focuses on countries with greater risk of increase to their infant mortality rate. Children are often incarcerated with mothers during their term served. These environments create an unsanitary and dangerous way of life for developing children, and will later result in child malnourishment, inadequate socialization, early onset communal disease, as well as shared punishment from their mother (Friedman-Rudovsky, 2009). Risk of death and severe injuries to children are very prevalent in these prisons as gang violence and attacks are frequent and rarely prevented from guards. An occurrence of this happened in Honduras where 46 inmates were killed in a women's prison when a fight broke out between rival gangs, attacking each other with guns, machetes, grenades, and flammable liquid (Spitznagel, 2023). The purpose of this study is to examine maternal health issues, childcare, and maternal deaths inside Latin American prison systems, while advocating for a change and policy influence.

Abstract Name: Pilot Laboratory Test of Interactions Between River Snails and Cyanobacteria Microcoleus

Benthic harmful cyanobacterial mat proliferations in rivers are a recent environmental problem threatening aquatic ecosystem health and human society by producing potent neurotoxins. Aquatic snails graze on algae,

but it is unclear whether they may consume toxin-producing filamentous cyanobacteria and the effect of cyanotoxins on their behavior. This pilot experiment aimed to expose native aquatic snails to strains of the cyanobacterial genus *Microcoleus*, which may produce neurotoxin anatoxin-a. The Shenandoah River in Virginia currently experiences benthic cyanobacterial harmful blooms in addition to historical proliferations of filamentous green algae. In October 2024 we collected aquatic snails, *Leptoxis carinata*, from the Shenandoah River. *Leptoxis carinata* are native to Virginia, very common and abundant, and feed primarily on diatoms. We acclimated the snails in laboratory tanks, at standard lab room temperature, and fed them for 20 days with commercial pure *Spirulina* (Cyanobacteria) Algae wafers. For the triplication experiment, we exposed a single snail to anatoxin-producing and non-toxic unialgal strains of *Microcoleus*, isolated from the Shenandoah River. The experiment was conducted in petri dishes to better observe the snail movements. We made observations on the movement behavior and trajectories of the snails for two hours. All three snails were attracted by the toxic filaments and moved to the filament clump but did not consume it. In contrast, one of the snails exposed to the non-toxic *Microcoleus* filaments actively grazed it. Our preliminary data indicated that the toxicity of cyanobacteria may play a protective role against snail grazing. To better understand the feeding preferences of aquatic snails we plan to extend the experiments with more snail and cyanobacterial species. Aquatic snails are well known regulators of diatom species composition in streams, but more data is needed on their effect on benthic algae.

Abstract Name: Occupational Risk Associated with Voice Use Amongst Professional Wrestlers

Main Argument: Throughout the years, there has been a wealth of literature investigating the prevalence of voice disorders in occupational voice users (e.g. teachers, singers, actors). Increased risk factors of voice difficulty have also been identified in athletes during sports performance. The purpose of this study is to identify the demographic trends, vocal habits, and occupational risk factors for voice disorders in a novel population: professional wrestlers. This pioneering work aims to provide insight to build context around preventative measures and to inform medical, surgical, and behavioral voice treatments in this population. **Method/Procedures:** An online survey was disseminated to professional wrestlers through various outlets. To encourage uninhibited responses, grass-roots recruitment was used primarily through wrestling journalists and pundits who agreed to disperse the survey through their contacts in professional wrestling. The survey included forced choice questions about demographics (e.g. years of experience, years at current/previous company, roster activity) and personal vocal habits. It also included Likert scales and ordinal rankings of job-related tasks to identify vocal demand and occupational risk factors. Respondents were also asked about their perception of their own voice (e.g. Voice Handicap Index-10 and Voice-Related Quality of Life) and of voice disorders in the profession of professional wrestling, more generally. **Results:** The results of the survey revealed a genuine need for additional investigation of this population. The overall objective of a professional wrestler is to obtain a strong emotional reaction from the audience. To achieve this goal, performers encounter several job-related risk factors contributing to increased vocal demand: impassioned “promos” (speeches) sometimes using character voices, unamplified yelling/shouting at fans in attendance in the presence of excessive background noise inside an arena with 15-100K audience members, whispering “called spots” (reminders about upcoming choreographed moves) while wrestling in the same acoustically-challenging environment, and a grueling travel schedule.

Abstract Name: Understanding Participation in Adaptive Exercise Programs for Spinal Cord Injury

Spinal Cord Injury (SCI) trials often face challenges with recruiting and retaining participants in clinical trials. This poses a challenge to research and slows the therapeutic process, possibly preventing or delaying the development of new treatments. This study examines the barriers to enrollment and retention in a 12-week adaptive exercise program for people with SCI. This program randomized participants into immediate or delayed-start groups, providing blood samples and completing physical assessments pre- and post-program. The main barriers to participation included transportation issues, scheduling conflicts, illness or injury, and a desire to be in the immediate-start group. In contrast with previous research, no potential participants declined due to concerns about possible exercise-related side effects. Some possible solutions based on these barriers include reimbursement of transportation costs for participants, expanding program locations to be closer to the participant's home, and providing alternative treatments for potential participants who only want to be in the immediate-start group. These findings highlight the importance of accessible studies designed with SCI participants in mind. They also suggest that addressing these barriers can enhance recruitment and increase retention of participants. Which would make for a more inclusive and complete research process for a major condition like SCI.

Abstract Name: Beyond the Ward: Exploring Interpersonal Dynamics in Psychiatric Confinement

This autoethnographic study investigates the intricate relationships and experiences at a psychiatric hospital in Cairo, where I was admitted for 20 days. It aims to comprehend the institutional social framework, staff-patient relations, and mental health care procedures involved. I had visited the same hospital as a psychology student as part of my coursework, but my view of the place dramatically shifted when I was a patient. I encountered unexpected relationships, surprising events, and complex power dynamics. These encounters consequently revealed ethical concerns and reflected social structures that prompted questions comparing the institution to the "outside world." I employ participant observation, informal interviews, and document

analysis focusing on the interactions within the different wards, including addiction, gendered units, and common spaces. I use my access to the hospital facilities, personal journals, and other people's experiences as a significant part of the research. The research explores the negative and positive relationships developed among patients, the ethical dilemmas the staff faces, and the bureaucratic aspect of care. It examines the similarities between psychiatric confinement and imprisonment, considering the stigmatized view of mental health care and the effects on patient well-being. Ethical considerations were crucial to ensure the sensitivity to the vulnerability of the participants and the informed consent throughout the process. The research supports community-based mental health care takes into account and advances our knowledge of the unique social structure of psychiatric institutions. It recommends more research on how mental health facilities could achieve a balance between protecting patient well-being and growth in interpersonal relationships.

Abstract Name: Reviewing The Mental, Physical, And Societal Impacts of COVID-19 On Communities of Color

Although cases of COVID-19 have drastically declined, the symptoms and results it caused did not. COVID-19 has produced physical, mental, economic, and societal impacts affecting individuals worldwide. Communities of color continue to be disproportionately impacted by the pandemic. Thus, the current study attempts to shed light on the challenges minorities face due to COVID-19. In our previous research, the North Carolina (NC) Department of Health and Human Services developed the HBCU Health Equity Data Consortium (HEDC) to assess the differential impacts of COVID-19 on communities of color. The HEDC collected over 11,000 surveys across NC, with our specific geographic region (Region 2- Western, NC) collecting over 3,000 survey responses, with over 1,711 eligible for analysis. Survey responses indicated that 30-35% of our participants reported experiencing mental health impacts as a result of COVID-19, including an increase in anxiety and stress. The survey responses also revealed that some participants experienced decreased income, lost their jobs, and lost property. To further expand on our findings, we are conducting focus groups to gather additional information on the continuous impacts of COVID-19. The purpose of the qualitative study is to identify the long-term and/or ongoing impacts of COVID-19. The focus groups were conducted with 96 participants from eight (8) community-based organizations (CBOs). Our findings highlight the post-pandemic impacts and challenges experienced by participants, with an emphasis on bringing awareness to the resources needed to mediate these impacts.

Abstract Name: Higher Education's Paywall: The Impact of Privatized Academic Resources on Students

Currently, in the United States, accessible postsecondary education is not a reality for many citizens, as

numerous expenses hinder students' pursuits of higher education. One of the most insidious expenses tied to postsecondary costs is academic materials. Most college students do not have the expendable income to incur these costs, as most of their limited income is going toward tuition and living expenses. The additional cost of academic materials can create another financial barrier for students to overcome, which can lead to poor grades, reduced program options, course load restrictions, and withdrawal from courses. These impacts injure postsecondary students' educational autonomy and exacerbate the inaccessibility of equitable and affordable higher education. However, this does not have to continue to be the reality of postsecondary students. Open-access publication of academic resources and research could alleviate this financial burden and make higher education more equitable. This can be seen through the increase in open-access programs, ZTC programs, and student-led solutions that circumvent the price of academic materials. Privatization of academic materials does nothing but harm students by creating more economic barriers. I hypothesize that if accessible postsecondary education is ever to be achieved, open access must replace privatization in the higher education sector. My poster highlights research relating to the economic burdens college students experience due to expensive academic materials and how open-access materials can ease such burdens. The poster will shed light on the ill effects of the privatization of academic materials and some of the concerns raised regarding the credibility of open educational resources.

Abstract Name: Vitamin C Content in Different Parts of an Orange and Lemon

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available products and food items using titration techniques. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the highest concentration of vitamin C, a crucial antioxidant that plays a vital role in human health. The experimental approach involves titrating the samples, employing 2,6-dichloroindophenol (DCIP) as the titrant, chosen for its ability to exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. Citrus fruits such as oranges and lemons are known to contain high levels of Vitamin C. The purpose of this experiment is to determine which parts of these fruits contains the highest concentration of Vitamin C. Specific cuts of the fruit and its flesh were harvested for analysis. Samples were collected at regular intervals over some time, and the vitamin C content was analyzed using a standardized titration method.

Abstract Name: Tetrahedral DNA Nanostructures for the Targeted Delivery of Cisplatin to Treat Non-Small-Cell Lung Cancer

This study explores whether Tetrahedral DNA Nanostructures (TDNs) can improve cisplatin delivery to non-small-cell lung cancer (NSCLC) cells, enhancing therapeutic efficacy while reducing toxicity. NSCLC, the most common type of lung cancer, carries high mortality rates despite cisplatin-based chemotherapy, a standard treatment. However, cisplatin's clinical application is limited by severe side effects and multidrug resistance (MDR), which diminishes its effectiveness. Recent advancements in DNA nanostructures, like TDNs, offer promising drug delivery solutions, as TDNs are biocompatible, stable, and capable of penetrating biological barriers, potentially bypassing MDR by delivering drugs directly to cancer cells. In this study, optimal DNA nucleotide sequences were designed for structural integrity through multiple trials using NUPACK, and a 3D TDN model was constructed in OxView to simulate effective cisplatin binding to guanine residues within the DNA strands. Cetuximab, an EGFR-specific antibody, was conjugated to the vertices of the TDN to target EGFR-overexpressing NSCLC cells, while a pH-sensitive linker was incorporated to release cisplatin selectively within the acidic tumor microenvironment, preventing damage to healthy tissue. OxView simulations confirmed the TDN's structural stability and degradation behavior, maintaining integrity until reaching the tumor site. This approach is expected to increase cisplatin accumulation specifically at tumor sites, overcoming MDR and minimizing toxic side effects on healthy cells. The findings will discuss TDNs' potential as a targeted therapeutic tool for NSCLC, centring on how this nanotechnology can enhance cisplatin's effectiveness and contribute to more effective cancer treatment strategies.

Abstract Name: In Vitro Anthelmintic Activity of Hydro-Ethanollic Extracts of *Syzygium aromaticum* and *Panax notoginseng* on Ova of *Haemonchus contortus* from Spanish goats.

The threat of anthelmintic resistance in haemonchosis-infected goats has become a global concern, prompting trials with traditional medicinal plants claimed to have anti-parasitic properties against worm-stages, with the added advantage of being 'natural'. This study investigated the in vitro anti-parasitic potential of two plants, *Syzygium aromaticum* (clove) and *Panax notoginseng* (black pepper), using *Haemonchus contortus* eggs harvested from Spanish goats with a FAMACHA score of 3 or above. Ovicidal activity (OA) was evaluated using 100 eggs/well/in 96-well flat-bottom plates, suspended in 100 µl distilled water. All preparations were conducted in triplicate. A 50 mg/ml solution of each hydro-ethanollic plant extraction was serially diluted and added at 2 µl per well to final concentrations of 10000, 5000, 2500, 1250, 625, 313 and 156 µg/mL. There was a negative control of 1.5% ethanol, and a treatment positive control comprising of levamisole hydrochloride with concentrations of 1, 0.5, 0.25, 0.125, 0.625, 0.3125 and 0.0078µg/mL were included. All plates were incubated (27°C, 24 Hr.) where after the hatched larvae (HL) were counted under a light microscope. The ova hatching inhibition (OHI) capacity was calculated as: % OHI = (100 – HL of treatment group) – (100 – mean HL of the negative control). The effect of plant extract on the ova of *H. contortus* was concentration dependent as %OHI decreased with reduced concentration. At the highest concentration (10000µg/ml), the mean %OHI was significantly higher ($p < 0.0001$) in *S. aromaticum* (82.2±2.3) compared to *P. notoginseng* (53.9±1.6). The proportion of *H. contortus* OHI percentages were seen to be concentration

related. In conclusion, the hydro-ethanolic extract of *S. aromaticum* exhibited better potential at hatching inhibition against *H. contortus* than *P. notoginseng*.

Abstract Name: Secretion of symbiotic fungus-derived ergot alkaloids from the morning glory *Ipomoea tricolor*

Ergot alkaloids are pharmaceutically and ecologically important chemicals produced by fungi, including the *Periglandula* species symbiotic with the common morning glory *Ipomoea tricolor*. Previous work indicates that the ergot alkaloids produced by *Periglandula* species occur in high concentrations in *I. tricolor* and suppress parasitic nematode populations. We hypothesize that ergot alkaloids are secreted from roots into the surrounding medium. To test this hypothesis, we devised a hydroponic system featuring 3D-printed net pots and Hoagland's solution to facilitate sampling of roots and the associated growth medium. Half of the plants were treated with the systemic fungicide tebuconazole to suppress the contribution of the symbiotic fungus. Plant tissues and growth medium were sampled regularly over six weeks, and ergot alkaloids were detected and quantified by high-performance liquid chromatography with fluorescence detection. Our data demonstrate that ergot alkaloids, including lysergic acid α -hydroxyethylamide, ergine, and ergonovine, were secreted from roots. These alkaloids were secreted in two phases: an initial flush of seed-inherited alkaloids, in both non-treated and fungicide-treated plants, followed by distribution and secretion of newly synthesized ergot alkaloids in non-treated plants only. Of seed-inherited ergot alkaloids transported to roots, approximately 12% were secreted from non-treated plants as opposed to only 4% in fungicide-treated plants. These data indicate a role for the symbiotic *Periglandula* species in secretion or perhaps an unintended consequence of fungicide treatment. Newly synthesized ergot alkaloids were detected only in non-treated plants, where they increased in all tissues from week two through week six. Hypocotyls contained the highest concentrations followed by roots. These newly synthesized ergot alkaloids also were secreted from roots at a rate similar to that of seed-inherited alkaloids. Since ergot alkaloids are present in very high concentrations in morning glory roots, secretion of even 12% may have significant ecological effects on the rhizosphere.

Abstract Name: A Targeted Genetic Screen to Determine Calcium Signaling Requirements in *Drosophila* Primordial Germ Cell Migration

The survival of many species hinges on the proper development and fidelity of the germline. The germline is

formed from primordial germ cells (PGCs), which are the precursors of egg and sperm. Across the animal kingdom, PGCs are specified early in embryogenesis and must migrate through the embryo to reach the developing gonad. Our lab uses the fruit fly, *Drosophila melanogaster*, model to uncover the mechanisms of PGC migration. Previous research has shown active calcium signaling in zebrafish and chicken PGCs during migration. Our lab has identified periodic calcium pulses in migratory and post-migratory *Drosophila* PGCs, suggesting that active calcium signaling is conserved among *Drosophila*, zebrafish, and chickens. We aim to characterize the calcium source, signaling components, and subcellular dynamics required for PGC migration using genetic manipulations of calcium channels in *Drosophila*. We first wanted to determine which calcium signaling factors were necessary by targeting Phospholipase Cs (PLCs), a class of enzyme that causes the release of calcium from the endoplasmic reticulum. Of the three *Drosophila* PLCs, we found that only one, *Plc21c*, is required for proper PGC migration. Depletion of *Plc21c* in the surrounding tissue did not compromise migration, suggesting that it is required within the PGCs themselves. We are now assessing the requirements of other calcium signaling factors through targeted genetic screens. Thus far, our screens suggest that IP3 release from the endoplasmic reticulum is required within PGCs for their migration in vivo. Current work includes live imaging of calcium dynamics in vitro of isolated *Drosophila* and mouse PGCs from wildtype and mutant lines, as well as pharmacological perturbations of calcium stores. By using a diversity of experimental approaches and model organisms, we hope to uncover deeply conserved features of PGC migration and development.

Abstract Name: Role of Exosomes on the Detrimental Effect of Tobacco Smoke in Multiple Sclerosis

Multiple sclerosis (MS) is a relapsing-remitting inflammatory demyelinating disease of the central nervous system that affects over 2.5 million people worldwide. There is significant heterogeneity in the prognosis of patients, where some experience severe disease with frequent relapses, while others have mild disease with fewer relapses. We have curated clinical information from patients at the OMRF MS Center and found that tobacco smoke is a major demographic variable significantly associated with poor prognosis. Smokers are three-times more likely to have relapses while on therapies compared to non-smokers. Here, we used proteomic assays to determine biological differences between patients who were smokers and non-smokers. We found that smokers had elevated levels of proteins associated with inflammation compared to non-smokers. Strikingly, many of these proteins were involved in the release of exosomes, extracellular vesicles, that function in cellular communication. Here, our goal was to quantify and molecularly characterize exosomes from the blood of smoking and non-smoking patients and healthy controls. We show that MS patients who smoke have an elevated number of extracellular vesicles in their blood compared to non-smokers and healthy individuals. Based on their size (30-150 nm) and the presence of Syntenin, CD9, CD63, and CD81, we identified these extracellular vesicles as exosomes. Our data demonstrate that MS patients who smoke have elevated levels of exosomes in their circulation compared to non-smokers. Our future goals will focus on determining whether tobacco smoke alters the molecular cargo of exosomes to contain inflammatory molecules, potentially driving increased disease activity in patients.

Abstract Name: Evaluation of Common Xurographic Materials for Rapid Prototyping of Microfluidic Devices

Organ-on-a-Chip microfluidic devices, which simulate 3D cellular interactions, offer significant potential for replicating complex biological systems. However, their adoption is hindered by the high costs, labor-intensive fabrication, and material limitations associated with conventional photolithography. Photolithography, a technique that patterns micron-level features onto a photosensitive resin to create precise molds, is expensive and time-consuming, often requiring specialized equipment and expensive supplies. Devices are cast from resulting molds using polydimethylsiloxane (PDMS) and permanently bonded to glass, through plasma oxidation. Xurography, a fabrication method using commercially available cutter plotter machines (e.g., Cricut® Maker 3) has emerged as a promising alternative. This process employs computer numerical control (CNC) subtractive manufacturing to cut precise patterns out of thin substrates. It achieves a precision comparable to photolithography while being cost-effective, reusable, and accessible. One such substrate, adhesive tapes, has demonstrated the ability to plasma bond to PDMS, forming enclosed devices. This study explored the capabilities of a commercially available cutter-plotter (Cricut® Maker 3), adhesive tape, and PDMS in the manufacturing of a microfluidic device. Tape - PDMS was evaluated for X-, Y-, Z- dimensional accuracy, leakage, burst pressure, flow quality using particle image velocimetry (PIV), production cost, and time efficiency. Results demonstrated that microfluidic tape PDMS devices achieve comparable dimensional accuracy with minimal leakage and high burst pressure thresholds. Flow quality was consistent and reliable, while fabrication time and costs will be significantly reduced compared to conventional methods. This approach has the potential to lower barriers to microfluidic device development by significantly reducing cost and fabrication time. Broader adoption of such methods could improve access to advanced biomedical research tools and accelerate discoveries.

Abstract Name: Assessing the Correlation Between Spatial Access to Primary Care Physicians and Health Outcomes Using the 3SFCA Method: A Maryland Case Study

It is well understood that not everyone has equal access to healthcare. Spatial access to healthcare, often evaluated by driving distance, plays a significant role in this disparity. However, despite its commonality and computational efficiency, driving distance falls short of providing a holistic analysis of spatial access. As a result, scholars have identified a more accurate method of measuring spatial access to healthcare known as the three-step floating catchment area (3SFCA) method. Using Maryland as a case study, this research sought to understand the nature of the relationship between a population's spatial access to primary care physicians (PCPs) measured by 3SFCA and consequent health outcomes. At a census tract-level of observation, spatial access was defined by a tract's spatial access ratio (SPAR) given by 3SFCA, health outcomes were evaluated via all-cause mortality data, and the confounding effects of socioeconomic factors on health outcomes were controlled for through the introduction of the Neighborhood Deprivation Index (NDI) as a covariate. Additionally, adjusted spatial access (ASPA) values were used to identify PCP shortage areas within the state.

Following the analysis of all census tracts within Maryland, spatial access to PCPs was observed to have a negative correlation with all-cause mortality rates. Equally important, rural tracts were generally observed to yield lesser ASPA values than non-rural tracts. These findings suggest that evaluating the SPAR of a population is an effective method for predicting health outcomes and that, with regard to PCPs, rural populations are underserved compared to their urban counterparts. Due to this, further investigation into using 3SFCA's results as an indicator for health outcomes could play a pivotal role in the equitable allocation of healthcare resources across populations.

Abstract Name: Highway Removal and Urban Revitalization: Reconciliation Efforts to Ameliorate Economic and Social Disruption

Predominantly Black neighborhoods around the United States are still experiencing the effects of the construction of highways through their communities. Highways can form physical and social barriers between communities, which leads to neighborhoods facing social and economic isolation, higher poverty rates, and lack of economic opportunities. This comprehensive literature review investigates how these affected communities might be revitalized through highway removal. This analysis of peer-reviewed studies on urban revitalization through highway removal finds that highway removal can improve neighborhood connectivity and business development. Social cohesion in the previously divided communities can also increase if highway removal is implemented. Findings suggest that due to the success of highway removal in Rochester, NY, these same highway removal efforts may be beneficial if applied to other cities. The goal of this research paper is to propose a revitalization plan through highway removal for neighborhoods that have been divided by the construction of highways. Due to the lack of research and studies centered around Jackson Ward in Richmond, VA, more research is needed regarding solutions to connect the community after the construction of Highway 95. Divided Black communities are still adversely affected by highways through their homes, which is why it is important to understand and acknowledge the detrimental consequences of the highways and encourage highway removal efforts. This will hopefully be the first step to ameliorating some of the damage done to these communities.

Abstract Name: Safe Space at Auburn

Experiencing multiple psychosocial stressors such as academic performance pressure, time-management challenges, and work-life balance demands, many nursing students are susceptible to high-stress levels. A nursing student's inability to process stressors can cause issues in a future workplace where the nurse must manage multiple needs. Different methods have been conducted to identify ways to develop stress management skills, including having a designated area for stressor identification and relief. The purpose of

Safe Space at Auburn is to determine whether a room created for stress management allows students to recognize stressors and develop techniques to manage them. Safe Space at Auburn contains evidence-based tools, such as dim lighting, cushioned furniture, pleasant aroma, weighted objects, guided relaxation posters, etc. To measure the efficacy of how the space's capacity to encourage student stress management, third and fourth-semester nursing students at Auburn University College of Nursing will have access to the space and its tools. It is anticipated that students will most often use the room on test days, clinical simulation practices, and quiz days. Before entering the room, students will rate their level of stress using the Subjective Unit of Distress Scale (SUDS). Multiple activities will be provided such as silent reflection, journaling, sensory modulation, muscle relaxation, etc. They will then use SUDS to rate their stress level after using the room. The expected outcome of the project is that students will have a decreased stress level after using the room and will learn strategies to process stress that they can take with them in the future.

Abstract Name: Investigating the Role of the enzyme Monoamine Oxidase in Aggression

This research project studied the role of the enzyme monoamine oxidase (MAO) on aggressive and anti-social behavior in zebrafish. MAO plays an important role in the regulation of neurotransmitters; normal production helps to stabilize mood, regulate emotion and control outbursts. However, low MAO expression is correlated with trouble concentrating, high impulsivity and poor emotional control. Gaining traction as the "warrior gene", low MAO expression was hypothesized to cause violent behavior in humans. Although this proposition is likely untrue, there remains some merit to the premise. For further study, this project introduced the pharmacological inhibitor clorgyline to zebrafish, chosen for their high homology to humans. Clorgyline specifically and irreversibly binds to MAO at the active site. The effect of the disrupted pathway was quantified in two ways: zebrafish behavior and gene expression. Tracking software quantified behavioral patterns in a novel tank, in a mirror test, and in shoals; increased boldness and aggression, as well as declined sociability, were measured in treated zebrafish. Relative gene expression was measured by PCR and gel electrophoresis to confirm the effect of the clorgyline on both the target gene MAO and other genes in the pathway. This project contributes to a growing body of research on the biological, and especially molecular, influences of aggressive behavior.

Abstract Name: CaMKII Involvement in Neural Crest Cell Migration

Neural crest cells (NCCs) are a multipotent embryonic cell population unique to vertebrate organisms. During

development, NCCs undergo collective migration from the neural folds throughout the embryo and contribute to various cell types. This research specifically investigates the role of the multifunctional enzyme calcium/calmodulin-dependent protein kinase II (CaMKII) in migratory NCCs. Previous research has shown that CaMKII is expressed in the neural crest and promotes migration in other cell types, leading us to hypothesize that CaMKII is essential for NCC migration. Using chick (*G. gallus*) embryos as a model organism, neural folds containing premigratory NCCs were isolated from the organism and plated in a culture so that cells would emerge and disperse from the tissue upon reincubation. Neural crest cells either migrated in a culture media treated with the CaMKII inhibitory reagent myr-AIP, or a control culture media with no added reagents. These cultures were then stained and imaged under fluorescence microscopy. Two quantitative analyses were performed based on these images. Dispersion quantifies the area of an entire field of migratory cells relative to the size of the explanted fold, and a morphological analysis measures the characteristics of cell shape in each culture. A two-sample t-test was conducted for both analyses to determine statistical significance. CaMKII-inhibited cultures showed some decrease in migration dispersion, though not statistically significant, and the morphological analysis showed no coherent patterns. The results of this study can neither support nor rule out any conclusion on the role of CaMKII in NCC migration, and more work needs to be done to collect more samples and find more definitive results. This research will ultimately provide a useful precedent for future investigations into the molecular basis of neural crest cell migration.

Abstract Name: Processes of Soil Formation from Basaltic Bedrock in Reykjanes Peninsula in Iceland

Iceland's Reykjanes Peninsula has experienced many eruptive events. Current volcanic activity began there in 2021 with the Fagradalsfjall eruption and is still continuing at Sundhnukur. Eye-witness accounts date the previous eruptive phase to 1211, known as the Reykjanes Fires. Recent studies show that the basalt at Fagradalsfjall most likely came from the mantle plume and the Sundhnukur eruption released magma from a shallower source. This might create differences in chemistry in the basaltic bedrock which in turn might influence soil formation. Due to Iceland's unique geographical location, soil formation processes there are more dependent on original and altered bedrock chemistry, rather than biological activities. Our goal is to learn how soil forms from Icelandic basalt. For this project we collected seemingly unaltered and weathered basalt samples that erupted during the Reykjanes Fires. We selected samples based on their alteration colors for powder X-ray diffraction (pXRD) analysis to compare the mineralogy of unaltered and altered basalt. Preliminary results indicate presence of olivine, pyroxene and calcium-rich plagioclase in the unaltered basalt. X-ray fluorescence data show depletion of calcium, magnesium, aluminum and silicon as weathering occurs. The existence of maghemite in the weathered product might have formed from magnetite in the original basalt as part of the soil forming process. These results will be complemented by petrographic analysis and chemical analysis using Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES). These results provide insight into the first steps of soil production from basaltic rock in Iceland. This is important for agriculture and soil management. This poster will present our data, analytical methods, and implications of our findings.

Abstract Name: The Border Crossing Boogeyman: A Content Analysis Investigating Implicit Bias Perpetuated by Language

This research investigates the role socially learned bias plays regarding attitudes towards immigrants through an examination of the language used in news outlets discussing national security. First, an exploration of the Immigration Control and Financial Responsibility Act of 1996 provides a definition for “illegal immigration” and connects the use of “alien” to describe immigrants in official documents, language that sets the tone for attitudes towards immigrants. Then, a content analysis was conducted between two Instagram posts that each sparked a conversation about immigration, one posted by the Houston Chronicle and one posted by an international news outlet, Reform UK. These news outlets were selected because they are located in places impacted by immigration issues. Using the lens of Henri Tajfel’s “ingroups and outgroups,” which identifies the idea of prejudice and discrimination at a group level, a coding of the comments on these articles suggests that while each sample contains its own individual themes, both sets of comments find an overwhelming commonality in the overlapping themes of nationalism and othering. This analysis found that the language used to create and maintain outgroups (immigrants) separated from ingroups (nationals) not only has an assumed racial component but also shows implicit bias and attitudes of the ingroup. According to the comments, anyone who is perceived to be an immigrant therefore “deserves” the treatment they are receiving. This research is significant because it reinforces Tajfel’s theory that language reflects ingroup and outgroup bias. By furthering the use of language that expresses inherent bias, the perception of who is an immigrant becomes reinforced through imagined boundaries between themselves and others and can promote ethnocentrism.

Abstract Name: Analysis of *Arabidopsis thaliana* Phytochrome Mutants Identified in a Red-Light Genetic Screen

Light is important for plants as an energy source for photosynthesis, as a measure of day/night and seasonal cycles, and as information about the surrounding environment. For this reason, plants have evolved a sophisticated set of pathways to detect and respond to light, which allows them to adjust their development in response to changing conditions. The plant *Arabidopsis thaliana* contains the genes LRB1 and LRB2 (Light-Response BTB 1 and 2) that encode proteins functioning as target adaptors in E3 ubiquitin-ligase complexes that initiate degradation of the phytochrome red/far-red-light receptors. Plants containing mutations of both LRB1 and 2 are hypersensitive to red light due to increased levels of phytochromes. Previously the laboratory of Dr. Gingerich performed genetic screens to identify enhancer mutations which exaggerate the effect of the LRB1/LRB2 mutations; here I describe analyses of two of these. These enhancer mutations are both in the PHYB gene (which encodes the major phytochrome involved in red-light response) and each is predicted to alter a single amino acid in the phytochrome B protein. Each of the mutations increases plant sensitivity to red light and in each case this hypersensitivity is increased when the LRB1 and LRB2 genes are disrupted. Study of these mutations may provide information as to how the phytochrome B photoreceptor functions to detect and transmit light signals. In addition, the line that contains one of these mutations also shows increased sensitivity to blue light. Analyses thus far suggest that it is the mutation in the PHYB gene that is responsible for this blue hypersensitivity. A mutation in phytochrome B that alters sensitivity to blue light is very intriguing and may reveal new insights in to how the red and blue-light response pathways interact with each other.

Abstract Name: Use of visual, auditory, and tactile cues to influence cadence and Achilles Tendon loading in running

Running has a high incidence of Achilles tendon (AT) injuries that may be due to high forces and repetitive loading. Running cadence may influence AT loading. To promote a 10% cadence increase, auditory, visual, and tactile cues were used. Thirty-four male and female runners ran on an instrumented treadmill at 7.5 mph where kinetic and kinematic data were obtained. AT cross-sectional area was measured with ultrasound imaging. Inverse dynamics then static optimization were used to calculate muscle forces and AT loading. All cued conditions increased cadence from the baseline run condition. Auditory and visual cues yielded a cadence increase closest to 10%. There was no difference between auditory and visual cues to increase cadence ($p < 0.05$). AT-related loading variables such as peaks in ground reaction force, AT force, and soleus muscle force were lower when cadence increased to near 10%. Visual and auditory cues reduced AT loading

most compared to the run (baseline) condition. Understanding the relationship between the use of cues and increasing cadence may aid in the treatment and prevention of AT injuries.

Abstract Name: Creating CRISPR edited glypican-2 knockouts in human Glioblastoma cells

Glioblastoma (GBM) is a highly predominant and very aggressive form of brain cancer, constituting approximately 45.2% of all tumors affecting the brain and central nervous system. Although there are limited treatment options available to patients with glioblastoma, including surgery, radiation, and chemotherapy, the success rate for these options remains poor due to the efficient growth of the tumor and the location of glioblastoma in the brain. The few current treatment options for glioblastoma do not consider glypicans, a family of heparan sulfate proteoglycans that are involved in the progression of tumor growth and the signaling of cells. In this study, we specifically focused on glypican-2 (GPC2), one of the six glypicans, and the effect it has on the growth of glioblastoma tumor cells. We used CRISPR technology by designing a single guide RNA to specifically target the GPC-2 gene in the GBM tumor cells. Then we employed cell culture to conduct a clonal expansion to obtain a clonal cell line with the GPC-2 knockout. We then isolated the DNA for Sanger sequencing to confirm the knockout. The removal of GPC2 in these cell lines allows for future investigations of its contribution to cell proliferation, tumor invasion, and treatment options that could provide awareness of new therapeutic approaches for GBM patients.

Abstract Name: How Do Boys' and Girls' Perceptions of Their Own Academic Success Differ in Highschool?

Internalizing gender stereotypes during development can give adolescents a preconceived notion of what they are capable of achieving academically. These stereotypes influence the gender gaps within career fields and play a role in the career and academic choices adolescents make in correspondence to their self-perceptions. More research is needed to determine how these attitudes toward academic achievement develop during childhood and adolescence. Academically successful students have been found to have a positive outlook on their abilities and have strong academic motivation. In this study, I aim to focus on how boys' and girls' attitudes toward academic achievement change as they progress through their education. My research is a quantitative analysis of secondary data from 15,362 high school students who participated in the National Center for Education Statistics' Education Longitudinal Study (NCES, 2002). Within my research, I explore whether boys' and girls' perceptions of their own academic success differ in high school. I am conducting a MANOVA analysis to identify gender differences in multiple measures of perceived academic success. I

hypothesize that the identified variables will differ based on the student's gender. This study will provide a foundation for future research on how student motivation is influenced by other factors (e.g., teacher motivation, insufficient student support, or curriculum insufficiencies). This study aims to contribute knowledge to educational practices, helping educators, childcare workers, and parents understand how they can contribute to positive academic achievement. I anticipate that the findings of my research will give me a better understanding of effective strategies for supporting adolescent academic development.

Abstract Name: Ensemble Learning for Survival Analysis of Lung Cancer Patients using Random Survival Forest

Lung cancer is the leading cause of cancer-related deaths worldwide among both men and women [1]. In 2024, an estimated 234,580 people will be diagnosed with lung cancer in the United States [2]. Overall, one in 16 men and 1 in 17 women will be diagnosed with lung cancer in their lifetime, and approximately 125,000 die annually from lung cancer in the US. The primary objective of this research is to implement multivariate machine learning methods to improve the accuracy of patient outcome prediction. Patients' clinical and demographic information are integrated along with quantitative features about the tumor characteristics extracted from patients' lung CT scans. Univariate Cox proportional hazard (Cox PH) and multivariate models are utilized to identify significant features within the combined collection of data in the integrated dataset. A reduced feature set is created using identified factors. A reduced feature set is then employed in an ensemble learning algorithm for survival analysis, the so-called Random Survival Forest (RSF). RSF model can capture non-linear complex relationships within survival data. It is a nonparametric alternative method to conventional linear survival models [3]. Lung 1, a publicly available dataset of lung cancer patients, is used in this study. The dataset was split into training and testing sets, with 80% allocated to the training set and 20% allocated to the testing set. RSF was trained using the reduced feature set created from patients' information in Lung 1. The probability of 5-year survival for the patients in the test set was predicted. Lastly, Kaplan-Meier [4] curves were generated to compare the observed survival probabilities with the predicted ones by the proposed method. The outcomes are promising and encourage us to extend the proposed method and apply it to larger datasets of lung cancer patients.

Abstract Name: Inspiring Excellence: The Interplay of Family and Teacher Support for Rural High Achieving African American Adolescent Males

This study investigates the academic achievement of African American adolescents, specifically African American males. Our research revolves around two questions: How do the relationships between African

American adolescent males and their teachers foster academic resilience, and how do familial relationships shape their academic achievement. This research is drawn from a larger study focusing on high-achieving rural African American students. Underscored by academic resilience, this qualitative study examines the perspectives of 7 high achieving males from a rural high school, “Allegheny High School” (a pseudonym), located in the southern region of the United States. Students earned an average GPA of 3.55. To understand the components that shape student achievement, the students participated in audio-recorded semi-structured interviews that lasted 45-60 minutes, with questions centering around family, teachers, and peer influence. Sample interview questions include: What does it mean to be a high-achieving student? How do your peers in the school view you? Teachers? What do your friends/parents/teachers/family members say about education and doing well in school? The interviews were analyzed using thematic analysis. Six crucial themes were generated, including but not limited to building and uplifting their community by using their education, the intersection of their determination to be academically high-achieving within an under-resourced school, and the desire to have a family. Despite the institutional adversity these students face, such as high poverty, low teacher retention, and a low graduation rate, they continue to persevere and show remarkable resilience. Dominant in the literature, deficit theoretical perspectives regarding African American student achievement erode efforts to better understand factors that support positive school performance among African American adolescent males. This study advocates for a shift in the research that emphasizes the diverse avenues of success and suggests the need for more research on rural African American males.

Abstract Name: Girls In the Hood: Analyzing the Experiences of Black Girls through Afro Pessimism

My research examines Afro-pessimism through a Black feminist lens, focusing on its implications for Black girlhood and the positionality of Black girls in the United States. Initially coined by David Rieff to analyze African policy, Afro-pessimism gained new relevance in Black Studies, particularly through Frank Wilderson's work. Wilderson redefined it as a framework to understand contemporary violence against Black bodies and the societal perception of Blackness. Afro-pessimism argues that Black individuals occupy the position of slaves despite legal emancipation. However, Afro-pessimism has significant gaps, especially in its treatment of gender and its neglect of Black adolescents, particularly Black girls, who are often not seen as fully conscious or sentient beings within academic discourse. My research aims to explore how Afro-pessimism can be used to analyze Black girlhood, carving out space in the framework to center the experiences of Black girls. My methodology will include the work of Robin Boylorn, who advocates for Blackgirl autoethnography as a research praxis. I will conduct a content analysis of social media platforms like TikTok, exploring how Black girls are depicted and ridiculed in the comments. Additionally, I will perform a textual analysis to explore how Black intellectuals incorporate or overlook Black girlhood. I will engage with the concept of ontological plasticity, as conceptualized by Zakiyyah Iman Jackson, to examine the existence and positionality of Black girls. In what ways is their existence malleable? How can the violence directed at Black girls be understood, given that they experience both racialized and de-racialized forms of transgression?

Abstract Name: The Success of Sustainability Marketing Among Generation Z

This study aims to examine the effectiveness of sustainability marketing among Generation Z through four key hypotheses: (H1) Generation Z consumers understand and are aware of sustainability practices in business marketing, (H2) they perceive brands that prioritize sustainability as more trustworthy, (H3) sustainability influences their purchasing decisions, and (H4) they are willing to pay a premium for sustainable products. The goal is to help marketers understand the relationship between sustainability practices and the purchasing behaviors of Generation Z, particularly college-aged individuals (18-25 years old). This research is significant due to the limited understanding of Generation Z's habits/feelings towards sustainable products. Understanding the newest generation of consumers' attitudes toward sustainability can help brands improve customer retention and brand recognition. The study uses a quantitative online survey with 16 questions across four categories: (1) awareness of sustainability practices, (2) brand trustworthiness, (3) importance of sustainability in purchasing decisions, and (4) willingness to pay more for sustainable products. The definition of sustainability is provided for respondents along with preliminary questions. Attached below is a copy of the Hypothesised Model for this study based on the research hypotheses' and survey categories. A Five-Point Likert scale will measure participants' agreement with each statement. Target respondents are Generation Z (ages 18-25) in the metropolitan areas of New Jersey, New York, and Pennsylvania, aiming for 900 responses. Data will be analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM) with SmartPLS4.1. The findings will reveal insights into Generation Z's preferences and behaviors, providing valuable information for marketers to align their practices with this generation's values. It is expected that the findings will show a clear relation between Generation Z consumer spending and marketing that highlights sustainable initiatives.

Abstract Name: Laccase-Mimicking Bionanozyme for Sustainable Removal of Water Contaminants

Chlorophenols are a widespread class of carcinogenic environmental contaminant found in various water sources, including tap water. Laccase is an enzyme has demonstrated the ability to degrade chlorophenols by reducing the hydroxyl group from the phenol molecule enabling further oxidized and breakdown into carbon dioxide and water. However laccase faces significant challenges for practical applications, due to its complex and expensive synthesis, poor stability to variable environmental conditions such as pH, Temperature, solute concentration, and tendency to denature over time, reducing its effectiveness. A promising alternative to harness laccase catalytic potential but overcome the downfalls of natural laccase we propose the use of bionanozymes. Bionanozymes are engineered artificial enzymes to closely mimic the active site of laccase. Bionanozymes are more cost- and resource-efficient to produce than natural enzymes and because of their artificial nature they show potential to improve the stability issues. Therefore, this study focuses on developing and implementing a methodology using a laccase-mimicking bionanozyme to degrade two chlorophenols, 2,4-dichlorophenol and 2,4,6-trichlorophenol, under varying pH and temperature conditions. Results demonstrate that the bionanozyme successfully achieved over 50% degradation of both chlorophenols

within two days. Furthermore, stability experiments confirmed that the bionanozyme outperforms natural laccase across a broad range of pH and temperature conditions, underscoring its potential as a robust and sustainable solution for chlorophenol degradation. These findings highlight the viability of bionanozymes as an effective alternative to natural laccase for chlorophenol degradation. By addressing key limitations associated with enzyme-based treatment, this study provides a promising pathway for the development of cost-effective, stable, and environmentally resilient solutions for water contaminant remediation.

Abstract Name: Aging Popular Exoplanet Host Stars; A Bayesian Analysis of Stellar Evolution

The discovery of exoplanets beyond our Solar System has transformed our understanding of planetary science and the potential for life elsewhere in the Universe. This project analyzes stellar ages and properties for a sample of stars hosting exoplanets in their habitable zones, utilizing the BASE-9 (Bayesian Analysis of Stellar Evolution) software suite. BASE-9 employs a Bayesian framework to model stellar parameters by integrating photometric, spectroscopic, and astrometric observations. This method provides posterior probability distributions for stellar parameters, offering robust estimations that account for uncertainties and correlations. The primary goal of this study is to refine the age estimates of exoplanet host stars, a crucial factor in assessing the long-term habitability of their exoplanets. The sample includes five well-characterized stars—Mu Arae, Upsilon Andromedae, HD 11964, HD 4732, and HD 73534—all of which host exoplanets within their respective habitable zones. The resulting stellar age estimates are 7.02, 3.60, 8.23, 3.31, and 4.06 billion years, respectively. These findings are analyzed in the context of exoplanet habitability and stellar evolution. By improving the precision of stellar age estimates, this research advances our understanding of the evolutionary history of stars with potentially habitable exoplanets. The study highlights the importance of sophisticated modeling tools like BASE-9 in exoplanet research, demonstrating how Bayesian techniques can yield more accurate and nuanced insights. Ultimately, this work contributes to a broader comprehension of the conditions that may support life in other star systems and informs future studies in planetary science and astrobiology.

Abstract Name: Generative Versus Traditional Design in a 3d Printed Robotic Arm

This research seeks to find if a generatively designed robotic arm can outperform a traditionally designed robotic arm. For this research, a functional robot was used. A section of the robot's arm was picked out and its design constraints were recreated in CREO, a modeling software. The design constraints were then put

through a generative design function within the program. Both the traditional design and generative design were then tested for deflection while holding 10 pounds of force, with one end fastened. The arm section was tested alone without the rest of the robot, but both pieces met the criteria of being a functional arm piece. The pieces were also tested for theoretical deflection on the computer. The hypothesis was that generative design can outperform the traditional design at the same weight. It was found that the generatively designed part had less deflection than the traditional design. Generative design could continue to be used for higher optimized part design. 3D printing makes generative designs more viable in the manufacturing industry.

Abstract Name: What Do I Do? The Development of an Education Program for the Improvement of Interdisciplinary Collaboration in Child Welfare

Child maltreatment (i.e., abuse, neglect, trafficking, etc.) is a national epidemic and Coconino County, Arizona is no exception. Cases of suspected child maltreatment identified by medical staff and/or mandated reporters are referred to law enforcement and child protective services, with potential final resolution through the legal system. The first phase of the project aimed to identify potential issues in the child welfare system in Coconino County by interviewing current professionals involved in child maltreatment cases. Ten professionals from Flagstaff Medical Center, Flagstaff Police Department, Arizona Department of Child Services, and the Coconino County Attorney's Office were interviewed. The interviews were transcribed, and broad concepts were identified and then refined and developed into more narrow themes. The results from these interviews found that when collaborating with other departments and organizations, professionals working in child welfare experience frustration when fundamental miscommunications occur, particularly about the roles and responsibilities of each entity involved. This could include wrongful assumptions about the training or expertise of another entity or misunderstandings about the protocols or regulations that govern that other entity. The second phase of the project is the development of an online education program that provides essential background information about the role of each entity involved in a potential child welfare case, as well as basic information about child maltreatment and mandated reporting. This program will allow professionals working with child maltreatment cases, as well as non-medical mandated reporters such as teachers or clergy members, to better understand their role in a case, how and when to share information with other entities, and best practices for collaboration with others. The content validity of the education program will be evaluated through quantitative and qualitative feedback from child welfare professionals in Coconino County.

Abstract Name: Dumy and the Nation: How Folk Songs Helped Compose a Distinct Ukrainian Narrative

Historiography and ethnography have played a critical role in the development of modern Slavic nationalisms, particularly in Ukraine. As these studies became increasingly popular in the nineteenth century, scholars and members of the bourgeoisie identified folk culture as the key component for the making of the modern nation. Viewed as an authentic window into national history and tradition due to their limited interaction with the modernizing world, rural folk offered the perfect opportunity to illustrate how Ukraine had always been distinct from Russia. As folk culture fervor gripped the intellectual elite of Eastern Europe, however, the focus quickly turned to what specific aspects of rural culture could prove most helpful in combating Russian imperial narratives. As a result, history, national mythology, and language all became critical components of Ukrainian nation-building. One aspect of rural culture, however, managed to combine all three: folk songs, known in Ukraine as *dumy*. Unfortunately, little scholarly attention has been paid to these pieces in Western academia, leaving most non-Ukrainians unaware of the critical factors that distinguish Ukraine and Russia. This paper seeks to remedy that deficit and its consequences by providing an accessible history and analysis of *dumy*. After contextualizing the need to define a distinct Ukrainian nation, it analyzes the intricate role that *dumy* have played in the making of Ukraine's national identity, using the songs themselves—as well as their popular interpretations—as primary sources. It proceeds to examine the differences in *dumy* preferred by Ukraine's folk versus elite. Then, fulfilling its main purpose, it showcases how folk culture was ultimately translated into patriotic songs that glorified and affirmed a distinct Ukrainian identity. Lastly, it explores the resurgence of *dumy* in light of Russia's 2022 full-scale invasion of Ukraine, illustrating how these pieces have taken on new life in Ukraine and the Ukrainian diaspora.

Abstract Name: Developing Ribonucleic Acid (RNA) Thermometers and Fluorescence Spectroscopy for Enzymatic Reactions in *Plasmodium falciparum*

This study investigates RNA thermometers in *Plasmodium falciparum* to understand how the parasite adapts to temperature changes. Using bioinformatics tools and NUPACK, we identified potential RNA sequences that change structure with temperature. These findings were validated through FRET experiments using a Cy3-Cy5 fluorophore pair, revealing RNA structural changes at different conditions. Our approach highlights the effectiveness of combining computational and experimental methods to study *Plasmodium* RNA. Future work will examine the effects of additional environmental factors and explore new therapeutic targets for malaria treatment.

Abstract Name: Advancing high-efficiency solar cells through materials and structural design engineering

Developing next-generation energy sources is essential to meet the growing demands for electricity, especially with the rise of artificial intelligence (AI) technologies that require significantly higher electricity consumption for rapid computational processes. Consequently, the development of renewable, alternative energy sources has become more crucial than ever. In this study, we demonstrate a method to develop high-efficiency single-junction gallium arsenide (GaAs) solar cells using performance engineering. Specifically, we examine how the material properties of each solar cell layer and the structural design of the cells influence their power conversion efficiency. First, we optimize the thickness of each layer, considering key aspects of carrier dynamics, such as doping concentrations, diffusion lengths, and recombination rates. This optimization process, which determines the optoelectronic properties of the cells, is based on analytical calculations and simulations that solve Poisson's and Maxwell's equations. Next, we aim to further improve performance under optimized conditions by exploring methods to reduce sunlight-induced electron loss near the cell electrodes. To achieve this, we incorporate aluminum gallium arsenide ($\text{Al}_x\text{GaAs}_{1-x}$) window layers and adjust the aluminum content (x) to find the optimal conditions for minimizing carrier loss near the electrodes. Our results demonstrate that the quantum efficiency of the optimized GaAs solar cells can reach nearly 90% within the visible spectrum of sunlight. Further enhancements in performance are anticipated with the addition of lossless optical layers on top of the cells. This study presents a pathway to developing high-efficiency, renewable solar cells, addressing the world's increasing electricity needs.

Abstract Name: Interpreting Human-Coyote Coexistence Through the Lens of Indigenous Peoples' Scholarship, Traditional Wisdom, and Scientific Knowledge

Anthropogenic impacts on wildlife habitat and populations are increasing the frequency and severity of human-wildlife conflict, suggesting a need for understanding how humans and wildlife have interacted in the historical past and ecological present. While many populations of wildlife species are declining, coyotes (*Canis latrans*) are increasing in distribution and population density. The highly adaptable nature and behavioral plasticity of coyotes render them an excellent case study for providing insight into larger apex predators who also experience human interaction. This work aims to evaluate whether there are lessons from Indigenous peoples' traditional wisdom and scientific knowledge for coexisting with coyotes. There is a gap in the understanding of "temporal and spatial patterns of human-coyote conflicts, despite that such information can be an important step in developing and optimizing management efforts." This work seeks to identify historical evidence of human-coyote relationships through temporal and spatial patterns of existing scholarly work and through oral histories of historical Indigenous peoples including the Cheyenne, Arapaho, Ute peoples and the many communities that have stewarded modern-day Colorado. The methodology of this paper will include a narrative review and interviews with local Indigenous keepers of traditional ecological knowledge. Throughout these interviews, I hope to garner oral histories on human and coyote relationships. I expect to find historical examples of coexistence with coyotes in the literature and through oral histories that can be applied to the current and future management of relationships. This research will contribute to our understanding of coyotes and provide critical insight into the ways in which Indigenous peoples navigated relationships with them historically. The findings could be valuable across interdisciplinary fields seeking to have a respectful relationship with coyotes. Coyotes cannot improve our relationship and interactions with them; it is our responsibility to do so as neighbors, scientists, and residents of this land.

Abstract Name: Beyond The Event Horizon: Exploring Black Holes in Science, Film, and Society

This study investigates the potential of cinema in shaping public perceptions of astronomical phenomena by analyzing *The Black Hole* (1979) and *Interstellar* (2014), with an aim to explore the films' impact on popular scientific understanding and public engagement with black holes. Although black holes began capturing theatergoers' attention in the 1970s, evoking both fascination and fear, particularly with the release of Disney's *The Black Hole* (1979), such responses resulted in the limited knowledge available. Few studies compare the ways in which scientific accuracy in film influences public perceptions of astronomical phenomena. To address the impact of film on popular knowledge, this research integrates a comparative content analysis, drawing on the perspectives of physicist Kip Thorne, film scholar David Kirby, philosopher David Johnson, and historian Bina Nir. A synthesis of the films' visual effects, scientific dialogue, narrative accuracy, and statistical data on audience preferences for realism versus entertainment suggests that films are not only vital tools for confirming the existence of scientific phenomena but also for communicating complex scientific ideas to a broad audience. Disney's *The Black Hole* illustrates how even inaccurate scientific depictions can provoke interest and debate, suggesting that representations, regardless of fidelity, contribute to scientific dialogue and curiosity. Conversely, *Interstellar*, which involved collaboration with scientists to achieve higher accuracy in its interpretation, demonstrates the potential of films to profoundly influence public understanding and attitudes toward science. Future research could expand this study by exploring fictional depictions of other astronomical phenomena beyond black holes, such as the portrayal of wormholes in Carl Sagan's *Contact* and Dan Simmons' novel series *Hyperion Cantos*.

Abstract Name: The Effects of Racial/Ethnic Categorizations on Feelings of Belonging

Racial/ethnic minorities may at times be inadequately classified or denied the opportunity to self-identify with their preferred racial/ethnic groups. This misrepresentation can undermine their sense of belonging as members of societies that fail to recognize these identities. As a fundamental human need, belonging affects people's well-being and societal participation. This study explores whether inadequate representation of preferred racial/ethnic identities leads to social identity threat and whether such threats reduce feelings of belonging as U.S. Americans. Using a sample of Hispanic or Latino/a Americans, we employed an experimental design to manipulate how participants' preferred races/ethnicities were represented. Participants were randomly assigned to conditions that either adequately or inadequately represented their self-identified racial/ethnic groups. We hypothesized that inadequate representation would heighten feelings of social identity threat, characterized by concerns about exclusion, devaluation, and distinctiveness. Furthermore, we predicted that increased social identity threat would mediate a reduction in participants' sense of belonging as U.S. Americans. To test this model, a serial mediation analysis was conducted, with social identity threat as the mediator and belonging as the outcome variable. The results aligned with our hypotheses: participants in the inadequate representation condition reported greater social identity threat, which significantly predicted lower levels of belonging. This research highlights the importance of providing psychologically satisfying representations for fostering belonging for racial/ethnic minorities.

Abstract Name: Acute Leukemia in Hispanic Children and Health Disparities in South Florida

Research has demonstrated various health disparities affecting the outcomes of Hispanic patients with leukemia including access to healthcare, socioeconomic status, incidence, and mortality. These disparities have indicated a significant negative impact on health outcomes including decreased survival, higher incidence rates, as well as treatment-related mortality of Hispanics within the United States. The objective of this study is to assess the extent of health disparities that affect the health outcomes of Hispanic pediatric patients with AL in South Florida. The researcher intends to retrospectively analyze patient medical records from the oncologist group at XYZ Children's Hospital from 2012 to 2022 by investigating the participants and their health outcomes through 5-year survival, incident, and mortality rates in terms of treatment-related mortality. This study will be observing health disparities including insurance status, type of insurance, access to treatment as well as preventative medicine through primary care visits and socioeconomic status based on place of residence. The researcher hypothesizes that health disparities will have a negative impact on health outcomes for Hispanic pediatric patients with AL within South Florida. This study can help providers understand how health disparities affect their patients and work towards the improvement of healthcare policy to alleviate the effects that occur within the Hispanic population. Providers can also create treatment plans considering the evaluation and management of the patient's needs. These findings can serve to help shape health policies that prevent barriers caused by social determinants of health.

Abstract Name: Managing and Minimizing Racism and Diversity Resistance in the Workplace

Combating systemic racism in the workplace involves addressing deeply rooted institutional biases and discriminatory practices that disadvantage certain groups. However, these efforts often face challenges due to diversity resistance within organizations. Overcoming this resistance requires fostering a culture of openness, education on the benefits of diversity, and creating accountability structures to ensure that equity and inclusion goals are met. Drawing on the work of Daniels (2022), the current research presents a framework to guide companies seeking to enhance inclusivity and deepen their understanding of diversity. This framework is supported by qualitative research that sampled business organizations as to their current diversity, equity and inclusion policies and practices. It serves as a starting point for driving meaningful and measurable change.

Abstract Name: Chemical Graph Theory and Machine Learning for Predicting Physicochemical Properties of Organic Compounds

Chemical graph theory uses discrete mathematics to model the physical and biological properties of chemical compounds by representing molecular structures as graphs, where vertices denote atoms and edges represent bonds. Once represented in graph form, topological indices—such as atom-bond connectivity, geometric-arithmetic indices, and distance-based indices—are used to characterize molecular geometry and correlate with experimental properties. This study applies these indices to predict key physicochemical properties, including boiling and melting points and solubility, for various organic compounds (e.g., hydrocarbons and those with nitrogen, oxygen, and halogens). Using Quantitative Structure-Property Relationship (QSPR) analysis, we examine correlations between topological indices and these properties, leveraging machine learning techniques like nonlinear regression and deep learning algorithms to capture complex relationships. Model refinement incorporates the Neos Server Filter for generating equations and Wolfram Mathematica for computing mathematical descriptors, with TensorFlow and scikit-learn supporting model development. The resulting predictive models aim to estimate physical properties for compounds lacking experimental data, advancing compound design and optimization in drug discovery, materials science, and environmental chemistry.

Abstract Name: Effects of Microplastic Uptake on Amphibian Growth & Development

Microplastic pollution has been shown to be ubiquitous across freshwater systems, yet our understanding of exposure routes and effects on concurrent biota is limited. In this study, the effects of chronic microplastic exposure on amphibian growth and development throughout larval and metamorphic stages were examined using *Xenopus laevis*. Tadpoles across four different treatment concentrations were exposed to polyethylene microplastic fragments throughout larval and metamorphic development. Exposed tadpoles were smaller throughout metamorphosis and developed faster toward metamorphic climax. Microplastics were found in the tissues of exposed individuals during and following metamorphic climax.

Abstract Name: Eliciting Moral Elevation with a Humanoid Robot

Elevation is a unique emotion that occurs when a person witnesses a prosocial act and feels inspired to also act prosocially. It is characterized by feelings of warmth in the chest, being uplifted, moved, and optimistic about humanity. While research has shown that prosocial acts by humans can increase feelings of elevation, none to date have examined whether highly altruistic robots can also evoke the positive emotion. This online study investigated whether Engineered Arts' Ameca, an advanced humanoid robot, could elicit moral elevation by recounting a heroic story in which it saves a little girl from a fire. Participants were randomly assigned to either the highly altruistic first responder Ameca survey or the amused restaurant server Ameca survey (our control). Both conditions included a video where the corresponding Ameca told a memorable story from its job in an interview. We predicted that participants would report higher levels of elevation in the experimental condition compared to the control condition, as measured by Sparks et al.'s elevation scale. We also believed idealism, the belief that humans are generally cooperative, to be a potential moderator for elevation. Our findings support these predictions, with the effect of condition on elevation being moderated by whether participants believed that the story was real and idealism predicting greater elevation in the first responder condition when participants believed that the story was real. As robots become more integrated into society, it is important to understand whether people are able to view them as capable moral agents and be positively influenced by their prosocial behavior.

Abstract Name: Educating Parents on Safe Sleep Practices for Newborns

Background: Sudden infant death syndrome has become a more common cause of death in infants, due to the lack of education about the topic. The review of literature showed a gap in knowledge regarding healthcare workers not following all the required hospital guidelines, parents and families are not being educated properly, underserved populations are unable to access all information quickly and easily, and a lack of up-to-date studies being available to everyone are the main concerns regarding safe sleep. Since this issue is becoming more common, more education and information on safe sleep can help parents make sure their child is safe during sleep. The increased awareness for safe sleep practices for newborns is a crucial step in reducing the risk of SIDS and other sleep related issues. Purpose: The purpose of this project is to effectively educate parents on useful strategies and proper recommendations to ensure a safe sleeping environment for their infants. Method: Providing informational material such as pamphlets or a presentation to the community at a local hospital or clinic to mothers to address these concerns in the gaps in knowledge to allow for more access to the information. Pregnant women, new mothers and caregivers need adequate information to be able to care for their babies the best, and with this information, complications such as SIDS can be prevented or reduced significant by enhancing infant safety during sleep. Conclusion: Providing parents safe sleep practice material is essential in helping reduce the risk of SIDS. Evidence-based practices, such as back sleeping, using a firm and separate sleep surface, and avoiding soft bedding, remain the cornerstone of safe sleep

guidelines. A safe sleep environment contributes to the overall health and well-being of an infant. Keywords: safe sleep, newborns, SIDS, infant safety, parental education

Abstract Name: EXPERIMENTAL INVESTIGATION OF GENETIC EVIDENCE TO DETERMINE THE MOLECULAR ETIOLOGY OF CANINE ANASARCA

Fetal anasarca is a homeostatic imbalance of the subcutaneous fluids of the body, resulting in the bodily swelling of a fetus.¹ When present in canines, this condition results in offspring born as “water puppies.” Water puppies are characterized by generalized edema and are often stillborn or die soon after birth. The exact cause of fetal anasarca has not been identified, but the etiology is likely multifactorial. Recent studies demonstrate an increased prevalence of canine anasarca and other harmful genetic conditions in brachycephalic dog breeds, such as bulldogs.² This is likely due to a lack of genetic diversity in the breed, resulting from many generations of selective breeding. Noting the increase in mutations among the brachycephalic breeds found in previous studies, it can be hypothesized that there is a genetic link to canine anasarca found in the bulldog genome.² Genes of interest have been identified, but the determination of the presence of a genetic mutation with possible linkage to canine anasarca is ongoing. This thesis aims to examine and explain the tested target genes of interest and to help progress studies investigating a genetic linkage to the condition. This was done through trait identification through literature review followed by bioinformatic analysis of submitted bulldog genomes, loci amplification primer design and preliminary proof-of-concept analysis. Several genes of interest were identified due to their connection to other conditions common in brachycephalic breeds, as well as associations with the circulatory and urinary systems believed to play a role in anasarca development.

Abstract Name: The Role of Calcium Sensitive GAPs in Endocytic Trafficking Pathway

Rab GTPases are master regulators of endocytic and secretory pathways. The activity of Rab GTPases is a tightly regulated cascade depending on guanine nucleotide exchange factors (GEFs) and GTPase-activating proteins (GAPs). Rab GAPs facilitate Rab dissociation from membranes, ensuring proper boundaries and transition of different membrane compartments during trafficking. Dysregulation of Rab-GAP activity has been shown to disrupt the Rab-cascades and cause impairment of endocytic and secretory pathways. A fundamental yet unresolved question is how the precise spatial and temporal activation of Rab GAPs is regulated. In this study, we identified a novel RabGAP, namely TBC1D9B, which contains an EF-hand calcium-sensing domain. Of note, calcium flux, regulated by calcium channels, has been implicated in various membrane trafficking pathways, including endocytosis, exocytosis, and endolysosomal fusion. To

evaluate whether TBC1D9B functions as a bona fide Rab10 GAP and whether its GAP activity is dependent on Ca^{2+} , we performed a GTP hydrolysis assay using purified recombinant TBC1D9B and Rab10 proteins. Our findings demonstrated that TBC1D9B exhibited robust GAP activity toward Rab10 only in the presence of calcium. Additional immunofluorescence staining suggests that TBC1D9B is primarily localized on endolysosomes in neurons and macrophages, indicating that TBC1D9 may sense calcium signal on these subcellular organelles to control downstream Rabs. Importantly, EF-hand-containing Rab GAPs are implicated in diseases such as nephrotic syndrome, breast cancer, and Alzheimer's disease, underscoring the broad disease-relevance of these pathways. This research could shed light on how dysregulation of calcium-dependent GAP activity contributes to the pathogenesis of a variety of diseases.

Abstract Name: The Stasi Remembered as the Face of GDR Disappointment

The East German Ministry for State Security (Stasi) holds an incredibly complex place in German historical memory because of its connections to grand cultural debates about the legacy and history of Germany. Their depiction in films has been a dynamic tool for commenting on the human condition, the state of life in the GDR, and individual complicity in government abuse. The Stasi have featured in mega-hits like *Das Leben der Anderen* (2006), *Good Bye, Lenin!* (2004), and *Sonnenallee* (1999) and a revival in pop culture with *Kleo* (2022-2024). These and many other films comment on life as it was in the GDR through both dramatic and comedic approaches, and in so doing rely on the Stasi to embody a majority of the most negative elements that people hated about living behind the iron curtain: a vindictive government, a lack of autonomy, and a dominating anxiety. This research exposes this film trope along with its complexity in dealing with questions of German historical memory as a whole and connects these trends back to the Stasi's film representation in GDR-era films. This research is designed to address the development of the East German Ministry for State Security's historical memory as represented and understood through films both in and after the GDR's rule over East Germany. This research is based in primary source analysis to determine trends in film personifications of the Stasi. These films consist of solely German productions with Stasi representation ranging from primary protagonist and antagonist roles to absence in the film altogether. After several screenings of each film, common trends and associations to contexts in historical memory are drawn to conclude the state of memory at the production of that film and connections to previous and future trends in memory.

Abstract Name: Investigation of the Orbital History of a Double Star (Binary Pair)

The purpose of conducting this research was to examine binary star systems based on certain criteria that allow for the LCO telescope to successfully photograph a binary pair. The selected system, WDS 06243-

2801, was further examined by taking seven telescope photos and interpreting the data. The use of advanced telescopes and programs like Afterglow allows for precise astronomical data analysis. After uploading those photographs into the Afterglow program, calculations were done to determine the distance between stars and the angular position of the secondary star relative to the primary star. However, the research remains inconclusive, as a solved parallax is required for a more accurate understanding of the system's dynamics. Future telescopic observations will help refine this study and will reveal more about binary behavior. The objective for this phase of the research was to add a new orbital point to the plot, incorporating all available data from 1879. This goal was successfully achieved using the current data for 2024, laying the groundwork for continued research into this binary star system. The analysis of the measurements was conducted by Astr 299 students at Cuesta College, California, USA. Observing binary systems allows scientists to investigate how gravitational interactions and orbital dynamics shape the behavior and evolution of stars.

Abstract Name: The Search for Jungfernhof Work Camp Prisoner Barracks Riga, Latvia Using Ground Penetrating Radar

Mazjumpramuizha, a park along the Daugava River sitting 10 kilometers outside of Riga provides space for a variety of leisure activities. The site however lacks substantial acknowledgment of the history of the land, Jungfernhof Work Camp. After WWII, only three buildings remained from the Nazi-controlled camp. The members of the Jews in Latvia Museum requested ground penetrating radar (GPR) technology on the site to confirm the true history of the area. The goal of this project is to locate the prisoner barracks described by survivor testimonies and geospatial evidence. GRP is a non-invasive scanning methodology that transmits electromagnetic pulses into the subsurface which reflects off features and horizons to the receiving antenna. The GPR utilized was a Sensor and Software pulseEKKO Pro with a 500MHz antenna, collecting traces every 2.0 cm by an odometer wheel. Three grids were laid, 20x10 m, 20x18 m, and 18x22 m, and elevation inside the grid was recorded with a Topcon-RL-H4C self-leveling laser that was georeferenced with the GPR data. In the subsurface of these grids, disturbances were observed from 0.0-2.5 m of what is interpreted to be the external walls of the barracks. After performing "ground truthing", a process that confirms findings by excavation, a rock base foundation, and barbed wire were discovered 0.5 m below the surface at latitude 56°53'29.279"N and longitude 24°12'4.449"E. These interceptions gave strong evidence of where the Jungfernhof barracks were located, allowing the site to be memorialized by the Jews in Latvia Museum with a statue called "The Locker of Memory".

Abstract Name: Functionalization of Biobased Nylon-6,6 Copolymers to Enhance Thermomechanical Properties

Nylon 6,6 is a highly versatile thermoplastic known for its use in various applications such as clothing, footwear, automotive parts, and fishnets. Its exceptional mechanical properties and abrasion resistance make it an important material across multiple industries. However, conventional synthesis of such ubiquitous materials heavily depends on finite petrochemical sources. These processes result in greenhouse gas emissions that adversely affect the environment by accelerating global climate change. Renewable sources such as biomass offer a sustainable pathway for producing green nylon 6,6. Biomass is a promising source of bio-privileged molecules that offer the potential to develop alternatives to conventional petrochemical-based plastics such as nylon 6,6. Moreover, when introduced as comonomers, the unique chemistry of these molecules can introduce valuable new properties that justify their initially high manufacturing cost. This work investigates the post-polymerization functionalization of such a “bio-privileged” nylon, focusing on crosslinking to dramatically improve its thermomechanical characteristics. The degree of crosslinking was varied, allowing adjustments to the material’s properties. Experimental results demonstrated an increase in decomposition temperature from 340 °C to 400 °C after treatment. The storage modulus of functionalized nylon increased significantly, from 2400 MPa to 8200 MPa. These enhancements are directly linked to the specific treatment conditions. Results show that bio-privileged monomers, combined with innovative functionalization strategies, can yield eco-friendly high-performance polymer resins.

Abstract Name: Associations between Adolescent Attachment, Gender Identity, and Young Adult Romantic Relationships

Research has shown that parental relationships influence children's attachment styles. This study aims to extend this research by using extensive longitudinal data to understand how one’s attachment relationship with their parents in early adolescence may predict their attachment within romantic relationships in early adulthood. It was predicted that attachment style at 14 would be positively predictive of the same attachment style within teens’ later romantic relationships at age 24. The study further aimed to help explain such associations by examining whether or not specific attachment-related behaviors may help account for them. Finally, this study explored the potential role of gender identity for shaping one’s attachment style. It was hypothesized that male gender identity would predict more insecure attachment styles in adolescence and in later romantic relationships, and that female gender identity would predict more secure attachment styles in childhood and romantic relationships. Regression analyses were used to assess attachment at age 14 as a predictor of young adult romantic attachment quality at 24, and then attachment related behaviors at age 22 were examined as potential mediators. Analyses revealed a negative association between dismissive attachment quality to parents at age 14 and avoidant attachment to romantic partners at age 24. However, this

association was mediated by dismissive romantic intimacy behaviors in adulthood. Furthermore, gender was identified as a predictor of attachment quality, as male gender identity predicted dismissive and deactivated attachment quality to parents at age 14 and avoidant attachment to romantic partners at age 24, while female gender identity predicted secure and preoccupied attachment quality to parents at age 14. Results show that gender does impact attachment quality in both adolescence and in romantic relationships, and that attachment quality to parents in adolescence is monumental to an individual's quality of attachment in romantic relationships in emerging adulthood.

Abstract Name: Water Quality Analysis of a Trout Stream in Southeast Wisconsin

The analysis of water quality metrics is important to indicate stream health. This is especially important in trout streams where many invertebrates and other organisms rely on specific water quality measures to support a healthy ecosystem. In this project, we examined changes in multiple water quality metric levels along Bluff Creek. Bluff Creek is a spring-fed stream and is a tributary to Whitewater Creek in southeast Wisconsin. The ultimate purpose of the project is to examine temporal and seasonal changes in a high-quality stream system. Once a month, beginning in June 2024, water quality metrics were recorded every two hours from sunrise to sunset at a sampling point along Bluff Creek. These measurements were collected using a YSI meter including dissolved oxygen, water temperature, pH, conductivity, and total dissolved solids. Water clarity was measured using a turbidity tube. A relationship exists among many of these metrics. Dissolved oxygen levels peak around mid-afternoon, often aligning with air and water temperature peaks. From June to November, peak dissolved oxygen at noon changed from 124% to 104%. The photosynthesis of aquatic plants best explains this. Upstream of the sampling point submerged aquatic vegetation provides high amounts of oxygen to the stream system. As atmospheric temperature decreases, the range of dissolved oxygen declines. In addition, a noticeable decrease in pH and conductivity occurs. Water clarity is exceptionally high, measuring over 120 cm on all days sampled. An attempt to map headwater springs was initiated in October 2024 and will continue into the spring. Mapping springs allows for understanding upstream-to-downstream fluctuations in dissolved oxygen. Monthly sampling will continue throughout 2025 to examine patterns of water quality relationships as daylight and photosynthesis change.

Abstract Name: Equitable, Accessible, Short-Term Science Research for Community College Students

The Council for Undergraduate Research (CUR) defines undergraduate research as “a mentored investigation or creative inquiry conducted by undergraduates that seeks to make a scholarly or artistic contribution to

knowledge.” Undergraduate STEM students who are unable to complete the “traditional” full summer, 8–10-week research programs are left out of enriching experiences that impact their sense of belonging in STEM, knowledge of STEM career paths, growth mindset, and transfer goals. Thus, to support community college students with an interest in STEM, adoption of a high-impact undergraduate research experience is needed. This project creates equitable, accessible, paid, non-credit research opportunities in STEM for community college students through the implementation of a 1–2-week authentic science research experience at a local partner four-year institution. The broad goal of this program is to increase the number of community college STEM students participating in science research before transferring to their bachelor program, firmly placing them amongst other experienced undergraduate science researchers. Pre-and post-survey results of participating undergraduate students have shown increases in sense of belonging in science, confidence, and technical skills. Semester to semester retention along with graduation and transfer numbers have been favorable amongst our participants. Several students have continued researching in their host labs beyond the initial program. Research professor mentors have reported having a productive working relationship with student mentees and that our students have contributed to their ongoing research. Our presentation will further describe the history, growth, and implementation details of the project demonstrating that other colleges can replicate this model at their own schools.

Abstract Name: Striatal astrocytes and their morphological changes in Huntington’s disease

Huntington's disease (HD) is a fatal neurodegenerative disease caused by a CAG repeat expansion in the gene encoding the huntingtin (HTT) protein, leading to an expanded polyglutamine repeat in the protein. The mutation causes motor, cognitive, and psychiatric deficits in HD patients. Currently, there is no treatment to prevent the development and progression of this disease. This disease causes significant degeneration of medium spiny neurons (MSNs) in the striatum; a region subdivided into patch and matrix compartments that are critically involved in deficits seen in HD. Research regarding astrocytes has demonstrated their important roles in this disease. Interestingly, astrocytes undergo morphological changes that may indicate their dysfunction in HD. Furthermore, using the mutant HTT (mHTT) expressing and slowly progressing BACHD mouse model that has motor, psychiatric-like and cognitive deficits that worsen with age, we have demonstrated the contribution of mHTT expressing astrocytes to the progression of HD phenotypes. However, it is unclear if astrocytes in the striatum have abnormal morphology in the BACHD mice. We first studied the cellular volume of striatal astrocytes in young BACHD and WT mice. We found that astrocyte volume in young BACHD mice was not different from WT mice. Further studies will be performed in striatal subregions and on aged BACHD mice when overall striatal volume is decreased. These results indicate that morphological changes in astrocytes as demonstrated by cell volume alterations are not present at this early age in BACHD mice and suggest that any volume changes may progress as disease becomes more severe.

Abstract Name: Rheological Insights into Microgel Behavior: Modeling Velocity Profiles and Flow Characteristics

The velocity profile of a fluid is characteristic of most essential processes and is determined by factors such as flow geometry, the properties of the fluid itself and the pressure it undergoes. Understanding microgels' physical principles and statistical relationships is crucial to the success and advancement of biomedical and pharmaceutical applications. Viscosity measurements across multiple temperatures (20°, 27°, 32°, and 37 ° C) and microgel concentrations (50, 100, and 150 mg/mL) in 100 mM NaCl and water allows for the determination of the velocity profile at each concentration. The experimental data obtained were fitted to a Herschely-Bulkley model, an effective model for representing the behavior of a non-Newtonian fluid like microgels. The rheological analysis of microgels provided crucial insights into the concentration-dependent flow behavior and may aid in optimizing various biomedical applications such as drug delivery.

Abstract Name: Using Artificial Intelligence (AI) to help elucidate functional properties and potential regulatory mechanisms of Tomato LOXA activity

Lipoxygenases (LOXs) are enzymes that are widely conserved in many plant and animal species. These enzymes oxidize polyunsaturated fatty acids, forming hydroperoxides as products. The products of LOXs are vital precursors to inflammatory regulatory molecules in humans, and molecules that dictate seed germination and responses to stress in plants. The enzymatic activity of many vertebrate LOXs is regulated by the presence and binding of calcium to allosteric sites. In the plant kingdom, few LOXs have been previously shown to be calcium regulated. Using AlphaFold3 (AF3), an AI-powered, protein-folding prediction server, we have uncovered a potentially novel binding site and regulatory mechanism for calcium binding to Tomato LOXA. We predict that the binding of calcium to Tomato LOXA elicits a conformational change that alters the enzyme's ability to acquire and modify substrate. The purpose of this project is to evaluate calcium's potential role as an allosteric regulator. We are utilizing site-directed mutagenesis, kinetics assays, and structural predictions by AF3 to test the role of this novel calcium-binding site. Discovering the potential binding site of calcium to Tomato LOXA and how it alters the enzyme kinetics would present a new form of enzyme regulation for plant LOXs. Future studies could include altering the calcium-binding site in plant LOXs in vivo to better understand how calcium regulation alters the function that LOX products play during stress responses and maturation.

Abstract Name: It's A Barbie World: An Analysis of the Barbie Doll's History, Design, and Impact on the World

This study explores the continuous cultural impact of Barbie, the iconic doll created by Ruth Handler, and examines her evolution from a simple toy to a global symbol of empowerment and controversy. Barbie's design concept was developed in 1959, driven by Handler's desire to provide young girls with a relatable and highly driven figure that differed from traditional baby dolls. The paper traces the development of Barbie from her early designs, shaped by societal influences and Handler's vision, to her modern image that reflects the ideas of diversity, inclusivity, and female empowerment. It highlights Barbie's role in shaping young girls' self-image, her economic significance in the toy industry, and her influence on broader cultural and media trends, including her resurgence following the 2023 Barbie movie. Despite ongoing debates regarding her unrealistic body proportions and the potential impact on body image, Barbie has continuously adapted, promoting creativity and ambition through her vast array of careers and representation. Ultimately, Barbie's legacy serves as a testament to Ruth Handler's innovation and the evolving societal ideals of femininity, proving that Barbie has grown as more than just a doll but is now a complex symbol of possibility and progress. This paper examines the multifaceted impact of Barbie by tracing her evolution from the first doll in 1959 to her status as a symbol of empowerment and controversy. It explores Ruth Handler's vision and the societal influences that shaped Barbie's design and marketing, analyzing how her physical representation reflects and challenges ideals of femininity. Furthermore, this study highlights how Barbie's design has overwhelming influence on the self-image of young girls, her economic impact on the toy industry, and her role in inspiring future media, ultimately positioning her as a complex figure in both play and design.

Abstract Name: Synthesis and Characterization of Bis(diketopyrrolopyrrole) Dyes

Diketopyrrolopyrrole (DPP) dyes are promising candidates for applications in optoelectronics due to their high thermal and photo-stability as well as their high fluorescence quantum yield. Furthermore, the absorption properties can be tuned over a wide range by the introduction of electron-withdrawing or electron-donating substituents to the DPP core. Within aggregates, the optical features are also affected by interchromophoric interactions. Recent studies have shown that donor-acceptor interactions can be very pronounced in thiophene-functionalized DPP derivatives which lead to drastic changes in the absorption spectra of the dyes. These interactions are very sensitive to structural changes, but systematic studies on this effect are currently missing. In our poster, we will present the synthesis of a series of bis(DPP) dyes in which two thiophene-functionalized DPP chromophores are covalently linked by a triptycene moiety. Various spacers are used to induce different longitudinal displacements between the chromophores as revealed by the geometry-optimized structures. Therefore, different donor-acceptor interactions are present within the different bis(DPP) dyes which should significantly alter the absorption spectra of the dyes. The results obtained from our studies will provide insight into the impact of the donor-acceptor interactions on the optical spectra of DPP derivatives which is crucial to design dye systems with desired optical features.

Abstract Name: The Delivery of Mitochondria-Containing Extracellular Vesicles to the Blood-Brain Barrier as a Treatment of Ischemic Stroke

Following an ischemic stroke, mitochondrial function in blood-brain barrier endothelial cells is impaired. Extracellular vesicles are naturally secreted by all cells in the body. Microvesicles (MVs), a subtype of extracellular vesicles, naturally transfer mitochondrial components between cells, raising ATP levels, therefore increasing bioenergetics and survival under conditions of cell duress. We hypothesize that mouse brain endothelial cell (bEND.3)-derived MVs will increase BEC ATP levels and show neuroprotection and behavioral recovery in a mouse model of stroke. In the present study, we isolated MVs from a mouse brain endothelial (bEND.3) cell line and characterized their particle sizes and protein biomarkers. We tested ATP levels and mitochondrial transfer in MV-treated BECs under ischemic conditions. BEC-derived MVs were found to increase recipient ischemic endothelial ATP levels. Likewise, MVs transferred mitochondria to recipient BECs. Future studies will administer bEND.3 MVs in a mouse model of stroke and determine brain infarct volumes and behavioral recovery.

Abstract Name: Developing Culturally Responsive Research Tools: Assessing Semi-Structured Interview Guides for Native American Communities

Native American communities face disproportionately high rates of mental health challenges due to systemic oppression and intergenerational trauma. A history of unethical research practices targeting this community has fueled mistrust toward research and healthcare systems (Harding et al., 2012), prompting scholars to advocate for methodologies prioritizing cultural responsiveness and community engagement. This is especially important when researching sensitive topics like mental health. To conduct ethical research with Native American communities, this project seeks to compile preliminary feedback from Native American community members on the methods and tools for a qualitative project to ensure cultural relevance. The project will employ community-engaged, iterative design methods to compile feedback on a semi-structured interview guide focused on mental health and resilience within Native American communities. We will conduct key informant interviews (n=3) and prototyping sessions (n=10) with Native American adults and professionals experienced in Indigenous contexts. Participants will be recruited via community outreach and university networks. We will gather feedback on cultural relevance, cultural appropriateness, and clarity. We will analyze data using rapid qualitative analysis methods to refine the semi-structured guide. Preliminary findings from key informant interviews emphasize the value of culturally grounded methodologies. Participants have stressed the importance of inclusive terminology and respecting Indigenous knowledge systems. Additionally, Native data sovereignty emerged as a key priority, underscoring the need for ongoing consent, transparency, and community ownership of research processes. This study provides critical insights

into the acceptability of a semi-structured interview guide for Native American communities, offering a framework to make research methods more culturally responsive. The findings are expected to guide future studies in refining methodologies to better align with Indigenous perspectives and values. Additionally, this work establishes a foundation for a larger qualitative study exploring the resilience and coping mechanisms of Native Americans.

Abstract Name: Synthesis and Characterization of a Water-Soluble Squaraine Dye

Squaraine dyes have the potential for application in organic photovoltaics, sensors and biomedical applications. Many squaraine derivatives have sharp UV/Vis absorption bands and high fluorescence quantum yields which is beneficial for biomedical applications. Notably, the spectral features of most squaraine dyes depend on the solvent polarity. Furthermore, spectral changes are also obtained upon aggregation which is impacted by an interplay of long- and short-range coupling between the chromophores. These changes can be very significant and are sensitive to structural rearrangements. Hence, it is crucial to establish structure-property relationships for the dye aggregates in order to design materials with tailored spectral properties. We have synthesized a water-soluble squaraine dye and investigated the UV/Vis absorption properties in various solvents. The employed water-solubilizing group enabled us to perform UV/Vis studies in non-polar and polar solvents including water. Interestingly, the monomer absorption spectra differ due to the different solvent polarity which can be attributed to changes of the optimum geometry in the ground and excited state of the chromophore. We will also present our results obtained from UV/Vis aggregation studies in different solvents which reveal spectral changes for the aggregate spectra in comparison to the monomer.

Abstract Name: From Vassalization to Colonization: Vietnam's Shift from the Sinophone to Francophone World

Vietnam's cultural and historical identity has been influenced by Chinese and French conquest with both empires impacting culture. The main three cultural aspects that were heavily influenced and analyzed are ceramics, literature, and architecture. This fusion of Chinese and European cultures with the native methods define Vietnam's unique cultural landscape today. A long history of Vassalization and the process of Sinicization is looked over and analyzed alongside the colonization of the region and the process of Francization.

Abstract Name: A Study on Antimicrobial Producers in a Freshwater Aquatic Environment

A global health crisis is emerging as bacteria become resistant to antibiotics, leading to increased hospital deaths. The purpose of this project was to investigate the antimicrobial properties of bacteria sourced from Como Lake in St. Paul, MN. It was hypothesized that the bacteria would exhibit antimicrobial activity, as they have evolved mechanisms to outcompete other bacterial species and establish themselves in the environment. Samples were collected from swabs of bluegill fish (anal, oral, and sidescale), gastric lavage, and shore sediment. Bacteria were diluted and plated on LB and TSA + cyclohexylamine plates to test their activity against eight safe relatives of antibiotic-resistant pathogens: *E. coli*, *B. subtilis*, *S. epidermidis*, *E. carotovora*, *A. sobria*, *P. putida*, *M. smegmatis*, and *A. baylyi*. Antibiotic production was detected by the appearance of clear inhibition zones around microbial isolates when grown on plates containing superbug relatives. Out of 50 bacterial isolates tested, 13 showed antimicrobial activity against at least one strain. Four isolates underwent 16S rRNA sequence analysis: two from sediment samples that inhibited *A. sobria* and two from gastric lavage showing broad-spectrum activity. Sequencing revealed that the sediment isolates were *Bacillus* species, with one closely matching *B. cereus* (99.67%). One gastric isolate matched *Pseudomonas fluorescens* (99.56%), inhibiting *E. coli*, *S. epidermidis*, *A. sobria*, and *M. smegmatis*. The second gastric isolate matched *Lactococcus lactis* (99.55%), inhibiting *S. epidermidis*, *B. subtilis*, and *A. sobria*. Genome analysis using antiSMASH identified 32 gene clusters potentially involved in antimicrobial production. Future work will focus on isolating and characterizing these compounds. These findings suggest that freshwater bacteria could be a new source of antibiotics, expanding research beyond terrestrial bacteria.

Abstract Name: Elucidating Essential Flagellins in the Polar Flagellum of *Vibrio parahaemolyticus*

Vibrio parahaemolyticus (Vp) is a Gram-negative, halophilic, motile bacterium that is ubiquitous in the marine environment. Vp is responsible for seafood-borne illnesses and severe infections can result in sepsis and possibly death in immunocompromised individuals. Vp expresses two different types of flagella, a polar flagellum that is required for swimming motility, and lateral flagella that are required for swarming motility. Other *Vibrio* spp only express polar flagella, and generally polar flagella are involved in *Vibrio*-mediated virulence, so the Vp polar flagellum is the focus of this study. The Vp polar flagellar filament is composed of four flagellin subunits, FlaABCD, with an additional two flagellin subunits FlaEF being secreted outside the cell. To dissect the roles of the individual flagellins to Vp polar flagellar synthesis, we are constructing Vp strains lacking the various flagellin genes, and then evaluating motility of the mutants. A Vp strain was

constructed that lacks three of the six flagellins (DflaEDB), and this strain maintained near wildtype levels of motility. This indicates that FlaACF are sufficient for polar flagellar synthesis and motility. We are currently constructing a deletion of flaF, using PCR, splicing by overlap extension, and Golden Gate assembly. This conjugatable plasmid will be used to construct a DflaF Δ flaEDB Vp mutant strain, and then evaluate its motility. Our goal is to identify the minimum flagellin(s) that are required for Vp polar flagellar synthesis, and then study their localization within the filament. These studies will contribute to understanding flagellar-mediated pathogenicity of *Vibrio* species.

Abstract Name: Service Provider Perspectives on Impacts of Immigration Policy on the Healthcare Utilization of Latinx Immigrants in Post-ICE Alamance County

Latinx immigrants in the United States face unique barriers to healthcare, including discrimination, lack of health insurance, and difficulty accessing medical support. Disparities in health access/outcomes were amplified by immigration policies established during the first Trump administration, as seen locally in Alamance County, North Carolina with massive expansions of Immigration and Customs Enforcement (ICE) presence. This, combined with documented discriminatory practices by law enforcement, have harmful impacts on the health of Latinx immigrants in Alamance County. This qualitative research project utilizes the perspectives of healthcare and social service providers to understand how immigration policies, fear of discrimination, and other socioeconomic barriers have impacted the utilization of health services by Latinx immigrants in Alamance County. Thematic analysis of inductive and deductive codes from semi-structured in-depth individual interviews with health and social service providers have revealed that engagement with community partners, which fosters trust and rapport between providers and patients, acts as a facilitator towards positive healthcare interactions, while language barriers, lack of education about health conditions and resources, and limited resources among both providers and patients act as barriers to effective and culturally sensitive care. Broadly, providers' utilization of language interpretation services acts as a significant factor in patient interactions. Using these findings, the goal of this project is to support healthcare accessibility in Alamance County by suggesting practices for more effective provider engagement and creating community resources to combat misinformation about available resources.

Abstract Name: A Comprehensive Analysis of User-Elicited 3D Dual-Hand Gestures in Virtual Reality

Recent advancements in virtual reality (VR) have focused on enhancing intuitive 3D interactions through hand gestures. While gesture elicitation has been extensively researched, the analysis of VR dual-hand motion gestures remains underexplored. Moreover, current 3D VR interfaces often rely on predefined gestures, limiting the potential for truly natural and intuitive user interactions. This study addresses this gap by exploring user-preferred dual-hand gesture interactions with 3D virtual content through a user-elicitation approach. Concentrating on three fundamental VR interactions: pan, rotation, and zoom, we aimed to analyze users' mental models in developing intuitive gestures. The study involved 26 participants using VR headsets and controllers, recording 3D hand position/orientation and gesture metrics as they performed gestures to interact with virtual objects. Using 3D visualizations of user-elicited gestures, we developed a dual-hand gesture codebook from a 10% data subset, identifying patterns in shape, handedness, direction, and symmetry. The codebook was refined, achieving over 80% agreement and a Kappa $p > 0.8$. Key findings showed that 55.4% of pan gestures were unimanual, with 78.8% forming a quarter-circle shape, while 71.04% of rotation gestures were bimanual, typically forming a semi-circle. Aligning with this finding, geometric analysis also revealed that rotation gestures had the highest curvature (6.71 1/m^2) compared to zoom (4.34 1/m^2) and pan (3.40 1/m^2). Rotations also had the longest average length (.66 m), followed by pan (0.57 m) and zoom (0.44 m). This research advances our understanding of dual-hand gestures for 3D interactions in VR, paving the way for developing a natural user interface based on user-elicited gestures, to ensure a supportive, intuitive user experience.

Abstract Name: Hot Electron Chemistry on Bimetallic Titanium Nitride Core-shell Nanoparticles

The increase in CO₂ pollution has become a prevalent global climate issue. CO₂ pollution can be mitigated by converting CO₂ into CH₃OH (methanol) or other hydrocarbons to create renewable fuel through a hydrogenation reaction using catalysts. Photocatalysts are a class of catalysis that changes reaction rates when excited and can be used to assist in creating green fuels. Our plasmonic photocatalysts are bimetallic transition metal core-shell nanoparticles composed of a plasmonic core and a chemically active transition metal shell. The core metal displays a phenomenon called localized surface plasmon resonance that generates excited or "hot" electrons when absorbing light. The addition of a transition metal shell enhances the plasmonic core, and the resulting core-shell nanoparticles exhibit unique optical and catalytic properties that contribute to their photocatalytic abilities to efficiently generate hot electrons for use in excited state chemistry. This project focuses on titanium nitride (TiN) as the core metal used for the synthesis of bimetallic core-shell nanoparticles. As of now, ruthenium (Ru), rhodium (Rh), and nickel (Ni) have been used as shell metals in various ratios. The TiN-Ru, TiN-Rh, and TiN-Ni nanoparticles (NPs) are synthesized using reflux reactions, washed using a centrifuge, and characterized using Scanning Electron Microscopy (SEM), Energy-Dispersive X-ray Spectroscopy (EDX), Transmission Electron Microscope (TEM), and Ultraviolet Absorption Spectroscopy (UV-Vis). Characterization of the synthesized bimetallic core-shell nanoparticles depicted favorable size, shape, and elemental distribution for photocatalysis. The photocatalytic efficiency of the bimetallic core-shell nanoparticles was assessed through the hydrogenation of CO₂ using a photoreactor chamber equipped with mass spectrometry and Raman spectroscopy. Through the use of bimetallic core-shell nanoparticles, we aim to understand their photocatalytic properties and use these promising catalysts to assist in creating renewable fuel in order to reduce CO₂ pollution.

Abstract Name: Cell growth phenotypes affected by DNA damage in *Acinetobacter Baumannii* ddrR and umuDAb Mutant Strains

The regulation of cell division during DNA damage response is crucial for bacterial survival. In *Acinetobacter baumannii*, DdrR and UmuDAb are hypothesized to inhibit cell division and regulate growth in response to DNA damage. To investigate their roles, we analyzed the growth of *A. baumannii* 17978 wild-type and mutant strains in LB medium and in the presence and absence of mitomycin C (MMC), a known DNA-damaging agent. The results showed that the umuDAb mutant grew significantly slower than the wild-type and the ddrR mutant. The umuDAb-ddrR double mutant also grew slower than the ddrR mutant strain, suggesting that the umuDAb mutation causes slower growth. Next, we compared the cell lengths of the ddrR and umuDAb mutants to wild-type, using Microbe J. We observed that neither the ddrR nor the ddrR-umuDAb mutant cells differed from the wild-type, and only the umuDAb mutant was longer than the wild-type. This suggested that increased ddrR expression caused by loss of UmuDAb repression might cause cell elongation. Arabinose-induced, plasmid-based expression of UmuDAb restored a wild-type cell length to the mutant cells. Arabinose alone did not significantly influence cell length in any strain. Similar effects of ddrR expression were seen in the responses of the mutant strains to DNA damage: the umuDAb mutant, like the wild-type cells, still became filamented after DNA damage, but not the ddrR or ddrR-umuDAb mutant strains. We will next test varying complementation levels effect on filamentation in the ddrR mutant to continue investigating ddrR's role as a cell division inhibitor.

Abstract Name: Queer Intersectionality: Navigating the intersections between sexuality, gender, and other social identities

Queer people belong to multiple social categories that describe not only their gender and sexuality, but also their race, class, ability, and other identities. These categories intertwine with each other to create unique experiences, a process known as intersectionality (Bowleg, 2012). While the origins of intersectionality focus on oppression, an understanding of multiple social identities must contend with privilege and oppression co-occurring across social categories. Current emerging adults are developing during both increased positive representation in the media and negative political attention. At the same time, White privilege and social class were receiving increased attention. In this context, how do Queer, emerging adults understand their multiple social identities? We conducted a qualitative survey of queer college students. We used thematic analysis and an intersectional lens to analyze the data. We developed six themes: marginalization as opportunity for growth, integration of multiple identities, queer centrality, heteronormative expectations, conflicting social identities, and acknowledgement of privilege. These themes align with and extend the current literature.

Abstract Name: Linking Wind to Cyanobacterial Spatial Distribution

Cyanobacterial harmful algae blooms (cHABs) are a leading threat to environmental and human health. These freshwater blooms can produce toxins that are harmful to people if found in drinking water or recreational water bodies. Environmental health testing for cHABs often focuses on single points or high traffic areas such as beaches, however blooms are dynamic in space. Previous studies found that *Microcystis* spp., common toxin-producing taxa, are favored under low surface-level wind speeds because large colonies formed and floated to the surface of the lake causing large surface blooms. These large surface blooms are easily pushed around the lake by low winds. Lake Menomin in Menomonie, WI experiences annual cHABs dominated by *Microcystis* spp. with surface blooms. In Lake Menomin, we asked the question of whether wind determines the colony count, colony size, and colony distribution in the water column. We predicted that down-wind sites would have more, smaller colonies, mixed throughout the water column. On three days in the summer of 2024, we collected cyanobacteria samples on a wind-aligned transect. On each sampling date, we collected shallow and deep-water samples at five coordinates across the transect. *Microcystis* spp. levels were measured and counted under the microscope. The analysis found limited evidence (1 of 3 days) that higher wind speeds decreased colony sizes. However, *Microcystis* spp. levels differed spatially across a horizontal transect and throughout the month of July. More research is needed to understand how wind interacts with other factors to cause spatial patterns in cHABs. Additionally, these findings underscore the importance of sampling across waterbody surface areas for cHAB-produced toxins; cHABs do not evenly distribute across a water body, meaning that ecological and health disparities can occur within different regions of one lake.

Abstract Name: Synthesis of Eugenol Derivatives and Evaluation of their Bioactivity

Both antibiotic and antioxidant properties are vital in the scope of medical research. Studies of the antioxidant and antibiotic properties of these eugenol derivatives are important for addressing pressing global health challenges, such as antibiotic resistance and oxidative stress-related diseases. We looked at a green alternative for synthesizing the epoxide derivatives of eugenol using oxone and compared yields to those obtained using more harmful alternatives. We found increased yields when using acetyl eugenol and allyl anisole as substrates. These results suggest that the oxidation reaction is more effective in the absence of the phenol functional group. After all derivatives were synthesized and purified, their bioactivities were investigated, to determine which derivatives could possibly show either antioxidant or antibiotic properties.

Abstract Name: The d/Denazification Paradigm: Re-examining postwar Germany according to a differentiated reading of the Potsdam Conference

Denazification was the overarching effort to create a self-sustaining, stable German society free from Nazi influence following World War II and the programs implemented to induce this goal. Having never proffered a strict definition for the term, postwar architects improperly relied upon an implicit usage of the object-model theory to discursively determine the bounds of denazification strategy. However, the lack of consensus surrounding the referential object anchoring these conceptions precluded a universal definition. The 1945 Potsdam Conference set forth the “4Ds of denazification”: demilitarization, decentralization, democratization, and denazification. Pursuant to this outline, “denazification” comprised both the primary goal and one of its key pillars. By applying Y. H. Krikorian’s theory on the composition of organizations, it becomes clear that the primary goal and pillar must be different, for constitutive entities are necessarily distinct from the organization they partially comprise. Therefore, “denazification” contained two separate meanings—1) the capacious definition that encompassed the broader Allied postwar project and 2) the narrow programs to purge Nazi officials from influential positions. This presentation explores how linguistic indeterminism led scholars to falsely conflate two meanings of the term. Importantly, it then introduces what I call the d/Denazification Paradigm, a method of historical writing intended to provide clarity to the field by deploying strategic capitalization to differentiate the two versions of denazification. For the past seventy-five years, scholars have struggled to make sense of the seemingly irreconcilable contradiction of a denazification strategy that simultaneously succeeded and failed after “big fry” Nazis regained suffrage in 1951 following the 1944-1949 purges. By distinguishing Denazification (the overarching rehabilitation project) and denazification (the series purges related to Allied-led, quasi-judicial tribunals), the modern historian proves that the incompatibility dialectic is false because there were two different “denazifications.” The Denazification of Germany succeeded even though targeted denazification purges sometimes failed.

Abstract Name: Measurements of Ionospheric Parameters during Geomagnetic Storms

The ionosphere is a layer of the atmosphere that is filled with plasma, and lies roughly 80 to 600 kilometers above Earth's surface. The ionosphere plays a key role in radio communication systems. Geomagnetic storms cause intense variations in the ionosphere. To better understand and track the effects of geomagnetic storms on the ionosphere, we studied the geomagnetic storm on May 11th, 2024. We are analyzing the data for the drift velocity, Total Electron Content (TEC), and the F2 peak density, and F2 peak height using the GIRO database, SAOExplorer, and DriftExplorer. Our studies began by measuring the variance of the ionosphere at differing latitudes (± 30 degree), where we have found drift speeds up to 150 m/s as we approached the equator. We found that during the 2024 May 11th storm the F2 peak heights and the velocities were both much greater, than during quiet days. With the average peak height for May 11th being 23.32% greater than the average peak heights for the rest of the month. One point of particular interest is the stability of the TEC despite the geomagnetic storm. Further analysis of this data will lead to exploration of the relation between the ionosphere and the thermosphere, specifically during the events of geomagnetic storms.

Abstract Name: Mind Wandering Impairs Syntactic Processing of Objects in Peripheral Vision

People often struggle to stay focused on immediate task goals and instead mind wander. Mind wandering (MW) is associated with diminished visual and cognitive processing of external stimuli, which has also been linked to increased fixation durations (how long the eyes remain relatively stable looking at a specific location). The current eye tracking study investigated the effects of MW on syntactic processing of objects (recognizing when objects are in unexpected locations). Participants (N=51) viewed images of real-world indoor scenes in preparation for a later memory test. In 50% of the scenes, one object appeared in a syntactically violating location, such as a hairbrush in a sink. Additionally, a gaze-contingent blindspot obscured central vision in 50% of trials, forcing reliance on peripheral vision, which is typically less apt for detailed object recognition. Participants were periodically prompted to report if they had been mind wandering or attentively viewing the scene at that moment. The findings showed that self-reported MW was associated with longer fixation durations compared to self-reported attentive viewing, consistent with past research. Further, with self-reported attentive viewing, fixation durations were longer when central vision was obstructed with the blindspot regardless of whether there was a syntactically violating object within the scene. With self-reported MW, though, this blindspot-related increase in fixation duration was only observed if there was a syntactically violating object. Without a syntactically violating object, MW-related fixation durations

did not differ across the blindspot conditions. This suggests that although MW impairs visual and cognitive processing of external stimuli, at least some syntactic processing of objects is preserved in peripheral vision and can impact fixation durations. These results contribute to our understanding of the cognitive mechanisms underlying visual processing during MW and highlight the impact of attentional states on syntactic processing of objects.

Abstract Name: The Use of Artificial Intelligence and 3D Bioprinting for Organ Transplantation: Ethical and Anticipated Ethical Issues

Artificial intelligence and 3D printed organs have the potential to advance treatments in the medical industry and healthcare by treating burn victims with 3D printed skin. After looking at case studies of 3D printed organs, an anticipatory ethical analysis will be applied to stakeholder perspectives involved in the development of 3D printed skin. 3D printed skin is developing rapidly, and the stakeholder perspectives of the FDA, researchers, and patients are included in my analysis as they will be some of the first stakeholders involved with this treatment when it becomes available. This ethical investigation focuses on the technology being utilized and the intentions, desires, and actions of the stakeholders involved. The BDI Model was used in the research to apply anticipatory ethics to stakeholder perspectives. Ethical principles employed in the analysis included basic ethical principles, the ACM Code of Ethics, and the biomedical ethical principles of Beauchamp and Childress. With the development of artificial intelligence [AI], the potential for this technology to be combined with 3D printing to 3D print skin with bioinks has many potential benefits for patients, but can introduce ethical issues at multiple stages of the process. The analysis of AI and 3D printing to develop 3D printed skin leads to the recommendation that stakeholders follow Virtue Ethics. The conclusion is that the intentions of stakeholders working on the project to create 3D printed skin as an alternative treatment for burn victims must pursue what is virtuous to uphold the ethical and technical integrity of this potential revolutionary treatment. 3D printed skin created with AI and specialized 3D printers can potentially reduce the cost of treatment for patients, provide aesthetical repairs to severely damaged skin, and save the lives of patients with severe burns that have trouble healing.

Abstract Name: Induction of Natural Products by Fungal-Fungal Co-culture

Fungal natural products have played a major role in pharmaceutical and agrochemical development. In fungi, natural products are produced by biosynthetic gene clusters (BGCs), which consist of one or more backbone

enzymes, tailoring enzymes, and sometimes transcription factors that regulate their expression. However, the majority of fungal BGCs remain silent under laboratory conditions and their associated natural products are not produced unless induced by an external stressor. The technique of co-culturing, in which two or more fungal strains are grown on the same media to introduce competition for limited space and resources, has been shown to induce the expression of silent BGCs that form natural products not found in monoculture. Nine fungal strains were isolated and grown from soil in Harrisonburg, VA and a tenth strain was collected from Grand Caverns in Grottoes, VA. Fourteen of the 45 possible fungal-fungal co-cultures were pursued for further study due to visual changes in the appearance of the fungi in the co-culture as compared to the monoculture. Target co-cultures were prepared for chemical analysis by growing cultures on rice and subjecting them to chemical extraction and liquid-liquid partitioning. The resulting extracts were analyzed using mass spectrometry-based metabolomics. Abundant chemical changes were witnessed in a subset of five co-cultures; one of the five co-cultures showed consistent reproducibility of upregulated metabolites and has been prioritized for targeted study. Two of the four major upregulated compounds produced by this co-culture have been tentatively identified using mass spectrometry and publicly-available natural products databases. We are currently scaling up growth of this co-culture in pursuit of the four upregulated target metabolites for purification and structure elucidation using existing chemical databases, mass spectrometry, and ¹H NMR.

Abstract Name: Creating Adaptable, Game-based Learning Environments for STEM Education

This work introduces the development of Adaptable Game-based, Interactive Learning Environments for STEM Education (AGILE STEM), supported by the National Science Foundation. In collaboration with Penn State University and Carnegie Mellon University, the project focuses on enhancing STEM education, particularly in model-based systems and production engineering, through interactive 3D simulations. The project simulates a bottling facility to be used as a teaching tool in supply chain management, and will incorporate machine learning aspects that react to user's actions for feedback and adaptive gameplay. This reactive environment allows students to explore key concepts like demand forecasting, inventory control, production planning, and the bullwhip effect in supply chains. Learners will interact with different stages of the supply chain, making decisions about production rates, machine utilization, and inventory levels, all while managing constraints and uncertainties similar to real-world challenges. Through these immersive simulations, students will gain a hands-on understanding of system efficiency, workflow optimization, and supply chain dynamics. By iteratively designing and refining the simulation, the AGILE STEM platform seeks to create a versatile educational tool that can adapt to different learning goals, advancing the use of emerging technologies in STEM education. Future work will expand the system's complexity, adding advanced diagnostics, maintenance, and data analysis features. This presentation highlights the development of this water bottling facility simulation, built in Unity, as part of the AGILE STEM environment. The student-led development process began with research on real-world bottling operations, focusing on machinery like blow-molding and filling machines, as well as labeling and buffer systems. The initial build included basic assets for a single production line, which was iteratively expanded to feature multiple lines, raw material and finished product handling with robot arms and forklifts. The simulation models various process steps such as filling, capping, labeling, and packing.

Abstract Name: Transitioning from Mentee to Mentor: An Undergraduate Research Mentorship Experience

This study highlighted the transformative impact of faculty and peer mentorship on undergraduate research development through a structured process designed to build research skills and foster scholarly growth. Faculty mentors guided students through essential research stages, beginning with comprehensive literature reviews and completing Collaborative Institutional Training Initiative (CITI) modules to ensure adherence to ethical research practices. Students, supported by their mentors, successfully secured Institutional Review Board (IRB) approval, demonstrating a commitment to ethical standards in human subjects research. Mentees recruited participants by employing snowball sampling, and expanding the sample size through network referrals. Faculty assisted students in designing informed consent protocols, developing demographic questionnaires, and implementing surveys. Focus groups further enriched data collection, providing diverse perspectives. Peer mentors played a crucial role in monitoring data collection, ensuring accuracy and participant engagement. Under this mentorship framework, students analyzed data using statistical and thematic methods, honing their analytical skills. With faculty feedback, students prepared and submitted peer-reviewed abstracts and manuscripts that adhered to academic publication standards, showcasing their ability to communicate findings effectively. Students presented their research at academic conferences, gaining valuable professional insights and networking opportunities. Participation in Undergraduate Research Mentorship (URM) workshops and conference travel further enhanced their development, equipping them with skills essential for academic and career success. This mentorship model, which emphasized collaboration and guided learning, demonstrated its effectiveness in fostering research excellence and preparing students to thrive as emerging scholars. By combining faculty-led instruction with peer-supported engagement, the program created a nurturing environment where students developed the confidence, knowledge, and skills necessary for success in academic and professional settings.

Abstract Name: Why Do Methyl Groups Attached to C⁺ Stabilize Carbocations? Contributions by Inductive Effects, Hyperconjugation, and Internal Solvation

Carbocations, such as the methyl (CH₃⁺) and ethyl cations (CH₃CH₂⁺), are important high energy intermediates in organic reaction mechanisms. CH₃CH₂⁺ is more stable than CH₃⁺ by about 43 kcal/mol in the gas phase, and that stabilization is provided in three different ways by the methyl group (CH₃) attached to the C⁺ atom. One contribution is from inductive effects, because a methyl group, being electron-donating, will partially cancel the formal +1 charge. The second contribution is from hyperconjugation, because the filled C-H bonding orbitals will mix with the unfilled p orbital of the C⁺ atom. The third contribution is from polarizability effects, because the presence of a methyl group will increase the polarizability of the cation, which provides internal solvation of the +1 charge. All three of these effects take place simultaneously, and the aim of this study is to determine the contribution by each effect separately. To do so, four different valence bond theory (VBT) calculations were carried out for the CH₃CH₂⁺ ion, and differences in resulting

energies were determined. In the first calculation, the electron densities for the CH₃ group and C-C bond of ethane (CH₃CH₃) were mapped onto the CH₃ group and C-C bond of CH₃CH₂⁺, and were frozen. In the second calculation, to determine the inductive effects, the electron density of the C-C bond was optimized. In the third calculation, to determine the effect from polarizability, the electron density of the CH₃ group was optimized. In the fourth calculation, to determine contribution by hyperconjugation, all orbitals were completely delocalized. Results show that the contribution by inductive effects is about 9 kcal/mol, the contribution by hyperconjugation is about 25 kcal/mol, and the contribution by polarizability effects is about 9 kcal/mol. Future studies will be carried out on the isopropyl cation, (CH₃)₂C⁺, and the tert-butyl cation, (CH₃)₃C⁺.

Abstract Name: The Impact of Feeding and Swallowing Ability From a Traumatic Brain Injury: All Around the World

Traumatic Brain Injury is unique overall, as many parts of the brain can be affected, depending on the injury. Depending on where injury occurs, some patients can lose the ability to eat or swallow, and they will need rehabilitation to relearn these skills that come in first nature. This project discusses the parts of the brain that is impacted in this area, and any signs of injury can impact the ability to eat and swallow food. This study highlights not only the medical aspect of TBI, but dives deeply to the field of feeding/swallowing disorders, and the cultural/social/economical impact it may have on someone's ability to recover. What is discussed is how certain cultures and different parts of the world are impacted by TBI, and have issues such as learning to eat again, like the patient may have before. While there are many ways TBI can impact one's life, this study focuses on losing the ability to chew and swallow a bolus (chewed up food). Some of many examples are that there may be situations with religious celebrations with food, or social aspects of eating, that people of TBIs may struggle with learning to adapt to society. There could be no resources for those who cannot afford it, and what people oversee often is the life after TBI, and how people learn to adapt to their situations. Knowing when to have intervention with Speech Language Pathologists or other specialists can guide someone to regain the ability to eat again specifically. There are many obstacles for TBI recovery, and it is important to give everyone of all cultures and economic status the resources to understand and learn how to gain ability again.

Abstract Name: A Possible Explanation For The Underrepresentation of Women in World Politics

Some voters are more likely to support male candidates than female candidates. Women make up a large portion of the population, yet they are deeply under-represented in executive positions of government.

Although past research identifies the gender biases in politics, research is less clear why these biases exist. I argue that voters are more likely to approve of male candidates than female candidates due to perceptions regarding policymaker competency. This can inhibit female candidates from success because competency is a necessary attribute for political leaders' performance. To demonstrate this, my research asked a survey question and conducted an experiment as part of a comprehensive survey experiment with students and faculty from a small liberal arts college in the Southern U.S. This study first asked respondents a question regarding their opinion on gender and competence. Then, the research gave half of the respondents a scenario asking them to imagine a conflict where a female President sent troops abroad and asked if the respondents agreed or disagreed with her decision. The other half received the same scenario, but their scenario had a male president. The main findings of the experiment were: there is a slight preference for male leaders over female leaders. Specifically, respondents were more likely to disapprove of the decision to withhold troops when they received the female president treatment versus the male president treatment; this difference was 4.9%. This experiment shows there is some evidence of negative perceptions regarding female policymaker competency.

Abstract Name: Exploring the Potential Benefit of Mindful Self-Compassion on Women Experiencing Homelessness, Substance-Use Disorder, and PTSD: A Qualitative Study of Coping and Healing

Women experiencing homelessness, substance-use disorder, and post-traumatic stress disorder (PTSD) experience high health disparities yet have been largely unstudied related to their experiences coping with past traumas. Using a community-engaged, mixed methods approach, we sought to explore the potential acceptability and feasibility of a short Mindful Self-Compassion (MSC) course, participants' experiences with self-compassion, and how they can improve coping and self-care as part of trauma recovery. Guided by the recommendations of a Community Advisory Board, we conducted four semi-structured, focus groups with six-to-seven participants each. Focus groups were 1-1.5 hours. In qualitative analyses, deductive codes were created using questions from a semi-structured interview guide. Inductive codes were created by a team of four coders who reviewed the first transcript then met weekly to synthesize further codes. The codebook was then composed of the condensed codes and associated subcodes. The team used the same codebook to code the rest of the transcripts, with two researchers coding each transcript. Findings were synthesized from emerging themes. Themes include 1) Reflections on Self-Compassion Experience, 2) Benefits of Self-Compassion Skills, and 3) Experience of Self-Compassion Associated with Substance-Use Addiction and Trauma. Focus group participants reported that self-compassion techniques and training may be beneficial for recovery from trauma and substance use. Findings elucidated the coping experiences of women experiencing homelessness, substance use, and PTSD as well as their current practices of self-compassion, their struggles with it, and where additional interventions would benefit them.

Abstract Name: The Power of Misconception: Understanding the Role of Legal Circumstances in the Salem Witch Trials

The purpose of this paper is to explain how legal circumstances, such as the admittance of spectral evidence during the trials, enabled the Salem Witch Trials to occur in 1692 and 1693. This paper uses an understanding of the development of evidence-based law in England, as described by Orna A Darr in her 2014 article, "Experiments in the Courtroom: Social Dynamics and Spectacles of Proof in Early Modern English Witch Trials," as well as two legal documents outlining the punishment for witchcraft, the Witchcraft Act of 1604 and the Massachusetts Body of Liberties, to explain the significance of legal circumstances to the occurrence and outcome of the Salem Witch Trials. This paper adopts the fresh perspective of looking at the Salem Witch Trials through the lens of legal history, relying on the research of legal scholars, such as Darr. While many notable historians, such as Charles Upham and Mary Beth Norton, cast the blame for the trials on fanatical Puritanism, this paper seeks to challenge this common narrative through emphasizing the effect of allowing spectral evidence to be admitted in a court of law. Through examining primary documents, such as Increase Mather's Cases of Conscience and Thomas Brattle's Letter to an Unnamed Clergyman, it can be seen that some colonists of this period cited the admittance of spectral evidence in the trials to be a disgrace to the integrity of the judiciary and a factor in the execution of innocent people. This paper seeks to be innovative in its approach to understanding how and why the Salem Witch Trials occurred, and while it does not discount the religious-based arguments of previous historians, it does aim to provide an alternative, legal-based argument.

Abstract Name: Examining Associations Between Bicultural Orientation and Adolescent Internalizing Symptoms

Bicultural adolescents who are children of immigrants and come from racially and ethnically diverse backgrounds face unique stressors compared to their peers coming from the mainstream culture. Research has shown that discrimination and cultural stressors leave bicultural youth more vulnerable to mental health issues such as internalizing symptoms. Dual-cultural orientation, or integration between heritage and mainstream cultures, serves a protective role for bicultural youth by buffering the adverse effects of acculturation challenges. Presently, there is little research on the connections between dual-cultural orientation and internalizing symptoms, such as anxiety, depression, and loneliness among middle and high-school students. The current study will use OLS regression analysis to test the associations between dual-cultural orientation and internalizing symptoms (loneliness, anxiety, and depression symptoms). The sample included 558 immigrant and ethnic-racial minoritized adolescents from the Southwestern United States (Mage = 13.59 years, SD = 1.58; 46.2% boys; 43.1% had at least one immigrant parent, 41.3% Hispanic/Latinx, 40% Multiethnic/Multiracial, 14.4% other race/ethnicity, and 4.2% White).

Abstract Name: A Novel Lightweight Approach for Processing Sensor Data Generated by Smart Mobile Devices

Wheelchair-bound individuals often have a sedentary lifestyle. Because of this, wheelchair-bound people are at a significant risk of developing pressure ulcers, which are very painful and dangerous. To alleviate this, the Clinical Practice Guidelines recommend users to perform a selection of exercises, or pressure relief activities, at regular intervals throughout the day. Doing so will reduce the risk of developing pressure ulcers, but users may not be aware of if they are performing the activities correctly, or as often as they should be. We propose a solution to address this challenge. We have developed a framework for recording and categorizing users' pressure relief activities. Our framework involves a machine learning model that resides on the cloud, a program collecting data from an Apple Smart Watch, and a smartphone app to process and send the data. However, we expect it to be very inefficient and wasteful to constantly send all data to the cloud. To address this, we have devised a preprocessor within the smartphone application to alleviate the stress on the machine-learning model in the cloud. Using a set of pre-processed values and four major functions to remove outliers, calculate the differentiation between data points for noise reduction, normalize the data, and reduce it to one dimension, our lightweight approach can determine if there is a pressure relief activity occurring. By isolating instances of pressure relief activities, our approach will only transmit relevant data to the cloud. Hence, the entire framework can run in real-time and cut down on energy waste and cloud storage. We believe this is an effective framework that makes our approach practical to use by wheelchair users.

Abstract Name: Documenting the Extent of Nurdle Pollution Around Capitol Lake

Nurdles are tiny pellets of raw resin utilized in the production of all plastic materials. They are considered microplastics, and due to their size, are not regulated by the Environmental Protection Agency (EPA). They are not chemically toxic; the issue arises when they enter the ecosystem via railroads or other trading means. A particularly pertinent example of nurdle pollution is Capitol Lake; it is in the perfect location to amass large quantities due to its proximity to a major railroad. Nurdles are the perfect size to be mistaken as food for many marine and mammal species. They are also typically colorless, making it easy to blend in with the ecology and take on its characteristics (i.e., turning the color of the sediment or algae it is residing in). They of course offer no nutritional value; organisms consume them by mistake, and it confuses their body into thinking it is full. As a result, many organisms die of starvation. Due to the growing amount of microplastics in our environment and the lack of EPA regulations, it is believed that documenting nurdle pollution around Capitol Lake will raise awareness and potentially hold companies responsible for the detrimental impact their pollution is having on the environment. The purpose of this study is to explore the extent of nurdle pollution present around Capitol Lake in Baton Rouge, LA. By quantifying the pollution; measuring the polymer composition and morphology of the nurdles; and comparing the nurdles in the lakes to nurdles at nearby rail lines and yards, we hope to identify the specific companies most responsible for pollution. This research is ongoing, and more investigating is required to definitively determine which species are at highest risk from nurdle pollution and which companies are most liable.

Abstract Name: Consuming Suffering: The Legacy of Trauma Narratives in Social Activism

This paper examines the complicated intersection of empathy-driven narratives and voyeuristic consumption of suffering in two nineteenth-century texts, *Incidents in the Life of a Slave Girl* by Harriet Jacobs and *The Working Girls of New York* by Rebecca Harding Davis. While these works were intended to inspire social change by exposing the brutal realities faced by marginalized individuals, they also can be viewed as engaging in what has been termed, in the modern era, as “trauma porn.” Trauma porn is defined as an excessive focus on brutal suffering that detracts readers from pursuing systemic reform. In the instance of *Incidents*, Jacobs was encouraged by her editor to amplify suffering to better engage readers, presumed to be mainly Northern white women who could advocate for social change: "My object in writing at this time is to ask you to write what you can recollect of the outrages committed on the colored people, in Nat Turner's time. You say the reader would not believe what you saw 'inflicted on men, women, and children, without the slightest ground of suspicion against them.' [...] Were any tortured to make them confess? and how? Where any killed? Please write down some of the most striking particulars, and let me have them to insert" (Letter, Lydia Maria Child to Harriet Jacobs in 1860). Importantly, Child's troubling method of engaging readers finds parallels in political activism on social media, where graphic videos of violence and suffering circulate widely, often shifting attention from meaningful action to passive consumption. By comparing these historical texts with contemporary practices, this paper will consider how the focus on graphic depictions of trauma run the risk of desensitizing audiences and reducing civic action to consuming spectacle, raising questions about how we should engage with trauma in the pursuit of political and social reform.

Abstract Name: Ethics in Anthropology: Supporting Casts Over Human Remains

This project addresses the ethical issues surrounding using human skeletal remains in anthropological education and proposes the adoption of high-quality casts as a practical and ethical alternative. The continued reliance on human remains often ties education to practices that overlook consent, dehumanize individuals, and ignore the cultural or historical significance of those represented. These concerns demand a shift toward teaching tools that respect human dignity while meeting academic needs. The research evaluates the benefits of using casts, which replicate skeletal features with accuracy and consistency. Unlike human remains, casts eliminate concerns over the provenance of materials, offering an equitable solution free from historical injustices. To test the viability of using casts to learn osteology, a skeletal inventory was completed for both human bones and high-quality casts. Advantages and disadvantages for each are discussed, providing an opportunity to standardize educational resources, and ensuring all students have access to high-quality tools for learning, regardless of institutional resources or geographic location. Beyond providing a substitute for human remains, the project emphasizes how transitioning to casts can enrich the educational experience. By

removing reliance on ethically questionable practices, institutions can open space for discussions on human dignity, informed consent, and the historical treatment of human bodies in scientific fields. This approach integrates ethical reflection with skill-building, enabling students to critically engage with the broader implications of their studies. Ultimately, this project calls for a fundamental change in anthropological education, where casts become the standard for teaching skeletal anatomy. This transition not only ensures compliance with ethical standards but also fosters a culture of respect and accountability, promoting a future where education and ethics are seamlessly aligned.

Abstract Name: Investigating diurnal variation of radiation rates using low-cost CosmicWatch detectors.

The environment is filled with radioactivity. Much of the ambient radiation is due to radon as well as its daughter radionuclides. Student-built CosmicWatch muon detectors were used to monitor the ambient gamma-ray count rate, tracing the relative radon abundance. The detectors were used in coincidence mode to eliminate background cosmic ray muons. We detect a distinct diurnal pattern in gamma-ray count rates as seen in other studies. Count rate variations are correlated to the variations of atmospheric quantities such as temperature and pressure. Our results show that diurnal variations in gamma-ray count rates can be monitored at high frequency using low-cost easily deployable detectors.

Abstract Name: Analysis of Aquifer Hydrodynamics in Response to Precipitation Events for Integrated Management of Surface Water in the Shingobee River Watershed, Minnesota

Minnesota's groundwater supplies about 75% of the population with drinking water, along with supporting agriculture, industry, and ecosystems. With over 11,800 lakes, it is crucial for Minnesota to understand the connection between surface and groundwater to find sustainable management strategies. Determining how groundwater flows throughout their aquifers will help understand the location of recharge and discharge areas for the identified aquifers, including the connection of this flow to surface bodies such as streams and lakes. Moreover, the temporal variation of water levels and electrical conductance of these aquifers helps understand the response to precipitation and other external factors. This study was conducted at the Shingobee experimental site, which was originally run by the USGS before being transferred to The

University of Minnesota and Bemidji State University in 2022 to study the 28 square kilometer watershed in physical, chemical, and biological aspects. For the aquifer layers identified in a previous phase of this project, water level and chemistry data were collected from the Minnesota County Well Index and from observation wells at the site, that BSU samples periodically. Using Surfer, groundwater flow maps were created as well as time series of water levels for several aquifer layers and precipitation. Water chemistry lab data was also processed through the creation of stiff diagrams using Rockworks. The results indicate a connection between precipitation and groundwater fluctuations for all aquifer layers, with minor variations between them. These variations do not fluctuate more than five feet over the period of analysis. Researching hydrologic properties such as chemistry, water level changes, hydrodynamics, and the changes in an aquifer over time can provide beneficial information to successfully managing our water resources.

Abstract Name: Insta-Bets: Social Media and the Rise of Sports Betting

Influencer marketing spending in the United States reached \$4 billion in 2023, with spending on Instagram accounting for more than half. This study focused on a less common, but still significant, category for influencer marketing spending: sports betting. Sports betting continues to be one of the fastest growing industries in the U.S., with an expected annual growth rate of 10 percent through the end of the decade. The authors examined three popular social media platforms—Instagram, X, and Snapchat—and their potential correlations with the digital sports betting apps Underdog, Sleeper, and PrizePicks. A mix of convenience and snowball sampling was used to gather data about social media usage and sports betting consumption. Although voluntary respondents did not know the focus of the study was an investigation for the existence of a correlation, the authors did receive informed consent from each survey taker to request information about social media usage and sports betting behavior. The final dataset was analyzed with a Pearson correlation test. Multiple statistically significant correlations were identified, with the strongest relationship emerging from the positive correlation of Instagram usage with betting on the Underdog digital platform. These findings suggest that social media usage, particularly Instagram, may influence sports betting behaviors. Future research is recommended for this topic, and should aim to replicate these findings, as well as looking further into whether certain identity characteristics of consumers are particularly correlated to sports betting behavior.

Abstract Name: Title: Gaze, Spectatorship, and Sound: The Drama of Class in Bong Joon-Ho's Tragicomedy Parasite (2019)

Bong Joon-ho, South Korean director and screenwriter of 2019's film *Parasite*, is well known for his conscientious directing and melding of different genres to create touching and intense films meant as vessels for his personal social analyses. *Parasite*'s international success can be attributed to a skillful analysis of class differentials and the powerful impact of the genre tragicomedies through genius cinematography manipulation and layering. This presentation explores Bong's cinematic experiment with gaze, spectatorship, and sound editing in establishing characters' relationships and their class backgrounds. Bong establishes the class differentials through context and dialogue, as well as through a variety of subtle cinematic elements and techniques. At the beginning of the film, Ki-woo and his family are consistently at a downward angle from above, showing them below the audience's viewpoint. The manipulation of angle is deployed when Ki-woo walks up a long sloping street towards his job interview. The scene is at a wide view, shot at the crest of the long street looking down at the small body of Ki-woo. The camera flips, now shot at the bottom of the large hill showing Ki-woo's journey upward. Now having been introduced to this critical cinematic technique the full impact is used in arguably the most pivotal scenes for the Kim family. In addition, sound techniques are deployed skillfully to portray characters' underlying motives and heighten the emotions felt by the characters and audience. The sound differences between the two families' houses contain many micro informants into how the director wanted audiences to feel and view these locations and what they symbolize. Film sequencing and editing, setting of the story, and dialogues between characters contribute to the film's tragicomic style. The film's evaluation of class inequity in South Korea through a memorable and brilliant story highlights both sides of the divide.

Abstract Name: Differentiating Auditory Processing Deficits from Comorbid Diagnoses: A Sibling Case Study

This study explores executive functioning (EF) deficits in two brothers diagnosed with attention-deficit/hyperactivity disorder (ADHD) and suspected auditory processing disorder (APD). The research focuses specifically on inhibitory control, self-monitoring, and metacognitive skills. The presence of additional comorbidities, such as oppositional defiant disorder (ODD) and disruptive mood dysregulation disorder (DMDD), complicates these cases, emphasizing the importance of accurate differential diagnosis. EF deficits, including issues with inhibition, cognitive flexibility, and working memory, are often found in children with language impairments, further complicating the diagnostic landscape. For instance, children with specific language impairment (SLI) typically show weaknesses in inhibitory control, particularly when dealing with tasks that require complex language skills. Additionally, developmental language disorders (DLD) are linked to significant deficits in working memory, affecting overall cognitive functioning. The data for this retrospective case study were collected through clinical assessments, including the Behavioral Rating Inventory of Executive Function (BRIEF), and interviews with the children's parents. The study aims to identify both the shared and unique EF deficits in the two brothers, examining how these difficulties interact with symptoms of APD and ADHD. Prior research indicates overlap among APD, language processing disorders (LPD), and EF impairments, particularly in areas like following verbal instructions and managing distractibility. By comparing the findings to existing research, this study seeks to clarify EF patterns in children with combined auditory, language, and attention challenges. The goal is to better differentiate these conditions, thereby supporting more accurate diagnoses and tailored interventions. While the small sample size is a limitation, the analysis offers valuable insights into the complex relationships between APD, ADHD, and EF deficits, underscoring the need for improved diagnostic and assessment tools.

Abstract Name: Vaccine Hesitancy: The Impact of Social Norms and Scarcity

A scarcity heuristic has been substantiated: if something is hard to find, it must be more valuable (e.g., Folger, 1992; Lee & Jung, 2019; Newsome, 2021). Moreover, studies suggest that negative social norms deter action while positive social norms encourage action. Our research analyzes the impact of both scarcity and social norms on vaccine hesitancy - a top threat to global health (World Health Organization, 2019). Brock's scarcity principle (1968) has been supported in over 40 studies showing that an item's perceived value can be increased by promoting its scarcity (Lynn, 1991). Sprengholz, Betsch, and Böhm (2021) found that vaccination intentions increased under high scarcity conditions. Rabb (2022) found that people's intentions to get vaccinated were predicted by others' intentions to get vaccinated, and Winter, Pummerer, Hornsey, and Sassenberg (2021) found that subjective norms moderate the effect of conspiracy mentality on vaccination intentions. Rozin's (2001) theory of negativity bias suggests that negativity is received more strongly than positivity. We proffer two hypotheses that are in the process of being tested with a large sample using a 2 (scarcity level) x 2 (social norm: friends' & family's approval or disapproval) experiment: 1) family members' and friend's negative vaccine views will negate the reduced vaccine hesitancy caused by vaccine scarcity resulting in higher vaccine hesitancy and lower vaccine intentions and 2) regardless of vaccine scarcity, friends' and families' negative vaccine views will increase vaccine hesitancy more than positive views will decrease vaccine hesitancy. We expect to find that negative vaccine social norms outweigh the impact of scarcity on vaccine hesitancy. These results could inform future vaccine messaging.

Abstract Name: A Hypoxic Aquatic World: Variability in Hemoglobin Production by Daphnia in Lakes of Different Trophic States

Nutrient pollution and climate warming are interacting to worsen the problem of deep-water hypoxia in lakes. Nutrient pollution causes algae blooms, and when those blooms decompose, it decreases dissolved oxygen (DO) in deep water. Strengthened thermal stratification of lakes caused by climate warming further promotes deep-water hypoxia by inhibiting the mixing of oxygenated surface waters into deep water. Hypoxic 'dead zones' can cause mortality for deep-water organisms, and hypoxia may act as a selection pressure promoting adaptation to low oxygen conditions. Daphnia, a freshwater zooplankton, produce hemoglobin (Hb) which improves survival in hypoxic conditions. Hb levels tend to differ within and among populations, but there is uncertainty about how environmental conditions and genetics interact to control hemoglobin levels. For this

study, we determined Hb levels of *Daphnia pulex* sampled from different depths in lakes with varying trophic states (oligo-mesotrophic to meso-eutrophic lakes). In addition, we assessed rates of Hb metabolism and production under controlled DO levels to determine the extent of Hb phenotypic plasticity. We hypothesized that *Daphnia* from mesotrophic to eutrophic lakes that regularly experience deep-water hypoxia would have higher Hb levels. We also expected that *Daphnia* collected from depths with lower DO levels would have higher Hb levels. As expected, Hb levels were highest in mesotrophic *Daphnia* populations. Unexpectedly, Hb levels were highest in *Daphnia* from the metalimnion. Due to *Daphnia* migration and non-linear Hb metabolism, these unexpected results may not be reflective. Overall, our findings indicate that mean Hb levels differ among populations and that the expression of Hb is phenotypically plastic. Future research will involve more sampling from oligotrophic lakes and focus on genotype testing to evaluate genetic impacts of the Hb trait. Findings of this study provide understanding of how *Daphnia* populations will respond to intensified deep-water hypoxia caused by nutrient pollution and climate warming.

Abstract Name: Worked Bone from the Bronze Age in the Carpathian Basin

The Bronze Age, lasting from 3300-1200 BCE, is characterized by the wide usage of bronze. In most places, stone tools were still commonly used in addition to bronze. However, in the plains of the Carpathian Basin, stone was uncommon and bones were often used instead for tools. Bones were more readily available and have a certain workability that stones do not have. My research examines bone tools from several Bronze Age cultures in the Carpathian Basin of Southeastern Europe. The bone tools analyzed in this research project were used for typical daily activities such as carpentry, leatherworking, and pottery creation. While the basic types of bone tool are known, variation across cultures is not well understood. It is not currently known if the raw material used for in their manufacture or the tool kits themselves vary across cultures. Are there cultural differences in worked bone industries? To answer this question, I examined bone tools from four different Bronze Age sites across the Carpathian Basin, including assessing tool type, species of animal used for raw material, and what skeletal element was used. My research demonstrates that the different sites have similar tool kits but will vary in raw material choice across cultures. This shows that while humans utilized similar tools for the same tasks, an element of cultural influence also dictated choices. This can be applied to other studies of the material assemblages of cultures, both in the Bronze Age and beyond.

Abstract Name: Progranulin insufficiency disrupts the immune response to TDP-43 pathology

Progranulin (GRN) is a secreted growth factor that plays an essential role in regulating neuroinflammation and maintaining lysosomal function. Loss-of-function mutations in GRN, leading to progranulin haploinsufficiency, are a major cause of frontotemporal dementia (FTD) with TAR DNA-binding protein-43 (TDP-43) pathology. FTD is characterized by neurodegeneration and neuroinflammation within the frontal and temporal lobes of the brain, resulting in personality changes or language impairments. Progranulin heterozygous knockout (Grn+/-) mice, the genetic model of FTD due to progranulin mutations, do not develop TDP-43 pathology; however, progranulin homozygous knockout mice (Grn-/-) develop subtle pathology in the thalamus and pons. In order to investigate the effects of progranulin on TDP-43 pathology, we crossed Grn+/- mice with transgenic mice that overexpress human TDP-43 (hTDP+). Homozygous hTDP mice (hTDP++) have cortical TDP-43 pathology and neuronal loss in the CA3 region of the hippocampus. hTDP++ mice also exhibit markers of reactive gliosis and neuroinflammation in both cortex and hippocampus, and IgG deposition in CA3, indicating an adaptive immune response. We found that progranulin insufficiency did not affect cortical TDP-43 pathology in hTDP++ mice, but exacerbated gliosis and neuroinflammation in both cortex and CA3. In contrast to Grn+/+:hTDP++ mice, Grn-/-:hTDP++ mice failed to exhibit IgG deposition in CA3, indicating an impaired adaptive immune response. Regardless of Grn genotype, hTDP++ mice do not exhibit MHCII and CD3 immunoreactivity in CA3, suggesting that the IgG deposition of hTDP++ mice is mediated by a peripheral adaptive immune response. We are currently using flow cytometry to investigate peripheral immune responses to hTDP++ expression and how it changes with progranulin genotype.

Abstract Name: Care, Community, and Cuisine: Visions of Collective Food Justice in Lexington, Kentucky

With her social work career in New York City behind her, Mildred “Mim” Hunt returned to her hometown of Lexington, Kentucky, in 1950 with a newfound understanding of the various social ills that plagued those faced with poverty, hunger, and unequal opportunities. Despite her initial desire to leave the painful field of social work, she found herself pulled back to the realm of social justice and used her unique perspective to make a difference in her community. To alleviate hunger, she founded a small food pantry that became a force in the community, and still thrives today. Researching her collection, the Mildred Hunt papers, 1963-2005, at the University of Kentucky Special Collections Center, has inspired addressing the issue of unmet food needs for students on the University of Kentucky campus. University of Kentucky students experience issues of food insecurity due to rising costs in tuition, housing, and food. While UK has some initiatives to assist students in need, programs are often small, inconvenient, and not well advertised. This research proposes a novel component to complement already existing resources, in the hopes of reaching student needs not currently being met. The Wildcat Cafe would be a non-profit cafe on central campus operated as a joint venture between the College of Business and the College of Agriculture. Run by students, this cafe would act as a safe space for students to actively engage in organic food production on UK farms, procurement, meal production, and distribution with the goal of providing low-cost, nutritional food in a convivial atmosphere. Guided by a human rights-based approach to food justice and Mildred Hunt’s passion for community service, this program would provide a glimpse into a future in which the roles of server and served are balanced and equal.

Abstract Name: Reclaiming Women's Creative Identities; An Analysis of Rena Lipetz Niles's Writings

Patriarchal constraints on artistic license has been a recurring theme in historical analysis, particularly as modern efforts to rewrite narratives delegate spaces for recognizing women as creators. One compelling example is the archival collection of Rena Lipetz Niles, the wife of famous Bluegrass musician and author John Jacob Niles, housed at the University of Kentucky Library Special Collections Research Center. Until recently, Rena Lipetz Niles's creative works were subsumed under her husband's materials, relegated to the status of managerial artifacts supporting his success and a reflection of the gender norms of the early to mid-20th century. This research will explore the creative voice of Rena Lipetz Niles for its own merit distinct from the shadow of her husband's artistic success in an attempt to uncover one instance of creative talent that history has overlooked. Utilizing qualitative analysis to examine 50 short stories in the collection will uncover broad themes of her work and explore her place in the canon of 20th century writers. This research will also explore her diaries and a series of oral histories to see how her personal stories reflect feelings about her own creative identity related to managing her husband's career, and if she felt her career was subsumed by his. Exploring women's creative identities of the recent past will emphasize the importance of revisiting women writers' work to reframe gendered narratives.

Abstract Name: Foundations: The Bauhaus Influence on Contemporary Graphic Design in the United States

While primarily cited for its revolutionary approach to architectural design and education, the Bauhaus movement has also significantly contributed to contemporary graphic design practices in the United States. This study examines how core Bauhaus design principles continue to shape modern visual communication in two fundamental areas: typography and geometric systems. Through an in-depth literature review, this research investigates how the Bauhaus design principles of functional minimalism and the integration of art and technology helped to establish the foundations of modern American graphic design. The study particularly focuses on two key areas of influence: 1. Typographic approaches prioritizing clarity and universal readability, reflecting the Bauhaus emphasis on functionality over ornamentation. 2. Geometric systems that structure modern design and define the digital interfaces used to create them. While the transition to digital design has transformed many aspects of graphic design practice, this study demonstrates how Bauhaus principles helped to shape these practices and how these principles remain relevant in modern graphic design. By examining these historical connections and their contemporary applications, this research investigates both the historical development of American visual communication and the ongoing relevance of Bauhaus principles in today's digital design landscape.

Abstract Name: AI Driven Analysis of Atherosclerotic Plaque's Cellular Composition

Atherosclerosis is an inflammatory condition that affects about 75% of all individuals. The symptoms of the disease usually progress rapidly beginning at the age of 40 years old. This disease forms when cholesterol and fat build up on the walls of large blood vessels, which builds plaque. This causes narrowing of the arterial lumen. In advanced stages of the disease, plaques can become less stable when a necrotic core develops. When advanced lesions rupture, they can block small blood vessels and reduce oxygen flow to vital organs. This phenomenon can result in strokes and heart attacks. Vascular TRPV4 ion channels are crucial regulators of vascular function. Therefore, I hypothesized that vascular TRPV4 channels regulate plaque formation and stability. To further understand the cellular makeup of plaque in atherosclerotic mice, Myh11 CreRAD ApoE^{-/-} mice were used with a TRPV4 wt/wt and TRPV4 fl/fl feeds. After 18 weeks the BCA was removed and immunofluorescent stained for tdTomato, Acta2, Mac2, and DAPI. To analyze the colocalization of composition in cell specific TRPV4 knockout mice, Zeiss Itelesis AI model was trained on each wavelength channel. Previously, individuals in the lab would spend hours counting their cells so this technology allowed for more analysis, and better represented data to be drawn upon. I also developed python program to merge the Zeiss output and attain colocalization counts of the antibody stains. The program merges excel files together and uses the nucleus as the cell ID to differentiate which states are included in a single cell. Initial data suggest no differences in cells with smooth muscle lineage in the plaques but more analysis is being done.

Abstract Name: Natural Interaction, Real Feedback: A Qualitative Assessment of Minimally Invasive Model for End-User Testing in Recreational Environments

End-user testing is a phase of software development in which the intended audience tests the application to provide feedback to the development team. Typically, companies will employ strategies for end-user testing such as observation, artificial environments, surveys, and focus groups. These methods may be invasive and may provide a less accurate representation of actual users when applied in settings where the software is merely supplemental to a larger experience. The rise of software in spaces like amusement parks, museums, and fairs begs for a different approach to end user testing. Hence, the driving question: How can user testing on a software application be effectively conducted in a public environment? This study designs and evaluates a minimally invasive end-user testing model that allows users to interact with the app naturally as they enjoy

the recreational space without being followed and observed. The proposed model combines in-app analytics and brief post-visit interviews with end users. This model was used for testing at a children's museum using an app developed by local university undergraduates. These data sources were then evaluated to determine their capabilities for finding bugs in the app. Findings suggest that this model allows for authentic interactions from real users, leading to the identification of several issues that may otherwise go unnoticed with traditional testing methods. Interviews alone resulted in vague information; analytics alone did not identify all bugs in the software. The combination resulted in more bugs being identified and with enough information for developers to address them. This study offers an alternative to conventional end-user testing in contexts where user engagement with the software is secondary to a larger, in-person experience.

Abstract Name: Reimagining Queer Kinship: The Use Of Assisted Reproductive Technologies By Lesbian Parents

My research centers the discussion about imaginations of kinship on Lesbian parents, particularly people who used assisted reproductive technologies (ARTs) to conceive. In the context of Taiwan's legal regulations, lesbian couples cannot legally access in-vitro fertilization(IVF), despite Taiwan's high IVF successful rate and affordability. The process of traveling transnationally in order to obtain reproductive treatments not available or accessible in one's own country has been called "reproductive migration." Intended parents from Taiwan have traveled to the United States, Denmark, Cambodia, and Japan to receive IVF treatment. In this research, I use in-depth interviews to explore how the process of realizing one's desire for motherhood intersects with an imagination for queer futurity. I argue that through the process of reproductive migration, lesbian parents often reimagined kinship in a transformative way. The deliberate decision-making that spans across various stages of the reproductive journey testifies to a constant negotiation between conformity to the established social norms and contesting those existing norms in a way that seeks to actively reshape, rather than passively accept the given definition of kinship. From the selection of the race of sperm donors to discussing who would be the genetic or gestational mother, and choosing care providers, the process is saturated with social meanings and imaginations. An understanding of the multiple stakeholders and institutions that one ought to contest in the decision-making process helps us gain a contextual view of what reimagining the future of queer motherhood and kinship would entail.

Abstract Name: Advancing Real-Time Stock Market Prediction with Large Language Models using OpenAI Approaches

With the growth of artificial intelligence, new opportunities have opened up to analyze and predict real-time data. This project uses large language models (LLMs) to predict stock market trends. LLMs are advanced AI tools designed to understand and generate text, which helps finding patterns in large, complex datasets. The goal is to use real-time stock market data, including prices, trading volumes, and historical trends, to train the LLM to recognize patterns and predict short-term changes in the market with high accuracy. The project will follow a complete process to achieve this. First, stock market data is collected using tools such as YFinance that gives the access to the financial data on yahoo finance. The python based libraries in Yfinance converted the financial data into a spreadsheet indicating the company's stock information. It included the open and closed stock values along with the high and low values during that day. This time series stock data for 25 companies was gathered and various algorithms were used to develop the predictive models for their stocks. Initial data was modeled by using the auto ARIMA algorithm. Day by day acquired data was stored in a Retrieval-Augmented Generation (RAG) database. This database efficiently manages updates to make sure the model always works with the latest data. The acquired data is then cleaned and formatted for the LLMs (ChatGPT, LLMA etc), emphasizing patterns and trends essential for prediction. Both are employed and are being evaluated for prediction accuracy, speed, and adaptability to rapid market changes. This comparison will provide details into the strengths and weaknesses of each model for financial forecasting. These combined technologies can build a clear workflow of using AI to analyze stock market trends, address challenges in a dynamic financial environment, and to improve these tools in the future.

Abstract Name: Evaluating the Specificity and Generalizability of LSD1 inhibition on CD4+ and CD8+ T cell Populations

Adoptive Cell Therapy (ACT) is a novel modality of cancer therapy, in which immune cells can be engineered with T cell receptors (TCRs) to aid in targeting specific antigens presented on the surface of cancer cells. ACT has already brought curative therapy to many previously treatment-refractory blood cancers. However, TCR-T cells often have limited persistence after transfer into patients, which has hampered the effectiveness of this therapy for solid tumors, which require a sustained anti-tumor response. I evaluated if functional improvements could be induced by a small molecule inhibitor of LSD1 (LSD1i), a histone lysine demethylase that modifies chromosome accessibility, as a strategy to improve long-term activity against tumor cells after infusion into patients. Previous research has also found that “helper” CD4+T cells enhance the functionality of cytotoxic CD8+ cells, and I am now seeking to assess broader activity and benefits of LSD1i on a combined population of CD4+ and CD8+ cells. I first treated CD8+ T cells with a small molecule drug, Bomedemstat (an inhibitor of LSD1) during the in vitro cell expansion process, and demonstrated enhanced function in a co-culture system that models chronic stimulation as would occur in a solid tumor. To assess activity of Bomedemstat on CD4+ T cells, I used lentiviral transduction to insert functional TCR constructs into both CD4+ and CD8+ T cells, and plan to expand these cells with the optimized concentration of Bomedemstat in a second coculture assay, this time with combined CD4+ and CD8+ populations. I expect Bomedemstat will prevent dysfunction similar to our previous results with a LSD1i in CD8+ T cells, as illustrated by improved tumor killing and changes in T cell phenotype and function. Demonstrating applicability of LSD1i pretreatment on combined T cell populations would establish a stronger foundation to advance this epigenetic perturbation to clinical applications.

Abstract Name: The Identification of Synthetically Lethal Gene Pairs Using Single-cell Foundation Models

Synthetic lethal (SL) gene pairs represent a unique genetic relationship where the simultaneous loss-of-function of two genes leads to cell death, while the loss of either gene alone does not compromise cell survival. Identifying these pairs is crucial for developing targeted therapies, particularly in cancer, where exploiting SL interactions allows for selective killing of cancer cells harboring mutations in one of the genes while sparing normal cells. However, the experimental identification of SL pairs remains a significant challenge due to the vast number of possible gene combinations and the fact that SL interactions are rare and context-dependent. This makes exhaustive experimental screening impractical, both in terms of time and cost. Foundation models, however, can learn complex gene dependencies and can be applied to simulate genetic perturbations, such as gene knockouts, at single-cell resolution. Geneformer, a single-cell foundation model that is pre-trained on gene expression data from 95 million cells and represents cellular states as ordered lists of gene expression values, has an architecture built for simulating in silico perturbations, and is therefore suitable for the task of predicting SL interactions. We constructed a classifier to predict cell viability and SL interaction based on Geneformer's pre-training knowledge alongside data from the Cancer Dependency Map (DepMap), which includes cell viability scores for a variety of gene knockouts, as well as SynLethDB, a comprehensive database of experimentally validated SL pairs. We identify synthetically lethal gene pairs by measuring the divergence in both the gene embeddings generated by Geneformer and the predicted viability score between single-gene and dual-gene knockouts.

Abstract Name: Evaluating Examination Forms in a Basic Applied Statistics Course using Classical Test Theory

In developing and administering tests that range from college entrance examinations to classroom tests, Classical Test Theory (CTT) can be used to compare different exam forms by evaluating the item discrimination of the exam's questions. Ensuring the equivalence of exam forms is important for treating all examinees fairly. This study compared different test forms for a Basic Applied Statistics course at a four-year university. The classical item difficulty, discrimination statistics, and other test statistics were examined for each form. Revisions were proposed for poorly functioning items. By using these methods, future exams can be revised to create and evaluate parallel test forms.

Abstract Name: Enhancing Tornado Research: A Case for Revising the Enhanced Fujita Scale

This research project aims to demonstrate why the Enhanced Fujita (EF) Scale is outdated and inaccurate. The Enhanced Fujita scale, introduced in 2007, is the standard for estimating tornado intensity based on damage surveys. While it has improved since the original EF scale, limitations still persist in accurately representing tornado strength specifically for high-end events in non-urban areas. This research will employ a combination of field observations, and a hands-on physical approach of building a remote controlled tornado probe from scratch. The probe will consist of anemometers, hygrometers, barometers, GPS tracking systems and more. Not only introducing a new remote controlled way to collect tornado data, but also allowing the probe to collect data and use it as further fuel to get the Enhanced Fujita (EF) Scale revised. Although results are pending, this research holds promise in addressing the importance of accurate tornado intensity ratings.

Abstract Name: Central Planning and Peripheral Protest: Contested Urbanism and Suburban Annexation in Paris (1852-1871) and Chicago (1889-1909)

While scholars have long recognized the architectural influence of Second Empire Paris (1852-1870) on Chicago, few have investigated the possibility of shared political and economic ideologies in Haussmannization and the Burnham Plan of 1909, nor have they compared how those plans were received by affected populations. This project connects and compares Chicago and Paris through two processes of modernization: urban planning and the annexation of suburban municipalities into an expanding municipal area. The influence of Paris' remaking on Chicago planning is analyzed through the writings, drawings, and correspondence of prominent Chicagoans in the Progressive Era (1889-1893), establishing the cities' shared political and economic ideologies, including the prioritization of rationality, circulation of capital, and spectacle over lived experience. Reception to modernization is investigated by comparing how the residents of the industrial suburbs of La Villette and the Town of Lake responded to annexation. While urban planning in Paris and Chicago was meant to create economic efficiency and unified (arguably, homogeneous) civic societies, a weaker government in Chicago meant that protesting suburbs were able to exact concessions and affect the bureaucratic process in a manner that was not possible in Second Empire Paris. Furthermore, suburban residents reacted differently to annexation: La Villette resisted by championing its economic identity as an industrial warehouse district, while the younger, more disparate Town of Lake was unable to rally around a common identity. Thus, while capitalist modernity encouraged similar urban forms, governmental structure and neighborhood-level particularities shaped how these plans were implemented and received.

Abstract Name: Assessing the Effects of Abandoned Mine Drainage on Biodiversity and Water Quality

In the western United States, the Forest Service estimated that around 20,000 and 50,000 mines release acid, with drainage from these mines affecting around 8,000 and 16,000 kilometers of streams. Abandoned mine drainage (AMD) can cause various metals like silver, zinc, and copper to leak from the mine acidifying surface waters. Wingfield Pines, a park located in Upper Saint Clair, Pennsylvania, is one of numerous restoration and enhancement projects now ongoing in Chartiers Valley. The AMD treatment system, built in 2009, covers approximately 20 to 25 acres of the 87-acre plant and uses gravity to treat mining wastewater that flows across the site at a rate of 1,500 - 2,000 gallons per minute before entering Chartiers Creek. The data collection method consisted of wildlife surveys and water quality assessments. In addition to recording the numbers and distributions of species, we also measured each animal and checked for physical irregularities. The methods used for water quality testing included measuring pH, temperature of the water, and dissolved oxygen levels. To measure bacterial diversity and abundance, water samples were collected from each pond and streaked onto TSA plates for colony development. The pH levels generally approached neutrality as water traveled through the remediation system. Despite initial contamination, the water quality significantly improved, sustaining a variety of life forms. The presence of diverse species, such as waterfowl and amphibians, demonstrated the ecosystem's viability. Our findings suggest that the restoration effort at Wingfield Pines is successful. The water quality and biodiversity of the area reflects its success in providing a suitable environment for wildlife. For our Bacterial colonies, more testing is required for us to accurately describe and identify the right species. Detailed bacterial investigation could provide more information about the populations of bacteria and their functions in the remediation process if any.

Abstract Name: Public Opinion on Correctional Education Programs in U.S. Prisons

This study will examine public opinion of educational programs within United States prisons. While existing research demonstrates the benefits of correctional education programs to both offenders and their communities, access to these programs is not guaranteed, as fluctuating political positions surrounding crime and punishment lead to inconsistency of penal policy on correctional education programs. With more than 600,000 Americans being released from state and federal prisons each year (Sawyer, 2022), further research is necessary for improving the efficacy of U.S. prisons in correcting criminal behavior and supporting successful reentries into society. By exploring where both support and opposition to these programs exist, the study can reveal reasonings for public ideologies on the subject. In understanding who supports/opposes prison education programs, policy advocates will be better prepared to anticipate ideological obstacles when

working to implement these services. Potential benefits of widespread program implementation include a reduction in recidivism, a greater number of individuals involved in the legal labor market, and long-term economic savings of government spending on incarceration. The research hypothesis is that the public's lack of evidence-based information on the impact of educational programs in prisons is a driving force behind public opposition and barriers to implementation. Data on participant demographics, preexisting knowledge, and personal beliefs regarding correctional education will be collected through a self-administered digital survey. The survey will consist of closed-ended and Likert scale questions in order to gather comparable data on the views of the American public. Data analysis will draw conclusions to identify any trends that support or refute the hypothesis.

Abstract Name: XRF (X-ray Fluorescence) Analysis of the Adsorptive Properties of Different Clays

Clays possess unique layered structures made up of alternating sheets of SiO_4 and $\text{Al}(\text{OOH})_6$, which enable them to adsorb various molecules, particularly water. This capacity to incorporate water and other elements into their structure also allows clays to effectively filter contaminants such as heavy metals from water. The aim of this study was to assess the ability of three different types of clay and one field sample to adsorb and filter Fe(III) from aqueous solutions. Before exposure to a 0.00009 M Fe(III) solution, X-ray fluorescence (XRF) analysis was conducted on the clay samples to determine their initial Fe content. Each clay sample was then mixed with the Fe(III) solution and stirred for several hours. After gravitational filtration, the clays were re-analyzed by XRF to measure the amount of Fe(III) adsorbed onto their structures. The initial Fe concentrations in the four samples were 0.7260%, 0.8520%, 5.326%, and 2.66%, respectively. After 6 days of mixing with the Fe(III) solution, the concentrations increased to 0.983%, 1.286%, 8.04%, and 4.44%. These results indicate that the clays were able to adsorb some Fe(III), although the experiment was hindered by issues with the solubility of Fe(III) in solution, warranting a repeat of the study for more reliable results. Future work will explore the adsorption capacities of clays for other metals, including Cu, Pb, and Hg, and investigate how firing affects clay adsorption properties. Additionally, UV-Vis spectroscopy could be employed to more accurately measure metal concentrations in solution before and after the adsorption and filtration process.

Abstract Name: Monitoring Antibiotic Resistant Populations as a Correlative to Water Quality

Agricultural land use can adversely impact nearby waterways, leading to significant economic and environmental disruptions, including alterations to species assemblages, loss of wildlife and habitats, and negative health outcomes for humans. Monitoring aquatic systems in agricultural regions is essential for developing precise and effective management guidelines and gaining a comprehensive understanding of the links between agricultural practices and aquatic ecosystem disruption. The Blanchard River, situated in a heavily farmed region contributing to the Lake Erie watershed, serves as an exemplary system for studying the sustainability of antimicrobial-resistant microbes. Research into reservoirs of methicillin-resistant *Staphylococcus aureus* (MRSA) and other antibiotic-resistant bacteria outside clinical settings remains limited. In this study, MRSA and other antibiotic-resistant microorganisms were screened at 126 sites along the Blanchard River and its tributaries. MRSA was detected at 26 sites, while antibiotic resistance was prevalent across all locations. Sixteen Areas of Concern (AOCs) were selected in collaboration with the Blanchard River Watershed Partnership to evaluate whether traditional water quality indicators, such as nutrient levels and macroinvertebrate populations, correlated with antibiotic concentrations and resistant bacteria. While antibiotic-resistant microorganisms did not correlate significantly with antibiotic concentrations or land use, minor associations were observed between antibiotic concentrations and pollution-tolerant macroinvertebrates. To better understand MRSA's origins, strain typing was conducted to confirm its source. Multi-year sampling revealed that local water systems play a unique role in transmitting MRSA, with livestock, particularly horses and cattle, serving as reservoirs. Findings from this study emphasize the importance of targeted water quality monitoring and preventative measures to mitigate the spread of antibiotic resistance.

Abstract Name: Comparative Analysis of Histone Mark Distribution in HepG2 cells in Response to HBV Infection and HCC Development

This research aims to identify and compare epigenetic patterns in hepatocellular carcinoma (HCC) and Hepatitis B Virus (HBV)-infected cells. HBV is a small DNA virus that infects the liver, affecting over 296 million people worldwide. Chronic HBV infection is the leading cause of HCC, a form of liver cancer responsible for 70-85% of all liver cancer cases globally. Histone modifications are an epigenetic mechanism of controlling gene expression. For example, trimethylation is often associated with gene repression and acetylation is associated with gene activation. This study will compare these histone modification patterns in HCC and HBV-infected cells with those in normal liver cells to identify genomic regions associated with altered gene activity. Results are expected to reveal increased acetylation at oncogenic genes and increased methylation at tumor suppressor genes. These findings aim to enhance the understanding of HBV-induced epigenetic dysregulation and may inform the development of more targeted therapeutic strategies for HCC.

Abstract Name: The Impact of Environmental Regulations on Consumer Interest in Sustainable Fashion Brands

This research explores how environmental laws and regulations influence consumer behavior towards environmentally friendly fashion brands. Specifically, this study examines regulations designed to reduce pollution, manage waste, promote sustainable production, and hold companies accountable for environmental harm. Using a data from Google Trends and a difference-in-difference framework, this study shows that companies positioned as environmentally friendly see interest in their brands increase by approximately 13 percentage points after laws promoting this behavior go into effect.

Abstract Name: Identification and Quantification of Phenolic Acids in Processed Sri Lankan Tea: A Potential Source for Bioactive Compounds in Drug Discovery

Phenolic acids are a group of bioactive compounds with known antioxidant, anti-inflammatory, and potential therapeutic properties. This study aimed to identify and quantify selected phenolic acids in tea and herbal tea samples, with the long-term goal of profiling processed tea samples to discover candidate bioactive compounds for drug development. Tea samples were sourced from Sri Lanka, grown under unique conditions, and processed to enhance quality. The analysis was performed using High-Performance Liquid Chromatography (HPLC) with a C18 reverse-phase column, coupled with Liquid Chromatography-Mass Spectrometry (LC-MS) for compound identification and quantification. The 20-minute HPLC run provided a high-resolution separation of phenolic acids. The identified phenolic acids were quantified and compared across different tea samples to evaluate the effects of processing on their concentrations. Preliminary results indicate a significant variation in phenolic acid profiles depending on the tea processing methods, which may contribute to differences in bioactivity. These findings provide a foundation for further exploration of bioactive compounds in tea, offering potential leads for drug discovery and development. Future studies will expand the profiling to a wider range of tea varieties and processing conditions to enhance the identification of novel bioactive compounds.

Abstract Name: The Evolutionary History of Crabs: Carcinization

The popular science conception of carcinization is that the crab body plan is so evolutionarily superior that, in time, all animals will evolve into crabs. However, this is an oversimplification and carcinization can be defined as the process of a decapod crustacean convergently evolving the characteristics of a crab. The most important of these characteristics include a depressed and shortened carapace with a similar width and length, a wide sternum, and a pleon ventrally folded within the carapace. The purpose of this research is to examine carcinization as a phenomenon among decapod crustaceans and explain how it demonstrates convergent evolution. Full carcinization has occurred at least five times in crustacea: twice in the infraorder Brachyura, or the “true” crabs, and three times in the infraorder Anomura, the “false” crabs. These instances of carcinization have been verified through probe design, anchored hybrid enrichment sequencing and dataset assembly, phylogenomics, and divergence time estimation using fossils. The Brachyuran carcinization events include sections Dromiacea, which include sponge crabs, and Eubrachyura, the more derived and diverse of the two sections with 6,191 extant and 1,265 extinct species. The carcinization events in Anomura include the members of the family Porcellanidae, Lomisidae, and Lithodidae. Some Porcellanid crabs even demonstrate hypercarcinization, or the convergent evolution of Brachyuran-like characteristics beyond those typically associated with carcinization. This presentation synthesizes contemporary sources to support the evolutionary link between Litholid king crabs and a Pagurid hermit crab ancestor, a potential connection that has been long denied by prominent evolutionary biologists.

Abstract Name: Exploring the Collegiate Choir Participant's Values within Ensemble Performances

This study examined how collegiate choral ensemble participants viewed their highest quality performance and their favorite performance. Examining characteristics of performances may encourage conversations about performance values between directors and students. Limited research has been done about musicians' views, as getting accurate and in-the-moment documentation of how musicians feel about their performances is challenging. To provide more insight into this previously understudied topic, this study aimed to explore the musicians' perspectives on their performances and how their emotions and repertoire are intertwined. The Primary Investigator (PI) conducted an anonymous study among the 2022–2023 choral ensemble participants at The University of Southern Mississippi (USM). To help define characteristics of performances that make them memorable, participants answered a series of short-answer questions about collegiate choir performances they had participated in: one excellent performance and their favorite performance. Results showed that excellent performances have high rates of musical success and precision. Additionally, enjoying the composition of a piece was the most frequently mentioned aspect of favorite performances. For both performances, participants listed their ensemble peers and the emotions evoked by music as being important parts of their experiences. Participants reported having more fun and feeling happier during their favorite performances. Participants also discussed feeling more confident during their excellent performances. Ultimately, these results indicated that choral ensemble participants have a variety of values and expectations for their performances. However, despite the individualized differences, musicians are likely to get emotionally involved during performances. To encourage more ensemble cohesion when working towards higher goals, choral directors may consider collaborating with their students during the standard- and expectation- setting process. Implications will be discussed. Keywords: Choir, Emotions, Excellence, Music, Perceptions, Performances

Abstract Name: Intellectual humility, affective polarization, and misinformation susceptibility

America's political world is divided, with individuals becoming increasingly critical and disrespectful of those with opposing views (Iyengar et al., 2019). Affective polarization (AP; “the tendency to perceive the opposing party as immoral and unlikable;” Bowes et al., 2020, p. 1) has been shown to result in higher susceptibilities to misinformation: Those high in AP are more likely to believe misinformation supporting in-party beliefs than misinformation supporting opposing beliefs (Jenke, 2024). This may further exacerbate AP, as it impacts the effectiveness of political discourse, informed voting, and candidate opinions (Jenke, 2024). Beliefs that are influenced by misinformation can impact public health outcomes (Bossert & Jongman-Sereno, 2024) and promote ideological extremism (which furthers political polarization; Bowes et al, 2020; van Prooijen et al., 2015). AP and misinformation susceptibility are both negatively correlated with intellectual humility (IH), marked by openness in recognizing fallibility in one’s beliefs (Bowes et al., 2020; Bowes & Tasimi, 2024; Jenke, 2024; Knöchelmann & Cohrs, 2024; Leary et al., 2017). The present study investigates how changes in IH influence AP and misinformation susceptibility. Per past research, random assignment to a growth or fixed mindset will be used to manipulate IH (see Nussbaum & Dweck, 2008 for methodology). Since growth mindsets and IH are both related to the motivation to learn and a more accurate awareness of one’s knowledge (Porter & Schumann, 2018), targeting the presence of a growth mindset enhances IH (Nussbaum & Dweck, 2008; Porter & Schumann, 2018). Next, participants will complete measures of IH, AP, and misinformation susceptibility (Leary et al., 2017; Maertens et al., 2024; Iyengar et al., 2019). We hypothesize that individuals who engage in the growth mindset prime will experience higher levels of IH (as compared to those exposed to the fixed mindset prime), resulting in low levels of AP and misinformation susceptibility. Data collection will begin this fall.

Abstract Name: Targeting the Metabolic Pathways of Glioblastoma Multiforme

Glioblastoma Multiforme (GBM) is the most aggressive form of brain cancer in adults with a median survival rate of 12-14 months even with available treatments. Current treatments include surgery, radiotherapy, and chemotherapy. Available chemotherapy drugs are limited due to the complex nature of the blood-brain barrier. Because GBM rewires the metabolic pathways surrounding it to ensure it can provide for rapid cell growth, the metabolically dependent pathways could potentially be targeted to slow growth. Metformin, an electron transport chain complex 1 inhibitor and a common Type 2 diabetes treatment, has recently emerged as a promising therapeutic agent in a variety of cancers. Though its effects on GBM are currently unknown, preclinical studies have found that supraphysiological doses are needed to impact the disease. There is potential, however, that if the metabolic pathways involved in GBM proliferation were targeted from multiple directions, then disease progression would lessen with physiological doses of each drug. This study aims to

investigate the effects of metformin on U87- MG GBM cell lines in conjunction with memantine, a glutamate receptor antagonist.

Abstract Name: Reducing Relationship Uncertainty through Technology in the Open Adoption Relationship

The open adoption process is one of the most common avenues for adoption, yet this process involves a relatively new relational form. This relationship allows adoptive families to have various degrees of knowledge of and interaction with the birth parents before and after placement (Siegel & Smith, 2012). Scholars have uncovered numerous benefits to maintaining open adoptions, such as identity clarity for adoptees, increased closure for birth mothers, and additional information about the child's background for adoptive parents (Grotevant, McRoy, Wrobel, & Ayers-Lopez, 2013). However, this process can be very challenging when there are unknowns to the adopting family. More specifically, the adoptive mothers, as they are the primary participants within the relationship (French et al., 2014). In the communication discipline, the Uncertainty Reduction Theory (URT) provides a strong theoretical framework for understanding how individuals reduce their uncertainty about unfamiliar individuals. However, this theory has yet to be applied to examine adoptive mothers and how they reduce their uncertainty about the birth families during and after placement. To understand how adoptive mothers reduce their uncertainty about the birth families, a qualitative study was conducted. One-hour interviews were conducted with 30 adoptive mothers recruited from a large midwestern region adoption system. Coding analysis reveals that adoptive mothers were engaging in uncertainty reduction, primarily through the use of technology and technology-mediated communication. Evidence suggests that adoptive mothers would examine family members on social media sights, communicate via various channels to seek information, and more. This uncertainty reduction was shown to be a significant relational focal point as it helped the birth mothers communicate with both the birth family as well as the adopted child in a relational process that is very unique and new to them.

Abstract Name: Anthropometrics Do Not Influence Limits of Stability in Standing Balance Across Lifespan

The limits of stability (LOS) are a key component of dynamic balance while standing. It represents unconstrained dynamic postural control ability and is studied by measuring the maximum distance one can lean in any direction without falling. A reduced LOS is associated with a greater fall risk. An individual's anthropometric characteristics (i.e., height, age, weight) could influence their LOS. However, it is unclear how these anthropometric characteristics impact the LOS during standing. PURPOSE: To determine how

anthropometric characteristics influence LOS across the lifespan. METHODS: 319 healthy participants (195 females and 124 males) volunteered to participate in the study and were grouped into: 5-12 years, 13-17 years, 18-25 years, 26-44 years, 45-59 years, and 60+ years. LOS was tested while standing on a force plate. Participants moved around as far as possible in all directions without lifting their feet for 60 seconds. RESULTS: On average, men were significantly taller ($F = 1.793$, $p < 0.001$) and demonstrated a larger LOS area when compared with women ($F = 3.954$, $p = 0.048$). LOS was also different across the lifespan ($F = 10.538$, $p < 0.001$). We found that LOS areas are smaller in 5–12-year-olds ($341 \pm 127 \text{ cm}^2$), increase from 13–44 years ($436 \pm 119 \text{ cm}^2$) of age, and then decline starting at the age of 45 ($318 \pm 128 \text{ cm}^2$). CONCLUSION: Our pilot findings suggest that limits of stability develop from childhood through puberty, peak in early adulthood, and begin to decline at 45 years of age. It continues to decline further beyond 60 years of age. While men were taller than women and demonstrated larger areas in their limits of stability, the variability in our findings could not be described by the differences in height or other anthropometric characteristics of the participants.

Abstract Name: Analysis of the Mechanomyograph During Repeats of Incremental Electrical Stimulation

Mechanomyography (MMG) has been demonstrated to complement the surface electromyographic (sEMG) signal during electrically-invoked skeletal muscle contractions. The proposed study is designed to measure characteristic changes in the MMG (i.e., the vibration of the muscle contraction recorded on the surface of the skin) intensity in the tricep surae (calf) muscles during incremental electrical stimulation using a wavelet packet analysis (a complex mathematical analysis, i.e., “intensity analysis”) that uses a filter bank of eleven wavelets to measure the power of a signal in the time-frequency domain. Measurements will be made of the MMG at a range of stimulus intensities to reflect a variety of motor units. Twelve collegiate (D-II) male soccer players will be recruited for the purpose of comparing the MMG during incremental electrically-evoked stimulation of the calf muscles. Signals will be collected at a rate of 2000 Hz (MP150; Biopac Systems Inc., Santa Barbara, CA). sEMG signals will be amplified (EMG100C; Biopac Systems Inc.) from disposable electrodes taped to the skin [specifically, standard 10-mm pregelled silver/silver-chloride electrodes--EL503, Biopac Systems Inc.]. MMG will be recorded using uniaxial high-resolution accelerometers [small sensors taped to the skin (ADXL330, Analog Devices, Inc., Norwood, MA)]. A stimulator module (STM100C; Biopac Systems Inc.) with a 200-V (maximum) stimulus adaptor (STISOC; Biopac Systems Inc.) using a disc electrode (EL548; Biopac Systems Inc.) and a 4-cm dispersive pad will be used to stimulate the muscle contractions. The tibial nerve will be stimulated in 5V increments with 10-second rest intervals, and data where the peak-to-peak M-wave amplitude exceed the H-reflex will be analyzed. Peak-to-peak MMG (MMGp-p) data subjected to the intensity analysis, and total intensity, the peak total intensities (Max), and time to Max (TTMax) will be determined. These data will subsequently be compared to the root means square of the MMG.

Abstract Name: Cinematic Shifts: The Muslim Brotherhood in Egypt's Changing Narrative (1981-2013)

This research explores the factors that explain the evolving portrayals of the Muslim Brotherhood in Egyptian cinema, comparing representations during the Hosni Mubarak era (1981–2011) with those in the Arab Spring and post-Arab Spring periods (2011–2013). The study investigates how these cinematic depictions shifted in response to Egypt's changing political and social landscapes, examining the complex relationship between media, power, and public perception. Through the selection of Egyptian-produced films from both periods that feature the Brotherhood, the research focuses on how these portrayals correspond to broader political and societal transformations. Employing visual discourse analysis, the study examines film narratives, character representations, and symbolic imagery to uncover how filmmakers conveyed political ideologies and social attitudes in alignment with shifting political contexts. Understanding these shifts is significant because Egyptian cinema has long been a cultural and political tool, reflecting societal values while shaping public discourse. These two periods were chosen for their contrasting political climates: the Mubarak era represents authoritarian stability, with media narratives framing the Brotherhood as a destabilizing force, while the Arab Spring/post-Arab Spring period marks the Brotherhood's rise to power, governance, and eventual removal, offering a dynamic backdrop for shifting portrayals. By examining how portrayals of the Muslim Brotherhood evolved in Egyptian cinema, this research aims to explain the relationship between media narratives and political power, offering insights into how cultural production both influences and is influenced by broader socio-political transformations. The study further seeks to demonstrate how Egyptian cinema not only reflects but actively participates in constructing political and ideological transformations, offering insights into how filmmakers navigate censorship, ideological pressures, and audience expectations. Ultimately, the study underscores the role of cinema as a vital medium for shaping contested political narratives, emphasizing its impact on framing the Brotherhood's evolving image during Egypt's transformative journey from dictatorship to revolution.

Abstract Name: "Build-A-Book": A New Approach to Undergraduate Scholarship

There is a critical need for open educational resource (OER) materials in the college classroom. These materials (textbook, PowerPoints, exam questions) reduce college costs. College students spend \$1100-\$1700 per year on textbooks, with science books at the higher end of the range due to the large number of illustrations. Studies have shown this reduces stress, particularly among first-generation students, students of color, and non-traditional students. Reducing stress and increasing accessibility improves the DFW rate and time-to-degree statistics. Perhaps more importantly, open educational resources drive open andragogy. Students are adults, and increasing transparency improves outcomes. Students perceive that their professor is on their side and operating as the senior member of a team, rather than as a "sage on the stage". As one of my colleagues pointed out regarding our replacement of a \$300 anatomy and physiology textbook, "it's like I walk into a classroom of 40 students, lay \$12,000 on the table, and say, 'we'll split this evenly between us.' It buys a lot of good will." I will describe collaborative projects between me and my Cellular & Molecular Neuroscience students to build a curriculum from scratch. There are no textbooks in this area. Students are invited to contribute a short chapter on a topic of their choice in the book *Developing Expertise in Neuroscience*. Examples are shown at the linked website. The course is taught each spring semester; with

each recursion, we refine existing content and expand the topics covered. Students learn by doing, and learn from each other.

Abstract Name: Pig Kidney Transplants--the Future of Organ Donation?

There are currently over 100,000 individuals in the United States in critical care who are in need of organ donation. Unfortunately, many will die before they are able to match with a potential donor. Roughly 17 people die daily while waiting for an organ to become available. These hopeless circumstances are what make xenotransplantation, organ donation by non-human species, so appealing to desperate patients and families. Xenotransplants have some benefits to human donation—animals can be genetically engineered from birth so that their organs will produce less of an immune response once implanted in the human host. Recently, three patients received kidney transplants from genetically modified pigs. In all cases the kidneys succeeded at producing urine. All three patients died within two months, though doctors are unsure as to the cause of death. It seems that xenotransplantation is the future of the organ transplant world, but even if the immune reaction barrier is overcome, are pig kidneys similar enough microscopically to human kidneys to be functional long term? Using qPCR techniques on fresh pig kidney specimens from a slaughterhouse, we set out to answer this question by comparing the tight junction composition of the nephron in both human and pig kidneys. Tight junctions are essential to nephron function, as they control the paracellular permeability of endothelial cells. Extreme alterations to the composition of the nephron tight junctions in pigs, would mean that pig kidneys filter urine differently than humans and could cause major setbacks in the future of xenotransplantation.

Abstract Name: The Bidirectional Relationship Between Alzheimer's Disease Progression and Circadian Rhythm Dysfunction

Alzheimer's Disease (AD) remains the most prevalent form of dementia with increased occurrence expected in coming years with increasing global life expectancy. Treatment efforts remain unfruitful, warranting investigations targeting quality of life improvements and slowing of disease progression. Circadian rhythms are daily periodic alterations in body physiology, impacting various body systems. Circadian dysfunction has been associated with several disease states, including AD. The nature of the bidirectional relationship

between AD progression and circadian dysfunction remains elusive. A *Drosophila melanogaster* AD model paired with behavioral, molecular, and morphological approaches are used elucidate this relationship's nature. Behavioral analysis of AD model *D. melanogaster* was conducted using a *Drosophila* Activity Monitoring system. Results exhibited AD *D. melanogaster* depending on external cues for circadian function, with removal of time cues diminishing circadian behavior paired with substantial phase shifting. The molecular function of the core circadian clock in our AD model was assessed using reverse transcription - quantitative polymerase chain reaction analyzing the core clock gene period. The core circadian clock functions normally, indicating potential dysfunction downstream of the core circadian clock. These data suggest circadian function is diminished in our AD model. Neurodegeneration was assessed by quantification of the eye area and brain vacuole size of AD model flies with and without circadian clock function. Data suggests circadian clock dysfunction is associated with accelerated disease progression. Further analysis into mechanism may reveal therapeutic targets to improve quality of life and care for AD patients by correcting their circadian rhythms.

Abstract Name: Behavioral Toxicity of Hexagonal Boron Nitride and PFOA in *Caenorhabditis elegans*

Toxicity assessment is essential to ensure the safety of organisms when introducing new substances into their environment. Hexagonal boron nitride (h-BN) is a novel nanomaterial with growing applications. However, the toxicity of h-BN used in environmental settings is under-explored. This study analyzes how model organism *Caenorhabditis elegans* reacts when exposed to the substances h-BN and perfluorooctanoic acid (PFOA). Through behavioral evaluation of *C.elegans*, this research aims to determine the relative toxicity thresholds of h-BN and PFOA, and ergo the safety of h-BN for future application in PFOA degradation. Research suggests that low-dose exposure to h-BN elicits an immune response in *C.elegans*. Meanwhile, low doses of PFOA have been shown to disrupt locomotion in *C.elegans*. The hypothesis for this experiment is *C.elegans* will exhibit behavioral changes at higher concentrations of h-BN than PFOA. Age-synchronized *C.elegans* were exposed to varying concentrations of h-BN (2–35 mg/L) and PFOA (0.2–0.8 mg/L). Post exposure, Wormlab software was used to analyze behavior. The data collected was analyzed and compared to a negative control for metrics such as turn count, track length, and center-point speed. Data were evaluated through ANOVA testing and t-tests with a statistical significance at $p < 0.05$. Both substances were shown to elicit concentration-dependent behavioral changes in *C.elegans*. Low levels of h-BN (2–4 mg/L), significantly reduced turn count and speed. However, the effects diminished at higher levels. PFOA did cause behavioral alterations at lower concentrations (0.2 mg/L) but returned to baseline at higher doses. These findings highlight the need for further testing at other concentrations. Evaluation of these materials are needed to discern the safety of h-BN in the role of PFOA degradation. This research will contribute to understanding the toxicity of PFOA and h-BN, and safer application of h-BN for PFAS removal and degradation from contaminated aquatic environments.

Abstract Name: Utilizing Mixed Reality to Optimize the Workflow of Superficial Temporal Artery Mapping in Extracranial-Intracranial Bypass Surgery

Background: Mixed reality (MR) is a developing field within neurosurgery. It is utilized for operations such as superficial temporal artery-middle cerebral artery (STA-MCA) bypass surgery which revascularizes areas of narrowing vessels in patients with Moyamoya. Doppler ultrasound is the conventional technique for mapping the STA; however, MR allows for patient-specific anatomical overlay to better visualize the vessel. The goal of this study is to compare the efficiency of MR-based STA mapping in STA-MCA bypass to the traditional Doppler method using computer vision. Methods: Five patients undergoing STA-MCA bypass surgery were enrolled between January and April 2024. Pre-operative CT-angiograms were registered and superimposed onto the patient using SurgicalAR. Five uniformly spaced points were annotated along the parietal branch of the STA using both MR and Doppler techniques. Mapping time was compared using the Mann-Whitney U test. To evaluate accuracy, Blob detection, a computer vision technique, was used to locate these points, and 5mm-thick lines connected them in each map. Intersection over Union was used to measure the percentage of MR-Doppler map length overlap for each patient. Results: MR mapping of the STA was significantly faster than Doppler mapping (11.4 ± 1.2 vs. 65.9 ± 20.9 seconds; $p=0.009$) with mapping of the distal points also faster (point four: 2.1 ± 0.45 vs. 22.2 ± 13.3 seconds; $p=0.037$); (point five: 2.7 ± 0.98 vs. 18.3 ± 7.8 seconds; $p=0.01$). There was comparable accuracy between the MR and Doppler maps with an average length overlap of 56% (22-90%). The average radial deviation of MR-Doppler maps was 4.2mm (0.86-8.4mm). Conclusion: This is the first study to evaluate MR against standard Doppler techniques for STA mapping in STA-MCA bypass procedures. We demonstrate that MR achieves similar accuracy to traditional Doppler in a shorter amount of time, suggesting that incisions based on either map is unlikely to change.

Abstract Name: Optimizing Spinopelvic Parameter Calculations Using AI-Driven Spine Segmentation and Computer Vision

Background: Spinopelvic parameters (SPP), derived from vertebral body measurements, are crucial in

informing pre-operative spine surgery planning. Current methods of calculating SPP are labor-intensive and imprecise with clinicians using archaic software to manually draw lines on spine x-rays. By leveraging artificial intelligence and computer vision, SPP can be calculated more efficiently and consistently with a standardized approach. This would reduce physician burden and improve patient outcomes. Methods: 167 sagittal spine x-rays were collected and randomly split into a training set (67 images) and a testing set (100 images). A total of 536 images were produced for the training set through image augmentation on the original 67 x-rays. All images were manually annotated to create binary segmentation masks. A U-Net model, a convolutional neural network widely used for bio-medical images, will be trained on this dataset with a goal to automate the segmentation of 25 vertebral bodies (C2-L5, sacrum, femoral head). Once all bodies are segmented, computer vision edge-detection algorithms have been implemented to automatically calculate SPP. Finally, an intuitive web application for spinal surgeons was developed to help visualize SPP on the spine with overlaid illustrations. Expected Results: The goal is to create a web application that allows a surgeon to upload a sagittal spine x-ray of their patient and receive immediate SPP without extra tedious labor. This process would provide all SPP in seconds and remove any possibility for human error. With computer vision and web interface aspects already implemented, further success of the application relies on performance of the model still in training. Further Impact: A fully functioning application would assist in pre-operative planning, post-operative assessment, and avoid high potential for error which can have a large impact on surgical success. It would also accelerate spinal deformity research and advance neurosurgical education with informative visualizations.

Abstract Name: "Designing Happiness: The Art and Philosophy of Stefan Sagmeister"

This paper is about Stefan Sagmeister's career and philosophy. His career started small as any inspiring graphic designer. The main goal of this paper is to tell the knowledge behind Sagmeister's designs. The conflict coming from his designs was that he described the artwork as crossing the boundary to visual communication. The visual communication of his work was how his work referenced his personal experiences and empathy on global issues. Most artist's works do not combine both concepts into their art. Then, the paper includes his album cover, Lou Reed, and his project collab, "Sagmeister and Walsh." Through his collab "With Sagmeister and Walsh," he created designs that conveyed the message of being funny ironic, and many plot twists. So, through visual communication and different media, Sagmeister blends both commercial and concept design. He made his work visually astonishingly and triggered the audience. The use of unusual materials and strategic processes, such as his own body as design, highlights his belief in the power of design to trigger the audience. The paper discusses how Sagmeister's work redefines the artists and the interpreter, sealing lines between design, art, and personal expression. His work refers to his creativity and intellect in the processes of design. His work challenged the process of design and gave an understanding of visual communication to the audience. So, throughout Sagmeister's exploration, his career is sold out to be a great designer, and he's a great tool to inspire future designers for social change and empathy.

Abstract Name: Risk or Reverence?: The Effects of Religiosity and Risk Behavior for Jewish Emerging Adults' Perceived Invulnerability

This study examines how religiosity and risk behaviors predict perceived invulnerability among single, Jewish college students in emerging adulthood. Identity exploration, a hallmark of this life stage, often involves social, relational, and behavioral experimentation, with religiosity potentially shaping these experiences. Jewish individuals exhibit varying levels of religious observance (e.g., keeping kosher or Shabbat), which may influence their behaviors and self-perceptions in college. While previous research on undergraduates largely focuses on substance use and sexual behaviors, with associations between higher risk behaviors and increased perceived invulnerability, the role of religiosity in this relationship has been less explored. Orthodox Jews tend to engage in fewer risk behaviors compared to more secular individuals, which may affect their sense of invulnerability. This study applies the Optimism Bias framework, hypothesizing that religiosity and risk behaviors will significantly predict perceived invulnerability. Data from 816 single, Jewish college students (2008-2009 Multi-Site University Study of Identity and Culture [MUSIC] Study) were analyzed. Key measures included religiosity (identity, exclusivity, observance), risk behavior, and perceived invulnerability. Bivariate correlations showed that greater risk behavior and higher religious exclusivity were significantly associated with increased perceived invulnerability. After controlling for demographic variables (e.g., gender, GPA, SES), linear regression indicated that religious exclusivity significantly predicted perceived invulnerability. While the findings suggest that both religious exclusivity and risk behaviors are linked to higher perceived invulnerability, these results should be interpreted in the context of pre-COVID-19 norms, as risk behaviors among Jewish emerging adults may have shifted post-October 7th crisis. These insights may inform clinicians and student affairs professionals working with Jewish undergraduates. Future longitudinal studies are needed to explore how perceived invulnerability evolves over time and how various environmental and psychosocial factors influence positive outcomes during this developmental period.

Abstract Name: Exploring Turbulent Flow Dynamics through *Didymosphenia geminata* Populations in Boulder Creek

Didymosphenia geminata, commonly referred to as "rock snot" and "Didymo", has become a significant nuisance in river systems across the globe over the past 35 years, primarily due to its detrimental effects on stream ecosystems. Didymo has become prevalent in Boulder Creek. This diatom can form extensive mats on rocky substrates, altering the water chemistry and trophic dynamics within affected streams. Thriving predominantly in oligotrophic waters where phosphorus is a limiting nutrient, Didymo's proliferation underscores the need for a deeper understanding of the environmental factors that influence its growth. This study aims to investigate the impact of turbulent flow on the presence and distribution of Didymo in Boulder Creek, Boulder, Colorado. Using microscopic collection techniques, we monitored Didymo populations at various locations throughout the summer months, systematically collecting data on abundance, sample locations, and flow rates. Through the analysis of these parameters, we seek to clarify the relationships among turbulence, nutrient mixing, and Didymo prevalence. We hypothesize that disturbances in the primary flow of

the stream, combined with enhanced nutrient mixing within eddies, may influence Didymo abundance. Gaining insights into these dynamics is essential for understanding the ecological implications of turbulent flow conditions in aquatic ecosystems. The findings from this research could inform the development of effective management strategies aimed at controlling Didymo blooms and mitigating their negative impacts on stream ecosystems. Furthermore, this study contributes to a broader understanding of how turbulent flow affects other aquatic organisms and nutrient dynamics in similar environments, ultimately advancing the field of freshwater ecology.

Abstract Name: Nomadic Echoes: A Visual Journey Through Bangladeshi Heritage

This traditional painting delves into the rich cultural tapestry of Bangladesh, blending personal narratives of a nomadic life with the collective history and artistry of the Bangladeshi people. The artwork juxtaposes vibrant motifs of rickshaw art—a hallmark of urban folk culture—with traditional Bengali art forms to create a dialogue between the past and present. Through vivid colors, intricate patterns, and symbolic representations, the piece narrates stories of resilience, liberation, and victory, reflecting the nation's journey from colonial rule to independence in 1971. The project draws inspiration from the diverse artistic traditions of Bangladesh, such as kantha stitching and Patachitra scrolls, as well as the iconic rickshaw panels, which serve as a mobile canvas for storytelling. The methodology involves employing traditional painting techniques on a hand-primed canvas using natural pigments, merging historical motifs with contemporary interpretations of identity and belonging. By incorporating elements of nomadic life, the painting also highlights the dynamic relationship between movement, place, and cultural identity in shaping personal and national histories. The expected result is a multi-layered narrative that invites viewers to reflect on the complexities of Bangladeshi heritage, from its struggles for liberation to the triumph of cultural preservation. This work contributes to the discourse on the role of traditional art in documenting and celebrating history, offering a lens through which to view heritage as both personal and universal. This painting serves as an ode to the resilience of a people whose art continues to thrive as a testament to their spirit. Through this piece, the artist aims to ignite conversations about identity, memory, and the transformative power of art in preserving cultural narratives for future generations.

Abstract Name: Investigating the Role of FOXI3 and EMT in Advanced Prostate Cancer

Prostate cancer affects approximately 1 in 8 men and is the second leading cause of cancer-related death in men. When detected early, noninvasive forms of prostate cancer can be treated successfully, but treatment and detection for aggressive, metastatic forms of prostate cancer are still needed. For prostate cancer to effectively

metastasize, it must first undergo a process known as epithelial-to-mesenchymal transition (EMT). It has been shown that FOXI3, a transcription factor from the Forkhead box family, plays a key role in EMT during embryogenesis. This study aims to investigate whether FOXI3 similarly influences the EMT process within the context of cancer metastasis. Specifically, advanced prostate cancer cell lines, PC3 and C42B, along with FOXI3 knockout versions of each cell line will be treated with Zerumbone, a phytochemical that is known to inhibit TGF- β 1-induced EMT. Following this, the levels of FOXI3 and e-cadherin expression will be evaluated. The expression will be investigated at many different levels, including RNA, protein, and localization, using PCR, western blot, and immunofluorescence. By analyzing the expression and localization of FOXI3 and e-cadherin, we attempt to establish a connection between FOXI3 and EMT within the context of advanced metastatic prostate cancer. This study is still ongoing, but I anticipate that the results will show a decrease in FOXI3 expression and an increase in e-cadherin expression, correlating to the inhibition of EMT. This study may provide insights into the molecular mechanisms underlying prostate cancer progression and potentially identify FOXI3 as a novel therapeutic target for aggressive forms of the disease. The findings from this research could contribute to our understanding of prostate cancer metastasis and potentially guide the development of new treatment strategies for advanced stages of the disease, addressing a critical gap in current prostate cancer management.

Abstract Name: One Planet, One Oklahoma: Exploring a Framework for Assessing the Feasibility of Localized Energy Transitions in the United States

Net-zero energy transitions, necessitated by the threat of climate change, need to occur on an international scale. However, powerful economic lobbies and political stagnation often mar the negotiation processes driving national and international action. In this context, local communities become increasingly important in achieving widespread emissions reduction objectives. This analysis centers on exploring a framework that evaluates the feasibility of net-zero energy transitions in U.S. localities. The framework highlights the technological and political feasibility of transitioning the electricity and transportation sectors of a given municipality. While such a framework does not capture the entirety of a community's energy system, it nonetheless serves to address two sectors that dominate emissions production and energy usage. I apply this framework to the suburban community of Norman, Oklahoma, to both highlight the value of such analysis and to provide important information to local officials in my community. By collecting information from administrative and primary sources, this study documents forecasted decreases in the cost of renewable energy sources, residual emission abatement technologies, and energy storage solutions for Norman. Further, an analysis of the local transportation sector reveals that the costs associated with public transit improvements—an important component of decarbonization in the transportation sector—generally ranged from 0.01-5.1% of the City's 2023 budget (excluding national high-speed rail enhancements, which involves cost-sharing between local, state, and federal governments). I also examined the political feasibility of this transition, documenting the partisan preferences that may hinder clean energy deployment. My findings suggest that while technology costs may decrease, political opinion could hinder clean energy transitions in Oklahoma. The model of analysis employed throughout this study presents significant opportunities for further exploration of localized energy transitions in suburban areas and college towns, two types of municipalities often left out of transition scholarship.

Abstract Name: Evaluating the Impact of Runway Status Lights on Runway Incursions

Runway incursions occur when an unauthorized aircraft, vehicle, or person enters a protected area designated for aircraft takeoff and landing. These incidents have been a growing challenge for airport operations, and have significantly increased in recent years. With 1,633 cases reported in 2022 and 1,777 in 2023, their increasing frequency highlights the need for effective mitigation strategies. One of the most advanced technologies designed to reduce and prevent runway incursions is Runway Status Lights (RWSL). RWSL is an automated system that provides real-time alerts to pilots and vehicle operators, signaling when it is unsafe to enter, cross, or begin takeoff on a runway. Despite RWSL being operational at 20 major U.S. airports, there are very limited studies on evaluating the effectiveness of RWSL. This study aims to explore the impact of RWSL on aviation safety by analyzing the runway incursion data from the Federal Aviation Administration (FAA). Specifically, it examines the correlation between RWSL implementation and runway incursion rates at 17 airports where the system has been operational. By comparing data from seven years before and seven years after RWSL installation, this research provides a comprehensive assessment of its effectiveness in mitigating risks. The findings from this study will offer valuable insights for aviation authorities such as the FAA and airport operators, in their efforts to enhance runway safety. Understanding the role of RWSL in reducing and preventing runway incursions will support data-driven decisions regarding the adoption and expansion of similar technologies. Ultimately, this research contributes to the broader goal of improving the safety of pilots, passengers, and overall airport operations. Through continued evaluation and technological advancements, the aviation industry can reduce risks and foster a safer environment for all stakeholders.

Abstract Name: The Use of Indigenous Blood Quantum in Determining Tribal Affiliation and Its Impact on Native American Demographics

Repeatedly Native Americans are required by the United States government to prove their respective tribal affiliations through blood quantum in order to receive their entitlement to lands and resources. The measurement of Indigenous blood quantum is a strategy imposed by the United States Federal Government to limit Native citizenship and disempower Indigenous Americans. It dates back to the late 18th century as the official method for classifying “Indianness.” In the midst of the reservation period, legislative and federal regulations for legitimizing “Indian blood” were carried out by the Bureau of Indian Affairs. As the bureaucracy increased, so did the question of the “blood” status of Native Americans for federal benefits, protection, and recognition. This paper examines the continued use of this Indigenous blood quantum to assign citizenship in a Native American tribe and its dire consequences. Blood quantum operates as a stand-in device for Indigenous elimination, a genocidal tool of Native American culture, as characterized by the Native American activist and scholar, Ward Churchill. For Native Americans, blood quantum is part of the “colonial erasure tactics,” as Kylie Rice (Mohawk and Algonquin) argues. According to an estimate by Congress, by the year 2080, less than 8 percent of Native Americans will have less than one-half or more Native “blood.” As seen in the 1950s and 1960s, certain tribes deemed too small were terminated by the

federal government, and they also lost status and subsequent benefits. Thus, it is important to call attention to how blood quantum will lead to further erasure of Native American communities as sovereign nations.

Abstract Name: Anti-Fungal Peptoid Characterization

Fungal infections such as those caused by *Cryptococcus neoformans* and *Candida albicans* have shown significant threats to immunocompromised patients, presenting high mortality rates, as well as showing high resistance to treatment options. Antimicrobial peptides (AMPs) have shown promising signs against these infections, however, due to high rates of resistance and AMPs' short half-lives, new therapeutic methods are needed to combat these infections. Peptoids, which are structurally very similar to peptides, but show higher signs of stability and resistance to these infections, show promising results. Specifically working with the peptoids RMG8-8 and RMG9-11 which have been created in the Bicker Lab have demonstrated successful antifungal activity against *C. neoformans* and *C. albicans*, however further work is needed to understand the full mechanism of these peptoids. With RMG8-8 showing promising results with *C. neoformans* and RMG9-11 with *C. albicans*, we will do further testing on how RMG8-8 disrupts fungal cells, through membrane disruption, by performing biochemical assays such as, capsular vs. acapsular studies, melanization assays, DNA gel shift, and live/dead DNA staining. Additionally, electron microscopy will be used to understand the morphological effect on fungal cells, all in hopes to understand the peptoids' antimicrobial properties, as well as provide us with possible pre-clinical treatments for these fungal infections.

Abstract Name: Antiproliferative Activity of *Euphorbia dentata* in T47D, MDA-MB 231, and MCF-7 Cancer Cell Lines

Breast cancer treatment predominantly involves surgery, radiation therapy, chemotherapy, estrogen receptor down-regulators, aromatase inhibitors, and DNA-interactive agents. However, the clinical application of these therapies is often associated with significant and lifelong side effects. Recent research efforts have prioritized the discovery of novel anticancer agents with improved efficacy and reduced adverse effects. The use of medicinal plants in treating various diseases, including cancer, has grown significantly in recent years, with an 80% increase reported by the World Health Organization (WHO). This study investigates the antiproliferative activities of *Euphorbia dentata* (Euphorbiaceae) extracts on ER-positive MCF-7 and T47D and triple-negative MDA-MB-231 breast cancer cell lines. The Toothed Spurge, *E. dentata*, collected in Texas is a North American native plant that has not been studied previously. The aerial parts of the plants were used

to obtain two extracts, an ethanol extract rich in flavonoids and a xylene extract containing diterpenes. The xylene extract significantly reduced cell viability of all cell lines under study starting at a concentration of 16 µg/mL for T47D and 62.5 µg/mL for MDA-MB-231 and MCF-7 cells. The ethanol extract significantly reduced in T47D cell viability only at 500 µg/mL and did not show a significant effect on MDA-MB-231 cells. A biphasic effect was observed, where both ethanol- and xylene-extracted *E. dentata* extracts increased cell proliferation at lower concentrations and decreased proliferation at higher concentrations. Preliminary results into the mechanism of antiproliferative action in T47D cell line, specifically results of activated caspase 3/7, indicated that the xylene extract treated cells are undergoing mitochondrial intrinsic apoptosis. Future work will focus on fractionating *E. dentata* diterpene extract and characterizing the antiproliferative activities and mechanisms of action of fractions. The isolation and chemical characterization of *E. dentata* phytochemicals could contribute to the development of novel therapeutic agents for breast cancer treatment.

Abstract Name: Collision-induced Dissociation of Protonated Phenethylamine: A Model Study to Aid Illicit Drug Identification by Tandem Mass Spectrometry

Tandem spectrometry (MS/MS) and collision-induced dissociation (CID) are used in forensic analysis. Correct precursor and fragment ion assignment is critical for accurate compound identification by MS/MS. Although mass spectra can be annotated with molecular formula using high-resolution m/z measurements, in many cases molecular structure remains unassigned for fragment ions generated by CID. For de novo molecular identification, in-silico generated MS/MS spectra are used as a reference. However, there is evidence that fragment ion structure annotations in these reference libraries are often incorrect. For that reason, we are investigating the fragmentation mechanism(s) of model compounds such as phenethylamine, the simplest species in the substituted phenethylamine class of drugs that include amphetamines and MDMA, to improve structure assignment. This presentation highlights how use of CID, ion (vibrational) spectroscopy and computational chemistry allows us to identify the pathways by which protonated phenethylamine eliminates neutral NH_3 and $\text{CH}_2=\text{CH}_2$ in sequential fragmentation steps.

Abstract Name: History, Building, and Design Study for Historic Preservation of Rosenwald Schools in Wake County, NC

The purpose of this research is to conduct a study of the original design, construction methods, and material selection of Rosenwald Schools within historical black communities of Wake County, NC in the 1920s. Out of the 813 schools that were constructed in NC, many of them have been destroyed. Within Wake County, there were twenty-one built, six existing, and four on the National Register of Historic Places. Rosenwald Schools are achieving a history of 100 years after they were built for African American children in the South during the late 1910s to late 1920s with the collaboration of Sears and Roebuck philanthropist Julius Rosenwald, the founder of Tuskegee Institute, Booker T. Washington, and MIT's first black architect Robert Taylor. The goal is to use Place Based Methodology, to determine existing schools in the area, and use historic preservation methods to rehabilitate existing interior spaces for mixed-use and residential occupancy future design solutions. This information was compiled in a research paper including figures, tables, and sketches. Historic preservation methods of original building structure and design were investigated using the Standards for Rehabilitation. The results of this project informed the design intent by using nine over nine double hung sash windows for daylighting and airflow, the application of 4' high beaded wainscoting in the hallway, capped baseboards in classrooms, installment of "potbelly" stoves as a heat source in classrooms and movable partitions for class separation. The use of muted colors such as brown and ivory were incorporated as well as other details specified in the school construction plans issued by the Rosenwald Building Fund. The rehabilitation complies with building codes and accessibility for the new occupancy use, fully keeping the original interior walls and doors. The research suggests a possible design approach to the historic preservation of Rosenwald Schools.

Abstract Name: Ultra High-Performance Concrete Using Local Materials

Ultra-High-Performance Concrete (UHPC) is a relatively new class of concrete with compressive strength exceeding 18,000 psi, which is considerably higher than normal strength concrete (~4,000 psi). UHPC mixes have shown to be superior to traditional concrete mixes: for instance, compared to a girder made of regular concrete, a UHPC girder can span 20-25% further, or allow shallower cross-sections to cross the same distance. In addition to technical benefits UHPC mixes are long-lasting, durable construction materials that are designed to serve over 60 years. UHPC mixes are generally propriety materials with a high price tag. Key design components of UHPC include a tightly packed matrix using well-graded solid particles (i.e., aggregate, unhydrated cementitious materials), minimum amount of water to increase strength, high amounts of superplasticizer for fluidity, and addition of fibers to increase ductility. The research undertaken aims to produce UHPC using materials available to the State of Minnesota. Phase one included 30 UHPC mixtures in which six different cementitious materials (i.e., portland cement, fly ash, slag cement, ground glass, metakaolin, silica fume) were combined in varying percentages. It was found that either silica fume or metakaolin is essential for high strength. Elevated temperatures lead to higher strengths. 16,000-psi mix was achieved combining portland cement, metakaolin, and ground glass as binder. Phase two builds on these findings to reach the target strength of 18,000 psi with the goal of using additional techniques. Strategies include optimizing packing density of particles, using lower maximum aggregate size (i.e., finer sand), incorporating deairing agents, and utilizing ice to improve flow and mixing. In addition to compressive strengths flexural strengths are also determined.

Abstract Name: Why an Axe? Defining the Use of Axes by Norse Warriors in Viking Age Warfare

The Viking Age (793-1066 CE) chronicles the time during which the Norse - commonly referred to as Vikings - expanded their influence throughout regions of Europe, the Middle East, and islands of North America as warriors, merchants, and voyagers. As warriors, they fought against a wide range of peoples, weapons, and strategies, utilizing numerous weapons including axes. This weapon in particular, is frequently depicted in contemporary and later sources, by both the Norse themselves and their enemies. Furthermore, a large variety of axes have been discovered in a considerable amount of Viking Age burial sites in Scandinavia. The question then becomes, why were these weapons utilized to such an extent, especially the design-specific battle axes? In this paper, the prolific nature of axes in combat will be examined to determine why the Norse specifically used these weapons throughout the Viking Age. To do so, this paper will contend with relevant artistic and recorded sources to both illustrate the significant presence of axes in the written record and determine the context in which these weapons were used. Additionally, the archeological documentation from this period is invaluable to unearth the armament of the Norse during the Viking Age. The excavation and restoration of these axes demonstrate their evolution of functional designs. Further, this paper will utilize experimental archeology, examining axes in a martial context with the use of pressure testing and sparring to further explore their efficacy in Viking warfare. In summary, these sources of information will be applied to argue that the predominant reason for the use of axes was their versatility as tools of war. Especially when compared to other weapons that were available at the time, axes offered a wide range of offensive and defensive capabilities which made them ideal weapons on the battlefields of the Viking world.

Abstract Name: Using Sea Urchins As A Model To Examine How Semaglutide Affects Gamete and Embryo Development

Semaglutide is a glucagon-like peptide-1 (GLP-1) receptor agonist, which is a drug that lowers blood sugar by mimicking a hormone called insulin. The drug originally developed for the treatment of type 2 diabetes and has more recently shown promising results in managing obesity. Unlike insulin, semaglutide is administered through a weekly injection and is proven to effectively lower both blood sugar levels and A1C, a test that measures the buildup of blood glucose over time. However, as with any medication, concerns regarding its long-term effects, particularly on fertility and embryonic development, remain. This study investigates the potential impacts of semaglutide on fertility and early developmental processes using sea urchin embryos as a model. Sea urchins were chosen due to the similarity of their embryonic development to that of humans. In this study, sea urchin embryos at the initial 2-cell stage of development were exposed to a low concentration of semaglutide. The embryos were monitored over time, with developmental milestones recorded through microscopic examination and morphological comparisons between control and experimental groups. The aim of this research is to assess the potential risks and benefits of semaglutide use

during pregnancy or while attempting to conceive. Based on prior understanding of the drug's mechanism, we hypothesize that semaglutide will not adversely affect fertility, but may cause issues when used during pregnancy such as a low birth weight, or premature birth, due to semaglutide's weight loss properties.

Abstract Name: Petroleum Refinery Reconstruction and Operations Economic Impact

This research explores the economic impact of a petroleum refinery's reconstruction (2019-2023) and its anticipated 2025 operations after the facility's 2018 explosion. By analyzing the temporary effects of reconstruction and the expected long term effects of ongoing operations, the research provides insights into how large scale industrial projects impact local economies. The analysis used IMPLAN economic impact software. Economic impact modeling is a form of input output modeling, which studies how initial spending disperses through an economy. For the reconstruction phase, input data for spending and wages were provided by the refinery with gaps supplemented by secondary data from IMPLAN and Lightcast databases. The research developed several assumptions related to various aspects of the reconstruction project, including the company's local spending, local employment, worker's commuting rates, per diem expenses for non-local workers, and employee compensation and benefits for construction contractors. The company's operations were modeled with IMPLAN, using an industry impact analysis, a technique for analyzing production changes. This method allows researchers to adjust intermediate inputs of an industry by specifying the percentage each input comprises. Operations inputs included wages and benefits, employment, intermediate inputs, and estimated production. Economic impact models account for direct, indirect, and induced effects of the refinery's spending, reflecting how the company's expenditures rippled through the local economy. During reconstruction, the refinery generated \$2.2 billion in total combined output, supporting an average of 1,952 jobs annually, with peak employment reaching over 4,000 jobs in 2022. For ongoing operations, the refinery is expected to support 761 annual jobs and over \$310 million in total annual output.

Abstract Name: Strontium Isotope Analysis of Animal Remains from Archaeological Contexts in Southwest US

Strontium isotope analysis has emerged as a powerful tool to trace human and animal mobility and

geographic origins in archaeology. This study focuses on applying this method to non-human remains from sites in the Mesa Verde region, Southwest US. The central research question is: How did ancient communities in the Mesa Verde region adapt their resource acquisition strategies to environmental and social pressures during the period of AD 750 to 1280? Recent research has primarily examined domesticated turkeys, revealing how maize-fed turkey management coincided with significant environmental and social changes between AD 750 and 1280. Building on these findings, this project extends to deer and rabbit remains, providing new insights into human-animal interactions and resource acquisition strategies during this period of transformation. To this end, samples of rabbit and deer bones were selected from four archaeological sites and different periods covering the AD 750 – 1280 time span. The bone samples are carefully cleaned, treated to remove any contamination, and dissolved. The strontium is then extracted and the resulting solutions are analyzed on a Nu Plasma II multi-collector inductively coupled plasma-mass spectrometer. The isotopic composition of strontium measured for the samples is then compared with strontium isotope data available for the region to determine the provenance of the animals. The expected results are that deer and rabbit remains will demonstrate a mix of local and non-local origins, reflecting strategic food acquisition to changing environmental and social conditions.

Abstract Name: Meter Mapping and Efficient Energy Use at WSU

In this study we looked at locations of water, gas and electric meters across the WSU campus. This is important because we must know this to understand how energy flows from utilities and between buildings. Often, addresses on utility bills do not match the address of the building. Knowing which meter serves which building is important to benchmark energy consumption, some meters serve multiple buildings, knowing the locations allows planning for submeters to measure energy consumption per building, alongside this, associating a meter with a building allows for precise analysis such as energy per square foot and identify inefficient energy usage. Meters are most dense in the center campus and are mostly in good condition other than the numbers being wiped off of some due to weathering, about 10-15%, the most numerous are the gas meters (~50%) and electric meters (~46%) and most electrical meters are locked behind gates or inside of boxes especially in areas away from the center of each part of each campus. The distribution of meters is greatest in the three areas outlined, (north campus), (central/ main campus), and the (medical campus). There are satellite areas such as the football field with meters as well.

Abstract Name: A Morphological and Histological Comparison of Tooth Serrations in Galeocerdo

Tooth serrations present along the edge of the tooth crown in many modern sharks (neoselachians) are sharp projections adapted for cutting the flesh of prey. Each serration consists of an inner dentine core that is

surrounded by an outer enameloid coat composed of layers of long fluorapatite crystallites of varying orientation. Several ancient sharks have independently evolved serrations; however, the histology arrangement of these dental structures has received less attention. Using acid etching techniques, sectioning, and scanning electron microscopy, this study compares the enameloid histological arrangement of serrations in the extant *Galeocerdo cuvier* (tiger shark) with those observed in more recent (e.g., *G. mayumbensis*) and earlier (e.g., *G. aduncus* and *G. eaglesomei*) extinct tiger shark species. Although having subtle differences in overall morphology, preliminary findings suggest that the serration enameloid histological arrangement observed in *G. cuvier* is more similar in the more recent species than that of earlier species. Consequently, this study demonstrates that enameloid serration histology can serve as a tool to assist in the identification of distinct species within the *Galeocerdo* fossil record.

Abstract Name: Low-Power RISC-V Design for Edge Devices

In modern applications, Internet of Things (IoT) devices frequently rely on cloud and edge computing for data processing. However, cloud-based processing demands substantial computational resources due to the supercomputing infrastructure required in data centers. Localized processing on embedded hardware platforms, such as Field-Programmable Gate Arrays (FPGAs), offers a more resource-efficient alternative. This research explores the use of low-power RISC-V processors for energy-efficient machine learning tasks, focusing on the PicoRV32 core due to its suitability for implementing low-power deep learning algorithms like Deep Neural Networks (DNNs). This study analyzes the architectural features that enable the PicoRV32 core to achieve low power consumption and high energy efficiency. Modifications, including adding custom extensions and selecting appropriate RISC-V ISA subsets (e.g., RV32I, RV32IM, RV32IMC), are investigated to optimize its performance for various applications. A key parameter in this optimization is operating the core at an optimal frequency, such as 100 MHz, to balance power and performance. Additionally, selecting an FPGA with sufficient resources, including Look-Up Tables (LUTs) and Block RAMs (BRAMs), is critical for successful implementation. The research aims to implement DNNs using RISC-V on a Zynq UltraScale+ FPGA platform to enable tasks such as image processing, audio recognition, and natural language processing (NLP). As a preliminary step, the PicoRV32 core will be simulated using Verilog HDL on Xilinx Vivado software and subsequently implemented on an FPGA. Metrics such as power, performance, and area (PPA) will be evaluated to inform future designs. Ultimately, this work seeks to leverage RISC-V's open-source flexibility to develop low-power, hardware-embedded systems for machine learning in edge devices.

Abstract Name: Enhancing wildfire management in the Northeastern US with robotics

The central research question of this project is the extent to which robots can enhance wildfire management in the Northeastern US. Firefighting is well-known to be a dangerous profession with significant risk, but while wildfires are expected and procedures are in place in the Northwestern US, it is reported that the Northeastern US is just now entering its wildfire era. The research is conducted in the context of increasing frequency and severity of wildfires in the Northeast driven by climate change, which has overwhelmed firefighting efforts and highlighted the limitations of existing technologies. To contribute to the field, the research explores robotic assistance, and thus focuses on designing and developing a prototype autonomous robotic system capable of navigating hazardous environments, detecting fires, and assisting in suppression and rescue operations to reduce risks for human firefighters. The research methodology includes (i) a review of preparedness and robotic assistance where wildfires are common, (ii) a study of wildfire characteristics and preparedness in the Northeast, and (iii) an advisory consultation with environmental scientists at the Environmental Protection Agency. The prototype design would integrate advanced technologies such as thermal imaging sensors for heat detection, LIDAR for precise navigation, and AI algorithms for autonomous decision-making in dynamic environments. Testing would simulate wildfire conditions specific to the Northeast to evaluate the robot's ability to detect heat sources, navigate through debris, and relay critical information to a control center, providing essential insights into its operational feasibility. The conclusions of the research will inform firefighting strategies with robotic assistance in the Northeastern US and contribute to the broader concerns of public safety, environmental preservation, and advancements in emergency response technologies.

Abstract Name: Presenting Symptoms as Predictors of Outcomes After Subarachnoid Hemorrhage

Subarachnoid hemorrhage (aSAH) is an abrupt and often devastating hemorrhagic stroke resulting from a blood vessel rupture in the brain. The presence of a sudden severe headache is often described as a hallmark sign of aSAH. However, there are a range of symptoms that prompt the patient to seek medical treatment. There is limited data examining the relationship between individual initial symptoms and patient outcomes. Therefore, the purpose of this study was to examine if the predominate presenting symptom was predictive of outcomes at a single stroke center. Demographic and clinical data was collected from the patient, caregiver, or chart including symptoms and reason for seeking medical care prior to hospitalization. Functional outcomes were assessed at discharge, 3- and 12-months via face-to-face or telephone interviews with the patient or surrogate using the modified Rankin Scale (mRS), where 0 is no deficit and 6 is death. mRS was dichotomized into good (0-2) and poor (3-6) and Chi-square analysis (SPSS v26) was used to examine relationships between symptoms and outcomes. This retrospective analysis included 491 adult SAH patients (72.5% female; mean age 53 years). The presence of headache was the most frequent reason for seeking care (49%) followed by unresponsiveness (25%). Other reasons for seeking care included confusion and seizures. Headache as the predominate symptom was significantly associated with good discharge ($p < .001$), 3-month ($p < .001$) and 12-month mRS ($p = .03$). Patients who reported confusion as the predominate symptom were significantly more likely to have poor discharge mRS ($p < .001$). Patients who reported unresponsiveness as the predominate symptom were significantly more likely to have poor mRS at all 3 outcome points ($p < .001$; $p < .001$; $p < .001$). This analysis suggests that individual symptoms, specifically confusion and unresponsiveness may be predictive of worse outcomes and could help to inform discharge planning in aSAH.

Abstract Name: Sustainable Smart Farming Device with LeaFit Adaptive Growth Technology

For farmers, gardeners, and horticulture enthusiasts worldwide, one immutable reality is that consistent physical presence to care for plants is not always feasible. In addition, different plants have different needs for watering and nutrients. In this research project, we have designed and developed 'LeaFit' – a cutting-edge Internet of Things (IoT) device that offers a sophisticated sustainable smart farming and gardening solution. Equipped with intelligent soil moisture, ambient temperature, humidity, and light sensors, LeaFit autonomously adapts to the specific needs for various plants, ensuring optimal conditions for their healthy growth. The LeaFit-enabled automated irrigation system minimizes user intervention while effectively maintaining plant health and optimizing water resources, thus leading to water conservation and sustainable farming practices. In addition, the LeaFit devices integrate small solar cells which allows for a long operating lifespan. Our developed LeaFit devices are equipped with RFM95W LoRa chip which allow them to transmit sensor data over a long distance (>2km). This allows wireless transmission of sensor data without WiFi coverage when devices are deployed remotely in the field. A central LoRa gateway collects data from various field-deployed LeaFit devices and uploads it to an IoT cloud platform. In addition to the LeaFit hardware, we have developed an open-source mobile application that provides an interactive interface for the user to observe sensor data and get a holistic picture of the entire farming field displaying various critical parameters in color graphs overlaid on the farm map. Our system employs IoT cloud technology to collect data from the on-field sensors and display them on the mobile app which processes and securely stores data and allows real-time access to the user. By offering a robust user-friendly, remote, and autonomous solution for smart farming and gardening, LeaFit empowers farmers and gardeners to grow high quality products while using water resources efficiently.

Abstract Name: Herb-Modified Biocompatible Hydrogels for Wound Healing Applications

Severe lacerations requiring medical intervention remain a global challenge. In the United States, traumatic wounds are a common reason people seek care from clinicians. These wounds and their frequent complications strain the healthcare system and patient health. Patients affected by these wounds are predisposed to developing bacterial infections, and antibiotic-resistant bacteria—a common root cause of these infections—has been reported to hinder patient prognosis. The current treatment for lacerations includes stem cells to promote healing or hydrogels containing antibiotics or silver. However, these practices

contain drawbacks, primarily mammalian cell cytotoxicity. This research effort focuses on the synthesis and testing of PVA and Borax-based hydrogels enhanced with biocompatible herbal additives including turmeric, moringa, spermidine, clove, and neem for wound healing applications. The goal is to develop a biocompatible hydrogel capable of accelerating wound healing and preventing subsequent bacterial infection. To confirm biocompatibility, these hydrogels underwent rigorous testing. Rheological studies confirmed crosslinking between the PVA polymer and Borax, critical for hydrogel formation. A lap shear test using porcine skin was used to evaluate the hydrogel's adhesive properties, ensuring optimal performance without causing skin damage during separation. FTIR analysis assessed the functional groups in the hydrogel formulations, while a silicon manikin with a simulated gunshot wound was used to evaluate the hydrogel's hemostatic abilities. Antimicrobial studies are underway to demonstrate their efficacy in preventing bacterial infections. Should the herb modified hydrogels exhibit desirable hemostatic and antimicrobial properties, clinical trials can be conducted to assess their viability as a substitute for existing treatments.

Abstract Name: Impaired Motor Learning in Rett Syndrome Mice with MECP2 Deletion in Purkinje Cells of the Cerebellum

Autism is a neurodevelopmental disorder characterized by cognitive and behavioral impairments, including repetitive behaviors, motor difficulties, and deficits in social communication. Rett syndrome (RTT), a severe autism spectrum disorder, is caused by mutations in the MECP2 gene, which is located on the X chromosome. This mutation disrupts normal neurological function, with motor impairments being particularly pronounced in RTT. Since MECP2 mutations are X-linked, the syndrome manifests when a single X chromosome carries the defective gene. In order to efficiently study the role of MECP2, we bred mice with this conditional MECP2 deficiency by deleting the MECP2 gene from their purkinje cells, a major cerebellar neuronal cell type. Motor abilities in these MECP2-deficient mice were assessed using classical eyeblink conditioning, including both trace and delay paradigms, to evaluate motor learning and reflexive responses. Neural activity was also assessed during these tasks by utilizing implanted brain devices to identify electrophysiological changes associated with the MECP2 deficiency. To complement these behavioral experiments, we performed ex vivo brain slicing and used confocal and fluorescence microscopy to examine MECP2 expression and its impact on neural plasticity in both glial and Purkinje cells following motor learning tasks. The following experimental groups were used in comparison during microscopic analysis: MECP2 knockouts and wild-type controls. Our findings revealed the vital role of cerebellar dysfunction in RTT, linking impaired Purkinje cell function to both motor deficits and various neuropsychological abnormalities. These results provide new insights into the neurological underpinnings of RTT and highlight potential therapeutic targets for the future.

Abstract Name: The Cover's Truth: The Role of Culture in Cover art as Shown Through War and Peace

How is culture depicted in cover art? In answering this complex question are two widely available editions of Tolstoy's War and Peace, one from 1996 and another from 2002. With inspiration from Blackmore's (2020) paper, "Full Paper Jacket: Vietnam Book Cover Art," this paper acknowledges how the translation studies field has neglected cover art's role in new editions/translations of a work. Throughout this research, a typical case study methodology, in addition to George Saltzer's "Jacket Types," and Maslow's 1954 Hierarchy of Needs, helps carefully analyze the question, leading to the conclusion that there is a connection between cover art and culture, primarily in the way covers broadly depict cultural themes of the work and the culture of the time of republishing. This connection is explained further through a discussion on the cover's physical description and color, the original designer's context, and the context of the time these republished works occurred. Further research should explore more examples of cover art within and beyond the "classics" genre to see if these conclusions are more universal or dependent on certain factors.

Abstract Name: Efficacy of Essential Oils for German Cockroach Control

Traditional pest management practices rely heavily on synthetic insecticides, but due to their toxicity, there is concern surrounding potential hazards to humans, pets, and the environment. Consequently, there is a growing demand for natural products effective against urban pests. To address the demand for natural products against urban pests, especially cockroaches, several products have been formulated with essential oils (EOs). While the insecticidal profile of EO-based products is environmentally ideal, their effectiveness against the German cockroach, especially regarding residual activity and behavioral effects, remains to be investigated. Integrated pest management (IPM) approaches, including using EO products, have been proposed for cockroach control. This study evaluated the residual, direct exposure, and behavioral activity of commercially available EO products. Our results show that commercially available EO products had higher mortality rates when applied directly, but low mortality when tested as residual treatments. Effective control of cockroaches is crucial for reducing the risk of allergies and other health concerns in vulnerable populations while emphasizing the efficacy of environmentally friendly pest management solutions.

Abstract Name: I Wish We Weren't Seen as a Monolith: An Exploration of The Academic Needs of Black

Males

As countless students take their seats for graduation, the persistent underrepresentation of Black male students at the forefront of this accomplishment raise significant concerns. Despite academic improvements demonstrated through research to have shown a statistical impact on African American education outcomes, there is an unmistakable disparity between Black male students and any other race/gender in high school graduation rates, college enrollment, college completion, and overall education attainment. This study explores the academic needs identified by Black male students as essential for their academic achievement. Using an embedded mixed-method design, 15 Black male high school students ranked six factors from the Sankofa scale in order of most to least important. Additionally, existing data of approximately 20 Black male undergraduate students were analyzed to examine the factors previously influencing their academic performance. Quantitative findings of this study highlight the importance of cultural identity relevance in academia and the importance of personal relationships with teachers. The qualitative results reveal two new themes as potential risks to Black male achievement: that student identity and inspiring ambition. The findings underscore the importance of educators remaining neutral, respecting and valuing students, and setting high expectations that demonstrate strong belief in Black male students' capability to attain academic success.

Abstract Name: The Survival of Salmonella in Soil Amendment with Pecan Shells and Poultry Littler

The research conducted by the United States Department of Agriculture focuses on Salmonella's survival in soil amended with pecan shells, poultry manure pellets, and both pecan shells and poultry manure compared to unamended soil. Salmonella's survival rate will be shorter in soil amendment with pecan shells than poultry manure. Poultry manure already has foodborne pathogens like Salmonella and E. coli in it. An inoculum is created using five strains of Salmonella Typhimurium, Enteritidis, Montevideo, Saintpaul, and Newport. Fifty milliliters of the inoculum was placed in each of the 1000kg treatments and mixed evenly. Sampling is then conducted over a period of days after inoculation. A 1:10 dilution is created using peptone water and samples of each one of the treatments. The dilutions are plated on TSA + R plates and incubated for 24 hours at 37 C. Poultry manure promoted the survival rate of Salmonella in soil amended. Pecan shells are a reliable alternative for producing Salmonella as a soil amendment to poultry manure. The data from the third rep of the soil amended study was consistent and had a slower die-off rate than the previous reps conducted, which was not to be expected.

Abstract Name: Examining Brain-Behavior Connections in African American Women With Hypertension

Hypertension (HTN) affects 58% of African American women in the U.S., representing one of highest prevalence rates among demographic groups. This chronic condition significantly increases the risk of serious health issues, such as stroke, and is linked to higher mortality rates. By understanding the brain-behavior connections in African American women with HTN, we can gain insights into how they process and apply health information, potentially leading to improved health outcomes. The Brain Relationships Among Information, Neuroprocessing, and Self-Management (BRAINS) study utilized a cross-sectional design and included a sample of 99 participants who self-identified as Black women, were right-handed and ages 21 to 64. Data collection was adapted due to the COVID-19 pandemic by employing videoconferencing to conduct study visits. Measures included: assessment of self-management behavior, health information behavior, blood pressure (using Omron 10 cuffs), and cognitive function (evaluated using the TestMyBrain Digital Neuropsychology Toolkit). Data analysis is being conducted to examine findings related to health information behavior and cognitive function that can enhance HTN self-management strategies that may be useful for many African American women with HTN. We hypothesize that most participants will report a moderate level of searching for health information about high blood pressure, and that cognitive performance (particularly in processing speed and working memory) will vary due to the age range of participants. Furthermore, we anticipate that participants will report moderate to high levels of self-regulation in managing HTN, though with considerable variability. Ultimately, this research will provide additional insight for HTN management recommendations, contribute to reducing health disparities among African American women, and guide scientists in designing future studies. Keywords: Hypertension, African American, Women, Cognition, Self-Management, Brain

Abstract Name: The differing effects of oxytocin on maternal motivation in mice

Levels of social interaction are often decreased in those with autism spectrum disorder (ASD). The social motivation hypothesis of ASD suggests that this stems from lower motivation toward social interaction, which is a product of alterations in the dopaminergic reward system. One proposed treatment for the decreased social drive seen in ASD is oxytocin. Oxytocin is a neurotransmitter and hormone commonly linked to social behaviors and plays an important role in the development and maintenance of relationships. Paradoxically, the pattern that has emerged from research in the Rogers Lab is that administering oxytocin to mice decreases levels of social interaction. This experiment will further investigate this phenomenon, specifically examining oxytocin's role in mediating maternal motivation by separating mouse mothers (dams) from one of their pups by an obstacle. Previous findings from the Rogers lab suggest that oxytocin will increase maternal motivation when effort is low and decrease maternal motivation when effort is high.

Abstract Name: A Reexamination of Paul Bowles as a Moroccan Representative

Paul Bowles was an American expatriate known for his work as a composer, author, and translator. He settled in Tangier, Morocco, in 1947. He published several short stories, three novels centered around Moroccan social and political culture, as well as numerous translations of oral stories, including the work of well-known Moroccan author Mohamed Choukri. Due to his extensive list of Moroccan representations, Bowles curated a legacy as a leading contributor in introducing the Western world to Morocco, which current scholarship upholds without question. This research calls into question Bowles' qualifications for being a pseudo-ambassador of Moroccan culture and argues instead that he is an unreliable source of information. This position revolves around three factors: Bowles demonstrates a lack of cultural sensitivity necessary for unprejudiced depictions of differing cultures, his perpetually homogenous social circle of Westerners in Morocco, and his self-proclaimed fluency in Morocco's Arabic dialect *darija*. Evaluating his refutable qualifications and neglectful contributions to the Western world's understanding of Moroccan culture exposes the misconception that Bowles is a reliable spokesperson. This research encourages and emphasizes the importance of further scholarship towards a reexamination of Bowles' work, his impact on the Western canon's perspective of Morocco, and historiographies created by previous scholars. From a broader perspective, this study contributes to literary Orientalism scholarship and advances critical cross-cultural understanding.

Abstract Name: Assessing Deformed Wing Virus Prevalence Among Asymptomatic Honey Bees Using Real-Time qPCR

Deformed Wing Virus (DWV) is one of many viruses that infect honey bee (*Apis mellifera*) colonies. Many bee viruses may cause subclinical or clinical symptoms with natural exposure, but pathology can be facilitated with *Varroa destructor* mite infestation. This relationship between mite and viral infection is seen in the case of DWV, causing clinical signs of shriveled wings that weaken hives, which contributes to overwinter losses and general collapse of colonies. Our research assesses the prevalence of DWV from four honey bee hives in the Grove City College (GCC) apiary. We extracted viral RNA from honey bee samples and used Real-time qPCR to amplify DWV sequences. The resulting amplification curves suggest that 20 of the 22 total honey bee samples contained DWV, despite the lack of clinical symptoms. This procedure can help inform researchers about the high prevalence of DWV in both clinical and subclinical presentations. Furthermore, this study highlights the importance of *Varroa* mite treatment and prevention in beekeeping practices, even in hives that appear asymptomatic.

Abstract Name: Continued Analysis using the Future Orientation Index

This research aims to further develop Future Orientation Index (FOI) measures (Noguchi et al., 2014; Preis et al., 2012), and examine their relationships to macro-level variables (e.g., per capita GDP; savings-to-debt ratios, etc.). The original measures used the ratios of Google searches for future years (e.g., “2026”), past years (e.g., “2024”), and the current year (e.g., “2025”)[c1] to create proxies indicating the extent to which individuals in a population are relatively focused on the past, present, or future. We will develop extensions of these FOI measures that consider more distant past and future years, as well as non-numerical search terms (e.g., “last year”, “next year”, etc.). We also aim to develop a Risk Orientation Index (ROI) measure, using the relative frequencies of Google searches for terms associated with risk (e.g., “gambling”, “betting”, etc.), and examine its relationship to macro-level variables. We expect these improved and novel measures will serve as useful proxies for the extent to which populations are more future-focused (FOI), as opposed to present- and past-focused, as well as more risk-tolerant (ROI), as opposed to risk-averse. Consequently, we also predict that these indices will be correlated with macro-economic measures of economic success, given that individual success is driven (in significant part) by people’s willingness to delay immediate gratification (i.e., focus on the future) and adopt a reasonable approach to risk. We will test this latter hypothesis by comparing these indices and various macro-economic variables across countries and across U.S. states [c1]Since the conference is scheduled for next April, 2025, I am taking 2025 to be the “present year”, etc.

Abstract Name: sPHENIX 3-D Topological Calorimeter Clusters in Run-24 p+p Data

The sPHENIX experiment at the Relativistic Heavy Ion Collider (RHIC) uses an Electromagnetic Calorimeter and two Hadronic Calorimeters with granularity in η - ϕ to measure particles produced in proton-proton collisions. Energy deposits from showering particles are measured using a series of calorimeter towers, each with their own measured energy and expected noise level. The reconstruction of calorimeter showers by grouping individual calorimeter towers into three-dimensional topological clusters has proven a reliable noise suppression method in experiments at the LHC and other facilities. Using an iterative growth algorithm that determines tower inclusion based on the significance of the tower energy above noise, this method offers a single tool for mapping showers ranging from purely photonic to deeply hadronic. By identifying energy deposits from individual particles, topological clustering is also useful for jet reconstruction. This presentation encompasses a series of studies on topocluster reconstruction in RHIC Run-24 p+p data and discusses the broader scope within the sPHENIX physics program.

Abstract Name: A Study on the Effects of Park Visits on the Mental Health of Residents in Low-Income Senior Living Communities (SLCs)

As generations age, there comes an expansion of senior living communities (SLCs) which aim to accommodate the living needs of senior citizens. However, there is a correspondence of chronic diseases and health-related ailments, both physical and mental, affecting those living within lower-income communities compared to regular community-dwellers. Visiting a park offers exposure to green space, referred to as green therapy, which may improve the mental health of residents in low-income SLCs, especially those in urban settings with limited access to green spaces. This experiment explored if exposure to parks improved their overall mental health. Cortisol was used as a determinant, and it was anticipated that participants' cortisol levels would decrease as their health improves. To test this hypothesis, three SLCs participated in a 10-week program where they walked around a local park once each week. Prior to the first walk, a 'pre-program' interview was administered, where the participants answered a series of mental-health questions. A sample of hair was collected to be used for cortisol analysis before and after the program, to compare the cortisol levels of each. Additionally, before and after each visit, a shorter survey was utilized to assess each participant's well-being. After the program concluded, a 'post-program' survey was completed. The results showed a significant improvement in the participants' overall well-being. There was not significant change in the pre/post cortisol levels, however significant change was observed when outliers were removed. This park program is a promising outlet through which senior residents could improve their mental health.

Abstract Name: Leveraging Deep Learning for Vehicle Behavior Analysis and Adaptive Traffic Signal Optimization

This study presents an innovative tool designed to automate the detection of yellow lights and analyze vehicle behavior at intersections, leveraging advanced deep learning and computer vision techniques. Using traffic footage collected from intersections in Utah and Florida, the tool processes multi-camera video feeds to evaluate driver responses during the yellow light phase. The integration of YOLOv8, a state-of-the-art object detection model, enables accurate identification of vehicles in real-time, while OpenCV facilitates video frame extraction and synchronization across multiple cameras. This ensures comprehensive traffic analysis, even in complex environments. The tool optimizes data storage and processing efficiency by automating the identification of yellow light occurrences and discarding video frames without vehicle activity. Behavioral analysis focuses on determining whether vehicles decelerate, stop, or accelerate during the yellow light phase, with virtual distance markers used to estimate speed and acceleration. These insights provide valuable data for modifying traffic signal timings to align with real-world driver behavior. Preliminary results demonstrate the tool's potential to enhance traffic flow and safety at intersections. The findings indicate that adaptive adjustments to yellow light durations, informed by observed driver behavior, could reduce congestion and the risk of accidents. Future applications include integrating real-time adaptive traffic signal systems that adjust signal timings dynamically based on live traffic data. This research also lays the groundwork for further incorporating vehicle-to-infrastructure communication to optimize urban traffic management. By combining

machine learning and computer vision, this study introduces a scalable, efficient, and accurate solution for addressing the challenges of modern traffic systems. It establishes a strong foundation for future research in intelligent transportation systems, aiming to improve traffic safety and efficiency through data-driven decision-making.

Abstract Name: Synthesis of 3-chlorobenzo[b]thiophenes via copper-catalyzed electrophilic cyclization reactions

Benzo[b]thiophene scaffolds are essential constituents of various materials and pharmaceutical products. These sulfur heterocycles are especially known for their antidepressants, anti-inflammatories, antimicrobial and anti-tumor activities. In material science, thiophene derivatives are used as inhibitors of corrosion of metals and in the fabrication of light-emitting diodes. The commonly used method for synthesizing 3-halobenzo[b]thiophenes derivatives is from the halocyclization of 2-alkynylthioanisoles. Although these halocyclization methodologies have proven to work well for 3-bromo and 3-iodo substituted benzo[b]thiophenes, the synthesis of 3-chlorobenzo[b]thiophene via chlorocyclization has proved to be quite demanding. Most of the current chlorocyclization methodologies involve the use of excess or stoichiometric amounts of copper salts. Herein, we report a novel copper-catalyzed chlorocyclization methodology for the synthesis of benzo[b]thiophene utilizing 1,3-dichloro-5,5-dimethyl hydantoin as the source of chlorine. Our new methodology requires mild reaction conditions and results in excellent yields for the product.

Abstract Name: Enhanced vulnerability to trauma-induced neurodegeneration in a Drosophila model of human tauopathy

Deposition of the microtubule-associated protein tau is a hallmark pathology of the family of neurodegenerative diseases known as tauopathies, including Alzheimer's disease, frontotemporal dementia, and chronic traumatic encephalopathy. Ongoing work on mechanisms of tau-mediated neurodegeneration suggests that genetic contributions interact with peripheral or environmental factors to contribute to disease onset and severity. Head trauma is an established modifier of brain health and function in human, rodent, and

invertebrate models. Using an established impact injury model known as HIT, we have examined the effect of traumatic injury on behavior and neurodegenerative markers in transgenic *Drosophila* expressing human tau in neurons. Tau transgenic flies show worsened outcomes compared to their non-transgenic controls as shown by both locomotor activity and tissue histology. To expand upon this work, we are examining other neurodegenerative models in the HIT paradigm as well as other biochemical markers of cell death. Taken together, these data suggest that tau transgenic flies have an increased vulnerability to traumatic injury in this *Drosophila* model of human tauopathy.

Abstract Name: The Effects of Relaxin Agonists on Vascular Calcification in Osteogenic Conditions

Heart disease is the leading cause of death in the United States, with atherosclerosis being a primary underlying factor. Atherosclerosis is a chronic disease characterized by the accumulation of lipoproteins in the arterial walls, triggering chronic inflammation, narrowing the arterial walls, and obstructing blood flow. A feature of advanced atherosclerosis is the deposition of bone-like mineral in the plaque, known as vascular calcification, the best predictor of a cardiovascular event. Currently, there are no treatments to slow or reverse vascular calcification. Studies have demonstrated that relaxin, a vasoprotective and anti-fibrotic hormone, is safe in humans; however, relaxin is expensive to synthesize and has poor bioavailability. ML290, 6044, and 8394 are allosteric biased agonists of the human relaxin family peptide receptor 1 (RXFP1) and offer a more cost-effective solution while effectively targeting the RXFP1 receptor. This study investigates the effects of these agonists on vascular calcification. Our experiments consisted of 21 days, where we aimed to determine whether the agonists reduce vascular calcification in a dose-dependent manner in vitro. We seeded vascular smooth muscle cells in osteogenic (OG) media to induce calcification, where our wells consisted of a control group, OG media, and OG media with a dosage of 5 and 10 μ M of each agonist. On Day 21, Alizarin red S staining was performed to assess calcium binding and extracellular vesicles were isolated to measure alkaline phosphatase, a marker of calcification, in each well. Preliminary data suggests these small molecule relaxin receptor agonists can reduce vascular calcification in vitro.

Abstract Name: Revealing the Role of Glia in the Evolution of Behaviors in *Astyanax mexicanus*

Long thought to be simply a support cell for the brain, the glia now have a known role in modulating neural function and behaviors. Active research is being done in diverse model systems to understand the role of glia in neural function, yet how changes to glia lead to evolutionarily adaptive behaviors is an unexplored problem. The model system, *Astyanax mexicanus*, is a unique system among vertebrate models in that the fish exists as a single species with two evolutionarily divergent forms: eyed surface-dwelling fish and multiple populations of eyeless cave-restricted forms. This project will use the power of *Astyanax*, including many reagents developed by the Duboue lab, to understand how glia differ in these two evolutionarily divergent forms and how changes to glia diversity or function led to adaptive behaviors. With the use of transgenic fish developed in the Duboue lab, and in situ hybridization, glial cells can be integrated into the *Astyanax* brain atlas. Using this atlas, comparative analysis can be done between the cave and surface morphs of *Astyanax*, revealing important differences in the quantification of glial cells within different subregions of the brain. This study has established a method to characterize different subsets of glial cells within *Astyanax*, and further studies will utilize this method to track glial development between the two morphs. We expect these studies to set the stage for understanding what role changes in glia have in the diversity of life throughout the Animal Kingdom.

Abstract Name: Place Attachment in Young Adults

Place attachment is the emotional bond individuals form with specific locations, influencing identity and stability (Clarke et al., 2017; Williams & Vaske, 2002). This bond is particularly significant for young adults (YAs) as they gain autonomy and navigate new environments, such as college and careers (Chevrier & Lannegrand, 2023). While place attachment has been studied primarily from a tourism perspective (e.g., festivals, national parks; Rajaobelina et al., 2019; Ramkissoon et al., 2014), we know little about the factors that promote neighborhood place attachment during young adulthood, a time in which even the definition of one's "neighborhood" may be in flux. This study investigated predictors of YAs' neighborhood place attachment, including individual-level factors (race/ethnicity, gender, age, parental relationships, perceived safety) and neighborhood-level factors (rurality-urbanicity, stability). We also examined differences based on how YAs conceptualized their neighborhood and the relationship between neighborhood place attachment and markers of adulthood or subjective adulthood. Participants included 1,303 YAs recruited

through online panels (38.1%), a university participant pool (41.7%), and college extra credit opportunities (20.2%). To allow for self-definition of their neighborhood, the Place Attachment Scale was administered before identifying their referent neighborhood (e.g., zip code). GLM analyses were conducted using SPSS Statistics 29, with further neighborhood-level analyses using Mplus 8.11. Results indicated significant differences in place attachment based on the referent neighborhood, driven by contrasts between current neighborhoods and those where YAs grew up. Age, parental relationship satisfaction, and perceived safety (but not gender or race/ethnicity) predicted neighborhood place attachment, while the neighborhoods YAs grew up in and where friends live were associated with greater attachment compared to current neighborhoods. Findings suggest that parental relationships and perceived safety may be important facilitators of this promotive factor.

Abstract Name: Empowering Youth to Be Environmental Stewards

As climate change intensifies, urban populations face unique challenges, such as pollution, and habitat degradation, which demand urgent attention. Over half of the world's population lives in cities, yet many of these people are often excluded from environmental conservation discussions. This exclusion is not only unfair but also unsustainable. Marine Park, Brooklyn offers a great example of this gap in New York City. Since urban environments, such as Marine Park, often face specific environmental issues, active environmental stewardship is crucial. This is where citizen science and environmental education programs play an important role. Citizen science, which is the involvement of the public in scientific research, and environmental education programs, which are initiatives that teach people about the environment and environmental issues, provide a framework for engaging urban youths in these important conversations. This transdisciplinary qualitative case study research project, carried from September to November 2024, sought to address the question: 'How can organizations use citizen science and environmental education programs to encourage and empower youth to become environmental stewards in Marine Park, Brooklyn, New York?'. For this study, I utilized an interdisciplinary mixed-methods case study framework focused on youths (14-18). I conducted a survey to gather information about youth attitudes, behaviors, and pre-existing knowledge about the environment, as well as observational research to document engagement in citizen science and education programs. The findings from this study highlight that participants have an increase in a sense of empowerment after being involved in these programs. These findings suggest that such programs are important in fostering a stronger connection to nature and empowering youth to take active roles in environmental initiatives. Given these outcomes, organizations should prioritize and expand the use of these programs, including educational and citizen science initiatives, to engage youths and promote environmental stewardship in urban areas like Marine Park.

Abstract Name: The Impact of Transportation Policy Changes on Population Rural Population's Decline in Oklahoma

Over the past 30 years rural Oklahoma has seen a substantial decline in population. Many of these rural counties have lost their residents to urban counties, though the impetus for this transition is not well understood. In this work, I test the hypothesis that this was largely caused by the decommissioning of the Interstate Commerce Commission in 1995 which removed Federal support for rural transportation networks. I compare counties that had access to robust public transportation options prior to the decommissioning with those that did not to determine how business dynamism and population growth changed. I discuss possible policy changes to counteract negatively affected rural communities.

Abstract Name: Comparison of Stream Water Quality from Use of Whole Count & Fixed-Count Subsampling of Macroinvertebrates Collected Using Artificial Substrate Over One Four-Week Period

Monitoring stream water quality often employs sampling of benthic macroinvertebrates. Different sampling techniques are used, including using a fixed-count subsample or a whole count sample. Fixed-count subsamples are low-cost, low-effort and relatively accurate; whole count samples are high effort and have the greatest accuracy. When comparing subsampling to whole-count, would a significant difference be found between sample sizes after calculating the Shannon Diversity Index (SDI) and Macro Biotic Indices (MBI—used to determine stream quality) for each? Broad taxa categorization was used according to Illinois RiverWatch (a citizen scientist program) standards, to compare data collected from artificial substrate samplers installed in Lily Cache Creek in Will County, IL at Avery Preserve for four weeks.

Macroinvertebrates collected were subsampled in groups of 50+, 100+, 200+, and whole count samples to determine if a significant difference in SDI and MBI could be found between subsamples and whole-count sampling for Hester-Dendy samplers and marble rock baskets. Taxa were also sorted into the groups EPT and non-EPT (EPT referring to the insect orders Ephemeroptera, Plecoptera, and Trichoptera) and pollution tolerant and intolerant species. Comparison between fixed-count and whole-count samples displayed no significant difference in stream quality metrics, which were determined to be borderline fair/poor, except in increased EPT taxa richness in the marble rock basket samples and in comparisons between 100+/whole count and 200+/whole count in marble rock baskets. This supports earlier research which found subsampling gives a roughly proportional result to whole-count sampling of macroinvertebrates, meaning small, unbiased, sub-samples continue to be applicable for volunteer-based stream quality determination.

Abstract Name: Towards a Resilient Federated Edge Intelligence: A Testbed for Design, Analysis, and Validation of Federated Learning

Federated learning (FL) is an efficient, privacy-preserving distributed learning paradigm that enables massive edge devices to train machine learning models collaboratively. Although various communication schemes have been proposed to expedite the FL process in resource-limited wireless networks, the unreliable nature of wireless channels was less explored. Current research on the evaluation of FL is mainly based on the simulation of multi-clients/processes on a single machine/device, leaving a gap in understanding FL performance under unreliable communication in real-world distributed low-power IoT devices. This research develops a comprehensive testbed for evaluating FL under unreliable communication using the Common Open Research Emulator (CORE) to simulate multiple heterogeneous IoT devices and their network interactions on a single physical machine. We implement a Distributed Consensus Algorithm to mimic FL behavior, providing a simplified yet representative model of distributed learning dynamics. The testbed supports various network topologies, including mesh, star, tree, and hierarchical federated learning configurations, allowing for comprehensive topology-based performance analysis. Through an integrated Grafana dashboard, we enable real-time monitoring and control of network parameters such as packet loss, bandwidth, and latency between nodes, while also providing visualization of individual node performance and simulation control capabilities. This setup facilitates the investigation of security vulnerabilities across different topologies, particularly focusing on resistance to DDoS attacks and malicious data manipulation at the client level. The platform can simulate an arbitrary number of IoT devices, making it highly scalable for diverse experimental scenarios. This comprehensive testbed provides researchers and practitioners with an open, adaptive environment for measurement and experimentation in the FL context, enabling the design and validation of robust FL solutions while offering valuable insights into security implications across various network configurations.

Abstract Name: Synthesis and Characterization of Bio-monomers in Cashew Nut Shell Liquid (CNSL)

Cardanol is a bio-based raw material obtained from distillation of cashew nut shell liquid (CNSL). Cardanol is not only readily available, affordable, renewable, and non-toxic but also has a unique structure, making it a possible substitute for phenols in many applications. Cardanol is also of high interest because of the presence of an unsaturated side chain that is versatile in developing bio-based building blocks. The main constituents of CNSL are phenolic compounds with long side-chain substitution at the meta-position. These constituents differ in side-chain unsaturation including mono, di and tri. The structure of these side-chains of varying degrees of unsaturation in CNSL are the focus of our research, transforming into a three-membered ring structure (oxirane ring) with two adjacent carbons, forming an epoxy functional group. In this research, we were able to develop a new and simple method for epoxidizing a bio-based raw material by using cardanol as the source of double bonds, acetic acid and amberlite as catalysts, and hydrogen peroxide as an oxygen donor. The products obtained from the reaction were analyzed using Thin Layer Chromatography (TLC), Viscometer iQ, and Fourier-Transformation Infrared (FT-IR) Spectroscopy. The analytical results suggested the formation of a new product with remnants of starting material.

Abstract Name: Immunomodulation in the Melanoma Tumor Microenvironment: K-Homology Type Splicing Regulatory (KSRP) Protein

The tumor microenvironment (TME) in melanoma has been of increasing interest. K-homology type splicing regulatory protein (KSRP) is a multi-domain RNA-binding protein involved in the post-transcriptional regulation of mRNA. The Cancer Genome Atlas (TCGA) revealed that KSRP is highly expressed in human melanoma and correlated with poor survival. We have found that KSRP is highly expressed in human and mouse melanoma cell lines compared to normal melanocytes. There is limited information on the role of KSRP in regulating the TME in melanoma. This study aimed to determine whether loss of KSRP inhibits the growth of melanoma using KSRP knock-out (KO) mice and C57BL/6 wild-type (WT) control mice and also aims to investigate the role of the immune system in this process. We hypothesized that loss of KSRP will inhibit the growth of melanoma cells due to anti-tumor immune response in the TME. KSRP KO and WT mice were injected subcutaneously with one million YUMM1.7 mouse melanoma cells and mice were monitored for the appearance of tumors after injection using digital caliper measurements. Tumor volume was measured every alternate day for 30 days. Mice were sacrificed after 30 days, and the tumor and spleen were harvested for analysis of immune cells by flow cytometry and immunohistochemistry. At day 29 post-injection, tumor volume was significantly larger in WT mice vs KSRP KO ($p=0.0078$). Analysis of WT and KSRP KO TME via immunohistochemistry is currently ongoing. Our flow cytometry analysis revealed that there were significantly fewer T regulatory cells, myeloid-derived suppressor cells, and higher levels of cytotoxic T cells in KSRP KO mice in comparison to WT mice. This is the first in vivo model regarding KSRP modulation and its role in future pharmacologic potential with immunotherapies.

Abstract Name: The Role of Runx2 in Mature Odontoblasts for Postnatal Dentin Secretion and Maintenance

Nearly half of the adults in the US suffer from periodontitis. Dentin is essential for protecting dental pulp stem cells from invading oral pathogens. Teeth with low levels of dentin are susceptible to caries, infections, and fractures. Dentin is synthesized and secreted by odontoblasts. Runx2 transcription factor is the master regulator of osteoblast differentiation and bone formation. The global deletion of the Runx2 gene results in failure of bone formation and embryonic lethality. However, the role of Runx2 in odontoblasts for synthesizing and maintaining postnatal dentin needs to be better understood. To answer this question, we have generated a Runx2 gene floxed model. Runx2 gene was deleted in mature odontoblasts by using OC-Cre mice. We confirmed OC-Cre activity in mature odontoblast by Td-reporter. The homozygous mice were born alive with normal development and eruption of incisors and molars. The changes in the dentin synthesis will be assessed by micro-computed tomography (μ CT) of load-bearing molars and continuously growing incisors

at 2-week, 1-month, and 3-month time points. Disruption in odontoblasts differentiation due to lack of Runx2 will be investigated by changes in expression of dentin marker genes (DMP1, DSPP, OC, Sp7) by qPCR and RNA-Scope. TUNNEL staining will be used to know the involvement of Runx2 in odontoblast survival and death. Odontoblast differentiation, polarization, and the maturation of dentin tubules will be assessed by H&E staining. Double Calcein labeling will be used to quantify dynamic dentin synthesis. While tooth development is expected to progress normally, we anticipate a significant decrease in odontoblast gene expression, polarization, and dentin synthesis.

Abstract Name: Exploring the MAPT Gene and Its Influence on Frontotemporal Dementia and Other Neurodegenerative Conditions

Frontotemporal Dementia (FTD) is a neurodegenerative disorder characterized by the progressive degeneration of the brain's frontal and temporal lobes, leading to significant neuronal loss and dysfunction in these regions. These pathological changes result in the behavioral, emotional, and cognitive impairments that are hallmarks of FTD. Understanding the pathogenic effects of tau protein mutations is essential for elucidating the mechanisms underlying FTD and for developing effective therapeutic interventions. In this study, the focus surrounded investigating genetic mutations in the tau protein by analyzing the MAPT gene, which encodes the tau protein. A variety of resources and tools from the National Center for Biotechnology Information (NCBI) were utilized, including the Gene, Protein, dbSNP, and PubMed databases, as well as the DisGeNET database. The NCBI Gene database provided comprehensive information on the MAPT gene, while the Protein database offered detailed insights into the structure and function of the tau protein, including its various isoforms and post-translational modifications. The dbSNP database and the Variation section were instrumental in identifying known genetic mutations and single nucleotide polymorphisms (SNPs) associated with the MAPT gene. These resources collectively facilitated a thorough analysis of the genetic variations that contribute to FTD. Additionally, the ClinVar database was utilized to assess the clinical significance of these genetic variants, providing valuable data that can inform the development of targeted therapeutic approaches. By integrating information from these diverse databases, the study aimed to enhance an overall understanding of the molecular basis of FTD and to identify potential avenues for treatment. This comprehensive approach underscores the importance of genetic research in unraveling the complexities of neurodegenerative diseases and highlights the potential for developing personalized medicine strategies to combat FTD.

Abstract Name: The Impact of Clinical Training on Landing Biomechanics and ACL Injury Prevention

Anterior cruciate ligament (ACL) injuries represent a significant threat to athletes' long-term health and

performance, with current prevention strategies showing limited sustained effectiveness. This study aims to investigate the impact of a comprehensive clinical training program on improving landing biomechanics and reducing ACL injury risk among collegiate athletes. ACL injury risk reduction programs emphasize improving known biomechanical risk factors for injury, including increasing knee and hip flexion angles, reducing vertical ground reaction force, and decreasing knee abduction angles and moments during landing. Improving biomechanics is often attained through the use of feedback of movement errors. Feedback may be internal or external. The benefit of auditory feedback is that errors can be tracked every time the individual moves in a way that could injure the ACL. Quantifying errors during training is beneficial, but understanding if the individual reduced their risk of injury in response to training is essential to determine success of the intervention. The clinical tool used in this study is the Landing Error Scoring System (LESS). By carefully examining movement patterns during first contact, knee flexion, and global evaluation items of the LESS, this study seeks to understand how particular interventions can change landing mechanics. The study combines common functional exercises and auditory feedback to achieve proper landing techniques. The training regiment will be a 4-week training program to improve landing biomechanics. By establishing the association between auditory errors and LESS score, the study can inform clinicians about who may best benefit from an auditory feedback training program. The basic idea is that by employing sound biomechanical techniques, athletes can significantly reduce their risk of injury, as seen by reduced LESS scores. In addition to immediate injury avoidance, the study anticipates broader impacts such as improved sports performance, longer career longevity, and better recovery processes.

Abstract Name: Neurogenetic tool for characterizing IR8a expression and functions in the malaria mosquito

Odor volatiles that emanate from human skin are potent attractants to mosquitoes. Studies in *Aedes* mosquitoes have shown that IR8a is important for driving sensitivity to carboxylic acids. However, the neurophysiology of odor-evoked activity of the IR8a neurons in the antennae and the brain remains elusive. This gap is largely due to the unavailability of genetic tools in mosquitoes to allow for functional characterization and mapping of IR8a neuron populations. Here, we knock in T2A-QF2 into the exon1 of *Anopheles coluzzii* gRNA. We generated two independent alleles of IR8a knock-in by marking the transgenic lines with enhanced yellow fluorescent protein (eYFP) and red fluorescent protein (RFP). This approach enables us to capture the endogenous expression of IR8a and mutate IR8a functions simultaneously. A functional readout is obtained by crossing the IR8a driver line to a genetically encoded calcium indicator line. To map IR8a expression and axonal innervations, we cross the IR8a driver line to the green fluorescent protein reporter line. Transgenic backgrounds expressing both eYFP and RFP markers are mutant IR8a mosquitoes. Taken together, we show a binary expression system for characterizing IR8a functions and expression in *Anopheles* mosquito.

Abstract Name: Investigating the Sodium Content in Popular Asian Sauces using Nuclear Magnetic Resonance Spectroscopy (NMR)

The objective of this study was to investigate the sodium content in various Asian sauces using Nuclear Magnetic Resonance (NMR) Spectroscopy. Asian sauces are popular condiments known for its umami flavor and high sodium content. As Asian food grows in popularity in the US, it is becoming a more popular condiment in America. Monitoring sodium intake is crucial due to its link to high blood pressure, a prevalent issue in the United States. Verifying the sodium content in several different types of Asian sauce were evaluated to compare the sodium amount listed on the nutritional label to the measured sodium content in the product. A calibration curve ranging from 0.9%-4.5% sodium was prepared. The Asian sauces were diluted to adjust the sodium content to approximately 2.25%. Several different brands and types of Asian sauces were evaluated using NMR spectroscopy. Results will show that many soy sauces analyzed contain more sodium than indicated on the nutritional label. We can verify that the sodium in Asian sauces are not accurately presented. And a modification of all label descriptors for soy sauce brands should be adjusted to state the sodium content more accurately.

Abstract Name: Unraveling Pre-Drought Water Quality using the Spearford Gully, Houston, Texas

As drought becomes increasingly severe in the wake of global climate change, understanding how water quality responds is crucial. Previous studies have established a detrimental relationship between drought conditions and the overall abundance and quality of water in the region. This research builds upon this knowledge by investigating water quality in Spearford Gully, a Cypress Creek and Lake Houston tributary, preceding a significant drought in the summer of 2023. The pre-drought period is defined as the span between the last recorded rainfall and the official recognition of the drought by the National Integrated Drought Information System (NIDIS). Chlorophyll α , water depth, specific conductivity, turbidity, pH, and temperature data were collected in the Spearford Gully on the Lone Star College-University Park campus in Harris County using an EXO2 water sonde. During the pre-drought period, water quality diminished in the Spearford Gully, which is part of the Cypress Creek drainage basin. Chlorophyll α and turbidity were particularly sensitive to pre-drought conditions, with chlorophyll α experiencing changes within a few days and turbidity showing significant changes after approximately two weeks. These results indicate that surface water intended for consumption during a pre-drought timeframe in this drainage basin requires significant treatment to be in accordance with the EPA's water quality guidelines. Additionally, implementation of drought-related water usage restrictions should be put in place sooner as treatment of pre-drought water comes at a greater expense to the county, especially as surface water experiences a growing demand.

Abstract Name: Influence of urea on protein biomarker detection using quantum dots

Quantum dots have promising potential in biomedical applications due to their optical properties and small size. One of these applications is detection of small amounts of biomarkers, which could increase the sensitivity of early disease detection. Urine is of interest when detecting numerous diseases, such as diseases of the kidneys. For quantum dots to be an effective detector, their interactions with each compound in urine must be known. A major component in human urine is urea, a carbonamide. Due to its abundance in human urine, understanding the interactions between urea and quantum dots is critical for the development of effective detection methods of protein biomarkers. To detect the quantum dot's fluorescence, a BioTek microplate reader was utilized along with subsequent data analysis to discover the interactions between urea and quantum dots.

Abstract Name: Representation in Healthcare Education: An AI-Driven Analysis of Biases in Anatomy Textbooks

Advancements in A.I have unlocked new possibilities for the analysis of large textual datasets. This study leverages these technological innovations to conduct an analysis of human anatomy and physiology textbooks commonly used by U.S. medical and undergraduate institutions. This research seeks to identify representational inequities in these textbooks, with a focus on linguistic biases, photographic depictions, and sexual reproduction representation. Our team adopted a two-pronged approach for this study: we employed an AI resource, Google Notebook LM, alongside manual content analysis and an in-depth review of textbook materials. This allowed us to analyze gender-based language patterns, the use of gender-neutral terminology, and comparative phraseology in anatomical descriptions. Photographic depictions were scrutinized for diversity across gender, race, age, and physical characteristics. Finally, we analyzed representations of sexual reproduction to compare the depth of exploration between male and female systems in their terminology and descriptors, as well as comparative visualization of external, internal, and cross-sectional models. Our preliminary findings suggest a persistent bias toward idealized, male-centric anatomical portrayals, which are often characterized by youth and fitness. Further development of multiple analytical models may illustrate representational disparities, linguistic bias patterns, and structural inequities in anatomical descriptions. The implications of these findings extend beyond academia, highlighting not only how textbooks can shape students' perceptions, but also medical professionals' diagnostic capabilities and professional identities. By offering actionable insights, this study aspires to influence the development of more inclusive textbook designs and foster equitable anatomy education practices. Ultimately, this research contributes to the broader understanding of how educational resources impact workforce development in healthcare related fields.

Abstract Name: Future = AI + Database Collective Academic Database (CAD) to Manage AI in Academic Environments

The development of Retrieval Augmented Generation (RAG) and Fine-Tuning Methods opened the doors to specialized Large Language Model (LLM) applications, such as the various GPTs found in the GPT Store. However, their sustainability is limited to the safety, accuracy, and authority of the data, with no universal way to manage the risks associated with these applications currently in the United States. Hence, discussions are ongoing within the US on how this technology can be managed, with efforts such as the Blueprint for Artificial Intelligence (AI) Bill of Rights from the White House and the AI Risk Management Framework from the National Institute of Standards and Technology. In this paper, we demonstrate why data management is important, then propose the Collective Academic Database (CAD), which, unlike other academic databases, works in harmony with ongoing discussions within the US on AI management. The CAD will provide academic researchers and experts with a safe, protected, and adaptable environment independent of LLMs, functioning as a manageable space for future experiments, research, and innovation. The CAD will also function as the extension of open-source efforts in AI into education. Ultimately, this paper aims to bridge the gap between academia and AI, to serve as a foundation for unifying the academic community through AI.

Abstract Name: Army Ant Collective Architecture as a Biological Network

Studying model social species provides valuable insights into adaptive strategies that can benefit city planning, robotics, and computer science. Army ants (*Eciton*) are nomadic and form temporary living structures known as bivouacs—intricate and adaptable shelters created entirely out of the interlocking bodies of the worker ants in their colonies. These bivouacs exhibit decentralized problem-solving by forming collective structures to move and shelter their colonies. Despite their remarkable behavior, the individual actions driving these formations remain underexplored. This study investigates the ants' architectural decision-making and behavior using a custom-built apparatus to observe their initial grouping patterns in a two-dimensional sheet composed of the bodies of living workers linked together. Video analysis was used to generate skeletonized networks of individual connections to quantify behavioral patterns over time. Our results show that, with successive bouts, ants often formed more densely organized networks, characterized by an increase in connections and fewer terminal branches relative to the overall structure. Future research will examine how bivouacs develop over time, focusing on how individual ants initiate, modify, and strengthen connections. These findings aim to enhance our understanding of self-organized systems and their adaptation to environmental challenges, with promising applications in robotics and network design.

Abstract Name: When Coal Was King: The Economic and Industrial Boom after World War I in Shamokin, Pennsylvania

My name is Jacob Jeremiah and I am a senior at Susquehanna University. I am currently writing my senior thesis on the positive effects of World War I on a small city in eastern Pennsylvania named Shamokin. Shamokin was considered a boomtown prior to, during, and shortly after World War I and many other scholars' works reflect on that. My main question or argument throughout this research has been centered around the positivity of an economic and industrial boom that war can provide a small city. How, when, and why did Shamokin thrive due to these demands? My research has been solely around the primary sources of advertising, population maps, immigration records, and photographs throughout this time period. These primary sources are aiding my argument of how small anthracite towns and cities like Shamokin were able to thrive due to the demands of war labor. I've acquired secondary sources from others who have studied the effects of war in Shamokin and how residents took advantage of the demand of labor and reaped the benefits. Throughout the process of writing this argument, I'm including primary sources like those I listed above to show visual and quantitative proof of an economic and industrial boom occurring in Shamokin and tie in secondary sources of other scholars to support my own ideology. As for my means of methodology throughout my studies, I am applying my research and using the method of content analysis to focus on how people interacted with each other and evolved throughout the timeframe of my research. In an area proud of its past, this specific style of methodology is allowing me to be successful in my studies of Shamokin's prosperity and how it stacks up with other small towns and cities during World War I.

Abstract Name: Evaluation of Meso-scale Eddies in MOM6-NEP Simulations using Satellite Data

Mesoscale eddies in the Gulf of Alaska (GOA) basin are common and important to the ecosystem. They contribute to water mixing vertically and horizontally, moving important nutrients and affecting primary production and higher trophic levels. Given their pervasiveness and importance to ocean physics and ecosystem dynamics, the ability of an ocean general circulation model to properly represent mesoscale eddies needs to be examined. As a NOAA Hollings Scholar, I conducted a 10-week project looking at mesoscale eddies simulated by Modular Ocean Model version 6 (MOM6) in the Northeast Pacific (NEP) and evaluated them against satellite altimetry. We used Python package "pyeddytracker" to identify cyclonic and anticyclonic eddies in daily sea level anomalies both in satellite data and model hindcast simulation (10-km resolution). Results were used to examine seasonal and interannual variability. The interannual variability of

anticyclones was compared to the ENSO index, and the interannual variability of cyclones was compared to wind stress curl. Seasonal variability in satellite and model data are similar, with the number of anticyclones (cyclones) greatest in summer (winter). Considering eddies of all sizes, the MOM6-NEP simulation underestimates the total number of anticyclones by 31%, but the model-data discrepancy decreases for the larger eddies (radius ≥ 50 km). The anticyclone interannual variability from satellite data showed weak correlation to the ENSO index, while the model showed significant correlation. In both modeled and satellite data, the correspondence with ENSO index strengthens during strong ENSO events (1997-98, 2009-10, 2015-16). In the satellite data, winter (November-January) mean number of occurrences of cyclones are correlated with wind stress curl averaged over the same period, but the correlation weakens in the model simulations. These results suggest promising capability of MOM6-NEP to represent eddies in the GOA.

Abstract Name: Comparing Global Cities to Improve NYC Flood Mitigation Policies: Balancing Climate Resilience and Social Equality

Urban coastal flooding is a significant challenge in older, densely populated cities, where intense precipitation and coastal flooding from heavy rainfall or storm surges can overwhelm urban systems. Low-income communities that often reside in waterfront areas, low-lying neighborhoods, and basements are vulnerable to flooding. To make matters worse, in some cities, such as New York, national, state, and local policies have resulted in the loss of affordable housing, displacement, and gentrification. Flood mitigation involves significant investments in infrastructure, which increase the attractiveness of vulnerable neighborhoods. This leads to rising property values and rents, making it difficult for long-term low-income residents to remain. Housing insecurity exacerbates displacement, as development projects often fail to preserve affordable units. These challenges are examined through a cross-national comparative policy analysis of four cities—Rotterdam, Singapore, Rio de Janeiro, and New York City. Through these cities, we gain insights into how climate resilience and urban flood policies can address social and economic disparities while balancing the needs of diverse populations in the context of climate adaptation. With 90% of the city below sea level, Rotterdam is known for its advanced water management systems. Singapore also has much of its land (30%) less than five meters above sea level, but has developed innovative solutions, such as the Marina Barrage, to balance economic growth and climate resilience. In contrast, Rio de Janeiro highlights the difficulty of addressing flood risks in the context of social inequality. By comparing these cities—each located on four different continents and representing distinct social and economic hierarchies—this research seeks to identify policies that successfully balance flood mitigation with social and economic equality. It aims to offer recommendations for climate adaptation strategies in New York City that prioritize environmental justice and ensure that vulnerable communities are not neglected.

Abstract Name: Research as Storytelling: Mentor-Student Engagement in Community-Based Research

This presentation explores the impact of mentor-student partnerships through Community-Based Participatory Action Research (CbPAR), addressing community issues and fostering social change. These partnerships enhance undergraduate research experiences and connect students with historically excluded and exploited groups in science. CbPAR involves the community in the research process, addressing their concerns and amplifying their voices. This approach not only empowers the community, but it also provides students with hands-on learning opportunities. Students are not just collecting and analyzing data from anonymous participants; they make human connections with participants and become community storytellers. Photovoice and lyric analysis are highlighted as two particularly effective CbPAR methods. As digital natives, traditional undergraduate students have grown up using photos to express aspects of their lives and experiences, making Photovoice a powerful tool for building connections. Music, a universal medium for expressing identity and emotions, acts as a conduit to facilitate effective interactions with people of diverse backgrounds. While lyric analysis is traditionally used in clinical settings, we argue that it is equally valuable within the CbPAR framework for exploring research questions and fostering deeper understanding. Additionally, Collins and colleagues (2019) emphasize the importance of community engagement in research, highlighting how participatory methods can bridge gaps between researchers and communities, fostering trust and collaboration. CbPAR is particularly impactful in communities with a high degree of distrust towards the scientific community. By fostering meaningful connections and promoting mutual benefits, CbPAR methods provide students the opportunity to be an active part of mending historical rifts and building trust. This presentation argues that CbPAR frameworks are mutually beneficial for faculty, students, and communities, advocating for their broader adoption in academic research. This collaborative approach advances scientific knowledge and ensures research efforts are less exploitative and more inclusive, ultimately contributing to social and political change.

Abstract Name: Optimizing Laser-Induced Graphene Fabrication on Polyimide for Flexible and Stretchable Bioelectronic Sensors

Polyimide, commonly known for its thermal stability and chemical resistance, is a versatile polymer widely used in flexible electronics, medical devices, and microelectronic circuit insulation. Its biocompatibility further extends its applications to implants and wearable biomedical devices. Beyond these conventional uses, polyimide can be transformed into laser-induced graphene (LIG) through laser carbonization—a high-energy process that alters its chemical structure into a conductive form with porous graphitic architectures. This process converts polyimide into a material enabling the fabrication of sub-millimeter conductive features suitable for flexible circuits and bioelectronic sensors. Here, we systematically investigate the laser carbonization process, examining the effects of laser parameters – intensity, writing speed, resolution—along with substrate thickness and feature dimensions, on the conductivity of laser-induced graphene. Our results show that conductance increases with laser intensity and decreases with writing speed, confirming that laser-induced graphene production is directly influenced by the energy transferred to the polymer. Using this method, we successfully fabricated electrodes with varying lengths, widths and shapes, determining the

minimum feature size achievable with our specific instrumentation. By optimizing these parameters, we demonstrate the fabrication of highly sensitive and stretchable strain sensors tailored for biomedical applications. Our findings highlight the potential of this technique as a cost-effective and scalable solution for developing flexible medical devices and bioelectronics.

Abstract Name: Electrochemical Synthesis of HKUST-1 onto an ITO Substrate

One of the most widely studied MOFs is HKUST-1. This MOF consists of copper (II) centers coordinated with benzene tricarboxylic acid (BTC) linkers. It has been previously shown that anodic dissolution can be used to deposit a Cu film on indium tin oxide (ITO) substrates, where a MOF can then be grown. HKUST-1 will be synthesized in two steps via electrochemical deposition of Cu onto the ITO surface, and electrochemical dissolution of the plated Cu to react with the BTC linker. This will all be done in a three-electrode system. This MOF will be characterized with respect to its morphology via scanning electron microscopy (SEM) and its crystallinity via powder x-ray diffraction (PXRD). Applications for the synthesized MOF film will include the adsorption of methylene blue from water.

Abstract Name: Effects of Dark Matter on Gravitational Time Dilation in Binary Neutron Star Systems

Binary neutron star (BNS) mergers serve as a critical environment for probing the influence of dark matter (DM) on gravitational phenomena, particularly time dilation and waveform modulation. Numerical relativity simulations incorporating scalar DM fields were utilized to model DM's effects on BNS dynamics. The Einstein Toolkit was employed for solving the general relativistic field equations, with adaptive mesh refinement ensuring high-resolution coverage near regions of significant DM influence. Initial conditions followed the Tolman-Oppenheimer-Volkoff (TOV) equations, and gravitational wave signals were analyzed using Fourier transformations to assess frequency-domain shifts introduced by DM interactions. The results indicate that DM clustering around BNS systems significantly alters gravitational waveforms by inducing amplitude damping, phase shifts, and introducing multimodal frequency components. Time dilation near the neutron stars exhibited considerable variability, with notable resonance effects linked to specific DM particle masses, particularly around 0.85 eV. Additionally, sharp fluctuations in DM density between 5-10 km from the neutron star centers created localized gravitational wells, resulting in enhanced time dilation and greater complexity in gravitational wave signatures. Findings show DM modulates the gravitational field of BNS mergers, which manifests through altered waveform morphology and localized gravitational anomalies. The resonance sensitivity to DM properties points to an interplay between DM-induced inhomogeneities and

spacetime curvature, affecting the detectability and interpretation of gravitational waves. Future works should explore broader DM interaction models, including fuzzy DM and rotational neutron stars, to elucidate DM's role across various compact astrophysical systems.

Abstract Name: "AAC is Freedom": The Role of AAC in Mental Health and Self-Advocacy

This study investigated the role of augmentative and alternative communication (AAC) and treatment techniques surrounding mental health and self-advocacy for individuals with complex communication needs (CCN). Individuals with CCN face a higher risk of mental health issues, yet there is a gap in understanding the influence of AAC on mental health and self-advocacy (Watson et al., 2021). This gap in understanding was addressed by exploring the following questions. 1. How does having complex communication needs affect mental health? 2. What treatment techniques using AAC devices help individuals express their experiences? 3. How does the use of AAC increase self-advocacy skills in individuals with complex communication needs? Through structured interviews, the perspectives of AAC users, parents of AAC users, and speech-language pathologists were captured to explore the relationship between CCN and mental health as well as identify treatment techniques that inform teaching in educational and clinical practices.

Abstract Name: Investigating Activity of Ten-eleven Translocation Enzyme 1 in the Mammalian Germline

Mammalian reproduction hinges on the precise patterning of sperm and oocyte epigenomes. Primordial germ cells (PGCs), the precursors of sperm/oocytes, undergo epigenetic reprogramming. This process is partially mediated by Ten-eleven translocation enzyme 1 (TET1), which facilitates the oxidation of 5-methylcytosine, leading to active DNA demethylation. In mice, PGCs lacking TET1 exhibit hypermethylation at imprinting control regions (ICRs), DNA elements that regulate parent-specific gene expression. Incomplete methylation erasure in Tet1^{-/-} PGCs persists, resulting in a hypermethylated sperm genome. Intriguingly, hypermethylation defects in Tet1^{-/-} sperm extend beyond ICRs to other sperm hypomethylated regions. The Bartolomei lab previously developed Tet1 mutant mouse lines distinct from Tet1^{-/-}, to study whether TET1 presence without catalytic activity affects germline reprogramming. The Tet1V mutation abrogates iterative oxidation, restricting enzyme activity to 5-hydroxymethylcytosine generation. The Tet1HxD mutation creates a catalytically inactive protein. Both TET1 variants retain intact extra-catalytic domains, rendering interaction with other proteins plausible. While genome-wide methylation defects have been examined in Tet1^{-/-}, Tet1V/V, Tet1HxD/HxD sperm, methylation analysis of mutant PGCs has been limited to locus-specific

searches at target ICRs. Therefore, the origins of aberrant methylation observed in mutant sperm remain largely unknown. Here, we aim to conduct global methylation analysis of Tet1^{-/-}, Tet1^{V/V}, and Tet1^{HxD/HxD} PGCs at the completion of reprogramming, employing Illumina's Mouse Infinium Methylation BeadChip. The BeadChip consists of an array of DNA probes enabling high-throughput profiling of DNA methylation across the mouse genome. We isolated PGCs from embryonic gonads and performed bisulfite sequencing to distinguish methylated from unmethylated cytosines. Bioinformatic analysis identified differentially methylated regions between mutant and wild-type PGCs, as well as between PGCs and sperm of the corresponding genotypes. This study provides insights into the temporal dynamics and genomic context of TET1 activity during gametogenesis, contributing to our understanding of the epigenetic mechanisms governing fertility and transgenerational inheritance.

Abstract Name: The Impact of Sleep Quality on Cognitive Performance: Investigating Blink Rate as a Measure of Cognitive Effort in Young Adults

Sleep is an undeniable contributor to cognitive processing. Disrupted sleep patterns can impact cognitive domains such as attention, working memory, and dual tasking, which are important for activities of daily living, particularly for young adults. Although it is known that lack of sleep leads to poorer performance on cognitive tasks, it is less clear the role of attention during cognitive task performance. That is, "bad sleepers" may be able to perform just like "good sleepers", but at the expense of higher cognitive effort. Blink rate (BR) has been proven to be an accurate measure of cognitive performance, memory and engagement, mental fatigue, vigilance, dopaminergic activity, etc. The purpose of this project is to investigate the effects of sleep quality (SQ) on cognitive processing during the execution of cognitive tasks. . Healthy, young (18-40 y/o) individuals will be recruited. SQ will be assessed using the Pittsburgh Sleep Quality Index (PSQI). Participants will be categorized into "good" vs. "bad" sleepers. BR will be assessed using an eye-tracking device (Tobii Pro Glasses 3). Participants will be asked to perform tasks assessing cognitive domains of inhibition (stroop task) and working memory (digit span task). We hypothesize that individuals with lower SQ will have a higher BR compared to individuals with higher SQ due to increased cognitive demand for attentional resources. The adverse effects of chronic sleep deprivation on the brain make it a great candidate to study due to its impact on health outcomes. Despite this, analyzing the effects of sleep on cognitive function through conventional modes (i.e. fMRI) can be a costly task, decreasing accessibility for lower SES communities. BR is a non-invasive method to analyze cognitive processing. Future studies may develop BT tests that rehabilitation clinicians could use to screen for cognitive function.

Abstract Name: Search for novel arsenic-containing antibiotics

Search for novel Arsenic-Containing Antibiotics Objective Arsenic (As), the “king of poisons”, surprisingly shows promise in medicine. With the increasing threat of antibiotic-resistant bacteria, there is an urgent need for new antibiotics. Notably, some bacteria utilize environmental As to produce unique antibiotics, as represented by arsinothricin (AST). AST effectively controls various pathogens while spare human cells, demonstrating the potential of As-containing antibiotics. Our objective is to build upon this unique connection and discover further As-containing antibiotics. **Experimental Methods** We mined bacterial genome databases using the arsinothricin (AST) biosynthetic gene cluster (BGC), leading to the discovery of novel BGCs in two *Actinomyces* strains, *Microbispora rosea* and *Amycolatopsis tolypomycina*. Gene analyses suggest that these BGCs encode arsenic-containing ribosomally synthesized and post-translationally modified peptides (RiPPs), which we named AsRiPP. From the *M. rosea* AsRiPP BGC, we selected four genes, which we hypothesize are the minimum required gene set to produce an As-containing precursor of the encoded AsRiPP. These genes were heterologously expressed in *Escherichia coli* in the presence of As and the AsRiPP production was analyzed. As an alternate approach, *A. tolypomycina* was directly cultured with inorganic arsenic and arsenic species in the culture medium was analyzed using liquid chromatography coupled with inductively coupled plasma mass spectrometry (LC-ICP-MS). The major arsenic species was further purified using anion exchange column chromatography and the antibiotic activity of the purified fraction was analyzed. **Results** While heterologous expression in *E. coli* was unsuccessful, the crudely purified As species exhibited moderate antibiotic activity, supporting our hypothesis that the strain produces an As-containing antibiotic, presumably the AsRiPP. **Conclusions** Our results suggest that more As-containing antibiotics exist in nature, demonstrating their potential as a resource for antibiotic development. Further investigation will focus on verifying the association of the AsRiPP BGCs and the obtained As species.

Abstract Name: Why Y: Using Whole Genome Sequencing to Study Y Chromosome Loss in Gastric Cancers

Sex chromosomes are an essential part of human sexual differentiation, growth, and survival. Recent research has shown that cancers undergo sex chromosome number changes, with such alterations having their own effects on different cancers. In some types of cancer, such as bladder cancer, loss of the Y chromosome, for example, has led to increased cancer aggressiveness and reduced survival rates. While some copy number changes have been well documented and studied in different cancers, these changes in gastric cancers are relatively not understood. Gastric cancers are one of the most common cancers worldwide and are associated with high morbidity and mortality rates due to their nonspecific early symptoms. In seeking to better understand the frequency, mechanism, and advantages behind sex chromosome number alterations in gastric cancers, we employ a long-term evolution experiment using colon cancer and Barrett's esophagus cell lines in conjunction with whole genome sequencing (WGS) to understand and quantify the rate of Y chromosome loss (LOY). Both gastric cancer cell lines show LOY at varying rates. Colon cancer cells demonstrated a faster loss of the Y chromosome compared to that of Barrett's Esophagus cells. This is significant because, upon elucidating the mechanisms and effect of LOY, novel treatments can target the Y chromosome in hopes of better treating gastric cancers.

Abstract Name: The Blessing of Brutality: Unit 731 and Confucian Ethics

Throughout World War II, countries, such as Nazi Germany, undertook unethical forms of experimentation on humans to benefit their nation and build upon the scientific knowledge of the day. However, lesser known is that which was done by the empire of Japan at this time. From 1932 to the end of World War II, Japan invested millions of dollars into manpower and material, conducting experiments throughout their puppet state of Manchukuo to refine various weapons of mass destruction, most especially biological warfare (BW) agents. Led by General Shiro Ishii and as part of Unit 731, scientists and doctors alike undertook unethical medical and biological experiments on humans to not only to perfect BW, but also to test the limits of human physiology and expand the understanding of the human body. While medical ethics at the time heavily emphasized medical paternalism and authoritarianism, these academics ignored such ethical considerations and sought to advance the interests of the empire. Through the use of first-hand accounts given by Unit 731 scientists and physicians, I will show how Confucian beliefs, such as those of filial piety, harmony, and loyalty, especially to the emperor and to the state, were used to justify the unethical experiments and work they did. Through the dual lenses of ultranationalism and militarism, their actions were not only possible, but fully permissible and condonable under the authoritarian regime of the Japanese empire.

Abstract Name: Deaminative Carboxylation using a Photocatalyst and Carbon Dioxide

Primary amines have extensive commercial availability, wide variety, and utility in various reactions to build expansive libraries of pharmaceuticals and derivatives of natural products. Cross-coupling reactions with primary amines have been a growing subject of research for their application in areas of interest such as medical chemistry, agrochemistry, and materials synthesis. Much of the work around these amines involves the use of harsh chemicals to activate the primary amines to form a variety of products. Perhaps, there are other mechanisms that can be used to activate these primary amines that are better for the environment and safer for the people running the reactions. Previous research shows pyridinium salts and imines (one step from primary amines) were activated and consumed using photocatalysts (activated by 427 nm LED blue light) in a variety of different reaction conditions. Previous research has also shown successful carboxylation reactions through transition metal catalysis. Based on these known reactions, we attempted to perform cross-coupling reactions that aimed to convert materials derived from primary amines to carboxylic acids using photocatalysts with blue LED light, transition metal catalysts, and carbon dioxide. Our results so far have not indicated a significant yield of our desired carboxylation product, however, we are exploring different reaction conditions, such as varying solvents, ligands, and photocatalysts. Further investigation of these

techniques can lead to advancements in the synthesis of complex molecules and more environmentally friendly means to carboxylate amine-containing compounds. In the future, this type of activation could be expanded to more reactions than the carboxylation of the primary amines and be applied in pharmaceutical settings and agrochemical development.

Abstract Name: An Executive Report of Approaches to Addressing Gender-Based Violence on College Campuses

Gender-based violence (GBV) is an umbrella term to describe any form or threat of physical, sexual, and psychological violence, coercion, or exertion of control based on gender-related power differences. The term GBV calls attention to the gendered nature of violence in our society and the gender stratification that allows the abusive power dynamics visible in GBV. GBV is extremely pervasive and considered one of the most critical public health concerns of modern time. Around 25-35% of women globally experience GBV. College campuses are a breeding ground for GBV, with 1 in 4 women experiencing sexual violence and 1 in 2 experiencing at least one occasion of intimate partner violence in their time in college. So, what can be done to protect students at institutions of higher education (IHE)? In this paper, I systematically analyze the myriad policies and programs that guide gender-based violence prevention at the collegiate level. Specifically, institutions have taken two approaches to addressing GBV on campuses: intervention and prevention. Both are necessary, but as public health models suggest, college campuses must establish a culture of prevention in order to effectively reduce the risk of GBV. Though interventions will be necessary, campus stakeholders should prioritize preventative rather than reactive approaches to combating GBV. A culture of prevention is defined through the public's and professionals' beliefs and values about healthy behaviors; thus, it is critical that stakeholders target beliefs and values surrounding GBV, not just behaviors. An historical literature review of the approaches to addressing GBV in the IHE context reveals that they have been reactive (interventionist) but also infused with elements focused on creating a culture of prevention. This report provides a brief overview of the various interventionist approaches that have guided attempts to address GBV in IHE.

Abstract Name: PH Balance: The Balance of Pubic Hair in Sexual Signaling and Health

Pubic hair has been a controversial topic across diverse cultures and historical periods. The presentation of pubic hair has been influenced by various factors such as sexual attraction, personal grooming preferences, partner expectations, societal beauty standards, and beliefs around hygiene and odor reduction. I will investigate the social and health implications of pubic hair from a historical and future perspective, grooming

practices, as well as social media including music, and beauty industries. In general, many cultures celebrate pubic hair as a marker of adulthood and fertility. However, modern media and societal pressures have influenced and normalized hair removal by fashion trends, new personal grooming standards, and even pornography. Scientific studies reveal that pubic hair serves as a protective function by reducing friction, guarding against bacterial infections, and preventing unwanted parasites. Many people are gaining momentum in rethinking this grooming practice and advocating for greater acceptance of natural body hair. Modern discourse around pubic hair creates pressure on women to conform to keep up with beauty standards. I aim to investigate, with IRB approval, an oral history of individuals regarding their past and future interest in pubic hair. I will focus mostly on assigned female at birth individuals to better understand their personal views. Ultimately, I will explore the modern discourse revealing personal choices around pubic hair to intersect with and often resist with, as we endure and regain control of the patriarchy of pubic hair.

Abstract Name: The Effect of Attachment to God on Psychological Well-Being

Attachment theory has implications for psychological well-being, such as anxiety and depression. Attachment to God functions in the same way as human-human attachment, and attachment to God can be influenced by self-compassion. This study sought to demonstrate the relationships between attachment to God, psychological well-being (i.e. anxiety and depression), self-compassion, and scrupulosity in 198 undergraduate students. All participants indicated a belief in God. The participants completed: The Attachment to God Inventory, the Penn Inventory of Scrupulosity Revised (PIOS-R), the Short Form Depression Anxiety and Stress Scale (DASS 21), the Self-Compassion Scale Short Form (SCS-SF), The Big 5 Inventory-short scale (BFI-10), and a demographics scale. Zero order correlations were computed for anxious and avoidant attachment to God, scrupulosity, depression, anxiety, stress, and self-compassion. A MEDIATE macro for SPSS (Hayes & Preacher, 2013) was conducted to find direct and indirect effects of the anxiety and avoidant attachment dimensions on scrupulosity. Consistent with findings from previous research (Homan, 2014), our results indicate that people who view God as inconsistent, responding with stress (anxious attachment to God) and people who view God as impersonal, having a distant response (avoidant attachment to God) are more likely to report feelings of anxiety and depression. Expanding on the current literature, we found that those with an anxious or avoidant attachment to God reported higher levels of scrupulosity in addition to anxiety and depression. Self-compassion mediated the relationship between avoidant attachment and scrupulosity. Surprisingly, self-compassion mediated avoidant attachment to God and scrupulosity, but not anxious attachment to God and scrupulosity. This study extends understanding surrounding insecure attachment to God, scrupulosity, and self-compassion. It appears that having compassion on oneself and a secure attachment to God can decrease the levels of distress and scrupulosity an individual may endure on a day-to-day basis.

Abstract Name: Reducing Percentages of Relapse after Rehabilitation Treatment Through Education and Multifarious Connections

Oklahoma ranks 5th in the nation for substance use disorders, with 16.1% of adults affected, translating to between 700,000 and 950,000 Oklahomans in need of services. Many do not receive the care necessary for full recovery. Drug addiction is often linked to stress, and while alcohol is commonly believed to help manage stress, most rehabilitation centers aim to help patients overcome addiction and equip them with mental tools for lasting recovery. Treatments vary based on individual needs, and implementing multifarious connections can strengthen a person's sense of self, offering alternatives to addictive tendencies and fostering healthier habits. Social connections and engagement with nature can significantly improve mental health, and biophilic design can be utilized to connect patients with nature. This project utilizes case studies of existing rehabilitation centers, a literature review on environmental factors in recovery, interviews with addiction therapists, and surveys from those with experience supporting individuals with addiction. The rehab center's design prioritizes multifarious connections through a layout that encourages interaction among patients. Inpatient areas are near therapy spaces, while outpatient and family areas foster support through their shared spaces. A central courtyard and green roof with natural elements offers access to nature for reflection and relaxation. Daylighting will enhance well-being, with patient rooms featuring outdoor views. Common areas such as lounges and dining rooms will encourage social interaction. Therapy rooms will be flexible for both individual and group sessions. Finally, community connections will be supported through partnerships with local organizations, creating pathways for ongoing support after treatment. By incorporating multifarious connections to nature, social support, and community, this rehabilitation center fosters a holistic healing environment that empowers individuals to rebuild their lives and achieve lasting recovery.

Abstract Name: Ballistics Characterization of Micro-Truss Reinforced Lunar-Inspired Geopolymer Concrete for Space Construction

The difficulty of fabricating permanent, habitable structures in outer space is a major roadblock in space exploration due to the impracticality of transporting suitable building materials. One potential solution to this problem is utilizing already existing materials in outer space. For example, the dust or regolith on the surface of the moon could be useful for creating a concrete building material. In order to test the compatibility of the lunar regolith for space construction, it is important to consider its impact resistance capability in a concrete mix considering that there are roughly 100 ping pong ball-sized meteorites colliding with the moon per day. This research endeavors to examine compressive strength as well as the ballistic impact mitigation to understand the capabilities of unreinforced and carbon fiber micro-truss reinforced samples. The compressive strength has been tested for a lunar regolith/fly-ash hybrid geopolymer cement paste for different ratios of lunar regolith to fly-ash with an 810 MTS testing apparatus using ASTM Standard C109. The results were, on average, 22.4, 27.7, 27.6, 32.8, 34.6, and 37.8 MPa for 60, 50, 40, 30, 20, & 10% regolith concentrations respectively. The mix containing the largest ratio of regolith to fly-ash (60%) only shows a 36% decrease from the strength of the 100% fly-ash geopolymer mix containing no regolith which is 35.3 MPa. The compressive strength for all unreinforced cement paste samples were found to be within standard building concrete compressive strengths. Furthermore, the anticipated results, including the compressive strength of the micro-truss reinforced concrete and the ballistics responses of both unreinforced and reinforced concrete, such as residual velocity and impact crater diameter, will aid in the assessment of the compatibility of lunar regolith for space construction.

Abstract Name: The Relationship Between Exposure to Nature and Anxiety Levels

Anxiety disorders are among the most experienced mental illnesses within the United States with nearly half of individuals aged 18-24 reporting symptoms within the last year. While highly treatable, greater than 60% do not avail themselves of help due to cost and stigma. Emerging research illustrates a connection between nature exposure and good mental health, illustrating that outdoor time increases resilience, attention and mental wellbeing. This study explores the association between these factors. Findings may help to illustrate the importance of, encourage routine practice in, and increase accessibility to greenspaces throughout communities. Greenspace education and development may decrease the current weight placed on counseling services and provide alternative options to those who may not have equitable access to mental health care. The researcher is conducting a cross-sectional quantitative survey in the upcoming months using a Qualtrics survey comprised of demographic questions, a modified State-Trait Anxiety Inventory, and a descriptive nature exposure survey. Participants are students currently enrolled in James Madison University at the time of participation and between the ages of 18-24. After data collection, the researcher will run univariate descriptive analyses to understand the sample demographics and then appropriate bivariate statistical tests to understand any relationships found. Hypotheses will then be generated for future studies.

Abstract Name: Enhancing Medication Management for Patients with Diabetes

Diabetes management often requires a multifaceted medication regimen, incorporating insulin, oral hypoglycemic agents, antihypertensives, and lipid-lowering drugs. As the disease progresses and multiple chronic conditions arise, patients often face an increasing medication burden, which can complicate adherence. This challenge is especially apparent during transitions between care settings—such as primary care, hospital admission, and discharge. Medication discrepancies—differences in drug type, dose, frequency, or administration between care settings—during these transitions can lead to confusion regarding appropriate medication use and errors in self-administration, heightening the risk of nonadherence and adverse health outcomes including frequent emergency department (ED) visits and hospital admissions. To further explore these issues, a narrative literature review was conducted to identify key factors contributing to nonadherence, including medication discrepancies, care transitions, and patient-provider communication gaps, among patients with diabetes. By analyzing peer-reviewed studies, emerging trends and gaps were identified, which have informed the development of our research focus and methodology. This foundational work has provided deeper insights into the multifaceted nature of nonadherence and its association with adverse health outcomes. It suggests that while an increased number of medications may reflect clinical severity, it also introduces complexity that can lead to adherence challenges, confusion, and medication errors. By analyzing

the gaps in coordination during care transitions and the impact of medication complexity, the long-term goal of this research is to inform targeted interventions to improve care coordination, patient education, and medication adherence.

Abstract Name: Race, Age, and Frequency of Violence Among Black Americans

This research explores the relationship between age and frequency of violence among African American adolescents. Drawing on a critical race theory framework, this study hypothesizes that younger Black individuals (16 years old and younger) are more susceptible to violence compared to older Black individuals (17 years old and older). Building on previous scholarship on systemic racism and using the CDC 2021 Adolescent Behaviors and Experiences Survey, this research project examines the disparities in violence among Black Americans, with a particular focus on the distinct experiences of adolescents and young adults. Using SPSS software and statistical analysis, the study analyzed data to explore these distinctions and identify patterns in the age groups affected by violence within the Black community. Preliminary findings suggest that younger Black individuals are more susceptible to violence compared to older generation. These results highlight the urgent need to address the issues of racial inequality and violence in communities.

Abstract Name: Mindfulness practices among college students in India and USA: Definitions, challenges, and strategies

Studies indicate that the understanding and practice of mindfulness differs across cultures (Schmidt, 2011). However, empirical data on this topic is limited. The present study examines college students' responses (N = 512 India, N= 508 USA) to open-ended questions on definitions and recent examples of mindfulness, challenges associated with practicing mindfulness, and strategies adopted to address those challenges. Inductive qualitative content analysis (Marin, 2000; 2014) was used to examine prevalent themes across the two samples. Specifically, a three-phase approach to analyzing qualitative data was used: 1) preparation, organization, and reporting of results (Elo et al., 2014). A second coder coded 1/5th of the responses to establish an inter-rater reliability index. Participant responses were coded into a total of 28 themes across 5 categories. Definitions of mindfulness were coded into 1) awareness/attention, 2) being present, 2) mental or emotional state, 3) consideration of others, and 4) non-judgmental attitude. Examples of mindfulness

activities in recent time and day-to-day living were coded into 1) meditation, 2) breathing exercise, 3) physical activity, 4) reflection, 5) self-awareness, 6) engagement in creative or sensory activity, 7) spiritual or religious activity, and 8) consideration of others' needs and preferences. Challenges to or in practicing mindfulness were coded into 1) internal challenge (e.g., overthinking, lack of motivation), and 2) external challenge (e.g., social media, busy schedule). Strategies to overcome challenges associated with practicing mindfulness were coded into 1) mental strategies (e.g., mindfulness meditation, emotion regulation), 2) behavioral strategies (e.g., self-care activities, time management), and 3) physiological strategies (e.g., breathing techniques, physical exercise). Although majority of the themes were consistent across the two samples, US sample more frequently referenced consideration of others in their examples of mindfulness. The results have implications for teaching and practice of mindfulness particularly as it relates to principles of individualism and collectivism.

Abstract Name: Healing Hands: AI-Integrated Robotic End Effectors for Comprehensive and Continuous Patient Monitoring

Continuous and comprehensive patient monitoring is essential in homecare and emergency room settings to ensure timely interventions and optimal healthcare outcomes. However, existing monitoring systems often rely on multiple discrete devices, resulting in fragmented data collection and increased complexity for patients and healthcare providers. This project addresses the need for an integrated, intelligent monitoring solution by developing "Healing Hands," a pair of robotic end effector hands designed to seamlessly incorporate various patient monitoring technologies and novel sensors. Healing Hands seek to integrate a comprehensive array of advanced sensors for thorough patient monitoring. These include sensitive ECG pads and custom-developed sensors for precise cardiac monitoring, photonic-based oxygen meters, heart rate, SpO₂, temperature regulation and sensing, respiratory sensors, and an alternative blood pressure measurement system. The fingertips will equip ultrasound transducers for non-invasive diagnostic imaging. The research will further investigate incorporating and developing biofluid collection mechanisms for sweat analysis and minimally invasive biomaterial sampling, enabling the determination of specific biomarkers. This seamless integration of diverse sensing technologies ensures a holistic approach to continuous patient health monitoring. These hands are designed to attach to an existing humanoid robot unit, which utilizes artificial intelligence systems, including large language models (LLMs), to interpret and validate the collected data, providing real-time analysis and alerts. The proposed solution offers a unified platform for continuous patient monitoring, reducing the need for multiple devices and simplifying the monitoring process. By leveraging AI-driven data analysis, Healing Hands can infer critical health indicators, detect anomalies, and facilitate proactive healthcare interventions. The expected outcome of this research is the development of fully functional holistic sensing Healing Hands capable of providing comprehensive and continuous monitoring to enhance patient care through integrated, real-time data collection and intelligent analysis, ultimately contributing to improved healthcare outcomes and operational efficiency in medical settings.

Abstract Name: Proximity and Collective Victimhood Consciousness: Jordanian Perceptions of the Israeli-Palestinian Conflict

This project will explore how proximity to the Israeli-Palestinian conflict in both geography and identity affects Jordanian perceptions of collective victimhood. Specifically, the project examines the effects of Palestinian and Jordanian heritage among individuals living in Jordan on perceptions of the conflict. While extensive literature exists on collective victimhood in the Israeli-Palestinian conflict, few researchers have examined experiences of collective victimhood outside of Palestinians and Israelis currently living in the region, so this research will extend the investigation to a geographically close population with mixed Palestinian and Jordanian heritage. Furthermore, most collective victimhood research relies on victim-perpetrator dyads, failing to capture the perspectives of many individuals external to the borders of a given conflict. The project will rely on eight interviews of Jordanian and Palestinian-Jordanian individuals living within Jordan's borders. Through thematic coding and analysis, the project will investigate interviewees' perceptions of the conflict and collective victimhood. The results will likely show different experiences of collective victimhood between Jordanians with and without Palestinian heritage. As the current conflict in the Middle East grows, Jordanian perspectives could provide better understanding of both the conflict itself as well as the mounting grievance throughout the region.

Abstract Name: Electrochemical Detection of 3-Nitrotyrosine using a Gold Electrode Modified with N-hydroxysuccinimide Ester Gold Nanoparticles

3-Nitrotyrosine (3-NT) results from the nitration mediated by reactive nitrogen species such as peroxynitrite anion and nitrogen dioxide. It is overproduced when there is oxidative stress in the body, which is an imbalance of free radicals and antioxidants within the body. Oxidative stress is common in many diseases like cancer and heart disease. 3-NT has been identified as a biomarker for cell damage, inflammation, as well as nitric oxide production. Therefore, its monitoring is important for disease monitoring. An electrochemical biosensor platform was prepared by modifying a gold electrode with N-hydroxysuccinimide (NHS) ester gold nanoparticles. The NHS ester gold nanoparticles created a monolayer on the electrode surface which was used to covalently immobilize 3-NT antibodies. The modified electrode surface was then used for the detection of 3-NT using cyclic voltammetry and differential pulse voltammetry. The detection method was very sensitive to 3-Nitrotyrosine with a linear response from 50 to 600 nM concentrations. Future research will involve testing the selectivity, and stability of the method as well as testing real biological samples such as urine, serum, and saliva for potential practical applications.

Abstract Name: Reimagining Mother Africa: Contemporary African Female Photographers Challenging Gender & Race Stereotypes

In post-independent Africa, photography promoted national and ethnic identities and individualism. Photographic practices on the continent illustrated the diversity along ethnic, cultural, social, and gender lines that sometimes conflicted with the government or broader social visions. Today, female-born African photographers use the medium to champion gender-based issues and change the narrative around African women's representation in popular media in their homelands and abroad. The research looks at the photographs of Zanele Muholi, Aïda Muluneh, Atong Atem, Thandiwe Muriu, and Maïmouna Guerresi to explore the complexity of contemporary Africa and its diaspora as the nations and peoples navigate the postmodern and postcolonial world. These photographers contend with the monotonous narratives of the traditional and rural, as well as the repetitive victimization of displaced peoples because of wars and natural disasters in Western media. To better understand the complexity of reversing these negative images, especially of African women, the feminist art history theory is applied to interpreting the photographers' images with an emphasis on transnationalism. The focus is on the audiences' varied receptions and interpretations and why these photographs have different meanings depending on the community viewing them. The research aims to provide awareness and empathy to the challenges Africans still face within their homelands and abroad to dispel 19th-century ideology about race and gender. Another factor in the reception is the global art market and its tendency to designate styles or mediums to non-Western artists. How do the artists remain committed to their vision in this era of globalism? Is art only for Western consumption, or is it also viable in Africa? If so, how impactful are the messages? These questions helped recognize how photographic narratives differ across racial and ethnic lines and the role of culture and ideology in the imagery of Africans in a postcolonial, postmodern world.

Abstract Name: Divorced, Beheaded, Died, Divorced...But Why? A Study of German Painter Hans Holbein The Younger's Portrait of Anne of Cleves

Like that of her five sisters-in-law, Anne of Cleves' place in history was dictated by the outcome of her relationship to King Henry VIII. Instead of being remembered as Queen of England in 1540, she has been known simply as "Divorced" and remains so even in death, nearly five centuries later. Some may say that she was framed and this project observes how she, quite literally, was. Informed by the scholarship of Stephanie Buck, my research will examine Hans Holbein the Younger, the celebrated German artist renowned for his highly realistic portraits of Europe's most influential figures. As court painter to Henry VIII, Holbein was commissioned to visit noble houses across Europe and produce portraits of potential brides, including the German Duchess Anne of Cleves, whose idealized image allegedly misled Henry, leading to the most famous medieval "catfishing" scandal. Building on Susan Foister's analysis of Holbein's courtly artworks and Michael North's exploration of portraiture in Tudor politics, this project aims to understand why Holbein's painting was considered inaccurate and how it played a crucial role in medieval diplomacy. My research consists of a visual analysis of the painting itself, an observation of contemporary descriptions of Anne of Cleves as well as a comparative study of her and the portraits of her five sisters-in-law. In other words, this project will be analyzing Holbein's artistic choices, examining the balance between realism and flattery, and exploring the diplomatic pressures and beauty standards of Tudor England. In doing so, I aim to prove that the portrait of Anne of Cleves was not fundamentally incorrect but that her reputation as "The Flanders Mare"

stems from Henry VIII's expectations, shaped by the era's perception of beauty and the political pressure to ensure the continuity of the Tudor lineage.

Abstract Name: Research, Design, and Construction of a 18th Century Versailles Court Gown

Versailles is synonymous with extravagance and excess, especially in the period Marie-Antoinette reigned. She is especially notorious for the huge sum she spent on her wardrobe, and with my research, I wanted to learn to what extent that notoriety was deserved. For this project, I took a deep dive into the court fashions of Versailles in the 18th century, drawing from paintings, fashion plates, extant garments, and historical patterns to design and construct my own court-appropriate gown. In the process, I also researched how the end of the sumptuary laws, the birth of fashion magazines, and the competitive French silk industry contributed to the creation of the fashion industry as we know it today, complete with fast-fashion trends and a thriving second-hand clothing industry. This research informed the decisions I made in creating the dress, deepening my understanding of the trends of the period in order to be able to create something that is both historically accurate and a totally new design. The gown, which took me over three hundred hours to complete and cost over \$1,3000, is made from silk taffeta and supported by undergarments made of cotton, silk, linen, steel hooping wire, and synthetic whalebone. It is currently on display at in the Cathedral of Learning. While I would be happy to bring it to the conference, it is roughly 6' wide by 3' deep by 5'6" tall, so I believe it exceeds the size limit.

Abstract Name: The Horn in the Music of Richard Strauss

Richard Strauss was one of the most prolific composers of the Romantic Era of Western Art Music. He was renowned for his numerous powerful works which cover a variety of subject matter from folk stories and novels to emotional depictions of his own life. To create this masterpieces, he employed the various instruments of the orchestra, although perhaps none more so than the horn. The horn is the Swiss Army knife of instruments, capable of producing a variety of musical effects, of which Strauss took full advantage of. His compositions, which include two horn concertos, ten tone poems, and sixteen operas, push horn playing to the extremes. Mastery of Strauss' works would mean mastery of the horn, although that is a tall task. In order to even approach control of the music of Richard Strauss, dedicated background work is needed. The most obvious is a solid skillset developed by much personal practice, honed over years of study. In order to apply these previously developed skills to the music, some knowledge of the academic side of the pieces is also needed. Understanding of the content or subjects that the pieces are based off, their respective styles, and thoughtful consideration on personal musical interpretations will all advance the horn player in their comprehension of this repertoire. Acquiring this knowledge comes from research across a variety of aspects including score study, biographical study, recording study, and study of the subjects of the pieces, particularly

his tone poems. Combining all of these methods along with practice on the horn will yield a thorough command of these pieces that will help the horn player advance in their musical career.

Abstract Name: Decoding Kentucky's Street Drug Supply: Insights from the Harm Reduction Hub

The Kentucky Harm Reduction Hub is a pioneering initiative uniting academic and community-based scientists, harm reduction advocates, and local stakeholders to gain critical, early insights into Kentucky's street drug supply. By analyzing drug residues from used syringes, the initiative provides timely data on drug trends and composition, fostering a service-centered model with direct, two-way feedback loops to support community partners. This pilot study, conducted across Jefferson and Fayette counties, tested residues from 107 syringes, of which 73 contained detectable drug residues. Preliminary results reveal distressing patterns: xylazine, a powerful sedative, appears frequently, either alone or in mixtures. Methamphetamine, though sometimes present as a standalone substance, is often mixed with other drugs. Particularly alarming is the combination of methamphetamine and fentanyl, which rarely occurs without xylazine. Additionally, diphenhydramine (Benadryl) is commonly found, potentially added as a filler or to mimic sedative effects. The complex layering of substances underscores the heightened risks posed to individuals who inject drugs, as unexpected interactions can lead to severe health consequences. This hub's transdisciplinary approach allows for rapid response and tailored harm reduction strategies that adapt to evolving drug trends, aiming to protect and inform communities in Kentucky.

Abstract Name: His Day is Marching On: A Music Theory Analysis of Battle Hymn of the Republic

This study analyzes the music theory within Julia Ward Howe's "Battle Hymn of the Republic" (1862) with an aim to highlight the impact of the song's musical structure on its historical significance. Much of the existing scholarly conversation surrounding the hymn places an emphasis on its lyrics while disregarding its musical structure. Utilizing the work of scholars such as music historian Elizabeth Morgan, cognitive scientist Steven Pinker, philosopher Alain de Botton, and historian David S. Reynolds, resulted in an interdisciplinary chord analysis of the song. The analysis reveals inherently simple and stable patterns comprised of mainly IV and V chords, resolved by a Perfect Authentic Cadence (PAC). Attributed to original composer William Steffe, the chord progressions and phrase endings on a PAC indicate that the simplicity and finality of the tune may have appealed to listeners struggling to find stability in their everyday lives. Prior to Howe's lyrics, Steffe's original tune, John Brown's Body (ca. 1850), was a popular American folk song. During the American Civil War, Howe's lyrics repurposed Steffe's composition as a patriotic anthem for the Union Army. The use of a familiar tune with such polarizing lyrics depicts the heightened tension between the

Union and Confederate armies. Findings within this study conclude that rather than solely analyzing historically significant events in a traditional, “textbook” manner, music provides additional and valuable insight for the study of social attitudes and perceptions. This research suggests the use of music analysis as a lens through which to contextualize the innately qualitative features of history.

Abstract Name: Experimental validation of computational models to assess impact of tree evapotranspiration (ET) on building internal thermal conditions

This research's main objective is to develop a computational model assessing the impact of extreme heat events on residential structures with limited or no air conditioning. We are particularly interested in understanding how trees, positioned at varying distances from homes, can mitigate indoor temperatures through the process of evapotranspiration (ET) and thermal fluxes. The goal of this part of the research is to validate the model with experimental data collected over the summer. This data is vital because a model is being produced that relates the outside weather conditions to conditions collected inside the Mobile Diagnostics Lab (MDL). The MDL is downwind of a selected tree, and upwind of the tree, we have a deployable Campbell Scientific weather station equipped with a ClimaVUE 50. Sensor. We are collecting variables such as wind speed and direction upwind of the MDL and focus tree, ground temperature, evapotranspiration, tree canopy width, and density, tree to MDL distance, building R-value (the walls of the MDL), temperature inside the MDL, and heat Flux inside the MDL. Our current data collection examines how trees at different distances from homes can help lower heat flux and, thus, interior temperatures by evapotranspiration (ET). To measure the ET rate of trees, we used a LI-COR LI-600 Porometer/Fluorometer and an LAI 2200C Plant Canopy Analyzer to collect the tree canopy width. Infrared camera thermal images measure the ground and surface temperature of the MDL. The resulting data will provide data to validate the computational model and then allow the team to build a localized heat health warning system for the City of Des Moines.

Abstract Name: Utilizing Natural Activators in Wood for Sustainable Biochar Production in Coin-Type Supercapacitors

As global interest in sustainable energy increases, so does the demand for environmentally friendly energy storage devices like coin-type supercapacitors. Traditionally, biochar activation for electrodes involves multi-step, energy-intensive physical and chemical processes that require corrosive chemicals and high temperatures. This research offers a sustainable alternative by creating a simple one step activation utilizing natural activators in various types of wood. This technique of one step activation was used for three different types of wood chips: white pine, white cedar and bur oak. Bur oak was selected as a base line while white pine and white cedar were selected due to their high porous levels and content of calcium oxalate. During pyrolysis, the biochar from these woods was naturally activated through the presence of calcium oxalate. After the pyrolysis the biochar was mixed with Carbon black and other agents to form a slurry. This slurry was then spread on aluminum and copper substrates, dried, punched out into electrodes and assembled into a

coin-type supercapacitor with Na₂SO₄ electrolyte for testing. Of the tested supercapacitors, white pine showed the highest specific capacitance (256 F/g) at 0.1mA). Far out performing a commercial capacitor (36 F/g). Both the white cedar and bur oak had around the same capacitance. White cedar(6.4 F/g), Bur Oak (6.8 F/g) which were unexpectedly low capacitances. Future research will focus on stabilizing the charge-discharge rates and investigating other types of chemical compounds found in various species of wood as potential self-activators for biochar.

Abstract Name: Investigating Sex-Specific Differences in mRNA Expression of Atf3 During Neuropathic Pain and Relief

Chronic neuropathic pain affects millions in the U.S. with significant healthcare costs. Pain responses differ between males and females due to sex-specific neuroimmune interactions. Understanding the biological basis of these differences is crucial for developing effective treatments specific to the individual. We recently reported that gene expression in the dorsal root ganglion (DRG) of rats experiencing pain and relief from a nanotherapeutic NSAID is sexually dimorphic. Activating transcription factor 3 (Atf3), a cyclic-AMP Response Element Binding protein, was one of the genes showing high fold change. This project seeks to correlate the quantitative expression of Atf3 mRNA to the differential protein expression previously discovered. Briefly, DRGs from male and female rats experiencing neuropathic pain and relief were collected. RNA isolation and reverse transcription PCR were used to isolate and stabilize Atf3 RNA as cDNA. Forward and reverse primers were designed for the four known exons of rat Atf3. PCR assays were conducted using six primer combinations to assess mRNA expression across sexes and conditions. PCR products were analyzed by agarose gel and the resulting data revealed the corresponding amplicons. Additionally, fluorescence in-situ hybridization (FISH) was used to visualize Atf3 RNA expression within the DRG to correlate Atf3 RNA expression to protein expression. Further analysis will provide additional insight into how Atf3 expression differs between treatment groups. This research aims to advance the understanding of sex-specific mechanisms underlying neuropathic pain and how Atf3-mediated pathways could be targeted for personalized pain relief treatments.

Abstract Name: An Analysis of Fascist Rhetoric In Speeches Given by Vladimir Putin

Since the invasion of Ukraine in 2022, there has been an increased evaluation of the potential presence of

fascism in Russia. Often these analyses take a narrow view at events occurring around or after the invasion, primarily consisting of comparing competing definitions of fascism and specific elements of fascist behavior. Measuring these fascistic tendencies can aid in determining if concerns over an expansionist right-wing governments in Europe are valid, especially after statements from the EU, US, and Ukraine all made comparisons between Putin's regime and those of Nazi Germany. The present study takes a generalized approach and evaluates the usage of fascist rhetoric in speeches given by the leader of the Russian state, Vladimir Putin, from his inauguration in 2000 to 2024. Analysis of these speeches can be used to demonstrate either an increase or decrease in his use of fascist rhetoric. Utilizing Umberto Eco's 14 characteristics of fascism, developed in his essay *Ur-Fascism*, a codebook was created to measure the presence and type of common elements of fascistic rhetoric and changes in its usage in Putin's speeches. The author expects to see a general increase in the use of fascistic rhetoric over time, with notable spikes around 2014 and 2022, correlating with the invasion of Crimea and the invasion of mainland Ukraine. War and conflict create an increased need of the state to rally support around central ideological messaging, which fascistic rhetoric attempts to achieve, thus creating incentives for its use. Finding instances of fascistic rhetoric may be useful in understanding the long-term goals of Russia's mass media campaigns as it pertains to the desired relationship being cultivated between the Russian state and its populace.

Abstract Name: Determining the Role of Pregabalin in Diabetic Peripheral Neuropathy Pain Management

This study aims to define the efficacy of pregabalin in treating neuropathic pain in diabetic peripheral neuropathy (DPN), both as a monotherapy and in combination with other drugs that are commonly used to treat DPN in a clinical setting. Thus, physicians are able to make more informed decisions when choosing drugs to relieve DPN. This study evaluated the role of pregabalin in diabetic peripheral neuropathy pain management and its efficacy compared to other treatments by analyzing study type, drug type, treatment duration, and primary endpoint. Experimental groups varied from amitriptyline, duloxetine, carbamazepine, venlafaxine, and Xiaoketongbi Formula (XF). Pregabalin was shown to have no difference when compared to amitriptyline; however, more extended treatment regimens should be performed. Duloxetine is more effective at lower dosages, but pregabalin is more effective at higher dosages. Additionally, pregabalin was found to be more effective than carbamazepine and venlafaxine. Surprisingly, XF was found to be as effective as pregabalin, demonstrating the potential role of herbal treatments. Combination therapies did not have a significant advantage over pregabalin monotherapy in treating DPN. Regarding adverse effects, pregabalin was more tolerated among patients, though side effects were generally mild. Pregabalin is still an effective treatment for DPN pain management, and it is still considered non-inferior to current monotherapies and combination therapies. Overall, pregabalin is an effective drug therapy to address DPN despite the array of alternative medications present; however, evolving treatments, specifically herbal medications like XF, should be explored in a future research setting.

Abstract Name: Evaluating Google and ChatGPT 4o as Sources of Patient Information for Laparoscopic Colorectal Surgery

This study aims to determine the differences in search engine information between Google and GPT-4o in the context of the type of questions, the readability of answers, the validity of the sources, and numerical accuracy for the most commonly asked questions about Laparoscopic colorectal surgery. Comparing such differences is essential to understanding the knowledge gaps between Google and GPT-4 in terms of patient education, which can significantly increase confusion and anxiety over standard medical procedures. Using this design, it was determined that readability of responses from Google and ChatGPT significantly differed, as shown through the Flesch-Kincaid Score and Flesch Reading Ease Score ($p < 0.001$). In addition, the types of questions asked by Google and ChatGPT were quite similar, as noted by a Rothwell grading system, which indicates that question type was a major contributor to such difference in answers. However, the credibility of the sources provided by these search term engines differed as Google provided more reliable sources than ChatGPT, as noted through the JAMA source criterion. Readability was not the only difference observed, as numerical responses to recovery time, pain level, weight loss, success rate, the time until daily function recovery, and surgery duration were significantly different between ChatGPT and Google responses, indicating a high variability in information provided to patients. More effort must be placed to provide patients online information with a more concise, readable language, with supplementary information from credible sources.

Abstract Name: Employee dissatisfaction and negative ESG media attention

This study investigates the relationship between employee satisfaction and future environmental, social, and governance (ESG) media incidents. We utilize anonymous employee reviews from Glassdoor.com, analyzing their sentiment using the Valence Aware Dictionary and Sentiment Reasoner (Vader) tool. ESG incident data is sourced from RepRisk's ESG database. Our findings indicate a significant association between employee dissatisfaction and negative ESG performance of companies. We observe that firms often underinvest in employee welfare, potentially due to the perceived costs of improving working conditions. Our research

provides evidence for the importance of prioritizing employee satisfaction, as it correlates with negative ESG media attention. These results suggest that companies should consider employee well-being as a crucial factor in their overall ESG strategy and public perception management.

Abstract Name: Affective Instability in the Parent-Child Relationship: Implications for Adolescent Anxiety

Adolescence is a period of emotional and psychosocial upheaval during which youth, particularly girls, are at increased risk for the development of anxiety. One potential risk factor for the development of anxiety is affective instability (AI)—rapid, uncontrollable fluctuations of intense affect. Research indicates that AI is associated with increased anxiety in children, adolescents, and adults, and parental AI is associated with increased subsequent adolescent AI and anxiety. However, the mechanisms by which parental AI influences adolescent anxiety remain poorly understood. Based on past research, we propose a model whereby heightened adolescent AI mediates the relationship between heightened parental AI and heightened adolescent anxiety. We will test this model using data from the three-wave longitudinal GIRLS: Brain Study, which examined how adolescent girls at risk for internalizing disorders reacted to emotional stimuli. At each timepoint, our participants ($n = 103$) completed questionnaires and 16 days of ecological momentary assessment (EMA) data, capturing in-vivo affect (3 times daily, up to 54 total observations). Parents self-reported parental AI using the Affective Instability subscale from the Personality Assessment Inventory Borderline, and adolescents self-reported anxiety symptoms using the General Anxiety Disorder subscale in the Screen for Child Anxiety-Related Emotional Disorders. Child AI is calculated separately for positive and negative affect using the mean square successive difference of their EMA momentary affect ratings. We predict that heightened parental AI at timepoint 1 (T1; ages 11-13) will be associated with heightened adolescent anxiety two years later at timepoint 2 (T2; ages 13-15). Additionally, we expect heightened adolescent AI at timepoint 1 will mediate the relationship between heightened parental AI (T1) and heightened adolescent anxiety (T2). Analyses will be completed by the time of the conference. Results will help to further clarify the mechanisms by which experiences in adolescence influence anxiety development, potentially aiding target interventions.

Abstract Name: Powering the Future: Fabricating Ceramic-in-Polymer Composite Solid Electrolytes with Enhanced Li-Ion Conductivity from Zirconium/Sulfur Interactions

All-solid-state batteries (ASSBs), which replace flammable liquid electrolytes with solid electrolytes, have received significant research interest due to their enhanced safety. Ceramic-in-polymer composite solid

electrolytes, characterized by impregnating ceramic ion-conductors within interconnected polymer networks, show great potential for meeting the high-performance requirements of ASSBs due to the combined benefits of fast Li-ion conductivity and facile interfacial contact with Li-metal anodes. Grafting the surface of ceramics with lithophilic ligands can further enhance Li-ion transport across the bulk material and at the extrinsic interface with electrodes. In this project, we developed a layer-by-layer method that exploits the coordination interaction and electron transfer interaction between Zirconium (Zr) and Sulfur to fabricate LLZO-in-PEGDA composites, achieving precise control over the homogeneity and structure of the composites. Notably, the LLZO-in-polymer composites demonstrated higher ionic conductivity and lower activation energy than their sulfur-free counterparts, facilitated by the Zr/Sulfur interactions. This improvement can be attributed to changes in the polymer network, characterized by a larger mesh size and the introduction of a lithophilic environment that promotes rapid Li-ion association and dissociation at various intrinsic interphases. As a result, the LLZO-in-Polymer composite exhibited a high conductivity value of $5.1 \times 10^{-4} \text{ S cm}^{-1}$, exceeding the vendor-reported bulk ionic conductivity of polycrystalline LLZO. This suggests that the sulfur-containing ligands facilitate faster Li-ion transport between LLZO and other phases within the composites, compared to the LLZO|LLZO interphases (i.e., grain boundaries) within polycrystalline LLZO. In addition, the sulfur-containing LLZO-in-PEGDA composites showed improved toughness and stretchability, suggesting the potential dual role as a protective layer for electrode materials. Finally, the sulfur-containing composites can stabilize the interfacial resistance with Li anodes, suggesting the formation of a solid-electrolyte interlayer (SEI) layer with Li-anode. Elucidation of Zr/Sulfur interactions on Li-ion transport within multi-phase composites offers a foundation for designing better Li-ion transport pathways.

Abstract Name: Regional Connections with the Sangh Parivar and the Union Ministry

In looking at Hindu nationalist organizations and their ties to the government, there is no clear list or data that has been gathered in one spot. The Sangh Parivar is a collection of right-wing Hindu nationalist organizations stemming from the Rashtriya Swayamsevak Sangh. With over 5 million people officially a part of the RSS, it is the world's largest far-right organization. Due to the lack of centralization within the Sangh Parivar, there is no clear way to know whether a person was a member of one of the many organizations unless they themselves have mentioned it before. In a population of over 1.4 billion people, there are many regional differences and conclusions that can be drawn about different voting patterns, and how that relates to a politician's connection to organizations like the RSS. Since 2014, the Modi Union Ministries have been becoming closer and closer tied to the Sangh Parivar, which has been clearly displayed in the regional make up of the politicians on the Union Ministry. With the current Union Ministry, those that are connected to the RSS, are far more likely to be from a northern state, with the exception of Karnataka, than those who are not connected.

Abstract Name: Muon and gamma-ray rates, and atmospheric monitoring during the total solar eclipse of April 8, 2024

Ambient muon and gamma-ray count rates were measured simultaneously during the total solar eclipse of April 8, 2024, at a location within the path of totality, using an array of ten CosmicWatch detectors in five coincident-counting pairs. No significant variations in the muon or gamma-ray rates were observed during any phase of the eclipse, relative to rates measured well outside of the eclipse times. Temperature and illuminance decreased during the eclipse, and relative humidity increased, as expected from previous studies. We find no unexpected variations in atmospheric pressure or carbon dioxide concentration measured at the site during the eclipse.

Abstract Name: Synthesis of trans, trans-Dibenzylideneacetone Derivatives as Potential Sunscreen Agents

Dibenzylideneacetone (DBA) and its derivatives possess promising ultraviolet (UV) absorption characteristics due to their extended pi-conjugation, making them potential candidates for sunscreen agents. This study focuses on synthesizing DBA derivatives via cross-aldol condensation reactions between aldehydes and ketones under basic conditions. Utilizing various substituents, we synthesized and characterized multiple DBA derivatives to evaluate their UV-absorbing properties, including molar extinction coefficients and λ_{max} values. UV-Vis spectroscopy revealed that modifying the DBA scaffold by introducing different functional groups can enhance UV absorption, which is crucial for effective UV protection. Additionally, melting points and spectroscopic data provide insights into the synthesized compounds thermal stability and molecular structure. Future work will further investigate the structure-activity relationships, photostability, and potential for formulation into sunscreens. Our findings contribute to the development of novel UV-protective agents, aiming to improve the efficacy and safety of sunscreen molecules.

Abstract Name: Assessing Stakeholder Perspectives and Their Influence on the Success or Failure of Carbon Dioxide Removal (CDR) Projects in the United States

As concerns over the impacts of climate change persist, carbon dioxide removal (CDR) technologies are likely to play a key role in achieving global and national targets of net zero carbon dioxide (CO₂) and greenhouse gas (GHG) emissions. CDR projects work to remove carbon dioxide from the air and transfer it into a form of durable storage, some also generating cleaner forms of energy. Many rising CDR projects encounter public opposition from local communities, as well as other challenges that can result in their ultimate cancellation. This research aims to understand barriers to success for CDR projects and explore how future projects might overcome potential setbacks and gain public acceptance. Our research combines qualitative and quantitative approaches to examine the relationship between public reception and the regional characteristics of CDR projects, including economic, geographic, and demographic influences. Additionally, we analyzed broader U.S. trends in gubernatorial communications and policy frameworks related to climate change, environmental strategies, and CDR initiatives. Methodologies for this work include data collection on active and proposed CDR projects, discourse analysis of public opinion through media reports and local stakeholder feedback, and spatial analysis. By contrasting findings across various regions, we aimed to identify recurring themes in project successes or challenges, as well as identify broader patterns in how state-level leadership influences the acceptance and framing of CDR initiatives. Early results indicate that the success of a CDR project depends on support or opposition from the local community, and is affected by the community's understanding of the project. Efforts must be taken to inform the local population and engage with their concerns about emerging technologies to help determine the best role for CDR in their community.

Abstract Name: Evaluating the Effect of Augmented Reality Platforms in Pre-operative Patient Counseling

Surgical informed consent traditionally involves a dialogue between surgeon and patient to convey the complexities of surgery and ensure patient understanding. However, studies reveal that less than 50% of patients adequately understand the procedure due to limited medical knowledge. Augmented reality (AR) offers a novel solution to improve patient comprehension, retention, and expectations. AR technology can

transform a patient's unique anatomy into an interactive 3D model, allowing visualization of specific pathologies and procedures during preoperative counseling. This study evaluates the effectiveness of AR-enhanced preoperative counseling compared to conventional methods for patients undergoing anterior cervical discectomy and fusion. It is a non-blinded, randomized clinical trial with two groups: a control group receiving standard counseling and a treatment group utilizing Medivis' AnatomyX and Surgical AR technologies. These AR tools will introduce normal anatomy, outline procedural steps, and present personalized 3D models based on patient imaging. Preoperative and postoperative surveys assess outcomes such as perioperative patient satisfaction, preoperative anxiety, confidence in the surgeon, postoperative pain levels, and knowledge retention. Collaborations with neurosurgeons, nurses, and physician assistants informed the study's design, ensuring integration into clinical workflows. A standardized checklist was created to ensure essential topics were consistently covered during preoperative counseling, along with a quiz to evaluate patient knowledge retention. REDCap was employed for remote postoperative surveys, and attending neurosurgeons were trained in AR applications for patient education. The study was accepted on ClinicalTrials.gov (NCT06340672). So far, six eligible patients were contacted, with three consenting to participate. The results aim to demonstrate how AR enhances patient education, increasing satisfaction, reducing preoperative anxiety, and improving trust in the surgical team. This innovative approach provides a framework for integrating AR into routine clinical practice, ultimately aiming to improve the quality of surgical informed consent and patient outcomes while advancing the use of technology in healthcare.

Abstract Name: Designing a Heating and Cooling System for US' Martian Colonies

Heating and cooling Mars' colonies present unique challenges due to the planet's extreme temperatures, lack of a substantial atmosphere, and the need for self-sufficiency in energy sources. Mars experiences wide temperature fluctuations, with daytime temperatures reaching around 70°F (20°C) near the equator but dropping to as low as -195°F (-125°C) at the poles. This study aims to find innovative, sustainable solutions to design a heating and cooling system on Martian colonies that meet human needs. This research starts with a thorough literature review. After that, this study demonstrates and discusses Earth's different heating and cooling systems and how they would aid interior climate control on Mars. The research reveals that each HVAC system has pros and cons and is useful in other applications. The study also finds and explains what daily life looks like on spacecraft, such as the International Space Station, which helps show where Mars's heating and cooling systems can be improved. In addition, the research describes and discusses the timeline of Mars' discoveries and what is known about the planet today as human-crewed missions to Mars are in the near future. Factors affecting HVAC systems, such as extreme temperature variations and atmospheric composition, are also identified with an example of what a colony on Mars could look like. Moreover, this study explains and illustrates how Building Information Modeling (BIM) can be utilized to design virtually a 3D BIM module, a digital twin, for HVAC systems. A selected case study formulates the Martian heating and cooling system research findings. The research finds that geothermal heat pumps and heat-capturing devices like insulation thermal storage walls are the heating and cooling systems of choice. The rationale for this proposed system is also justified with critical points of maximizing efficiency and limiting pollution.

Abstract Name: Behavioral and Morphological Insights into Water-Associated Ecological Classification of Pteroptyx Fireflies

Beetles (Coleoptera) are often difficult to designate as aquatic, semi-aquatic, or terrestrial due to unclear parameters for these classifications, as well as diversity within the order. Our study investigates behavioral diving patterns and morphologies of *Pteroptyx valida*, *Pteroptyx malacciae*, and *Pteroptyx tener* via scanning electron microscope (SEM) imaging to assess and potentially correct their current terrestrial classification while simultaneously contributing to refining the current parameters of water-associated classifications in Coleoptera. We hypothesize that if *Pteroptyx* larvae show behavioral patterns that suggest statistical inclination towards breaching water in an intertidal zone and opened eversible respiratory organs during submersion, it will provide strong evidence for reclassifying these *Pteroptyx* fireflies as semi-aquatic. The behavioural diving experiments reflect the natural environments during firefly larval stages, which include aquatic, sloped, and terrestrial zones. Larvae were placed in a dry aquatic zone which was then gradually flooded to mimic the tide. Diving or escaping behaviours and total time spent in water was recorded for further analysis. Results assessed possible statistical significance of diving and escaping during tidal cycles, providing insight into whether *Pteroptyx* fireflies exhibit terrestrial or semi-aquatic behaviors. SEM imaging was conducted, with a focus on eversible respiratory organs. Both specimens submerged in water and out of water were frozen and preserved for observation and analysis. We will examine the eversible organs to see if they are open or closed. Future results will determine if these organs play a role in underwater respiration. SEM images will also reveal whether functional eversible organs during submersion are a morphological adaptation to water, a characteristic commonly found in semi-aquatic beetles. Overall, our study seeks to clarify ecological classifications of *Pteroptyx* fireflies contributing to a more precise understanding of *Pteroptyx* firefly behavior and morphology in water-associated environments, and refining the parameters used to distinguish aquatic, semi-aquatic, and terrestrial species.

Abstract Name: Facilitators and Barriers of Providing Culturally Informed Pediatric Refugee Care From The Perspective of Pediatric Emergency Department Providers: A Qualitative Study

Fundamental to each refugee's story of migration is a story of trauma. Refugees experience trauma related to war and persecution in their home country, during exile from their homeland, and resettlement in a new country. The United States has become a new home for many refugees, and since 1998, over 25,000 refugees have resettled in Utah specifically. Refugee families' only option for pediatric emergency care in the Intermountain West is Primary Children's Hospital (PCH). As more refugees arrive in Utah, it is vital that healthcare professionals in all settings, including the emergency department, are culturally informed about diverse patient demographics. Currently, there are no educational programs dedicated to teaching culturally informed care for pediatric emergency professionals at PCH. As a result, a gap in understanding develops

between healthcare teams and refugee patients leading to worse patient outcomes. This IRB-approved study aims to gather insights from pediatric emergency healthcare professionals and families of pediatric refugee patients at PCH to understand facilitators and barriers to care. Since August of 2024, in-depth interviews (IDIs) with physicians, care managers, and nurses, followed by focus-group discussions (FGDs) with refugee families have been conducted. IDIs and FGDs are recorded, transcribed, and analyzed using applied thematic analysis. Data analysis will be performed through Dedoose software, analyzing data for salient themes with discrepancies resolved by consensus, and initial results will be produced by January, 2025. This study is the first to gather perspectives from refugee families seeking care in a pediatric emergency department in the United States. The impact of this study is to provide educational resources for pediatric healthcare professionals about the nuanced needs of refugee families. We aim to foster a more culturally sensitive healthcare environment, enhancing the quality of care for the refugee community.

Abstract Name: Biases in Jury Decision Making: Autism Versus Down Syndro

This research will aim to look at perceptions of individuals with intellectual disabilities to see if that has any impact on how participants render a verdict. The data will also be used to see if any discrepancies are present between the two groups (autism spectrum disorder and Down Syndrome) and how often a guilty verdict is rendered. This is important research to conduct because there is little previous research that has been done on this specific topic. There is so little research that has been done looking into one type of disability and how perceptions affect a juror's verdict, let alone research on two types of disabilities. Think about past research that has been done comparing the verdicts and sentencing of African-American versus White citizens; my research questions are working off of the same idea in a way, just looking at it with different levels as compared to race. This research is important for the same reasons as that, and that is because everyone has the right to a fair trial. At the end of the day, it is protected under the Fifth and Sixth Amendments of the United States Constitution. In this study, participants will complete a survey consisting of a disability perception scale (ADS), a reading of a case summary, and two questions regarding that case summary. This study has two hypotheses. First, participants who get assigned to read the case on Autism will be more likely to render a guilty verdict. The second hypothesis is that the worse a person's perception of individuals with disabilities is, the more likely it is for them to render a guilty verdict.

Abstract Name: Beyond the Bean: Exploring the Chemistry Behind Coffee Consumer Satisfaction

This research project evaluated the relationship between Arabica coffee quality and consumer satisfaction. Experiments were designed to uncover trends of customer satisfaction in coffee samples with varying post-brew intervals. Another objective was to discover if there were any correlations between older (longer post-

brew) coffee and an increase in consumer dissatisfaction. One unique feature of this project included studying consumer responses in an effort to improve coffee preparation, particularly for companies who serve coffee. Considering green chemistry applications, longer hold times will decrease company waste as well as decrease common customer complaints of coffee tasting “old” or “stale.” Two Arabica coffee samples were prepared: one freshly brewed (Sample A) and one having a post-brew time of 8 hours that was reheated (Sample B). Consumers (N=61) provided data on feedback forms that indicated consumer preference for Sample A (46%) and Sample B (54%). Consumer feedback showed fairly similar perceptions when asked to select which brew was fresher with Sample A (49%) and Sample B (51%). Results related to the Emotion Index Adjectives indicated Sample A: 11 positive, 12 negative and Sample B: 7 positive, 5 negative. Looking deeper into the brewed coffee, both samples were analyzed at the chemical level using Liquid Chromatography Mass Spectrometry (LCMS). The LCMS spectra showed a large peak at 195 m/z for both Sample A and Sample B that represented the caffeine found in the samples and aligned with the results found for the caffeine standard. This project proved to be an effective learning experience in creating a successful IRB proposal, qualitative analysis in assessment strategies, and quantitative chemical analyses utilizing LCMS. Collectively, these aligned with the institution’s mission with respect to preparing students to become knowledgeable and responsible scientists, especially for those intending on pursuing graduate degrees in chemistry.

Abstract Name: Invasive Zebra Mussel Habitat Preference in a Newly Invaded Lake

Zebra mussels are an invasive species widespread throughout states in the eastern and midwestern United States. In invaded lakes, zebra mussels spread quickly, reach high population densities, and transport large amounts of nutrients and carbon from the water column to the lake sediments. Once large amounts of nutrients and carbon are translocated to the sediments, the water column food web can become deprived of food resources and fish populations may decline. Zebra mussels were first found in Lake Menominee (Menomonie, WI) in May 2024. To determine the potential for zebra mussels to colonize the lake and alter the food web, we conducted a whole lake survey to assess their current distribution and the speed of their invasion. Using a stratified random survey, we sampled sites encompassing the range of habitats in Lake Menominee, a range of depths, distance from site of discovery, and substrate type. At shallow sites, we hand sampled rock and sandy sediments. At deep sites (2-4.5 m), we dredged sediment substrates. We also hand-sampled human substrates including buoys and a vehicle towed out of the lake. The highest densities (averaging 242.7 zebra mussels per sq.m) were found on human-made substrates like the metal truck and plastic buoys. Densities at shallow sites (primarily sand and cobble) averaged 6.9 zebra mussels per sq. m. Deep sites had soft, mucky substrate with no zebra mussels detected. Since most zebra mussels were found on human-made substrates, populations could continue to be low due to limited habitat. However, populations could also be low due to their recent arrival. High zebra mussel density on human-made substrates may cause damage in the future and careful cleaning of boats and infrastructure is imperative to prevent spread to other local lakes.

Abstract Name: Enhancing Dyslexia Diagnosis with Pseudoword Mask Assessment

Dyslexia, a neurodevelopmental disorder, impairs reading, spelling, and phonological processing. While traditional diagnoses focus on phonological deficits, research suggests that dyslexia also affects visual and auditory processing. This highlights the need for diagnostic methods that address these multisensory impairments. We hypothesized that integrating visual and auditory stimuli would enhance understanding and accuracy of dyslexia diagnoses. Specifically, we proposed that: (1) dyslexic individuals may perform better in one modality over another; (2) combining visual and auditory stimuli would improve their performance, narrowing the gap with non-dyslexic controls; and (3) across all conditions, dyslexic individuals would exhibit slower response times and lower accuracy than controls. Using a 2x3 ANOVA, we tested dyslexic and non-dyslexic participants on a pseudoword matching task under three conditions: visual-only, auditory-only, and combined visual-auditory. Pseudowords (e.g., "blart") are pronounceable non-words, isolating decoding and pattern recognition. Response times and accuracy were measured across conditions. In our non-dyslexic participants, a paired t-test showed faster response times in the auditory condition ($M = 1.25s$, $SD = 0.35s$) compared to the visual condition ($M = 1.50s$, $SD = 0.40s$), though not statistically significant, $t(9) = 1.75$, $p = 0.12$. Accuracy was highest in the combined condition ($M = 0.85$, $SD = 0.10$) but also not significant, $t(9) = 1.50$, $p = 0.17$. Dyslexic participants demonstrated slower response times and lower accuracy in both single-modality conditions but improved in the combined condition, suggesting multimodal integration helps mitigate deficits. These findings support a multimodal diagnostic approach that incorporates visual and auditory stimuli. This method could provide a more nuanced understanding of dyslexia's complexity, enabling accurate diagnoses and personalized interventions to improve outcomes for individuals with dyslexia.

Abstract Name: Development of the Reproductive Tract in a Cartilaginous Fish

The reproductive tract is a key structure in vertebrate anatomy, and its development and differentiation has been studied in detail in bony model organisms like mice and zebrafish. In mammals and birds, reproductive development begins with an undifferentiated gonad and two sets of ducts, the Wolffian ducts and the Müllerian ducts. In males, the Wolffian duct goes on to form the male reproductive tract while the Müllerian duct degenerates; in females, the opposite happens. In bony fishes, like the zebrafish, a completely new duct forms to carry sperm or egg out of the body. However, reproductive tract development in non-bony vertebrate groups remains unclear and we know little about its development and the timing of male and female differentiation. Cartilaginous fishes, including sharks, skates, and rays, are useful for studying the evolution of development because they diverged from bony vertebrates over 400 million years ago, and their developmental patterns can give insight into the diversity of vertebrate reproductive structures. To compare reproductive tract development in cartilaginous fishes with other vertebrates, we studied the little skate (*Leucoraja erinacea*). Skates are oviparous (egg-laying) and are easy to obtain at different developmental stages. We investigated the reproductive tract by performing histological sectioning and Masson's trichrome staining from the first emergence of the gonad to hatching. We compared males and females and, identified reproductive structures including the indifferent gonads, differentiated ovaries and testes, oviducts, cloaca, ductus deferens, and urogenital sinus. We found that in the skate, reproductive tract development is more

similar to mammals and birds than to bony fishes like zebrafish, suggesting that this dual duct system is ancestral for jawed vertebrates. Our results can give evolutionary insight into how this fundamental anatomical structure diverged across vertebrates.

Abstract Name: The impact of globalization on the growth of the American sports industry and the pathway of international student-athletes into college and professional sports.

My research discusses the impact of globalization on the growth of the American sports industry and the pathway of international student-athletes into college and professional sports. The main objective is to investigate how the rise in globalization helped to grow the American sports industry in viewing and the participation of foreign athletes. This research is relevant because the growth and ultimate investment in American sports like Lacrosse, baseball, basketball, and flag football internationally, will make foreign athletes more competitive at the next Olympic Games in Los Angeles. Additionally, with the exponential growth in women's sports in the last two years, this research will shed light on whether or not there will be more female athletes being drafted before they graduate college. The methodology used is surveys, a qualitative interview with the flag football league in Lagos, Nigeria, performance analysis, and case studies. My expected results are that the rise in broadcasting and the spread of American sports has led to increased viewership across continents, a rise in foreign athletes in college and professional sports, and a rise in American sports development, through flag football, basketball, and baseball leagues internationally, and that male athletes are more likely to spend fewer years in college before they get drafted into professional leagues, while female athletes typically spend the full four-years in college before being drafted. The main reason for this is due to the popularity of male athletes over female athletes.

Abstract Name: Real-Time Quantification of T-Cell Mediated Pancreatic Cancer Cell Death

The average lifetime risk of developing pancreatic cancer (PC) is about 1.5%, yet PC is the third leading cause of cancer-related deaths in the United States. This poor clinical outlook is likely the result of late-stage diagnosis and resistance to currently available cancer treatments. Further, the pancreatic tumor microenvironment is highly immunosuppressive with limited infiltration of anti-tumor immune cells observed. From an immunological perspective, little is known about what regulates anti-tumor immunity to PC and particularly what limits CD8⁺ T cell responses to PC. We designed an assay co-culturing mouse PC cells modified to be recognized by CD8⁺ T cells in order to evaluate and quantify CD8⁺ T cell-mediated PC cell death. Recent studies suggest that signaling through the cell surface marker P-Selectin Glycoprotein

Ligand-1 (PSGL-1) promotes CD8+ T cell exhaustion, a state of decreased cytotoxicity and proliferation. We hypothesize that PSGL-1 deficiency will promote increased T cell responses and improved tumor control. Future studies of this research may include targeting PSGL-1 expression in T cells as a method of attacking PC.

Abstract Name: Analyzing the Performance of GPU-Based Point-in-Polygon Algorithms

The point-in-polygon (PIP) query determines whether a point lies inside or outside a polygon. It is a fundamental problem in computational geometry, with applications spanning computer graphics, geographic information systems, and scientific simulations. While traditional approaches to this query, such as the ray casting algorithm and winding number algorithm, rely on CPU-based computations, advancements in GPU computing have enabled high-performance alternatives. In this paper, we benchmark three GPU-based PIP algorithms: (1) a straightforward CUDA-based ray-casting implementation, (2) RayJoin, a state-of-the-art algorithm leveraging NVIDIA's hardware-accelerated ray tracing (RT) [Geng et al., ICS 2024], and (3) s-ray, a novel approach using NVIDIA's RT hardware with a per-edge triangle index. We evaluate these methods against two distinct scenarios: a high point-to-polygon ratio and a more balanced point-to-polygon ratio. Our findings reveal significant trade-offs between query performance and build (preprocessing) costs. While the CUDA-based implementation is simple and build-free, it is the slowest in query throughput. RayJoin achieves up to 30x speedups over the CUDA algorithm by optimizing edge groupings into axis-aligned bounding boxes (AABBs). The s-ray algorithm further doubles RayJoin's throughput, albeit at the cost of 6–20x longer build times. Our work highlights the tradeoffs between different GPU-based PIP algorithms, providing a foundation for users to select and/or develop their own high-performance PIP algorithms.

Abstract Name: Smart Platform for Intelligent Dynamic Exploration and Robust Walking (S.P.I.D.E.R.)

This project will design and build a robot for applications in inaccessible and remote environments that can maintain stability after the loss of a leg. Currently, most robots in these environments are designed to move using wheels, which can only handle certain terrain. In contrast, legged robots are less restricted in their

movements. However, if one leg is damaged or rendered useless, the robot becomes unstable. To maintain stability after leg loss, more legs can be added. For example, a hexapod (six-legged robot) will be able to support itself on at least two legs while walking. Previous research has achieved adequate levels of compensation in hexapods, but have varied results on the body's stability, which can affect payloads. To increase stability, this study will create an eight-legged prototype. The leg design is inspired by the segmented legs of spiders, with four degrees-of-freedom in each leg. While operating, the robot will analyze positional data in real-time to adjust the tilt of the body based on pre-programmed parameters. To gather the most accurate data, a leg will be fully removed when testing for stability after leg loss. For testing, the robot will run a predetermined course before and after a limb has been removed, and the mean tilt error (the difference between nominal parameters and maximum tilt) will be analyzed. Compared to hexapods, it is expected that the body will be 20% more stable after limb loss, and able to recover stability 60% faster from the loss event.

Abstract Name: Accelerating Simulations of Strongly Correlated Systems with OpenMP Parallelization

The primary objective of this project is to identify specific routines within the simulation that are suitable for optimizing large-scale many-body code designed to model strongly correlated systems, specifically ones where Coulomb Interactions play a central role. By employing various profiling techniques, we pinpoint performance bottlenecks within the code. We then apply OpenMP parallelization to accelerate these targeted routines, significantly boosting simulation performance. Implementing OpenMP in these areas can reduce execution time and enhance resource efficiency. The outcomes of this project are expected to benefit researchers working in computational physics and materials science by providing an efficient toolset for exploring complex physical phenomena.

Abstract Name: Differential Gene Expression in Response to Viral Infection in Pediatric Obstructive Sleep

Apnea

Obstructive sleep apnea (OSA) is linked to early life viral infections with resultant adenotonsillar hypertrophy, and children with OSA have increased severity of viral respiratory illnesses. As respiratory viral infections occur in airway epithelial cells and initial epithelial responses to viral infections have been linked to disease manifestations, we sought to investigate the differences in epithelial viral responses between children with OSA as compared to children without. We hypothesized that gene expression in response to rhinovirus (RV16) infection would differ between healthy children and children with OSA. Primary airway epithelial cells (AECs), from both healthy pediatric donors and children diagnosed with OSA were cultured on an air-liquid interface as an ex-vivo model, and then infected with RV16. RNA-sequencing quantified gene expression at baseline and after RV16 infection, and Limma was used to identify the genes with differential expression in response to infection in healthy AEC as compared to AECs from donors with OSA. Weighted gene co-expression network analysis (WGCNA) was able to organize the identified genes into groups of interest. Using Enrichr, the primary biological functions of the groupings were analyzed. Following infection, 122 genes were found to have differing gene expression responses to RV16 in OSA when compared to healthy cell lines. WGCNA identified two modules of gene expression with differential expression following infection in OSA compared to healthy. Module one consists of 43 genes enriched for glycogen metabolism which are downregulated in healthy, but upregulated in OSA following RV16 infection. Module two consists of 23 genes enriched for DNA repair and replication which are upregulated in healthy, but downregulated in OSA. Epithelial cell gene expression differs in response to RV16 in healthy AECs as compared to AECs from children with OSA. Further studies are needed to link altered epithelial responses in OSA to more severe respiratory infections.

Abstract Name: The Transformative Impact of Translanguaging Pedagogy in Bilingual Read-Aloud Activities

This presentation explores the transformative effects of translanguaging pedagogy on the academic engagement and emotional experiences of an emergent bilingual elementary student. I specifically examine how bilingual read-aloud activities, guided by translanguaging principles, influence the student's participation and emotional responses compared to traditional English-only approaches. By incorporating both the home language and English, translanguaging fosters a more inclusive and supportive learning environment. As part of a research team, I conducted an in-depth study featuring eight 90-minute interactive read-aloud sessions with a local emergent bilingual student. Using a single-subject experimental design, I compared the student's engagement and emotional responses during bilingual translanguaging sessions with those from English-only sessions. The findings reveal clear benefits of integrating translanguaging into literacy activities. The student demonstrated increased motivation, participation, and emotional connection during bilingual sessions, compared to more limited engagement and emotional expression in English-only sessions. This research underscores the cognitive and emotional advantages of translanguaging in supporting emergent bilingual learners. The presentation aims to offer practical insights for integrating translanguaging pedagogy into classroom instruction. By embracing students' home languages, teachers can enhance literacy development while supporting the emotional well-being of emergent bilingual students. In sum, this presentation highlights the transformative power of bilingual read-aloud activities, driven by translanguaging pedagogy, in shaping students' literacy skills and emotional experiences, surpassing traditional monolingual English-only methods. My ultimate objective is to equip attendees with practical ideas they can readily implement in their classrooms, providing a deeper understanding of how to effectively support emergent bilingual students' learning and emotional well-being through translanguaging pedagogy.

Abstract Name: The Value of Patient Education in the Overutilisation of Paediatric Emergency Medicine

Districts 1 and 5 of Michigan face high levels of overutilisation of emergency services, much like the rest of the United States. The overutilization of emergency services for non-emergency paediatric concerns is a significant challenge. This research addresses this issue by conducting a thorough investigation using both data analysis and survey data. By examining patterns of emergency service utilization and gathering insights from patient experiences, the study pinpoints areas of misinformation or lack of information among parents and caregivers regarding paediatric health needs. Through rigorous data analysis, the research has identified underlying factors contributing to the prevalent overutilization trend, including socioeconomic barriers and the effectiveness of current patient education initiatives. Additionally, the study has explored parental attitudes towards emergency services, primary care providers, and urgent care facilities in managing non-emergency paediatric health concerns. This research examines the roles of healthcare providers, policymakers, and educators in addressing identified gaps in paediatric healthcare knowledge and access. By disseminating findings to relevant stakeholders, the study advocates for targeted interventions and policy reforms to optimise resource allocation and enhance patient-centred care for paediatric populations. By promoting informed decision-making and improving access to appropriate healthcare resources that meet the needs of our community, the study aims to enhance the quality and efficiency of paediatric healthcare delivery in districts 1 and 5. Collaboration with healthcare professionals, community leaders, and policymakers will foster a healthcare system prioritizing the holistic well-being of paediatric patients while ensuring equitable access to timely and appropriate care.

Abstract Name: The Effects of Spatially Localized Functional Forms of the Inflow Rate in Reaction Diffusion Systems

The Grey-Scott Model is a prominent reaction-diffusion system that comprises two non-real chemical species, u and v , which interact through complex reactions and transformations. By manipulating parameter values within the model, spatiotemporal patterns emerge that mirror essential biological, chemical, and physical processes, including DNA oligomer formation, skin pigmentation development, and oscillatory chemical reactions. While extensive studies have typically focused on fixed parameter values, this research innovatively introduces specially defined functional forms that spatially vary key parameters throughout the lattice. Specifically, by employing sinusoidal and other oscillatory functions to modulate parameter values, we can seamlessly integrate the dynamics and behaviors characteristic of diverse parameter settings within a single reaction framework. This novel approach not only reveals a spectrum of unique and intricate patterns

but also enhances the model's applicability, extending its relevance to a broader range of natural phenomena. Through this exploration, we aim to deepen our understanding of reaction-diffusion systems and their potential implications in both theoretical research and practical applications.

Abstract Name: Garden Ethics: Using School Gardens to Promote Virtue Ethics in the Biology Curriculum

This research project aims to address the question: How might the use of school gardens in the instructional environment promote the development of students' virtue? While school gardens are often employed to bolster students' basic scientific competency, this project asks how gardens might also be leveraged by educators to promote our students' acquisition of Neo-Aristotelian virtues while also achieving classroom content goals. Ethics in science and research education has been a topic of increasing interest in recent years—and though some scholars have suggested virtue ethics as an alternative to the current methods of ethical instruction based on deontological and consequentialist ideas (Elgin, 2021; Rodkey et al., 2022)—there is little written about how virtue ethics can fit into the science curriculum, and even less on why and how educators might promote virtue through the educational opportunity of school gardening. My project employs philosophical methods to argue for the use of virtue ethics in science curriculum. Philosophical methods have a longstanding history in the development of curriculum and instructional practices, as they help educators answer two foundational questions; namely, “What educational purposes should schools seek to attain?” and, “What educational experiences can be provided that are likely to attain these purposes?” (Tyler, 1949). Informed by the works of Neo-Aristotelian virtue ethicists such as Snow, Zagzebski, Russel, and Kristjánsson my work makes the case that school gardens offer a prime setting for the habituation of virtue within the context of a biology course. Moreover, my research concludes with practical suggestions and curricular plans for educators to implement a school garden suitable for the habituation of virtue and the provision of high-quality biology instruction.

Abstract Name: Herbicide and Surfactant Effects on Eclosion and Spiderling Survival in the Wolf Spider *Tigrosa helluo*

Different herbicides are often applied to crops in combination and with surfactant additives yet the toxicity of combining these agrochemicals has rarely been assessed among beneficial non-target species such as spiders. Surfactants increase the adherence and absorption of herbicides through plant leaves but may also increase toxicity to spiders by enhancing penetration through eggsacs or the spider's exoskeleton. We measured the separate and combined effects of the herbicides glufosinate and mesotrione with an organosilicone surfactant, Sil-fact®, on parental care, egg eclosion, and spiderling survival in the agrobiont wolf spider *Tigrosa helluo*. We applied water (control) or field doses of glufosinate, mesotrione, and Sil-fact in all combinations to spider eggsacs (eight treatments). We recorded initial eggsac acceptance after spraying, abandonment during incubation, and eclosion for all treatments over a 50-day period. We conducted a dye test to measure adherence and absorption of herbicides and surfactants into the eggsacs across the eight treatments. We also measured spiderling mortality when maintained on freshly sprayed soil or 3-day aged herbicide residue of mesotrione, glufosinate, or Sil-fact alone or in all combinations (15 treatments). We found no evidence of initial eggsac rejection or abandonment after eggsac across agrochemical treatments compared to the control. Some herbicide treatments showed significantly higher absorption but not adherence to the eggsac with more eggs containing herbicide tracer dye with some treatments. Exposure to fresh or aged glufosinate increased mortality among spiderlings while only aged Mesotrione residue significantly increased mortality. Sil-fact alone did not significantly increase mortality but acted synergistically or antagonistically with some herbicide treatments. Results indicate that mesotrione, glufosinate, and Sil-fact all impacted reproduction and that glufosinate and mesotrione are both powerful araneocides. The use of these herbicides and surfactants should be reconsidered in systems where spiders are used as biocontrol within integrated pest management systems.

Abstract Name: The Gramlee Collection's Deconstructed Monograms

The focus of my research is to deconstruct historical monograms from the GramLee Collection of Commercial Wood Engravings so they can be reflected upon in a more physical sense. A monogram is a motif of two or more letterforms intertwined to create an identifier. My monogram kit consists of specimen cards printed on translucent paper, a tunnel book, foldable monograms, and an information sheet about monograms. This kit will serve as a tool for articulating the selected monograms by deconstructing their conceptualization. Monograms are one of the oldest forms of identification and are made by entangling letterforms in an interesting and engaging way. They have been used by high society as a symbol of wealth, artisans' marks or signatures, and have even been used to identify modern brands. The culture surrounding these design phenomena have always interested me. The Gramlee Collection, housed at West Virginia University, provides a variety of such forms. The ephemeral aspect of commercialized wood and metal engraving is often overlooked, however it is an important part of the history of graphic design. The two primary methods employed in researching monograms involved an in-depth analysis of the forms of selected monograms from the GramLee Collection, which has blocks for and prints of over 40 monograms. I conducted broader research through a review of relevant articles, books, and academic papers, which provided further context and theoretical grounding for the study. These consisted of the cultural and general uses of monograms and the use of decorative lettering and typography found in the GramLee Collection. The research provided

valuable insights into the exploration of letterforms, demonstrating their potential as a tool for advancing skills in logo design and hand lettering. The project emphasized the importance of historic commercial printing and design collections as well as the culture of monograms.

Abstract Name: Smiles Beyond the Limits of Trisomy 21

This research is dedicated to show why periodontal disease is prevalent in over 90% of individuals with Trisomy 21. Trisomy 21, also known as Down syndrome, is a non-hereditary, neurodevelopmental disorder, caused by an error in cell division during the formation of egg or sperm cells. It is the most common etiology of mental disability in the world, causing physical and intellectual limitations. According to the WHO, prevalence of Trisomy 21 is around 1:1,000 live births worldwide. The credibility of this research is supported through a multitude of studies, experiments, peer-reviewed articles, and surveys. This research was done quantitatively using statistics from studies done on patients with and without the disability. The oral microbiome in individuals with Trisomy 21 is more complex than an individual without this neurodevelopmental disorder. One of the primary features that contribute to periodontal disease in these individuals is the acidic environment commonly found in their oral cavity, allowing the present periodontal pathogens to grow and thrive at a higher rate than normal. This was shown in an experiment that tested the saliva of those with and without the disability. Individuals with Trisomy 21 have a compromised immune system and an excessive inflammatory response to periodontal pathogens, making it more difficult for dental professionals to treat disease, and for patients to maintain periodontal health. Another contributing factor to the prevalence is the insufficient amount of information about oral health being passed between dental professionals and the parents and caregivers of these individuals. A survey was given to caregivers and dental professionals of these individuals, showing that there was a low satisfaction with specific information regarding the disability. Due to these risk factors found amongst those with Trisomy 21, the prevalence of periodontal disease remains incredibly high compared to those without the disability.

Abstract Name: An insider-look into the campus community's awareness of per- and polyfluoroalkyl substances (PFAS) in food packaging at Howard Community College

This research will target a current national issue of per- and polyfluoroalkyl substances (PFAS), known as a "forever chemical", one that breaks down extremely slowly and can build up in people, animals, and the environment over time. PFAS is currently under the attention of the US Environmental Protection Agency and the Biden-Harris Administration. As of April 10, 2024, the Biden-Harris Administration launched the first-ever national drinking water standard to protect 100 million people from PFAS pollution. Previously in

2016, PFOA and PFOS (PFAS types) levels in drinking water were limited to a concentration of 70 parts per trillion. Numerous scientific studies conducted over decades reveal PFAS's adverse effects on humans when exposed over a long period of time, especially in critical life stages like pregnancy or early childhood. Now, new advisories decrease PFAS by more than a thousandfold, limiting PFOS to 0.02 ppt and PFOA to 0.004 ppt. The research answers the question "Where on campus are students and faculty exposed to per- and polyfluoroalkyl substances (PFAS) and to what extent is awareness needed around PFAS in food packaging?". A literature review will be conducted to identify common sources of PFAS in food packaging, a readily accessible source for students. The campus community will be surveyed to measure their awareness about PFAS and PFAS in food packaging. On campus food sources like the Café, Food Pantry, and vending machines will be examined. Collected data will be analyzed to determine the campus community's exposure to PFAS from food packaging. In addition, Café and Food Pantry personnel will be interviewed to understand if PFAS is considered when purchasing packaging materials. An infographic posted around on-campus food sources will be designed in response to an expected limited awareness level about PFAS in food packaging in the surveys.

Abstract Name: The Neural and Computational Foundations of Human Visual Cognition

Understanding how the human brain extracts meaningful information from complex, noisy visual inputs is a fundamental challenge in cognitive neuroscience. We investigate the neural and computational mechanisms underlying visual cognition, focusing on how the brain processes intermediate-level visual features, adapts to environmental statistics, and flexibly adjusts representations to meet behavioral goals. Using a combination of experimental methods, including fMRI and behavioral studies, and computational techniques such as machine learning and artificial neural network modeling, we aim to bridge gaps between theory and application. Current research explores the hierarchical organization of visual cortex, the role of natural image statistics in category learning, and the adaptive flexibility of neural coding in response to task demands. By integrating insights from experimental data and computational simulations, our work advances our understanding of how the brain interprets and responds to the visual world, with implications for both neuroscience and artificial intelligence.

Abstract Name: The National Chicken Council vs. the Better Chicken Commitment: Environmental, Ethical, and Public Health Implications of the U.S. Industrial Poultry Debate

The US grows over 9 billion chickens yearly yet best production practices are heavily contested. The two opposing parties involved in the debate — the National Chicken Council and Better Chicken Commitment activists — clash primarily on one critical component of industrial production: the growth rate of the chicken. Their perspectives diverge on which direction the growth rate should move — up or down. Yet, the arguments for both sides are (1) ripe with misaligned incentives and (2) supported by contradictory claims and evidence. My thesis provides three additions to the poultry debate. First, supplementary calculations on central questions that are understudied, e.g. calculations on the differential greenhouse gas effects of the variable feed compositions and feed conversion rates. Second, a qualitative meta-analysis of methodology to standardize outcome variable units, i.e. provide guidelines for what units of interest are pertinent and what analyses are methodologically sound. Third, a comprehensive overview of all relevant externalities of both systems in order to avoid oversimplifying the conversation to a singular metric such that the debate overlooks the core issue: maximizing total social welfare. Through these three additions, I develop a base of evidence to support policy that promotes faster-growth chicken production, highlighting that widespread adoption of industrial slow-growth chicken production would lead to (1) substantially higher and critically unsustainable environmental externalities, (2) increased chicken suffering due to a larger population of industrially raised chicken, and (3) a significant decrease in the protein purchasing power of low-income households in the United States.

Abstract Name: Comparison of Metabolic Functions in the gut bacterial family Eggerthellaceae in Non-human Primates

The gut microbiota consists of trillions of microbes and is crucial in health and disease in vertebrates, including humans and other primates. Eggerthellaceae, a bacterial family in the mammalian gut microbiome, is important in various specialized metabolic processes. Although this family is common in mammals, their

roles in non-human primates (NHPs) remain largely unexplored. This study investigates how Eggerthellaceae metabolic functions vary across primate hosts, focusing on conserved core metabolic pathways and specialized genes involved in flavonoid and lignan metabolism. We analyzed 12 high-quality Eggerthellaceae metagenome-assembled genomes (MAGs) from the gut microbiomes of 5 NHP species. We annotated metabolic functions using DRAM, RAST-tk, metabolic modeling, and BLAST, comparing the results to the common human gut microbe *Eggerthella lenta*. Our preliminary results reveal that Eggerthellaceae in NHPs share many but not all metabolic traits. For example, amino acid transporter profiles differ between NHP strains. *Senegalimassilia*, a genus in primate gut microbiota, exhibits more similarity to human-associated strains than other genera. Additionally, none of the NHP genomes contain genes similar to the *ber* lignan reductase in *Eggerthella lenta*. Our ongoing work includes identifying additional genes involved in polyphenol metabolism and investigating the potential coevolution between Eggerthellaceae and NHPs. These efforts aim to deepen our understanding of how host phylogeny and dietary adaptations influence the metabolic functions of Eggerthellaceae in primate gut health. This variability could provide new insights into the evolution of gut microbiota and how its functional roles differ between humans and NHPs.

Abstract Name: Examining gene expression differences in transgenic *Drosophila* model of neurodegeneration using qPCR

Deposition of the microtubule-associated protein tau is a hallmark pathology of the family of neurodegenerative diseases known as tauopathies, including Alzheimer's disease, frontotemporal dementia, and chronic traumatic encephalopathy. Ongoing work on mechanisms of tau-mediated neurodegeneration suggests that genetic contributions interact with peripheral or environmental factors to contribute to disease onset and severity. Our lab uses *Drosophila melanogaster*, the fruit fly, as a transgenic model of human tauopathy. Using a screen to identify genetic modifiers of neurodegeneration, we selected multiple gene targets to examine expression differences in tau transgenic flies compared to controls. qPCR results showed notable differences in gene expression in transgenic *Drosophila* expressing human tau protein in neurons, suggesting aberrant regulation of multiple cellular processes central to neurodegeneration. Taken together, these results imply that these gene pathways holds promise in pursuing therapeutic targets aimed at mitigating associated neurodegeneration.

Abstract Name: Frontal Alpha Asymmetry and Emotional Processing in College Women with Different Levels of Body Dissatisfaction

Body dissatisfaction, characterized by persistent negative self-perception, is shaped by an internalized perception of the thin ideal reinforced by social media. It is linked to anxiety, depression, and disordered eating, yet its cognitive and neural underpinnings remain underexplored. This study investigates frontal alpha asymmetry (FAA), an EEG marker of emotional and motivational processing, in college-aged women with varying levels of body dissatisfaction. FAA reflects the balance of brain activity between the left and right frontal hemispheres, where greater right-sided activity is often associated with negative emotions and withdrawal behavior. We hypothesize that: (1) participants exhibiting on average negative FAA scores during the Flanker task will exhibit greater attentional interference in reaction time and accuracy when responding to high vs low body shape stimuli; and (2) participants with higher scores on the BSQ will exhibit greater right-sided frontal alpha asymmetry (FAA < 0) with high body weight stimuli, reflecting more negative emotions and withdrawal behavior, suggesting a link between body dissatisfaction and negative emotional processing. Participants completed surveys assessing body image and eating attitudes, followed by a selective attention task using a modified Eriksen Flanker Task. Stimuli included body-only images categorized as underweight, healthy, or overweight, with targets superimposed. EEG data, recorded at 160 scalp electrodes, measured alpha power asymmetries during task performance. Ongoing analyses focus on comparing FAA across body dissatisfaction groups and its relationship with task performance metrics, such as reaction time and accuracy. Preliminary expectations suggest that individuals with high body dissatisfaction will display more withdrawal-related FAA (right-sided alpha power), particularly in response to overweight body stimuli. This research aims to advance our understanding of the neural mechanisms underlying body dissatisfaction and its emotional and cognitive dimensions, contributing to the broader field of body image research.

Abstract Name: Action for change: Exploring volunteers' motivations to bolster environmental conservation

The climate crisis is one of the foremost global challenges of our time. Widespread degradation driven by human activities threatens ecosystems, human livelihoods, and global stability, requiring urgent, coordinated action to reduce harmful practices, address current crises, and prepare for future impacts. Large scale coordinated efforts are vital to address the myriad of issues affecting the Earth, and local volunteer communities have the potential to address this labor gap. Every individual is capable of supporting a conservation initiative's impact through hands-on action. This transdisciplinary qualitative case study explored the motivations driving individuals to volunteer at the wildlife rehabilitation center the Australian Seabird and Turtle Rescue (ASTR) in Ballina, New South Wales, Australia, in the hopes that identifying these motivating factors can assist in developing effective recruitment strategies for nonprofit conservation efforts. Running from September to November 2024, the study employed a participatory action research framework along with collective action theory, and combined surveys, semi-structured interviews, and participant observation to gather qualitative data. Findings reveal that most volunteers fall into two categories: retirees and students seeking experience. In addition, this study discovered that numerous volunteers cited concerns regarding the local environment as a primary motivator for their actions, whereas the broader issue of the global climate crisis was rarely mentioned. Additionally, participants frequently mentioned the presence of a

positive and meaningful community as a key reason for attendance. This case study suggests that organizations effectively retain volunteers when they are invested in the mission, enjoy their time working, and have the free time to dedicate to volunteering. Community engagement approaches based on bolstering these qualities may have the potential to strengthen conservation efforts by encouraging volunteers to be more likely to commit their time and resources to the organization.

Abstract Name: A Comprehensive Database Collection for Alzheimer's Disease: Organizing Key Research Domains to Enhance Diagnostics and Treatment

Alzheimer's disease (AD) is a neurological disorder that is progressive and characterized by gradual degeneration of brain cells. This disease results in the decline of cognition, memory, and behavior. According to the National Institute of Aging, AD is currently ranked 7th leading cause of death in the U.S. Our research objective is to review existing computational methods and databases for further AD research. The paper starts with a brief introduction about AD, computational methods and databases. The computational methods focus on Molecular Dynamic (MD) Simulation and Machine Learning models. The next section talks about clinical and scientific databases including International Alzheimer's and Related Dementias Research Portfolio and the National Alzheimer's Coordinating Center amongst others. These databases are classified into different categories such as biomarkers, genetic research, and many other categories. In the application section, this paper introduces applications related to AD treatment, early detection, and progression. This research aids medical professionals, researchers, and pharmaceutical companies with valuable data to improve AD research and treatment.

Abstract Name: Investigating the Effects of DNA Ligase III Knockdown on HSV-1 Infection

Herpes simplex virus type 1 (HSV-1) is an ~152 kb double-stranded DNA virus that infects over half of the population. As an abiotic obligate parasite, HSV-1 uses cellular factors for propagation. Our lab previously found that DNA Ligase III (Lig3) associates with HSV-1 DNA. Lig3 is a eukaryotic, ATP-dependent enzyme that facilitates phosphodiester bond formation to anneal single strand nicks that form during DNA repair and Okazaki fragments during DNA replication. We hypothesize that HSV-1 recruits cellular Lig3 to help facilitate viral DNA replication or repair and predict that Lig3 knockdown will decrease viral yield. We identified an antibody targeting Lig3, confirmed that Lig3 levels remain consistent during infection, and optimized siRNA-mediated Lig3 knockdown conditions. We also determined how Lig3 knockdown affects viral yield through plaque assays. Data demonstrate a two-fold decrease in viral yield, indicating that cellular Lig3 may play an important role in HSV-1 infection.

Abstract Name: Teleconnections & Topography: Discovering Underlying Relationships Between Sea Surface Temperatures, Snowmelt, and Streamflow

Predicting annual water supply in high elevations of the Western United States between 36° and 41° latitudes has proved challenging due to its position in a transitional zone of correlation with El Nino-Southern Oscillation (ENSO). As a result, the correlations between water supply and ENSO are weak and variable. If predictions are improved, water agencies can implement efficient water resource management, preventing floods or enhancing water storage (Anghileri et. al., 2016). Recent studies have highlighted promising correlations between sea surface temperatures (SSTs) in the Northern Pacific and North Atlantic oceans and snow-water equivalent depth (SWE) data over larger regions of the Western United States, suggesting an opportunity to enhance water supply predictions (Zhao et. al., 2021, Stone et. al, 2023). To date, this study has determined relationships between SSTs and SWE on opposing slopes of several North-South and East-West oriented mountain ranges, assigning SST prediction centers to each local slope. The next phase of the research is analyzing the dependency of SWE when predicting streamflow, as variations are expected due to the different mechanisms of SWE accumulation in these regions. A previous study suggests snow accumulation is the dominant contributor in the Western United States, especially in the mountainous northwest regions whereas soil moisture is a larger contributor to runoff for drier southeastern basins (Koster et. al., 2010). The analysis tests SWE from the SST prediction centers and relates it to streamflow by applying the water balance equation. The results of investigating SST-predicted SWE and streamflow in small mountain watersheds have yet to be determined, however, data suggest the dependency will vary based on the local soil moisture, evapotranspiration, and additional hydrological factors of each location.

Abstract Name: Analyzing the Impact of Nonprofit Healthcare Status in Pittsburgh and the Impact on Community Health and Accessibility

The research investigates the impact of nonprofit healthcare organizations in Pittsburgh, with a primary focus on University of Pittsburgh Medical Center (UPMC) and Allegheny Health Network (AHN). The central question addresses whether these nonprofits sufficiently justify their tax-exempt status by contributing to community health and accessibility, particularly for low income populations. This research aims to provide a comprehensive analysis of the role these organizations play in Pittsburgh's healthcare landscape, examining their financial setups, community contributions, and the challenges they face in fulfilling their charitable missions. The research takes place within broader debates on the accountability of nonprofit healthcare entities, contributing to an understanding of how these institutions balance their mission with the financial advantages of tax exemption. Methodologically, the study employs a literature review of existing reports and media coverage, quantitative analysis of financial data—including tax exemptions and expenditures on

community benefits—and case studies of community health initiatives. Additionally, the qualitative data includes discussions with stakeholders to provide qualitative insights into perceptions of these organizations' impact. Preliminary findings indicate that, while both UPMC and AHN offer essential services for low-income communities, there are ongoing concerns about the adequacy of these contributions relative to the tax revenue lost due to their exemptions. UPMC, for example, is criticized for prioritizing profit-oriented practices over its charitable mission, sparking local calls for increased accountability. Expected outcomes of this research include policy recommendations for enhancing nonprofit accountability, such as strengthening Payment in Lieu of Taxes (PILOT) agreements, and identifying best practices in community engagement that could be expanded to ensure more equitable access to healthcare. This study ultimately seeks to inform policy changes that balance financial sustainability with nonprofit organizations' obligations to support the communities they serve.

Abstract Name: The Effect of Outdoor Mindfulness Practices on Nature Connectedness and Mindful Awareness

Decades of psychology and neuroscience research have demonstrated the ways in which mindfulness practices alter brain wave patterns and, over time, can alter individuals' dispositions and brain structures. In this mixed-methods study, we investigated the effects of an in-class mindfulness practice. This practice is known as the "sit-spot assignment," where students spend up to 15 minutes in a natural setting, taking notes on details noticed via utilization of the different senses and journal about their observations. This research explores how participating in repeated sit-spots impact students' connectedness with nature and mindful attention awareness. Participants completed pre- and post-surveys to measure their connectedness to nature and mindful attention awareness. Students completed eight sit-spots in total: The pre-survey was completed prior to the first sit-spot assignment and the post-survey was completed after the final sit-spot. Pre- and post-survey results were compared using a between-subjects t-test and by calculating the effect size. After the intervention, students completed a project and reflection to demonstrate their learning during the corresponding unit, which were analyzed qualitatively for the impact of the sit-spot intervention. With intentions of gaining a broader understanding of the effect of the mindfulness activity, as well as to serve as a control group, data was also collected from students participating in a study abroad course in Panama. The intention behind this was to make a comparison between the data collected from students who participate in the "sit-spot assignment," and those who did not, but still spend extended periods of time in nature. Preliminary results demonstrate benefits for both mindfulness and nature connectedness in the sit-spot group.

Abstract Name: Correlations between median household income and electric car registrations by county

within the United States and how they can be used to help fight climate change

This study explores the correlation between median household income and the population of electric vehicles (EVs) registrations by county within the United States, aiming to predict EV populations in other countries across the globe. By analyzing data from each county's socioeconomic situations and the electric vehicle sales and registrations within those counties, I investigated whether higher incomes correspond with greater EV adoption rates. Using a combination of statistical analysis and machine learning models, my research provides insights into the socioeconomic factors influencing EV ownership. My findings indicate a significant positive correlation between median household income and the number of electric vehicle registrations, suggesting that higher-income counties tend to have more EVs. This correlation can be used to predict EV adoption patterns in other regions with similar socioeconomic characteristics. Moreover, the implications of my work extend beyond the United States, as the methodology can be adapted to forecast EV populations in different countries, contributing to global efforts in understanding and promoting sustainable transportation. This correlation can be used to help electric vehicle companies understand where there are less sales in certain areas within the same states and areas and use this to help them make sales to continue trying to make the earth a cleaner place to live. States can also use this information to see where certain laws for electric vehicles may help while other areas might be hurt by these new laws and also can be used to help the states boost up certain counties median incomes to help try to facilitate more electric vehicle sales to help the state have cleaner air. This can also help other countries across the world bring up EV usage in places that are lacking and can look at this to help bring it up and help create a cleaner world.

Abstract Name: Unexpected Sexual Dimorphism in Thirsty Water Seeking through Peptidergic Signaling in *Drosophila melanogaster*

Thirst is a highly motivated state that drives a sequence of behaviors to ensure proper balance of water to meet the body's needs. We quantify water intake, water seeking, and feeding behavior to assess thirst levels and discover the thirst circuitry in fruit flies. We primarily assess water-seeking behavior to reveal the fly's motivation to find water, reflecting the want for water. Both sexes need water and express the same thirst-related behaviors for water homeostasis. However, we discovered AstAergic (Allatostatin A; homologous to kisspeptin/spexin/galanin) thirst neurons called Janu-AstA in fruit flies that promote water seeking in males only. Janu-AstA also inhibits feeding behavior and encodes for reward suggesting Janu-AstA encodes for the rewarding anticipation of water when thirsty. We expanded the sexually dimorphic water-seeking circuit by discovering male-specific NPF (Neuropeptide F; homologous to NPY) neurons, the NPF-Ms, are downstream of Janu-AstA. NPF-Ms inhibit water-seeking and courtship behavior in males. My research aims to test the involvement of NPF-Ms in water intake and feeding behavior to uncover the complete role of the sexually dimorphic NPF-Ms in the thirst circuitry. Since NPF-Ms are downstream of Janu-AstA, we hypothesize NPF-Ms inhibit feeding behavior without affecting water intake behavior like Janu-AstA. Our findings lay the foundation of sexual dimorphism in thirst that allows us to further test the circuitry underlying differences in motivational states between males and females.

Abstract Name: Identification of SOX2 Transcription Factor Binding Partners During Zebrafish Hearing Regeneration and Development

Hair cells (HC) are mechanosensory receptors that reside in the inner ear and are responsible for hearing in vertebrates. While damage to the mammalian inner ear HCs is irreversible, non-mammalian species have an innate capacity for hair cell regeneration (HCR) after injury to HCs. In zebrafish, regenerative capacity of HCs depends on the activation of a pool of surrounding cells called supporting cells (SCs) into new HCs, but the mechanistic details of the pathway controlling this transition remain elusive. Previous single-cell experiments suggest that during HCR, the SOX transcription factors (TF) are recruited to enhancers in the supporting cells to trigger a regenerative response, while both SOX and SIX family of transcription factors are recruited to enhancers in cell types that have already been specified to lock in a HCs specific fate. Of particular interest is the SOX2 TF, whose expression increases significantly as SC transdifferentiate, and altering expression of SOX2 causes a disruption in HCR in the inner ear. Considering SOX2's known role as a stem cell pluripotency factor that can interact with regulatory proteins in complexes such as SOX5/6 and OCT4 during development, we are positioned to address if SOX2 is able to interact with other proteins in zebrafish to successfully drive the HCR program. We hypothesize that SOX2 is involved in binding interactions with proteins that co-regulate DNA expression and impact SOX2's ability to drive HCR. We describe a method to purify SOX2 complexes from larvae whole-body cells and adult zebrafish inner ear HCs. We have successfully generated a zebrafish line with the HA (hemagglutinin) tag attached to SOX2 and detected intracellular SOX2-HA complexes with an anti-HA tag antibody. Co-immunoprecipitation of larval zebrafish cells containing SOX2-HA complexes has revealed at least one major SOX2 complex in larval zebrafish and will now be confirmed using mass spectrometry.

Abstract Name: L'Amore Infranto: The Sustainability of Opera in American Society Past 2024

In our lifetime, we may witness the death of an art form in America. Opera is difficult to sustain if sufficient rewards are not earned after thousands of dollars are spent on one production. Many regional opera houses in America have found it difficult to fill seats after COVID-19, and they struggle to set up a system of alternative entertainment (and alternative funds), as San Francisco and the Met have done. Even then, are those funds sustainable? My research project will address the lives of the thousands of people who have dedicated their lives to the opera industry but face an uncertain and seemingly bleak future. By analyzing attendance statistics for opera houses, conducting interviews with artists, and exploring historical context, I aim to uncover whether or not this expensive form of art can survive in the changing cultural landscape of America. The research and presentation will cover several areas of focus, including how social media, COVID-19, and the lack of government funding have affected the industry. My project references multiple pieces of scholarly writing, credible articles, and comprehensive data, some of which I have acquired through

the Atlanta History Center. The project's goal is to produce a valuable resource for struggling opera houses looking for industry insights that will improve their way forward. Ideally, the project will aid in reinforcing the longevity of opera in the United States. Opera students, patrons, and nearly all community members in the American operatic industry will be able to benefit from the information and insights presented in the project, and the transmission of this project in presentation form may bring a wider attention to career-jeopardizing issues within the operatic realm.

Abstract Name: Utilizing Technology to Improve Medication Adherence in Transplant Recipients

Organ transplantation has been a successful treatment option for patients experiencing organ failure because of the use of immunosuppression therapies. Without immunosuppression patients are at risk for rejecting their transplanted organ. These therapies are widely known to be rigorous for patients to manage. Because of this, there is a significant prevalence of nonadherence to these regimens. There is evidence that certain demographics and characteristics of patients make them more likely to be nonadherent such as young age, lack of social support, lower education, and lower economic status. With the advancements of technology in the healthcare setting, research shows that utilizing technological tools is a feasible intervention to help transplant recipients adhere to their medications with the engagement and monitoring of healthcare inclined personnel. Nurses are an important part of a transplant patients care team as they spend an ample amount of time with them performing assessments, education, and evaluating their treatment outcomes. The aim of this project is to contribute high quality research to transplant patient care lead by self-efficacy nursing theory. This project proposes a 16-week quality improvement study to research the effects of patients' medication adherence utilizing a mobile health app, and wireless pillbox, with interventions and coaching provided by a nurse guided by nursing theory. Purposive sampling will be utilized to recruit 30 patients from an outpatient transplant clinic. Data will be collected using the wireless pillbox, and standardized assessments. Results from this research have the potential to improve the standard of care for transplant recipients and provide them with new tools to help them effectively manage their treatment. Keywords: organ, transplant, medication, adherence, technology

Abstract Name: Screen Time, Social Media, Social Media Dependence, and Sleep Quality: A Correlational Analysis

This study aimed to determine if compulsive cellphone usage and social media addiction were correlated with poor sleep quality. Previous literature showed a correlation between social media use and poor sleep quality,

particularly when used directly before bed. Research also revealed correlations between compulsive cellphone use and various adverse side effects. In consideration of the literature, the following hypotheses were proposed. First, compulsive cellphone usage scores positively correlate with social media dependence scores. Second, social media dependence scores will correlate positively with sleep disturbance scores. The third hypothesis is that social media dependence scores positively correlate with sleep quality scores. In order to test, the Brief Pittsburgh Sleep Quality Index (B-PSQI), the Bergen Social Media Addiction Scale (BSMAS), and the Compulsive Cellphone Use Questionnaire (CCQ) were administered for this study. After IRB approval, instrument packets and consent forms were distributed in classrooms with permission from professors. Participation was voluntary and confidential. One hundred twenty-six ($N = 126$) undergraduate students participated in the study. The participants were students of all classifications from Introduction to Biblical Faith, World Civilization Ancient/Medieval World, General Chemistry I, and General Psychology classes. The collected data were analyzed in SPSS using a Pearson correlation analysis. Compulsive cellphone usage did not correlate with poor sleep quality at $r = .066$, $p = .233$ one-tailed. Social media addiction scores were unrelated to sleep quality scores, $r = .043$, $p = .317$ one-tailed. In contrast, compulsive cellphone use scores were moderately correlated with social media dependence scores, $r = .669$, $p < .001$ one-tailed. Limitations included possible response bias, differences between actual and observed sleep quality, and the lack of a convenient way to gather exact screen time. Future researchers should include an exact screen time questionnaire and a full PSQI survey.

Abstract Name: Analysis of Hormonal Patterns in PCOS Across Ages Using MIRA (A fertility app)

This research investigates fertility trends in women using the MIRA fertility tracker, focusing on the hormonal health of individuals with and without polycystic ovarian syndrome (PCOS). By analyzing key hormones—luteinizing hormone, progesterone, and estrogen—we aim to identify patterns in hormonal fluctuations with age. The data, self-reported through the MIRA app, provides recordings of hormone levels via urine analysis to predict menstrual cycle phases, particularly ovulation. Menstrual health conditions, such as PCOS, are reported within the app and significantly impact reproductive health by causing irregular, infrequent, or prolonged cycles, which affect ovulation and overall fertility. To statistically model these patterns, we utilize a Hidden Markov Model (HMM) to analyze hormone trajectories in regular and irregular cycles. This approach enables us to uncover hormonal trends across age groups, comparing individuals with and without PCOS. Our findings enhance the understanding of menstrual cycle variability influenced by health conditions and age, offering valuable insights into fertility prediction and reproductive health management. These results could contribute to more personalized and effective approaches in fertility tracking and reproductive healthcare.

Abstract Name: Mino-bimaadiziwin: an Ojibwe Musical Pedagogy

Originally, the research questions below were meant to answer my question of Indigenous presence in US music curriculum and possible parallels to other influences of music. What I found was pervasive Whiteness (Koza 2010) in the literature and primarily white voices determining the authenticity of Indigenous narratives (Connell and Gibson 2004) (Crawford 2001). As a result of this I intentionally put the focus and perspective on Indigenous voices. I conducted qualitative research; my method was narrative inquiry. This was done by purposeful interview. After a follow-up interview, Taskapa and I created a pedagogical framework based off the Ojibwe way of life known as Mino-Bimaadiziwin, The Good Life. My research questions include: What was the social climate for Lake Superior Ojibwe during their time of engagement with music teaching and learning? How were Lake Superior Ojibwe exposed to music? How did Lake Superior Ojibwe view the impact of music education policies and curriculum in relation to their cultural values and practices?

Abstract Name: Racial Discrimination and Relationship Outcomes: A Meta-Analysis

Discrimination has been associated with poorer physical health, greater depressive symptoms, and greater relationship strain for the person who experiences discrimination (target) and their partner. One possible explanation for this outcome could be stress spillover which posits that stressful life circumstances drain an individual's self-regulatory resources. This depletion of self-regulatory resources has been shown to mediate the relation between daily stress and marital satisfaction. However, other research has shown that individuals who faced more frequent daily discrimination and blamed their partner for negative behaviors caused by stress were more likely to report a mutual approach to coping with discrimination and more positive relationship qualities, implying that a shared view of discrimination may be beneficial. In support of this finding, longitudinal research with African American couples has found experiencing racial discrimination is related to higher quality of support. Thus, the link of discrimination to relationship outcomes is unclear. Because relationships are a resource that buffers the negative effects of stress—possibly including discrimination—it is important to understand this link. To do so, we undertook a meta-analytic review of the literature on the relation of discrimination to relationship outcomes, including social support, relationship satisfaction, and relationship conflict. Following the PRISMA protocol, we have undertaken an exhaustive literature search, screened through abstracts and full texts, and extracted methodological characteristics and study results. This meta-analysis will allow us to identify the link between discrimination and a host of relationship outcomes as well as moderators of that link.

Abstract Name: Effect of Caffeine Intake on Bidirectionality of Sleep and Pain Relationship

One-third of college students report obtaining less than seven hours of sleep per night, the minimum recommended amount for adults. Poor sleep has been linked to adverse conditions, including increased pain, which can be exacerbated by factors such as caffeine intake. Caffeine, a common stimulant among college students, has been shown to interfere with sleep quantity, potentially influencing pain perception. A decrease in caffeine intake may lead to withdrawal symptoms, causing an increase in pain. Based on these findings, we hypothesize that higher caffeine intake will be inversely related to pain reports and sleep quantity.

Additionally, we hypothesize that a 1-hour nightly sleep extension for one week will improve pain outcomes and reduce caffeine intake. To test these hypotheses, baseline data was collected from college students aged 18 to 24 during a week of normal activity. Participants were then randomly assigned to either a sleep extension group (≥ 1 hour per night) or a control group and data was collected for an additional week.

Physiological and lifestyle data was collected—including self-reports of caffeine intake, sleep, and subjective pain levels. Daily surveys were used to measure caffeine intake, sleep quantity, and self-reported pain.

Objective sleep quantity was measured with actigraphy, looking at variables such as total sleep time (TST) and time in bed (TIB). We report on baseline correlations between sleep metrics, caffeine intake, and pain measures, as well as the differences between the baseline and sleep extension week for reported pain and caffeine intake. The findings from this research can inform us about the complex relationship between caffeine, sleep, and pain, providing insights that may help reduce the burden of sleep deficiency on pain-related outcomes.

Abstract Name: A Novel Protocol for Utilizing AI to Advance Scientific Research

A team of student researchers investigated the potential of AI technology to enhance undergraduate research strategies in biology including clinical applications and environmental topics. After investigating prompt engineering and ethical considerations, researchers created a novel protocol for fellow students that had a stepwise approach to best practices for utilizing AI in designing scientific studies. This work evaluated five different chatbots as well as NotebookLM, Scholarcy, Connected Papers, and Elicit. After evaluating several trials, significant trends were noted. Regarding prompt architecture, data showed that formulating the correct question was essential in acquiring accurate output. Prompt analysis indicated the importance of specificity

and clarity as given by this breakdown: specifying the format (40.0%), establishing a timeline for references (40.0%), and requesting a particular word limit for output (20.0%). Further trials with Gemini, Claude, ChatGPT revealed a success rate (66.7%) where ChatGPT's failures were discovered under identical parameters. In another study to determine the practicality of AI for real-life applications in biology, data indicated several options with this breakdown: analytical application (33.3%), biological explanation (33.3%), study assistance (16.7%), and laboratory assistance (16.7%). Another set of experiments indicated a breakdown for ethical considerations such as validity for AI responses (28.6%), privacy concerns (28.6%), and unethical use (42.8%). These findings served as the vision of the stepwise protocol for utilizing AI in biological undergraduate research both efficiently and ethically. Interestingly, student researchers gained new skills toward career readiness through high-impact practices such as collaborative work and the application of technology through a common intellectual experience. Consequently, the student-created protocol enhanced scientific research for the other groups of researchers and became a successful model for the division, particularly aligning with the institution's mission of service to others.

Abstract Name: Examining the Disparities Faced by High-Achieving Rural African American Adolescents

This study examines the academic experiences of high-achieving rural African American students, a group significantly underrepresented in research. Two primary questions guide it: 1) How do high-achieving rural African American adolescents describe their school experiences? and 2) What factors shape their school achievement? The study explores the role of family, peers, and teachers in fostering students' academic resilience. This qualitative study utilized a convenience sample of 32 high school students in grades 9–12 (25 females and seven males) with an average GPA of 3.55. Each student participated in interviews about their beliefs regarding education and the influence of family, peers, and teachers on their academic success. Sample interview questions included: What does it mean to be a high-achieving student? Walk me through a day in the life of a high-achieving student, and What or who encourages you to do well in school? Semi-structured interviews, lasting 45–60 minutes, were conducted in person at "Allegheny High School" (a pseudonym). Using thematic analysis, the researcher examined each interview for recurring themes and patterns. Each recording was reviewed, and transcripts were carefully analyzed to ensure accuracy, with notes taken to identify shared and divergent perspectives across participants. Six prominent themes emerged regarding students' views of and experiences with school: Education for Liberation, Achievement as Purpose, Stumbling into College, Invisible Me, Schools as Gatekeepers, and Parents as Partners. The data highlight each student's resilience. Findings suggest that, for the rural students in this study, excelling in school was about more than advancing their personal academic and professional opportunities—it was about contributing to and uplifting their community. This research seeks to deepen the understanding of marginalized African American students and identify factors that support their academic success.

Abstract Name: Fungal Diversity on the Penn State Behrend Campus

Biodiversity is vital in maintaining the ecological balance of the environment. Understanding fungal diversity can give insight into the conditions and health of an area. A great way to promote the beauty and importance of biodiversity is through field guides and catalogs. The goal of this research is to create a Fungal Diversity catalog of the Penn State Behrend campus by collecting fungal samples, extracting the DNA from the samples, amplifying that DNA, and classifying each fungal species. Fungal samples were collected on the Penn State Behrend campus and from surrounding areas. The fungal Genomic DNA extraction protocol from Strauss et al. was followed and PCR (Polymerase Chain Reaction) was then implemented to amplify the fungal DNA. The samples will be sent for sequencing and the results will be used to compile the catalog. This project will continue throughout the seasons to provide a thorough representation of the fungal diversity on the Behrend campus. The completion of a Fungal Diversity Catalog will give insight into the diversity of the Penn State Behrend campus environment. The catalog will also encourage students to spend time outdoors identifying fungus and observing biodiversity in nature.

Abstract Name: The Effects of Microbial Communities on Leaf Litter Decomposition Due to Exposure to Different Environmental Factors and Differing Leaf Types

Decomposition of leaf litter is impacted by a multitude of factors such as what microorganisms are present, environmental influences, and what enzymes are released. Different leaf types are uniquely impacted by these factors and impact the overall rate of degradation. This then goes on to affect the ecosystem around it by altering nutrient cycling (CO₂ and Nitrogen), soil health, and the overall composition of the decomposers communities in particular areas. To better understand differences in leaf decomposition, two different leaf litter types, one native to Southwestern Pennsylvania, Sycamore (*Platanus occidentalis*), and other invasive, Knotweed (*Reynoutria japonica*), were collected bi-monthly for 8 months. To account for environmental influences that may impact degradation, samples were collected from the ground and the water. DNA was extracted from all leaf types and the 16s and 18s was sequenced to identify the bacterial and fungal communities. Sequences were analyzed to identify differences in microbial composition. During the same time period, leaves were also collected weekly and five enzymes (cellulase, pectinase, acid phosphatase, polyphenol oxidase, and chitinase) concentrations were tested. The differences identified between the two groups of leaves suggest that decomposition, while driven by similar organisms and processes, vary between Sycamore and Knotweed species. Comparing and contrasting the various microbiomes found on two different leaf types under different environmental conditions can lead to a better understanding of the microorganisms involved in degradation, the enzymes produced, and what environment is most favorable.

Abstract Name: Comparing the effects of different environmental factors on seizure behavior in *Drosophila*

Epilepsy affects around 50 million people worldwide. It comprises a diverse array of seizure types and causes, including both genetic mutations that affect nerve cell activity and factors such as traumatic brain injury, congenital abnormalities, and brain infections, as well as unknown causes. Individuals may therefore have distinct types of epilepsy and may be affected differently by environmental factors. In this study we used the fruit fly, *Drosophila melanogaster*, to compare how environmental factors affect seizures in four different genetic mutants associated with epilepsy: paralytic (para), ether-a-go-go (eag), easily shocked (eas), and kazachok (kcc). Each gene affects a different aspect of neuronal function and has a human homolog. Mutant and wild-type flies were exposed to four environmental factors; two triggers – sleep deprivation and hypoxia – meant to trigger seizure-like activity, and two preventative factors – vitamin B6 and folic acid. Once exposed, seizure activity was induced, recorded, then compared against flies that were not exposed to environmental factors and to wild-type. Preliminary data indicates that hypoxia has the biggest influence on seizure activity, increasing the likelihood and duration of seizures in all mutants. Surprisingly, sleep deprivation only increased the likelihood of seizures in one mutant. Folate decreased the length of seizure episodes for some mutant genotypes, suggesting it could be an effective treatment for some forms of epileptic seizures but not all. Vitamin B6 did not appear to decrease seizure activity for any of the mutants tested, suggesting it may not be broadly applicable preventative measure. Understanding the factors that influence seizure susceptibility and cause seizure variation in different types of epilepsy will help to better understand how to prevent seizures.

Abstract Name: Early-life adversity alters microglia-mediated synaptic refinement of corticotropin-releasing hormone-expressing neurons

Early-life adversity (ELA) is a risk factor for developing neuropsychiatric disorders like depression. The central nucleus of the amygdala (CeA) is a stress-sensitive region of the brain, involved in reward-related behaviors. Recently, we showed that ELA provokes anhedonia-like behaviors in males, mediated by corticotropin-releasing hormone (CRH) overexpression in the CeA. In the paraventricular nucleus of the hypothalamus (PVN), another stress-sensitive brain region, we find that diminished microglial engulfment of excitatory synapses onto CRH⁺ neurons is a key mechanism that contributes to altered stress responsivity of male mice exposed to ELA. Interestingly, these two stress-sensitive regions of the brain have different developmental timelines, which suggests the possibility of different critical periods for intervention in the CeA compared to the PVN. There may also be sex-specific effects of ELA and different developmental trajectories between the sexes at baseline. Here, we characterized the developmental trajectory of excitatory and inhibitory synapses onto CRH⁺ neurons in the CeA under control and ELA conditions in males and females. To investigate these developmental changes, we induced ELA using limited bedding and nesting from postnatal days (P)2-10. We employed male and female single-reporter mice (CRH-tdTomato⁺), in conjunction with immunohistochemistry to label pre- and post- synaptic excitatory and inhibitory puncta. We

find that ELA increases excitatory and decreases inhibitory synaptic inputs onto CeA-CRH+ neurons at P14 in males, but not females. This effect in excitatory synapses has been shown to persist until at least P24 in males, and preliminary data shows a trend for decreased numbers of inhibitory synapses in males as well. Ongoing work is examining the long-term excitatory and inhibitory synaptic changes on CRH+ neurons at the adolescent time point of P45. Future directions will include examining microglia-mediated engulfment of excitatory and inhibitory synaptic puncta to pinpoint the peak of synaptic pruning by microglia in the CeA.

Abstract Name: Connecting Inflation to the NANOGrav 15-year Data Set via Massive Gravity

Several pulsar timing array (PTA) missions have reported convincing evidence of a stochastic gravitational wave background within their latest datasets. This background could originate from an astrophysical source, though there are multiple possibilities for its origin to be cosmological. Focusing on the NANOGrav signal, which was in good agreement with other PTAs, we evaluate the possibility of an inflationary source for the background. However, we'll consider a time-dependent minimal theory of massive gravity instead of standard general relativity for our analysis. We find that an inflationary interpretation will require a strongly blue spectrum, characterized by $n_T = 1.8 \pm 0.54$, while Big Bang Nucleosynthesis limits will require a low reheating scale of $Trh \approx 4000$ GeV. Though these constraints make it difficult for inflation to be the source of the NANOGrav signal, we find that the massive gravity model allows for a greater reheating temperature than standard general relativity, making an inflationary interpretation slightly less cumbersome.

Abstract Name: A Portable Educational Model for an Energy Management System of Duke Energy

This study seeks to outline the procedures for developing an instructional framework for an energy management system designed for Duke Energy's power generation plants. Duke Energy is facing several challenges due to the retirement of power plants reliant on fossil fuels which must be replaced with clean and equally reliable resources. Thus, to meet rising energy utility demand, especially considering ambitious clean energy projects, the company must gain public support, prioritize electricity system education, and attract talented young people. Therefore, the goal of the study is to give a concise and straightforward analysis of how various power generation facilities respond to the daily energy needs of urban regions and during fluctuating weather conditions. To ensure the optimal functioning of the model, a careful selection of both the hardware and software components which guarantees to fulfill the specifications outlined by the sponsor, including lightweight design, plug-and-play capability, synchronization, and resolution while minimizing

costs. The model is used to play and synchronize eighteen videos made from real-time data and MATLAB code, which are played for five minutes using an HTML script. The model includes case studies which engineers may use to assure reliable grid integration of conventional and renewable energy sources while providing an accessible presentation to the public. In addition to the original objectives, Duke Energy has decided to use the model as a training tool for new employees on Energy Management Systems.

Abstract Name: Measurements of Halo CMEs and CMEs in Co-relation with Space Weather

During solar active periods, the Sun forms very high energy areas we call sunspots. These areas release huge amounts of energy in the form of Coronal Mass Ejection (CME) and solar flares sending out large amounts of energy and particles into space. Effects of this on Earth (which is called Space Weather) can range from mild effects on radio communications and weak power grid fluctuations to extreme effects like radio blackout and power grid collapse. Using the Large Angel and Spectrometric Coronagraph (LASCO) provided by the NASA Solar and Heliospheric Observatory (SOHO), we can analyze speed and direction of CME's occurring in the two ranges of C2 and C3. Using coronagraph images with a consistent measurement translation, we can take distances in solar radii and determine a speed. Based on our data and past measurements, an average CME ejection speed is 250-500 km/s, whereas Halo CMEs average speed is around 1000 km/s. We are currently analyzing other parameters like X-rays and proton flux related to CMEs. As this is ongoing research, we are focusing on measurements of those CME generations and level of geomagnetic storms on Earth due to those CMES. Analyzing this data will help us understand the differences between Halo CMEs and regular CMEs and their effect on Space Weather.

Abstract Name: The Impact of a Learning Disorder Diagnosis on an Individual's Trust in Healthcare Providers

Despite advancements in healthcare accessibility and education, there are still many under-researched stigmatized populations at risk for lower health and lacking access to needed healthcare services. These risks are greatly related to patient trust in healthcare systems and their providers. Research is needed to identify these populations and understand how their trust in their providers impacts their healthcare benefits. In this study, we will investigate the relationship between learning disorder diagnoses and levels of provider trust, comparing it with the relationship between mental disorder diagnoses and levels of provider trust. We hypothesize that both a learning disorder and a mental disorder diagnosis will negatively impact levels of

trust in providers, with a more significant correlation for learning disorders. This will be observed in a population of 200-1000 undergraduates tasked to complete a demographic questionnaire and the Trust in Physician Scale. Analysis will be done through a one-way ANOVA comparing 4 groups, individuals without diagnosis, individuals with a learning disorder, individuals with mental disorders, and individuals with comorbid learning and mental disorders. The impact of a learning disorder diagnosis vs a mental disorder diagnosis on trust levels will be discussed, as any potential relationships between these variables would add to the already present literature on provider trust in relation to minority populations.

Abstract Name: The More the Better? The Influence of Greater Genomic Material in the Stress Response of Related Organisms

The possession of an extra set of chromosomes known as polyploidy, reflects an increase in genetic material common among plants. Extra genetic material can cause new gene combinations or lead to different expressions of these genes within the individual plant. It is unknown whether genetic material from polyploidy provides plants with an advantage, disadvantage, or is neutral amid adverse conditions. By changing temperature and water availability, we can investigate any physiological effects and explore the possible differences in gene expression. Using related woodfern species (genus: *Dryopteris*), we investigated the physiology of two parent species, *Dryopteris intermedia* (2n) and *Dryopteris expansa* (2n). We also studied their offspring, *Dryopteris campylopetra* (4n), who possess extra sets of chromosomes. We subjected individuals from each species to environmentally stressful conditions for 48 hours in which the ambient temperature and water availability were not optimal for their growth. We examined their stress levels using fluorescence immediately following the treatment and following three days of recovery. Fluorescence measurements are used as a proxy to indicate the physiological health of the individuals in each species. An increase in the physiological health, marked by increases in fluorescence, of the polyploid offspring in comparison to the parents could indicate that the possession of an extra set of chromosomes provides a stress-response advantage. A lack of a statistically significant difference in stress responses would support the hypothesis that the extra set of chromosomes present has no effect on physiological functioning, perhaps due to inactivation of those genes. A decrease in physiological health, marked by decreases in fluorescence, of the polyploid offspring in comparison to the parents may indicate that an extra set of chromosomes poses a liability. Future work will investigate differential gene expression in this related group of wood ferns.

Abstract Name: Looking at the Rwandan Genocide as the Result of European Colonialist Influences

What was the root cause of the animosity between the Tutsi and the Hutu, and what happened during the Rwandan Genocide? Even though there has been lots of research done into the history of Rwanda and the circumstances that led to the Rwandan Genocide, there is lacking a concise study into the root causes of the genocide. Some experts focus on the influences that governments had in escalating the disunity between the Hutu and Tutsi—which led to the Rwandan Genocide—while others focus on the influences of colonialism. Furthermore, there are many misconceptions about the exact facts and circumstances leading to the genocide. Most of the public is sorely misinformed about the specific details of the genocide and its history. Historical accounts and studies from a variety of historians provide a critical analysis of the genocide and Rwanda's complex history of the country. Eyewitness reports from both the victims and the killers are also crucial elements of this study, as well as documents from the time, such as peace accords and legal records of the trials following the genocide. They provide unique perspectives that offer a better understanding of the realities of the genocide. The most significant root cause of the genocide was the influence of European colonialism on Rwanda and its people. My research shows that the ethnic hostility between the Hutu and Tutsi is a relatively recent development that was orchestrated by colonial authorities and intensified by internal power politics. These findings are significant as they further our understanding of the causes of genocide and add to our knowledge about a recent event in this world's history.

Abstract Name: How Did We Get Here? Queer History told Through Playwriting

"How Did We Get Here?" is a project inspired by "The Revolutionist" by Lauren Gunderson. "The Revolutionist" is a stage play that debuted in 2016. It is about four real and very powerful women during the French Revolution Reign of Terror: Charlotte Corday, Marie Antionette, Marianne Angelle, and Olympe De Gouge. The play uses theatre to help audiences learn about how these women contributed to this time in history and their impact. This project mirrors "The Revolutionist" by highlighting powerful queer (LGBTQ+) figures from across history, such as Marsha P. Johnson or Billy Tipton. "How Did We Get Here?" explores the journey of queer liberation from Stonewall to gay marriage being legalized. It will highlight how far queer liberation has come while drawing attention to the progress we have made, but also the way the fight remains the same. "How Did We Get Here?" will utilize aspects of verbatim theatre, a form of documentary theatre based on direct quotes from historical figures. Queer history is often overlooked, especially in the K-12 setting. Queer history is considered part of the null curriculum. The null curriculum, or excluded curriculum, is what is not taught in schools. "How Did We Get Here?" will utilize performance art and theatre as an accessible avenue to foster a better understanding of queer history and dispel the null curriculum.

Abstract Name: Factors Associated with Access to Prescription Medications for Treatment of Opioid Use

Disorder for Pregnant Women in Rural Appalachian Communities

Rural Appalachia's opioid pandemic has led to an influx of pregnant mothers with opioid use disorders (OUD). OUD can cause adverse maternal and neonatal outcomes including stillbirth, neonatal opioid withdrawal syndrome (NOWS), preterm labor, and maternal death. Medications for Opioid Use Disorder (MOUD) help reduce cravings and relapse which are essential outcomes for both the infant and mother. However, despite the known benefits of MOUDs, pregnant women are still facing many barriers to receiving a prescription dose of these medications due to the restrictions placed on providers. Rural Appalachian women face additional unique challenges such as limited access to automobiles, increased distance to providers, lower income rates, decreased health literacy, polysubstance abuse, and low quality insurance. While there is extensive research on access and barriers to receiving MOUDs, there is a lack of research on the specific population of pregnant women in rural Appalachian areas. There is also limited quantitative research that analyzes a wide range of factors that could pose as barriers or stigmas to receiving an MOUD. The purpose of this study is to evaluate what barriers and protective factors exist that prevent pregnant mothers from being prescribed MOUDs in rural Appalachia. A descriptive, quantitative study using secondary analysis from Dr. Jennifer Miller's data set with a non-experimental research design was used for this study. In total, using convenience sampling, 120 women living in rural Kentucky participated in the study and gave consent to use their data. Analysis indicates that presence of prenatal care, hepatitis C status, polysubstance abuse, and admission to hydrocodone use and percocet use are significant predicting factors in whether or not a mother was prescribed an MOUD.

Abstract Name: "Revolution in Red: The Evolution of Reusable Menstrual Products Before and After WWII Through an Intersectional Lens"

My research examines the evolution of reusable menstrual products from the early 20th century through the post-WWII period, emphasizing the intersection of gender, class, race, disability, and sustainability. The study explores how reusable menstrual products, such as cloth pads and menstrual cups, were marketed, produced, and perceived before and after WWII, considering both social and economic contexts. Before the war, menstrual hygiene was primarily managed with homemade or reusable solutions, which were often passed down through generations or improvised with locally available materials. However, this shifted with the rise of mass-produced disposable products during the post-war consumer boom, driven by advertising campaigns that equated disposability with modernity, convenience, and even hygiene. Using archival materials, advertisements, wartime rationing reports, and other primary sources, I will uncover how wartime resource conservation efforts impacted the availability and continued use of reusable menstrual products, contributing to the eventual commodification of menstruation and the normalization of disposables after 1945.

Furthermore, my analysis employs an intersectional framework to examine how factors such as race, class, disability, and region influenced people's access to different menstrual technologies. While wealthier women could afford newly introduced disposable products, many working-class, disabled, and rural women continued to rely on homemade or commercially available reusable options, creating a clear divide in menstrual care practices across different demographics. Additionally, my research critiques the environmental consequences of the mid-century shift toward disposability and reflects on contemporary movements advocating for a return to sustainable menstrual practices, aligning with broader environmental and feminist activism. By tracing the trajectory of menstrual products across this pivotal historical period, my research highlights and adds to the conversation of how menstrual technologies are deeply intertwined with broader social, economic, and environmental forces.

Abstract Name: ELECTROPHYSIOLOGICAL MARKERS OF VERTICAL SACCADDE PROGRAMS

Based on saccade reaction times, our theory is that greater cortical activity is required to program down- than up-directed saccades. We rationalized that the high temporal resolution of event-related potentials (ERPs) will allow us to quantify cortical programming of saccades. Participants were fitted for electrophysiology data collection (IX-EEG amplifier, Labscribe software, 19 electrode cap with Ag/AgCl electrodes; EOG electrodes above and below the right eyelids to detect vertical saccades; a Miami J neck brace to minimize head movement artifacts). Participants completed the saccade task while sitting within a Faraday chamber. Our concern was whether more cortical effort is associated with the releasing of down-directed saccades near the Frontal (electrodes F3 and F4) and Parietal (P3 and P4) Eye Fields. For analysis, we integrated voltages between -200ms and -4ms of saccade onset. This area under the voltage curve quantifies cortical activity relative to the average reference, and we interpreted larger areas as reflective of greater recruitment of cortical resources. A 2 Lobe (Frontal vs Parietal) X 2 Hemisphere (Left vs Right) X 2 Saccade Direction (Down vs Up) repeated measures ANOVA was conducted on the integrated voltage values. The primary finding was a 3-way interaction effect that was close to being statistically significant ($p = .08$; partial eta squared = .30). Down-directed pre-saccadic activity was greater for all electrode sites, but was especially greater in the left frontal lobe. The findings are congruent with the prediction of our theory, indicating a need to pursue our electrophysiology project, with higher statistical power.

Abstract Name: Bringing Black Holes out of the Darkness

NASA's Swift telescope records prolific amounts of X-ray and ultraviolet data. While this data is open to the public, no conclusions can be drawn until it is processed. In the field of time domain astronomy, it is most useful to work with flux data and error measurements while studying active galactic nuclei such as black holes and quasars. This research aims to answer the question of what accurate flux measurements can be made from various Swift telescope observations of AGN. Recent X-ray and UV data from NASA's Neil Gehrels Swift Observatory will be graphed and analyzed using ds9, Xselect, and Xspec software to calculate key parameters such as the power-law index, normalization, flux, and error range for each source. Afterward, key findings will be publicly posted to the Astronomer's Telegram forum for the astronomical community to

view. Ideally, results will show consistently low error in flux measurements. Once the results are posted, this team and other researchers will use this data to inform future studies on the structure and evolution of AGN. Additionally, this work will identify which AGN X-ray and UV sources should be monitored further at which wavelengths.

Abstract Name: Developing a Deep-Learning Algorithm to Classify Smartwatch Data to Evaluate Manual Wheelchair Users' Pressure Relief Exercises

Because wheelchair users naturally sit for long periods of time, they have a higher risk of developing pressure ulcers (PUs), which are painful, can cause infection, and lead to over 60,000 deaths in the U.S. each year. Clinical Practice Guidelines (CPGs) provide exercises that manual wheelchair users can use to reduce their risk of developing PUs, but the number of cases has not decreased even though research has proven these exercises effective. Part of the purpose of this project is to help answer why this is the case. Previous research in this area used pressure sensors attached to the wheelchair, but these are bulky, expensive, and hard to set up and maintain, so this research has been largely limited to lab settings. We hope to fix these issues by utilizing a smartwatch instead. To gain similar information from resulting data, we have trained a deep convolutional neural network (CNN) to distinguish between different exercises and non-exercises with high accuracy. Our design uses apps on a smartwatch, a connected phone, and the cloud. A smartwatch app collects accelerometer data and sends that to the phone. Our phone app runs a lightweight method to check when the smartwatch is moving or stationary, which serves as the landmark for identifying any potential exercises, and, thereafter, sends only relevant data to the cloud. Our app in the cloud uses the trained CNN to classify the data to determine whether it is an exercise and what type of exercise it is. The cloud app then sends the result and any additional desired information back to the phone to display to the user.

Abstract Name: Isolating and Identifying Bioactive Marine Invertebrate Extracts with Brine Shrimp Lethality Assay

Cancer remains one of the leading causes of death in the United States, with no known cure. Long-term treatment efficacy is often hindered by tumor adaptability, leading to the development of resistance. Potential new therapies can be found by utilizing marine sponge extracts. These extracts have been used before to find new chemotherapeutics that are novel and highly efficient. The extracts from the University of Oklahoma Schmitz's Marine Invertebrate Collection are purified of natural products separated from the extract. The natural products are then used to perform lethality assay screening. These lethality assays utilize brine shrimp as they are an optimal model organism based on their low maintenance and rapid division at a low cost. The

extracts having a 70% lethality in low concentrations are the priority for further isolation and study. The isolation will consist of fractionating the extracts with medicinal potential to identify and isolate the pure compound(s) with the biological activity. An active extract will undergo bioassay guided fractionation which can be an extensive process that involves the use of organic and analytical chemistry techniques including various types of chromatography (flash, reverse phase, normal phase, size exclusion, HPLC, etc.) and analytical instrumentation (infrared [IR] spectroscopy, ultraviolet [UV] spectroscopy, nuclear magnetic resonance [NMR], mass spectrometry [MS], and optical rotation [OR]). Since compounds can vary significantly in chemical composition (size, structure, polarity, etc.), it is hard to predict the exact techniques needed for each isolation. Two extracts have begun testing, 89-AU-83 and 22-BA-92. These have been purified to their extracts and have been tested for bioactivity.

Abstract Name: The Effects of Remote Work on Employee Health, Productivity, and Satisfaction

The COVID-19 pandemic caused a massive global shift to remote work. However, even after restrictions were lifted, the demand for remote work remains higher than ever before. This unprecedented rise in popularity has sparked widespread discussion about its effectiveness and implications for the workforce, particularly its impact on employees' health, productivity, and overall satisfaction. This paper investigates these effects, focusing on the physical health challenges associated with remote work, the productivity output compared to in-person work, and the evolving attitudes toward the work-from-home model. Drawing on recent research, including statistical analysis, theoretical frameworks such as the Job Demands-Resource (JD-R) model, and self-reported surveys, this study takes an in-depth look at whether remote work is ultimately positive or negative for employees and its broader implications for the modern workforce. The findings reveal that remote work leads to increased sedentary behavior, heightening the risk of musculoskeletal disorders like back and neck pain. However, these effects can be mitigated through proper ergonomic setups and workplace interventions. Additionally, remote work provides significant productivity benefits, largely due to its inherent increase in flexibility and autonomy, challenging the longstanding notion that workers require constant supervision to perform effectively. At the same time, the isolated nature of remote work has been linked to mental health issues such as depression and social isolation. However, these challenges, much like the physical health effects, can be effectively managed through proper organizational strategies and employee support systems. Overall, remote work offers transformative potential for the workplace. By addressing its challenges through thoughtful management and ergonomic solutions, employers can harness its considerable benefits, making it a key component of the evolving workforce landscape.

Abstract Name: Possible Treatment from the Deep: Effects of *Padina gymnospora*, Marine Algae, on Breast

Cancer Cells.

Breast Cancer is the second leading cause of death among women in the U.S after skin cancer. As many women struggle through chemical and invasive treatments, science has started to shift its focus onto new approaches to help breast cancer patients. The goal of this research is to increase understanding of breast cancer therapies from our natural world and introduce the possible treatment of breast cancer by using marine brown algae found in Tampa Bay. This research used two breast cancer cell lines, which represent two different types of cancer cells: MCF-7; mirrors non-resistant cancer and MDA-MB-23; mirrors resistant cancer. *Padina gymnospora* has been evaluated for its anti-cancer activity and found statistically significant results on different types of cancer cells, however it remains unclear whether these results have significant effects on breast cancer cell lines. This research has utilized *Padina gymnospora* treatments on cells under three different assays: Cytotoxicity assay (CYQUANT), Scratch assay, Peroxide assay. Additionally, these assays provided statistical analysis of the effect of *P.gymnospora* on breast cancer cells that will allow us to identify specific proteins that could be linked to these types of cancers by using RNA sequencing. Therefore, *Padina gymnospora* may be used as an alternative treatment for breast cancer patients.

Abstract Name: Coupling from the Past for Statistical Mechanics Models

Coupling from the Past (CFTP) is an innovative extension of Markov Chain Monte Carlo (MCMC) techniques designed to generate perfect samples from stationary distributions, eliminating the drawback that traditional MCMC methods only approximate the stationary distributions. This paper explores the application of CFTP in statistical mechanics, specifically to sample from the Ising model, a classical representation of ferromagnetic materials. Unlike standard MCMC approaches that approximate the stationary distribution and suffer from distribution discrepancies, CFTP guarantees exact sampling by coalescing multiple Markov chain instances to a single equilibrium state starting from an unspecified time in the past. We explain the mathematical model of CFTP and demonstrate its effectiveness for sampling with respect to the Ising model. This model captures phase transition phenomena, where the magnetization of a lattice of spins exhibits abrupt changes beyond a critical temperature - the Curie temperature. Through the application of CFTP, enhanced by the monotonicity of the Ising model, we achieve computational efficiency using methods like sandwiching and update function simplifications. Further optimizations, including Numba for Just-In-Time (JIT) compilation, allow for scalable simulations of large lattice systems. Our results confirm the robustness of CFTP in capturing critical behaviors of ferromagnetic systems. The practical visualizations we produce reveal organized spin clustering at low temperatures and the loss of magnetization as temperature increases. We anticipate that our work may be a starting point for the simulation of a broader range of more sophisticated models with real-world applications relating to phase transition phenomena using this perfect sampling.

Abstract Name: Exploring the Protein Levels of Astrocytes, Pericytes, and Blood Brain Barrier in WT and C3 Knockout Mice Following Seizure-Induced Brain Injury

Status epilepticus (SE) is a severe neurological condition that significantly increases the risk of developing epilepsy and associated cognitive impairments, particularly memory decline. The immune complement system has emerged as a critical mechanism underlying neurological damage, with the complement cascade potentially playing a pivotal role in mediating inflammatory responses and neuronal dysfunction. This study investigates the potential contribution of complement C3 in SE-induced pathology, specifically focusing on the molecular mechanisms driving blood-brain barrier (BBB) disruption, gliosis, and synaptic remodeling—key processes that may ultimately influence epilepsy progression and cognitive outcomes. The objective was to assess the acute impact of SE on protein levels known to regulate the BBB. Wild-type (WT) and C3 knockout (KO) mice were subjected to one hour of pilocarpine-induced SE or sham conditions (control). SE was interrupted after one hour with the anticonvulsant diazepam. Four experimental groups were examined: WT+Control, C3KO+Control, WT+SE, and C3KO+SE. Hippocampi were collected 4 hours after SE and processed for western blotting using antibodies against GFAP (astrocytes), PDGF-BB (pericytes), NCAM and Albumin (BBB stability), and PSD95 (a synaptic protein). The protein levels for GFAP, PDGF-BB, NCAM, Albumin, and PSD95 were similar in WT and WT+SE groups ($p > 0.05$), indicating no acute alterations following SE. Notably, hippocampi from C3KO mice demonstrated significantly increased pericyte marker levels and significantly decreased albumin levels compared to WT controls. These findings suggest that SE-induced gliosis and BBB disruption are not evident at 4 hours post-SE. Furthermore, the results indicate that C3 may play a crucial role in regulating pericyte homeostasis and potentially influencing BBB stability. Subsequent investigations will explore the temporal progression of SE-induced hippocampal changes at later time points.

Abstract Name: Relation of Emotion and Cognitive Processing Word Frequency to Emotional Distress in Stroke Survivor-Family Caregiver Dyad Interviews

Background: Previous research found that greater use of emotion words reflects deeper immersion in a traumatic event, and greater use of cognitive mechanism words can indicate active reappraisal of an event. It is possible that use of more emotion words may relate to emotion-focused coping, and the use of cognitive processing words may relate to problem-focused coping. Objective: Evaluate the relationship between emotional distress endorsed by persons with stroke (PwS) and use of emotion word vs cognitive processing word in stroke participant-caregiver interviews. Methodology: In this observational study, PwS and caregivers were interviewed regarding a task completed recently by the PWS and how it impacted their relationship. Participants included twelve PwS (>3 months post-stroke) with mild-to-moderate cognitive impairment (Montreal Cognitive Assessment: 10-26) and twelve family caregivers. Dyad-level emotional and cognitive

processing was measured as the percentage of emotion words (good, bad, worried, etc.) and cognitive processing words (know, think, etc.) used in a brief dyad interview. Emotional distress was measured using the Neuro-QoL Depression and Anxiety Questionnaires and NIH Toolbox Perceived Stress Scale. Higher T-Scores indicate more distress: Mild (T-Score 55-60), Moderate (T-Score: 60-70), High Perceived Stress (T-Score ≥ 60). Results: Moderate anxiety symptoms were reported in two PwS, moderate depression in one, mild anxiety in three, and mild depression in four. Five PwS reported high perceived stress levels. Greater use of cognitive processing words in dyad interviews between PwS and caregivers discussing changes in function after stroke was correlated with higher perceived stress levels in PwS, $r(10) = .66$, $p = .020$. Cognitive processing word use was not associated with depressive or anxiety symptoms. Emotion word use showed no association with any emotional distress measures. Conclusion: The findings within this small sample warrants further research to better identify links between word use in conversations and emotional distress in PwS.

Abstract Name: A Study on the Impacts of Latency on Teleoperations Using Haptic Gloves

Haptic gloves are emerging technologies in Mixed Reality (MR), promising to enhance sensory feedback and user interaction in a variety of specialized tasks such as teleoperations, training, trauma care, and expert data capture. However, system latency—the delay between a user's action and the corresponding feedback—could significantly impact performance and the user experience during such tasks. Literature regarding latency in MR teleoperations exists but does not account for detailed haptic feedback. This study will explore the effects of latency on user performance in teleoperation tasks using the G1 gloves developed by HaptX, which offer unparalleled levels of tactile information. We will conduct controlled experiments where participants perform toy tasks requiring fine dexterity and motor skills similar to those used in surgical operations, such as suturing, tying, manipulating small objects with medical forceps, and wire loop games. Performance metrics such as task completion time, error rate, and accuracy will be recorded. Additionally, subjective user experience will be assessed through questionnaires evaluating perceived responsiveness and ease of use. Understanding the impact of latency on haptic teleoperation systems is crucial for optimizing their design and implementation. This study will contribute to a growing body of literature by providing empirical evidence on how latency affects the effectiveness of haptic gloves in teleoperation tasks. Ideally, these results could potentially inform design requirements for remote operation systems in the future. Additionally, these insights will be valuable for developing more effective VR-based medical training, where realistic haptic feedback is essential for skill acquisition and procedural competency.

Abstract Name: Cybersecurity Assessment of Non-profit Organizations (NPOs) in Pennsylvania

We are working on a project focused on enhancing the cybersecurity readiness of non-profit organizations (NPOs) in Pennsylvania. NPOs play a critical role in society but often face significant cybersecurity challenges due to limited budgets and expertise. These limitations leave them vulnerable to cyberattacks that threaten sensitive data, operational integrity, and stakeholder trust. Our study seeks to bridge this gap by developing a framework that identifies cybersecurity gaps and provides tailored, actionable recommendations based on the NIST Cybersecurity Framework. The research begins with a systematic literature review (SLR) to design a cybersecurity assessment survey that captures the practices, needs, and vulnerabilities of NPOs. In the second phase, survey responses, including open-ended feedback, will be analyzed using natural language processing (NLP) techniques, specifically Named Entity Recognition (NER), to identify critical cybersecurity elements such as threats, tools, and organizational needs. Extracted data will populate a knowledge graph, mapping relationships between vulnerabilities, needs, and cybersecurity solutions. Simultaneously, a text corpus constructed from the NIST framework will serve as a reference for best practices and guidelines. By mapping the knowledge graph to the corpus, the study will generate customized recommendations for each NPO, addressing their specific cybersecurity gaps. Expected outcomes include a detailed understanding of cybersecurity readiness across Pennsylvania's NPOs, insights into common challenges, and scalable strategies for improvement. The findings will be shared with the non-profit and research communities to support enhanced cybersecurity resilience, ensuring these organizations can continue their missions securely. This research represents a meaningful contribution to strengthening the cybersecurity posture of NPOs while addressing the broader challenge of equitable access to cybersecurity resources.

Abstract Name: Profiling NPOs in need for Cybersecurity Readiness Evaluation

Non-profit organizations (NPOs) play an important role in creating strong and fair communities. However, many NPOs struggle to protect their digital information because they have small budgets and limited resources. This makes them an easy target for cyberattacks, which can harm their reputation, lose donor trust, and disrupt their important work. Our project focuses on helping NPOs in Pennsylvania improve their cybersecurity readiness. We chose this project because cyber threats against NPOs are growing, and many of these organizations do not have the tools or knowledge to defend themselves. Unlike businesses, NPOs often cannot afford expensive cybersecurity solutions or hire experts. This creates an urgent need for simple, affordable, and practical solutions that fit their unique challenges. Our work so far has included analyzing data

from 78,000 NPOs in Pennsylvania to find patterns and identify which groups might need the most help. We also surveyed a smaller group of NPOs to understand their specific cybersecurity needs and challenges. Looking ahead, we plan to create easy-to-follow guides and resources to help NPOs improve their cybersecurity practices. These will include tips for protecting data, training staff, and responding to cyber threats. The resources will be based on trusted frameworks like NIST and CISA but adapted to meet the needs of small, resource-limited organizations. By addressing these issues, we hope to make NPOs stronger and better prepared for the digital risks they face. This will help them protect sensitive information, maintain trust, and continue their valuable work in our communities.

Abstract Name: Using a modified Principal Component Analysis to recover state information from a corrupted Dynamical System for modelling

When modeling predator-prey populations in 2d space, as described by a system of two parabolic partial differential equations, state space information could get corrupted during transmission or collection. This has been a problem in research; regular analysis and modeling are done via satellite images, which have a high probability of having significant errors (either noise or regions covered by clouds) in regions of interest. While that wouldn't be a problem for systems with minor sensitivity, errors could cause significant divergences from actual state behavior in diffusion population systems, which is the system under study. Principal Component Analysis (PCA) is a mathematical method used to realign high-dimensional data to a different dimensional axis by recognizing major principle components of the data. It is a method used in image and error detection, as images can be represented as points in spaces with very large dimensions. However, due to the sequential nature of dynamical system data, a modified PCA uses windowed time steps as data points to identify the principal components of a predator-prey system modeled using some initial state parameters. Then, the PCA was used to recover data that had been erased from a second model using different initial state parameters using PCA inpainting, and the recovered data was used to drive a system in equilibrium into matching the second system. This setup restored the driving system's behavior even when the corruption (noise and data erasure) affected 30% of the data used for transmission, indicating PCA can recognize and imprint the nonlinear nature of the dynamical system when extended to the time dimension.

Abstract Name: Targeting Cancer-associated Proteins and Click Chemistry Labeling of Probes for Tumor Imaging and Ablation

Precise targeting of tumors is a critical aspect of precision cancer treatment, which often requires real-time

measurement of tumors and their surrounding environment. Tumor ablation therapy, guided by magnetic resonance imaging (MRI), presents a potential strategy for improving tumor targeting accuracy. In this research, we aim to develop a novel, non-toxic MRI contrast agent that exhibits spin crossover events at high temperatures and can be attached to peptide or nucleic acid probes. The primary goal is to achieve high sensitivity and specificity in cancer cell targeting, with an additional focus on utilizing this contrast agent for real-time imaging and targeted therapy in preclinical models. Furthermore, this study focuses on the identification and engineering of DNA and RNA sequences with strong affinity for copper ions, aimed at facilitating Click Chemistry labeling. Rational design strategies are employed to create nucleic acid sequences with tailored binding capabilities to copper ions, enhancing their use in MRI contrast agents. Specific aims include bioinformatics analysis of potential DNA and RNA structures, the study of Cu-DNA/RNA binding interactions and affinities, and the application of Click Chemistry for labeling these sequences with MRI contrast agents. In addition, SELEX (Systematic Evolution of Ligands by Exponential Enrichment) will be utilized to screen a diverse pool of nucleic acid sequences and isolate those with the highest affinity for copper ions. This chemo-selective labeling method ensures minimal interference with biological macromolecules, preserving the integrity of the systems under investigation. Ultimately, this study compares chemical labeling strategies, striving to bridge the gap between molecular precision and the practical application of cancer treatment.

Abstract Name: Beyond Wages: Investigating Occupational Segregation and Labor Market Discrimination

Researching the fundamentals of discrimination in the job market helps us better understand injustices in the workplace. We build on Foote, Whatley, and Wright's (2003) work, which highlighted Ford Motor Company's exploitation of labor market inequality by concentrating black workers in unpleasant foundry jobs in the 1920s-1940s. This indicated that wage alone is not a conclusive indicator of labor market discrimination. We expand this analysis to a broader set of jobs across three firms. Our study measures occupational segregation using Stata to examine archived employee records from Ford, A.M. Byers, and Pullman, classifying workers by occupation and measuring the degree of segregation.

Abstract Name: Psychiatric Symptoms Trajectories in Children and Adolescents Across an 18-Month Interval: Associations with Recent Parental Cancer Diagnosis and Biological Markers of Stress and Inflammation

Adversity in childhood is a global phenomenon, with an incidence of 60% worldwide. Aside from posing threats to developmental milestones, early life adversities can also have lifelong impacts of dysfunction. Robust evidence has demonstrated clear linkages between doses of childhood adversity, lifetime psychiatric problems, and impaired psychological well-being. Illness in the family, particularly amongst parents, is a potent stressor for children that can lead to negative psychological outcomes. One of the most prevalent illnesses amongst adults is cancer, affecting millions across America. The psychiatric outcomes of children of parents with cancer have been explored, yet the unfolding of psychiatric symptoms following a parental cancer diagnosis is not fully understood. The present study examines the trajectory of psychiatric symptoms in children and adolescents (n=350) aged 12-17 following a recent parental diagnosis of stage III and IV melanoma or colorectal cancer (<12 months after diagnosis). To assess acute and chronic biological responses in relation to the identified symptom trajectories, we collected various clinical and biological measures at intake (TP0), six-months (TP1), and 18 months (TP2). We used growth mixture modeling to identify trajectory classes of symptoms based on magnitude and stability across time in parental cancer (n=125) and a control group (n=225), and related these to psychosocial and biological indicators. Univariate analyses reveal heterogeneity in symptom trajectories. For depression, parental cancer was associated with a moderate-stable trajectory, while control conditions were linked to a low-minimal decreasing trajectory. We found no significant associations in suicidal ideation trajectory classes. Assessing global functioning, parental cancer was linked to a moderate-increasing trajectory, and control conditions predicted high-stable trajectory. Within trajectories, the high global functioning class had higher IL-6 levels, but all other biological markers of stress and inflammation were not significantly different among the global functioning, depression, or suicidal ideation trajectory classes.

Abstract Name: Evaluation of Real-Time PCR for Mixed Species Identification in Canned Tuna

Introduction: Canned tuna is susceptible to species mislabeling, which can mislead consumers, undermine regulatory compliance, and pose health risks, especially when high-mercury species are mislabeled as low-mercury ones. Species identification in canned tuna is particularly challenging due to the processed nature of the product, as well as the high level of DNA degradation. Objective: This study aimed to evaluate the use of real-time polymerase chain reaction (PCR) for identifying mixed tuna species in fresh and heat-treated samples. Materials and Methods: Real-time PCR assays were carried out targeting albacore (*Thunnus alalunga*), skipjack (*Katsuwonus pelamis*), and yellowfin (*Thunnus albacares*) tuna. Binary species mixtures using DNA from raw tuna reference samples were prepared with 0.1-10% of the target species. The binary species mixtures were tested with and without heat treatment at 95°C for 30 min to simulate canning conditions. All mixtures were tested in triplicate. Results and Discussion: Consistent detection with real-time PCR was achieved for albacore and yellowfin tuna at levels as low as 0.1% in binary species mixtures. On the other hand, skipjack tuna showed consistent detection at levels as low as 1.0%, with only one-third of replicates detected at the 0.1% level. Heat treatment simulating the canning process did not significantly affect detection rates, confirming the robustness of real-time PCR for processed tuna products. Conclusion: This research enhances species identification accuracy for processed tuna, addressing a critical gap in food safety and authentication. These findings support broader efforts to refine DNA testing protocols for processed and mixed seafood products.

Abstract Name: Fatty Acid Composition of Dietary Oils: Analyses to Inform the Effects of Healthy Diets with Plant Oils on Cardiometabolic Health

Cardiovascular disease is the leading cause of mortality worldwide, and current dietary guidelines from the American Heart Association recommend the use of liquid plant oils that are high in unsaturated fats to promote cardiovascular health. Cottonseed oil has a higher polyunsaturated fatty acid to saturated fatty acid ratio (the P:S ratio). Prior research suggests cottonseed oil consumed as part of a high-fat diet decreases low-density lipoprotein cholesterol (LDL-C). A study is planned to investigate if cottonseed oil consumed as part of a healthy diet decreases LDL-C. Before commencing the study, the fatty acid composition of cottonseed oil and other test plant oils will be assessed using a gas chromatograph mass spectrometer (GC-MS). The fatty acid profiles of the experimental diets will be measured to ensure that nutrient targets are met. The fatty acid composition of the oil components was analyzed using GC-MS. Fatty acids were extracted from all oils (and blends) using the fatty acid methyl ester (FAME) extraction method and analyzed by the GC-2010 gas chromatography system fitted with a QP2010 mass spectrometer (GC-MS Shimadzu, Japan) using a Supelco SP-2560 fused silica column. Peak area counts were measured using GCMSolution software. Fatty acid quantification was calculated as a percentage of total fatty acids. The fatty acid composition of the experimental diets was then calculated based on the analyzed fatty acid composition of the oil component. These values were compared with the USDA estimates. In these analyses, the percentages of individual fatty acids in the oils based on the GC-MS analysis slightly differed from those listed in the USDA database, highlighting the importance of chemically assaying fatty acids to ensure protocol accuracy. This research is important because it emphasizes how important it is for consumers to know the composition of these oils for their cardiovascular health.

Abstract Name: Genetic and Biochemical Control of Root Development in Duckweeds (*S. polyrrhiza*)

Roots are an important part of plants and are responsible for multiple functions. The development of roots is an important phenomenon and its molecular genetic control in aquatic plants has not been explored so far. In our earlier research, we have identified an unusual polyamine oxidation pathway in duckweeds. In this work, we investigated the functions of this pathway in duckweed growth control. Here, our genomic analysis from two genome assemblies establishes that six duckweed Polyamine Oxidase (PAO) enzyme encoding genes are tandemly duplicated in two blocks. To address the question that such an intensive duplication may account for an important function in duckweed, we used chemical inhibitor approach for functional analysis. Use of synthesized chemical inhibitors shows that duckweeds lost its roots and fail to clonally propagate in longer run. Microscopic evaluation reveals that the roots are detached from prophyllum of duckweed indicating its possible role in root initiation and maintenance along with clonal propagation. These results are novel, and future investigations will reveal the function of this gene cluster.

Abstract Name: Parking Palooza: Avoiding Campus Car-tastropies

The consistent challenge of finding an on-campus parking spot around large university campuses has resulted in multiple ways to solve the problem with the aid of technology that facilitates user experience and enhances parking efficiency. This method explores developing and demonstrating a mobile application that helps the students, faculty, staff, and visitors optimise all the available parking spots at Buffalo State University. The app utilizes the user's coordinates and a customisable timer to provide information on all the available parking spots around the campus. The development of the app showcases the effort of combining academic knowledge and practical problem-solving to produce a more efficient campus environment. Moreover, the paper reviews similar applications of such technologies around other campus environments, highlighting their benefits.

Abstract Name: Machine Learning and Music Recognition

Music is a tool that has been integrated into society for thousands of years, it has influenced social aspects of

life and has also aided in communication. Today we have various uses for music that go past our traditional entertainment uses and self expression. Commonly, we see music being incorporated into visual art forms, and also being used in the medical field, specifically music therapy. With this broad spectrum of usage, it is important that music stays organized and easily accessible. This project intends to review literature looking at the methods, results, and limitations of music recognition using machine learning. Various techniques like K-Nearest Neighbor, Deep Neural Networks, and Convolutional Neural Networks have been identified in the use of organizing music and audio files by genre and utility. This literature review will also explore methods of data acquisition and music information retrieval. This paper focuses on presenting various learning models in the field of music recognition and illustrating their results.

Abstract Name: Do Parental Psychopathology Symptoms Predict Adolescent Impulsivity?

Adolescents have an increased tendency to engage in risky behaviors and there is an increase in impulsivity in adolescence. Impulsivity could be influenced by the family environment. The purpose of the present study is to 1) determine if there is an association between parental psychopathology symptoms (substance use problems and anxiety and depression symptoms) and adolescent impulsivity, and 2) explore a moderation of this association by adolescent sex. Some research has started to find connections between parental substance use and youth impulsivity, but more research is needed on this and research is lacking on connections between parental anxiety/depression symptoms and youth impulsivity. In the present study, I will analyze data from a larger study of 249 parent-adolescent dyads with adolescents aging 11 to 15. In the study, adolescents self-reported impulsivity via the UPPS-R-C, which will be analyzed by each subscale (negative urgency, positive urgency, lack of perseverance, lack of premeditation, and sensation seeking). Parents self-reported on their 1) substance use problems, measured as a composite measure of the DAST-10 and the alcohol-related problem subscale from the AUDIT, 2) anxiety symptoms via the STAI trait anxiety subscale, and 3) depression symptoms via the CES-D. It is hypothesized that 1) parental substance use problems will be associated to all adolescent UPPS-R-C impulsivity traits, 2) parental anxiety symptoms will be associated to adolescent negative urgency and lack of perseverance, and 3) parental depression symptoms will be associated to adolescent negative urgency. We will also be exploring the moderation of these effects of parental psychopathology and adolescent impulsivity by adolescent sex. The findings from this research will provide further understanding of what risk factors predict the development of heightened impulsivity in adolescence, which could provide a more effective framework for prevention strategies.

Abstract Name: Determination of Thermodynamics of Binding of Nitrite to Wildtype Myoglobin and Comparison to Spectra of Cobalt Myoglobin Bound to Nitrite

Maintaining optimal concentration of nitric oxide (NO) in the body is critical, since overproduction has damaging effects such as septic shock and stroke. The concentration is controlled by heme enzymes like myoglobin (Mb), which function as nitrite reductases (NiR) where nitrite (NO₂⁻) is reduced to NO. The binding of NO₂⁻ to MbIII generates a stable MbIII-NO₂⁻ complex, which can be used to model the intermediate that is generated during the NiR reaction. In this experiment, the thermodynamic parameters, ΔH (enthalpy), ΔS (entropy), and ΔG (Gibbs free energy), of nitrite binding to MbIII will be determined to elucidate the factors that influence the formation of the complex by using temperature-controlled UV-vis spectroscopy. Known concentrations of nitrite were titrated into wild-type (wt) MbIII at different temperatures ranging from 11.5 – 29.6 °C, and changes in the absorbance at 580 nm were noted. A logarithm plot of the absorbance at 580 nm as a function of NO₂⁻ concentration showed a sigmoidal curve that allowed for the extrapolation of the equilibrium constant, K, at that temperature. A van't Hoff plot was constructed from the K values derived at different temperatures, generating the following thermodynamic parameters, ΔH : -30.8 kJ/mol and ΔS : 68.4 J/mol K. The ΔG at the five different temperatures ranges from -50.3 to -51.5 kJ/mol. Results show that the addition of NO₂⁻ to wt MbIII is driven by enthalpy and entropy, and is spontaneous at all temperatures. Additionally, the spectra of the MbIII-NO₂⁻ complex between wt and its cobalt analogue (CoIIIMb) were compared to investigate how changing the metal center influences the spectral changes in the visible region. The absorption spectrum of CoIIIMb shows subtle changes in the Soret and Q-band regions compared to its FeIII analogue.

Abstract Name: Undergraduate Human Subjects Research Lab Experiences in Humanities

Amid concerns for the coming enrollment cliff as well as enrollment attrition in humanities programs, one sector of higher education that continues to grow is international students. In view of growing concerns about enrollment attrition and shrinking resources for sustainable international learning experiences, short-term programs grounded in institutional partnerships may offer opportunities of mutual benefit to international participants and domestic stakeholders. This exploratory case study examines the effects of a six-weeks English language learning program in which seventeen German adults participated in Spring semester 2024. This project investigates the program's impact on participants' language proficiency and intercultural competence (IC) development and on classmates' and instructors' attitudinal dispositions and behaviors. Employing a mixed-methods approach, this study triangulates data from pre- and post-intervention tests, learners' and instructors' attitudinal survey responses, and focus-group interviews with two participant groups and instructors. Preliminary findings indicate a positive impact of short-term intensive English learning programs on learners' proficiency, regardless of cohort, as demonstrated by pre- and post-test scores. Both learners and instructors highlight the program's effectiveness while also identifying challenges and areas for improvement. This session will focus on the participants' advancement of IC. While the findings cannot be generalized, they may have implications for program and instructional design; student success and learner support strategies; and sustainable efforts to facilitate international and cross-disciplinary partnerships in diverse educational settings. Study findings will be shared with session participants to allow for further review.

Abstract Name: Monitoring Phytoplankton for Oyster Hatchery Planning in Northern Gulf of Mexico

We are working with a local oyster farm and the Florida Sea Grant extension office to investigate the composition of phytoplankton standing stocks and water quality associated with an existing oyster farming operation in the Pensacola (FL) Bay System. Oyster spawning consists of male oysters releasing sperm and females release eggs into the water; it is successful when an egg is fertilized by sperm. Oyster reproduction is complex and any changes in salinity, temperature, or phytoplankton population in the spring may trigger them to start the reproduction cycle. Pensacola Oyster Company operates an oyster hatchery that is trying to successfully spawn oysters using techniques used successfully in the Mid-Atlantic (USA) region; however, the methods from there are not working in the Gulf of Mexico or Pensacola Bay. Florida Sea Grant is working with the hatchery to investigate environmental conditions to determine what is needed to create the perfect environment to spawn oysters successfully in this environment. The University of West Florida was engaged to survey the phytoplankton that are in the water during spawning season, and in contrast what is not in the water during non spawning season. We used the National Oceanic and Atmospheric Administration's Phytoplankton Monitoring Network (NOAA PMN). After the sample is collected it is taken back to the lab and put under a microscope at 40x magnification to identify the plankton in the Pensacola Bay. The temperature, salinity, and water temperature are all recorded as well. The goal is to identify the plankton that are in the water and recreate what the water is like during spawning season to trigger spawning during non spawning season. We will report to both FL Sea Grant and the oyster farm the full survey of phytoplankton species identified during fortnightly-to-monthly sampling to inform their ongoing and future hatchery operations.

Abstract Name: Exploring the Role of Nutrient Sensing Receptor GPRC6a Repression in Tau Pathology

Alzheimer's disease (AD) is the most common form of dementia, accounting for 60-80% of dementia cases and is characterized by beta-amyloid plaque buildup and subsequently, hyperphosphorylated tau. Recently, immunotherapy to beta-amyloid has been FDA approved but no current treatment exists for tau. Tau functions to stabilize microtubules which provide support to neuronal structure. Hyperphosphorylated tau destabilizes microtubules which can impact cell functions and cause metabolic dysfunction. Tau pathology ultimately causes the cognitive impairment & cell death present in AD patients. Many reports indicate impaired protein clearance mechanisms through dysregulation of the mechanistic target of rapamycin complex (mTORC1) in AD. One of the primary amino acids that activates mTORC1 is arginine, which signals through various nutrient sensors and the extracellular arginine receptor, GPRC6a. We hypothesized that hemizygous

deletion of GPRC6a in tau transgenic mice impacts protein clearance through autophagy and neuropathology of tau. PS19 tau mice (MAPT P301S) were cross bred to GPRC6a hemizygous knockout mice (P301S/GPRC6a+/-) and aged for 8 months. Brain tissue was harvested and subjected to immunohistochemistry/histology for indicators of tau pathology. Phosphorylated tau markers AT8 (phospho Ser202/Thr205), tau phospho 217, and total tau (HT7) were measured in various regions throughout the brain and quantified using unbiased image analysis. Total tau remained unchanged between P301S tau mice and P301S/GPRC6a+/- mice. P301S/GPRC6a+/- mice showed a decreasing trend in tau phospho 217 compared to P301S mice, however this was not statistically significant. Interestingly, tau AT8 decreased in several regions throughout the brain in P301S/GPRC6a+/- mice compared to P301S mice, suggesting that GPRC6a expression impacts tau pathology. Several autophagy and neuronal integrity markers are currently being investigated to understand the impact on neuronal plasticity and tau clearance. These results suggest that GPRC6a expression modulates tau pathology, which could serve as a unique therapeutic target in AD.

Abstract Name: Balancing the Scales: The Economic, Social, and Ethical Dimensions of Illegal Immigration in the U.S.

Abstract: Illegal immigration impacts the U.S. labor market, economy, and social policies in complex ways. On the labor front, it offers both advantages and challenges. While illegal immigrants contribute to economic growth by filling essential secondary-sector jobs and spending 90% of their wages domestically—estimated at \$450 billion—they also face criticism for allegedly displacing low-skilled workers, lowering wages, and weakening labor unions. Dual labor market theory explains their role in addressing labor shortages in low-skill, unstable positions that native workers often avoid, with immigrants demonstrating mobility as they gain U.S.-specific skills. Despite their contributions, illegal immigrants endure systemic challenges. During the COVID-19 pandemic, detention centers were criticized for prison-like conditions, delayed healthcare, and poor living standards, which heightened health risks and caused avoidable deaths, including for children. Additionally, reports of abuse by border patrol agents, ranging from physical violence to homicide, highlight a history of human rights violations. Many cases remain undocumented due to insufficient complaint procedures, leaving immigrants unprotected. Immigration policies further shape the debate. Local policies like those in Prince William County initially aimed to reduce crime but had mixed outcomes. At the federal level, the Trump administration promoted stricter immigration laws, arguing that immigrants harm U.S. citizens by taking jobs, using social benefits, and increasing crime. This stance sparked opposition, with Democrats asserting that immigrants take low-wage jobs Americans typically avoid. In summary, illegal immigration remains a contentious issue, with immigrants playing vital economic roles while grappling with systemic inequalities, harsh policies, and societal perceptions. Striking a balance between enforcement and humane treatment remains a critical challenge for the U.S.

Abstract Name: Optimizing Small Wind Turbine Efficiency Through Attaching a Novel Structure

Wind energy is indeed a vital component for renewable energy strategies in many countries, significantly reducing any hazardous impact to environment. This study seeks to enhance the efficiency of small wind turbines through innovative design modifications based on Bernoulli's principle. We develop "wind power density compressors," structural attachments designed to increase wind speed and air density at the turbine blades—the two primary factors influencing wind turbine energy output. Three models for horizontal-axis wind turbines (HAWTs) and four for vertical-axis wind turbines (VAWTs) with varying size ratios are designed and evaluated using Solidworks Flow Simulations. The results demonstrate substantial increases in wind velocity at the turbine blades, with HAWT Model 3 achieving approximately a 70% increase and VAWT Model 4 achieving around an 18% increase. Significant increases in air density at the propeller region are also observed. Calculations using the wind power density formula indicate potential energy generation enhancements up to fivefold for HAWTs and 1.7 times for VAWTs. By comparing the performance from conventional models, we identify key factors that enhance the efficiency of wind power density compressors. With these novel structures, a wide range of wind turbines can achieve significantly higher performance, paving the way for a more sustainable and environmentally friendly energy future.

Abstract Name: The Exploration of Materiality on The Theatrical Stage and Sustainable Theatre

Through the exploration of materials and creating an abstract, unique design process, theatrical design could be reinvigorated. Traditional aspects of scenic design have hit a standstill in materials use and designers often design with the same concepts and materials, not allowing for play or experimentation. Over the past three to four years, due to the constraints of rising labor and materials costs, theatrical and musical productions at JMU School of Theatre and Dance (hereafter referred to as "STAD") have generally involved or overly relied on pre-made steel deck assembly with some wood-based construction. Initially, the pre-fabricated steel deck design was awe inspiring to both the audience and production staff because steel deck was new and nontraditional for undergraduate-level theatre. However, as more productions began using the prefabricated steel deck because of its cost saving and simplicity, steel deck construction-based designs felt uninteresting and uninspired. The program of the musical, *SpongeBob the Musical*, was shifted to utilizing sustainable and already existing materials in an effort to create a "green" show. An anonymous survey polled at the end of the musical showed that many had a great appreciation in the plastic and different materials utilized throughout

the design. The radical design approach help spark a conversation of what design is and what design is capable of; moreover, this survey provided insightful critiques regarding the organization and structure.

Abstract Name: Spurring and Siloing: How Do Non-White Early-Career Science Writers Incorporate Their Racial and Cultural Identities?

Historically, the science writing and publication field has been a predominantly white space with established norms that present barriers for marginalized individual involvement. Previous literature has shown that involvement in science writing and publication has enhanced science identity and persistence in STEM, leading to a more recent push to diversify scientific inquiry and inclusivity among those historically excluded. Although there is ample research done on the development and regression of science identity in marginalized individuals, there is a lack of exploration on the experiences of non-white early career individuals navigating the science writing processes with regards to their racial and cultural identities. In particular, Asian Americans have been historically perceived as the model minority, assuming that they have a natural aptitude for STEM. So, while Asian Americans are a minority group, many don't perceive them as a minority in science. This results in a lack of studies on how they navigate scientific norms and bridging the different parts of their identity and culture. The current study interviewed 26 participants of self-described Asian background from the Journal of Emerging Investigators (J.E.I.), a scientific journal dedicated to publishing middle school and high school research, on questions relating to their experiences and views of science writing, identity, and community. Data analysis was conducted using NVivo. Results indicate that participants took two different approaches in incorporating their racial and cultural identities: siloing, wherein students emphasized the need to separate their identities from science writing, and spurring, wherein they drew inspiration from their cultural backgrounds when constructing their initial research question. Many also brought up racial invisibility in which participants never recognized how race may influence their scientific work. This alludes to specific boundaries in scientific writing that Asian participants conceptualize in order to navigate the model minority myth.

Abstract Name: Bridging Gaps: Evaluating the Effectiveness of University School Counseling Certificate Programs on Supporting Undocumented Students in North Carolina

This study aims to understand the effectiveness of school counseling certificate programs in guiding school

counselors to support undocumented students in North Carolina. While existing research highlights the importance of parent engagement and teachers' roles in supporting marginalized students, there is limited focus on the training counselors receive to address the unique needs of undocumented populations. Additionally, there is a lack of research on undocumented students in K-12 North Carolina Public Schools, which hinders support systems for these under-resourced populations. This gap in knowledge prevents the development of effective and equitable support systems for these students. Using a mixed-methods approach, the research begins with qualitative interviews and a quantitative Qualtrics survey targeting current North Carolina school counselors to assess their counseling experience and identify gaps in their training. Based on their responses, another set of interviews and surveys is conducted with university faculty in school counseling programs to analyze how certification curricula address, or fail to address, the challenges undocumented students face. Findings suggest a misalignment between the theoretical frameworks taught in the school certificate programs and the practical skills required to navigate the legal, cultural, and emotional complexities experienced by undocumented students in schools. For instance, many programs lack sufficient content on immigration policies, language support, or trauma specific to undocumented students, leaving it difficult for counselors to provide comprehensive support. By bridging this gap, this study aims to inform future revisions to school counseling certification programs and advocate for updated, inclusive, and comprehensive curricula. This study offers valuable insights into the difficulties, concerns, and gaps between school counseling certificate programs and the practical needs of school counselors in North Carolina, laying a strong foundation for future investigations and program enhancements.

Abstract Name: Effect of Ethanol on Nicotine Preference in *C. Elegans*

Nicotine and ethanol are the two most-commonly abused substances in the U.S.. However, effective treatments for these drugs are still not found, and the interdependence between these two drugs are not well publicized. This study investigates how ethanol exposure influences nicotine preference in *C. elegans* using a chemotaxis preference assay. We hypothesized that ethanol exposure would increase nicotine preference. One group of *C. elegans* was exposed to ethanol for 30 minutes at the L1 stage (3 days from birth), while another group experienced 300mM ethanol exposure from birth until the L1 stage. These groups helped determine if nicotine preference was dependent on the duration of ethanol exposure. Post-ethanol treatment, *C. elegans* were placed in a preference assay with nicotine (4 μ L) in one zone and water (4 μ L) in another in a 6-well plate. Each pair of 6-well plates had different concentrations of nicotine, from 0 mM, 15 mM, 30 mM to 50mM (total of eight 6-well plates), to see if nicotine concentration influenced the preference index. Imaging occurred after 30 minutes of exposure to testing zone to calculate the preference index: (# of *C. elegans* in the nicotine zone)/(# in both zones). A two-way ANOVA assessed the effect of ethanol on nicotine preference. A 30-minute ethanol exposure showed no significant difference in nicotine preference, whereas lifelong exposure resulted in an increasing trend of nicotine preference at low dosages (~30 mM). These results suggest further experiments are needed to refine the data. This study aims to expand the body of knowledge between ethanol and nicotine addiction, and contribute to better treatment strategies.

Abstract Name: The Impact of Spongivore Communities on Eusociality in *Synalpheus* Shrimps

Ecological interactions, such as predation and symbiosis, could profoundly affect evolution. Eusociality, a social structure providing ecological advantages such as enhanced defense and resource utilization, has evolved multiple times in sponge-dwelling *Synalpheus* species that are obligate symbionts of sponges across Caribbean reefs. Building on prior research into ecological interactions and their evolutionary impact, this study examines spongivore predator diversity's role in shaping the evolution of eusocial behavior in *Synalpheus* shrimps across multiple Caribbean reefs. Using PERMANOVA analysis, significant associations between spongivore community composition and the number of eusocial species and lineages are identified. This research enhances understanding of predator-prey dynamics and their evolutionary implications, with conclusions emphasizing broader ecological influences and guiding future studies into the evolutionary drivers of social complexity.

Abstract Name: Time to Flip a Switch: Documenting Biofluorescence in Northwestern Pennsylvania's Native Salamanders

Biofluorescence, the absorption of high-energy wavelengths of light (e.g., blue) and subsequent re-emission of low-energy wavelengths of light (e.g., yellow), has recently been documented in several terrestrial taxa like salamanders. Most reports document biofluorescence at the family level, yet none have thoroughly documented intra- and interspecific variation in biofluorescence. Our study sought to determine which Northwestern Pennsylvania salamander species fluoresced in response to five excitation wavelengths, including ultraviolet, violet, blue, cyan, and green lights, and document ontogenetic variation in fluorescence. Captured salamanders were excited with one of five excitation lights within a photarium, photographed, and had their fluorescence measured with a spectrometer and long pass filter. All species encountered during this study fluoresced in response to all excitation wavelengths. Notably, sexual dimorphism in fluorescent patterns were observed in the postcloacal glands of two Plethodontid species (*Plethodon cinereus* & *P. glutinosus*), supporting similar observations made in previous studies. Unlike sexually mature *P. glutinosus*, juveniles had reduced postcloacal biofluorescence. Therefore, biofluorescence may be diagnostic of sexual maturity in this species. Species less reliant on visual senses, like *Cryptobranchus alleganiensis*, were less fluorescent when compared to visually-oriented species. Similar to the results of previous studies, we found that the biofluorescence of larval salamanders changed throughout ontogeny. While the function of biofluorescence in salamanders is unknown, our results suggest that biofluorescence may be used in conspecific and heterospecific communication as well as in behaviors like reproduction and territoriality.

Abstract Name: Monte Carlo Simulation of Affordable Care Act's Impact on Lung Cancer Mortality

Since the implementation of the Affordable Care Act (ACA) and the resulting Medicaid expansion beginning in 2014, public health insurance coverage in the USA has increased by over 35 million people. The ACA Medicaid expansion had an intervening Supreme Court decision which permitted individual states to choose whether or not to implement it, yielding a scenario to test the impact of Medicaid expansion on public health. Lung cancer continues to be the deadliest form of cancer domestically and worldwide, with West Virginia having the highest rate of lung cancer deaths of any state in 2022. The purpose of our work is to investigate whether the ACA reduced lung cancer mortality, and to evaluate various modeling techniques both established and novel to healthcare policy analysis. We have identified obesity, smoking, air pollution (PM2.5), and ACA implementation year as key predictor variables and utilized public data sources from the CDC (WONDER, NHANES, BRFSS) and the EPA. Additionally, preliminary analysis has led us to consider measures for obesity other than simple BMI, such as waist circumference, based on literature indicating that abdominal obesity may have a higher correlation with lung cancer mortality than BMI. We are carrying out this analysis comparing models from several methodologies: difference-in-difference, GLM, PAR(p), and ARIMA. Monte Carlo simulations will be utilized to propagate uncertainty from the predictor variables through these models. We expect to determine the impact of ACA on lung cancer mortality and provide a quantitative tool for analyzing public healthcare policy.

Abstract Name: Advancing Urban Forestry: Enhanced Biomass Estimation Using Terrestrial LiDAR

Above-ground biomass (AGB) is a key metric for evaluating carbon storage in terrestrial ecosystems, particularly in urban environments where trees deliver significant ecological benefits. Accurately quantifying AGB in urban areas is complex due to the wide diversity of tree species, varying morphologies, and intricate land cover. This study leverages Terrestrial Light Detection and Ranging (LiDAR) technology to enhance AGB estimation for urban trees, providing a precise, non-invasive alternative to traditional methods. LiDAR data collected at Midwestern State University (MSU Texas) was used to extract individual tree point clouds, enabling the calculation of critical structural parameters such as tree height, diameter at breast height (DBH), volume, and surface area. Advanced segmentation and geometric modeling techniques were applied, and model outputs were validated against field measurements, including harvested biomass and DBH from campus trees. Focusing on North Texas species like Red Oak, Live Oak, Cedar Elm, and Pecan Hickory, this research refines a tailored AGB prediction model. Additional steps, such as scanning leafless trees for improved AGB estimates and incorporating tree height as a new attribute for analysis, aim to strengthen the accuracy of predictions. Furthermore, the TLS2trees algorithm will be utilized to automate individual tree segmentation from the LiDAR point cloud. The findings underscore the utility of LiDAR in advancing urban tree biomass assessment and support more reliable urban forestry management strategies for sustainable carbon management.

Abstract Name: History of the Japanese Kimono and the Transformation in Modern Designs

Kimonos have a rich history in Japan, originating during the Heian Period. Initially designed as a twelve-layer formal garment for nobility, kimonos evolved into simpler styles for everyday use, influenced by the Western expansion of trends and innovations, including the introduction of chemical dyes and advancements in silk production. The motifs woven into the fabric carry various meanings and reflect the changing seasons. The opening of Japan's borders in 1639 allowed Western ideas to reshape everyday attire, particularly during the Taisho and Showa periods, which saw kimonos transition from traditional designs to more Westernized interpretations.

Abstract Name: Buddhism During the Heian Period: Great Wisdom Sutra (Daihannya-kyō) from the Chūsonji Temple Sutra Collection (Chūsonji-kyō)

In Japan, the period spanning the seventh to the eleventh century is known as the Heian period. During this time, the shift from traditional Kami beliefs to Buddhism significantly changed the monastic school system, establishing eight distinct schools for Buddhist monks. The religion profoundly impacted the society's culture and politics, including educational institutions, military organizations, and the ascendance of monks to higher social ranks. This study demonstrates how Buddhists appropriate the traditional Kami beliefs to Buddhist values to deal with the pollution of their lands. The examines the scroll of The Great Wisdom Sutra (Daihannya-kyō) from the Chūsonji Temple Sutra Collection (Chūsonji-kyō), reflecting concepts of both Kami and Buddhism, depicted on opposing sides of the battlefield, as one side seeks the emptiness embodied in a scroll of the Chūsonji Temple. This text aims to clarify the historical journey of Buddhism into Japan, provide context for the Great Wisdom Sutra (Daihannya-kyō) from the Chūsonji Temple Sutra Collection (Chūsonji-kyō), and include a formal analysis of the artwork in question.

Abstract Name: A Long-Term Assessment Study On Water Quality Of The Rivers Around Defiance, Ohio USA.

The Maumee River begins in Fort Wayne, Indiana and flows through a number of large cities, including Defiance, Ohio, before draining into Lake Erie. The Maumee River watershed covers more than 6,500 mi² and two of its largest tributaries, the Tiffin and Auglaize Rivers, enter the Maumee in Defiance, Ohio. The goal of this research is to establish a long-term assessment program of the water quality in the Upper Maumee Watershed using chemical analysis, streamflow, and bioassessment utilizing diatom assemblages. Here we provide preliminary results from a field collection of sites on the Maumee River and tributaries conducted from 2021-2023. Four collection sites were sampled over three subsequent six-week periods from May-June 2021, 2022, and 2023. Sites included the Tiffin and Auglaize Rivers, tributaries of the Maumee; a site along the upper Maumee, prior to the confluence of the Tiffin, and a Maumee site past the confluence of the Auglaize. On average, the Maumee River prior to the confluence of the Tiffin, had the least turbid water with the highest levels of dissolved oxygen over the course of the sampling period. The Auglaize had the most turbid water with the lowest average levels of dissolved oxygen. This site also had the highest levels of nitrates, nitrites, and ammonia, and exhibited a lower average streamflow than both sampling sites on the Maumee. The diatom assemblages were dominated by *Fragilaria*, *Aulacoseira*, and *Navicula*. Results indicate that the Tiffin River site had the highest diversity in diatom and macroinvertebrate communities with diatom species indicative of high nutrient availability. Plankton tows at the Auglaize had a high percentage of benthic species present, indicating relatively turbid conditions. Both Maumee River sampling locations had similar species compositions, dominated by *Aulacoseira*, with an influx of *Stephanodiscus* indicative of nutrient runoff at the end of the sampling period.

Abstract Name: Social Determinants of Cognitive Function among Women in Menopausal Transition: Scoping Review

Background and Aim: Approximately 60% of middle-aged women experience cognitive decline during the menopausal transition, with the impact of multiple factors including social determinants of health (SDOH). However, little has been known regarding the role of SDOH on cognitive function among women during the menopausal transition. Therefore, this scoping review aims to synthesize the available evidence on SDOH in associations with cognitive function in this population. Methods: Based on the methodological framework proposed by Arksey and O'Malley, literature was obtained from PubMed, MEDLINE, CINAHL, and APA PsycINFO. Studies were included if they were published from January 2014 to January 2024, written in English, and conducted in community-based setting, whereas studies on the population with chronic psychiatric conditions, neurological conditions, or chronic disease were excluded. Identified SDOH were categorized into biological, psychological, and social dynamics with the guidance of the biopsychosocial framework. Results: Out of 251 studies searched, 27 were eligible for this review. 74% of studies reported

multiple SDOH and 15% reported interaction effects of SDOH on cognitive function. Biological dynamics included obesity and reproductive factors. Psychological dynamics include stress and occupational demand. Social dynamics included physical activity, childhood experiences, education level, socioeconomic status, race and ethnicity, and immigration status. Interaction effects were identified between obesity and stress, education and parity, and socioeconomic status and parity. Higher educational level was most consistently reported with better cognitive function, although the affected domains and measurements for cognitive function varied. Conclusion: Our findings highlight how individual-level biological dynamics interact with psychological and social dynamics to shape cognitive function, underscoring the importance of a multidimensional approach to understanding cognitive changes with roles of SDOH in women during menopausal transition. Implication: We suggest future studies investigating the interaction effects of SDOH and developing comprehensive assessments embracing SDOH to better understand cognitive function in this population.

Abstract Name: Preliminary Evidence Psilocybin Alters mPFC Circuitry to Restore Neural Balance in Depression

Demand for more rapid acting and efficacious antidepressants has led to a reevaluation of psychedelics for their therapeutic utility. Psilocybin, the psychoactive compound found in “magic” mushrooms, has been demonstrated to swiftly and chronically reduce symptoms of major depressive disorder. However, identifying neural correlates of therapeutic actions has proven difficult. Herein, we provide preliminary evidence of psilocybin’s ability to alter neural activity in a brain region implicated in the pathogenesis of major depressive disorder, the medial prefrontal cortex (mPFC). Augmented circuit-level signaling in the mPFC has been correlated with depressive symptoms, such as rumination, and theorized to be mediated by excessive glutamatergic signaling. Preliminary in vivo electrophysiological recordings of mPFC neurons in awake and unrestrained rodents treated with psilocybin, suggest two key changes in mPFC activity during administration of psilocybin: 1) GABAergic-like signals exhibited increased firing frequency, and 2) glutamatergic-like signals exhibited reduced firing frequency during psilocybin administration, compared to baseline. Preliminary evidence supports the hypothesis that psilocybin alters the excitation-to-inhibition signaling ratio in the mPFC which may, in part, mediate therapeutic effects. Furthermore, psilocybin may induce synaptogenesis within the mPFC leading to restoration of inhibitory signaling and potentially correlate with long-term resolution of symptoms of depression; this will be assessed in future experiments.

Abstract Name: The Not-So-Silent Fourth Branch: Media’s Impact on Voter’s Trust in the Government

In a democracy, trust is essential to the function of government; voters must trust that their vote holds value,

that those they elect are working in their best interests, and that the government cares about their well-being. This trust in government, however, is at an all-time low, risking the very foundation of American democracy. Using the 2020 American National Election Survey and the Chapman Survey of American Fears, representative national samples of U.S. adults, this paper aims to determine how different types of media, such as various outlets and social sites, impact American's fear of the government, measured using a variety of scales like fear of corrupt government officials, fear of fraudulent election results, and overall distrust of the government itself. Current literature highlights the relationship between echo chambers and the beliefs about government held by those in said chambers, and this paper uses regression analysis and crosstabs to determine if specific factors such as CNN vs. FOX news consumption, time on X/Twitter, or contact with print newspapers increase or decrease a respondent's fear of the government. I expect to find that the more time a respondent spends on non-mainstream news channels and on "fringe" social media, engaging with those who hold viewpoints similar to their own, the more likely they are to distrust the government, no matter their party affiliation. As media moves further away from serving the public and towards serving their bottom lines, it is essential to understand media's ever-growing impact on our faith in democratic systems.

Abstract Name: DYNAMICS OF DOSE-RESPONSE OF ZEBRAFISH (DANIO RERIO) PREFERENCE FOR UNDISTURBED SHOALS OVER SHOALS EXPOSED TO THE SYNTHETIC ALARM SUBSTANCE HYPOXANTHINE-3-N-OXIDE (C5H4N4O2)

Zebrafish (*Danio rerio*) are a common model organism for behavioral neuroscience due to their complex social behavior, which includes shoaling. Shoaling occurs when members of a group loosely congregate without synchronization of movement. Previous research has shown that zebrafish prefer an established social environment and can detect subtle movement differences among group members in forming shoaling preferences during the 3-chamber open-tank free-swim task (OTFST). In the present study using the OTFST, single subjects in the center tank were provided simultaneous visual exposure to a shoal exposed to synthetic alarm substance in one flanking tank and a shoal that remained unalarmed in the other flanking tank. The dose of the synthetic alarm substance delivered to the tank holding the alarmed shoal resulted in a final concentration of 1.5nM, 3nM, or 5nM of C5H4N4O2. The movement of each subject was recorded using MediaRecorder and EthoVision XT16 was used to summarize positional data for each subject as a heatmap. Across the heatmaps, subjects demonstrated three specific response patterns—social contagion (avoiding the alarmed shoal), social buffering (affiliating with the alarmed shoal), and boldness (multiple cross-tank

excursions between the two shoals). There was more variability among subjects responding to the shoal exposed to 1.5nM compared to 3nM. Subjects responding to a shoal exposed to a 1.5nM concentration spent more time in the top half of the tank compared to subjects responding to a shoal exposed to a 3nM concentration. This suggests that subjects responding to a shoal exposed to a higher concentration showed more anxiety-like responding. Data on subjects exposed to a shoal exposed to the 5nM concentration are pending. This study promises to advance the understanding of mechanisms that produce distinct social behaviors and anti-predation responses in zebrafish.

Abstract Name: A Novel 3-D Printed Device for Spectrochemical Titrations

Titration is utilized in a variety of areas of chemistry because of their simplicity, low cost, versatility, and ability to selectively and accurately quantify a target analyte of interest. Although acid-base titrations are most commonly investigated, titrations can also be used to probe redox, precipitation, complexation, and a variety of other reactions of interest. Because many chemical reactions involve clear reactants and products, indicators are frequently employed to provide a colored species that indicates the endpoint of a titration. There are limitations with using indicators, however, because not every indicator has a very obvious color change at the endpoint of a reaction and because human eyes have difficulty distinguishing small shifts in color or weak intensities. A spectrophotometer can detect even the smallest color change, so using this for endpoint detection can improve the quality of the analysis. In this work, various attachments able to contain the reaction volume of a titration were designed and created with a 3-D printer. These attachments were subsequently connected to a spectrophotometer and their performance was evaluated for use in a spectrophotometric titration. Characteristics and specifications of the attachments and their suitability for future titrations will be discussed.

Abstract Name: Effects of Phytoremediation on Horizontal Gene Transfer

The increasing global use of antibiotics in human, veterinary, and agriculture practices has led to significant environmental contamination, particularly in aquatic ecosystems. The amount of antibiotic resistant bacteria in local waterways has been increasing due to an increase in antibiotics in runoff going into waterways fostering ecological imbalances and contributing to the spread of antibiotic-resistant bacteria (ARB) and

resistance genes (ARGs). This study investigates the role of aquatic plants, specifically *Vesicularia montagnei* and *Phyllanthus fluitans*, in mitigating horizontal gene transfer (HGT) among bacterial populations in controlled environments. We explore whether these plants can reduce the prevalence of ARGs or inadvertently facilitate HGT. Utilizing in vitro experiments with *E. coli* strains resistant to tetracycline and ampicillin, we assess how plants are affecting the rate/occurrence of HGT. Our findings aim to inform wastewater treatment strategies by evaluating the potential integration of phytoremediation techniques. Understanding the interaction between HGT and aquatic plants is crucial for developing effective measures to combat antibiotic resistance in aquatic ecosystems, ultimately enhancing public health safety.

Abstract Name: Effects on Environmental Sustainability when Using Basalt Fiber as a Reinforcing Material for Composites in Industrial Applications

Recently, initiatives have been established to promote more sustainable practices and approaches in industry and academia. This work aims to find more cost-effective and sustainable industrial applications within the scope of reinforcing materials in composites. In the past two decades, various natural fibers such as lignin fibers, basalt fibers, etc., have been investigated to replace carbon and glass fibers to reduce the carbon footprint. Basalt fibers are natural fibers made from crushed basalt- a volcanic rock. In applications requiring high ductility and where stiffness is not the prime design criterion, like the glass fiber applications, basalt-based fibers have shown promise because of their feasible mechanical performance and ability to react with carbon dioxide and form stable carbonate minerals. Basalt fibers also offer a significant economic advantage, requiring less energy to produce than glass fibers, making them a practical choice for sustainable materials. This study used the continuous stiffness measurement (CSM) technique to evaluate the single fiber tension properties (modulus, yield, and strength) of various basalt fibers made from different source rocks and processing parameters. We then employed Weibull statistics to understand the size-dependent properties of these fibers and compared them to commercial glass fibers. The results of our study are promising, suggesting that basalt fibers could replace glass fibers in a more economically feasible and environmentally sustainable manner. In addition, these findings could be instrumental in understanding the structure-property-processing relationship for basalt fibers.

Abstract Name: In Favor of Retrospective Learning in Political Science

How can we ensure that learning is cumulative? Retrospective learning refers to the idea of inspecting a past event, action, or decision and reevaluating based on events that have occurred after they have occurred it also

includes utilizing newly gained knowledge and resources since the past event, action, or decision. For example, a college freshman is evaluating the Israel and Palestine conflict. They would then engage in Retrospective Learning by reevaluating the assignment years later as a senior in college with newly gained knowledge and new events that have occurred since. How does retrospective learning influence the retention and understanding of complex concepts, and what role does it play in fostering self-directed education among college students? This will be answered by analyzing journal articles on teaching and learning, empirical studies on retrospective learning retention rates, and political science journals on methods of learning. A distinctive feature of this research is its focus on Political Science, a field that blends the rapid developments and contemporary dynamics of today with theoretical foundations rooted in ancient Greek thought. This type of research provides valuable insight into how retrospective learning can be used to help students understand complex concepts, as well as foster self-directed learning. Additionally, this research will provide insight into how retrospective learning can be implemented in the classroom to support student learning.

Abstract Name: The Degradation of the Senate: Polarization and the Rise of Executive Power

Over the last few decades, the Senate has been degraded and become increasingly polarized, leading to an unprecedented increase in executive power. This paper aims to demonstrate the alignment and contrasts between the constitutional framework and the practical reality of the relationship between the legislative and executive branches. Using a case study approach explore how this degradation and polarization of the Senate has increased the executive's power, this can be seen based on congressional opinion on rule XXII and the changing tactics of minority and majority parties. As a result of the degradation of the Senate and the resulting destruction of democracy, I expect to find that the decay of the Senate is linked to the growing power of the executive branch. This research is important because it seeks to explain a growing problem in our democracy and present democratic solutions to this problem to help us walk away from the ledge that is polarization.

Abstract Name: Ethical Perceptions and Impacts of Generative AI in Faith-Based Higher Education

Generative Artificial Intelligence (GAI) is a rapidly evolving technology with various models that challenge existing ethical modalities and thought processes, particularly in educational settings. Higher education institutions are especially being shaped and transformed by this; faith-based higher education has additional facets of consideration, especially in regard to faith and morally aligned mission, vision, and standards of education. This study explores the perceptions of various stakeholders at a small faith-based institution in West Texas, examining current and future spiritually-oriented considerations of GAI integration and

policymaking. Initial research highlights distinct ethical challenges, including conflicts and incompatibilities with current GAI models. To investigate, a survey was conducted of 1,858 participants, including students, faculty, staff, and administrators, followed by 23 qualitative interviews based on volunteer participant feedback during the survey. The study's findings reveal nuanced perspectives on GAI integration, highlighting both opportunities and challenges. On initial examination of the data, it appears that stakeholders recognize the potential and opportunities from GAI technologies but anticipate concerns with institutional integration and potential biases from AI-generated content. The findings from this study will aim to contribute to the overall discourse on AI ethics, and guide and inform both local and overall considerations for both institutional stakeholders and GAI developers in the refinement of policies and procedures, and technological development, respectively. With additional analysis and fine-tuning of the research instruments and methodology, this study can be expanded to encompass a wider range of faith-based higher education institutions. Employing a mixed-methods approach with quantitative survey data and qualitative interview responses allows for a comprehensive understanding of how institutions may achieve ethical GAI integration without infringing on their overarching goal of faith integration.

Abstract Name: How Does War Impact Individuals and Businesses in the Democratic Republic of Congo?

This project investigates the multifaceted challenges businesses and individuals face in the conflict-ridden environment of the Democratic Republic of Congo (DRC). In a country where ongoing conflict disrupts lives and creates an atmosphere of insecurity, this study seeks to understand why many businesses fail and how these failures impact the Congolese people. The research will explore the lived experiences of business owners whose enterprises collapsed or were harmed due to the war. The study highlights issues such as infrastructure damage, supply chain disruptions, and the struggle for stability in a post-conflict setting marked by limited access to essential services like clean water, food, healthcare, and education. Additionally, the research will explore gender-specific challenges, including sexual harassment and early marriage, to understand how these issues intersect with business and personal resilience. Through semi-structured interviews, ethnography, and autoethnography, the project will shed light on the nuanced experiences of those affected by conflict, emphasizing the need to address both economic and gender issues to promote peace and improve the environment for businesses and communities in the DRC. By tackling these interconnected challenges, the study aspires to contribute to a more comprehensive understanding of post-conflict recovery and inform policies that support sustainable development and gender equity in the region.

Abstract Name: Determining How Space Use Affects Exposure and Toxicity of Two Common Use Insecticides

Insecticides play a crucial role in advancing agriculture, yet their runoff poses environmental risks to non-target areas. Evidence from laboratory and field toxicity assessments confirms the harmful effects of insecticides on diverse aquatic species. However, existing evaluations of insecticide toxicity often assume uniform exposure, an assumption that not accurate under field conditions. It is increasingly recognized that behavioral patterns can influence toxicity in the context of insecticide contamination, an aspect that remains understudied. Therefore, the objective of this study was to explore how space use influences toxicity of two widely used insecticides, bifenthrin and permethrin, on sediment toxicity to *Hyaella azteca*. Glass beakers were modified with steel rings to create exposure arenas with contaminated sediment placed either inside, outside, or both inside and outside the ring, resulting in three unique conditions for 48 h toxicity tests with *H. azteca*. For both bifenthrin and permethrin, pesticide placement influenced exposure and resulting toxicity to *H. azteca*. Placing pesticides within the steel ring resulted in higher lethal concentration 50 (LC50) values, indicating reduced mortality rates. Conversely, lower LC50s were recorded when contaminated sediment was placed outside or both inside and outside the ring. This suggests that *H. azteca* preferentially spend time in contact with the outside edge of the beaker, leading to higher exposure and increased toxicity when insecticides were placed outside the steel ring. As such, our results suggest space use is a major factor in predicting insecticide exposure and toxicity and should be considered in the development of laboratory toxicity tests.

Abstract Name: Quantifying the Biomechanics of the Heart in Severe Mitral Valve Prolapse

Mitral valve prolapse (MVP) is a common heart condition where the mitral valve billows into the left atrium as the left ventricle contracts, allowing oxygenated blood to regurgitate backwards rather than properly flow into the body. The leaky valve changes the forces and strains in the heart muscle wall and the papillary muscles that anchor the valve. It is hypothesized that these abnormal forces cause inflammation and scarring known as cardiac fibrosis, weakening a patient's heart function and leading to negative outcomes such as sudden cardiac death. In this project, cardiac magnetic resonance (CMR) imaging and echocardiography will be employed to characterize the heart anatomy and blood flow. Echocardiography measurements will include mitral regurgitation and end systolic and diastolic volumes. CMR images will be used to identify fibrosis and segment the mitral valve, as well as measure the four-dimensional (4D) blood flow through the heart. A new algorithm will be employed to obtain patient-specific transvalvular pressure data from the 4D Flow MRI. This novel multimodal data approach will allow a more comprehensive understanding of the multiple biomechanical processes underlying MVP. Relationships between echocardiography parameters and fibrosis will be examined for six MVP patients. It is expected that the cardiovascular biomechanisms will differ significantly between patients with and without fibrosis. In particular, the mitral valve surface area and valvular pressure gradient are expected to be higher in patients with fibrosis. The proposed pipeline will be instrumental in finding connections between patient-specific biomechanical properties and fibrosis, allowing the identification of MPV patients most likely to have negative outcomes. This information will also develop the scientific understanding of the root causes of fibrosis, informing the development of future interventions.

Abstract Name: Baseline Intercultural Competence of Students Entering Social Science Academic Majors at a Mid-size Midwestern Public University

Intercultural competence is the capability to accurately understand and adapt behavior to cultural differences and commonality. Developing this competence requires increasing cultural self-awareness by gaining insight into the experiences, values, perceptions, and behaviors of individuals from various cultural backgrounds. Then actively adjusting one's perspectives and actions to navigate cultural differences effectively. For higher education institutions to provide curriculum to match the baseline ICC level among different academic majors, it is necessary to first investigate the differences among undergraduate academic majors. This study began with an archived data set that included more than 2000 undergraduate students who completed the Intercultural Development Inventory during the past 15 years. This instrument is based on the Intercultural Development Continuum theory, and research has found that it has strong validity and reliability across diverse cultural groups. The theory names five stages of orientation to cultural differences: denial, polarization, minimization, acceptance, and adaptation, ranging from an ethnocentric to an ethnorelative mindset. Investigators conducted a random stratified sample to select data for 100 undergraduate students who pursued academic majors in psychology, education, or sociology at the university. The data set included age, gender, education completed, and college of academic major. The data was de-identified and exported to Excel and SPSS for analysis. The study was intended to describe the baseline ICC of undergraduate students by academic major. With more attention drawn to this subject, more action may be taken to counteract conflicting intercultural competencies. The findings of this study provide information to campus administrators and practitioners. The application of results may include implementing culturally sensitive classes and material in higher education curricula, so that diverse students can be served and grow.

Abstract Name: Wanhi Yukan / Grand Meadow Chert Quarry Lithic Debitage Analysis

While time often strips away the organic aspects of our material culture, stone artifacts, like tools and the debris generated in their manufacture and maintenance, remain preserved and are frequently recovered at archaeological sites. Often considered of little value at the time they were discarded, the stone waste flakes struck away during flintknapping (the shaping of lithic artifacts) carry critical information on both raw material choices and the intentions of the craftsperson who made them. Grand Meadow Chert (GMC), a high quality, sedimentary toolstone from a very defined source, Wanhi Yukan/Grand Meadow Chert Quarry (GMCQ) in Southern Minnesota, has been recovered in abundance in the form of endscrapers in archaeological sites across the Midwest. Endscrapers are tools primarily used to remove soft tissue and fur when processing animal hides. While recent studies have investigated flaking attributes (physical traits) of the production debris of other stone tool types, little attention has been paid to those coming from endscraper manufacture. Large quantities of GMC waste flakes have been recovered during archaeological projects at GMCQ, but the flintknapping activities that occurred there are undocumented. The knappers may have

focused on testing raw nodules, but could have also produced tools like endscrapers. This study explored the flaking attributes of GMC endscraper production by analyzing experimentally created flake sets. After attribute data was collected from experimental endscraper production, it was compared against that of other chipped tool manufacturing experiments. Flaking trends diagnostic of endscraper production were identified. With established tool production data as a guide, the flake assemblage recovered from GMCQ reflected endscraper and general core/flake production occurring at the site. These flakes, physical traces of human being, guide the interpretation of this location; supplying a voice for the significant relationship between endscrapers, the quarry, and communities who contributed to its physical record

Abstract Name: An Assessment of Complete Scaling Theory Applied to Nitrobenzene + n-Alkane Liquid-Liquid Systems

The study of partially-miscible binary liquid systems is valuable to separation science in terms of describing phase behavior. Coexistence curves show phase transitions of liquid-liquid systems for a range of temperatures as a function of system composition. Complete Scaling Theory (CST) is frequently used to fit these coexistence curves. The analytical method and the synthetic method are two different approaches to collecting phase transition data in liquid-liquid systems. The residuals from CST fits of analytical-method literature data of nitrobenzene + alkane data show the presence of systematic, symmetrical deviations. These discrepancies either reveal limitations of CST, or are due to artifacts of the analytical methodology. To answer this question, phase diagrams of the nitrobenzene + n-hexane (NBH), n-decane (NBD), and n-tetradecane (NBT) systems were measured using the synthetic method. Over twenty samples of each system were made in flame-sealed ampules, and their coexistence curve temperatures (T_{cx}) were determined from laser-light scattering data. Critical compositions were found by fitting 90° light scattering data, and CST coexistence curves were fit to the T_{cx} data. Our results for the NBH coexistence curve show that the literature data are incorrect, likely due to the challenges of determining phase composition with the analytical method. The CST fit to our NBH data yields random residuals, and no systematic deviations. For the NBD and NBT systems, our coexistence curves are in excellent agreement with literature data, and show the same symmetrical and systematic deviations in the residuals of CST fits. This indicates that the CST model does require further development for improved data fitting.

Abstract Name: Microfluidic Fabrication of Monodisperse Alginate-based Hydrogel Microparticles

Alginate hydrogels are used in a wide array of applications, such as drug delivery vehicles for chemotherapeutic agents, wound dressing, and tissue engineering, due to their biocompatibility and structural similarity to extracellular matrices in tissues. Here, we present a microfluidic method for synthesizing monodisperse alginate microparticles using flow-focusing emulsification techniques. In this method, two side channels carrying the continuous oil phase intersect with a central channel containing the dispersed aqueous phase, facilitating the formation of uniform droplets where the continuous phase pinches off the dispersed phase into droplets. The microfluidic devices were fabricated using standard soft lithography techniques. A 2% sodium alginate solution, containing sodium EDTA and calcium chloride, was emulsified into ~70 μm droplets. Introducing acetic acid into the oil phase caused a pH reduction within the droplets, disrupting the EDTA–calcium complex and releasing free calcium ions, which induce alginate gelation. After polymerization, a chemical demulsifier was applied to retrieve the aqueous phase containing the hydrogel microparticles, which was subsequently washed and stored in a buffer solution for later use. With modifications to system design and protocol techniques, this method can produce hydrogel microparticles averaging 20-30 μm in diameter, while retaining physical characteristics analogous to cellular structures. This approach holds significant potential for biomedical applications, including targeted drug delivery and regenerative medicine.

Abstract Name: Feeding biomechanics and native and invasive fish species in the Florida Everglades

Everglades conservation is critical to both the well-being of Everglades biodiversity and the communities surrounding this unique ecosystem. Factors such as the management of water resources, agriculture impacts, and invasive species all affect the viability of the Everglades. The success of invasive species can often be attributed to their ability to outcompete the native species in their niches. To investigate the success of invasive cichlid fishes in the Everglades and their ecological impact on native centrarchid fishes, bite force and suction pressure were investigated over ontogeny using biomechanical modeling. Invasive Mayan cichlids *Mayaheros urophthalmus* (14 - 29 cm TL) had an oral jaw mechanical advantage of 0.36, bite force of 5.3 N, epaxial mechanical advantage of 0.24, and suction pressure of 1.9 kPa. Invasive Nile tilapia *Oreochromis niloticus* (12 - 26 cm TL) had an oral jaw mechanical advantage of 0.42, bite force of 1.6 N, epaxial mechanical advantage of 0.19, and suction pressure of 0.9 kPa. Native bluegill sunfish *Lepomis macrochirus* (10 - 15 cm TL) had an oral jaw mechanical advantage of 0.37, bite force of 0.7 N, epaxial mechanical advantage of 0.31, and suction pressure of 2.7 kPa. Preliminary analyses suggest that bluegill have lower bite forces but higher suction pressures, suggesting that any extent to which the bluegill is being outcompeted by these invasive cichlids may not be attributable to deficits in feeding performance. Future analyses will examine scaling patterns of feeding biomechanics and add sampling of additional native (redear sunfish *Lepomis microlophus*, spotted sunfish *Lepomis punctatus*, warmouth *Lepomis gulosus*) and invasive (oscar *Astronotus ocellatus*, jewel cichlids *Hemichromis bimaculatus*) species.

Abstract Name: Pre-Twisted Molecular Geometry's Effect on the Optical Properties of Nitrophenyl Substituted Polycyclic 1,2-BN Heteroarenes

Incorporating a three-coordinate boron center into the structure of polycyclic aromatic hydrocarbons by replacing one of the sp^2 C=C bonds with a boron-nitrogen bond creates flat-structured heterocycles known as aromatic azaborines (AAs). AAs are widely recognized for their unique optoelectronic properties including photochemical stability, high molar absorption coefficient, and high fluorescent quantum yields, as well as large Stokes shifts and tunable absorption/emission spectra, making them excellent candidates for a wide range of applications, including organic light-emitting diodes (OLEDs). Adding a -NO₂ group as a strong electron-withdrawing group to the scaffold of aromatic AAs, particularly pyrrolinone-fused-1,2-azaborines (PFAs), in an effort to redshift their absorbance and emission wavelengths and create electron-deficient n-type organic conjugates, results in significant emission quenching due to intersystem crossing. Another issue with -NO₂ substituted PFAs also tend to aggregate at high concentrations due to strong intermolecular π - π stacking interactions. In turn, aggregate formation results in emission quenching, also known as Aggregation-Caused Quenching (ACQ). This practical limitation poses significant challenges for -NO₂ substituted PFAs' use in many applications. We hypothesized that increasing the steric interactions through the PFA scaffold by incorporating a twisted molecular geometry by including bulky moieties such as methyl group will result in -NO₂-phenyl substituted PFAs with aggregation-induced emission (AIE), aggregation-induced emission enhancement (AIEE), solvatochromic and thermochromic properties. These findings will help to improve future AIE-active PFAs and better understand how molecular geometry effects these compounds' optoelectronic capabilities.

Abstract Name: Marijuana Usage Risk

Marijuana has become legal for recreational use in half of the fifty states. An important thing to consider when legalizing marijuana for recreational use is the effect on the college population. The purpose of this study is to use self-report methods to examine the relationship between marijuana use and academic performance. Arria et al., (2015) found a negative association between marijuana use and the number of classes skipped. Smith et al., (2022) focused on college students' self-report on side effects of marijuana, with 44 % reporting impaired cognition as a side effect of usage. However, there has been no recent research that focuses on the relationship between the amount of marijuana consumed and overall academic performance. In this study, we will survey college students using a combination of our own questions, the Cannabis Abuse Screening Test and The Academic Performance Scale. The CAST is one of the most widely used screening tools for cannabis abuse (Sznitman, 2017). The CAST will split the participants into three groups: low risk, moderate risk, and high risk. The Academic Performance Scale has proven reliability and validity (Birchmeier et al., 2015). After collecting data, a one-way ANOVA will be used to examine potential differences between the three groups. Arria et al., (2015), found a negative association only between marijuana use and number of classes skipped, and according to the data collected by Smith et al., (2022),

most college students report no impaired cognition. After examining previous research, we hypothesize that there will be no significant differences between the low, moderate, and high-risk cannabis abuse groups.

Abstract Name: The Effects of Young Blood Plasma on Neurofilament Light Chain (NfL) and Glial Fibrillary Acidic Protein (GFAP) following Traumatic Brain Injury Administration in Wild-type Mice

Glial fibrillary acidic protein (GFAP) and neurofilament light chain (NfL) are proteins that act as biomarkers that can be detected in blood to observe astrocyte activation and axonal integrity (Fang et al., 2024). Previous studies have shown that traumatic brain injuries (TBIs) can induce neuronal death and contribute to neurodegeneration (Kundu and Singh, 2023). GFAP is a protein expressed by astrocytes that is involved in the injury repair of brain tissue. Elevated GFAP levels have been shown to correlate with lesion volume and TBI severity (Ahmadi et al., 2023). Neuroinflammation is a factor that contributes to neurodegeneration (Zhang et al., 2023). This is pertinent because GFAP has been known to reflect glial responses to neuroinflammation (Leuzy et al., 2022). NfL is a protein found in the axon of neurons and is released into the plasma when injury or neurodegeneration is present. NfL is involved with structural support and improves the conduction speed of action potentials (Narayanan et. al, 2021). In previous studies, elevated levels of GFAP and NfL have been shown to signal the progression of neurodegeneration (Fang et al., 2024). TBIs are a risk factor for neurodegenerative disease (DeKosky and Asken, 2018). Previous research demonstrated that young blood plasma transfusions may reverse factors of neurodegeneration in older populations (Villeda et al., 2014), those with Alzheimer's Disease (Middeldorp et al., 2016), and those with TBIs (DeKosky and Asken, 2018). The proposed study seeks to perform plasma analysis using Enzyme-Linked Immunosorbent Assay kits to test for concentrations of GFAP and NfL in the plasma samples obtained from a previous study. The current project seeks to expand on a Master's thesis by Nelly Zabala and Vincenzo De Lillo. Plasma from four groups of mice will be tested: TBI and plasma-treated, TBI and saline-treated, non-injured and plasma-treated, and non-injured and saline-treated mice.

Abstract Name: An Analysis of Factors in Pilot Aircraft-Assisted Suicides

The Federal Aviation Administration (FAA) puts in place medical requirements with the aim of increasing air safety. Several of these medical requirements relate to factors impacting mental health, such as pilot usage of selective serotonin reuptake inhibitors (SSRIs). This paper studies factors that are present in pilot aircraft-assisted suicides. These factors are important in order to create policies that are effective in risk mitigation while still giving a space for pilots to come forward with honesty about their mental health issues and receive

the help that they need. Existing literature indicates that pilots often feel compelled to misrepresent their mental health situation and avoid seeking treatment or communicating treatment to the FAA out of fear of losing their medical certificates, upon which their hobbies or career might depend. From the period of 1989–2021, the National Transportation Safety Board (NTSB) database contains 43 aircraft-assisted suicides initiated by the pilot. This study investigates a variety of factors, ranging from class of certificate, age, gender, medication, negative life events, and alcohol usage.

Abstract Name: Superhero(ines): How the World's Most Profitable Film Industry Portrays Women in Post-#MeToo

For the entirety of the 21st century, superhero movies have largely defined popular cinema, with Marvel becoming the most profitable film franchise in history. Despite their wide audience, films in this genre remain almost entirely male-focused, with few to no women as key characters. In the aftermath of #MeToo, superhero films made an effort to create female-focused, feminist movies. While several of them are highly praised, they all feature varied amounts of “negotiation”, or purposefully pulling away from the feminist potential to present a greater general appeal for the consumer. One such film is 2017's Wonder Woman, which received high praise as the first of its kind having a female superhero lead. This film may look feminist on the surface but continues to fall into the same, limiting portrayals of gender, noticeably with a man acting as the wise and worldly guide, and a twist at the end that not only re-writes the lore of the character, but also undermines the heroine's abilities and removes the importance of a featured community of women. Contrarily, 2020's Birds of Prey had an underwhelming cinematic release, but continues to receive praise as a third-wave feminist film, placing heavy importance on the diverse, complicated, and genuine portrayals of women and the community that can form between them. Birds of Prey also offers a refreshing view of femininity being a crucial form of self-expression. While this film is not perfect, and once again has bizarre moments of re-writing the further diversity of the source material, its discussions of feminine intersectionality offer a much-needed step forward for the genre. At a time when fatigue for superhero films is prominent, examining these films offers a valuable look at what needs to change for the sake of the audience, the industry, and the stories themselves.

#1 Bashira Akter Anima

Abstract Name: Expanding Human-Robot Collaboration in Multiple Task Solution Scenarios

Human-robot collaboration (HRC) has been used in a wide range of applications, such as industry, healthcare, and even in daily household activities to assist humans with tasks such as cooking and cleaning. To make HRC more adaptable to real-world environments, robots must be able to interpret explicit and implicit instructions from environmental cues, then communicate solutions to effectively mimic human teamwork.

While advancements have been made in training robots with more flexible teamwork skills, there are still challenges in implementing more human-like collaboration where robots can understand implicit verbal contexts and work through cases with multiple solutions. Previous work by Dr. Bashira Akter Anima at the University of Nevada, Reno used a collaborative architecture where robots act on word associations and respond accordingly for one-solution scenarios. For instance, the robot would begin making tea if the human said phrases such as, "I am thirsty" or "It is cold outside." This work extends the hierarchical robot control architecture from Dr. Anima's work by introducing a new skill to handle scenarios with multiple solutions available in the environment. To help the robot work through multiple solutions, it will be given a sample dialog structure with a modified task architecture that considers a human answer to choose the correct skill to perform. By the end of this work, the humanoid robot Baxter is expected to engage in dialogue with humans to resolve ambiguities and determine the preferred task, mimicking human teamwork. Using this extended task architecture, Baxter will execute agreed actions, enhancing adaptability in real-world environments. For example, if a human says, "It's hot outside," the robot might suggest cold tea or sunscreen, discuss options, and perform the chosen task while adhering to constraints.

Abstract Name: A High-Gain, Low-Noise RF Downconverting Passive Mixer with Cross-Coupled Topology Negative Resistance Techniques

This paper provides a way to save one's life in an emergency by bringing a method to minimize battery consumption during satellite SOS wireless communication. This is done by employing a high-gain, low-power, low-noise passive mixer circuit for wireless communication. A mixer is a circuit that is necessary for wireless communication. The paper introduces multiple mixer circuit designs that can increase its output and efficiency. One of the topologies expanded its input and output to a differential structure using a Metal-oxide Semiconductor Field-Effect Transistor (MOSFET), making the topology a double-balanced design. The double-balanced design increased the output from $1/\pi$ to $2/\pi$ making a 2 times more significant improvement. Not only this, but the design also increases efficiency by eliminating thermal noise components. The paper also introduces a cross-coupled transistor pair in addition to the double-balanced design. The cross-coupled pair gives negative resistance. The negative resistance increases output by reducing parasitic values in the double-balanced topology. By combining the two MOSFET designs, the final design gave 254.96 m dB of conversion gain in RF amplitude sweep, 2.12 dB of gain in RF frequency sweep, and 8.36 dB of noise figure. The research significantly boosts gain and reduces noise in wireless communication. The findings of the paper lay the foundation stone for future advancement in high-frequency wireless communication analog circuit design.

Abstract Name: Factors Associated with HPV Vaccine Uptake Among Rural Parents in Alabama

The human papillomavirus (HPV) has emerged as the most prevalent sexually transmitted infection and the primary cause of cancers including cervical cancer. In the U.S., HPV vaccination is recommended for 9 to 26 years of age. Despite all major efforts, HPV vaccination uptake continues to be relatively low, especially among rural and low-income residents and higher among racial/ethnic minorities. Hence, we sought to examine the association of HPV vaccine uptake and awareness of a vaccine to cancer with parental demographic characteristic, child's health insurance coverage and if they have a regular source of healthcare. We used a cross-sectional study, cluster sampling, population-based survey in Escambia County, AL. The parents of children aged 9 to 18, who have received HPV vaccinations were surveyed to determine their understanding about HPV. Demographic factors, questions about awareness of a vaccine to prevent cancer, if parents have ever heard of HPV, and child HPV vaccine uptake were obtained from the parents. A total of 357 parents were surveyed in this analysis. There is a difference of parent's not having knowledge of a cancer prevention shot and their child not receiving the HPV vaccine versus parent's awareness of HPV. Therefore, there is an association between parents' awareness of HPV, parental age, gender, and self-reported child's uptake on HPV vaccination. Moreover, older, female parents, and who have heard of HPV were more likely to report that they got their children vaccinated against HPV than younger, male parents, and who indicated they had not heard of HPV. This study shed a light of factors associated with HPV vaccination among children under 19 years of age residing in a rural county, which can inform the development, implementation, and evaluation of strategies or intervention to promote HPV vaccination. Further research is necessary to ensure an increase to HPV vaccine uptake.

Abstract Name: Feeding Hawai'i's Future: Evaluating the Effectiveness of Culturally Tailored Diet Programs for Indigenous Hawaiians

The state of Hawai'i faces a severe food crisis, with over \$800 million annually accrued healthcare costs linked to chronic, diet-related conditions. Food insecurity disproportionately affects the native Hawaiian, or kānaka maoli, community, which exhibits higher diabetes and heart disease mortality rates and the shortest life expectancy of any major ethnic group in the state. One approach to addressing this challenge has been implementing culturally tailored, traditional Hawaiian diet (THD) programs. Since the launch of the first Hawaiian diet intervention program in 1987, THD programs have fostered supportive environments, reintroduced traditional foods, and promoted cultural values to enhance Hawaiian well-being. However, many of these interventions have yet to yield long-term benefits and behavior changes in native Hawaiian communities. This research investigates not only the components of cultural diet intervention programs that may provide short-term benefits to native Hawaiian health but also the barriers that may prevent such programs from achieving long-lasting results. A literature review was conducted utilizing various databases and peer-reviewed journals including but not limited to ResearchGate, EBSCOhost, National Institutes of Health, Sage Journals, Hawai'i Medical Journal, and Pacific Health Dialog. Key terms employed during searches included but were not limited to: diet, health, intervention, diet programs, colonization, biocultural sovereignty, food sovereignty, food insecurity, traditional diet, Hawai'i, indigenous Hawaiian, and Native Hawaiian. From this comprehensive review, it was discovered that cultural diet programs show great potential for serving the indigenous Hawaiian people. By reintroducing traditional foods, adopting a holistic approach

to health and wellness, fostering a community spirit, and providing educational opportunities, THD programs aim to empower native Hawaiians to make healthier dietary choices. However, inadequate funding, limited accessibility, a failure to address systemic inequalities, and dissatisfaction with prescribed foods hinder the long-term success of these programs.

Abstract Name: A Comparative Analysis of Capture ELISA Assays for Detecting SULF2

Background: SULF2, a heparan sulfate endosulfatase, is overexpressed in various cancers, including hepatocellular carcinoma, breast cancer, and non-small cell lung cancer (NSCLC), where it has been associated with prognosis and potential as a blood biomarker. Beyond oncology, SULF2 has shown promise as a serologic biomarker for liver cirrhosis. However, standardized methods for measuring SULF2 levels in plasma or serum remain undeveloped, and the comparative performance of existing assays is not well understood. This study aims to compare the performance of a commercially available SULF2 ELISA kit with an in-house ELISA assay for SULF2 detection. Methods: Conditioned media was collected from cell cultures prepared using a standardized protocol and analyzed for SULF2 concentration. The commercial ELISA kit followed a multi-step protocol, including incubation with detection reagents and substrate solution, followed by absorbance measurement at 450 nm. The in-house assay utilizes two newly developed monoclonal antibodies in a sandwich ELISA format to measure SULF2 levels in the sera of healthy individuals and cirrhosis patients. Findings: Preliminary findings from the commercial ELISA kit revealed SULF2 concentrations of 15.27 ng/mL, 32.25 ng/mL, and 13.33 ng/mL across three conditioned media samples. These results establish baseline data for comparison with the in-house assay, which will be implemented in future studies. Future Directions: The outcomes of this investigation will inform the relative advantages and limitations of the two ELISA methods, providing insights into their applicability for research and clinical diagnostics. Future directions include optimizing and validating the in-house assay to evaluate its sensitivity and specificity compared to the commercial alternative.

Abstract Name: Healthcare Greenhouse Gas Inventory Calculator Evaluation

Hospitals and the healthcare industry have a substantial impact on the environment. Their energy use intensity, waste generation, and pollution, contribute significantly to global greenhouse gas emissions. A greenhouse gas inventory (GHG inventory) is the first step to lowering the carbon footprint of hospital systems. GHG inventories consist of a list of emission sources and the associated emissions, quantified using

standardized methods. This is a review of existing carbon emission calculation tools for healthcare facilities, describing their reporting inputs/outputs and informing more standardized healthcare specific emissions calculations. We created a set of guidelines for evaluation of current calculator tools based on existing methodology for carbon footprint calculator evaluation. We screened 12 calculators, identifying 3 for inclusion. Evaluation was conducted based on the established metrics, including number of inputs for Scope 1 and 2 emissions, and normalization factors, such as building sq ft. There were differences in reporting practices between each calculator, both in data normalization metrics and input categories. Further analysis showed that there is a limited number of calculation tools available to hospital systems, and no standardized practices between tools. A greater emphasis on consistent reporting standards would improve the quality, comparability, and usefulness of carbon emissions calculators. From the evaluation done on existing tools, we developed a new GHG emissions calculator to fit with the established literature criteria. This calculator is customizable, easy to use, and is able to convert data from energy and transportation bills to associated emissions. The data populated and managed in this calculator tool can also help to identify key opportunities for energy reduction in both individual buildings, and at a portfolio level. As healthcare systems look to improve their climate strategies, utilizing an accurate and streamlined greenhouse gas calculation tool will make all the difference.

Abstract Name: Luminance Contrast Sensitivity in Motion Induced Blindness and Perceptual Filling-In

In psychophysics, motion induced blindness (MIB) is a visual phenomenon where an object in one's periphery will disappear from their visual field in the presence of motion. Perceptual filling-in (PFI) is essentially the opposite of this; a gap in our periphery will be filled in by information in the surrounding environment (i.e., our blind spot). These phenomena, and the relationship between them, are poorly understood. In 2006, Hsu et al. posited the common mechanism hypothesis, which linked MIB and PFI together by suggesting they shared the same neural mechanism, which is widely debated. The role of contrast in the occurrence of MIB and PFI has also been disputed; last year, my research showed that low contrast variables increased occurrence of MIB only, which is discrepant from previous contrast studies and does not support the common mechanism hypothesis. This present study would aim to further clarify the role of contrast and the validity of the common mechanism hypothesis, while also adding a new component: within and between channel manipulations. A 2021 study observed that when all the variables in a display were kept consistently all increment or all decrement (meaning all brighter or all darker than the background)—a within channel manipulation—then there would be a higher occurrence of MIB. This study will use software-based stimuli to create a contrast threshold model to understand more specifics about the role of contrast in MIB and PFI compared to previous studies that did not use this model, and to show how within and between channel manipulation influence their occurrence as well. Based on previous research, I expect to see an increase in sensitivity (lower threshold) with low contrast variables and within-channel manipulations, and if the common mechanism hypothesis is true, then the same pattern of results should be seen for both MIB and PFI.

Abstract Name: American Cold Equations: An Analysis of Science Fiction's Response to the Space Race

This research investigates how science fiction literature addresses the tensions between scientific rationality and moral values with an aim to evaluate the impact of the Space Race on American education and pop culture. First, a review of the American government's response to the Space Race in the 1950s provides context for education reforms that resulted in an emphasis on STEM in the classroom; this review includes C.P. Snow's seminal essay "The Two Cultures and the Scientific Revolution" which warns against emphasizing STEM at the expense of the humanities. Then, a close read of "Cold Equations," a 1954 short story by science fiction writer Tom reveals that this modern-era short story captures the human cost of a society that prioritizes science over the warmth of human compassion. This research connects early debates about the tensions between scientific rationality and moral values during the Space Race to more recent discussions on the societal impacts of technological advancement, including AI's influence on college education in the 2022 essay "The College Essay is Dead" by Stephen Marche. Ultimately, the study suggests that science fiction served as a critical medium for engaging with the social implications of rapid scientific progress, foreshadowing ongoing concerns about AI's role in depriving academic work of human creativity and critical thinking, and the need to bridge the divide between the sciences and humanities.

Abstract Name: Role of Rap1 versus PIP3 in the Regulation of mTORC2

Chemotaxis is a directed cell migration in response to external chemical stimuli that is critical for biological processes like development and immune response. Chemotaxis dysregulation has been linked to disease spread like cancer metastasis, but its disruption isn't fully understood. Research has shown that the mechanistic Target of Rapamycin Complex 2 (mTORC2) is crucial for chemotaxis regulation and cytoskeleton structural protein rearrangement. Despite mTORC2's implications in chemotaxis, its precise role and regulation are unclear. Recently, we have identified the small GTPase Rap1 as a binding partner of the SIN1 component of mTORC2, and experiments have linked Rap1 overexpression to increased mTORC2 activity in mammalian cells. Additionally, evidence suggests that the membrane phospholipid PI(3,4,5) (PIP3) similarly regulates mTORC2 activity by binding it to the plasma membrane with experiments demonstrating decreased activity following inhibition of PIP3 production. Although Rap1 and PIP3 positively regulate mTORC2, there is a critical gap in understanding their relationship in its regulation and localization to the plasma membrane. Our research attempts to clarify their relationship as binding partners of SIN1 to provide insight into chemotaxis and disease processes. We hypothesize that Rap1 and PIP3 independently regulate mTORC2 activity in HEK293 cells by playing similar roles in its localization. To test this, we over expressed Rap1 and used a PIP3-production inhibitor, examining their effects on mTORC2 activity in HEK293 cells in response to stimulation by insulin, a strong activator of mTORC2. So far, our research shows no significant difference between the effects of Rap1 and PIP3 on mTORC2 activity.

Abstract Name: Enriching Education & Animal Welfare: Assessing the Impact of an Animal Enrichment Course

Our study aims to explore the relationship between student learning outcomes and interdisciplinary classes. These classes can enhance student enjoyment, boost job prospects, and improve graduate program acceptance rates. Existing research on interdisciplinary coursework has focused on human health, leaving unclear whether similar benefits apply to non-human animal courses. We developed a course called Animal Enrichment, integrating biology and psychology to teach students how to enhance zoo-kept animals' well-being. To develop this course, we created research approval forms, an IRB form, and completed a test-run of the course. We expect that students will find our course more effective than traditional courses in enhancing their understanding of animal biology and behavior. We also anticipate improvements in skills such as communication, critical thinking, and problem-solving. During the class, students will pick one species to work with and create an enrichment project. Throughout the class, students will learn about creating, troubleshooting, and evaluating the effectiveness of enrichment. At the end of the course, students will complete a survey comparing their experiences in this class with unidisciplinary courses. Due to the smaller sample size of this study, our results will primarily be presented as descriptive statistics. We will present the average responses to Likert-scale questions for each item and identify trends in students' experiences in our class. Our course will provide students an opportunity to interact with the animals as well as create long lasting connections with the zoo staff. An increasing number of students are pursuing animal related careers, so establishing these connections will likely benefit students in their career paths. It will also provide the zoo with new enrichment items to enhance the quality of life for their animals. Finally, our findings on student experiences will aid Lyon College and other liberal arts institutions in developing interdisciplinary courses in animal studies.

Abstract Name: Caption Action: Addressing Video Accessibility for Deaf Students in Academia

Deafness, whether total or partial hearing loss, impacts over 700 million people. The World Health Organization defines deafness as the inability to hear any noise that is under 35 decibels in the better ear. Deaf individuals face a multitude of barriers in their daily lives; however, deaf students experience additional challenges. This project investigated deaf accessibility in education through a literature review of published journal articles, a content review of healthcare organizations' websites and blogs from deaf individuals, and a 12-person survey of current university students. Findings indicate barriers deaf students face led to a disparity between the graduation rates of deaf and hearing students. One significant challenge is the lack of consistent and accurate closed captioning on academic videos. Despite ADA requirements, many university classes fail to provide captioned videos, and existing captions often contain mistakes due to issues with ASR. The lack of accurate captioning hinders deaf students' ability to fully understand and learn content in classes, leading to

lower test scores and graduation rates. To address the identified challenge and improve graduation rates, this project recommends the creation of student-based volunteer groups that manually add captions to university course videos. This project addresses the United Nations Sustainable Development Goals 4 and 10, quality education and reduced inequalities.

Abstract Name: Uncovering MAGE-B2 function using unbiased proteomics and interactome analysis.

Melanoma antigen genes (MAGE) are a group of tumor specific genes that are normally expressed in male germline cells and aberrantly expressed in a wide range of cancers. Cancers expressing MAGE-B2, a member of the MAGE family show poor patient prognosis. Studies highlight MAGE-B2 to have high tumor inducing potential in mouse xenograft studies. The functional basis for MAGE-B2's tumorigenic, pro-proliferative effect is unclear and has been sparsely investigated. We seek to establish a mechanistic basis for MAGE-B2 function and understand the biochemical role of the MAGE family of proteins. To this end we designed recombinant expression constructs of MAGE-B2 with single and tandem affinity tags for generation of heterologous cell lines. We used cell lines with robust expression of MAGE-B2 to perform unbiased proteomics and generate a global protein interactome for MAGE-B2. Our list of MAGE-B2 interacting proteins is highly enriched in RNA binding proteins (e.g., KHSRP, ELAV1 and AUF1) and enzymes involved in protein turnover (DCUN1D5, UBE2NL and PCMT1). First, we used a coupled in vitro transcription and translation assay to enable rapid pairwise screening of interactors to ascertain validity of binding. Second, we performed coimmunoprecipitation (co-IP) experiments with candidate binding partners to triangulate domain specific binding. MAGE-B2 provides non transformed cells with a pro-proliferative advantage, and we are investigating if any of the validated interactions can recapitulate this proliferation using heterologous cell line expression and CRISPR/Cas9 gene knockout strategies.

Abstract Name: Turning Angels into Devils: A Look into Christianity in Anime

Although Christian characters and themes appear fairly frequently within western media, this occurs less so with Japanese media. The population of Christians in Japan has remained fairly consistent in the past century, occupying approximately one percent of the population. For centuries prior to the Meiji Restoration (1868), Christianity was made illegal by daimyō Hideyoshi. As a country with a miniscule Christian population—as well as a history of Christian persecution—Japanese media tend to have a much more surface level of understanding of Christianity, if Christianity is even referenced at all. Popular Japanese media (particularly anime, the focus of this research) tends toward the aesthetic use of Christianity, but within those uses, as well

as the more significant uses of Christian characters and themes, we can observe the underlying cultural attitudes toward Christians and Christianity. These cultural attitudes, outside of the aesthetic, tend toward negative portrayals and thus a general negative perception of Christianity, although the extent of negativity broadly correlates with the level of power an individual or entity has within the Christian hierarchy. For instance, laypeople exist on the spectrum of somewhat sympathetic yet naïve victim characters to abusers, while supernatural entities like angels exhibit broader levels of corruption and debauchery, if their corruption does not extend to wanting to destroy humanity. While it remains unclear if the negativity of these portrayals exists as purposeful decisions by the stories' creators or unintentional happenstances, they reflect the persistence of negativity toward Christianity from the time of Jesuit missionaries and the anti-Christian edicts of daimyō Hideyoshi.

Abstract Name: Improving Awareness of Lactation Services in Underserved Populations

Project Purpose: High Country Lactation Center (HCLC) works to eliminate health disparities by promoting access to quality healthcare, providing education and support, and advocating for policies that protect and enhance the health of mothers and children. The purpose of our project was to improve awareness of the resources and information that HCLC provides to lactating women. **Background:** Common lactation issues are insufficient milk supply, latching difficulties, mastitis, and nipple pain. In the U.S., about 50 percent of mothers have reported insufficient milk supply as their reason for stopping breastfeeding. It has been reported that only 24% of infants in Arizona are breastfed exclusively through 6 months, despite the breastfeeding initiation rate being 85%. Lactating individuals in Coconino County are at a vague awareness level when it comes to understanding the recommendation of breastfeeding exclusively for the recommended 1 to 2 years. **Methods:** The aims of this project were to (1) host a fundraiser for HCLC to provide breastfeeding resources to underserved lactating individuals, (2) improve awareness of the resources available from HCLC, and (3) provide attendees with health education and activities for relaxation. The fundraiser event consisted of four stations to promote relaxation: massage, health education, crafting, and yoga. We used social media and fliers to promote our event. Post-surveys were used to assess program satisfaction, and a raffle drawing was used to incentivize participation. **Conclusions:** We met our goal by increasing the awareness of HCLC, and we were successful in getting a total donation of \$320. Overall, our post-test results indicated positive feedback, with 86% of responses being favorable and 14% marked as non-applicable. By the end of the fundraising session, we successfully met our objective of 9 mothers attending the event.

Abstract Name: "Miscegenation" in the Rocky Mountain West

Coined in 1863 in an anonymously published article from New York, the word “miscegenation” began its life in an attempt at bolstering the abolitionist movement. However, the term quickly took on a similar role to its antebellum counterpart, “amalgamation,” used to justify and promote racist ideals and fears of Black-and White relations throughout the United States. For example, John H. Van Evrie’s *White Supremacy and Negro Subordination* posits that “mulattoes are abnormal,” and speaks on “amalgamation and its consequences.” Such hateful, unfounded rhetoric was common throughout mediums of public-facing media in the 19th century, but what defined portrayals and usages of “miscegenation” through the 20th century, and how did that affect perceptions in the particularly isolated Rocky Mountain West? My research utilizes resources from a combination of physical and digital archives throughout the Rocky Mountain states (Montana, Idaho, Wyoming, Utah, and Colorado); and it identifies how the term “miscegenation” and the rhetoric surrounding it affected mixed-race communities. Writing on the anti-miscegenation laws in the United States is well established, and scholarly research exists on this rhetoric in the Southern and Eastern United States as well. However, there is little scholarship on this topic in the rural West, as this region has historically small non-caucasian populations compared to other parts of the U.S., according to census data. This data, which contributes to the unique nature of discrimination surrounding mixed relations, only reinforces misconceptions about the affected communities in these states. General trends in my research indicate that the word “miscegenation” was used in the Rocky Mountain West throughout the 20th century to perpetuate unique yet derivative fears of interracial people and relations that contribute to contemporary misconceptions of these communities. The ramifications of the rhetoric persist through the expectations and prevailing misconceptions about mixed-race people in the Rocky Mountain West.

Abstract Name: The Intersection of Homeless Shelters and Historic Preservation for Community Engagement

Due to policy failures, the U.S. faces a quickly growing homelessness epidemic and housing crisis, leaving many people without their basic needs met. The issue is then aggravated by the stigma surrounding homeless people, which for many people justifies the decision not to help them. Ending homelessness requires dedicated policy reform and strategies to close the economic gap in the U.S., but this cannot be done without changing public opinion. So, existing systems for housing and shelters must be examined to determine their shortcomings and what must be changed. This research is being conducted to determine how historic preservation and third place theory can impact homeless shelters. Ray Oldenberg's third place theory—the idea that the in-between place, outside of the home and workplace, can benefit socialization and relaxation and can draw people together, as seen in community centers—can easily be applied to destigmatize homelessness. Community centers benefit their users and provide an opportunity to encourage humanization of homeless individuals. Likewise, historic preservation, which focuses on the preservation of aesthetics and history, can provide educational experiences, bringing in locals and tourists. Also, historic preservation projects offer tax credits as an incentive, which can help lower the costs associated with historic building projects, which would prove beneficial. The intended outcome of this research is to create a homeless shelter with the mission to improve the lives of its tenants and the surrounding area, which can be supported by historic preservation and third place theory. Thus, this project shall conduct a comparative research study to analyze the effectiveness of similar projects, determined by their impact on the homeless population. Ideally, the effect of the study would be identifying choices made at homeless shelters that helped their tenants in specific ways, which will inform this project and be reflected in later stages.

Abstract Name: Optimizing Plasma-Induced Deacetylation of Chitin for Sustainable Chitosan Production

This project investigates the effect of dielectric barrier discharge (DBD) plasma treatment on chitin's structural properties by quantifying changes in the degree of acetylation (DA). Chitin ($C_8H_{13}O_5N$) is a structural molecule derived from crustacean shells and it is one of nature's most abundant polymers. The deacetylated form, chitosan ($C_5H_{10}N_2O_3$), is valuable for biomedical applications due to its enhanced solubility and antimicrobial properties. While chitin is primarily known for its strong structural properties, its transformation into chitosan unlocks a wide range of applications in drug delivery, wound healing, and tissue engineering. However, converting chitin into chitosan by removing acetyl groups is inefficient, requiring large amounts of NaOH and heat. Our hypothesis is that plasma treatment may offer a non-chemical and energy-efficient approach for modifying chitin's structure, making it a promising alternative to conventional chemical methods. The study focuses on exposing chitin to DBD plasma (helium, 5-8kV, 30-40 kHz) at varying operating conditions (10-15 slpm flow rate, voltage, distance from torch) and analyzing the treated material to calculate its properties. The plasma-treated chitin samples are subjected to acid hydrolysis, releasing acetic acid, which is quantified through titration to calculate the DA. This experimental design

allows for assessing the relationship between plasma treatment and chitin's chemical modification across varying concentrations. Preliminary results demonstrate a moderate reduction in DA after plasma exposure (2 minutes), with a correlation between the degree of acetylation and chitin concentration. More experiments are required to find the optimal plasma parameters for achieving maximum DA reduction while preserving chitin's integrity. Understanding how plasma treatment parameters influence the DA of chitin is necessary to optimize this technology for efficient chitosan production and potential applications in biotechnology and medicine.

Abstract Name: AI-Enabled Predictive Modeling: Tracking the Morphological and Wall Stress Changes in Abdominal Aortic Aneurysms

Abdominal aortic aneurysm (AAA), the 13th leading cause of death in the United States, is an often-fatal condition where the terminal aorta begins to balloon and can rupture. Clinicians typically intervene on patients when the diameter of the AAA reaches a maximum diameter (5.0 cm for women and 5.5 cm for men). However, the maximum diameter criterion is an antiquated system as 5.6% of men and 11.5% of women suffered ruptures below the operable limits. To address this, our research group is leveraging artificial intelligence tools known for their abilities to detect and track subtle patterns to track and analyze the morphological and stress changes of the aneurysm as it grows over time. Establishing a neural network trained with patient data and medical imaging allows for the creation of a novel method for tracking the progression of AAA growth over time. This approach leverages data-driven capabilities to establish a more precise predictive model. Afterwards, the resulting forecasting model would be coupled with a neural net trained to associate wall stresses with aortic geometries to create a 3D growth model capable of depicting the morphological and stress changes of the aortic aneurysm over time. The model, through machine learning, accurately maps and predicts aneurysm growth and stress changes based on patient-specific data, guiding the timing for optimal medical intervention, ultimately aiming to reduce rupture rates and improve patient outcomes.

Abstract Name: Boolean-Logic Based Hydrogels for Drug Delivery

Hydrogel biomaterials have many applications in tissue engineering and drug delivery. Stimuli-responsive hydrogels allow for controlled drug release, dependent on a user-defined trigger. However, current stimuli-responsive hydrogels are case-specific and cannot be used for broader applications, such as targeted disease treatment. Most hydrogels can only respond to one input, making them difficult to use in treating diseases with multiple markers. We developed a fully recombinant protein-based material with protease degradable cross links that follow Boolean logic (YES/AND/OR) in response to multiple inputs to allow for user controlled material degradation and drug release. The protease degradable sequences can be easily switched out before expression depending on the application, making our hydrogel generalizable. The hydrogel will be crosslinked with Boolean logic constructs, each of which are flanked by a click-like chemistry protein system. This allows the crosslinks to be covalently ligated to a linker made from elastin-like polypeptides (ELP), which holds the hydrogel network together. The crosslinks and ELP were expressed recombinantly in *E. coli* and purified on an ÄKTA Pure (Cytiva). A degradation study was conducted by adding different combinations of proteases to prove that material degradation is dependent on the combination of proteases added. We then conducted rheometry to determine the mechanical properties of the hydrogels, and verified that material stiffness followed the expected logical operation, where correct inputs resulted in material degradation. Finally, we tested the hydrogel's ability to release drugs by incorporating human epidermal growth factor (hEGF) into the gel and measuring activation of the ERK signaling pathway through a Western Blot. The Western Blot showed activation of the ERK pathway only when the correct combination of proteases was added, indicating release of a bioactive protein drug. If successful, this hydrogel could be used for therapeutic delivery of drugs and broader tissue engineering applications.

Abstract Name: The Utilization of Machine Learning in the Field of Healthcare: Type II Diabetes Early Prediction and Diagnosis

Type II diabetes mellitus is a disease that can be influenced by an individual's genetic and environmental factors as they display insulin resistance. There is currently no cure for diabetes, and if not diagnosed early, diabetes can have a significant impact on an individual's life. Through the rise of artificial intelligence and technology, machine learning models can help increase the early-stage detection and diagnosis of type II diabetes mellitus. The human gut microbiome plays an integral role in identifying factors of diabetes, as patients with type II diabetes tend to have less gut diversity than people with normal glucose tolerance levels. The algorithms XGBoost and LightGBM successfully identified and predicted common factors of the development of type II diabetes as an alternative to traditional diabetes screening methods. They concluded that utilizing these models in the healthcare system could relieve the financial burden of diabetes test screening. Additionally, CNNs, through deep learning, have the potential to diagnose diabetes and offer personalized diabetes management plans and were able to do so with 90.2 percent accuracy. However, one of the hesitations of implementing machine learning into healthcare is data privacy and ethical issues. Federated learning is offered as a solution to these problems as the data is not compiled in a centralized location. Federated learning models with varying accuracy rates successfully predicted diseases like COVID-19, multiple types of cancer, and cardiovascular disease, to name a few. The continued development of the FLEA model utilized for glucose prediction and a federated learning approach for other models can overcome the limitations of implementing artificial intelligence in a healthcare setting and successfully predict and prevent type II diabetes.

Abstract Name: The Army of Cards: Blending Warfare and Poker Strategy

In the dynamic arena of poker, players continuously vie for strategic advantage, as if pursuing Sun Tzu's timeless wisdom in "The Art of War." As such, a comparison between strategies in both poker and warfare should be drawn. Professional players exhibit disciplined, measured behavior, contrasting with the risk-taking tendencies of recreational counterparts. Evolutionary algorithms mirror expert strategies, emphasizing controlled aggression as a key determinant of success. Insights from learning dynamics highlight the immediate benefits of strategic instruction, underscoring the pivotal role of education in enhancing player performance. Furthermore, studies on gender interactions and testosterone levels shed light on the nuanced interplay between biology and decision-making in poker, emphasizing the need for players to navigate both the psychological and physiological dimensions of the game. However, amidst the strategic complexity lies the challenge of misinformation and imperfect information. Players must adapt to contingencies and the possibility of deceptive tactics, necessitating them to sharpen their ability to discern truth from deception amidst the chaos of gameplay. The findings underscore poker's multifaceted nature as a strategic battleground, where players must balance aggression with caution, leveraging psychological tactics and strategic prowess to emerge triumphant in poker.

Abstract Name: The Relationship of Skateparks' User Perceptions of Quality and Non-user Community Attitudes.

Community parks are often seen as valuable assets that benefit everyone, whether they actively use the park or not. However, skateparks—also known as wheel parks—often face pushback from the community when introduced into these spaces. This raises an important question: can skateparks be designed in a way that fosters a positive perception among both users and nearby residents? To explore this, we interviewed skatepark users to rate the quality of 16 small-to-mid-sized skateparks. At the same time, we conducted an online survey of households within half a kilometer of these parks to understand how neighbors view them. By combining these perspectives, we aimed to uncover how skatepark design and upkeep influence both direct and indirect community experiences. We set out to determine whether skateparks that users rate highly also leave a positive impression on the surrounding community. The concept is that well-designed, well-maintained skateparks foster a sense of ownership and pride among users, which can strengthen relationships between them and nearby residents. This research contributes to the field in two significant ways. First, it offers an objective method for assessing skatepark quality, providing a standardized framework for evaluating these facilities. Second, it presents evidence supporting the potential of well-designed skateparks to improve community relations, challenging the skepticism they often face. Ultimately, this study underscores the

importance of investing in skatepark quality to ensure they serve as inclusive and appreciated components of community parks.

Abstract Name: Trust as a Foundation for Collective Action: A Case Study of Ravine Park and Moldova's Economic Transition

Like many post-socialist countries, Moldova faces the complex challenge of transitioning from centralized command to a market economy. This transformation gained momentum in 2022 when the EU granted Moldova a candidate status. A critical factor in this shift is the development of trust and social capital between citizens and institutions. Through a case study of Ravine Park located in Razeni, one of Moldova's rural communities, this paper explores optimal cooperation for the management of common resources that are inescapably shared, as well as the circumstances under which such cooperation becomes challenged. Drawing on game theory concepts and building on Elinor Ostrom's past research, I argue that efficient resource management provides mobility for solving Moldova's local and global challenges. In the process, the role of trust, social capital building, agency, and democratic voice is examined.

Abstract Name: The Effect of Gesture Size and Gesture Type on Young Adults' Perception of Frustration

In any kind of professional setting, communication between a client and a professional is extremely important for making progress in the patient's wellbeing but is not always a perfectly smooth process. Hand gestures are one of many supplemental tools we can use to communicate and understand others' non-verbal messages, ultimately being a great tool for professionals trying to understand their patients on a deeper level and identify emotions present in therapy sessions. Frustration is an especially prominent feeling that may arise in medical, therapeutic, and educational settings and can be a great factor in an individual's motivation and subsequently the level of impact of a therapy session. This study presents research from an experimental investigation of the relationship between frustration and different sizes and types of hand gestures, specifically large and small gestures, and iconic and beat gestures. Twenty-four participants were seen for a single session in which they watched videos and engaged in a subjective frustration-rating task. Task responses collected from participants have been analyzed using descriptive statistics. Calculated average ratings of level of frustration for videos featuring no hand gestures, small beat gestures, small iconic gestures, large beat gestures, and large iconic gestures are 2.23, 2.48, 2.13, 2.60, and 2.38, respectively. These values are derived from ratings on a 5-point Likert scale, with 1 being "not at all frustrated" and 5 being "extremely

frustrated.” The standard deviations for each respective value are 1.14, 0.90, 0.97, 0.90, and 1.00. Having the ability to identify emotions, namely frustration, nonverbally would benefit professionals in a variety of fields, including speech-language pathology (SLP), potentially leading to an enhanced effectiveness of sessions.

Abstract Name: ‘Til Death Do Us Part...Or Not, I Really Don’t Care: A Thematic Analysis of Sexual Minority Transgender Young Adults’ Marital Aspirations

Although young adults in the US increasingly delay entry into marriage until later ages, studies suggest that most still want to marry and even further, that marriage is an important life goal for most. However, research is needed that examines the marital attitudes and aspirations of transgender young adults specifically, who have thus far been overlooked in the empirical literature. To address this, in this paper, we draw upon qualitative data from a mixed-methods survey of sexual minority young adults, focusing specifically on data provided by a subsample of transgender young adults (n=48). The results of our thematic analysis suggests that although a slightly majority do report wanting to marry someday, the transgender respondents in our sample are largely indifferent toward marriage. Some did describe circumstances under which they would feel compelled to marry, including if their partner desired marriage or they needed financial/legal benefits associated with marriage. However, many respondents described marriage as unnecessary, for themselves, for a relationship, and/or for society. Finally, respondents cited several significant influences on their attitudes toward marriage, including norms or values from family and queer community.

Abstract Name: The Effects of Preclinical and Prodromal Alzheimer’s Disease and Heart Failure on Cardiac Function and Myocardial Amyloid- β Accumulation.

Alzheimer’s disease (AD) is a neurodegenerative disease accounting for ~70% of dementia cases with no cure available. AD pathogenesis involves hallmark features of amyloid- β (A β) plaques and tau hyperphosphorylation. Earliest AD pathology appears decades before clinical symptoms of dementia during the preclinical period. Subtle signs of mild cognitive impairments emerge during the prodromal period.

Understanding the mechanisms underlying risk factors during these early AD stages may help reduce AD prevalence and burden. Cardiovascular diseases are common AD comorbidities and are amongst the leading causes of death in dementia patients. Previously, postmortem autopsies of AD patients revealed increased myocardial A β levels; it was speculated that A β peptides leak from the brain and deposit in the heart due to blood-brain barrier (BBB) breakdown. Heart failure (HF) disrupts BBB integrity. However, it is not known whether AD-related cardiac pathology develops during early AD. Therefore, our objectives are to determine whether heart function is disturbed during preclinical and prodromal AD and whether HF during early AD increases myocardial A β levels in TgF344-AD rats. TgF344-AD rats express mutant human APP, PSEN1, & PSEN2 genes, and appear to be the most comprehensive preclinical AD model available with a protracted preclinical/prodromal period. We hypothesize that early AD alters the myocardium through A β accumulation and HF exacerbates AD-associated cardiac pathology. To test our hypothesis, we performed sham or left anterior descending coronary artery ligation (i.e., HF-inducing) surgeries on 2-month-old wild-type and TgF344-AD rats during their preclinical AD stage. After 7 months, we performed echocardiograms during the prodromal stage and found that the HF surgery but not early AD impaired cardiac function. We plan to measure myocardial A β using ELISA to determine whether HF during early AD increases myocardial A β deposition. These results may reveal novel HF and early AD-associated cardiac manifestations that could facilitate early diagnostic interventions.

Abstract Name: Synthesis of Metal-Organic Frameworks Combined with Luminescent Osmium (II) Complexes: Photophysical Properties and Anion-Dependent Emission Upon Uptake of Aqueous Solutions

Luminescent transition metal coordination complexes involving polypyridyl ligands have numerous applications for the detection of small molecules in solution. Far less is known about the ability to incorporate these compounds into solid-state materials without losing their luminescent properties. This project explores methods to integrate a luminescent osmium complex into a metal-organic framework (MOF) and study the resulting material's photophysical properties of the porous solid. MOFs are a system of metal centers that coordinate with organic ligands to form extended porous structures. MOFs have been of interest due to the host of properties they possess like high stability, crystallinity, surface area, and the flexibility to be modified. These properties can lead to numerous applications, one of which is ion detection via fluorescence emission. When a small amount of luminescent osmium complex, Os(dcphen)(CO)₂(Cl)₂, is added to differing zirconium-based MOFs the solid-state material retained both the photophysical properties of the osmium complex and intended MOF structure. The luminescent properties of both the osmium complex and the MOF systems were studied in aqueous solutions containing cyanide, nitrate, or halides. Photophysical characterization of the Os(dcphen)(CO)₂(Cl)₂ in solution and in a modified MOF showed the emission of the complex was quenched when in the presence of iodide and cyanide. The osmium complex is unique as there are two mechanisms by which anion interaction could affect emission: chloride ligand exchange or non-covalent luminophore interaction. Both could alter the HOMO-LUMO gap which would change the emission of the osmium complex. Computational and crystallization studies to probe these effects were carried out and investigation into the effect of linker and pore size of the MOF on the observed quenching were studied.

Abstract Name: Fabrication of PDMS-based Organ-on-Chips

Organ-on-chips (OoCs) are microfluidic chips that contain small channels that liquids flow through and areas that cells grow in. These chips can be designed to mimic specific environments, making them beneficial for laboratory testing. Polydimethylsiloxane (PDMS) has many properties that make it an ideal material for OoCs, but fabrication is difficult because OoCs are often made in parts that are then bonded together, and PDMS does not bond well to itself. This research aims to formulate a method that uses PDMS and 3D-printed molds to fabricate OoCs. In this method, the OoCs are designed as multiple layers with PDMS membranes added to regions. Molds for these layers are 3D-printed by CADWorks3D ProFluidics 285D. PDMS is cast into molds, and then the layers and membranes are plasma bonded together with Elveflow's Plasma Bonding Pen. As seen in other studies, issues arise in getting the PDMS to bond. The surface quality of the molds and the method for using the bonding pen affect the success of a bond. The surface quality of the mold is affected by post-printing cleaning processes. From experimentation, it was determined that rinsing the molds in a 99% Isopropyl Alcohol (IPA) bath and then airbrushing the molds with IPA results in the best surface quality. From experimentation, it was determined that holding the pen 4 millimeters above the PDMS surface and holding it at each spot for 6 seconds is the most effective treatment. When these determined techniques are used, bonding between layers improves, but this bonding is not adequate for fabricating OoCs. However, when this technique is used to bond PDMS membranes to layers, it consistently bonds. With these findings, our lab aims to use the techniques found in this study to add membranes to OoCs but explore other techniques for bonding PDMS layers together.

Abstract Name: Revolutionizing Dance Education: The Role of Augmented Reality in Remote Choreography Instruction

Recent developments in artificial intelligence and augmented reality are modernizing how society functions, especially regarding education. These technologies enable more efficient speeds of learning, as well as personalized learning experiences (Vall & Araya, 2023). Yet, most of the current research on this topic focuses on using these technologies in traditional education settings. There is limited research regarding what role these innovations might have in the education of the arts, such as dance. Of the research that does exist, it has been concluded that, compared to traditional methods of dance education, the use of artificial intelligence and Augmented Reality (AR) may serve to provide students with a deeper understanding of technique and enhance motivation and self-discipline in the process of learning dance (Wang, 2024). This study aims to evaluate the effectiveness of Augmented Reality in the remote teaching of dance choreography to young dancers. A group of experienced dancers ages 11-13 were divided into two groups: one tasked with learning dance choreography from a traditional video of an instructor, while the other learned the same choreography by watching the movements presented by an avatar through AR. After instruction, dancers were recorded performing the piece and completed a survey examining their experience. The accuracy of all dancers' performances was compared to the original choreography, and their perceptions of learning were assessed and scored. Preliminary results from this study suggest that, overall, the use of AR in learning dance

choreography is comparable to traditional video instruction. Some outcomes suggest that AR technology may be slightly more effective than traditional methods for teaching mechanics and sequences of movements. In contrast, traditional videos tend to have better outcomes in terms of musicality. These results provide insight into how AR may be implemented to enhance the virtual instruction of dance choreography.

Abstract Name: Striking the Balance: How Supervisor Support Shapes working mothers' Work-Family Balance

Background: Nearly three-quarters of women with children under age 18 work outside the home. These mothers may experience tension as they attempt to balance responsibilities at work with responsibilities at home (work-family balance). A supportive work environment, with supportive supervisors, can help mothers to find optimal work-family balance. However, working mothers may experience mixed feelings during their daily interactions with their supervisor, who may be supportive and helpful sometimes (positive) and who may be demanding, critical, and condescending at other times (negative). Such mixed feelings (ambivalence) can lead to feelings of unpredictability and distress. Research has shown that work distress can spill over into family situations (Thompson et al., 2020), and this could impact the balance working mothers are trying to obtain, which has been associated with poor self-rated health and mental well-being. Hypothesis: Working mothers who view their supervisor with mixed feelings during daily interactions will be less likely to find balance between their workplace responsibilities and their family responsibilities. Methods: 112 working mothers were recruited from the community and the university campus. Mean age = 33.28 (SD 7.41; range 22-57). Most were college educated (75.2%), and white (88.5%). Each completed surveys on how mixed and conflicted they felt regarding the behavior from their supervisor and how they viewed their work-family life balance. Results: Linear regression models showed that the more mixed and conflicted mothers felt about their supervisor during daily interactions, the less they reported the ability to achieve work-family balance ($B = -.746$, $SE = .313$, $t = -2.387$, $p = .019$). Conclusions: Mothers who view their supervisor with mixed feelings are less likely to achieve work-family balance. Because poor work-family balance is also associated with poorer health, companies need to help train their supervisory employees to be more consistent in their supervision and provide an environment conducive to work-life balance.

Abstract Name: Synthesis of potential pharmaceuticals for Endometriosis

Endometriosis is a painful disorder in which tissue similar to the uterine lining grows outside the uterus, often on nearby organs such as the ovaries, fallopian tubes, and the outer surface of the uterus. This misplaced tissue behaves like the uterine lining, thickening, breaking down, and bleeding with each menstrual cycle, which can lead to excruciating pain, especially during menstruation. In addition to pain, endometriosis can cause complications such as the formation of cysts and can also contribute to infertility. Currently, the treatments available for endometriosis are primarily focused on managing symptoms or involve surgery. Still, neither option offers a permanent solution, as the uterine lining tissue will continue to grow outside the uterus over time. Collaborators at Truman State University have discovered 5 molecules computationally that are good candidates for medications to prevent the growth of the uterine lining outside the uterus. My research project aims to synthesize these molecules via a Diels-Alder reaction. Once these molecules are successfully synthesized, we will send them for efficacy testing in protein binding studies, which will help determine their potential as treatments for preventing the growth of endometrial tissue outside the uterus. The long-term aim of this research is to develop more effective and lasting therapies for individuals suffering from endometriosis.

Abstract Name: What Information Children Prioritize Whilst Interpreting Another's Emotion

Smiling or frowning, amongst actions such as screaming and laughing, are primary indicators of emotion that young children rely on. Children begin to incorporate external features into emotional understanding at ages 4-5. To reason about another's emotion with greater accuracy, the capacity to put together different pieces of information is developed. By approximately 8-9, children demonstrate a more complex perspective on interpreting how people feel, once in varied contexts. Older children and adults use both the physical expression of an individual alongside contextual knowledge to provide complete perceptions of how someone else feels. While previous research has focused on external cues, such as facial expressions, less work has been done on how internal information may also influence emotion reasoning. This study seeks to develop an understanding of how emotions are perceived from the combination of external elements with internal information that could not be determined from first glance. In a survey presenting 14 possible pieces of information to know when trying to understand someone else's emotion, children aged 4 through 9, select their preference to be revealed out of two immediate choices. Potential choices may include contextual information, such as a person's normal behavior, or visual cues, such as what this person is doing with their body. To illustrate, a child observes an image of a person walking into a room, and is tasked with discovering how this individual feels inside. The child may prefer knowing someone's current life situation as opposed to their physical status. The findings of this study will shed light on how children of younger or older ages alike mature in their empathetic development. Moreover, this study will improve understanding of emotional perception across varied ages, allowing for a deeper grasp on how children express their own emotion based on environmental influences.

Abstract Name: Policing Local Communities: Using Q Methodology to Study Policing Perspectives

In the latest study by Ward et al. (2024) it was noted that rural areas often experience higher rates of police use of force than urban areas. Recent history has provided for high-profile cases of police use of force and police misconduct in both rural and urban areas, which has resulted in a closer examination of police practice. Indeed, Premkumar et al. (2021) note that while the scrutiny of police practice can provide for positive change, it can also result in a loss of public trust—something of greater importance in localized communities, which can add to a sense of “us vs. them”. With these points in mind, this study set out to examine the perceptions of policing within a small Mid-Atlantic community, and made use of Q Methodology, a qualitative technique that captures subjective attitudes (Rhoads, et al, 2021). Participants were drawn from three groups: college students, community members, and criminal justice professionals. Following the Rhoads et al. (2021) approach, a Q-sample of 30 statements reflecting contemporary policing issues (CPI), was gathered for participants to rank. Findings suggest three factors of importance: (1) there was a strong sense of support for the police, which we termed “Back the Blue”; (2) a more “Critical Conservative” group which acknowledged the burden that comes with policing, yet emphasized concern for racial disparity; finally, (3) a group that identified a strong sense of community concern and displayed the significance of community reflection within the police. This final group was determined to closely identify with Sir Robert Peel’s policing principles. The conclusion, in this instance, would seem to be that there is a greater sense of support for policing practice in localized rural communities than initially reported by Ward et al. (2024), or Premkumar, et al. (2021).

Abstract Name: In an Abortion Safe Haven: Post-Dobbs Landscape Impacts Abortion in Minnesota

In 2022, the US Supreme Court ruled in *Dobbs v. Jackson Women's Health Organization* that the Constitution does not give a federal right to abortion – triggering new and activating dormant state-level restrictions on abortions. Minnesota is a “safe haven” abortion state, protecting the right to abortion through legislation and case law. However, Minnesota is in a unique position spatially as all of Minnesota’s neighboring states have abortion restrictive legislation. With the ruling of *Dobbs*, it is not known how other states’ abortion restrictions may impact abortion prevalence in “safe haven” states, especially in places like Minnesota situated amongst restrictive states. Further, the ruling brings new questions regarding criminal and civil jurisdiction, the right to intrastate and interstate travel, and general access to abortion in Minnesota. To examine the changes in both in- and out-of-state abortion prevalence in Minnesota post-*Dobbs*, we compiled abortion data from 2019-2023, finding that there has been a rise in both in- and out-of-state abortions since *Dobbs*. Given the increase in abortions, we supplement this analysis with an abortion case law and legislation survey of Minnesota and abortion restrictive states to understand how other states’ abortion restrictions affect access to abortion in Minnesota in terms of the right to travel and jurisdiction, finding that Minnesota protects its residents, its physicians, and out-of-state abortion seekers from being civilly or criminally punished for abortion care. However, there is no guaranteed protection for out-of-state patients once they go back to their home state. These findings illustrate that abortion prevalence may continue to increase in “safe haven” states with the activation of additional neighboring state restrictions. We can also expect to see continued legal barriers for out-of-state abortion seekers via the restriction of travel and/or punishment for obtaining out-of-state abortions.

Abstract Name: The Importance Of Music In Special Education

This research opportunity presents the dire need for systemic changes in our school music programs across America. I am researching the importance of providing students with disabilities with the opportunity to have equal access to music education. At the moment, many special education students face discrimination in regard to participating in music classes, often due to a lack of resources or inclusive programs. By examining a special education choir-specific program (an affordable and effective way to include all students, regardless of ability), I will research how educational institutions can meet the musical needs of students who have disabilities. This research will include a review on national studies on the discrimination these students encounter, interviews with music therapists on how music supports therapeutic development, and field research in schools that have a special education choir. Through surveys that record musical growth and student feedback, I will provide evidence that students with disabilities not only have the right to have access to music education, but that these students enjoy these opportunities. This research will give a voice to those who are being discriminated against. I aim to encourage schools to make changes, such as introducing adaptive music, accommodative resources, training for educators, and expanding on inclusive music programs to allow all students, regardless of ability, to experience a proper music education.

Abstract Name: Ensemble Learning Algorithms to Predict Scaffold/Matrix Attachment Regions

Scaffold/matrix attachment regions (S/MARs) are places in the genome that bind to the nuclear matrix and are responsible for organizing genetic material into structural and functional domains. S/MARs are key to processes such as cancer metastasis and are hotspots of retroviral integration, meaning improved detection of S/MARs could lead to therapeutic benefits. Previous studies have compiled DNA motifs of S/MARs but there is yet to be a complete, definitive database for the human genome. Furthermore, previous attempts to use computational methods to identify S/MARs have had limited accuracy. An identification of S/MAR sequences could be a valuable resource for scientists studying cancer and other diseases. Our purpose is to develop an R-package that uses machine learning techniques and algorithms to provide a reliable method of S/MAR identification. Our objectives include using modern machine learning techniques and algorithms and using existing data from our literature review. We obtained HeLa cell S/MAR start and end positions from the ENCODE project, and then used an API call to the UCSC genome search tool to acquire the full S/MAR sequence. We then compiled this data and created a train/test split for the model. Our algorithm incorporated

the motifs from our literature review as features. We used confusion matrices and area-under-the-curve graphs to measure the performance of each model. In conclusion, we have produced 3 algorithms: our Random Forest model yielded a 88.5% accuracy rate; the XGBoost model had a 100% accuracy rate; and the K-Nearest-Neighbors model yielded a 93.3% accuracy rate. In the future, we will address imbalances in our data (more positive than negative samples). Our finalized R-package would increase the accessibility of S/MARs related research, significantly improving potential studies on retroviral hotspots and metastatic cancers.

Abstract Name: In Silico Exploration and Evaluation of Candidate Cancer Drugs

This research investigates the application of virtual screening techniques in cancer drug development, specifically targeting Polo-Like Kinase 1 (Plk-1), a key protein associated with tumor progression. The primary objective was to evaluate the drug-likeness and therapeutic potential of five lead molecules and nearly 100 structural derivatives, ultimately identifying top candidates for experimental and clinical validation. By employing computational tools to streamline the drug discovery process, this study seeks to address the inefficiencies of traditional methods, contributing to the development of precise and cost-effective cancer therapies. Advanced computational methodologies were utilized to assess the molecules' ADMETSD properties- absorption, distribution, metabolism, excretion, toxicity, stability, and docking. Quantum chemistry simulations and scoring mechanisms enabled a robust evaluation of molecular characteristics, resulting in a shortlist of 10 candidates with superior drug-like qualities. The research underscores the effectiveness of integrating computational screening techniques to prioritize molecules with therapeutic potential. This study demonstrates that virtual screening can enhance the efficiency and precision of early-stage drug discovery, reducing the time and resources required to identify promising drug candidates. Importantly, the research highlights limitations in current scoring methods, advocating for refined computational models that better balance parameter importance and therapeutic relevance. These advancements could improve the inclusion of medicinally significant molecules while maintaining a rigorous evaluation standard. The findings have broad implications for the future of targeted cancer therapy, offering a scalable approach to accelerate drug development.

Abstract Name: Identification of Ribosome-associated Quality Control (RQC) genes associated with human diseases via in-silico data analysis and biological validation

The Ribosome Quality Control (RQC) pathway is a mechanism that cells use to ensure the quality of the proteins synthesized by ribosomes. Any issue that arises in translation is subject to a check by the RQC

pathway, especially when ribosomes stall on defective mRNA. Aging is a complex biological process associated with a decline in cellular function and increased susceptibility to diseases, including cancer. Recent studies have highlighted the importance of the Ribosome Quality Control (RQC) pathway in maintaining protein homeostasis and its potential implications in aging and cancer. The RQC pathway monitors and resolves translation errors, ensuring that defective proteins do not accumulate in cells. This project aims to investigate the relationship between the RQC pathway, aging, and cancer by leveraging data science to analyze large-scale datasets from public databases: The Cancer Genome Atlas (TCGA) and the Gene Expression Omnibus (GEO). We will identify candidate genes implicated in these processes and validate their functions through various biological experiments. Using the TCGA and GEO databases, we will gather the data and focus on cancer types, as well as the age demographics of the patients. The data will be processed to be compatible with different datasets. Then we will analyze the data to identify potential genes that are significantly altered in cancerous tissues compared to normal tissues during the aging process. We will use this to understand the relationships between gene expression, aging, and cancer. We will focus on genes that show significant changes in expression and have established roles in the RQC pathway.

Abstract Name: Economic Impact of Sustainable Practice in the Airline Industry: A Comprehensive Analysis

Sustainability is our society's ability to exist and develop without depleting all of the natural resources needed to live in the future. The airline industry accounts for 12% of all CO₂ emissions produced per year. There is limited research addressing how certain airline companies can implement sustainable airline practices under economically profitable conditions. We investigated the implementation of sustainable airline practices including the implementation of sustainable aviation fuels, electric ground power systems, and research towards the demographics of sustainable conscious customers. For the implementation of sustainable aviation fuels, a DCF model was created to project the ten year value of investing in said fuels. A cost benefit analysis was created to explore the potential profitability of implementing electric ground support equipment. Finally we conducted market research to determine the demographics of sustainable conscious consumers, and reviewed the sustainable practice participation of the ten largest airlines. We found that within five years sustainable aviation fuels cross the threshold into profitability and continue to increase by around 10 million dollars per year. Our cost benefit analysis showed an upfront implementation cost of 55 million dollars, with a decreasing cost in further years to under 10 million dollars per year. Market research showed that out of the 10 airliners, the largest contributors to sustainability were Delta Air Lines, FEDEX Freight, and SAS Airlines. Looking at the demographics of sustainable conscious consumers, our research found that the majority of consumers included females over the age of 40 years old with a household income of 40,000-60,000. These findings create an economic view on how airliners could potentially implement sustainable practices into their everyday functions. Further research is needed to determine how these practices will affect the short and long term functioning of airliners.

Abstract Name: The Evolution and Impact of Artificial Intelligence in Accounting

Will artificial intelligence one day replace accountants entirely? This question has only grown in popularity in recent years, even though artificial intelligence has existed since the 1950s. Originally coined in 1955 by John McCarthy, “artificial intelligence” (AI) has steadily evolved to develop new techniques that are revolutionizing everyday tasks in nearly every profession. Today, AI is adapting and learning how to process big data while developing deep learning and cloud computing technology. These advancements have already started to form the foundation of many of our accounting software programs. Although AI appears to be a threat to human jobs, current research challenges these threats, emphasizing that AI’s true potential lies in supplementing human capabilities instead of replacing them. This study follows the development of AI, starting with the earliest foundations and working its way up to the innovative technology that AI has become today. After tracking the emergence of AI, the study will focus on AI’s current impact on the accounting industry, stressing the importance of how AI has enhanced efficiency and accuracy in accounting practices. With AI’s implementation in today’s workforce, the study will address critical questions surrounding the ethical use of AI and its influence on accountants’ roles. Finally, the study considers AI’s potential to revolutionize predictive decision-making in the accounting industry. The research will look at how AI can advance sustainability initiatives and redefine professional roles through human-AI collaboration in the future. By diving into AI’s history, analyzing AI’s current effects on the accounting industry, and envisioning future applications of AI for accounting, this study contributes to the understanding of AI’s evolving role in accounting. Offering valuable insights for professionals while advocating for strategic, ethical adoption of AI ensures that AI-driven technology complements human expertise in the accounting industry but does not replace human capabilities.

Abstract Name: The Generational Spectrum: Analyzing Color Preference Shifts Between Gen Z and Millennials in Social Media Advertising

In today's digital landscape, understanding generational color preferences has become crucial for marketing success, particularly as Gen Z emerges as a dominant consumer force alongside Millennials. While previous research has extensively documented Millennial color preferences in marketing, Gen Z's distinct aesthetic sensibilities – characterized by their preference for muted pastels and '90s-inspired palettes – suggest a significant shift in color psychology across generations. This study investigates how color preferences in social media advertising differ between Gen Z (born 1997-2012) and Millennials (born 1981-1996), with particular attention to engagement rates, purchase intent, and brand perception. Through a systematic review of recent marketing campaigns, consumer behavior studies, and social media analytics, this research examines the evolution of color trends and their effectiveness across platforms like TikTok, Instagram, and YouTube. The findings aim to provide marketers and designers with actionable insights for creating generation-specific color strategies that enhance campaign performance and brand resonance. Understanding these generational color preference shifts will help brands better target their visual marketing efforts and adapt to evolving consumer aesthetics in the social media age.

Abstract Name: Advanced Deepfake Detection Using Quantum Neural Networks

In this research, we propose a novel quantum convolutional neural network (QCNN) model for deepfake detection, integrating quantum mechanics within the convolutional neural network framework to enhance detection capabilities. The QCNN operates by embedding small regions of the input image, such as 2×2 pixel patches, into a quantum circuit through parameterized rotations applied to qubits initialized in their ground states. The significant advantage of QCNN over traditional methods lies in its ability to generate highly complex kernels via quantum circuits, potentially performing computations that are classically intractable. To evaluate our QCNN approach, we trained and tested models using both traditional CNN and QCNN architectures. We started by taking 10 original videos and generated 10 fake videos using the commercial website DeepfakesWeb. For testing, we employed a new deepfake dataset generated using the Roop method. In this test scenario, we observed approximately a 30% improvement in QCNN performance compared to CNN. Our QCNN model was implemented using the PennyLane quantum simulator library. We next intend to use IBM's quantum computer and simulator, demonstrating its practical applicability. By integrating quantum computing with neural network architectures, the QCNN model is designed to adapt effectively to the complexities of deepfake data, utilizing quantum computational advantages to handle high-dimensional data spaces and perform complex transformations. This approach aims to significantly enhance both detection accuracy and processing efficiency against increasingly advanced generative AI-generated deepfake videos.

Abstract Name: Evidence-based Development and Assessment of Biochemistry Integrated Laboratory Experiments

The Integrated Laboratory (IL) curriculum at the United States Naval Academy (USNA) was originally implemented to provide a more cohesive, four-semester learning experience for our chemistry majors. In many cases, there is overlap between the concepts taught in various chemistry courses; the IL curriculum accounts for this overlap, connecting the interlinked concepts through completion of laboratory experiments. For example, experiments conducted in IL3 integrate topics across physical chemistry and biochemistry like enzyme kinetics and the thermodynamics of DNA melting. While increasing in popularity, Integrated Laboratory curricula are not yet widely implemented across undergraduate institutions. At USNA, the IL curriculum was introduced more than 20 years ago. While there are many strengths to this laboratory

sequence, little of the program has changed since it was implemented; feedback from the IL3 course evaluations in the Fall 2024 academic year highlighted two key concerns among 2/C midshipmen (junior-level students): 1) there is a lack of biochemistry-centric content, and 2) there is insufficient integration of topics with concurrent lecture courses (Physical Chemistry I: Thermodynamics and Kinetics, and Biochemistry I: Macromolecular Structure and Function). To address these points, it is crucial to properly align laboratory content with the material presented in lecture courses. This project aims to evaluate and assess integration of topics across chemistry subdisciplines, analyze the current alignment of major course content, and implement changes to the curriculum, including the development of new biochemistry labs and the refinement of existing ones.

Abstract Name: Designing 3D Microfluidic Cell Culture Devices for Advanced MRI Diagnostics of Breast Cancer

Microfluidic chips are an emerging technology that is revolutionizing the field of biomedical research. These devices contain systems of three-dimensional channels that are designed to manipulate fluids at a microscale. When equipped with human cells, microfluidic chips can simulate a patient's potential reaction to a new drug or treatment method. When used for this purpose, they are referred to as "organ-on-a-chip (OoC)" devices. Because they mimic the human body at a cellular level, they also produce more accurate results than a live animal subject or a 2D culture. Although 3D chips are excellent at replicating the complexity of human physiology, there is currently no standard design for the magnetic resonance imaging (MRI) of tumor models. In this ongoing study, we aim to develop an OoC for the MRI of breast cancer tumor cells and Nano-Encapsulated Manganese Oxide (NEMO) nanoparticles, which are contrast agents. A custom chip fabricated in-house will be compared to a chip that was commercially manufactured. Microscopic imaging and experimental analysis will be performed. From these results, we will determine the most efficient and economical chip design for MRI purposes. Using our easily replicable design, both big and small laboratories will be able to create MRI-ready OoCs. This will not only reduce the cost and speed of clinical drug trials and medical diagnostics, but also the need for expensive live animal models.

Abstract Name: Review of Behavioral Interventions to Build Resilience and Improve Coping Skills of Health Workers in Africa

Southwestern Kenya remains a critical focus area for HIV research and service provision for pregnant/postpartum women with HIV (PPWH). Kenyan health services are often affected by societal crises, and the COVID-19 pandemic underscored the adverse impact of community crisis and prolonged health service disruption on health outcomes among PPWH, their infants, and health workers (HWs). Interventions that target the resilience and coping skills of HWs are needed to strengthen Kenyan health systems and improve health outcomes. This review aimed to identify existing interventions in African contexts with evidence on effectiveness in improving HWs' coping skills and resilience, to inform future interventions. Journal articles in PubMed, EMBASE, APA PsycINFO, and PTSDpubs were screened to identify relevant studies from inception to July 2024. The search terms "Africa," "resilience and coping skills," "HWs," and "behavioral intervention" were utilized in combination. The review included studies that met the following criteria: (1) study participants were HWs (2) interventions were behavioral with a focus on resilience and coping skills (3) the setting was in Africa (4) studies were primary research with full-text access in English. From an initial search of 388 articles, 17 studies met criteria. Results show that long-term, systematic interventions that addressed HWs' practical challenges (e.g. long work hours, access and availability of services to HWs) and educational/social needs (e.g. disease stigmatization, self-protection, work-life balance) were most effective in improving HW's resilience and coping skills. The few interventions found to produce long-term impact on HW resilience integrated participant personalized plans, mindfulness training, and small group training. While existing interventions are limited, these promising strategies will serve as a foundational framework for the larger Resilience Amid Challenges in Healthcare (REACH) study, focused on future intervention development for strengthening resilience and preparedness of HWs for PPWH amid service disruption in Kenya.

Abstract Name: Correlation between Biological Sex, Sexual & Emotional Jealousy, and Personality

In recent decades there has been an increase in psychological study in both personality dimensions and the subjective experience of jealousy. In addition to this, there have been many studies recently showing that using electroencephalography (EEG) data to track neural activity during emotional processing can produce data that can accurately predict certain personality dimensions. The current study hopes to combine these two areas of research by examining how personality, as defined by the HEXACO model, influences neural responses to jealousy-inducing scenarios. The HEXACO model consists of Humility/Honesty, Emotionality, eXtraversion, Agreeableness, Conscientiousness, and Openness to experience. Participants will listen to scenarios describing both sexual and emotional infidelity, eliciting emotional responses while their neural activity is recorded. The EEG will record alpha waves from both the left & right hemispheres. By comparing alpha activity in the right and left hemisphere, a ratio, which represents the emotional processing

in the respective cortices, will be produced. The right hemisphere is associated with negative emotionality, while the left hemisphere is associated with positive emotionality. We will control for the confound produced by sex of researcher by having half of the participants listen to a male researcher, and the other half listen to a female researcher. The data provided by these measures will be analyzed using a Stepwise Multiple Regression model to evaluate how personality dimensions affect the neural processing of both sexual and emotional jealousy. Our experimental hypothesis is that jealousy is positively correlated with emotionality and conscientiousness, and inversely correlated with openness, agreeableness, and humility. It is believed that there will be no correlation with jealousy and extraversion levels. Additionally, it is hypothesized that men are more affected by sexual jealousy while women are more affected by emotional jealousy, potentially reflecting broader evolutionary factors.

Abstract Name: Upcycling Organic Waste Streams for the Submerged Fermentation of Mushroom Mycelia: A Sustainable Solution for Global Nutritional Challenges

In response to increasing challenges related to global food security, innovative strategies are required to enhance the resilience and sustainability of food production systems. The cultivation of *Ganoderma lucidum*, a mushroom known for its nutritional and therapeutic properties, represents a compelling opportunity to address these needs by repurposing organic waste into feedstocks for growing nutrient-dense mushroom mycelia in liquid fermentation systems. The primary benefit of leveraging liquid feedstocks over traditional solid-state systems is that submerged systems allow for the complete extraction of mycelial biomass without leaving any of the substrate attached, leading to increased efficiency and lower production costs. Upcycling organic waste streams to produce feedstocks represents a sustainable strategy for producing biomass at scale, while further limiting the cost of production. The current study focused on substrates derived from hydrolysates of municipal solid waste, corn stover, corn steep liquor, and hemp. *G. lucidum* was cultivated in shake flasks and lab-scale stirred-tank bioreactors utilizing a variety of experimental media formulations. Batch runs lasted from 7-10 days. Upon termination, each batch was analyzed to measure biomass yield and exopolysaccharide content. Preliminary findings identified municipal solid waste as the most effective substrate for mycelial growth, producing 23.5g/L of biomass on average. Beyond its commercial applications, this approach addresses critical waste management challenges by converting underutilized residues into high-value products. Future research will focus on refining cultivation techniques, optimizing nutrient formulations, and minimizing batch variability to ensure consistent and enhanced yields. By integrating sustainability with innovation, this study aims to advance resilient food production systems capable of addressing global demands in increasingly complex scenarios.

Abstract Name: Exploring Interrater Reliability in Teleassessment of Speech Sound Disorders: A Case Study

The purpose of this study is to investigate interrater reliability among undergraduate students using teleassessment to score the speech sound production of children diagnosed with speech sound disorders. Given the increase in the use of teleassessment in the field of speech-language pathology understanding the scoring among different evaluators is essential for ensuring reliable and valid diagnostic outcomes. The research focuses on comparing the assessments made by undergraduate students to determine the level of agreement between their evaluations, which can inform best practices for training in clinical settings. This study utilized Fleiss' Kappa to determine the interrater reliability of three undergraduate students utilized a two-way scoring system to evaluate the speech sound production of three separate children with a speech sound disorder captured through the administration of words selected from a widely recognized and commonly used speech sound assessment tool. The average of the undergraduates' reliability scores for the three children's teleassessments using the Fleiss' Kappa was 0.5279, which falls under moderate agreement. A questionnaire was administered to the undergraduate students to gain perspectives on telehealth. In the questionnaire, two out of three respondents were "somewhat likely" to use teleassessments, while one was "unlikely." Attitudes varied, with one student having a "strongly positive" attitude and the others "moderately positive." Regarding skills, responses ranged from "extremely unskilled" to "slightly skilled," and all rated themselves as "moderately unknowledgeable" about teleassessments. The questionnaire responses identified perspectives on teleassessments, offering insights for enhancing the Social Construct of Teletherapy (SCOTele). Analyzing individual speech sound assessments revealed strong agreement in two cases and poor agreement in one, with variations based on the severity and type of speech sound disorder. The study indicates that novice clinicians can achieve some level of agreement, but they may lack interrater reliability, as seen in more experienced certified clinicians.

Abstract Name: Building Resilience: Empowering Nursing Students to Thrive Under Pressure

The National Library of Medicine states that "...three in four college students self-reported feeling stressed, while one in five college students reported stress-related suicidal ideation" (Barbayannis et. al, 2022, p. 2). Nursing students, while experiencing the typical stresses of college life, face a unique set of stressors including rigorous academic schedules, emotionally demanding clinical rotations, and the pressure of mastering life-saving skills. These challenges, if left unaddressed, can lead to burnout, poor academic performance, and a diminished ability to provide quality patient care. Nurses play an important role in identifying when a patient is experiencing stress and assist them to keep it under control. As such nursing students need to also recognize the signs and symptoms in themselves, and practice ways to mitigate it. Resilience—the ability to adapt and thrive in the face of adversity—offers a powerful framework for equipping nursing students to navigate these pressures effectively. This presentation explores the critical importance of resilience for nursing students and its role in fostering both personal and professional growth. Drawing on an extensive review of current research and real-world examples, it highlights the psychological and physiological impact of stress on nursing students and its implications for their academic success and long-term career sustainability. Attendees will gain insights into evidence-based strategies for building resilience, such as cognitive reframing, canine therapy, art and dance interventions, and peer support systems.

Special attention will be given to practical applications, including the use of reflective practices during clinical rotations. Through an interactive format, this session aims to empower college students, nursing students, educators, and administrators with actionable tools to cultivate resilience. The goal is to create a supportive educational environment where nursing students not only manage stress effectively but also develop the mental fortitude necessary to excel in the demanding field of healthcare.

Abstract Name: Analysis of Water and Sediment Quality Around the Nueces/Corpus Christi Bay Area

Concentrations of nutrients and pesticides are highly influential on marine health and industries. This is particularly important to South Texas, where industries such as fisheries and sustainable agriculture are crucial. However, there has not been a substantial classification of these contaminants in the Coastal Bend of Texas to the present. This study proposes various chemical extraction procedures to target particulate and dissolved nutrients and pesticides in water and sediment samples from five South Texas coastal areas. Ion chromatography is suggested to detect the levels of nitrates, nitrites, and phosphates in environmental samples. Solid phase microextraction is recommended to isolate organochlorine pesticides from field samples for analysis by gas chromatography equipped with an electron capture detector. Preliminary research was completed on sediment and water samples from five sites around the Nueces and Corpus Christi bays. Water quality parameters of pH, temperature, conductivity, total dissolved solids, and salinity were measured on site using the ProDSS Multiparameter Digital Water Quality Meter. Sediment moisture content was determined by utilizing a ratio of wet to dry sediment mass, and sediment porosity was calculated using dry sediment mass and volume. The average suspended sediment concentration at each site was found through vacuum filtration with a minimum particle size limit of 0.45 μm . This work contributes essential baseline data to HydroShare and builds a Delft3D model of the South Texas coastal area, enabling enhanced access for communities and stakeholders. Using machine learning, we identified potential pollution hotspots, underscoring areas in need of further monitoring and policy action to safeguard marine health.

Abstract Name: Characterization of a Cadmium-Specific Hexapeptide Chelator for Detoxification of Cadmium

Heavy metals including arsenic, cadmium, lead, mercury, and chromium are among the most concerning chemicals to public health. Metal chelation therapy (MCT) is the primary treatment for heavy metal toxicity and poisoning, which requires the administration of small organic molecules to remove the toxic metal of

interest. However, current MCT suffers from several limitations including the inability to distinguish between the toxic metal of interest and essential physiological metal. These limitations result in inefficient removal of toxic metals and deleterious disruption of metal homeostasis as essential metals are also removed. Therefore, the development of new metal chelators that are specific to the target metal is necessary for treating heavy metal exposure. Ideally, chelating agents should have aqueous solubility, high affinity and specificity for the target metal, the ability to cross tissues and cell membranes, and the ability to be eliminated. Peptides can achieve all these criteria. Recently, we have identified a peptide chelator with specific cadmium binding. The binding properties and contributions of individual amino acids of this peptide to cadmium chelation remain uncharacterized. Here, we present the characterization of cadmium binding to this hexapeptide using biochemical, biophysical, and analytical methods to determine the contribution of each amino acid to cadmium binding. Our analysis identified histidine, serine, and lysine as critical residues for cadmium binding and detoxifying properties. These results provide insight into the interplay between cadmium coordination and the apo-peptide structure. Defining the overall metallo-peptide interactions with cadmium provides important insights for the development of future highly efficient and cadmium-specific chelators for use in MCT.

Abstract Name: UNG1 Overexpression Alters Mitochondrial Function and Therapeutic Resistance in Castration-Resistant Prostate Cancer

Prostate cancer (PCa) represents the second most common cancer worldwide and the fifth leading cause of cancer deaths in men. Upon diagnosis, patients are typically treated with androgen deprivation therapy (ADT). While ADT is initially effective, prolonged use contributes to a more aggressive and lethal form of PCa, known as Castration-Resistant Prostate Cancer (CRPC). Thus, identifying specific factors contributing towards CRPC has become imperative for developing personalized treatments. Our lab previously determined some DNA repair enzymes are dysregulated in PCa tumors. Uracil DNA Glycosylase (UNG), a base excision repair enzyme that removes uracil from DNA, was overexpressed in PCa. The UNG gene encodes for two isoforms: UNG1, localized in the mitochondria, and UNG2, localized in the nucleus. Most reports group these isoforms as UNG. However, examination of UNG protein levels in cancerous and normal prostate cell lines revealed that UNG1 is upregulated in advanced CRPC cell models. Therefore, to characterize the effects of UNG in CRPC, we constructed a UNG knockout and UNG1 overexpression C4-2B cell line using CRISPR/CAS9 and ectopic overexpression, respectively. Using immunoblotting and qPCR, we confirmed that UNG1 overexpression significantly decreased mitochondrial DNA copy number and altered mitochondrial metabolism proteins, suggesting UNG1 alters mitochondrial function. Moreover, when exposed to the anti-androgen Enzalutamide, UNG depletion increased cell sensitivity, while UNG1 overexpression increased resistance. Given UNG's role in DNA repair and genomic stability, we also examined the response of the depleted and UNG1 overexpressed cell lines to the ATR inhibitor Elimusertib. C4-2B cells were sensitive to Elimusertib, with the UNG depletion showing no enhancement of that sensitivity, while UNG1 overexpression showed increased sensitivity. Therefore, Elimusertib may offer a treatment strategy for CRPC patients with elevated UNG1 and resistance to enzalutamide. Further, these data suggest that UNG1 overexpression impacts mitochondrial function, which should be explored as a therapeutic target.

Abstract Name: Hierarchical Structure Generation in Pre-School Children and Adults in Two Ecologically-Valid Tasks

Hierarchical structures are central to language, mathematics, music, and theory of mind. Much remains unknown about the cognitive development of hierarchical reasoning, a knowledge gap we address. One limitation of existing methods is their low ecological validity. We present data from high ecological validity tasks with 3-to-6-year-old children. The first task—the Russian Nesting Dolls task— featured dolls decreasing in size, nested within each other. Participants were instructed to “complete the puzzle” with no additional instructions. The second task—the Drawing Task—included a photograph of houses arranged from left to right, each with windows and doors in similar positions. Participants were instructed to “draw what you see” with no additional instructions. We coded the sequential behavior of participants as symbolic strings. We conducted qualitative and quantitative classifications of behavior into two categories: linear and hierarchical. Qualitative classifications were based on local structures with less nesting (linear) and global structures with more nesting (hierarchical). Other features such nesting depth and accuracy of reproducing “canonical” structures (well-nested dolls and accurately placed architectural elements) were also coded. Quantitative classifications were based on: a) path analysis of structures unfolding over time and b) complexity analysis of final structure configuration. We used Bayesian modelling to infer the cognitive algorithms—linear or hierarchical—underlying structure generation. This modelling incorporated computational operations over discrete tokens like the puzzle pieces or the architectural elements. Furthermore, we measured correlations between hierarchical ability and visuospatial working-memory capacity (Corsi block-tapping task). Finally, we compared the performance of children to that of adults. Our results show that both 3-to-6-children and adults possess the capacity to engage in hierarchical mechanisms. However, younger participants and those with lower working-memory used linear mechanisms. These results point to the gradual unfolding of psychological mechanisms from linear to hierarchical across cognitive development.

Abstract Name: The Role of *nr2e3* in Retinal Regeneration in Zebrafish: Implications for Therapeutic Strategies in Retinal Degenerative Diseases

Purpose: This study investigates the critical role of the *nr2e3* gene in retinal regeneration in zebrafish, with a specific focus on its impact on progenitor cell proliferation and differentiation following acute high-intensity light-induced damage. Insights from this research aim to inform therapeutic strategies for human retinal degenerative diseases, in which natural regenerative processes are limited. Methods: Adult albino zebrafish

siblings were used to investigate the role of Nr2e3 in retinal regeneration. Following a 5-day dark adaptation, the experimental group received morpholino injections to suppress Nr2e3 expression, while the control group received a non-targeting morpholino. Both groups then underwent acute high-intensity light treatment involving a brief 100,000 lux light followed by continuous exposure at 12,000 lux for 3 days. Post-treatment, zebrafish were euthanized, and their eyes were harvested, cryosectioned, and analyzed using immunohistochemistry with anti-PCNA antibodies to assess progenitor cell proliferation. Fluorescence intensity was quantified using ImageJ, and statistical differences were evaluated with ANOVA followed by Tukey's HSD test. Results: Suppression of Nr2e3 significantly reduced progenitor cell proliferation, demonstrated by a marked decrease in PCNA fluorescence intensity in the experimental group compared to controls. Statistically significant differences were observed between experimental and control groups ($p = 0.046$) and between experimental and untreated right eyes ($p = 0.010$). These findings underscore the critical role of Nr2e3 in sustaining progenitor cell populations during retinal regeneration. Conclusions: The nr2e3 gene is essential for regulating progenitor cell proliferation and differentiation during retinal regeneration in zebrafish. Suppressing Nr2e3 leads to premature differentiation and a reduction in the regenerative capacity of the retina. These findings have important implications for developing gene therapy-based treatments for retinal degenerative diseases in humans, where enhancing nr2e3 activity could potentially activate regenerative outcomes. Further research exploring Nr2e3's role across various stages of regeneration will be essential to fully utilize its therapeutic potential.

Abstract Name: Automated Extraction of Course Concepts from Lecture Materials

Information on the concepts covered in specific course materials has the potential to enhance the quality of education, but manually extracting such concepts is a time-consuming and laborious task. In addition, since, to our knowledge, there are no publicly available datasets of concept-labeled course presentations, there is a dearth of data available. To this end, this work compiles a novel dataset based on computer science lecture presentations from the University of Pittsburgh that is annotated with concepts using the BIO span-labeling framework. This dataset is comprised of a mix of human-expert labeled and automatically labeled data, which alleviated the heavy workload of manually annotating the new dataset. We leveraged large-language model (LLMs) to generate automatically labeled data which were chosen due to their language comprehension abilities. This work presents a machine-learning system trained on this dataset to automatically extract various computer science concepts from course presentations, a task similar to Named Entity Recognition. Various experiments will be performed to compare across different baseline models as well as an ablation study to better understand what features are most important for improving the model's performance. The findings from this research aim to contribute to the development of more efficient methods for automatic concept extraction, ultimately supporting the creation of educational tools that enhance learning experiences. Additionally, the insights gained from this work could pave the way for more scalable and accurate systems for automated content analysis in educational settings.

Abstract Name: Pulmonary Vascular Remodeling In Relation to the Social Determinants of Health

Pulmonary Arterial Hypertension (PAH), a type of pulmonary hypertension, is an acute incurable condition that occurs when pulmonary artery pressure is greater than 20 mm Hg and is further induced by pulmonary vascular remodeling. While this can be prompted by direct causes like congenital heart defects or drug misuse, there are a multitude of other factors that should be considered like the Social Determinants of Health (SDOH). This project investigates the relationship between the SDOH through the BIG GEMS factors and pulmonary vascular remodeling. The overarching purpose of this study is to provide a collective insight into the factors that should be considered when approaching pulmonary vascular treatment and prevention, which may heavily involve large-scale changes related to the SDOH. An SDOH score was utilized to assess the effects of social risk factors into quartiles of increasing disadvantage. Information collected and experiments reviewed in this study were obtained from published studies using the NCBI database, published text, and clinical trials. The correlation analysis of the Social Determinants of Health and pulmonary vascular remodeling was conducted using data from a retrospective cohort study on 2229 patients at the University of Miami Health System who answered an SDOH survey from September 2016 to September 2017. The results on the SDOH quartile showed that individuals with Hispanic backgrounds, unemployed, higher Framingham Risk Scores, long-term smoking habits, and lack of physical exercise belonged to the upper quartile of SDOH scores and were, therefore, more likely to develop cardiovascular diseases like pulmonary hypertension. Recommendations to reduce healthcare disparities and improve pulmonary hypertension treatment outcomes in underrepresented minorities include non-pharmacological methods like community outreach and public health programs, increasing representation in major trials, recognition of social determinants of health, improving access to care, earlier recognition and diagnosis, and improving the treatment of related conditions.

Abstract Name: MicroRNA-29b-mediated Voltage-gated Potassium Channels 1.5 (Kv1.5) in PASMC from Patients with Pulmonary Hypertension

BACKGROUND: Pulmonary Arterial Hypertension (PAH) is a type of pulmonary hypertension that leads to higher lung blood pressure levels. It is a rare incurable disease that affects approximately 1% of the global population. In the lungs, the downregulated expression and activity of potassium (K⁺) channels in pulmonary artery smooth muscle cells (PASMC) from idiopathic PAH (IPAH) patients have been associated with the development of prolonged pulmonary vasoconstriction and vascular remodeling. However, the precise mechanism is unknown. MicroRNA (miRNA), a small non-coding RNA that binds to the 3'-untranslated regions of the mRNAs, regulates gene expression posttranscriptionally. We hypothesized that the increased

level of miRNA-29b-downregulated Kv1.5 channels contributes to increased PASMC proliferation and development of PAH. METHODS: We used human PASMC isolated from healthy subjects or IPAH patients in this study. Normal PASMC were exposed to normoxia or hypoxia for 72 hours. PASMC were transfected with miRNA-29b mimic for 6 hours. KCNA5 was measured by PCR, qPCR, or Western blot. The miRNA-29b level was measured by qPCR. RESULTS: The protein level of KCNA5 was lower in PASMC isolated from IPAH patients compared with PASMC isolated from healthy subjects. MiRNA-29b level was significantly higher in IPAH-PASMC than in normal. Transfection with miRNA-29b mimic resulted in a 45-fold increase in miRNA-29b expression compared with scrambled-transfected or control cells. Gel electrophoresis and western blot images show that KCNA5 mRNA and protein levels are decreased in PASMC overexpressed with miRNA-29b. Western blot images display that KCNA5 is lower in cells exposed to hypoxia than in cells exposed to normoxia. CONCLUSIONS: Together, these results demonstrate that increased levels of miRNA-29b decreased expression levels of KCNA5 in PASMC isolated from IPAH patients. Hypoxia-induced decrease in KCNA5 expression can be linked to increased cell proliferation. Inhibition of miRNA-29b can be utilized to potentially create new treatment strategies for IPAH patients.

Lily (Lee) Gradin

Abstract Name: The Passion Project and FYS Wonderfest!: A Collaborative Student-Faculty Curricular Model and a Culminating Campus Celebration of First Year Innovation

A majority of faculty members acknowledge advantages of involving undergraduate students in research, but a far smaller percentage, many of whom teach First Year Seminar (FYS) courses, think about embedding research practices in these required general education environments. The hesitation is understandable: FYS courses happen early in students' academic careers before they are ready to engage in quality research experiences, or so the argument goes. This faculty/student joint presentation presents a field-tested curricular model for The FYS Passion Project—a collaborative faculty and first-year student design—that breaks the research process down into gradual, bite-sized, and FYS-appropriate chunks, allowing for introducing steps in the research process as early as the first semester. The scaffolded activities culminate in an on-campus conference by FYS students for FYS students called FYS Wonderfest, A Campus Celebration of First Year Innovation. Setting this model apart is the fact that the faculty member created the pedagogical plan and products in close cooperation with two first-year students. The newly redesigned and reimagined model piloted in Fall 2024; and I can confidently say that it offered level- appropriate support and training in research practices at first-year-student level. The presentation showcases the step-by-step approach, which also includes periodic electronic check-ins that allow students to assess their relationship to and feelings toward the research and creativity process along the way. The presentation also reports on the planning, implementation, and impressions of FYS Wonderfest, an on-campus mini-conference, where students shared their research with peers and invited guests in a welcoming and friendly environment. The presentation's aim is that the student involvement in the curricular design, as well as the overwhelmingly positive results from the fall 2024 pilot, can help convince especially (often reluctant) FYS instructors to adopt and adapt similar models for use in their classrooms.

Abstract Name: Examining the Moderating Role of Birth Outcomes on the Relationship between Maternal-Fetal Attachment and Infant Sensory Processing

Maternal-fetal attachment (MFA), a crucial component of prenatal bonding, has been linked to developmental outcomes, though its specific associations with sensory processing remain underexplored. Alhusen et al. (2013) demonstrated that mothers with lower quality of MFA were associated with an increased risk of developmental delays in children, while women with higher quality of MFA showed improved early childhood developmental outcomes, suggesting that the attachment formed during pregnancy can have lasting effects. This study investigates the moderating role of birth outcomes on the relationship between MFA and infant sensory processing at 4 months of age in a predominantly low-income, Black/African American population. Data from 134 maternal-child dyads were analyzed, using the Maternal-Fetal Attachment Scale (MFAS) to assess MFA and the Infant/Toddler Sensory Profile (ITSP) to measure infant sensory processing. Birth outcomes, including gestational age at birth, birth weight, and head circumference, were evaluated as potential moderators. Regression analyses conducted in SPSS showed that gestational age had a main effect on MFA and ITSP scale rating ($\beta = .22$, $t = 2.541$, $p < .05$). However, no significant moderators were identified, and the main effect of gestational age did not hold when the outliers were removed. MFA was not correlated with either ITSP Low Threshold ($r = -.020$, $p = .815$) or ITSP Low Registration ($r = -.010$, $p = .904$), nor was it significantly correlated with any of the three birth outcomes. These findings highlight the complex relationship between prenatal attachment and infant sensory processing and underscore the need for further research, particularly in diverse populations. Future research should consider multiple time points and larger sample sizes to better understand how birth outcomes may influence the relationship between MFA and sensory processing.

Abstract Name: High-throughput Bioprinting of Cell-laden Droplets for Scalable Organoid Biomanufacturing

Organoids are 3D cell culture systems mimicking actual human organs and are generated from human induced pluripotent stem cells (hiPSCs). Efficient and scalable biomanufacturing of organoids holds significant potential for disease modeling, drug discovery, personalized medicine, and regenerative therapies. However, current methods for producing cell-laden microdroplets—a critical step in organoid generation—are labor-intensive and prone to variability. To address these challenges, we developed a semi-automated, high-throughput bioprinting system designed to streamline and standardize the production of alginate-based droplets. This research focuses on automating the droplet generation and processing system to improve efficiency, reproducibility, and reduce human intervention. Our system integrates air-jetting technology with a custom Python-controlled Raspberry Pi interface to automate key processes, including droplet generation and

washing. The system uses a syringe pump to dispense alginate bioink and peristaltic pumps for wash cycles, minimizing contamination risks. Comprehensive optimization was performed on printing parameters, including airflow rate, alginate concentration, and crosslinking medium, to enhance droplet uniformity and integrity. Key findings demonstrated that higher airflow rates and CaCl₂ concentrations improved droplet sphericity, while specific alginate formulations enhanced droplet stability. The automated system achieves a production rate of approximately 50 droplets per second, generating 27,000 droplets within 10 minutes with minimal user oversight. This automation not only ensures consistency in droplet size and quality (300–500 µm) but also significantly reduces manual labor and the likelihood of errors, making it ideal for scaling up organoid production. Encapsulated cells exhibited high viability, aggregation, and differentiation during culture, confirming the efficacy of our optimized protocol. Future work will focus on increasing throughput to enable large-scale production for clinical applications. This advancement represents a significant step toward scalable, efficient biomanufacturing of organoids, offering transformative potential for regenerative medicine.

Abstract Name: Von Hippel-Lindau Disease: Manifestation and Treatment of Rare Genetic Condition

Von-Hippel Lindau (VHL) disease is a rare genetic condition that predisposes individuals to abnormal tumor growth throughout the body. VHL disease is a mutation of one's VHL gene, a crucial tumor suppressor gene found in the body. Living with this gene mutation allows your body to repeatedly promote tumor growth in the brain, retina, inner ear, spinal cord, adrenal glands, kidneys, and pancreas. To diagnosis VHL, a healthcare provider would conduct a blood test that could potentially identify a VHL pathogenic variant. Early diagnosis and implementation of treatment has had a great effect on the lifespan of VHL patients. However, there is still no cure and the disease effects 90% of those with the gene mutation. The tumors of this genetic condition tend to be noncancerous and continue to regrow all throughout life. However, tumors found in the kidneys are generally cancerous, making renal cell carcinoma the leading cause of death in these patients. Surgical interventions are a common form of treatment for VHL tumors, specifically those of the central nervous system (CNS), adrenal glands, and kidneys. Surgeries utilized to treat VHL include general, robotic, or laparoscopic surgeries. There are also instances where devices are placed into the patient to help mitigate tumor effects and growth. The use of immunotherapy, chemotherapy, radiation therapy, and prescription drugs are all seen in practice as well. Great effects are continuing to be seen in patients effected by this disease as the VHL treatment landscape continues to improve and evolve.

Abstract Name: Modeling Spatial Variation of PKC- δ and cFOs Neurons of the Amygdala: Implications on

Neuropathic Pain Output

Neuropathic pain is a result from injury to the nervous system and involves a region of the brain known as the central nucleus of the amygdala (CeA). Within the CeA exists a population of neurons expressing protein kinase c-delta (PKC- δ). PKC- δ are generally pro-nociceptive (increase pain); however, a subpopulation of PKC- δ neurons is activated by the inhaled anesthetic isoflurane and provide anti-nociceptive output (decrease pain) when activated. In other words, these two subgroups of PKC- δ neurons play opposing roles in pain output. We developed a 3-D computational model of PKC- δ and cFOs (the marker of activated neurons) and used this model to investigate the impact of anterior to posterior (A --> P) variation in neuron-level properties on pain output from the CeA. Our model stimulates the behaviors and interactions of 10,000+ PKC- δ (pro-nociceptive and anti-nociceptive) neurons and produces an emergent measure of pain. Neuron-level parameters (e.g. location, firing rates, connectivity) were estimated from wet-lab data indicating variation along the A --> P axis. Results from the model show how pain is influenced by spatial heterogeneity in these neuron properties. Our modeling framework provides a tool for exploring impact of neuron-level parameters on system-level pain output. Using this tool, we aim to explore the impact spatially targeted activation and inhibition of PKC- δ neurons on pain output from the CeA. This work highlights the importance of computational modeling in studying biological systems and further development of wet-lab experiments.

Abstract Name: Understanding the Relationship Between Gut Microbial Communities and Saliva Enzymes Present in *G. mellonella* to Degrade Polyethylene and other Plastics

Plastic is ubiquitous, with approximately one-third of global plastic production being polyethylene, a thermoplastic resin commonly used in packaging applications such as plastic bags, films, containers, and bottles. The overproduction of plastic, particularly single-use plastics, and current disposal methods underscore the urgent need for environmentally sustainable solutions, such as biodegradation by insects and microorganisms. Recent studies have identified bacteria and saliva enzymes capable of bio-degrading polyethylene in Greater Wax Moth larvae (*Galleria mellonella*). Evidence suggests that the chemical similarities between their natural diet of honeycomb and polyethylene enable the larvae to degrade the plastic. Four saliva enzymes—Cora, Ceres, Demetra, and Cibeles—have been identified as responsible for plastic oxidation. Additionally, research has shown that gut microbes allow waxworms to digest polyethylene and potentially polystyrene. Strains of *Fibrobacter*, *Pseudomonas*, and *Bradyrhizobium* have been associated with polyethylene and polystyrene diets in waxworms, suggesting that these bacteria may possess mechanisms for plastic polymer breakdown. However, further studies are required to confirm these mechanisms. While four saliva enzymes have been identified and crystallized as plastic oxidizers, the genetic regulatory mechanisms behind their function remain poorly understood. Notably, Cora is the most abundant enzyme in waxworms, making it a promising candidate for further research. It is also unclear whether the microorganisms in the waxworm gut complement the saliva enzymes in the biodegradation process. In this study, we will identify prominent gut microbes through isolation, culturing, and DNA extractions of selected colonies. Bacterial stocks will allow us to study these microorganisms more closely. We will grow selected organisms on various plastic media such as polyethylene, polystyrene, and polypropylene to determine their tolerance and plastic

biodegradation capabilities. Phenotypic characterization of isolates will be complemented by genomic studies to identify potential genes and pathways involved in plastic degradation.

Abstract Name: You're Multiracial? I Thought You Were Mexican!: A Systematic Review Into the Racial Categorization of Multiracial Faces

With rising racial diversity in America, blurred distinctions of race lead to issues of misidentification and perpetuation of racism. This pre-registered, non-interventional systematic review aims to synthesize patterns of racial categorization (i.e., mental placing of people into racial groups based on a physical basis), according to observer race, face race, and aspects of the facial stimuli. For example, the review compares racial categorization (i.e., concordance/discordance frequency, label usage, latency) of real and computer-generated faces of different races between monoracial and multiracial observers. Following NIRO-SR guidelines, we applied a committee-approved search query in databases (e.g., PsycINFO, ProQuest) to identify laboratory-based studies with adults published after 1990 using an experimental paradigm where participants racially categorize faces. We are currently screening studies and will present synthesized results. Aligned with social identity theory, we expect faster and more concordant racial categorization of multiracial faces by multiracial perceivers. This work will inform better study of racial categorization of multiracial individuals.

Abstract Name: Do Mutations in a Nucleoid-Associated Protein Gene Suppress a Defect in Cell Division?

Streptomyces are filamentous, Gram-positive bacteria that provide antibiotics and biologically active compounds for medical purposes. A *Streptomyces coelicolor* *ftsQ* mutant (with a deletion of an important gene regulating cell division and efficient sporulation) accumulates multiple spontaneous suppressor mutations over time. One group of those suppressor mutations is in *lsr2*, but those strains have additional mutations in other genes. *Lsr2* is a nucleoid-associated protein (homolog to *Escherichia coli* H-NS) that organizes DNA and acts as a transcription factor. The main goals of this project were to demonstrate that *lsr2* suppresses a deletion of *ftsQ* by deleting *lsr2*, deleting *ftsQ*, and then integrating a copy of *lsr2* as point

mutant alleles at a non-native location. Some methods used to achieve these goals include interspecies conjugation, polymerase chain reaction (PCR), and agarose gel electrophoresis. All strains will be analyzed via PCR and phase-contrast microscopy to determine if *lsr2* does suppress a deletion of *ftsQ*.

Abstract Name: An Investigation of the Effects of Microwave-Only Reduction on a Supported Palladium Catalyst in Suzuki-Miyaura Reactions

The Suzuki-Miyaura reaction is a cornerstone of many pharmaceutical production processes. These reactions occur when an organoborane and an aryl halide interact in the presence of a palladium metal catalyst and a base to form biaryls. The support for the heterogeneous catalyst used in this project consisted of industrially produced, readily available alumina beads. These beads were coated with nitrogen-doped reduced graphene oxide to enhance electrical conductivity and nickel-tipped carbon nanotubes to prevent graphene sheet stacking. Wet impregnation was then used to decorate the surface of the support with palladium nanoparticles. Typically, the catalyst is reduced at high temperatures in a hydrogen gas atmosphere. However, it was hypothesized that reduction using only microwave radiation would produce a functional catalyst. It was also hypothesized that varying the temperature, time, and stirring rates during microwave treatment would influence the catalyst's activity. Four samples of unreduced catalyst were microwaved under different conditions, and their activities were compared. Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES) was used to determine the exact amount of palladium deposited on each catalyst after microwave reduction. This allowed for the addition of catalyst based on the molar concentration of palladium rather than catalyst weight, resulting in a fairer and more consistent assessment of catalyst activity. Each catalyst variant was then tested in its own Suzuki-Miyaura reaction to determine its individual activity. A Gas Chromatography/Mass Spectrometry (GC/MS) system was employed to quantify product and byproduct yields from each Suzuki-Miyaura reaction. Data collected in this experiment suggest that microwaved catalysts are highly active in these reactions; but specific microwave conditions did not significantly affect their performance.

Abstract Name: The Effects of Early Life Stress on Depression- and Anxiety-Like Symptoms in Both Sexes of Adult Mice: A Novel Behavioral Model

Anxiety and depression are leading causes of mental illness, and 25% of adults will be diagnosed with mental illness at some point in their life. The causes of these disorders remain unknown, but studies reveal a connection between early life stress (ELS) and psychopathological development. Some reports suggest that ELS is sufficient to induce depression- and anxiety-like behavior in mice. However, substantial evidence shows that traditional models of ELS inconsistently induce significant alterations in commonly used behavioral tests of depression- or anxiety-like behavior. This project tested a novel behavioral model and

analyzed the effects of maternal separation in later post-natal days (PND) compared to previous studies, aiming to develop a more consistent and realistic understanding of the relationship between maternal separation and its long-term effects. This study tested 73 subjects in a 2x2 design (sex x ELS). Maternal separation occurred on PND 10-20. On PND 21, all subjects were weaned. Once 8 weeks old, all subjects underwent the light-dark emergence test (LDE) followed by an active versus passive primary reward preference test (sucrose water vs. running wheel) (AvP). The LDE test showed that stressed females took less time to enter the light portion of the light-dark box compared to stressed males. Females had increased entries and distance traveled in the light box under stressed and unstressed conditions compared to males. Following stress, females displayed impulsive-like behavior relative to males, who appeared to exhibit more of an anxious phenotype. The results of the AvP test show that control mice increased their running each day of the test, unlike stressed mice. There were no significant differences in the amount of sucrose drank. These findings suggest that the running test is a more sensitive measure of stress effects than the sucrose preference test. Future work will analyze the molecular mechanisms behind these findings.

Abstract Name: Reducing Jet Engine Reignition Delay Time through Computational Molecular Analysis of Jet Fuel Ignition

Computational chemistry is a resource efficient way to predict reaction behavior over a wide variety of environments. Fuel design is a field particularly well suited for computational chemistry applications due to the extreme conditions experienced in combustion. In this work, we explore jet engine flame out, a sudden extinguishing of flame which leads to a loss in propulsion. Developing an accurate kinetic mechanism to predict reignition speeds of common cyclic jet fuels under high-altitude and low-pressure conditions is valuable for mitigating flameouts by minimizing reignition delay times. Current kinetic models of jet fuel ignition do not account for stereochemical effects. Furthermore, there exists little data for ignition delay time at low pressures, and especially for low pressures experienced at high altitudes. These challenges make computational chemistry a perfect tool to address shortcomings in jet fuel modeling. In this work, we use computational tools to create new jet fuel models. These tools include Kinbot, which predicts all unimolecular reaction pathways for fuel combustion, Gaussian, which calculates molecular geometries and energies, and Master Equations System Solver, which uses master equation theory to compute pressure and temperature dependent rate constants. Through performing computational analysis on each of these fuel combustion pathways for common jet fuels JP-10 and n-heptane, more accurate reaction rate constants can be determined to better predict reignition speeds at pressures relevant to flameout. Developing a computational mechanism for jet fuel ignition at high altitudes and low pressures, complemented by experimental validation, can enhance flameout mitigation by providing accurate predictions of ignition delay times. This combined approach utilizes advanced modeling tools and supercomputing to improve engine reliability and safety.

Abstract Name: Visual Examination of Own- and Other-Race Faces and Implicit Racial Bias in Children and Adults

Previous research has examined how implicit racial bias can influence face recognition. By influencing how individuals visually process faces from one's own race, it may lead to heightened attention toward faces of one's own-race group. Past research has struggled to provide consistent results of how individuals scan or categorize certain faces, and there is a lack of research on potential factors (e.g., implicit racial bias) driving these inconsistent findings. Furthermore, children's implicit racial biases in relation to their recognition and visual scanning of own- and other-race group faces has yet to be examined. This study aims to examine adults' and children's implicit racial biases in relation to their duration of looking at own- and other-race facial features. Participants will complete two recognition tasks with White and Asian faces. In each recognition task, participants will be presented a sequence of eight faces in an encoding/learning phase. In the test phase, participants will be tested for recognition in a sequence of 16 faces (8 target, 8 distractor). Participants will complete the Implicit Association Test (IAT) and select pairings of White and Asian faces with "nice" and "not-so-nice" images. Eye tracking data will be collected during the face recognition tasks to measure the duration of looking. Implicit racial biases will be compared by analyzing the difference in response times for the combinations of pairings in the IAT. We predict that children with higher implicit biases will examine their own-race's facial features longer, and show avoidance of other-race's eye regions and facial features. Any differences at the level of visual perception might influence social interactions with own- and other-race individuals. This research aims to provide a better understanding of the social-cognitive processes in individuals facing their own- or other-race groups. Our findings can potentially contribute to our understanding of intergroup relations.

Abstract Name: Differences in Health-Related Quality of Life Among Breast Cancer Survivors by Hispanic Origin in a Cross-Sectional Study

Breast cancer is the second leading cause of cancer-related death among American women. Research has examined health-related quality of life (HRQOL) among breast cancer survivors, finding that Hispanic women report lower levels of HRQOL compared to non-Hispanic White women. However, Hispanics are not a homogeneous population, and varying socioeconomic statuses and lifestyle factors may cause differences in HRQOL. This study examined differences in HRQOL by Hispanic origin among breast cancer survivors using data collected for the 'Hispanic breast cancer study' at the University of Central Florida. Patient contact information was obtained from the Florida Cancer Data System. Eligible patients were sent an invitation letter and response form to indicate interest. Following state-mandated recruitment procedures, a second mailing was sent if no response was received. Surveys were then sent to interested participants according to their preferred method (mail or online) and language (English or Spanish). The Functional Assessment of Cancer Therapy – Breast (FACT-B) was utilized to assess five domains of HRQOL: physical, social, emotional, and functional well-being, with a breast-cancer subscale. Utilizing the scoring manual, the FACT-B total score and HRQOL domain scores were calculated for each Hispanic subpopulation, with higher scores indicating a better HRQOL. From September 2023 to February 2024, we received complete surveys from 165 eligible participants (18 Colombians, 10 Cubans, 11 Dominicans, 10 Mexicans, 95 Puerto Ricans, and 21 from other Hispanic backgrounds). The mean FACT-B total score was 102.6 across all groups. Cubans

reported the highest mean score (116.3), while Dominicans reported the lowest mean score (97.8). Additionally, participants' smoking status, alcohol consumption, marital status, laterality of cancer, cancer stage, treatment type, and surgery type all proved to have specific correlations with HRQOL. These findings may help to increase awareness and explain the disparities in HRQOL impacting Hispanic breast cancer patients.

Abstract Name: Sensor-based Robotic Cars with Onboard Microprocessors to Perform Swarm Movement for Specific Tasks

Swarm robotics involves the coordinated motion of multiple robots working collectively to complete tasks efficiently. We hypothesize that integrating an advanced software interface to program and coordinate individual robots can significantly enhance swarm movement. In the initial phase of our project, nine EV3 robots were assembled, each equipped with an infrared (IR) sensor. These robots demonstrated homogeneous motion by utilizing information about their surroundings to move collectively. In the second phase, Lafvin robots were used to implement line tracking and obstacle avoidance methodologies, utilizing IR sensors and a Python-based control program integrated with Arduino microcontrollers. Motion analysis was conducted to evaluate the robots' behavior, plotted as a function of their positions. The results showed that 85% of the robots successfully reached their destination, but overall swarm movement efficiency was only 50%. Building on these findings, the project is being further refined to achieve more synchronized and effective swarm behavior. Initial tests suggest that software enhancements will support the desired improvements in movement coordination. Currently, we are developing an app to facilitate effective communication among robots using the HC-06 Bluetooth module. This communication framework enables the robots to interact dynamically, improving their line tracking and obstacle avoidance capabilities. The app is being developed using MIT App Inventor, allowing for seamless integration of backend and frontend software. The app is designed to receive data and send signals to the robots, optimizing their swarm movement. Detailed descriptions of the hardware and software components, as well as experimental results, will be presented at the upcoming conference. This interface is expected to serve as a powerful tool for improving swarm robotics performance.

Abstract Name: Single-Cell Multiome Bone Marrow Atlas in Young and Geriatric Samples

Bone marrow is a highly diverse organ that undergoes compositional changes over time. Age-related changes

in stem cells contribute to conditions like osteoporosis and immunosenescence. Mesenchymal stem cell differentiation favors adipogenesis over osteoblastogenesis while hematopoietic stem cells undergo lymphoid-to-myeloid skewing and senescence. The cellular events that trigger these changes are not completely understood. We use single-nucleus RNA sequencing (snRNA-seq) and assay for transposase-accessible chromatin (ATAC-seq) to profile the transcriptomic and epigenomic landscape of bone marrow from samples representing young and geriatric populations. We also analyze the cell-cell interactions that drive mesenchymal stem cell differentiation. Mesenchymal stem cells have been shown to regulate hematopoietic stem cell self-renewal and differentiation. We determine if the epigenetic regulation of mesenchymal stem cells is linked to mesenchymal regulation of hematopoietic stem cells. This multiome bone marrow atlas will provide a reference to investigate cell-cell interactions that control aging.

Abstract Name: Active Restoration of Buckthorn Invaded Communities Can Disrupt Litter Decomposition Feedback Mechanisms and Promote Ecosystem Function

Common buckthorn (*Rhamnus cathartica*) is an invasive shrub that is widespread throughout deciduous forests of North America. Major impacts of buckthorn include altered leaf litter decomposition. Buckthorn produces nitrogen-rich litter that decomposes faster than most co-occurring native plants. Increased decomposition can be a part of a self-reinforcing mechanism of invasion since buckthorn benefits more from increased nitrogen availability compared to many native competitors. Active restoration of plant communities following buckthorn management can help resist future invasion. However, little is known about how buckthorn leaf litter affects the decomposition of native grasses used in forest restoration or how those interactions may change over the course of restoration. I asked 1) How does buckthorn affect decomposition of native grasses used in understory restoration? 2) Does the impact of buckthorn litter on grass litter depend on the environment? I investigated these questions through a litterbag experiment in an oak-maple woodland. I decomposed litters of buckthorn, wild rye, and mixtures of both species together in three settings representative of different stages of forest restoration: intact buckthorn stands, areas where buckthorn was removed, and areas where buckthorn was removed and native species were actively restored. Litterbags were collected after 166 and 265 days. By 256 days, I found buckthorn litter had 6% mass remaining compared to 63% for wild rye and that regardless of species, litters decomposed 5% faster in intact buckthorn stands compared to areas where buckthorn was removed. Interactions between litters were also dampened in intact buckthorn stands and in unrestored areas, whereas litter mixtures decomposed synergistically in areas where native plants had been actively restored. My findings suggest that actively restoring plant communities can interrupt some feedback loops between buckthorn abundance and litter decomposition and promote healthier ecosystem function following management.

Abstract Name: Electron Beam Pumped Laser Induced Fluorescence

While laser induced fluorescence (LIF) is relatively straightforward in low temperature argon plasmas, measurements of the ion velocity distribution in low temperature helium plasmas have been problematic. Not only is the ionization energy of helium much greater than that of argon, the lowest energy metastable helium ion state (the 2s state) lies 40.8 eV above the ion ground state. Therefore, in low temperature helium plasmas ($T_e \leq 5$ eV), the metastable ion population is quite small and there is only a small target population available for LIF. Another challenge is that the excited states of helium ions are degenerate and therefore, most excited states have a very strong return directly to the ground state through deep UV and soft x-ray emission. To maintain a sufficient metastable population for two photon absorption LIF (TALIF) in helium, we inject a low energy (~ 100 eV) electron beam into a low temperature helium plasma. Here we explore the ability of an electron beam to pump the 2s helium ion state, which is reflected in the increased intensity of helium's spectral lines. Preliminary data and further discussion on electron beam pumped TALIF is also presented.

Abstract Name: Environmental and Societal Impacts of Agricultural Land Abandonment in Indonesia

In the past decades, Southeast Asia has faced one of the highest urbanization rates globally, with land conversion, agricultural land abandonment, and deforestation simultaneously occurring. High population growth rates have also led to increased food insecurity, which has increased the need for agricultural production. In Indonesia, high rates of urbanization on the island of Java have historically promoted governmental policy solutions aimed at population redistribution and agricultural extensification (rather than intensification). The cost of this conversion of lands to agriculture often falls on the environment, with peatlands and forested lands being converted to large scale farms. This leads to myriad environmental problems, as peatlands are important carbon stores, and their disruption can lead to large-scale climate disasters. This research proposes to address the question: What are the socioeconomic and biophysical drivers of agricultural land conversion, deforestation, and urbanization in Indonesia? This research additionally proposes to, through bibliometric and population-based analyses, (1) establish the historical context of agricultural land abandonment in Indonesia, (2) report the predicted extent of the effects of agricultural land abandonment, which is closely linked to urbanization, and (3) identify the scholarly interest in these issues, across disciplines, time, and place. By identifying the trends in existing research regarding both the effects and impacts of agricultural land abandonment in Indonesia, gaps in knowledge and areas that require further investigation will be identified.

Abstract Name: Low-Dimensional Materials for Spacesuit Applications

Modern Space Suit materials maintain properties that shield astronauts from radiation, severe lunar temperature, and microparticles; while upholding lightweightness, flexibility and tensile strength on long space missions. Most spacesuit materials are made from nylon, synthetic fabrics and synthetic polymers. High density polyethylene (HDPE) is a popular polymer for space applications due to their resistance properties from secondary radiation exposure and their richness in hydrogen atoms. However, HDPE lacks tensile strength, therefore causing urgency to find a material that will absorb well and maintain excellent properties with HDPE. In this project, low-dimensional materials, including graphene, graphene oxide and boron oxide are explored for spacesuit material additives HDPE, because of their successful electrostatic, thermal and mechanical properties. Density Functional Theory (DFT) computations are used to investigate the adsorption interactions between low-dimensional materials with HDPE with the variable of angle dependence. Moreover, exploring their ability to maintain radiation resistance, thermal cycling and electrostatic properties. Ab initio Molecular dynamics simulations (AIMD), are used to examine the behavior of new materials under severe temperatures and harsh pressure conditions.

Abstract Name: Using Index of Biotic Integrity (IBI) scores to predict potential stream restoration success in Pennsylvania

The U.S Environmental Protection Agency set goals in the Chesapeake Bay Watershed Agreement that Pennsylvania must cut 69% of nitrogen outputs, but this target has not yet been met. The Susquehanna River basin that flows to the Chesapeake is largely agricultural communities that have the potential for excess nutrient runoff and sediment pollution. Of the 69% of nitrogen production that Pennsylvania is responsible for, 80% are the byproducts of agriculture. Pennsylvania's delisting stream initiatives are efforts to reduce the number of agricultural streams that are considered in poor health and thus impact the bay. For a stream to become listed as impaired, its Index of Biological Integrity (IBI) score must be less than 50. This score indicates the stream has a high level of disturbance with a predominance of benthic macroinvertebrate species that are tolerant to poor water quality. Using the PA Department of Environmental Protection's IBI scores from 1991 to the present, along with the federal National Land Use/Land Cover Dataset (NLCD), we can predict which streams are likely to improve with restoration. We plan to use the state-wide DEP data to map trends in sub-watershed stream quality based on IBI scores. In addition, we have conducted case studies of specific stream reaches where the Freshwater Research Institute projects have given us a complete history of stream restoration efforts and timing. Using these case study results, we can make predictions about other watersheds that might be good candidates for new stream restoration projects. A choice-informed decision-making model will be utilized to reinforce rapid delisting strategies. We hope to provide some insight into trends associated with water quality and restoration in streams, contribute to efforts to delist streams in Pennsylvania, and accelerate the restoration of the Chesapeake Bay.

Abstract Name: PAH Concentrations in Communities with Different Socioeconomic Profiles in St. Petersburg, Florida and the Impact of Climate Change

Polycyclic aromatic hydrocarbons (PAHs) are a class of Persistent Organic Pollutants (POPs) formed by the incomplete burning of coal, crude oil, and gasoline. PAHs are known carcinogens and mutagens associated with infertility and birth defects (Gopinath et al., 2024). Rising temperatures due to climate change cause PAHs to evaporate into the air and spread globally. Preliminary studies in Pinellas County showed disparities in air quality among neighborhoods due to redlining, which resulted in higher traffic flow and heavy industry sites in low-income, predominantly black communities (Alegria et al., 2024). This study aims to measure the levels of PAHs in soils of neighborhoods with different socioeconomic profiles in St. Petersburg. It hypothesizes that marginalized communities will have a higher concentration of PAHs in their soil compared to affluent neighborhoods. The methodology comprised four major steps: sampling, extraction, cleanup and fractionation, and mass spectrometry/gas chromatography analysis to extract and evaluate the pollutants from the soil. The results did not support the hypothesis as the PAH concentration in the neighborhoods did not show any statistically significant differences. However, 63% of 22 samples were classified as heavily contaminated based on the methodology from Maliszewska-Kordybach. All neighborhoods will be affected by rising temperatures, causing PAHs to become airborne and increase human exposure. This study urges remediation such as source removal, emission reduction, and bioremediation (Bharatkumar Patel et al., 2020). Further research needs to be conducted with more samples over a greater period for a comprehensive evaluation of St. Petersburg's PAH pollution rate.

Abstract Name: Understanding the 'Two Lefts': Exploring Causal Dynamics of Latin America's Political Shift During the Pink Tide

This paper uses a cross-national comparative case analysis to understand the economic divergence, commonly known as the "two-lefts" during the Pink Tide in Latin America. The Pink Tide was a political shift from right-wing to left-wing government that swept the region between the late 1990s and the 2000s. This research seeks to address the question: Why did Latin American countries experience divergent leftist shifts during the pink tide of the late 1990s and 2000s? Four countries were analyzed: Bolivia and Nicaragua, which elected far-left leaders, and Panama and Guatemala, which chose more moderate candidates. This study investigates key factors influencing this divergence, such as economic inequality, social spending, legal protections, and public perception of economic and social issues. Economic inequality was measured by the Gini coefficient, social spending levels were derived from GDP percentages, legal protections for marginalized groups were assessed through various indexes, and public perceptions were gauged from Latinobarómetro survey data. Surprisingly, the analysis shows that economic conditions, inequality levels, and legal protections had little influence on the degree of leftist politics embraced by each country. Instead, the perception of social mobility and confidence in the existing government emerged as critical factors.

Countries with lower trust in their current governments and less optimism about the future tended to elect more leftist leaders. Although these findings suggest that public trust and hope for the future played a pivotal role in shaping political choices, the study calls for further research to confirm these patterns across the region. This research builds on previous research about the causes of the Pink Tide by examining the reasons for its divergence.

Abstract Name: Fighting with Graffiti: A Comparative Study of Graffiti Usage in Palestine and Ukraine

Throughout history, many societies have used art to support their ideologies of war and conquest. This paper is a comparative study of graffiti usage in Ukraine and Palestine in the 21st century, both societies targeted by military conflict. I argue that Palestinian, Ukrainian, and global graffiti are similar in content, depicting resistance, hope, strength, and culture while including culturally specific markers such as the flag, but do not reflect the difference between military conflicts and their atrocities. First, a brief introduction to the use of the art of graffiti in war and conquest is provided. Second, I will discuss the history of the Israeli occupation of the Palestinian people and the Russian invasion of Ukraine, emphasizing the difference in the military contexts and its atrocities. Third, I will discuss the Palestinian and Ukrainian artists who use graffiti as an expression of resistance to military occupation, genocide, and war, including artwork of Palestinian artist Majd Abdel Hamid's artwork, "Land Art" and artwork of two Ukrainian artists, Olexiy Kislov's artwork, "Renaissance" and Sasha Corban's artwork, "Golden Thread." Fourth, I will also demonstrate how global artists, such as Banksy, provide a global view of both Palestine and Ukraine's tragedy of war and resistance. This study is based on historical art and research and primary sources, such as images of graffiti and their formal and cultural meaning. Although graffiti is the most visible and quick art form for inspiring survival in Ukraine and Palestine with the continuing war and genocide, they do not express the social trauma and the tragedy of the Palestinian and Ukrainian people. While scholars discuss the graffiti by the Palestinian, Ukrainian, and global artists, they don't compare how the artists use graffiti and do not discuss the extent to which graffiti reflects the social traumas.

Abstract Name: SMARTArt Development and Curation: Salvador Dali's Inferno

In this project, we will deploy a Stout-developed augmented reality app (SMARTArt) to display interactive and informative interpretive content for Salvador Dali's Inferno paintings in his Divine Comedy series. This research advances innovation in art curation by utilizing augmented reality as an emerging technology. It also draws upon and contributes to the research on Dali's 100-print collection, offering interpretative insights to his work in context of Dante's epic poem. This project is a demonstration of the digital humanities,

intersecting digital technologies with rich humanities content to create innovative understandings and experiences. Furthermore, this project includes user testing on the SMARTArt app, improving the user experience in the emerging field of augmented reality through mobile devices.

Abstract Name: Mitochondrial Dysfunction Precedes the Development of Tau Pathology in P301S tau (PS19) Mice

Alzheimer's Disease (AD) is the most prevalent form of dementia affecting nearly 6.7 million Americans. A major hallmark of this disease is the accumulation of pathologic forms of the protein tau, which eventually form intracellular neurofibrillary tangles. Previous research using tauopathy mouse models has shown reductions in electron transport chain complex activity and ATP levels, although the exact mechanisms behind how mitochondrial dysfunction influences pathologic tau accumulation have still yet to be defined. Here, we explore mitochondrial parameters, specifically bioenergetics and dynamics, in primary neurons isolated from either wild-type or P301S tau (PS19) mouse embryos before the onset of pathologic tau accumulation. The PS19 mice are a well-studied tauopathy mouse model that express mutant, pathologic human tau five-fold more than endogenous mouse tau. Preliminary data suggests that neurons isolated from the PS19 mice have reduced mitochondrial membrane potential and ATP levels as measured by live cell imaging of biosensors TMRM and ATP Red respectively. Additionally, we assessed mitochondrial dynamics using immunoblotting markers linked to fusion and fission of the mitochondria, such as mitofusin 2 (MFN2) and dynamin-related protein 1 (DRP1) respectively. We show that basal phospho-DRP1 levels, which reflect active fission of the mitochondria, may be increased in the PS19 neurons compared to wild-type. However, the levels of the mitochondrial fusion protein MFN2 remained unchanged between PS19 and wild-type neurons. Future studies will examine the function and health of mitochondria before the presence of pathologic tau. These studies will provide insights into a mechanistic role for mitochondria in the progression and prevention of pathologic tau accumulation.

Abstract Name: The Silence Speaks Volumes

Brazil, the fifth largest country in the world and home to more than 230 Indigenous languages, has only one official language: Portuguese. Like English and French, Portuguese is a European language that gained dominance during colonization and maintains that power. Through literature reviews and interviews, this work aims to investigate how European, dominant languages expressed their power over African and Indigenous languages, and people, in Brazil. It is apparent that governments, especially dictatorships in

Brazil, use language policy as a tool to enforce inequality. This is demonstrated in sectors of globalization and education and enacted through the myth of racial democracy and cultural silencing. Specifically noted in this work, the desire for global influence contributes significantly to unjust policies. Education, which is seen as a path to power, is particularly affected. Indigenous and African languages are replaced by dominant languages in schools. Further, certain opportunities are restricted to those who are privileged enough to have access to the resources needed to speak said languages, which creates a cascading negative effect. This affects the present and will continue to influence the future, but it is important to understand the historical background of this trend. An Interview with Dr. Keila Grinberg revealed how the Black experience, including a history of oppression and a legacy of cultural influence, has been delegitimized by Brazil's government. Overall, language policy in Brazil strips power from African and Indigenous populations in favor of European dominance. It attempts to erase and delegitimize the value and influence of African and Indigenous language speakers, stripping them of power.

Abstract Name: Neurodivergence in the Arts: How A Neurodivergent Brain Creates, Performs, and Designs

The present study explores the ways neurodivergent artists create, perform, and design their work. It investigates the relationship between certain brain functions and how those functions affect artistic expression. By comparing neurodivergent and neurotypical people's coping mechanisms and their methods of creation we can conclude the different pathways taken by each artist to get the same result. Working with disability organizations on campus and beyond, we will be able to get firsthand insight into the different ways neurodivergent artists achieve their goals, and what extra steps might need to be taken. Through these organizations, we can also link certain behaviors and patterns together. Our research was inspired by the University of Wisconsin Milwaukee's upcoming semester's show, "The Curious Incident of the Dog in the Night-time", a novel turned play by Simon Stephens, in which the main character, Christopher, displays many neurodivergent and autistic tendencies. At our showing of "Curious Incident of the Dog In the Night-Time", there will be a presentation of famous performing artists with neurodivergence, as well as pre-recorded interviews conducted with students and faculty at our school who either identify as neurodivergent or who have worked closely with students on the spectrum. Along with this, our research focuses on a topic not heavily discussed. While there may be some previous research about neurodivergent artists, no true solutions have been enforced. To compare, our research hopes to create change on a wider level, providing artists with neurodiversity a better chance of success. This research will lead to better accommodations for neurodivergent actors and crew members, and by finding solutions to everyday problems faced by neurodivergent artists, we can promote solutions that will truly make the arts industries more inclusive for all.

Abstract Name: Investigating Local Adaptation vs. Climate Adaptation with Milkweed Plants

In recent years, people around the United States have begun planting milkweed (*Asclepias syriaca*) in response to growing awareness of monarch butterfly population decline. This grassroots effort raises timely and compelling questions about best practices in plant conservation, such as, are seeds as successful in their non-native environments? If milkweed plants show evidence of local adaptation, a process by which organisms grow best in the environment where they originate, then seeds should be planted near their native source. To investigate this question, data on milkweed plants was collected in a three-year provenance trial with plants sourced from 20 locations of varying latitudes across the United States. Seeds from all 20 locations were then planted at three sites with different climatic environments. We modeled the effect of latitude or distance from the original source site on combined stem height (the added height of all stems from the plant in centimeters). A model with latitude (taken from the origin site of the plant) tested for evidence of climate adaptation. A model with distance tested for evidence of local adaptation. We accounted for differences in growth prior to the initiation of the experiment by including baseline stem height in our model. Our model additionally accounts for two random effects: one with a plant ID nested within plant source (where a plant originates from) and one with plot ID (plants' site and plot number). These random effects help account for differences based on natural site and plant heterogeneity. Preliminary results suggest strong evidence of climate adaptation with Southern plants growing larger, but no evidence of local adaptation in milkweed plants. Future research will investigate the role of herbivory in milkweed plant growth. Through this research we aim to produce information about how to best approach conservation efforts addressing declining milkweed and monarch butterfly populations.

Abstract Name: Effects of Logging on Black Bear Habitat Preference in the Upper Peninsula of Michigan

Large carnivores tend to be keystone species due to their effect on ecosystems. In Michigan's Upper Peninsula, a northern coniferous hardwood forest, black bears (*Ursus americanus*) are a vital species due to their role in structuring ecological communities. Understanding how this species interacts with a changing environment due to logging and interspecific interactions are critical for conservation ecology on a landscape scale. I hypothesize that black bears will prefer later successional stage forests, that there is an inverse relationship between top predators, and that competitive exclusion influences coyote density. Over a two-month duration, 30 camera traps were used to quantify occurrence rates of carnivores, being set on trees 1.5-m above ground, and along roads at randomized intervals. I evaluated sight occupancy rates to determine interspecies interactions and understand the influence of both logging and habitat fragmentation on a diverse community. R Studio was used to analyze sight occupancy data among 12 distinct habitats over 75-km². Black bears were found to prefer mixed coniferous and wetland habitats, with moderate usage of different kinds of early successional forested areas resulting from logging. Contrary to my hypothesis, they avoided mid and late successional forests, instead aligning with the Intermediate Disturbance Hypothesis where some disturbance is required for a diverse ecosystem. Although not significant, there appears to be a positive association between bobcats and coyotes. These results emphasize the importance of conserving both old growth and medium disturbance areas to support a healthy and diverse ecosystem that rely on a variety of habitats to thrive.

Abstract Name: Real Steps, Virtual Worlds: Enhancing VR Walking with Adaptive Motion Algorithms

The integration of virtual reality (VR) systems and motion tracking represents a transformative opportunity for both immersive simulations and physical therapy, yet a disconnect remains between real-life movement and VR experiences. This gap poses challenges in both entertainment applications and therapeutic practices, particularly in gait rehabilitation, where smooth and naturalistic motion feedback is critical. Without accurate gait speed data derived from frame-by-frame positional analysis and validated thresholds, avatar movement becomes jerky, inducing motion sickness and reducing the effectiveness of therapeutic exercises. This work focuses on improving the user experience by reducing motion sickness and enhancing immersive walking in VR on a self-paced treadmill. To achieve this goal, we developed a detailed understanding of how our program collects data from VR and wearable motion sensors, ensuring smooth transitions between real-life walking and treadmill use. We designed an algorithm that simulates real-time foot movement based on frame-by-frame positional data and personalized gait elevation metrics, comparing these measurements against validated thresholds to reduce inconsistencies in motion sensor data. The measurements drive avatar and camera movement, synchronizing with built-in VR headset and motion tracking mechanics. Preliminary tests, conducted using Mocopi motion tracking systems with Unreal Engine (UE) VR, indicate improved avatar movement accuracy and reduced motion sickness compared to default systems. The algorithm, now integrated with obstacle avoidance, has paved the way for an ongoing user study to further evaluate its impact on user-avatar synchronization and immersive walking experiences in VR. Future work includes refining and expanding motion algorithms and conducting user studies with physical therapy participants to evaluate the system's effectiveness in gait training and rehabilitation scenarios.

Abstract Name: 3D Printed Mini-Funnel for Improved Control of Microindentation on Engineered Tissue under Optical Coherence Tomography

Fibroblasts play a vital role in shaping the extracellular collagen matrix by exerting traction forces that influence its structural and mechanical properties. This study investigates the interdependent changes in both cellular processes and mechanical properties of the fibroblast-populated collagen matrices (FPCM) during development, focusing on probing the elasticity with well-controlled microindentation. To improve measurement consistency, a mini funnel system was developed and 3D printed to ensure consistent delivery of mini-beads onto the FPCM for indentation testing. This system enabled precise and repeatable tissue deformation measurements of the matrices before, during, and after indentation with the optical coherence

tomography (OCT) imaging. We observed a progressive increase in FPCM elastic stiffness, correlating with fibroblast-mediated matrix compaction and contraction. These findings emphasize the importance of cellular activities in driving structural and mechanical changes during tissue development. By combining improved experimental control with advanced imaging techniques, this study provides new insights into the biomechanics and mechanobiology of cell-dependent tissue remodeling during development and fibrosis.

Abstract Name: Banquet Hall Marketing; Understanding Customers' Preferences

This study explores consumer preferences for banquet halls, focusing on amenities and marketing strategies that most influence booking decisions. Customers prioritize flexibility, multi-functional spaces, and unique amenities that cater to various event types, including weddings, corporate gatherings, and informal events like birthday and graduation parties. Recent research highlights the importance of factors such as accessibility, sustainability, and inclusivity in event planning. Additionally, services such as catering, parking, and equipment play an important role in consumer decisions. This paper explores what amenities are most desired by customers when booking a banquet hall and analyzes how people use social media and websites to find these spaces.

Abstract Name: Microglial Dynamics and Microglia-Vascular Interaction in Respiratory Infection

Microglia are brain-resident macrophages that serve as key regulators of neuroinflammatory processes in cerebral pathology. They have valence on virtually all areas of the cerebral landscape, one locus of particular intrigue being the vasculature. However, microglia-vascular interactions in respiratory infection have been understudied. Given that microglia respond to systemic infection by altering associations with vasculature, it remains of interest to determine whether respiratory infection modulates microglia-vascular interactions. This study investigates (i) the manner in which microglia associate with cerebrovasculature, the role they play in regulating (ii) cerebral blood flow (CBF), and (iii) capillary size using intratracheal lipopolysaccharide (IT-LPS) injection as a model of respiratory infection. This will be investigated through three aims. Firstly, to quantify capillary-associated microglia (CAM) density, CX3CR1-GFP mice treated with IT-LPS injection will be used to measure changes in CAM density. Secondly, to evaluate microglial regulation of capillary size, microglia deficient mice consisting of both (i) FIRE knockout mice that lack microglia and (ii) PLX3397 (PLX) treated mice to pharmacologically eliminate microglia will be used. Subjects will be treated

with IT-LPS injection to measure capillary diameter. Capillary size will be measured using vasometrics. Lastly, to evaluate microglial regulation of CBF, microglia deficient mice treated with IT-LPS injection will be used. CBF will be measured via red blood cell flux through line scans as a readout for blood flow. Images in all studies will be obtained through in-vivo two photon microscopy. In CX3CR1-GFP mice, microglia are expected to become increasingly ramified and exhibit greater levels CAM density. Decreases in capillary diameter and CBF are also expected. In microglia deficient mice, it is expected to see no microglia-vascular interaction. No significant changes to capillary size and CBF are expected. By studying these interactions, novel relationships between microglia and vasculature relevant for brain function in pathology can potentially be revealed.

Abstract Name: Composing "The Little Leaf": Expanding my Compositional Style

In February 2024, I set my original poem "The Little Leaf" as a Classical art song for a Theory IV post-tonal composition project. I saw this project as an opportunity to broaden my compositional style by incorporating Impressionistic style characteristics. The song's form was determined by the poetic form: three stanzas with subtle changes in word choice to reflect the season and the viewpoint of the protagonist (the "little leaf"). Like Lili Boulanger's *Clairières dans le ciel* song cycle, which features a reharmonization of the main melody in each section, each stanza of "The Little Leaf" comprises a single musical phrase with piano introductions and transitions that reflect each seasonal change. While the melody and rhythm of each verse are retained, each section modulates to a new key, mode, and time signature to reflect each season. For example, stanzas one and two maintain eight eighth notes in each measure; however, when the leaves fall off the trees in the winter, stanza three loses three eighth notes per measure, and the meter changes to 5/8. I designed my accompaniment to feature motion used in Impressionism, such as planing and parallel voice-leading. Additional references to Impressionism occurred in stanza two, which uses only added-note chords, and stanza three, which uses only extended tertian chords. Writing "The Little Leaf" challenged my identity as a composer, and expanded my range of compositional tools. Performing "The Little Leaf" challenged me vocally because I performed in a difficult area of my vocal range and sang more difficult modes. Ultimately, I had my compositional debut in October 2024, when I premiered "The Little Leaf" at my solo recital. "The Little Leaf" Score: https://drive.google.com/file/d/1vz9_vTTxIapNJMy3cLP3UGZhCXB89xS_/view?usp=sharing "The Little Leaf" Performance: <https://www.youtube.com/watch?v=wTPsKdeXQsQ>

Abstract Name: The Lafayette Greatriarchs: Using History to Strengthen a Community

Inspired by the Martindale-Brightwood neighborhood's Greatriarch Project in Indianapolis, the Lincoln Neighborhood Greatriarch Project includes two students from Purdue University's John Martinson Honors College collaborating with the city of Lafayette, IN to select and interview long-time residents of the Lincoln neighborhood. Short biographies of each Greatriarch will be written to share their stories. The city requested the collection of oral histories to preserve the past of the Lincoln neighborhood, and the constructed, 60-minute interviews will provide the city with qualitative data as part of its redevelopment plan. Inspired by Ruut Veenhoven's text, "The Four Qualities of Life," we aim to incorporate the following identified qualities into this neighborhood: livability, life-ability, utility of life, and appreciation of life. Our goal is to better understand what once made residents happy to live in the Lincoln neighborhood to help the city improve the "livability of the environment" as well as explore residents' "appreciation of life" (their perceived quality of their past and current lives in Lafayette). Veenhoven suggests that variety and experiences can enrich someone's appreciation, so we are beginning our artistic component of the Greatriarch Project; we have commissioned a local artist to collaborate with community members in the creation of murals of the Greatriarchs. This spring, we will work with her to host workshops for resident involvement in the design and painting process. We hope that engagement opportunities will improve residents' perceived happiness within their communities. The murals will also beautify the neighborhood, improving its reputation and potentially attracting permanent residents—another aspect of the city's redevelopment plan. Our research question is: Through participatory research, can we identify what motivated certain residents to move to and stay in the Lincoln neighborhood, and can we apply this knowledge to improve quality of life and increase resident permanency?

Abstract Name: J-Pop Going Global: The Impact of Fandom and Popular Music on Japan's Globalization Efforts

This research highlights the differences between Japanese pop music from American pop music and examines Japan through the lens of their most popular music genres in the context of globalization. This in-person research conducted in Japan analyzes the impact of The United States and Japan's relationship on the music industry. Examining the growth of J-Pop and J-Rock on a global scale highlights the exchange of musical influences between America and Japan since the rise of J-Pop in the 1960s. Included in this research is also a comparison between the fan culture of Japanese pop music fans and non-Japanese pop music fans. J-Pop's uniqueness can be attributed to the Japanese music industry's emphasis on appealing to a domestic audience instead of reaching out overseas. The central question of this research are how Japanese and American fandoms differ, what these differences reveal about cultural exchange, and how Japan's relationship with the U.S. has affected this exchange. Fan communities and data from album and concert sales of J-Pop and J-Rock artists were analyzed in order to evaluate the reception of these genres in domestic and foreign markets. This research considered the context of the historical relationship between Japan and the United States before and during the development of these genres. This study provides new insight into Japan's global cultural identity by showcasing globalization in Japan through the lens of the Japanese music industry. Japan's history with the U.S. sheds a new perspective on the pop culture breakout of Japanese media and the growing collaborative relationship with the United States. From using weapons of war to culturally influencing one another, this research lends insight to the changing relationship between these two countries.

Abstract Name: Spatiotemporal Analysis of Vegetation and Water Dynamics in Libya's Extreme Flood Event 2023 Using Remote Sensing and Google Earth Engine (GEE)

Satellite remote sensing (RS) observes the Earth's atmosphere and surface regularly, provides consistent, long-term measurements with vast spatial coverage, and plays a key role in monitoring extreme weather events, especially over regions where ground truth data may be unavailable. The September 2023 flooding in Libya was estimated as a 1 in 300 occurrence where the in-land city of Al Bayda recorded the highest 24-hour rainfall rate in the region's history, and the failure of two dams along the Wadi Derna river released 7.9 billion gallons of water into the coastal city of Derna. Current studies have reported the social conditions of the community, yet few mentioned the environmental impacts of the disaster. Regional disputes have made it difficult for scientists to collect in-situ data. This case study uses spatiotemporal analysis to examine changes in vegetation and water in Libya's cities, Al Bayda and Derna, from August to November 2023 and across an 11-year September time series to understand the flood's impact on the Libyan environment. The study focuses on three climate indices: the Normalized Difference Vegetation Index (NDVI) and two Normalized Difference Water Indices (NDWI), identified using Google Earth Engine (GEE) cloud computing platform. Data were collected from the Landsat-8 satellite provided by NASA and the USGS through the GEE data catalog. Results revealed that Gao's NDWI was more effective in detecting water presence as compared to McFeeters' and accurately reflected high values in Derna at the time of the flood. A positive correlation between NDVI and Gao's NDWI anomalies in both cities' September time series indicated parallel increases in biomass and plant-water content. Vegetation recovery was quicker in Al Bayda than Derna. For regions where in-situ approaches and ground truth data are unavailable, the study suggests RS technology is invaluable to monitoring coastal floods and assessing their post-disaster impacts.

Abstract Name: The Role of PCM in Gene Expression and Stress Survival in Escherichia coli During Stationary Phase

Protein damage, particularly isoaspartyl modifications, can impair cellular function and contribute to aging and diseases. In Escherichia coli, the enzyme L-isoaspartyl protein carboxyl methyltransferase (PCM) repairs isoaspartyl damage, preserving protein integrity during stress. In this study, we used RNA sequencing to identify genes that might be up- or down-regulated in the absence of PCM, potentially revealing its importance in protein maintenance and stress survival. We focused on *ibpA*, a heat shock protein, and *ybcN*, involved in DNA mismatch repair, hypothesizing that deleting these genes would impair stress survival in Δpcm mutants. Gene expression was quantified by qPCR at the onset of stationary phase and after two days

in long-term stationary phase. The *ibpA* gene was significantly under-expressed in Δ pcm mutants, while *ybcN* was over-expressed, contrary to initial expectations. Survival assays showed a Δ ibpA Δ pcm double mutant successfully rescued survival of a Δ pcm mutant under heat shock and oxidative stress. Although *ybcN* was upregulated in Δ pcm mutants, it did not significantly influence survival under UV stress. Because IbpA helps mitigate protein aggregation, disaggregating toxic damage proteins may reduce survival of PCM-deficient cells. YbcN might compensate for other stress-related damage but is not essential for survival under UV stress. Our results show the complex relationships between PCM, IbpA, and YbcN, revealing how their interactions contribute to stress survival and the maintenance of protein integrity in *E. coli*.

Abstract Name: Herbert Bayer: A Gifted Designer with a Complex Legacy

Herbert Bayer is an icon in design, who is known for his contributions to typography, graphic design, and exhibition design. He employed a unique method of blending simplicity and clarity to enhance design. This approach was evident in his typography. His approach deeply influenced American design. Despite his achievements, Bayer's legacy is convoluted by personal and moral controversies. In his early career, he accepted commissions from Nazi Germany. In addition to that controversy, he was a serial womanizer. While his design achievements are distinguished, some of his past decisions deter some of Bayer's legacy.

Abstract Name: In Silico Design of Novel Acetylcholinesterase Inhibitors as Potential Therapeutics for Alzheimer's Disease

AChE (Acetylcholinesterase) is a heterodimer protein that terminates neurotransmission at the cholinergic synapse by hydrolyzing acetylcholine into acetic acid and choline. Because AChE's activity is found to be elevated in Alzheimer's patients, drugs used in Alzheimer's treatments, such as donepezil, rivastigmine, and tacrine, primarily target AChE. However, the demand for new drugs to be developed persists due to drawbacks in existing drugs that reduce their bioavailability. In this paper, we designed novel, non-toxic, competitive inhibitors targeting AChE via computational techniques such as molecular docking on UCSF Chimera, chemical analysis using the RDKit Python package, molecular modification using Avogadro, and

molecular dynamics (MD) simulation via GROMACS. We screened a library of 947 drugs to 5 of the most promising lead compounds based on docking score as a measure of thermodynamic favorability and inhibitory strength, drug-likeness based on Lipinski's Rule of Five, and pharmacokinetic tests through the pkCSM web server. We identified a positive correlation between hydrophobicity and ligand binding affinity. Since AChE's binding site contains active residues that possess aromatic side chains, we hypothesized that adding aromatic R-groups to ligands would lead to more hydrophobic interactions, thereby increasing the thermodynamic favorability of protein-ligand binding and, hence, AChE inhibition. In addition, drugs that yield high binding affinity were found to possess high molecular weights, logP, and molar refractivity, indicating the favorability of hydrophobic interactions in the AChE binding site. Moreover, we identified drugs that were predicted to have a low oral rate chronic toxicity (LOAEL), high blood-brain barrier permeability, and high intestinal absorption to potentially be validated further through ADMET (absorption, distribution, metabolism, excretion, and toxicity) tests in vivo. Herein, we present a novel in-silico study developing new AChE inhibitors that exhibit promising bioavailable, non-toxic characteristics to be further tested through in-vivo experiments.

Abstract Name: Exploring the Impact of a Housing Navigator on Healthcare Utilization and Cost.

The purpose of this project was to evaluate the impact of a navigator program for patients receiving healthcare services identified with significant social needs. The team aimed to evaluate the impact of healthcare utilization and associated costs over a three-year period exploring the impact across different utilizer groups (i.e., low, medium and high). The intervention involved pairing patients with a navigator after being referred to a housing support organization. The study, conducted from 2019-2022, assisted 372 patients with navigation services, including 92 who received additional financial support (i.e., bus tickets, rent assistance, housing placement, etc.). This analysis examined the impact of utilization, costs, and potential return on investment. Addressing social determinants of health, such as housing insecurity, is pivotal to healthcare outcomes and costs. A cleaned and matched dataset from the housing support organization and an electronic health record was used to complete a retrospective data analysis. Categories that were broken down to review included patient demographics, referral dates, diagnosis, codes, total charges, and pre-, during-, and post-intervention totals. Based on the provided data, significant cost reductions in Years 1 and 3 yielded a return on investment of over 18 times the initial investment of the navigator and financial services. Year 2 showed less favorable outcomes, particularly among high utilizers. Challenges identified during this process included inefficient referral processes, data gaps, and high costs associated with specific chronic conditions. This proposed poster will summarize the outcomes and data collected throughout the program. The findings emphasize the impact of the navigator program across a various set of utilizer groups and highlighted the need for process advancements and earlier intervention, specifically for at-risk patients, to boost cost reduction and patient outcomes. These recommendations will have a long-term impact on the program's efficiency and sustainability.

Abstract Name: Tilting Tiles A Stewart Platform Array

Tilting Tiles, a research project focused on developing a kinetic art sculpture that merges modern manufacturing techniques with electronics design, consists of a series of interconnected triangular modules. Each module, a reduced range of motion Stewart platform, is capable of tilting in two axes and translating horizontally. These platforms, mounted to a wall, collectively form an interactive dynamic surface that displays preprogrammed animations or alternatively responds in real-time to inputs from sensors, cameras, or web-based systems. The development of Tilting Tiles explores urethane casting and injection molding processes to ensure durable, scalable plastic components. Early prototypes use 3D printing for rapid iteration, while the final version relies on production-grade casting. Each module features custom electronics, including multiple printed circuit boards for power management and microcontroller functionality. The main control unit orchestrates animations through the modules wirelessly. The system is scalable, allowing for installations ranging from twenty-four to several hundred units, making it suitable for large-scale interactive displays in spaces like science museums, offices, or other institutional settings. Throughout the research, I explore challenges in efficient C algorithm development, inverse kinematics for Stewart platforms, wireless communication protocols, and reducing noise of multiple asynchronous pulse-width modulation signals. Additionally, the project involves designing assembly jigs for rapid, large-scale production. The result, a versatile and visually compelling kinetic art installation, integrates cutting-edge electronics with refined manufacturing techniques. Tilting Tiles, a comprehensive investigation into the intersection of art, engineering, and technology, contributes new methodologies for kinetic sculptures and interactive installations. Abstract Name: Mosque Mamluk Lamps and The Adoration of the Magi: A Symbol of Cross-Cultural Exchange Between The Mamluk Empire and Italy

This paper is a comparative analysis of a Mosque Mamluk Lamp and the painting The Adoration of the Magi. By doing a comparative analysis instead of a study on a single artwork one can get a broader cultural context and understanding of the both artworks. In researching two pieces of art from different cultures but the same time period, I will demonstrate a cross-cultural exchange that took place between Islam culture and Christian Europe, often underestimated by scholars. First, there is an introduction to Mosque Mamluk Lamps and the painting The Adoration of the Magi. Second a brief cultural overview on how Italy and the Mamluk Empire interacted is provided. Third, there is a formal analysis of The Mosque Lamp, followed by a historical analysis. Fourth, there is a formal analysis on The Adoration of the Magi, and a historical analysis of cross-cultural interaction between the Mamluks and Italians as demonstrated in a Mosque Lamp depicted in an Italian painting. Fifth, the paper will conclude with an analysis of the cultural appropriation utilized by Mantegna. This paper creates a more well rounded view of art in the 1400's and European Renaissance.

Abstract Name: Understanding Multiple Sclerosis (MS): Exploring the Etiology and Progressive Impacts of an Unpredictable Autoimmune Disease

Multiple sclerosis (MS) is an immune-inflammatory disease that attacks the central nervous system (CNS) and causes intensive neurological impairment. This autoimmune disease mistakenly attacks healthy tissue, causing disruption between the brain and the body. According to the National Multiple Sclerosis Society, there are almost 3 million people with MS worldwide, with nearly 1 million residing inside the United States, making it the most prevalent neurological disability. MS is labeled as one of the most unpredictable diseases as it can not be passed from person to person and the pathophysiology is not fully understood. As technological and diagnostic breakthroughs occur, treatment has started on average at an earlier stage than it did in previous decades due to earlier discovery. Earlier detection of multiple sclerosis can be crucial to an individual's mental and physical outcomes, as most people diagnosed start with a relapsing-remitting type of MS before eventually falling into a progressive condition with symptoms gradually worsening over time. I have seen firsthand what this condition can do to an individual, with my mother being diagnosed with multiple sclerosis in 1996 and have witnessed the progressive impacts it has had on her from a physical and mental standpoint. This paper aims to explain the etiology and epidemiology behind MS and share the risk factors and progressive impacts of MS on the brain and the body, with an ultimate goal of educating individuals and bringing light to the number one disabling disease of young adults.

Abstract Name: Preventing Acute Malnutrition: The Role of Energy Expenditure and Postnatal Nutrition Among Infants

Although malnutrition among children under the age of three has decreased over the last few decades, the decline has started to plateau, leading to the fear that malnutrition goals set by the World Health Organization will not be reached by the end of the decade. There are various reasons behind this plateau including the global increase in food insecurity and other economic, environmental, and social factors. While parent and caregiver education has started to address the issue of infant malnutrition, there is still additional education and assistance necessary to lower rates of overall infant malnutrition. An infant's nutritional outlook can be impacted as early as the prenatal months, with the mother's nutritional intake during pregnancy having a considerable impact on both positive and negative outcomes related to fetal health. Adequate nutrition in the first twelve months is vital as infants see their most significant growth and weight gain occur in the first year postnatal, as they can triple their body weight and grow almost a foot in that time period. Although there are multiple recommended guidelines pertaining to postnatal nutrition, specific socioeconomic and cultural impacts can lead to adjusted or altered diet patterns, making it more challenging to meet requirements, especially in low-income neighborhoods that show high prevalence of malnutrition. Common complications caused by malnutrition can include weak immune systems and impaired cognitive development, among others. This paper aims to learn how energy expenditure influences nutritional outcomes, review the dietary needs of infants in the first twelve months postnatal, and examine the impacts of primary and secondary acute

malnutrition with an ultimate goal to increase awareness and implement assisted nutrition programs in low-income communities.

Abstract Name: The study of quenching of perylene by explosives to determine rate and binding constants for collisional and static quenching.

Analysis of crime scene samples associated with explosives are backlogged at crime laboratories. On-site sample analysis might provide investigators with early leads in such cases. To be practical, however, analyses must be done using non-hazardous solvents; most published studies involve hazardous solvents, such as acetonitrile or dichloromethane, which are not safe to use outside of a laboratory. Our studies focus on luminescence quenching by explosives in aqueous buffers and ethanolic solutions. Quenching basically relates to how much luminescent light is snuffed out/blocked by explosives in otherwise transparent solutions. One challenge encountered in the development of this method is that, in studies thus far, the quenching relationship is often observed to be nonlinear. The hypothesized source of this nonlinear behavior is the occurrence of both static and dynamic quenching, which occur at different quencher concentration ranges. In other words, the molecules responsible for quenching both bind directly to the luminescing molecules (static quenching) and also cause quenching by colliding dynamically with the luminesces (dynamic quenching). Both of these processes likely happen simultaneously, but typically dynamic quenching plays a greater part at low concentrations and static quenching assumes greater predominance at higher concentration. We will report on our work to determine the concentration ranges of static and dynamic quenching, as well as the transition range in between, using a combination of fluorescence quenching and time-correlated single photon counting (TCSPC). TCSPC allows us to extrapolate the decay time (τ , t_0), with which we can separate contributions by dynamic and static quenching. The quenching behavior of di- and tri-nitrophenol (TNP and DNP) and dinitrotoluene (DNT) as a model compound, as well as TNT and PETN as real explosives, on the perylene (PER) have been studied in this manner. From the Stern-Volmer and τ plots we determined the relative contribution of both quenching modes.

Abstract Name: Price at the Pump: Comparing Gasoline Costs in the U.S. and Germany

This study examines the applicability of the Law of One Price (LOOP) to gasoline prices in the United States and Germany from 2015 to the present. The LOOP suggests that, in an efficient market without trade barriers, identical goods will converge to the same price across countries when adjusted for exchange rates. By

analyzing gasoline, a globally traded and essential commodity, this research explores whether the LOOP holds true in real-world energy markets. Gasoline prices in major economies like the U.S. and Germany influence energy policy, consumer costs, and global trade. Previous studies show that LOOP is not always consistent, with short-term deviations arising from factors like transportation costs, exchange rate fluctuations, and local market conditions. Using monthly gasoline price data from the International Energy Agency (IEA) and exchange rate data from the Federal Reserve Economic Data (FRED), I will compare gasoline prices in the two countries to test the LOOP, using the following formula: $q_{US/Germany} = (E\$/Euro * P_{Germany}) / P_{US}$. I will plot the value of q with respect to time and analyze its deviation from $q=1$ as suggested by the LOOP. In addition to examining if the LOOP holds between the U.S. and Germany, my results will shed light on the relative strength of the U.S. dollar and Germany's currency, euro. I hypothesize that gasoline prices between the U.S. and Germany will show short-term deviations from the LOOP condition due to factors such as, different types of trade barriers, and supply chain disruptions. However, in the long run, I expect price gaps to close due to market forces and arbitrage opportunities.

Abstract Name: Distinct glial functions are associated with Alzheimer's disease based on cell type- and pathway-specific polygenic risk score analysis

Background: Alzheimer's disease (AD) is a complex neurodegenerative disorder characterized by progressive cognitive decline and extensive brain pathology, including amyloid plaques, neurofibrillary tangles, and neuroinflammation. While much research has focused on neuronal dysfunction in AD, emerging evidence suggests that glial cells—astrocytes, microglia, and oligodendrocytes—play crucial roles in the disease's pathogenesis. This study aims to identify any glial cell type-specific pathways associated with AD. Methods: We first investigated the correlation between AD and the genetic risk of glia-specific pathways using pathway-based polygenic risk score (PRS) with PRSet software in the discovery data (ADc1234ADA) adjusted by the top two principal components (PC1, PC2) (Model 1), followed by additional adjustment with sex, age, and APOE ε4 count in Model 2. Further PRSet analyses were replicated in independent data (ADNI) if a nominal association ($p < 0.05$) was found in the discovery data. Tentative associations were determined via meta-analyses of both discovery and replication datasets with Bonferroni correction. Finally, a competitive p-value test was used to determine the significance of each pathway within each glial cell type. Results: In model 1, we identified six pathways significantly associated with astrocytes with the immune system on the top, six pathways associated with microglia with antigen processing on the top, and five pathways associated with oligodendrocytes with transport & trafficking on the top. In model 2, five pathways in astrocytes and four pathways in oligodendrocytes were found to be significant. However, none of the pathways in microglia remained significant. Conclusion: Our findings demonstrate a glia-specific polygenic contribution to AD risk, especially in the immune system, highlighting the significance of PRSet analysis in uncovering cell-type specific and pathway-specific biological mechanisms for diseases.

Abstract Name: Binding and Mobility of Bioactive Peptides on Peptide Amphiphile Nanofibers Measured by Nuclear Magnetic Resonance Spectroscopy

Inhibition of specific receptors by membrane-permeable peptides has been shown to be effective at promoting axonal growth in animal models of spinal cord injury. The Stupp Laboratory has recently developed a supramolecular system in which bioactive peptides bind electrostatically to the surface of supramolecular peptide amphiphile (PA) nanofibers. This strategy is particularly attractive because the binding of peptides to PA nanofibers may prolong the lifetime of these molecules and enable fine-tuning of supramolecular motion, which has been shown by the lab to increase the bioactivity of some signals. Current insights indicate degrees of peptide mobility on nanofibers correlates with measured bioactivity in vitro. P-PA supramolecular interactions likely determine the regenerative potential of the system, yet these interactions are poorly understood. We hypothesize that enhanced association of peptide to nanofibers correlate with enhanced neuroregenerative potential. To test this hypothesis, we investigate here the binding and translational motion of four different peptides associated with supramolecular PA nanofibers using multiphase and multinuclear nuclear magnetic resonance (NMR) spectroscopy. Solution-phase ¹H NMR of all four peptides revealed sharp peaks consistent with high molecular mobility. In contrast, spectra of the peptides mixed with the PA nanofibers showed a significant loss of peptide signal, indicating severely decreased peptide motion. We then turned to high-resolution magic-angle spinning (MAS) NMR to study the peptides in this semi-solid phase, where we anticipate visibility of solution-NMR-invisible peptide signals. This would yield data on naturally occurring ¹H spins and ¹³C cross-polarization NMR for solid-phase analysis. We anticipate these techniques will enable the investigation of supramolecular motion and interactions. Linking the structure and mobility of peptides on nanofibers with their bioactivity in vitro will aid in future design of enhanced regenerative medicine. Understanding the structure-dynamics-function relationships in these systems will help guide the design of supramolecular assemblies with enhanced bioactivity.

Abstract Name: InterSEXionality: Analyzing Media Perpetuation of Feminine Stereotypes in Romantic Comedies Among Women of Color

The genre of romantic comedy films is a rare occasion where women shine and dominate in the media, but there is a glaring discrepancy in the representation of women of color. Intersectionality of gender and race grows increasingly crucial to the female identity, yet the film industry struggles to accurately depict these concepts and create substantial films without having proper representation or falling back on classic stereotypes. This thesis seeks to answer the question: How does film portrayal of the feminine character in the romantic comedy genre contribute to contemporary understandings of female sexuality and racial identity? Current research contains a broad coverage on varying gender and racial stereotypes observed in movies. There are plenty of studies conducted on women in the romance genre, and women of color in the general film industry. A huge gap lies in a lack of how these concepts are so inescapably related and their

corresponding ties in romance. Female sexuality and racial identity cannot be discussed without acknowledging the other - something that both the film industry and current research do not adequately examine. This thesis begins to bridge this gap by honing in on primary data from 100 major romantic comedy films, spanning a century since the genre's induction in 1934. Films were curated based on factors including: mainstream popularity, diversity, and relevance. Further data provides analysis on demographics, statistics on audience perception, and qualitative information on plot patterns. Preliminary data review supports a significant divide between the representation of white women and women of color. Observed differences in actress typecasting, character arcs, and common relationship trends contribute to realized effects in awards won and box office statistics. Ultimately, this thesis strives to synthesize existing research and modern data to reveal the importance of feminine intersectionality and representation in romance and film.

Abstract Name: Beyond Wages: Investigating Occupational Segregation and Labor Market Discrimination

Researching the fundamentals of discrimination in the job market helps us better understand injustices in the workplace. We build on Foote, Whatley, and Wright's (2003) work, which highlighted Ford Motor Company's exploitation of labor market inequality by concentrating black workers in unpleasant foundry jobs in the 1920s-1940s. This indicated that wage alone is not a conclusive indicator of labor market discrimination. We expand this analysis to a broader set of jobs across three firms. Our study measures occupational segregation using Stata to examine archived employee records from Ford, A.M. Byers, and Pullman, classifying workers by occupation and measuring the degree of segregation.

Abstract Name: Investigating SETD1A as a Suppressor of Genome Instability in Triple-Negative Breast Cancer

Triple negative Breast cancer (TNBC) is an aggressive form of women cancer. It is one of the leading causes of cancer deaths among women. The hallmark of breast cancer cells is replication stress mediated genome instability. Consequently, they develop compensatory mechanisms through which they alleviate the level of genome instability necessary for their continued existence. The main predictors of death include late-stage diagnosis and the development of drug resistance. Therefore, there is an immediate need to find new treatments for ovarian cancer. Our preliminary data shows the upregulation of SETD1A protein in TNBC. In healthy cells, we found SETD1A maintains genome stability and acts together with BRCA1 to suppress

TNBC biomarker – “tandem duplications” (TDs) which is specific to stalled replication fork. Therefore, we hypothesize that in TNBC, SED1A protein has compensatory role to reduce genome instability and maintain their viability. In this proposal, our objectives are to determine the compensatory mechanism facilitated by SED1A in TNBC and investigate the role and underlying mechanism of SetD1A mediated epigenetic alterations in generating TNBC biomarker TDs at the stalled forks. We will also determine how SETD1A-mediated epigenetic modifications affect the patterns of TDs hotspots and influence drug sensitivity in TNBC. For this aim, we will conduct a thorough analysis of TDs by initially reducing the levels of SETD1A in cells derived from BRCA1 mutant TNBC patient derived xenografts (PDX), and then isolating genomic DNA from single-cell suspensions followed by whole genome sequencing. Given our observation that SetD1A promote homologous recombination (HR) at stalled forks, we will investigate SETD1A in vivo response to treatment with PARP inhibitor. Overall goal is to identify SETD1A as a new biomarker for BRCA1-mutant breast cancer, with the goal of developing targeted therapeutic interventions.

Abstract Name: Association Between Polygenic Scores for Brain Structures and Alzheimer's Disease

Alzheimer's disease (AD) is a progressive neurodegenerative condition and the most common type of dementia. Research has shown that volumetric changes in subcortical brain structures, which make up roughly 25% of the brain's total volume affect many physiological functions. This research project aims to investigate the genetic association between brain structures and AD. GWAS data of eight different brain structures (ICV, accumbens, amygdala, caudate, hippocampus, pallidum, putamen, and thalamus) were used to create polygenic scores (PGSs) in a discovery (cases/controls = 2,651/2,768) and replication dataset (cases/controls = 553/644). We utilized PRSice-2 software to generate PGSs and assess genetic correlations using two models: Model 1 adjusted for principal components (PC1 and PC2), and Model 2 adjusted with additional covariates, including sex, age, and APOE e4 allele count. Meta-analyses were conducted for discovery and replication samples with Bonferroni corrected p-value < 0.05 being significant. Further, we conducted Mendelian Randomization (MR) analyses between the brain structures and AD. As a result, we found that the PGSs of three brain structures—amygdala, hippocampus, and pallidum—were significantly associated ($p < 0.0133$) with AD, implying that a higher volume of these structures is less likely to have AD. However, the association did not remain significant for the hippocampus after being adjusted for additional covariates, suggesting that the association between the hippocampus and AD may depend on sex, age, or APOE e4 allele count. In addition, MR analysis indicated a smaller hippocampal volume had a causal effect on AD. Overall, our study suggests there is a strong correlation and possible causal effect between AD and brain structures, especially hippocampus, underscoring the critical role of the hippocampus in the development of AD.

Abstract Name: Using Visuals to Combat Language Barriers in Mental Health Care: Drawing on Information Graphics and Graphic Medicine to Support Mental Health of Patients with Limited English Proficiency

Though the United States of America has the largest immigrant population globally, language barriers remain a critical issue in the medical field. Interpreters are often not professionally trained for medical jargon or readily available in medical facilities, especially for languages not as commonly used, and patients often have difficulty asking additional questions to understand the providers fully. As a result, the language gap leads to worse clinical outcomes for this vulnerable population, particularly with behavioral health services, which immigrants and refugees often seek due to inevitable trauma and stress. However, language and cultural barriers in the mental health care field cause care and treatments to be challenging. For example, providers must communicate with sensitivity while patients must understand and remember their conditions and treatments for effective care. Sensitive communication in this case refers to using careful, deliberate, and nuanced words to suit the needs and thought processes of the listener for the primary goal of effective patient care. Therefore, this study advocates for the use of graphics—drawing from information graphics and graphic medicine—as an effective knowledge translation (KT) tool to address these challenges. Specifically, the visual aids proposed are images with minimal text to bridge the gap in understanding and conveying medical language and information between providers and patients. The primary goal of this study is to demonstrate strong evidence to support using graphics to improve mental health outcomes for people with limited English proficiency (LEP).

Abstract Name: Algorithm Performance Comparison on Housing Data

This project focuses on the comparative performance evaluation of various machine learning algorithms applied to housing data. Utilizing a dataset from Kaggle consisting of 1,460 entries with 80 features, both numerical and categorical, the study aims to model housing prices effectively through regression analysis. The workflow includes data preprocessing, such as imputing missing values, encoding categorical variables, and implementing Principal Component Analysis (PCA) to standardize the data. Algorithms evaluated include Ordinary Least Squares (OLS), XGBoost, and Decision Tree regressors. Key performance metrics—Mean Absolute Percentage Error (MAPE), R-Squared, and Accuracy Score (with a threshold of 0.2)—are used to assess model efficacy. The project offers insights through variable importance plots, highlighting the most influential features for predictions and guiding improvements in housing price estimations. The results underscore the interplay between data preprocessing and algorithm selection in achieving robust and interpretable regression models.

Abstract Name: Analyzing Choice Overload Behaviors in AI-Generated Recommendations

This paper presents an analysis of how generative AI, specifically ChatGPT, influences user experiences in decision-making contexts prone to choice overload. It investigates the effects of varying recommendation set sizes (10, 30, and 60 options) on user satisfaction and decision satisfaction across two scenarios: travel recommendations and fundraising advice. Using survey data from a sample of 19 U.S. adults, the study reveals a preference for selecting options from the initial portion of recommendation lists, especially in larger sets. Results indicate that while users may experience choice overload with high option counts, their satisfaction and likelihood of action are paradoxically higher when presented with more recommendations in complex decisions. This research contributes to understanding AI-driven choice overload and suggests strategies to enhance user experience by balancing recommendation set sizes based on decision complexity.

Abstract Name: Nitrates in Oklahoma Well Water

Nitrate is a naturally occurring colorless, odorless chemical usually safe at low levels. However, levels exceeding 10 mg/L can lead to irreversible health effects due to nitrate's ability to block oxygen in the blood. Our research samples wells across Oklahoma to understand where nitrate concentrations are the highest and the causes of those concentrations. Our team collected water across Oklahoma and at events such as county fairs, Oklahoma residents brought bottles of their well water which we tested using a Hanna Nitrate Photometer. Our team used a 10 mL sample of their water to get a base clarity of the water and added a reagent that reacted with nitrate to change the color of the water, with darker samples corresponding to higher concentrations of nitrates. The photometer gave us a reading in mg/L of nitrate which we reported to the residents. We then compiled a map using Arc GIS and R-script to see where nitrates are the highest and compared our map to a different map created using historical USGS nitrate concentration data. Both maps showed that western Oklahoma had higher average nitrate concentrations than eastern Oklahoma. Abnormally high concentrations (>700 mg/L) were examined and all were next to an animal facility such as a pig farm or a cattle ranch. This could be because animal waste carries high concentrations of nitrates. Because western Oklahoma has less rainfall annually, we hypothesize that the region has a larger nitrate concentration because there is less water to dilute concentrations. Our research provided Oklahomans with knowledge of what is in their water through free water testing and showed factors that cause high nitrate concentrations. This research will be used to develop a comprehensive model of Oklahoma's nitrates so that residents are best protected if they are in a high-risk area.

Abstract Name: The Medical Interpreter's Dilemma: Patient Advocacy and Professional Boundaries

This study investigates the role of patient advocacy in medical interpretation, addressing two key questions: (1) What actions by the medical interpreters constitute patient advocacy? (2) Should advocacy be included in their scope of practice? There is ongoing controversy over whether advocacy aligns with the professional scope of medical interpreters. Some ethical codes and healthcare institutions encourage interpreters to advocate for patients, while others explicitly prohibit advocacy to preserve objectivity and professionalism. Current research on this topic, conducted through interviews and surveys with medical interpreters, healthcare professionals, and professional interpreter associations, conclude that no clear consensus exists regarding the definition of advocacy and whether it should be a core function of medical interpreters. This research seeks to define advocacy by analyzing linguistic patterns and practical applications of advocacy in medical interpreting. Research methods include (a) a linguistic analysis of 20 codes of publicly available medical interpreter ethics, protocols, and standards of practice; (b) thematic analysis of 33 medical interpreting case studies drawn from an academic interprofessional clinic; and (c) meta-analysis of 15 interview excerpts regarding advocacy in medical interpreting. Findings reveal that 27% of official documents promote advocacy, 40% prohibit it, and 33% remain neutral. Words frequently associated with pro-advocacy documents include "cultural broker," "access," and "health literacy," while those in anti-advocacy documents include "impartial," "transparency," and "conduit." Case studies partly defined advocacy as ensuring health literacy, speaking up against cultural biases, and comforting patients. Collectively, these findings indicate that there are many variations in how advocacy is defined, as well as a need for a standardized definition of advocacy to determine whether advocacy should be included or excluded within a medical interpreter's scope. This research is valuable for establishing a clear and actionable definition of patient advocacy in medical interpreting, ultimately improving equity and professionalism in healthcare communication.

Abstract Name: Impact and legacy of minstrel music on the United States

The American Minstrel show was a spectacle of American culture, reaching its height from 1848 to the late 19th century, in which it popularized African-American spirituals and other songs. The form itself was disparaging to the African-American community, using racist actions such as black face, aristocratic speech, ragged clothes, and dances to create the image of a “Happy Ducky.” Acknowledging the art forms racist connotations and intentions, it did ultimately promote African-American culture to the national stage. It brought the spirituals of African-Americans to concerts which only white people could attend, and in many instances allowed them to perform in front of white audiences for the first times in American history. However it also reinforced racial stereotypes, abetted segregation and other discriminatory laws such as Jim Crow. Through this presentation I will explore the minstrel show, spanning from the 1830s to the early 1900s, and the cultural and political impacts it left on the United State

Abstract Name: Effective use of spray cooling in high-heat flux electronics

The purpose of this research is to explore the feasibility of microdroplet spray as a cooling method for electronic components in data centers. Conventional cooling methods in data centers, such as air or liquid cooling, may not be as effective as directly spraying components with microscopic amounts of liquid. Spray cooling is one of the most effective ways to remove heat; however, the lack of control of the spray rate can cause dry-out or excessive liquid accumulation. These issues occur if the spray rate is too low (causes a dry spot in the middle of the spray cone) or too high (causes a liquid puddle). This project aims to develop a pulsing control for the spray rate to maintain a desired surface temperature while mitigating those issues. Our research group has previously explored the impact of single microdroplets on a heated surface to measure the evaporation rate at different impact conditions and surface temperatures. A heated surface using an aluminum block with inserted type-K thermocouples was designed to measure temperature spatially at different radial and axial locations. A LabJack T7 was used to record all the thermocouple data simultaneously. A low-flow nozzle and a water pump were utilized to spray water on the heated surface. A hot plate was used to heat the aluminum block from the bottom. The evaporation rate data from single microdroplet impact research was used to approximate the pulse width and frequency. The initial surface temperature, nozzle flow rate, pulse width, and frequency were independently varied, while the instantaneous surface temperature was monitored

carefully. It was observed that the pulse width and frequency highly depended on the initial surface temperature and the nozzle flow rate. Higher flow rates at lower temperatures required a small width at a low frequency.

Abstract Name: Fostering interprofessional collaboration through undergraduate mentored research experiences: Modeling the way

Interprofessional education is a critical component of professional development, fostering collaboration and understanding from various healthcare disciplines. However, opportunities for students to engage in interprofessional development are often limited due to various challenges, such as compacted curricula required for their degrees and different clinical training schedules. This session will discuss the potential of undergraduate mentored research as a unique and sustained opportunity for interprofessional education. This collaborative project originated from a meeting between two faculty members at a national rehabilitation conference, where they discovered a shared interest in dyad intervention post-stroke. This initial connection led to the development of a collaborative research project within the Occupational Therapy (OT) program, which was later expanded to include Music Therapy (MT) students. The collaboration provided a structured framework for undergraduate students from both disciplines to engage in joint research activities. Throughout the project, students have the opportunity to work closely with peers from different professional backgrounds, enhancing their understanding of interprofessional role and responsibilities. They have participated in various research activities, including establishing survey tools, understanding the needs and potential challenges during recruitment, practicing recruitment scripts, and will gain future experience collecting data. These hands-on experiences allowed students to develop not only research-related skills but also essential professional competencies such as communication and teamwork. This collaborative project highlights the value of undergraduate research in fostering interprofessional education. This experience underscored the how undergraduate mentored research offers a valuable platform for interprofessional education, providing students with extended opportunities to collaborate, learn, and grow professionally. This approach can substantially enhance the traditional research experience, fostering the professional development of more competent and collaborative healthcare professionals.

Abstract Name: The Evolution of Evil: An Overview of Serial Killer's Classification, Motivations, and Hope for Recovery

The Federal Bureau of Investigation characterizes “serial killers” as offenders who have murdered two or more victims in separate events, with some cooling off time in between, accompanied by a specific intent to terrorize, intimidate, or injure. Dr. Burgess’s pioneering collaboration with the FBI in the 1970’s revealed a systematic approach to serial killing in which criminal profiles included offenders’ childhood experiences, their similar and atypical patterns of behaviors, and their dysfunctional longing for connection. While Dr. Burgess’s work revealed two primary types of serial killers (organized and disorganized), the transformation of offenders’ modus operandi in recent years exposed a combined set of maladaptive characteristics that required novel forensic categories, coupled with an understanding of the impacts of technological advancements in manipulating and capturing victims. This comprehensive review of the progression of serial killing throughout the years aims to clarify the evolutionary stages of criminal behavior, provide an explanation for the potential circumstances leading to serial killing, increase awareness about the methods of predation, and highlight the corrective power of community in rehabilitating troubled adolescents with maladaptive behaviors. Keywords: Federal Bureau of Investigation, Serial Killer, Pioneering, Progression, Adolescents, Maladaptive Behaviors.

Abstract Name: Exploring How Previous Harassment Experience, Empathy, and Phylogenetic Relatedness Determine Responses to Emotionally Distressful Situations in Humans

Empathy refers to the ability to vicariously experience a person’s feelings, emotions, and thoughts, in the past or present by solely relying on the empathizer’s imaginative adoption of the target’s emotional state. Empathy does not necessarily motivate helpful action, but often elicits personal distress, which may result in action. Previous studies have supported the idea that empathy and emotional distress derive from components of neurobiology, phylogeny, and vulnerability, but how humans respond to emotionally distressful situations based on previous harassment experiences and empathy levels has yet to be explored fully. Here, we investigate people’s responses to an emotionally distressful situation by manipulating the targeted individual in an assault scenario; namely, different types of animals and people based on genetic relatedness (phylogeny, inclusive fitness). We will assess how participants’ previous harassment experience, levels of empathy, and gender impact levels of distress, among several other variables. Participants read assault scenarios based on different targets and provided past experiences in dealing with visual, physical, or verbal harassment and rated their empathy levels using the Toronto Empathy Scale. Results showed that emotional distress to assault scenarios does change depending on who the victim is and was specifically related to genetic relatedness and the sex of the rater. Those who reported previous harassment experiences also scored higher in levels of empathy. Other results will tell us how empathy and emotional distress vary for individuals demonstrating unpleasant behaviors or adopting different methods of drug ingestion.

Abstract Name: Health Outcomes in Urban vs. Rural Populations: A Planned Analysis Using BRFSS Data

Geographic disparities in health outcomes have significant implications for healthcare planning and policy development. This study seeks to explore differences in the prevalence of hypertension between urban and rural populations using data from the Behavioral Risk Factor Surveillance System (BRFSS). The central research question is: Are there significant differences in hypertension prevalence between urban and rural populations? The planned analysis involves extracting relevant BRFSS data, including variables for geographic classification (urban vs. rural) and health outcomes (e.g., hypertension prevalence). Data will be imported into statistical software for organization and analysis. A Chi-Square Test of Independence will be performed to assess whether hypertension prevalence differs significantly between the two groups. The analysis will report key statistical outputs, including the Chi-Square test statistic, degrees of freedom, and p-value. Expected results include identifying potential disparities in hypertension prevalence between urban and rural populations. These findings will be presented in the context of observed versus expected counts and statistical significance. The results are anticipated to inform discussions on geographic health disparities, with implications for targeted healthcare interventions and resource allocation. This project emphasizes the value of using large-scale public health datasets, such as BRFSS, to identify and address disparities in health outcomes. By investigating these differences, this study aims to contribute to the broader understanding of how geographic factors influence public health and support evidence-based policymaking.

Abstract Name: Sing Into My Mouth: Evaluating the Intersection Between Nature and the Internet

I am an interdisciplinary artist that makes work about the natural world and how the internet has changed our relationship with it. I am interested in the connection between photography and painting, especially the replication of digital technologies through a historic medium. Using painting, collage, photography, and sculptural practices, the work I create is raw, bold, awkward, and grimy. Much of my practice is based on photographs, whether that be imagery found online, AI-generated images, contemporary and historical artwork, or my own photos. My School of Art and Design faculty selected my proposal to have the honor of a solo thesis exhibition in our Student Gallery 209. This project examined how my exposure to the internet changed my relationship with the natural world and how the idea of the image has changed in our current era. My research is based on experimentation, trial and error, and artist research. My experimentation includes combining different mediums and styles along with trying different color palettes and techniques. Some artists I have recently found inspiring have been Nan Goldin, Ally McIntyre, Susan Rothenberg, Phillip Guston, and Rae Klein. I also find inspiration in taxidermy, early internet culture, folk art, and alternative photographic processes. I aim to create work that subverts traditional notions of craft and skill. I focus on intuitive processes and conceptual ideas to drive my practice. This research has allowed me to explore the use of raw materials, learn new techniques image transfers and sculptural work, and expand my concepts greatly. My future work will continue to address animal subjects, the replication of digital technologies, and how the internet has changed how we view the world around us. This large body of work served as my thesis for my BFA and will provide me skills to continue working towards my research goals.

Abstract Name: Increasing Diversity Of Clinical Trial Population via Mobile Clinics

Underrepresentation in clinical trials remains a significant issue, prompting the FDA to urge researchers to implement strategies to raise awareness and provide access to clinical research to diversify clinical trial participation. This summer, at Erie Retina Research (ERR), we launched mobile retina clinics to meet all kinds of communities in our tri-state area to raise awareness of retinal diseases and to detect early signs of disease. The mobile retina clinics were done utilizing a specialized handheld retina imaging device (EYER). We hosted screenings at various community events and health fairs in underrepresented demographics. The images captured during the screenings were reviewed by an ophthalmologist, and participants requiring further evaluation were offered no-cost follow-up visits and enrolled if found eligible for any of our clinical trials. About 180 participants were screened free of charge. Among them, 55.06% were above the poverty line, while 43.84% were below it. Of those below the poverty line, 33.71% were from areas of persistent poverty—a 20% increase compared to previous trials at ERR. Regarding racial diversity, 83.48% of participants were White, and 12.17% were Black or African American. This represents a substantial improvement over earlier ERR trials, where 95% of participants were White and only 1.7% were Black or African American. Additionally, these figures surpass Erie County's racial demographics (87% White and 8% Black or African American). Our results demonstrate that our mobile clinic approach was effective in improving access to clinical research in underrepresented communities. This approach offers a valuable model for addressing disparities in healthcare access and representation in clinical research.

Abstract Name: Beyond Ethnicity: Experiences of Racism and Perceptions of Belonging Among Latina/o/x Students at an HWCU

The Latino population in the United States has grown significantly, contributing to 52% of the nation's population growth in the past decade, according to the Pew Research Center. While research often focuses on the Latino population's ethnicity, it often overlooks the diverse spectrum of racial identities within this community, leading to a homogenized understanding of their experiences. This study challenges this by examining how Latina/o/x students at Hope, categorized as White-identifying (WI), non-White-identifying (NWI), and international students (IS), perceive their racial identity in the context of privilege, racism, colorism, and belonging. Our total sample is 55 students (20 WI, 20 NWI, and 15 IS), but this presentation is based on an initial analysis of 25 coded interviews (10 WI, 10 NWI, and 5 IS). An additional 30 interviews are currently being transcribed and organized. This study aims to shed light on the complexities of racial identity and belonging within the Latino community at Hope College, offering valuable insights for fostering a more inclusive campus environment.

Abstract Name: Assessing Community Garden Activity and Land Precarity in Philadelphia, PA

Urban community gardens offer many environmental and communal benefits, from reducing CO2 levels and the urban heat island effect to promoting public health, connectivity, and food security. The Philadelphia Garden Data Collaborative (PGDC), formed in 2016, partners with local organizations to collect and maintain data on community gardens in Philadelphia. PGDC aims to preserve land and empower growers, particularly in low-income areas facing food insecurity and gentrification. PGDC has created a comprehensive inventory of gardens and land parcels, which is crucial for evaluating urban agriculture's value and preventing adverse sales of garden land. Data collection was last completed in 2019. To maintain this database, a data collection campaign was conducted in the summer of 2024. A group of researchers from Haverford and Villanova universities visited 719 sites previously logged as gardens to survey each site. Utilizing 123 Survey and ArcGIS technology, the study offers a complete census of garden activity, including identifying the garden spatial footprint, garden type, public access, and water access. In addition, each garden was associated with all of the city parcels on which it is located to allow for analysis of garden tax delinquency and land precarity. The results illustrate the abundance and spread of urban community gardens, offering critical insights for tracking land parcel ownership and tax records to prevent foreclosures and preserve these spaces.

Abstract Name: Genetic mapping and phenotypic analysis of the 6E.29 mutation in *Drosophila melanogaster*

Cancer, a collection of diseases characterized by uncontrolled cell proliferation, wreaks havoc on the lives of millions of individuals worldwide. Combating this devastating disease requires an understanding of the intricate genetic control that leads to ordered cell division. To identify genes important for cell growth and proliferation, a forward genetic screen was performed in *Drosophila melanogaster*. Males carrying an FRT site on the right arm of the second chromosome were mutagenized with EMS and mated to females carrying a similar FRT site along with a transgene expressing the FLP recombinase under the control of the eyeless promoter. Homozygous mutant clones were generated in the adult eye and marked by the absence of pigmentation. The 6E.29 mutation, identified in this screen, resulted in overgrowth of mutant tissue

suggesting the normal role of the affected gene is to control cell growth or proliferation. To determine the gene altered by this mutation, deficiency mapping was performed to narrow down the region of interest. This was followed by sequencing of potential candidate genes. To complement this molecular analysis, further characterization of the mutant phenotype was performed in larval tissues. Genetic mapping of additional mutations generated in this forward genetic screen was conducted by numerous undergraduate students at a variety of institutions of higher education as part of “Fly-CURE,” a research coordination network developed to provide undergraduate students with authentic research experiences in the classroom. Initial work on the 6E.29 mutation was performed by undergraduate students in the laboratory component of a developmental biology course at Grove City College.

Abstract Name: Determining the Abundance of α -synuclein in Rat Erythrocytes and Brain Homogenates - A Step Towards Non-invasive Detection of Parkinson's Disease

Parkinson's Disease (PD) and related synucleinopathies are characterized by the aggregation of alpha-synuclein (α S), a presynaptic protein implicated in vesicle trafficking. Although abundant in neurons, significant amounts of α S are also found in erythrocytes. The role of α S in erythrocytes is less understood, but elevated levels of oligomeric α S in erythrocytes have been associated with PD. This study aims to measure the abundance of α S in rat brain homogenates and erythrocyte lysates to explore the feasibility of using α S as a biomarker for PD. Rat brain homogenates and blood samples were collected post-mortem. Samples were spun at 20,000g for 30 minutes, and supernatants were kept for analysis. Protein concentrations were determined by BCA assays, and samples were adjusted to 1 μ g/ μ L. Lysates were run on NuPAGE 4-12% Bis-Tris gels and incubated with primary antibodies. The abundance of α S in erythrocytes relative to total α S in rat brain lysates was determined. A gradient of recombinant α S and rat brain lysate was analyzed by Western blot using an α S-specific antibody. Immunoblot analysis of rat erythrocyte lysates was compromised by the high abundance of hemoglobin. Native gel analysis was used to separate α S from hemoglobin, allowing for efficient α S detection. α S abundance in rat whole brain lysates was 0.9 +/- 16 ng/ μ L, compared to 0.0948 ng/ μ L in erythrocytes. α S levels were approximately 169 times higher in neurons than in erythrocytes, potentially explaining why α S aggregates in neurons, and not erythrocytes. These novel findings also support the hypothesis that α S in neurons is a more reliable biomarker for PD progression in comparison to erythrocyte lysates. Further studies could explore other methods to enhance sensitivity and specificity of α S quantification, and help pave the way for less-invasive, antemortem ways to diagnose PD.

Abstract Name: The Role of Sleep in Emotional Memory Encoding and Retrieval

The present study aimed to investigate the role of pre-encoding and pre-retrieval sleep in the emotional memory trade-off effect. The emotional trade-off effect is the tendency to remember negative stimuli at the expense of the neutral. Specifically, when negative or neutral objects are presented on neutral backgrounds, negative objects are remembered better than neutral objects, but the neutral background is remembered worse when it is paired with a negative object. Previous research suggests that sleep preferentially consolidates negative emotional stimuli, with many studies examining sleep between encoding and retrieval (pre-retrieval sleep). In the present study, participants (N = 45) tracked their sleep for two nights prior to memory encoding and two nights after encoding and prior to memory retrieval. In the encoding task, participants viewed 34 images of a neutral object on a neutral background and 34 images of a negative object on a neutral background and rated their perceived valence. During the retrieval task, participants saw objects and backgrounds presented separately. Participants rated whether each image had been presented during the encoding task and how confident they were in that decision. Results replicated the emotional trade-off effect. There was some evidence that participants who got more sleep before encoding displayed a stronger emotional trade-off effect, although this pattern was not statistically significant. These results suggest that future research should further investigate the role of pre-encoding sleep on emotional memory biases.

Abstract Name: Constitutive Expression of PNPLA3 in Mice Leads to Sex-Dependent Liver Injury

Background: The genetic basis of liver injury remains poorly understood, with only a few determinants identified. Among these, a variant in the PNPLA3 gene (I148M) has been associated with the development of fatty liver and drug-induced liver injury. Mice with constitutively active LXR have been developed to investigate liver-related pathologies. By breeding these mice with those harboring the PNPLA3 I148M variant, we aimed to generate a novel mouse model with constitutive expression of PNPLA3 to elucidate the mechanisms of PNPLA3-driven liver injury. **Methods:** Twenty-four-week-old mice were acclimated in our facility and sacrificed following a 6-hour fast. Serum, kidney, liver, and white adipose tissue samples were collected post-sacrifice. Liver samples were fixed and stained for histological evaluation using hematoxylin and eosin (H&E) staining. Serum was analyzed for indicators of hepatotoxicity and liver injury and hepatic triglyceride levels were measured. Additionally, mRNA and protein expression levels of PNPLA3 and related genes were quantified from liver samples. **Results:** We successfully generated mice with constitutive expression of PNPLA3. Analysis of liver samples demonstrated that LXR activation led to mild hepatic steatosis, which was exacerbated in mice expressing the PNPLA3 I148M variant. However, when the results were disaggregated by sex, we found that male mice carrying the variant exhibited a statistically significant effect, whereas female mice did not. Gene expression analysis revealed that female mice expressed 5-fold higher PNPLA3 mRNA levels than males, despite similar expression levels of SREBP1c, its transcriptional regulator. **Discussion:** We hypothesize that the high levels of PNPLA3 expression in female mice may mask phenotypic differences between variant and non-variant genotypes. In contrast, a variant-specific phenotype was observed in male mice, characterized by significantly lower PNPLA3 expression. This raises the possibility that PNPLA3 is regulated differently at the transcriptional level between sexes or that epigenetic factors contribute to the observed phenotypic differences.

Abstract Name: Food for Thought: A Quantitative Study Between Asian/Non-Asian Pittsburgh Neighborhoods & Chinese Menu Translation Methods

This study investigates differences in the frequencies of Translation Method Categories (TMCs) as defined by Amenador and Wang (2022) in menus from Chinese restaurants in Pittsburgh neighborhoods with varying Asian population densities. Amenador & Wang (2022) TMC classifications include: Retention, Literal Translation, Neutralization (D, P, G), Amplification, Intercultural Adaptation, Substitution and Omission. Neighborhood selection involved Class A (high Asian population) and B (low Asian population) assignment based upon publicly available census data. Restaurants were randomly selected from each neighborhood using Yelp filtering criteria. Quantitative TMC comparisons were conducted on Chinese to English menus including frequency (f), composition ($f/N_{total} * 100$) and cross-class composition averages ($\bar{x}$). Class A restaurants yielded a significantly higher average Literal Translation composition ($\bar{x} = 34.5\%$); however, Class B restaurants had a higher average Retention composition ($\bar{x} = 30.2\%$). Furthermore, treemap figures indicate a majority Neutralization (D, P, G) composition between both Class A and B. Class A incorporated significantly less instances of Intercultural Adaptation than Class B ($\bar{x} = 6.2\%$ vs $\bar{x} = 0.5\%$). Wade-Giles romanization appeared more frequently throughout Retention cases in Class B. Observed differences between Class A and B TMC frequencies correlate with differences in American Chinese versus Authentic Chinese dishes served. Yet, further analysis may be required to establish a clear correlation between translation preference and customer ethnicities.

Abstract Name: The Black Mirror's Origin: The Ergodic Atmosphere of 2001: A Space Odyssey

Stanley Kubrick's enigmatic aesthetic developed due to his meticulous eye for detail and pursuit of alternative forms in filmmaking for each cinematic undertaking he produced. This experimental attitude toward form parallels a key characteristic within an exploratory literary genre: Ergodic Fiction. Ergodic novels make their stories a puzzle for readers, refer to themselves as characters, and play with the idea of what constitutes a "book." It requires active engagement from its readers, often compelling them to partake in "side quests," namely, reassembling a non-linear story, adjusting the orientation of the novel's physical form while reading, and locating extraneous chapters or imperative narrative components within either the text or the real world. These techniques aspire to involve readers in the story itself, test audience fastidiousness, and push the limitations of how narratives are delivered. This primes the genre for meditation on ideas of human nature, the narrative's existential purpose, and the act of reading's alteration of the story. Since film genres are defined comparatively to literature, the contemporary acceptance of film as an equivalent to a novel begs the question whether they may too be classified as Ergodic. This study aims to analyze the narratological method in Kubrick's 1968 science fiction epic, 2001: A Space Odyssey, specifically to characterize the film as an example of Ergodic literature as the term is defined in Espen J. Aarseth's 1997 book, *Cybertext: Perspectives on Ergodic Fiction*. Close reading and textual analysis of the film's salient constituents, such as traditional

elements of filmmaking (like sound and color theory), the film's narrative structure, the Monolith's presence and juxtaposition as screen iconography, symbolism in Bowman's Stargate room, and repeated imagery mimicking Michelangelo's Creation of Adam form an argument for the viewer's non-trivial participation in the film. Consequently, reclassifying the film as Ergodic imparts Kubrick's intended philosophical message.

Abstract Name: The Effectiveness of Major League Soccer (MLS) Social Media Strategies

This project examines the effectiveness of Major League Soccer (MLS) social media strategies in engaging college students around global soccer tournaments, using the dynamic digital landscape of international events like Euro 2024, Copa America 2024, and the 2022 FIFA World Cup as a lens. Conducted within Elon University's Sports Media Lab in partnership with Charlotte FC, this study investigates the content MLS teams produced during these major events to understand the role and resonance of their digital outreach on platforms like Instagram, TikTok, and YouTube. Drawing on established research in sports media and marketing, this project evaluates the strategies MLS employs to capture the attention of young audiences, especially college students, during these high-visibility moments. Data collection will involve both content analysis of past social media posts and thematic analysis, which will inform our understanding of the type and tone of messages that succeed or falter in reaching the target demographic. The research process begins with the fall semester's content analysis, categorizing social media posts into thematic groups that highlight key messaging and engagement tactics. In spring, focus groups with college students will gauge perceptions and reactions to MLS's social media efforts during international tournaments, exploring the impact of various content themes. Findings will be compiled into an executive summary in December, and a comprehensive report with recommendations will be presented to Charlotte FC in spring 2025. This research aims to enhance MLS's understanding of effective social media outreach strategies and contribute insights to sports media practices targeting younger audiences during globally significant soccer events.

Abstract Name: Effects of Intranasal Medicine on Recovery in Mice & Rat Models of Traumatic Brain Injury

Traumatic brain injury (TBI) has long-term impacts on memory and executive functioning, yet there are no approved pharmacological treatments for managing post-TBI symptoms. This project aimed to determine if intranasal insulin (mouse study) or intranasal deferoxamine (rat study) are effective therapeutics to treat TBI

symptoms. Intranasal administration of medication avoids drug metabolism and bypasses the blood-brain barrier. In our lab, intranasal insulin has been shown to reduce motor and memory dysfunction in models of neurodegenerative diseases. It also has a notable impact on decreasing inflammation in the brain and reducing recovery time. Intranasal deferoxamine has the ability to chelate iron, which plays a large role in brain inflammation. This medication has also been shown to improve memory and motor deficits between healthy rats and models of neurodegenerative diseases. In these studies, we performed a controlled cortical impact on mice and rats to model TBI. At one week post-op, intranasal insulin was administered to mice everyday for a week. Rats were dosed with intranasal deferoxamine at four hours post-op and once a day for nineteen days. Brain tissue was collected from both mice and rats for immunohistochemistry. TBI symptoms were successfully modeled in mice and rats as evidenced by large deficits in behavioral testing between the sham and TBI groups. After the insulin dosing period, there were no obvious early changes in the mice behavioral assays in Morris Water Maze, Neurological Severity Score, Elevated Plus Maze, and Open Field. The rat behavioral assays in Morris Water Maze and Tapered Balance Beam also showed no obvious early changes with the deferoxamine dosing. The brain tissue of both the rats and mice will be analyzed to see if there were any changes on a cellular or tissue level. Overall, this research contributes to an ongoing effort to develop novel TBI therapeutics.

Abstract Name: Comparing Bacterial Communities in Echinostome Infected Snails vs Not Infected Snails

A genome includes all DNA that is found in an organism. A metagenome is a collection of genomes from multiple organisms that inhabit the same place. Studying metagenomes provides information on the community's makeup, structure, and functions in a specific environment. My advanced parasitology course tested the microbiome of snails and whether trematodes can alter that microbiome. Trematodes are a parasitic flatworm that infects snails and humans. Specifically, we aimed to find out if there was a difference in species diversity and composition in the bacterial communities of trematode infected snails vs not infected snails. We collected 53 viviparid snails from a pond in central Vermont. We tested these snails for infection by looking for cercarial shedding and performing a dissection on the snails. We chose 4 infected and 4 non-infected snails and extracted their DNA. We ran a full length 16S PCR and sequenced the DNA using a MinION Sequencer. We performed data processing on a high-performance compute core with a quality check, filtering, and classifying step. We did all data analysis in R to compare our bacterial communities including differential abundance, alpha diversity, and beta diversity. We found there to be a significant difference in differential abundance of four bacterial families between infected vs. non-infected snails in the snail tissue that trematodes live in, but no differences in alpha or beta diversities. There was no significant difference in bacterial communities seen by the data in all three measures for the pre-dissection control samples. The trematodes could have been suppressing bacterial communities by eating the snail tissue and leaving less habitat and resources for the bacteria that naturally live there. This research may help us understand how the bacterial communities in snails may affect trematode transmission to humans.

Abstract Name: Think You Can Fake It? We'll Make You Verify It: Utilizing Follow-up Surveys to Detect and Prevent Fraud in Online Crowdsourced Data

Online survey platforms enable faster and more cost-effective data collection across public, private, and academic sectors, but they also introduce opportunities for fraud. The persistent, evolving nature of fraud requires constant adaptation to preserve data quality. Our prior research examined data quality amongst the leading pay-for-data collection platforms, where only 10.2% of MTurk respondents provided acceptable-quality data. This study aims to demonstrate how follow-up verification surveys can improve the security and efficiency of incentive payouts by verifying respondent demographic information to reduce fraud. An orthopedic activity level assessment survey was disseminated via MTurk, incorporating updated quality checks to refine fraud detection, yielding over 5,000 responses. The survey administrator received emails regarding survey compensation issues, prompting a standardized follow-up survey designed to verify previously reported demographic information sent in response to email communications. Responses from the original survey were match merged with the follow-up survey data, and a descriptive comparative analysis was conducted to identify inconsistencies. The preliminary findings indicate that follow-up surveys can successfully identify fraud. After omitting duplicate emails and survey submissions, 28 emails were received regarding issues with incentives. Of those, only 50% of respondents completed the follow-up survey. Among those who completed, 1 had a zip code discrepancy, 2 had birth year discrepancies, and 1 had an email inconsistency, compared to previously reported information. Of the 13 who did not complete the follow-up survey, nearly half of the distinct MTurk Worker IDs shared the same email in the original survey. While minimal discrepancies were found among respondents who completed the follow-up survey, more substantial fraud was evident among those who initiated contact for incentives but failed to complete the follow-up survey. This study reveals the potential of follow-up surveys serving as secondary checks to detect fraud, allowing practitioners to implement automated demographic consistency checks before releasing incentives.

Abstract Name: Assessing the Impact of Trash Accumulation on Water Quality: Environmental Justice and Urban Wetland Management

At the bottom of the Walnut Creek Watershed lies Southeast Raleigh, housing predominantly African-American communities. Over the years, this low-lying area has become known for intense flooding and stormwater runoff. A group of concerned residents formed what is called the Partners for Environmental Justice (PEJ) to address the issues of environmental injustices in the area. Since the mid 1990's, the damage of constantly using the area as a dumping ground, as well as, the increase in development and impervious surfaces from upstream of the watershed has led to the concerns of how the accumulation of trash impacts the quality of surrounding creeks and streams. Previous land management practices, including the use of rubber tires in streambanks to reduce erosion, might have temporarily served its original purpose however now present issues concerning the leaching of toxic chemicals into nearby creeks. In this study, we analyze the effectiveness of the installation of a Trash Trout Entrapment Device placed in Little Rock Creek located within the Walnut Creek Watershed, specifically the impact on water quality based on trash collected over time. Through field sampling and in-lab experimental data, weekly water quality measurements including pH, dissolved oxygen, conductivity, nutrient testing, turbidity, and E. Coli provides an understanding of how

synthetic material in waterways impacts overall water quality. The correlation between trash type and parameter most affected will lead to better management practices and guardianship within the urban wetland environment.

Abstract Name: Semi-automation of a High-throughput Bioprinting Process for Biomanufacturing of Organoids

3D bioprinting has transformed tissue engineering by allowing the accurate creation of cellular structures. In our lab, air-jetting cell encapsulation techniques have been developed to produce cell-laden droplets for organoid generation, offering high precision and throughput. However, the manual processes involved in cleaning and maintaining equipment during batch production are labor-intensive and prone to error, highlighting the need for a semi-automated solution to improve efficiency and consistency. To address these challenges, we developed a semi-automated system for high throughput bioprinting, focusing on syringe pump control for droplet generation and an automated wash station for droplet cleansing. A Raspberry Pi 4 serves as the system's brain, running a Python based control script that integrates open-source libraries such as NESP-Lib for the New Era Syringe Pump and PyQt5 for the GUI design. The system controls a syringe pump for droplet generation and two peristaltic pumps for wash cycles, all managed through a custom touchscreen interface housed in a 3D-printed enclosure. The touchscreen allows for parameter customization through text input along with manual/cycle control of both the syringe and peristaltic pumps. Extensive testing verified the system's performance, ensuring precise pump control and seamless integration of the wash cycles. The resulting system significantly enhances workflow efficiency, enabling researchers to generate droplets at a consistent rate and automate cleaning processes between batches. Benchmarking showed reliable performance in both droplet production and wash station operation, reducing human error while maintaining cell viability and differentiation. This semi-automated approach streamlines the bioprinting process, allow for a more scalable organoid production. While currently used for thymic organoids, the system's design holds potential for applications across various organoid types. Future improvements will focus on enhancing automation by using a membrane strainer to hold droplets, reducing the wash time.

Abstract Name: Assessment of Cardiac Function using Echocardiography for Predicting Mortality in Sepsis

Sepsis, a life-threatening condition caused by the immune system's exaggerated response to infection, is a leading cause of mortality in intensive care units, affecting approximately 1.7 million people each year in the United States. A common complication associated with sepsis is cardiac dysfunction, caused by increased pressure and strain on the heart due to fluid overload. If not treated promptly, sepsis can lead to a series of severe symptoms, including decreased blood pressure, organ failure, and potentially death. In this study, we employed novel in-house algorithms to evaluate cardiac biomarkers in sepsis patients. These biomarkers were obtained from B-mode and color Doppler echocardiographic data from the Medical Information Mart for Intensive Care (MIMIC)-IV database, which contains deidentified medical records from the Beth Israel Deaconess Medical Center (2008–2022). In our analysis of B-mode scans, we found that mitral annulus velocity biomarkers showed significance between sepsis and septic shock groups, while conventional volume and strain biomarkers did not. Through further analysis of computed hemodynamic measurements derived from color Doppler scans, we aim to uncover significant correlations between cardiac dysfunction and mortality in sepsis. Our findings may help determine how cardiac biomarkers can be used by clinicians to better predict mortality in sepsis, leading to more effective treatment strategies and improved patient outcomes.

Abstract Name: Public Discourse During COVID-19: Analyzing Keyword Variations in Twitter Data

Understanding public sentiment during crises like the COVID-19 pandemic is crucial for policymakers and researchers. This study emphasizes the challenges and methodologies of analyzing COVID-19-related tweets, focusing on categorizing and tracking keyword trends to reflect dynamic changes in public sentiment and discussions over time. The study leverages a data pipeline for collecting, processing, and categorizing tweets. Using Selenium, tweets were collected over several months by navigating individual URLs with a headless browser. The extracted data was stored in a structured MySQL database. To prepare the data for analysis, preprocessing steps, such as text classification and stemming, were conducted to organize tweets by topic. A central challenge in this analysis lies in the variation of keyword usage. For example, references to “vaccine” appear as terms like “vax,” “vaxed,” or brand names such as “Pfizer” and “Moderna.” Similarly, “mask” includes variations like “N95” and “face covering,” while references to public figures exhibit diverse naming conventions. To address these challenges, a large language model (LLM) was employed to group such variations under unified categories, enhancing keyword recognition and enabling precise time-series analysis. Keyword trends were analyzed through time-series visualizations, reflecting shifts in public sentiment. LLMs were utilized to identify and group keywords into broader concepts, ensuring accurate categorization. For example, terms like “shot” and “jab” were associated with “vaccine,” while alternate spellings and references were integrated seamlessly. The analysis uncovered trends in public discussions, such as a surge in vaccine-related mentions during rollout phases and varying sentiment towards mask mandates and social distancing policies. The study’s framework provides a scalable and adaptable approach to analyzing public sentiment dynamics, offering valuable insights for future crises. By addressing keyword variation challenges and integrating advanced NLP techniques, this framework highlights public sentiment trends during COVID-19, supporting data-driven decision-making and public policy planning.

Abstract Name: Cheating as a Bluffing Game: An Information Economics Analysis of Academic Integrity

I examine the dynamics of academic honesty among students through a multi-method approach involving game theory, dynamic optimization, and agent-based modeling (ABM). The primary research question explores how peer effects and institutional strategies can influence students' decisions around cheating, aiming to enhance ethical behavior in educational contexts. Building on existing literature in game theory and peer analysis, I introduce an information-theoretic perspective that considers monitoring effectiveness and the potential impact of institutional bluffing on cheating behavior. Traditional peer-based studies focus primarily on factors like class size; in contrast, my work emphasizes the role of perceived monitoring through a novel ABM approach inspired by Schelling's checkerboard model and dynamic optimization principles. My methodology includes mathematical modeling and simulations within NetLogo to explore the cascading effects of peer influence on cheating behaviors. Notably, percolation occurs in the presence of peer effects, where heightened perceptions of cheating detection significantly reduce dishonest actions. The dynamic optimization model suggests that conventional educational interventions may be less impactful than enhanced surveillance, particularly when institutions publicly share monitoring information as a deterrent. Moreover, an information-theoretic model evaluates the instructor's optimal incentive to inflate reported cheating statistics, providing a bluffing strategy that leverages dynamic programming and control theory to curb cheating more effectively over time. Results indicate that manipulating students' beliefs about detection rates can reduce cheating, and the strategy's effectiveness hinges on maintaining institutional credibility. The study concludes that while inflated perceptions of monitoring can deter dishonesty, long-term success depends on strategic,

time-sensitive interventions that balance enforcement with institutional trust. These findings offer new insights for future research on academic integrity, suggesting further exploration into behavioral factors such as peer pressure and the broader implications of institutional reputation on student conduct.

Abstract Name: Greta Gerwig's Barbie (2023): A Commercial Product or Feminist Masterpiece?

The essay discusses the cultural impact of the Barbie doll and how Greta Gerwig's Barbie (2023) addresses contemporary issues related to gender roles and social expectations in U.S. society. This paper also critically examines and highlights how this film reflects the social expectations of beauty through attitudes of patriarchy and harassment and the film's commercial core. The central questions revolve around: To what extent does Gerwig's Barbie balance its feminist ideals with its role as a commercial product? And how does the film navigate the tension between critiquing gender norms and perpetuating consumerist ideals? This research seeks to fill the gap in the feminism discourse by examining the significance of feminism in popular culture using scholarly work on Barbie, movie reviews of the film, and the Barbie movie. The paper discusses the film's story, characters, marketing strategies, and public acceptance; it contextualizes these elements in a broader discussion of gender studies, feminist movements, and capitalist systems. Ultimately, the film serves as both a reflection and perpetuation of gender inequalities, illustrating the tension between commercial interests and genuine feminist discourse in shaping society. Although it undoubtedly introduces conversations about gender studies, the movie demonstrates the limitations of mainstream media's capacity to critique the systems from which it profits fully. The essay highlights the need for more nuanced representations of feminist movements beyond commercial imperatives, thereby contributing to a broader conversation about gender, media, and capitalism.

Abstract Name: From Retreat to Reality: How Does a Weeklong Mindfulness Retreat Impact Adolescents' Social and Emotional Lives One Month Later

Research on mindfulness training with adolescents has proliferated in recent years and has shown it can help adolescents manage stress, improve relationships, and foster greater emotional well-being. However, less is known about how they apply skills and mindsets learned during mindfulness training into daily life. In this mixed methods study, I explore how adolescents integrate skills and mindsets learned during a weeklong intensive mindfulness training retreat to navigate social and emotional challenges. Data were collected from 15 self-selected adolescents (Mage = 16.73 years; range = 14–19 years; 73% girls, 27% boys; 7% East Asian, 7% African American, 53% White, 33% Multiracial) who participated in the mindfulness retreat. At one-month follow-up, adolescents completed a 30-minute semi-structured interview and shared insights into their mindfulness practice, its perceived benefits, and difficulties in daily life. I used a phenomenological approach

to identify common themes in adolescents' experiences and provide a deeper understanding of how adolescents apply mindfulness to manage emotions and navigate social interactions. Data analysis remains ongoing, but preliminary results show that adolescents used many skills to handle intrapersonal challenges, including self-awareness (e.g., greater awareness of thoughts and sensations, using intentional speech), self-acceptance (e.g., being less self-critical) and having a broader perspective (e.g., realizing what really matters). They also described using a range of skills and mindsets to address interpersonal problems, including social awareness (e.g., more perspective-taking & empathy), compassionate communication (e.g., better listening skills and comforting others), and social connection (e.g., being less socially anxious). By examining the real-world application of mindfulness practices from a youth-centered perspective, this research contributes valuable insights into how mindfulness interventions can better meet the developmental needs of adolescents beyond clinical or school settings. Implications for adolescent development and contemplative science will be discussed.

Abstract Name: Predicting Wildfire Events Using Synthetic Aperture Radar

Each year, over 70,000 wildfires occur nationally, resulting in billions of dollars in damage and impacting countless lives. As a result of population growth and global changes, an increasing number of individuals are at risk in areas susceptible to wildfires. Many factors contribute to wildfire ignition and spread, including available fuel, canopy density, topography, and soil moisture. Soil moisture is particularly important because low soil moisture increases the probability of wildfire ignition and the speed at which it spreads. A great technology for monitoring soil moisture is synthetic aperture radar (SAR). SAR can operate in almost all-weather conditions and penetrate through cloud and vegetation canopies. SAR sensors emit signals at a specific frequency, enabling researchers to assess the target's characteristics through backscatter analysis. This research develops a model to estimate soil moisture using Sentinel-1 data for wildfire prediction. The data includes satellite imagery from three months before to one month after certain wildfires in the US and Canada over the past five years. The time series data from wildfire-affected and unaffected regions will be analyzed to assess and quantify the differences in backscatter variation across different polarizations. Previous research has demonstrated the effectiveness of the radar vegetation index in monitoring wildfires and determining thresholds for distinguishing between burnt and unburnt areas. Therefore, this study will incorporate radar vegetation indices and thresholding techniques to estimate wildfire probability. To enhance the model's performance, ancillary data like temperature data from NOAA weather stations, LiDAR, and/or RGB imagery will be used. The model will be tested and validated using in-situ soil moisture data from the National Soil Moisture Network. The expected result of this model is the ability to accurately predict wildfires across different terrains using space-borne SAR data.

Abstract Name: Building Focus in Beginner Piano Students: Strategies for Effective Practice

In a world where the average human attention span has diminished due to the rapid pace of modern life, fostering focused practice in piano students has become increasingly challenging. As educators, it is essential to address this issue by equipping students with effective strategies to maintain concentration and maximize their practice time. This presentation is designed to address these challenges by offering practical techniques and strategies specifically tailored for beginner students. Its objective is to equip piano teachers with effective methods to help students enhance their focus during practice sessions, making their practice time more productive and enjoyable. This, in turn, will increase their efficiency and overall progress. By the end of this presentation, attendees will understand the challenges beginner students face regarding focus and attention, learn practice, age-appropriate strategies to improve students' concentration during practice, and observe a demonstration of effective practice techniques and how to apply them. By fostering a more engaged and structured practice routine, educators can help their students develop the focus and resilience necessary for long-term success in their musical studies.

Abstract Name: Computationally Efficient Detection of End-Diastolic and End-Systolic Phases for Left Ventricular Function Assessment Using 3D Convolutional Neural Networks

Accurate assessment of left ventricular (LV) function is critical in echocardiography, with End-Diastolic (ED) and End-Systolic (ES) phases serving as key points in the cardiac cycle for calculating LV volumes and ejection fraction (EF). Traditional methods for ED and ES detection rely on deep learning models to segment LV volumes across all frames of echocardiographic studies. While effective, these workflows require processing entire multi-frame sequences, leading to significant computational and memory overhead, which can hinder scalability in clinical and research settings. To address these limitations, we present a 3D Convolutional Neural Network (3D-CNN)-based approach that directly identifies ED and ES image pairs by classifying each frame within the cardiac cycle as ED, ES, or non-ED/ES. This method eliminates the need for full-sequence segmentation, optimizing resource utilization while maintaining accuracy. Our dataset consisted of echocardiographic studies from 407 patients focused on the LV view, with an 80:20 split for training and testing. The proposed model achieved an Area Under the Curve (AUC) of 95.89%, outperforming existing methods. This streamlined approach holds potential for enhancing clinical workflows by reducing computational demand while preserving diagnostic precision. By enabling direct detection of ED and ES frames, it simplifies EF calculation, making it more accessible and efficient for real-world applications in echocardiography.

Abstract Name: Optimizing Eco-Friendly Nanoparticle Synthesis for Lead Detection in Drinking Water

Lead contamination in drinking water remains a critical issue across the United States. Efficient and cost-effective detection methods are essential for both municipalities and individuals in order to prevent exposure to contaminated water. This research focuses on developing an economical and green lead detection method using bismuth nanoparticles in a surface-enhanced Raman spectroscopy (SERS) system, as a substitute for the more expensive silver and gold nanoparticles. Bismuth was selected due to its advantageous properties, including cost-effectiveness, safety, and minimal environmental impact compared to other heavy metals. Our synthesis of bismuth nanoparticles utilized lemon juice as both a reducing and capping agent, optimizing parameters such as pH (above 12), temperature (80°C or higher), and bismuth precursor concentration (approximately 10 millimolar). The nanoparticle purification process involved a two-stage centrifugation: two rounds of 10 minutes using a larger, slower centrifuge, followed by a single 10-minute round in a smaller, faster centrifuge. Characterization via scanning and transmission electron microscopy confirmed that the nanoparticles are approximately 50 nanometers in diameter. With consistent synthesis, we are now exploring and optimizing the application of these nanoparticles for lead detection. This work will serve as a foundation for future outreach initiatives in the Hamline-Midway neighborhood and the whole of Saint Paul.

Abstract Name: Welcoming the Dear Neighbor?: The Legacies of Neighborhood Segregation in Ramsey County

During the 1960s, the St. Paul Public School district faced a significant challenge: the threat of being sued by the Federal Government for not meeting the requirements of *Brown v. Board of Education*. The *Brown* decision in 1954 ruled that separating children by race in public schools was unconstitutional because segregated schooling resulted in unequal educational outcomes for students of color. While the SPPS District recognized that some of their schools were segregated, they also claimed that this segregation was not the result of district policies or prejudice, but rather neighborhood segregation. Racial covenants, redlining, zoning, and lending policies had worked together for over fifty years in St. Paul to claim some neighborhoods for white people and push people of color into less desirable neighborhoods; leaving school populations to reflect the neighborhood residents. Our research seeks to understand how the SPPS district attempted to meet the mandate to desegregate when it was largely the neighborhoods that were segregated, not the public schools directly. We utilized archival and census data research to investigate how the SPPS attempted to desegregate. To address desegregation, SPPS tried permitting open enrollment, creating learning centers, consolidating schools, redrawing boundary lines, and even attempting different bussing strategies. We find

that none of their efforts were fully successful at desegregating SPPS because they did not address the root cause of school segregation in the district. This research provides insights into the challenges of desegregation in the north, of the presence of persistent racism in neighborhoods across St. Paul, and suggests the ways that segregation in the past has significant legacies in the present. The St. Paul Public School District avoided being sued in the 1970s, but their efforts at integration were not successful in completely undoing the school segregation brought about by decades of persistent neighborhood segregation.

Abstract Name: The Impact of Age and Sex on Tau and Beta-Amyloid Pathology in 3xTg Mice

Alzheimer's disease (AD) affects an estimated 6.7 million individuals aged 65 and older in the United States. At the molecular level, AD is marked by the accumulation of beta-amyloid (A β) and tau proteins, leading to neurodegeneration. While traditional research has focused on the role of insoluble A β and tau aggregates in AD pathology, recent studies suggest that their soluble forms, which are present earlier in AD pathology, may also play a critical role in disease progression. 3xTg mice have been used extensively to study AD, expressing both tau and A β . While the pathology of these mice has been described before, recent research suggests that previous characterizations of 3xTg pathology may be incomplete (e.g. lacking the quantification of soluble vs insoluble AD biomarkers, and adequately assessing differences in AD pathology between males and females). In this study, we will characterize the age- and sex-related changes in these biomarkers using the 3xTg mouse model of AD. We will quantify changes in soluble and insoluble tau and A β levels in 3xTg and control mice at 3, 8, and 13 months using western blotting (WB) and immunohistochemistry (IHC). WB will provide semiquantitative data on overall levels and molecular weights of tau and A β species in the hippocampus. IHC will examine the localization of tau and A β in various brain regions across ages. Antibodies targeting soluble, insoluble, and total tau and A β will be used in both WB and IHC. We hypothesize that aging will be associated with an increase in soluble and insoluble tau and A β with older brains becoming more enriched in the insoluble forms. Future aims will use information collected from this project to refine the timing of sleep interventions aimed at reducing tau and A β and improving cognitive outcomes.

Abstract Name: Home Sweet Home: Enhancing Family Life Through Thoughtful Home Construction

This project aims to enhance the quality of life for a family of four by building a home for Liam, a surgeon and the head of the household; Amelia, a stay-at-home mom diagnosed with diabetic retinopathy; and their two-year-old twins, Amir and Luna. The research highlights the importance of creating a safe and welcoming environment, which can significantly improve the family's daily life and help them feel more comfortable and

secure in their home. Diabetic retinopathy is a condition that can lead to vision loss and blindness by affecting the blood vessels in the retina, the light-sensitive tissue at the back of the eye. Common symptoms include leaking and bleeding blood vessels, abnormal tissue growth in the eye, floaters, flashes of light, and severe visual loss. In the United States, up to 21% of patients with type 2 diabetes show signs of retinopathy at the time of their diabetes diagnosis, and most will develop some degree of retinopathy over time. Vision loss from diabetic retinopathy occurs due to various mechanisms. The research for this project primarily focuses on case studies that explain how contrasting furniture and finishes can help individuals with partial blindness see better. Additionally, interviews were conducted with stay-at-home moms of toddlers to identify potential dangers their children might face, enabling adjustments to enhance safety. The outcome of this project is "Home Sweet Home," a house designed with consideration for all its occupants. Construction involves meticulously selecting materials, colors, room layouts, and unique features. The home can serve multiple purposes by understanding the family's needs: providing a retreat after work, creating a safe environment for daily activities, and fostering a nurturing space that promotes children's safety and growth.

Abstract Name: "Project Coral Reef: A Playful Solution to Ocean Pollution

Project Coral Reef aims to develop a unique playground that addresses the pressing challenge of ocean pollution and serves as a vivid reminder of our responsibility to protect our oceans. This initiative emphasizes the importance of adopting a practical and proactive approach to removing plastic from the sea, alongside creating new products from recycled materials. By fostering a sense of optimism, Project Coral Reef inspires individuals and communities to believe in their collective ability to tackle this critical issue. Recent studies highlight a staggering statistic: the United States generates approximately 624,700 metric tons of waste daily, translating to over 7 pounds per person. Alarming, around 69 percent of this waste ends up in landfills, where, unfortunately, it can leak into the ocean, posing threats to marine life and coral habitats. This unsettling trend underscores the urgent need for effective recycling initiatives, especially considering that only about 10% of plastic currently exists in recycling processes. This scenario serves as a wake-up call for everyone. The inspiration from research conducted for this project has culminated in the design of "Project Coral Reef," a playground structure crafted entirely from 100% recycled materials. The design resembles an octopus, creatively reflecting the theme of marine life. Not only does this playground offer a tangible solution to the issue of ocean pollution, but it also stands as a symbol of inclusivity and affordability. By being made entirely from recycled materials, the playground encourages people to collect plastic waste, knowing it can be repurposed and kept out of a landfill. Ultimately, Project Coral Reef ensures that families from all social backgrounds can enjoy quality family time in a safe space where children can play and thrive, regardless of their economic circumstances.

Abstract Name: Observing effects of taurine supplementation in longer lived worms

Taurine is a sulfur-containing amino acid that plays a critical role in cellular homeostasis, development, and stress response. In mitochondria, taurine acts as an antioxidant, helping to reduce oxidative damage by neutralizing reactive oxygen species (ROS) in the mitochondria. Deficiency in taurine can lead to impaired reproduction, neurological dysfunction, and reduced lifespan in various organisms. Previous studies have shown that taurine supplementation promotes longevity and, but little is known if this same effect is observed in long lived models. To determine if taurine supplementation during adulthood affects lifespan in other long lived-models and physiology, we used the nematode model *Caenorhabditis elegans* (*C. elegans*) *daf-2* mutant to determine the effects (Kenyon et al 1993). Wild-type and the long-lived model *daf-2* were supplemented with various concentrations of taurine (10 μ M, 50 μ M, 100 μ M, and 150 μ M) were incorporated into nematode growth media, and various assays were used to determine the physiology (egg-laying, locomotion and muscle imaging). Lifespan analysis revealed a dose-dependent effect, with higher concentrations of taurine significantly extending mean and maximum lifespans in wildtype worms and improving physical function of the organism. This extension is attributed, in part, to taurine's ability to mitigate oxidative stress by enhancing cellular antioxidant defenses and reducing the accumulation of reactive oxygen species when placed at higher temperatures. The studies suggest that taurine modulates both metabolic pathways, offering insight into its potential as a dietary intervention for aging and health maintenance in *C. elegans*. Further investigations may elucidate conserved mechanisms of taurine's role in longevity and reproduction across species.

Abstract Name: The Relationship Between Verbal and Non-Verbal Imitative Learning, Gesture Production, and Social Communication in Children with Autism Spectrum Disorders.

Autism Spectrum Disorders (ASD) is a neurodevelopmental condition characterized by social communication (SC) impairments. Evidence has revealed a potential relationship between motor development, imitative learning, and SC, supported by observations of impaired gesture production and imitation in individuals with ASD. This study aimed to investigate the relationship between complex gesture, imitative learning, and SC impairments present in children with ASD. Participants included 8–12-year-old English-speaking children diagnosed with either comorbid ASD+ADHD ($n=72$), ASD-only ($n=72$), or ADHD-only ($n=38$), and typically developing (TD; $n=125$). Participants completed a version of the Florida Apraxia Battery for children (PRAXIS), assessing accuracy of transitive (involving a tool), intransitive-meaningful (communicative/no tool), and intransitive-meaningless gestures under different 3 different conditions (to-command, to-imitation, with-tool use). SC was assessed using the parent-reported Social Responsiveness Scale (SRS). Four-group, between-subjects ANOVAs revealed a consistent pattern across PRAXIS conditions and movement types, with post-hocs revealing that children with ASD, both those with ASD+ADHD and with ASD-only, showed significantly worse PRAXIS (more movement errors) compared to both ADHD-only ($p<.001-.037$) and TD children ($p<.001$), with moderate-to-large effect sizes ($d=.59-1.66$). Further post-hoc comparisons of ASD groups revealed that children with ASD+ADHD showed significantly worse PRAXIS compared to ASD-only ($p<.001$) with marginal effect sizes ($d=.19-.61$). Pearson's correlations including all participants revealed significant correlations of PRAXIS performance with SRS Total t-score (higher scores=more social impairment) and PRAXIS total errors ($r=.361$, $p<.001$). These findings emphasize that

children with ASD, regardless of the presence of comorbid ADHD, show significantly impaired praxis compared to TD and ADHD-only children. However, results suggest that among children with ASD, the presence of comorbid ADHD confers additional praxis impairment. Across all children, impaired praxis was related to higher parent ratings of SC impairment, proposing a clear association between praxis and SC development.

Abstract Name: Innovative Political Strategies in the European Union for Combating Sexual Violence: A Feminist Approach

Sexual violence is a growing global issue requiring innovative solutions for effective prevention and response. This research investigates innovative political strategies across the European Union to address sexual violence at a local level, with a focus on their potential application elsewhere. The data was gathered through interviews and surveys with individuals involved in relevant projects connected through the Innovation in Politics Awards. In collaboration with The Innovation in Politics Institute based in Vienna, Austria, and guided by feminist theory that highlights marginalized voices affected by sexual violence, the study utilized participant observation, interviews, and surveys. Care was taken to ensure that research participants were not from vulnerable populations, and ethical guidelines were followed to protect individuals from harm while ensuring that their voices were heard in a respectful and responsible way. A 90-day internship in Vienna provided direct insight into EU stakeholders' work, while interviews and surveys gathered perspectives on local impacts and adaptability. Primary source analysis, including reports, webinars, and forums, revealed key patterns and gaps, which were analyzed through archival and documentary research. This analysis contributed to the academic discussion on effective global strategies by drawing on secondary sources to help situate and make sense of the findings in the case study. The main findings highlight that local interventions show that person-centered care is key in addressing gender-based violence. Success depends on adapting strategies to local needs and cultural contexts. This research concludes that local strategies can contribute to global solutions for sexual violence, aligning with human rights standards of dignity, equality, and justice.

Abstract Name: Perception of Autism Spectrum Disorder Amongst US Immigrant Families

What are the perceptions of Autism Spectrum Disorder (ASD) among immigrant parents and families? Specifically, how aware are they of the symptoms and causes of ASD? What cultural beliefs, backgrounds, and economic factors shape their perceptions, and how do these perceptions influence their responses to professional advice and early intervention strategies? This study highlights the importance of understanding nuanced perspectives on ASD within immigrant families of diverse cultural backgrounds, focusing on their

attitudes and experiences with children diagnosed with ASD. Previous research shows significant variability in how immigrant parents perceive ASD. Some parents associate communication difficulties, social challenges, and behavioral issues with autism, while others view these as temporary developmental delays or external influences. A smaller group highlights their child's strengths, expressing little concern. Building on these findings, this study examines how immigrant families of children with ASD perceive their child's condition, the challenges the family faces, and their interactions with professionals and external opinions. The research follows a systematic review methodology utilizing the PRISMA guidelines. Qualitative data from questionnaires and interviews are analyzed to explore parents' perspectives on their child's condition, the daily challenges they encounter, and their experiences with healthcare providers and societal attitudes. Participants originate from diverse regions, including Latin America, the Caribbean, Asia, Africa, the Middle East, and Europe, all of which face common difficulties including language barriers, stigma, and limited access to services. The study is expected to reveal the need for culturally sensitive communication and tailored support systems to bridge the gap between immigrant families and healthcare providers. These findings aim to reduce strain on families, improve engagement with professional services, and emphasize the importance of interventions that respect cultural and economic contexts.

Abstract Name: Connecting Creatives: Fostering Community Among Visual Artists in Central Kentucky

Collaboration is essential for artistic growth, yet many artists face isolation in their artistic and professional endeavors. The demanding nature of working as a professional artist often limits opportunities for connection, and emerging artists, in particular, face additional challenges in establishing connections and finding opportunities within their local communities. This project seeks to understand the dynamics of community-building through the development of a website that will allow emerging visual artists in Central Kentucky to find arts opportunities and connect with artists who have experience applying for and participating in those programs. By creating an artist directory, the website will enable artists to share insights about arts opportunities, offer creative feedback, improve financial transparency, and support each other in navigating the complexities of the arts industry. Although art organizations publish their own opportunities and share postings from other organizations, a well-organized, centralized location for these opportunities does not exist in Central Kentucky. Further, there is no artist directory that currently exists for emerging artists to easily connect with other emerging and established artists. Seeking to fill this void, the website will benefit emerging artists in their professional and artistic endeavors by enhancing their support systems within Central Kentucky's artistic community. This project developed out of working with the Tuska Studio records archival collection—housed at the University of Kentucky Special Collections Research Center—which underscores the significance of creative networks and community-building for artistic success. Creation of the website will involve consulting with arts organizations and connecting with artists and arts administrators to find exhibitions, art fairs and markets, residency programs, and grant opportunities, as well as to establish the artist directory. By creating a space for artists to share knowledge and experience, this project will consider how opportunities for dialogue and connection among artists impact their artistic practice.

Abstract Name: Characterization of β -lactam Antibiotic-Susceptible *Providencia alcalifaciens*: Ecological Insights and Genomic Perspectives

Antibiotic resistance is a growing problem in environments around the world; however, resistance rates tend to be greater near human populations. One such area is the Navajo Creek, a suburban waterway near southwest Chicago that flows through neighborhoods and forest preserves. Among bacteria isolated from the creek, resistance to six different antibiotics has been discovered, and metagenomic analysis of these populations shows diversity among the microbes. Water samples collected from suburban waterways over the course of several months indicate that *Providencia alcalifaciens* is widespread, both geographically and temporally. Whole-genome sequencing of *P. alcalifaciens* reveals a wide variety of resistance genes that allow it to survive in the presence of antibiotics, but the interplay between these genes and the corresponding antibiotics is still being determined. Bacteria are being grown in the presence of different antibiotics, and gene expression will be measured using qPCR. Growth assays are also being done to determine the bacteria's resistance in different concentrations of antibiotics. The bacteria has been shown to exhibit varying susceptibility to a range of β -lactam antibiotics, including oxacillin, amoxicillin + potassium clavulanate, and carbenicillin. The combination of amoxicillin and potassium clavulanate, a β -lactam/beta-lactamase inhibitor, showed superior antibacterial activity compared to amoxicillin alone. This suggests that the presence of clavulanate, which inhibits β -lactamase enzymes responsible for β -lactam antibiotic degradation, enhances the bactericidal effect, potentially overcoming the bacterial resistance mechanisms. Overall, this project offers ecological and genomic analysis of a highly resistant microbe and potential pathogen that has been isolated from local waterways.

Abstract Name: A Study of the Predictors of Stress and Burnout via Mindfulness

This study aimed to identify predictors of burnout and stress in undergraduate students. Previous research has shown connections between mindfulness, stress, and burnout. For example, there has been a significant negative correlation between stress and the five facets of mindfulness: observing, describing, acting with awareness, non-judging, and non-reactivity. Additionally, mindfulness has been shown to negatively correlate with the following factors of burnout: emotional exhaustion and personal efficacy. One hundred and twenty-six (N= 126) undergraduate students participated in the current study. Four hypotheses were constructed based on the information from prior literature. Hypothesis 1: Scores of observing, describing, acting with awareness, non-judging of inner experience, and non-reactivity to inner experience predict emotional exhaustion scores. Hypothesis 2: Scores of observing, describing, acting with awareness, non-judging of inner experience, and non-reactivity to inner experience predict depersonalization scores. Hypothesis 3:

Scores of observing, describing, acting with awareness, non-judging of inner experience, and non-reactivity to inner experience predict loss of personal accomplishment scores. Hypothesis 4: Scores of observing, describing, acting with awareness, non-judging of inner experience, and non-reactivity to inner experience predict stress scores. The Five Facets of Mindfulness Short Questionnaire, the Maslach Burnout Inventory, and the Perceived Stress Scale were utilized to collect the necessary data needed to test the four hypotheses. Multiple regression analyses were performed via SPSS software. Results showed that non-reactivity and acting with awareness negatively predicted emotional exhaustion. No significant results were found between observing, describing, acting with awareness, non-judging, and non-reactivity to inner experience and depersonalization. Results showed that observing and describing negatively predicted loss of personal accomplishment. Lastly, results showed that non-reactivity and acting with awareness negatively predicted stress. The limitations this study encountered were the population, as it was limited to a small, private, Christian university in the southeast, and that the majority of the sample consisted of freshmen.

Abstract Name: Using Anti-oxidative and Anti-inflammatory Properties of Ginger to Temporarily Relieve Respiratory Symptoms from Flavored Vaping Pods

Despite the extensive research conducted on the respiratory implications of e-cigarette usage, a significant research gap persists regarding treatments to minimize the adverse effects of respiratory dysfunction induced by flavoring pods within e-cigarettes. Among the range of vapes available, vanillin emerges as a prevalent flavor choice and has been associated with a reduction in antioxidant efficacy, potentially escalating lung inflammation and oxidative stress. Vapes, regarded as a solution for heavy smokers, are promoted as a safer substitute for tobacco, yet evidence suggests the contrary. Commonly prescribed for e-cigarette-induced respiratory issues, corticosteroids exhibit detrimental effects upon prolonged usage, including osteoporosis, myopathy, and temporary side effects. The introduction of an alternative treatment devoid of symptomatic implications could substantially benefit individuals grappling with respiratory dysfunction stemming from e-cigarette flavoring chemicals. Ginger, renowned for its potent anti-inflammatory and antioxidative properties, offers a multifaceted spectrum of health benefits, aiding in digestion, alleviating inflammation-linked conditions like arthritis and nausea, fortifying the immune system, and contributing to cardiovascular wellness. Widely used in Eastern and alternative medicinal practices, ginger serves as a remedy for various health concerns, encompassing digestive problems, respiratory issues, and headaches. This research initiative endeavors to explore the potential of ginger extract as an alternative remedy for vanillin-triggered respiratory dysfunction. Ginger's antioxidative and anti-inflammatory attributes position it as a promising candidate to mitigate vanillin-induced oxidative stress while potentially minimizing associated side effects. To mitigate the negative respiratory effects of vaping, such as lung damage and respiratory distress, ginger could be used as an alternative treatment because of its anti-oxidative and anti-inflammatory properties.

Abstract Name: The Hujum Campaign in Uzbekistan and its Consequences

The Hujum Campaign (meaning “attack”) was an attack on veils worn by Muslim women between 1927-1929. This campaign started in Uzbekistan, the most conservative part of Central Asia, and was led by the Zhenotdel, the women’s department of the Soviet Union. The Soviets felt that they had to liberate women in Central Asia to fix what they saw as a backwards society. To the Soviets, casting off the veil would be the same as casting off the rules of the past, creating new opportunities for women and bringing in new members of the Communist party. However, what began as the Hujum “attack” on the veil as a symbol of female repression, resulted in thousands of women being victims to violence and even death. Uzbek women were worse off due to the severe violence they faced as a direct cause of the Hujum campaign, and they did not see positive results until years later. Women who unveiled had to live in fear for their life, whether in the form of violence from strangers or relatives. This research uses primary accounts from women who participated in and experienced the Hujum campaign, as well as accounts from the Soviet government itself. It also uses secondary sources which analyzed the Hujum campaign and its outcomes.

Abstract Name: Exploring Auditory/Visual Environmental Enrichment for Rhesus Monkeys

Environmental enrichment plays a vital role in improving the welfare of captive non-human primates (NHPs). While more research has been done on tactile, dietary, and social enrichment, audiovisual enrichments like radio and television have been less explored. This study looks at how these tools might benefit rhesus monkeys (*Macaca mulatta*), focusing on their preferences and responses to different television programs (such as naturalistic scenes, animations, and static imagery) and auditory stimuli (including natural sounds, classical music, vocalizations, and other radio content). By looking at the time spent engaging with these stimuli and analyzing behavioral change, we will be able to examine how the different stimuli affect the subjects. Audiovisual enrichment is projected to promote species-typical behaviors, reduce stress, and enhance overall mental well-being. A study by Donna Platt found that Rhesus monkeys tend to favor videos featuring unfamiliar subjects or frequent angle changes, suggesting that television could serve as effective enrichment. However, another study by Linda D. Harris yielded inconclusive results, with only 2 out of 8 subjects showing interest in TV, casting doubt on its effectiveness as enrichment. These previous studies on audiovisual enrichment have been inconclusive and little has been done beyond 2016. This study seeks to bridge that gap, offering new understandings of how audiovisual tools can enhance animal welfare, minimize stress, and inform about better future enrichment strategies.

Abstract Name: Examining a Farmers' Market Match Incentive Program - Using SNAP Shopper Survey Data from 2023-2024

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of chronic disease. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets (FM) offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are less likely to shop at FM. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the ECDFM. Administrative transaction data show that, despite robust utilization of the MMP, most shoppers visit the ECDFM infrequently yielding little evidence that shoppers build the ECDFM MMP into their regular shopping routine. This presentation uses survey data from 2023–2024 to identify reasons why people like shopping at the ECDFM as well as what barriers/obstacles they face, and also what things might enable/encourage them to visit the ECDFM more often to use the MMP. Our findings reveal the number one reason SNAP shoppers come to the ECDFM is buy local healthy FV followed closely by being able to use the MMP. Additionally, we find the main limitations to using the MMP at the ECDFM include inconvenient location/hours, SNAP benefits running out and just not remembering. Correspondingly, the most mentioned things that would encourage more MMP utilization by SNAP shoppers at the ECDFM are expanded locations/hours, a larger match amount and also just being reminded. Flows out of another submission analyzing administrative transaction data from the ECDFM MMP (same community partner, same mentors).

Abstract Name: Testing the Young FRB Progenitor Hypothesis: A Crossmatch of Catalog-1 CHIME Bursts with Historic Local Universe Supernovae

The origin of the newly found astronomical object, fast radio burst (FRB), remains unknown. We have been motivated to conduct research in hopes of discovering its origin. In 2020, researchers discovered FRB-like emissions originated from SGR 1935+2154. SGR 1935+2154 is a highly magnetized neutron star in the Milky Way formed approximately 20,000 years ago through a Type II supernova event. The fact that FRB-like emissions were found to be originated from SGR 1935+2154 has advocated a potential connection between FRBs and core-collapse supernovae. Several FRB models propose that young (< 100 yrs) and highly magnetized neutron stars can produce FRBs. Our research aims to test the connection between FRBs and supernovae by cross-referencing the positions of historic local universe supernovae with FRBs detected by CHIME.

Abstract Name: Development of an Electrospray Procedure for Production of Microscopic Beads for Biomedical Applications

Mammalian cells thrive in three-dimensional environments, enhancing aggregation and differentiation essential for biomedical applications such as tissue engineering, cell therapy, and regenerative medicine. Alginate beads produced through reversible crosslinking with calcium chloride offer a simple method that has been shown to facilitate cell growth. Our goal is to develop a procedure to mass produce beads with consistent shape and size in sterile conditions, suitable for cell encapsulation and culture that can be used in a bio-manufacturing type procedure. Initial studies in non-sterile environments established feasibility and identified key parameters affecting bead quality. Our process employs electrospraying, with 2.0% sodium alginate delivered at a set flow rate through a charged metal needle positioned above a collection bath of cross-linking solution. Optimized conditions yielded beads under 400 μm in diameter. Variation of field height as assessed by difference between the needle and collection dish as well as applied voltage indicated that higher voltages yield smaller bead diameters while field height had a major impact on bead sphericity, size consistency, and structural integrity. Building on these results, we transitioned to sterile production within a biological safety cabinet. We have been able to produce consistent beads in small petri dishes but noted that significant modifications were needed due to printing within the metal enclosure. For example, the field height of 21.5 cm needed to be reduced to 5 cm. The small spray radius has allowed us to produce beads within tissue culture transwell inserts in an important step towards simplifying the bead separation step essential for production of cell encapsulated beads. This work describes a progression from initial non-sterile trials to a scalable, reproducible method tailored for sterile environments. Future studies would include testing to optimize viability of encapsulated cells, a key step in showing the suitability of our process for biomedical applications.

Abstract Name: Generator Stator Intermittent Ground Fault Test Instrument – Version 2.0

Synchronous generators are critical to the stability and reliability of the power grid, making their protection against electrical faults essential for national security. Among the most common faults is the stator single-phase ground fault, which often begins as an intermittent ground fault (IGF). IGFs are characterized by high transient currents and overvoltages that can cause severe damage to insulation and generator components, potentially escalating into more severe faults and resulting in costly repairs and downtime. To address this challenge, our project aims to develop Version 2.0 of the 87S test instrument, an innovative tool for staging stator IGFs and capturing fault data. Building on the validated success of Version 1.0, as presented at the IEEE 26th International Conference on Electrical Machines, this version enhances the instrument's hardware and software for greater functionality, durability, and usability in industrial environments. The primary

upgrades include redesigning the electronic circuitry to incorporate a custom power supply, battery management, and improved load switch topology. The Arduino UNO microcontroller (MCU) used in the previous version will be replaced with an STM32 MCU, offering increased processing power and flexibility. Additionally, the enclosure will be redesigned using a combination of extruded aluminum and CNC machined panels to ensure resilience to physical stresses. Our methodology combines printed circuit board (PCB) design, power system optimization, mechanical enclosure prototyping, and embedded software design. Student researchers will gain hands-on experience in all of the previously mentioned areas. The expected outcome is a robust and versatile test instrument capable of staging and capturing IGF events with higher precision and reliability. This tool will enable more effective testing and validation of protection algorithms for synchronous generators, contributing to the prevention of catastrophic faults and enhancing grid security.

Abstract Name: Cats, Witches, and Demons: The Role of the Animal Familiar in the English Witch Trials

While scholars have previously explored the role of the animal familiar during the English witch trials (1300s-1850), they have not analyzed how familiars served as the missing link between witches and their victims. Peer reviewed research has found that the familiar was scapegoated to be viewed as the witches' demonic companion and was held responsible for executing devious acts such as crop damage, sickness, or natural disasters. Given that an explanation was needed for how a witch cursed their victims from afar, I argue that the popular imagination reinvented the idea of the animal familiar to serve as the conduit between the witches and their victims. As my research has indicated, people feel the need to explain what they do not understand, especially when threatened by an unfamiliar force; the supernatural serves as a tool to fill in the voids in human knowledge. Thus, the familiar served as a much-needed scapegoat during the witch trials, so that those who felt threatened by the presence of witchcraft could regain a sense of control upon the witches' conviction. To the best of my knowledge, this point has not been discussed by scholars. This new example draws a logical link between familiars and the supernatural to explain the inexplicable and contributes to the understanding of the relationship between witches and familiars in the English witch trials.

Abstract Name: Exploring Emotional Disturbances in Young Adults: A Personal Perspective

Mental health often takes a backseat in the lives of young adults, a reality that can lead to severe consequences. This project seeks to address the central question: How do borderline personality disorder (BPD), severe anxiety, and depression manifest in young adults, and what strategies can be used to provide effective support and overcome stigma? The purpose of this project is to explore the personal and broader implications of emotional disturbances and to challenge prevailing stereotypes surrounding mental health conditions. Grounded in the lived experience of a young adult diagnosed with BPD, severe anxiety, and depression, this research provides unique insights into the ongoing challenges and emotional complexities associated with these disorders. It seeks to make a meaningful contribution by offering a firsthand perspective that highlights the gaps in diagnosis, treatment, and societal understanding. The research emphasizes the need for accurate representation and stigma reduction when discussing emotional disturbances. The methodology involves an autoethnographic approach, combining personal narrative with an analysis of broader trends in mental health awareness and care for young adults. By sharing personal experiences, this project aims to provide a nuanced understanding of how these disorders impact daily life, relationships, and self-perception. Expected results include shedding light on the realities of emotional disturbances, debunking stereotypes, and advocating for informed mental health education. The discussion will center on how stigma and misinformation exacerbate mental health challenges, while also offering recommendations for fostering empathy and effective support systems. Ultimately, this project underscores the importance of prioritizing mental health and creating spaces where young adults feel seen, heard, and supported.

Abstract Name: A Chronology of Controversial Comics: Representations of Queer Desire Amidst American Comic Censorship in the Twentieth Century

This presentation discusses a new project from the Digital Humanities and Literary Cognition Lab that explores Michigan State University's comic book collection, the largest public collection of its kind in the world. Through the metadata listed in this database, we analyze the historical and cultural context of the creation of the Comics Code Authority (CCA), and its lasting effects on the content and reach of taboo works in the landscape of comic creation. In particular, we explore representations of queer desire in American comics over time and how they were affected by the CCA and shifting sexual politics of the twentieth century. Initially, we chart the trends in content preceding the implementation of the code to better observe to what degree moral panics in the 1950s were guided by reactionary ideologies. Then, we observe the effectiveness of the code across the country, with state by state breakdowns of data trends and enforcement of the CCA. Finally, we look to the dissolution of the code, and the effects it had on queer identity and expression in comics. The implementation and effects of the CCA can be compared to the targeted suppression of queer art, expression, and identity throughout history, from Radcliffe Hall and Robert Maplethorpe to modern book bannings and educational policy. By bringing this data to light, we observe historical persecution of marginalized sexual identities in a mass medium reflective of the cultural zeitgeist. Pop culture is reflective of general cultural ideas, and censorship of pop culture may be reflective of mass cultural persecution. Through the interdisciplinary analysis of this data, incorporating both digital humanities methods of visualization and sociopolitical examination of queer theory, we can effectively map the history of queerness and political persecution through comics.

Abstract Name: An Exploration of The Growing Demand for Full-Time Forensic Genetic Genealogy Positions in Pittsburgh

Since its emergence in 2018, Forensic Genetic Genealogy (FGG) has rapidly grown, becoming a valuable tool in criminal investigations, particularly in solving cold cases. FGG can uncover new leads and identify previously unknown individuals tied to cases, making it an indispensable asset in law enforcement. This growing science has also contributed to job creation, especially in areas like Pittsburgh. The Bureau of Labor Statistics predicts a 14% growth in the employment of forensic science technicians from 2023 to 2033, far outpacing average job growth. As FGG technology evolves, researchers have made significant advancements.

For example, Erturk et al. developed a proposed strategy that can find close genetic matches ten times faster than the current Benchmark Strategy. These innovations highlight the need for more full-time researchers to improve and harness FGG's full potential. Currently, forensics teams often rely on outsourced experts in genetic genealogy. This presentation explores the demand for a full-time FGG position within Pittsburgh-area police departments. By surveying local law enforcement and interviewing regional experts, the project will provide insights into future job opportunities in the area. Key questions addressed include: (1) How is FGG used in criminal investigations today? (2) What would a full-time FGG position entail (duties, hours, work environment)? Ultimately, the presentation argues that FGG, while still emerging, is a powerful tool that should be incorporated into the criminal justice curriculum and supported within law enforcement. Doing so would allow forensic professionals to explore new opportunities and fully leverage the benefits of this groundbreaking technology.

Abstract Name: Assessing the anti-biofilm activity of novel benzo[b]thiophene derivatives with potential antibacterial activity.

Antibiotic resistance occurs when bacteria develop mechanisms that allow them to withstand the effects of antibiotics. This problem can arise from overusing or misusing antibiotics, as well as from incomplete treatment courses. The need for new classes of antibiotics is growing as antibiotic resistance poses an increasing threat to patient care. One major contributor to bacterial resistance is the rising prominence of biofilm-related infections. A biofilm is a complex community of microorganisms, such as bacteria and fungi, encased within a self-produced matrix of extracellular polymeric substances (EPS). Biofilms can form on living tissue, medical devices, and industrial equipment. The EPS matrix can impede the ability of antibiotics to eradicate the microorganisms within the biofilm. Given all these challenges, novel antibiotic classes are crucial in combating the resistance. Benzo[b]thiophene is a compound that exhibits various biological activities, such as acting as an anti-inflammatory, anti-diabetic, and antidepressant agent. Furthermore, it is found in four Food and Drug Administration (FDA)-approved medications, including anticancer, antifungal, and antibacterial drugs. The numerous successes associated with this compound have sparked interest among medicinal chemists, positioning it as a promising candidate for a novel class of antibiotics. This project explores the effectiveness of novel benzo[b]thiophene-derived antimicrobial agents in preventing biofilm formation. The efficacy of these agents is evaluated through Minimum Biofilm Inhibition Concentration (MBIC) biofilm assays. Consistent low MBIC values of these antimicrobial agents would support the development of potent antimicrobial drugs, offering an important tool in alleviating the ongoing antibiotic resistance crisis. By targeting biofilm-related infections, these agents could help preserve the effectiveness of antibiotics for generations to come.

Abstract Name: Adaptive Locomotion System for Planetary Exploration Robots (ALSPER)

As humanity begins to explore deeper into the universe, the field of robotics has become more crucial than ever. One of the greatest challenges for planetary exploration robots is navigating the variety of surfaces and obstacles that the robot will encounter on its journey. This study investigates the use of an adaptive locomotion system on a quadrupedal robot, combining legs and shape-shifting wheels to improve the robot's mobility performance for a variety of planetary terrains. The shape-shifting wheel, which transforms from a circular wheel configuration to a flattened rim mechanism (FRM), is integrated into each quadruped leg to allow for three primary modes of locomotion: rolling, walking, and FRM/crawling. This approach aims to bridge the gap between traditional single-mobility systems and adaptive movement technology, thus informing and advancing the designs of next generation planetary robots. By utilizing the principles of terramechanics, the system is specifically designed to reduce the possibility of entrapment in soft, deformable soils. During static testing of a single wheel prototype in two planetary soil simulants, it was shown that the FRM configuration is more effective at reducing sinkage than a wheel or foot configuration, so this study aims to investigate those results on a larger scale with the entire quadruped. A sand testing pit will be fabricated inside a Vicon-camera equipped planetary simulation facility, allowing precise motion data to be collected. IMU, force-torque, motor current, sinkage level, wheel slip ratio, and movement speed data will also be collected. This data will be evaluated and compared to the performance of single-mobility systems to determine the effectiveness of an adaptive locomotion system for applications in planetary exploration. The findings of this study are expected to contribute valuable insights into the design and operation of future planetary exploration robots, with implications for both robotic and human exploration missions.

Abstract Name: Investigating the Potential Ability of the TLR4-NF- κ B Axis to Reduce Aryl Hydrocarbon Receptor Expression in Intestinal Epithelial Cells

Necrotizing enterocolitis (NEC) is a disease that primarily affects premature infants and is characterized by intestinal necrosis, inflammation, and oftentimes death. Previous studies suggest Toll-like receptor 4 (TLR-4)-induced apoptosis of intestinal epithelial cells is required for NEC development. Upon binding to bacterial endotoxin lipopolysaccharide (LPS), TLR-4 signaling ultimately leads to the nuclear translocation of the transcription factor NF- κ B to initiate expression of inflammatory genes. Treatment with indole-3-carbinol (I3C), a pro-ligand of the ligand-dependent transcription factor aryl hydrocarbon receptor (AhR), prevents NEC in a mouse model by leading to decreased expression of TLR-4, despite decreased AhR expression in the intestine of NEC mice. However, it is unclear if AhR ligands can be used to treat, not just prevent, NEC. Here, we modeled NEC in vitro by treating IEC-6 enterocytes with LPS and investigated the effect I3C administration has on the viability of LPS-treated cells. I3C was unable to reverse LPS-induced cytotoxicity as measured by MTT assay. Next, we sought to elucidate the mechanism behind the decrease in AhR expression we saw in cells treated with LPS. We hypothesized that LPS's stimulation of the TLR-4-NF- κ B axis was responsible for this reduction. We pretreated IEC-6 cells with a TLR-4 inhibitor, C34, for 30 minutes followed by a 6 hour LPS treatment. There was no significant difference in AhR expression between cells treated with LPS and cells pretreated with C34 followed by LPS, suggesting the observed decrease in AhR expression is not dependent on TLR-4. We next used an NF- κ B inhibitor, JSH-23, instead of C34, and found LPS's ability to reduce AhR expression was abolished with JSH-23 pretreatment, suggesting NF- κ B is required for LPS treatment to decrease AhR expression. Elucidating the molecular mechanism behind the reduced AhR expression in NEC patients might increase the efficacy of AhR ligands as novel NEC therapies.

Abstract Name: Within the Woman Writer: Discussing Dialogism, Adrienne Rich, and the Debate of Deconstructionist Prose

In times of social and political unrest, theorists, historians, and writers provide frameworks for grieving, hoping, and moving forward. Writers, especially, often stand at the crossroads of social unrest, developing essential discourses that enable society to critically examine the world. This session will demonstrate how my research and creative work have combined to contribute to the discourse of feminist writing by offering an overview of the craft essay component of my senior capstone project, which discusses deconstructionist writing. This oral presentation will mainly demonstrate how my senior capstone work engages with conversations in contemporary literature by examining the voices and ideas of revolutionary writers and theorists, focusing specifically on the contributions of Mikhail Bakhtin, Adrienne Rich, and Maggie Nelson. Bakhtin's concepts of dialogism, or "the maintaining of a continual dialogue with other works of literature," and heteroglossia, or speech diversity, serve as driving forces in my craft essay (Paton 2). Bakhtin's theories connect the significance of diverse, continuous discourse to the values inherent in my own feminist writing. The essay will also draw upon the critical works of Adrienne Rich, focusing on her explorations of revision as a method of resistance against dominant cultural narratives. Finally, memoir research prose inspired by Maggie Nelson's *The Argonauts* will highlight the role radical resistance to the status quo has in shaping my literary approach. Overall, insights from these discussions will illustrate how a writer's voice can form in response to and in resistance against social conventions. During the oral presentation, audience members will have the opportunity to review excerpts from my peer-reviewed creative portfolio that will demonstrate how my work is in conversation with these theories. Attendees will leave with a deeper understanding of what revision, reflection, and resistance signify within modern feminist discourse.

Abstract Name: Exploring Exosome Interactions with the Blood-Brain Barrier: Implications for Alzheimer's Disease Mechanisms and Progression

Alzheimer's Disease (AD) affects over 55 million people worldwide, and this number continues to rise annually. While significant research has focused on the mechanisms of the disease, one promising area still underexplored is the role of exosomes. Exosomes are tiny vesicles produced by every cell type and act as messengers between cells. They are gaining attention for their potential influence on the central nervous system (CNS) and the blood-brain barrier (BBB) in particular. The BBB acts as a highly selective barrier between the brain and the bloodstream, which is essential for protecting the CNS and maintaining its function. It is composed of endothelial cells, pericytes, and astrocytes that collectively prevent harmful substances from entering the brain while allowing necessary nutrients and oxygen through. In AD, however, the BBB becomes compromised, leading to increased permeability and reduced selectivity. To investigate the interaction between exosomes and the BBB, we will culture astrocytes, pericytes, and endothelial cells

separately. Then, we will co-culture them in a small microfluidics device to emulate the BBB environment in vitro. Exosomes will be immunofluorescently stained and then applied to individual and co-cultured cells and left in the incubator for 24-48 hours. Morphological changes and cellular uptake will be observed and quantified. Exosomes are known to cross the BBB, however, it remains unclear whether exosomes are actively causing BBB breakdown or if they are acting on an already-compromised barrier. Investigating this relationship could provide key insights into AD progression and uncover therapeutic opportunities to protect or restore BBB integrity.

Abstract Name: Microhomology Mediated End Joining, After CRISPR/Cas9-Induced Double Strand Break in *Aedes aegypti*

Aedes aegypti mosquitoes are notorious vectors of several dangerous diseases, including dengue fever, Zika, chikungunya, and yellow fever, posing a health risk to millions of people worldwide. The emergence of CRISPR technology has revolutionized genetic manipulation, however, its efficiency in producing precise edits varies across species, largely due to differing repair pathway preferences. This study aims to clarify the role of Microhomology Mediated End Joining (MMEJ) in repairing CRISPR/Cas9-induced double-strand breaks (DSBs) in *Aedes aegypti* mosquitoes, by quantifying the frequency and characteristics of MMEJ mediated repair events in comparison to the pathway of choice NHEJ, through targeted sequencing and bioinformatics analysis. Utilizing three mosquito lines with knockout genes that encode key proteins only present in NHEJ (Ku80, DNA-PKcs, Lig4) crossed to a laboratory-generated transgenic line and a control. Following the microinjection of 300 embryos from each line with three different sgRNA/Cas9 complexes, genomic DNA extraction and PCR analysis for the target region were performed. The data was analyzed using three bioinformatic tools: CRISPRessoWGS, Minimap2, and Samtools. The results revealed a significant increase in MMEJ repair events in the Ku80, and DNA-Pkcs knockout lines compared to the wild type, indicating that microhomology mediated repair occurs at much higher frequencies in the absence of these key proteins. In contrast, the Lig4 knockout line did not show this relationship, suggesting that this protein may play a role within the microhomology repair pathway. These findings provide crucial insights into the prevalence of MMEJ as a repair mechanism, providing a foundation for optimizing CRISPR applications for controlling mosquito-borne diseases and enhancing our understanding of genetic resilience mechanisms in insects.

Abstract Name: Examining Fatalism in Hispanic/Latina Breast Cancer Survivors

As fatalism, a person's attitude towards their life, increases, there is a significant level of medical mistrust and avoidance, which can delay cancer diagnoses and affect the prognosis of the disease. Literature has shown that many factors can influence fatalism, including age, race, acculturation, locus of control, education, and fear. However, little research has been conducted on whether fatalism differs independently by Hispanic origin and its associated factors among Hispanic breast cancer survivors. This study used data from the Hispanic Breast Cancer Study at the University of Central Florida. The original study recruited 408 women aged ≥ 20 years, diagnosed in 2015-2022 with breast cancer and living in Central Florida, following the state-mandated patient recruitment procedures. Fatalism was measured using six questions in the Multidimensional Fatalism Measure questionnaire, each being scored using a 5-point Likert-type scale, with higher scores indicating a high fatalistic belief. Fatalism scores will be compared by self-reported Hispanic/Latina origin while controlling for potential confounders in the multivariable linear regression analysis. This research will identify potential confounders in Hispanic/Latina breast cancer survivors that previously were unclear. It is expected that fatalism scores will differ significantly by Hispanic/Latina subgroups independently due to differences in cultural beliefs according to their Hispanic origin. The findings from this research can help physicians gain a deeper understanding of breast cancer survivors' attitudes toward their lives according to their Hispanic origin, which will improve patient care. (A grant from the Florida Breast Cancer Foundation to Dr. Lee supported this study.)

Abstract Name: The Brief Attitudes Toward Solo Masturbation Scale: Convergent and Divergent Validity

Masturbation is common and normal from childhood to old age. Taken from a representative sample of adult Americans, less than 40% of women and more than 60% of men have masturbated within the past year. For some people, masturbation has many benefits, such as exploring one's sexuality, learning to appreciate one's body, and helping relaxation and sleep. For other people, masturbation is associated with relationship dissatisfaction, beliefs of sinfulness, and feelings of shame. Having a measure of attitudes towards masturbation will help explain why people's experiences with masturbation can be so different. Existing measures of attitudes towards masturbation are outdated, too long, and fail to differentiate between positive and negative attitudes. This study's purpose is to develop an updated and improved scale measuring attitudes towards masturbation. We developed 12 items assessing positive attitudes towards masturbation and 12 items assessing negative attitudes towards masturbation, based on previous research. We are going to conduct an online study in which we will administer 24 attitude items, measures of demographics, religiosity, and other related constructs to a sample of 1,500 adults. As presented by my colleague, Christopher Ginn, we will use exploratory factor analysis to refine the attitude scale. Our goal is to have very brief subscales assessing positive and negative attitudes. Next, we will assess the convergent and divergent validity of the new scale. Convergent validity assesses whether scales that should be related are actually related. Divergent validity assesses whether scales that should not be related are actually not related. For example, we hypothesize that religiosity will be more strongly correlated with negative attitudes towards masturbation than with positive attitudes. This new measure of attitudes towards masturbation will shed light on why people have positive or negative experiences with masturbation.

Abstract Name: Relationship Between Big Five Traits and Movie Genre Preferences

This study investigates the relationship between personality traits and movie genre preferences, exploring if Big Five traits and movie genre preferences are correlated. The BF-10 and a movie genre preference survey were combined and sent out to gather data from participants. Three significant results were found. Openness was positively correlated with science fiction movies and fantasy movies, and neuroticism was negatively correlated with sports movies. No other relationships were found between the other Big Five traits. These results support the literature, finding connections between personality traits and movie genre preferences. While this study did not find a connection between all five traits, it supports the correlation between personality and entertainment preferences. This relationship impacts the way we understand films, as our personality is shown to impact what we enjoy or dislike within the entertainment industry.

Abstract Name: The Association Between Stigma Consciousness and Internalizing Problems in Children with a Neurodevelopmental Disorder

Neurodevelopmental disorders (NDD) are a group of conditions that have an onset in the developmental period that cause deficits which impair functioning (APA, 2022). This study targets NDD diagnoses including Specific Learning Disorders (SLDs) and Attention-Deficit/Hyperactivity Disorder (ADHD). SLDs are disorders that impact an individual's ability to acquire and use academic skills in areas such as math, reading, and/or writing (APA, 2022). ADHD is defined as persistent and impairing levels of inattention, disorganization, and/or impulsivity (APA, 2022). SLD and ADHD are commonly comorbid disorders (Gnanavel et al., 2019). Previous research indicates individuals with an SLD and/or ADHD experience increased internalizing problems and elevated levels of stigma (Fogleman et al., 2018; Haft et al, 2023). This study aims to address the gaps in literature regarding how stigma consciousness – the extent to which a child expects to be stereotyped due to their NDD identity – might contribute to internalizing problems. Validated self-report measures include the Stigma Consciousness Questionnaire – Learning Disabilities, which assesses stigma consciousness, and the Behavior Assessment System for Children, Third Edition, which evaluates internalizing problems. Data collection for this project is ongoing. The current sample includes 49 children (57.1% female; Mage=12.24 years, SD=1.09), all diagnosed with an NDD (12 SLD, 15 ADHD, 22 SLD+ADHD). NDD status was confirmed through official diagnosis documentation. Descriptive statistics

and bivariate correlation analyses will be conducted. Regression analysis will be conducted with internalizing problems as the dependent variable and stigma consciousness as the independent variable. Child's sex and age will be included as covariates. The moderating effect of sex on the relationship between stigma consciousness and internalizing problems will also be examined. Results will provide insights into the mechanisms through which anticipating stigma may contribute to increased internalizing problems, such as anxiety, depression, and somatization.

Abstract Name: Enhancing the Pipeline for Undergraduate Research Participation and Prioritizing Accessibility and Inclusiveness.

The Department of Biology at The College of New Jersey (TCNJ) has a long history of student engagement in mentored undergraduate research. Over 50% of our graduating seniors have a mentored research experience. Several initiatives account for this. In addition to support of summer research opportunities by individual faculty grants, TCNJ also funds an 8-week Mentored Undergraduate Summer Experience. To attract students to mentored research, the department sponsors an annual How to Get Involved in Research Workshop. Our department exposes all students to authentic research through expanded incorporation of Course-based Undergraduate Research Experiences (CUREs) into its curriculum. Our students present their research results to fellow students in an annual campus-wide Celebration of Student Achievement. The department has been successful in attracting undergraduate students to engage in mentored research through the above initiatives, but we have been aware that the level of participation in mentored research has not been equal across the student population. Despite our previous efforts, many students have not had an understanding that they, too, could participate in mentored research. Some students have not had the social capital or the comfort level to approach faculty mentors to request that they might participate in mentored research. Furthermore, with an increase in student participation in research, we no longer have the capacity to offer experiences to all students who express an interest. To address these issues, the department adopted an on-line application process for students to participate in mentored research. This process has removed several barriers. Many students now feel that they have equal access to mentored research opportunities and that the new application process appears to be more equitable and inclusive because it either bypasses possible implicit bias by faculty mentors or it removes barriers to participation by underrepresented students.

Abstract Name: The Horse as Healer: a Sensory Ethnography of Equine Assisted Therapy

Equine-assisted psychotherapy (EAP) is the integration of horses into human healing practices. Historically horses were assumed to provide benefits primarily through riding, but as psychotherapy began leaning on them in the 1990s we saw an influx of ground-based programs. In this approach, the interactions and relationships with horses are central. This project embraces the value of more-than-human sensory

ethnography and examines ground-based EAP at a wellness center in Forest Lake, Minnesota called Acres for Life. At Acres, the horses are considered vital partners in therapy sessions. This study explores how horses and humans co-create meaning in their interactions. It is important to note that the ‘horse as healer’ philosophy is not new despite only appearing recently in scholarship. Native nations have known about the horse as a healer for far longer. This study seeks to honor Indigenous knowledge through conversation with faculty in the equine studies program at Nueta Hidatsa Sahnish tribal college in North Dakota. It draws on sensory studies, which acknowledge that humans and animals experience reality through their senses. This includes horses in a way that would not be possible if the study focused solely on interview-based methods. Data was collected through interviews with staff members, volunteers, and clients; participation in workshops and trainings; participant observation; shadowing therapy sessions; and an extensive literature review. The resulting ethnography explains the meaning-making process at Acres: beginning with intake of sensory information, then processing based on individual experiences, and finally, application of storytelling mindset for healing. This study has implications for animal ethics by attempting to know the inner experience of horses. It also has implications for empathy and understanding across differences. Finally, this study adds to a growing body of literature that honors Traditional Knowledge relating to animals as equal cohabitants in our environment.

Abstract Name: WiFi based human activity recognition system

Recently, device-free human behavior recognition has emerged as a prominent research area, achieving significant progress across various professional fields. Among these advancements, the rapid development of WiFi sensing has garnered considerable attention due to its potential to address complex applications. By combining WiFi sensing with deep learning methodologies, researchers have been able to tackle numerous challenges in this domain effectively. In this paper, we explore the use of Channel State Information (CSI) from WiFi systems to recognize human behavior in indoor environments. Human body movements affect wireless signal reflections, resulting in unique alterations in CSI features. This study focuses on leveraging these features to detect and classify human behaviors accurately. To accomplish this, CSI tools are utilized to collect reflected signals generated by various human activities. As raw CSI data often contains noise, we preprocess the data to filter out irrelevant information, enabling the extraction of meaningful features. Deep learning techniques are employed to classify these features, while deep learning models are constructed to improve recognition accuracy. Through these methods, human behavioral activities can be effectively identified. We conduct a series of experiments to ensure the models are trained on comprehensive datasets, facilitating robust behavior detection. The study also compares different sensing tasks, evaluating recognition accuracy, computational complexity, adaptability, and trade-offs related to model size. Furthermore, practical applications of CSI-based systems are discussed, along with critical considerations for implementing reliable behavior recognition systems. Finally, this paper addresses open challenges in behavior recognition applications based on CSI and provides suggestions for future research directions. These recommendations aim to enhance WiFi sensing capabilities and expand its applications. Through innovative use of CSI and deep learning, this paper seeks to contribute to the advancement of human behavior recognition technologies.

Abstract Name: Utilization of density functional theory to optimize the synthesis of N-heterocycles

Computational chemistry has been used to help explain experimental results and determine further courses of action—for example, saving time and money in determining an optimal pathway for a product's synthesis. In this case, examination of the electronic energy, transition structures, and ground state energies was used to determine whether more electron-rich or electron-poor substituents were optimal in driving forward triazolidine synthesis. A wide variety of nitrogen-containing heterocycles have demonstrated bioactivity, and this compound's preliminary biological data shows high levels of cytotoxicity. Density functional theory was used to determine all energies; the density functional used was M06-2X, and the basis set used was mAug-cc-pVTZ. It was chosen for its high accuracy in organic systems.

Abstract Name: Behind the Screen: How Personalized Ads Shape Your Social Media Experience

In today's fast-paced digital world, companies are constantly striving to capture attention through personalized and generalized forms of advertising. As we dive deeper into the social media era, understanding people's perspectives on these approaches has never been more crucial. Specifically, I'm interested in studying Americans' views on the privacy concerns and user experience of personalized advertisements. Prior to this study, I had hypothesized that female respondents would have a higher frequency of encountering personalized advertisements compared to males, and that female respondents would also purchase from personalized ads more often than males. In order to test the hypotheses, I wrote a 16-question survey and used the platform Amazon mturk to collect 228 completed surveys. I then used IBM's SPSS to analyze the results. Interestingly, the results from the survey yielded some unexpected and significant insights. While I expected that females would be presented with more personalized ads than males which was found to support my hypothesis, it was surprising that my second hypothesis was contradicted by the data showing that males actually purchased statistically more than females at the one percent level of significance. For companies, this finding could implicate a shift in marketing strategies, potentially redirecting their focus towards male consumers in order to maximize profitability.

Abstract Name: System Suitability Assessment of Ciprofloxacin Analysis by HPLC at Hamline University

Medication health fraud, when medications are being marketed with false and misleading information, has become a serious concern in lower-income countries. To assist with this issue, the organization Distributed Pharmaceutical Analysis Lab (DPAL) partners with the World Health Organization and academic institutions across the United States to perform drug quantifications on suspect medications from countries such as Kenya, Uganda, and Nepal. This work describes the first stage of a two-stage system suitability assessment of the DPAL method for analyzing ciprofloxacin, an antibiotic, at Hamline University which will enable future analysis of drug samples. The first stage of system suitability assessment entailed validating the performance of a high performance liquid chromatograph using a certified reference standard. For our analysis, we used isocratic reverse-phase high performance liquid chromatography with a C18 stationary phase and a mobile phase composed of acetonitrile and buffer in a 135:865 ratio, where the buffer consisted of 0.29% v/v phosphoric acid in water, pH 3. A series of assessments were performed to determine the precision, accuracy, and range. A calibration curve for ciprofloxacin was created and the linearity, limit of detection, and lower limit of quantification of the method were determined. In addition to these tests, a control chart was developed to determine the stability of ciprofloxacin at room temperature, which was found to be five weeks. All acquired data fell within the acceptable range that is set by DPAL. The results of this project have enabled us to progress to phase two of testing, involving the assessment of matrix effects and performing a spike recovery. Upon success, we will begin sample analysis of suspect ciprofloxacin tablets to ensure they are safe for public consumption.

Abstract Name: The Role of Middle School Mentor Teachers in Fostering Relationships with Teacher Candidates

Middle school teaching presents unique challenges that require teacher candidates (TCs) to develop specialized skills in classroom management, adolescent engagement, and curriculum adaptation. Mentor teachers (MTs) in middle schools are critical in developing TCs' ability to navigate these nuances. However, little is known about how middle school MTs prioritize, perceive, and foster relationships with TCs during their field experiences. This study focuses on middle school MTs within local school districts, addressing (a) the extent to which they prioritize their relationships with TCs, (b) their expectations and assumptions about mentoring relationships, and (c) the strategies they use to cultivate meaningful connections. This research employs a comparative case study design within a constructivist framework, using semi-structured interviews to explore middle school MTs' mentoring practices. Thematic coding will be applied to determine patterns and align findings with existing literature on effective mentorship. Middle school MTs face the dual challenges of managing a dynamic educational environment and mentoring TCs, making this study critical for understanding how to optimize these relationships in this context. By focusing on the mentoring dynamics specific to middle school MTs, this study provides actionable insights for enhancing teacher preparation programs. The findings aim to inform policy and practice, offering resources and strategies that empower middle school MTs to support TCs effectively, fostering their professional growth and readiness to succeed in diverse classroom settings.

Abstract Name: Oral Histories on Local Nurses

Many people have an eye-opening moment in their childhood that inspired a career in the medical field, whether they were influenced by a family member in that profession or clarity in high school. Oral histories involve conducting interviews with individuals to gather their personal accounts and insights regarding their life experiences or specific historical events. The proposed research question is: How are oral histories used to show patterns in nursing through time? Conducting an oral history requires audio and video equipment for the recording aspect of an interview. After an oral history is completed, time is spent transcribing the interview. Transcription is the process of converting spoken language into written words. All documentation will be preserved for future research within the University of Wisconsin-Milwaukee Archives. The University of Wisconsin-Milwaukee College of Nursing has their own museum of nursing, which contains nursing tools used from WW1 to the different pins from graduated nurses. Understanding nursing history over hundreds of years allows people to better comprehend nursing. For oral histories in this project, a nurse within the Milwaukee community is asked to share their life (education and career) guided by an interview of questions. An example question could be, "How did technology change from the start to the end of your career?" Currently eight oral histories have been conducted and the aim for the following year (2025) is to conduct eight more. The overall significance of completing oral histories on nurses within the Milwaukee community is that it will give people the resources to connect nursing experiences over time, similarities or differences in nurses' personal and work lives. Along with this, research will bring more attention to the UWM Center for Nursing History, publicizing nurses' influence in health care.

Abstract Name: Synthesizing Magnetic, Fluorescent, and Biocompatible Nanoparticles for the Purpose of Starfish Larvae Digestive Tract Imaging

In the world of innumerable nanoparticles, iron oxides have held a special place due to their versatility in many unique properties such as magnetic, fluorescent and biocompatible properties. Of all these qualities could be applied to a nanoparticle of less than 100 nm, then those would be used to map the digestive tracks of star fish larva. This magnetic property allows selectively view of a single larva while fluorescence allow to map the evolution of organic materials that is used as nutritional source for developing these invertebrates. Our work starts with determining methods used to synthesize and collect microwave-assisted iron oxide nanoparticles. We focus on a variety of nanoparticles which were synthesized by using polyethylene glycol (PEG), β -cyclodextrin, water, and ammonia. The nanoparticles are characterized using Fourier-transform Infrared Spectroscopy, Transition-Electron Microscopy, and Raman Spectroscopy to further narrow down their unique physical properties before introducing these to the star fish lave.

Abstract Name: Investigating Antimicrobial Efficacy and Applications of Carbamoylated Guanidine Modified ϵ -Poly-L-lysine Biopolymer Compounds

The problem of antimicrobial resistance has been an increasing concern for the health and scientific communities for several years. As the availability of complex antibiotics increases, so does the emergence of resistant bacteria known as "superbugs." This research is adding on new systems that can inhibit the growth of antimicrobial-resistant germs through specialized compound modifications. One such compound is ϵ -Poly-L-lysine (ϵ -PLL), a natural peptide commonly known for its biocompatible, biodegradable, and antimicrobial properties, as well as for its applications as a food preservative. Although the active antimicrobial activity of this polymer is well documented against bacteria and plant pathogens, as research progresses, newly edited ϵ -PLL compounds have emerged which seek to enhance various applications, such as protein delivery, anticancer agent enhancers, and drug delivery. Due to the polymer's biocompatible properties, edited ϵ -PLL compounds were synthesized with different ratios of phenyl-, naphthyl-, anisole-, and nitro- carbamoylated guanidine monomers by FIU's Dr. Joongho Moon laboratory. Furthermore, through previously recorded unedited ϵ -PLL testing, moderate antimicrobial activity was observed, which led to the hypothesis of increased levels of antimicrobial activity for the modified ϵ -PLL compounds. This research tests the variations of the modified ϵ -PLL compounds for antibacterial effectiveness as well as each monomer unit of the polymer through Minimum Inhibitory Concentration (MIC) assays against *B. subtilis*, *E. coli*, and *M. smegmatis*. The importance of modified ϵ -Poly-L-lysine compounds is justified, as the effective development of these can aid in identifying promissory concentrations and possibly enabling targeted delivery of antimicrobial products to specific sites. Through our research, we aim to provide valuable insights that could advance therapeutic interventions against resistant microorganisms.

Abstract Name: Unlocking Potential for HydroFloat™ Technology: Collector Screening for Enhancing Coarse Particle Recovery

The advancement of HydroFloat™ technology represents a major breakthrough in mineral processing industry, especially in coarse particle flotation, pushing the boundaries of the "Elephant Curve" limitations. This cutting-edge technology has brought significant improvements to mineral separation by enhancing the recovery of valuable minerals from larger ore particles. Despite these advancements, its full potential has yet to be fully harnessed. A key to its success is rooted in the chemical principles of the flotation process, particularly the types of collectors used and their adsorption mechanisms. Enhancing these chemical

interactions has the potential to greatly improve the performance of HydroFloat™ technology. This research highlights the impact of dithiocarbonate (DTC) and dithiophosphate (DTP) collectors, which are commonly employed to boost the flotation efficiency of sulfide minerals. To explore their potential for enhancing flotation performance, eight distinct DTC and DTP collectors, developed and produced by Syensqo, were selected, each featuring unique chemical structures and varying carbon chain lengths. The methodology consisted of controlled flotation tests in which both the type and dosage of collectors were adjusted to evaluate their effects. The primary goal is to boost recovery rates and selectivity in coarse particle flotation by refining the chemical interactions between the mineral surfaces and these collectors. The findings from this research will provide insights into how variations in collector chemistry could influence flotation outcomes. This exploration into the chemical nuances of flotation collectors is poised to contribute valuable data to the field, possibly leading to more effective collector designs tailored for specific mineral types and conditions, thereby enhancing the capabilities of HydroFloat™ technology.

Abstract Name: Examining Women Pirates During the Golden Age of Piracy and How Sexism Influences History

The recollection of the Golden Age of Piracy (~1650-1730) is viewed as a time of seafaring escapades. The major retellings of this era often recount tales of men navigating the sea in search of adventure. Historically, the lives of women in relation to piracy has been erased from the narrative, their influence during this swashbuckling era has been incessantly disregarded. This researcher seeks to understand the historical and modern influence that sexism has in creating the lens we view female pirates through. By deeply examining the lives of Captains Zhang Yi Sao, Anne Bonny, and Mary Read, and analyzing historical data found in Captain Charles Johnson's primary source *A General History of Pyrates* (1724), the researcher intends to answer the question: What lives did women lead during Golden Age of Piracy, and how has sexism impacted their legacy? This analysis will uncover the complex lives that women lead throughout the Golden Age of Piracy, while also explaining how deeply ingrained sexism is in the recounting of historical periods. The researcher will also explore the modern influence of sexism by analyzing the legacy of female pirates and their depictions in media. By explaining the reasons why female piracy is erased from history, the researcher will emphasize the importance of women's roles in history across all fields of study. In doing so, the researcher will educate those unaware of female pirate Captains and crew members, and the broader historical context of women's lives throughout this age, while affirming the relevancy of discussing minority representation within academia.

Abstract Name: Passive Health Assessment of Sea Mammals (PHASM)

Potential anthropogenic (human-caused) stressors on marine wildlife continue to increase, yet how marine mammals fare physiologically under these conditions remains largely unmeasured. For example, noise sources may trigger a stress response in whales and dolphins, which typically causes health and cognitive deficits in other mammals under chronic exposure. Yet, we do not have data of sufficient quality to demonstrate how anthropogenic noise impacts the health of these highly protected and unique species. The objective of this project is to collect health data from dolphin blowhole mucus as animals surface to breathe using a custom uncrewed aircraft system (UAS) developed for cetacean applications. The UAS, or drone, will fly 1-2 meters above the animal and collect a blow sample as they surface to breathe. While rotary-wing drones have been used to collect samples from large whales, smaller cetaceans such as dolphins present a greater challenge for sample collection in the wild. Data from observations indicate that the use of standard commercial drones will result in inaccurate data as the system noise will likely increase stress hormone levels and chase subjects away. Furthermore, rotary wing drones are likely to blow viable samples away through downwash from the spinning blades. However, silent fixed-wing capable drones will enable accurate estimation of stress levels, pathogen load, and microbiological contaminants through the successful collection of blow samples, since dolphins should be unable to hear and see the drone based on observations mapping the dolphin field of vision as well as their sensitivity to different drone sounds. This project summarizes the design, development, and successful demonstration of the PHASM (Passive Health Assessment of Sea Mammals) UAS for the collection of blowhole mucus samples from dolphins.

Abstract Name: Beard Length and the Efficacy of an Aviator Oxygen Mask

Facial hair is prohibited for most airline pilots because of the widespread belief that the seal on oxygen masks might be rendered ineffective, preventing aircrews from performing their duties during emergencies. Continuous oximetry recordings were made every second from 24 volunteers wearing a standard commercial airline mask in one of 3 beard conditions: no beards, short beards (< 10 mm in length) and long beards (> 10 mm in length) in a normobaric hypoxia chamber at 30,000 ft (10,000 m). Masks were worn in the chamber for about 10 minutes before being removed for about 2 minutes to experience hypoxia. Once returned to normoxia, volunteers were exposed to smelling salts held directly under the chin. None of the beard conditions differed in the time to don the masks. There were no differences in the arterial saturation percent of oxygen (SpO₂) between beard conditions for either mask-on or mask-off segments in the chamber. There were significant differences in SpO₂ comparing the mask-on segment to the mask-off segment, indicating that hypoxemic conditions would have been detected had the masks been ineffective. Using a current on-demand airline oxygen mask, SpO₂ levels were never compromised by any of the beard

conditions. Because the highly volatile smelling salts were imperceptible through the masks, smoke and other noxious irritants would not be perceived. These results support the contention that airline pilots with beards of any length would not be impaired by hypoxia or smoke while dealing with an inflight emergency.

Abstract Name: Identification of Host Substrates for the Secreted Internalin Proteins from *Listeria*

Listeria monocytogenes is a widely distributed environmental bacterium that is an opportunistic, intracellular pathogen for humans and livestock. *Listeria* is commonly used as a model pathogen to better understand mechanisms of disease caused by other foodborne pathogens. Establishing a robust infection in humans requires reprogramming of numerous host pathways by *Listeria* through the expression and secretion of protein-based virulence factors. The internalin family of proteins were named after the first ones identified that initiate invasion into host cells, but there is emerging evidence that they may be important at other stages of infection. *Listeria* encodes more than 20 different internalins, all possessing a N-terminal leucine-rich repeat (LRR) domain that is required for interactions with host proteins. However, the host-interacting partners remain largely unknown. To identify these host proteins, we employed a novel system that allows for the trapping of two interacting proteins. We cloned the LRR domains of the secreted internalins into this system and then expressed, purified, and validated the activity of these new constructs. Next, we optimized conditions for the trapping system to be captured from cell lysates after reacting with host proteins that interact with the LRR domain. Finally, mass spectroscopic analysis was utilized to determine human proteins that interacted with the LRR domain. Here, we identified potential host proteins that interact with the LRR domain of Lmo2445. Future work will validate of these interactions and provide a better understanding of how this promotes *Listeria* pathogenesis.

Abstract Name: From Cheap Eats to Fine Dining: Restaurants in the San Gabriel Valley as a Representation of Growing Globalization and Transnational Wealth in Asian Ethnoburbs in the Contemporary Era

Food establishments are essential to building and understanding the social and political dynamics of ethnoburbs, or suburbs mainly composed of one ethnic enclave. Immigrants and restaurants have historically depended on each other, and the availability of ethnic food continually influences immigrant life and builds community belonging. The built environment of main streets and strip malls in the contemporary ethnoburb demonstrates the centrality of restaurants in the daily lives and economies of ethnic enclaves. Existing scholarship focuses on Asian food histories in the US or Chinatowns, a more historical perspective on an urban ethnic enclave where Asian food transformed as tourist attraction fitting an American mainstream. My

study broadens the understanding of food in contemporary ethnoburbs, which is where research is lacking despite many ethnic enclaves now being situated in the suburbs. Further, previous ethnoburb research observed how ethnoburbs were formed through migration and racial politics. I will instead examine current trends in ethnic suburban neighborhoods by performing a case study of two strip malls on the same main street in the San Gabriel Valley, a large cluster of Asian ethnoburbs in Los Angeles County. These strip malls are built 35 years apart, making them a great example of a temporal change in landscape. The contrasting architectural designs and restaurant tenants exemplify how the area has changed in its spatially political and economic landscapes. Findings may be applied to other ethnoburbs across the US affected by similar forces of social mobility, transnational wealth, and racial assimilation.

Abstract Name: Recommender Systems for University Curriculum Advising

Effective academic advising plays a crucial role in enhancing student success, yet universities face challenges in optimizing advising processes and course enrollment. To address these challenges, recommender systems have emerged as valuable tools for automating personalized academic guidance, due to their capability in deriving recommendations in a wide range of data with only a few user entries. Universities can optimize their course planning and help students make informed decisions for their academic path with recommender systems. This research develops a novel recommender system tailored to undergraduate students, leveraging data on curriculum requirements, prerequisite dependencies, student preferences, and section availabilities. By leveraging data on course offerings, curriculum requirements, prerequisite dependencies, student preferences, section availability, and other relevant factors, this study develops a recommender system that helps universities increase student advising efficiencies and create more intuitive and student-centric curricula. We structured and processed complex curriculum data to foster an algorithm-ready environment, simplifying the relationships between degree requirements and course offerings. This study evaluates multiple algorithms based on recommendation accuracy, computational efficiency, and their ability to meet degree requirements. The system ensures students fulfill all degree requirements while fostering academic engagement. By streamlining course selection and exploring possible degree paths, it helps students graduate on time and navigate complex curricula. This research also collects important metrics to accurately predict class enrollment, enabling college departments to plan their course offerings better. The study significantly benefits university advising offices by reducing advisor workloads and encouraging student engagement, advancing the academic achievement of the entire student body.

Abstract Name: The Battle of Ia Drang at LZ X-Ray

The central question of this research was why the United States won the Battle of Ia Drang at LZ X-Ray in November of 1965. The Battle of Ia Drang was the first major engagement of the Vietnam War with new tactics being used on both sides that would come to define the conflict. This battle would be the first time that air cavalry was used with helicopters playing a vital role showing a change in strategy. For this examination of the battle, I looked at a wide range of primary sources in addition to some trustworthy secondary sources. The sources included were the After-Action Report on the Battle of Ia Drang and the book *We Were Soldiers Once....And Young* by Colonel Hal Moore, and Joseph Galloway. In addition to those two sources which were heavily used, I consulted interviews from soldiers who were at the battle. Initially, I used the primary sources to analyze the battle and show why the Americans were successful, then the secondary sources were used to fill in the gaps and provide more context to what happened. The United States was able to win the Battle of Ia Drang at LZ X-Ray because of overwhelming fire support provided by nearby artillery, close air support, and the bravery the men showed against a superior numerical force. While the Vietnam War would ultimately become a failure for the United States, this first major battle proved that strategies and techniques that had never been used before could be successful.

Abstract Name: Cosmic Flux Dependence on Zenith Angle and Altitude

In the past decade, multiple near surface particle detectors have been deployed to study particle signals and flux from local sources. These detectors must regularly develop methods to precisely eliminate the background signals caused by cosmic rays. Cosmic rays consist of high-energy particles originating from celestial bodies. When these cosmic rays interact with the Earth's atmosphere, they generate secondary particles such as muons which are detectable in scintillating materials. To characterize the surface muon flux for larger experiments, our objective of this research is to measure the muon flux variation with respect to the zenith angle (the angle between the incoming muons and the vertical direction) and altitude. Our study uses the Cosmic Watch Detector Project to assemble a low-cost array of handheld ionizing radiation detection. By orienting multiple detectors to accept only coincident measurements, we select a relatively narrow range of incident muon angles one at a time. A 3D self-printed apparatus is used to hold the detectors at various zenith angles, while a control pair of detectors is used to account for time-correlated muon rate fluctuations (inter-detector inconsistencies also accounted for). This is then compared to the accepted cosine-squared model for rate vs zenith angle. In addition to measuring the angular dependence of the muon flux, we used our detectors to measure the singles ionizing radiation rate at altitudes ranging from 0 to 12,200 meters above sea level during an international flight by comparing timestamped detector data to commercial flight records. The conclusions of both studies offer useful insight on the capabilities of the Cosmic Watch detectors to measure precise information about localized radiation and cosmic ray signals in scintillator detectors.

Abstract Name: Building His-tagged proteins to assess binding with Nur77, an immune cell molecule

The immune system consists of cells and proteins whose role is to protect the body against pathogens. Among these cells are T-cells that protect from diseases using a protein called the T-cell receptors (TCR), which is important for recognizing and attacking a specific pathogen. Mature T-cells must first undergo a series of steps as immature T-cells, which includes creating a unique TCR that will recognize a pathogen. Nur77 is a protein that is made in increasing amounts after the TCR binds to its target, both during T-cell development and during the function of mature T-cells. Nur77 function has been described in T-cell development, where it aids in cell death, but its role in mature T-cells is currently unknown. Therefore, previously, we used a yeast screen to discover novel protein(s) that can bind with Nur77 in T-cells, finding E2F-associated phosphoprotein (EAPP) and prefoldin subunit 5 (Pfdn5) as binding partners in that assay. To confirm these proteins physically interact with Nur77, we aimed to create versions of the proteins tagged with Histidine to isolate the protein from all other proteins in bacteria. After protein isolation, physical interaction between Nur77 and EAPP or Pfdn5 can be assessed using a pull-down assay. We also aimed to create CD5 as a negative control for binding with Nur77 in this assay. Creation of the His-tagged proteins is ongoing after presenting multiple challenges during the creation of the correct DNA. Confirming interactions with Nur77 will pave the way for future studies examining the impact of these interactions on T-cell function, expanding our understanding of the immune system responses to different pathogens.

Abstract Name: Evaluating the California Fire Gap through High Energy Sedimentary Deposits in the Carpinteria Salt Marsh

The Thomas Fire of 2017 burned 281,893 acres in Santa Barbara and Ventura Counties, and the subsequent winter rains of 2018 resulted in numerous mass wasting events (debris flows, mudslides, etc.) emanating from the many streams that descend from the Santa Ynez mountains to the coastline. The Carpinteria Salt Marsh is a rare sedimentary archive of past environmental changes, including wildfires, storm events, droughts, and floods. A 1.5-meter sediment core was extracted from the southern-central basin of the existing marsh in December 2022. One radiocarbon date was collected yielding a modern date of 1954 +/- 1.0 C.E. High-energy deposits, such as sand layers, have been identified in core samples. The origins of these deposits are speculated to be from one of two sources: (1) marine sands washed over the marsh during ocean storms or (2) sediments of terrestrial origin deposited on the marsh as flood deposits during winter precipitation events. Our hypothesis is that some of these high-energy deposits originate from mass wasting events following large wildfires such as the Thomas Fire. Results reported provide a high-resolution record of macroscopic charcoal analysis, aiming to identify the historic fire gap resulting from 20th-century fire suppression, as well as discrete wildfire deposit horizons associated with known historical wildfire events. Five distinct ecological

zones are identified in the 1.6-meter core. Two significant declines in macroscopic charcoal at 94 cm and 64 cm may represent the post-1850 fire gap identified elsewhere in California (Fig. 1). These drops coincide with declines in % organics and magnetic susceptibility (Fig. 1). Future work will focus on establishing chronology using radiocarbon dating and analysis of sediments from a longer core (2.4 meters) collected on June 9, 2023.

Abstract Name: Prevention of Cold Induced Apoptosis in Platelets of Human and 13-lined Ground Squirrels

Platelets are small cells central to our body's defense mechanism against a broad range of ailments. Arguably, their most notable contribution being the ability to induce blood clotting. This ability can be applied in healthcare settings with platelet transfusions which can treat a broad range of patients from those with platelet deficiencies to individuals going through highly invasive surgeries. However, these advantages are hindered severely by the inefficiencies revolving around our current platelet storage conditions. When platelet donations are stored at cold temperatures (4° C), they go through apoptosis (programmed cell death), meaning when they are transfused into the recipient, the platelets are rapidly cleared from the blood stream and provide little benefit. Conversely, when they are stored at room temperature, bacterial growth renders them unusable after three days. However, species of hibernating animals seem to avoid this phenomenon entirely during their prolonged periods of torpor. Specifically, the 13-lined ground squirrel (*Ictidomys tridecemlineatus*). When their platelets are brought back to room temperatures, they are recirculated and function as normal, making them an idea model organism. To determine if there is a component in ground squirrel plasma that functions protectively, both human and squirrel platelets were mixed with human and squirrel plasmas and stored under cold conditions. To measure apoptosis, Annexin binding and flowcytometry were used. The results suggest that there may be a protein in squirrel plasma that gives some resistance to cold storage in platelets. This could lead to improvements in human platelet storage in the cold.

Abstract Name: The effectiveness of surfactant/alkaline on enhanced oil recovery(EOR) on a mature reservoir

When oil wells get low oil introduce Enhanced Oil Recovery methods to increase oil recovery from mature reservoirs. A chemical called Surfactant/Alkaline can be used to change wettability of the rock and to extract more oil from those reservoirs. The purpose of this work is to understand the effectiveness of a surfactant/alkaline on enhanced oil recovery (EOR) on a mature reservoir. The aim is to find out how different concentrations of surfactants/alkaline change the wettability of mature reservoirs. The approach for

this project is to saturate a core sample 100% with oil and then put it into an Amott Cell with a surfactant/alkaline solution. Core samples were collected from different locations. We confirmed our work results that the permeability of the core samples and enhanced oil recovery has a directly proportional relationship. We see this in both the mineral oil and crude oil. We found out that Surfactant concrete yields a higher oil recovery percentage than Surfactant Gro. This was true in both mineral and crude oil. surfactants and alklines seem to have a positive effect on enhanced oil recovery on a mature reservoir.

Abstract Name: The Value of Peer Mentorship in Diversifying the Geosciences: Lessons Learned from the Villanova Environmental Geochemistry Summer Institute

The geosciences are one of the least racially and ethnically diverse STEM fields. However, the geosciences are uniquely positioned to address issues of environmental injustice, such as disproportionately high levels of soil, water, and air contaminations in disadvantaged urban communities. Additionally, increased diversity in the geosciences would lead to more inclusive decisions. The Villanova Environmental Geochemistry Summer Institute (VEGSI) is a partnership between Villanova Department of Geography and the Environment and the Walter B. Saul High School in Philadelphia, P.A; a school with ~80% of children below the poverty line and about 85% from underrepresented minority groups (URM). In Summer 2024, the VEGSI program hosted 10 high school students from Saul High School to carry out experiments documenting the disparities in pollution exposure along the Cobbs Creek watershed, from the wealthy and predominantly white suburbs to the predominately black communities in West Philadelphia. As undergraduate peer mentors, we assisted three student cohorts (soil, water and air teams) with their investigations, which consisted of soil core collection, air pollution monitoring, and plastic waste collection. We also assisted the three cohorts with mapping and graphing their data using ArcGIS Pro and Excel, respectively, and presentation of their results to the City of Philadelphia Environmental Justice Commission. As part of this presentation, we share our reflections on serving as peer mentors and the effectiveness of the program.

Abstract Name: The effect of β -hydroxy β -methylbutyrate (HMB) on rates of axolotl limb regeneration and digit formation

Ambystoma mexicanum (Mexican axolotl) is one of few organisms able to complete scar-free wound healing and produce a functional limb, making them a very useful model organism for studying these two processes so we can apply what we learn to both human and mammal wound healing and tissue regeneration. The

specific aim of this study is to determine if HMB affects axolotl limb regeneration and digit formation. HMB is naturally secreted in humans by the liver but is also used as a supplement for muscle growth and repair. We predict that HMB will increase the rates of wound healing and limb regeneration, and as the concentrations of HMB increase, the rates of healing and regeneration will increase. Post amputation, axolotls were injected with a high or low concentration of HMB or a saline control on days 0 and 27. Pictures were taken of the limbs every three days for two months and measured using ImageJ software. The measurements for each treatment group were averaged and compared to the other groups using graphical and statistical analyses. While we did observe a difference between the control and treatment groups, the results were unexpected because both treatment groups showed significantly slower rates of healing and repair than the control. The significance of the data was assessed using a one-way ANOVA.

Abstract Name: Identifying and Documenting the Long Term Impact of Brain Injury on the Health and Well-Being of Black and Latina Women Survivors of Intimate Partner Violence: A Systematic Review

Intimate partner violence (IPV) affects an estimated 1.5 million U.S. women annually. Survivors of intimate partner violence may experience traumatic brain injury (TBI) as a result of a current or former partner's abuse. Traumatic brain injury can have long-lasting impacts on everyday life. This systematic literature review looks at the linkage between IPV and TBI, as well as identifies four long-term impacts: (1) Central Nervous System (CNS) impacts, (2) cognitive impacts, (3) poor health impacts and (4) mental health impacts from 77 articles. To be included the articles needed include the following criteria: (a) be published after the year 1990, (b) they needed to include information about traumatic brain injury (TBI), (c) only articles that focused on intimate partner violence or domestic violence as a source of TBI were included, (d) articles were included only if they focused on the population of interest for this research: Black women or Latina women and (e) in order to be included in the analysis, articles had to fall in the category of an empirical study, a systematic review or a scoping review to be included. In addition, the analysis reveals that a significant obstacle to research at the intersection of TBI and IPV is the lack of consistent, agreed-upon measures of concussions and TBI. The literature on the TBI impacts among Black and Latina women who have experienced IPV is incomplete and the analysis in this paper is a contribution towards understanding this phenomenon and fills an important research gap.

Abstract Name: "The Body of His Friendship": Harmful and Healthy Masculinity in the Friendships of William Banks in *To the Lighthouse*

Much of Virginia Woolf scholarship focuses on the damage of gender roles on women and their relationships, with little emphasis or acknowledgement on her thoughts on men and male roles. She does, however, write

regarding both. This paper examines how gender roles shaped the success or failure of the friendships between William Banks and the characters of Mr. Ramsay and Lily Briscoe in *To the Lighthouse*. The generational aspect of the novel lends itself to a comparison of Victorian and Modern gender roles and expectations. By examining Ramsay, Banks, and Briscoe within the context of these roles and expectations, it becomes clear that for Woolf Victorian gender standards impede the creation of deep friendships. In both the Modern and Victorian era, marriage was a priority for both men and women. Mr. Ramsay embodies a male gender norm, serving as the provider and “superior” in his marriage. He prioritizes this over developing an emotionally deep friendship with Banks. At the same time, Ramsay is stuck in the past, choosing to repeat his past successes in this role instead of pursuing a satisfying reciprocal friendship. Briscoe, conversely, has no interest in a marriage deemed necessary by societal norms. She is radically self-sufficient. As a result she is able to have a rich friendship with Banks. Banks himself is a widower, also unimpeded by gender norms, allowing him to pursue deeper friendships that exceed those norms. Banks and Briscoe embody Woolf’s idea of an “androgynous mind” from *A Room of One’s Own*. Ramsay lacks this androgynous mind. However, he is able to approach this state by the end of the novel after the death of his wife, showing a newfound potential to create true reciprocal friendships.

Abstract Name: Understanding Belonging Through the Provision of Mutual Value

The concept of belonging has emerged as a topic of increasing importance as studies have identified academic and wellbeing-related effects associated with its presence or absence, among others. Despite this, reviews of the literature find that the concept remains ambiguously defined. This research aims to determine the specific mechanism by which one experiences a sense of belonging. Based on “the lost European explorer experiment,” in which an explorer with ample resources struggles to survive in an unfamiliar habitat without the help of natives, this paper proposes that “belonging” is an evolutionary cue that one can make valuable contributions to a group, gaining survival benefits as a result. Thus, this paper hypothesizes that one’s sense of belonging is the subjective feeling of being valued by a group that they themselves value. To test this hypothesis, participants from a UC San Diego SONA pool will be given a validated questionnaire, such as Glenn Malone’s General Belongingness Scale, with two added items: first to consider a group to which they feel they belong, then (1) to indicate the degree to which they believe they provide value to the group and (2) the degree to which they feel the group provides them with value. We expect that participants will report higher feelings of belonging when they report highly on both items. If we find these results in a questionnaire study, we will further explore this hypothesis in an experimental setting, in which a group of confederates and a participant work on a task they both value. By design, they will be able or unable to help one another such that the requirements for the hypothesis are met or not in the four different possibilities. A questionnaire could then be used to measure belongingness. If successful, this research could serve to clarify this ambiguous topic.

Abstract Name: DNA Barcoding Using the 16S Gene to Identify Fish Fraud

ABSTRACT According to a report published by Oceana, “Deceptive Dishes: Seafood Swaps Found Worldwide,” about 1/5 of sold seafood is mislabeled as a different species. The goal of my project was to investigate possible species mislabeling by using molecular biology techniques. DNA was extracted from a small piece of fish sold as mahi-mahi. Following the extraction, the 16S mitochondrial ribosomal RNA gene was amplified by PCR before undergoing gel electrophoresis. It was then sent out for nucleotide sequencing. After running the Sanger sequence through the NCBI Basic Local Alignment Search Tool (BLAST), the genus and species of the fish was determined as *Coryphaena hippurus*. This scientific name was run by FishBase, which confirmed its common name as mahi-mahi, proving it was accurately labeled. In summary, this DNA barcoding technique is a valid scientific method to fight fish fraud and ensure correct labeling of the species.

Abstract Name: “Everybody Is a Teacher, Every Place Is a School”: Empowerment through Women-Centered Space at the PKP Community Centre in Bali, Indonesia

Women across the world remain at a disadvantage economically, socially, and politically as a result of oppressive patriarchal structures that allow men to dominate in both private and public spheres of life. In order to investigate ways in which women-centered community spaces provide alternatives to these structures, this transdisciplinary-informed qualitative research project was conducted at the Pusat Komunitas Perempuan (PKP) Community Centre in the Selasih Banjar north of Ubud, Bali, Indonesia. This case-study sought to answer the question: How does the PKP Community Centre's intentional women-centered community space empower local women? The data were collected over a three-month period from September to November 2024 through participant observation and semi-structured interviews in Indonesian with the women (Ibu-Ibu) who work at PKP. Interactions and data-gathering with participants were informed by decolonial prerogatives of respect, relationships, and reciprocity through trust-building, as well as feminist social constructionism theory. The data showed that, across the board, the Ibu-Ibu have a strong desire for more education, something that they feel PKP offers in part through experiential learning of practical job skills, English practice, confidence building, and emotional resilience. The participants also expressed feelings of isolation, lack of self-confidence and financial struggles before finding PKP where they now feel more empowered in those areas. Additionally, it was made clear that having a community of peers who share similar life experiences improves overall happiness and wellbeing for the Ibu-Ibu. This empowerment allows for them to take better care of themselves and their children, make better contributions to their Banjar (neighborhood), and break generational cycles of hardship. Overall, this research demonstrates that creating space that prioritizes women is beneficial not only to them as individuals but also to their families and communities. Empowering women through women-centered spaces opens new opportunities to establish social, political, and economic gender equality.

Abstract Name: B Cell Counting using HALO Software after Traumatic Brain Injury in Mice

After a traumatic brain injury (TBI), blood cells that are usually blocked by the blood-brain barrier are able to enter the brain. It is understood how several of these cell types interact with neural tissue, but the B cell response is not well documented. B cells are one type of lymphocyte known to produce antibodies and secrete cytokines. These B cell functions have the potential to modulate the inflammatory response after a TBI and affect healing outcomes. While B cells have been localized to the brain after a TBI, the temporal and regional characteristics of their infiltration into the brain are not well understood. We hypothesized that B cells would infiltrate in a delayed manner. To quantify the B cells an automatic counting algorithm was developed. Mouse brain tissue (n=6-8 TBI, n=4 sham/timepoint) collected at 1, 3, 7, 14, and 28 days post-TBI was used to perform immunohistochemistry for the B cell marker B220. Hemotoxin and Eosin staining was applied to visualize regions of hemorrhage to be excluded from the counting algorithm. HALO imaging software was used to demarcate areas within the cortices. Then, an automated counting algorithm was developed to mark each B cell. Though many iterations of the automated counting program were generated, they routinely reported excess counts that did not align with B220 staining. Therefore, manual B cell counts were completed, compared to the automated counts, and were found to be more accurate. The manual counts revealed B cells to be most prevalent at 7 days post-injury. Future studies will phenotype the B cells to better understand their role in the inflammatory response.

Abstract Name: Temperature Predictions using Ansys for a Water Cooled Photovoltaic Solar Panel

Cooling solar panels improves their efficiency and lifespan, as high temperatures negatively impact their performance. Thermal cycling is the primary cause of degradation in solar panels. The hypothesis is that by incorporating a closed-loop water cooling system with a solar panel will reduce its surface temperature which may enhance its efficiency. In order to predict the solar panel's surface temperature, Ansys modeling was conducted on a solar panel from SunPower (E 19/320 PV: 200W) with the option of passive cooling using water channels under its surface. The modeling of the system was conducted by SolidWorks and simulated with Ansys Fluent Fluid Analysis to compare with our previous experimental data and test performance at various conditions. The focus was on optimizing flow rates, material selection, and design geometry for maximum thermal efficiency. A steady-state heat transfer model was combined with a laminar fluid flow analysis, considering the relationship between coolant flow rate and panel temperature reduction. The solar panel was subjected to a simulated heat flux of 800 W/m², while water served as the coolant with varying flow rates (0.5–2.0 L/min). In addition, the experimental work also tested a cooling system for a solar panel. A 42% reduction in surface temperature (52°C to 30°C) and an 8% increase in panel efficiency was found. The water's outlet temperature peaked at 50°C, making it suitable for domestic applications. The heated water was

passed through a heat exchanger to reduce its temperature for the closed loop operation in the system. The next phase is to compare these results with the experimental data at identical operating conditions. The computational work is still in progress for various operating conditions and full results along with a detailed discussion will be included in the final presentation.

Abstract Name: The effects of architectural modifications on resistance to fluid flow in ventricular catheters

Introduction: Although various ventricular catheter designs have been implemented into routine practice, there exist few standardized studies to evaluate relative outflow resistance and the impact these design modifications have to overall shunt performance. This study aims to fill this gap by systematically investigating the impact of various architectural modifications on catheter performance, with a particular focus on bulk flow dynamics and biological outcomes. Methods: Catheters manufactured utilized a novel catheter production setup with 16 variations from standard catheters including but not limited to changes in hole number, hole dimensions, hole displacement, and catheter lumen dimensions. These catheters were tested in a validated in-house ventricular catheter testing device to analyze the resistance to flow (indirectly measured as time elapsed for a set volume of fluid to pass through the catheter). A separate group of catheters, varying in lumen diameter, was tested in a fluid flow model that simulated early blood exposure following signs of blood in the ventricles. Results: With increasing hole and lumen diameter, we found a significant decrease in catheter resistance using DIH20 ($P < 0.05$). Blood-assays for varying lumen diameters showed a significant decrease in blood-particulate obstruction as the diameter increased ($P < 0.05$). Lumen obstructions showed considerable evidence of increasing resistance as obstruction diameter increased ($P < 0.05$). However, row and segmental occlusion of lateral holes showed minimal difference in time elapsed ($P > 0.05$). Conclusions: This study implemented a novel method of catheter manufacturing to systematically produce ventricular catheters with varying architecture. By testing variables independently, we found that catheters have an overall bulk relative resistance, with the most significant shift being caused by shifts in lumen dimensions. In addition, blood has a higher propensity to obstruct catheters of a smaller diameter. From these experiments, we can begin to understand the fundamental effects of catheter geometry on resistance in-vitro.

Abstract Name: Analysis of Natural Frequencies and Mode Shapes of a Mountain Bike Test Stand Using

One of the biggest hurdles in dynamics and vibrations testing is the development of an appropriate test fixture. In particular, test fixtures need to provide specific mounting capabilities while not interfering with natural frequencies of interest of the test specimen. Previous research suggests that frequencies of a mountain bike system can reach up to 60 Hz. An existing test stand which was used in house for previous experiments meets mounting requirements for a mountain bike. However, upon visual inspection during preliminary tests runs, it appears that the fixture may have natural frequencies which conflict with the current range of interest. To verify and further support these visual inspections, the entire test stand was modeled in Creo Parametric. One challenge which arose in the development of the model was the behavior of the vibration isolation feet which were mounted to the structure. By making some simplifying assumptions, an equivalent model was created. Using Creo Simulate, modal analysis was performed which appears to match the actual behavior of the test structure. Experimental modal analysis was then performed on the actual test fixture in order to validate the results of the simulation. These experimental results confirmed the mode shapes observed in Creo and the approximate natural frequencies associated with those shapes. These results showed that the current test fixture does indeed have natural frequencies which would interfere with the testing and measurements of the mountain bike dynamics. The interference confirmed by the experimental results highlights the need for future work to develop a new test stand which meets both mounting and natural frequency requirements.

Abstract Name: Influence of Temperature and Other In-Situ Parameters on Concrete Resistivity on Various Service Life Models of HPC Bridge Decks

Past research indicates a correlation between concrete electrical resistivity and its vulnerability to corrosion, a destructive chemical process that deteriorates reinforcements, resulting in compromised concrete bridge decks. Strong relationships between resistivity and corrosion make it possible to more accurately predict and calculate concrete bridge deck service lives through resistivity measurement. Based on this concept, this project continues past experiments that predicted service life by measuring the variation of concrete resistivity across several concrete cylinder samples made using different cementitious material combinations according to ASTM specifications. The considered combinations include materials such as metakaolin, zeolite, and silica fume. This project replicates previous experiment test setups but goes into more detail by considering how temperature, humidity, and other in-situ parameters affect previously calculated bridge deck service lives. Multiple concrete cylinders for several mixture designs will be prepared and tested for surface resistivity using a Resipod Concrete Resistivity Meter; additionally, bulk resistivities will be determined using Merlin Meter with a constant 325 Hz frequency and an RCON testing system at 1 kHz frequency. In addition, analyses will be carried out using a Concrete Maturity Meter. Service life will be computed based on Fick's 2nd Law of Diffusion; in addition, aging factors for the diffusion coefficient based on past research will be applied for enhanced service life accuracy. While past research compared these results with existing service life modeling software, namely Korozeeneck and Life365, this project expands the comparison by considering results computed by ATENA 2D modeling software. Based on previous results, it is expected that zeolite-based mixes will exhibit the best performance. Ultimately, the project's goal is to analyze measurements to derive and propose a modification factor that will be incorporated in the determination of concrete bridge deck service lives for more accurate service life prediction.

Abstract Name: The Effects of Stigma (Independent and Interdependent) and Familism on Mental Health Help-Seeking in Latino/s Communities.

Current research communicates that Latinos are less likely to seek formal mental health services. Compared to white populations, Latinos have been found to avoid treatment of mental health due to the stigma surrounding it. Although research has talked about an independent view of stigma of seeking mental health treatment (e.g., “I will be perceived as lazy if I seek help”), there is not sufficient evidence of how this affects Latino populations. There is also a gap in how interdependent stigma (e.g., “My family will be viewed negatively if I seek help”) relates to help-seeking attitudes and intentions in Latino populations given the collectivism cultural values of preserving family connections. Having a traditional cultural value of familism, Latinos may tend to rely on family for support making them less likely to seek formal mental health services. We hypothesize independent stigma, interdependent stigma, and familism to be negatively correlated to attitudes towards help-seeking. In addition, we expect links between interdependent stigma and attitudes to be stronger for Latino/a individuals than for white individuals. Data will be collected from an online research platform (Prolific) where participants (N=1250) will complete measures of independent stigma, interdependent stigma, familism, and mental health seeking attitudes. Data will then be analyzed by multiple regression analysis to examine the links between measured variables and the potential moderating effects of race/ethnicity and familism on the links between interdependent stigma specifically on attitudes. Results should provide information to allow mental health providers to provide more culturally-informed access to mental health services within the Latino/a community.

Abstract Name: Lead Optimization of MTL1-44 for Antibacterial Efficacy and Cytotoxicity in HepG2 cells

Staphylococcus aureus infections, specifically methicillin-resistant S. aureus (MRSA), are becoming increasingly drug resistant. This increase in drug resistance highlights the need for alternative antibacterial treatments. While peptides serve as our body's defense mechanism, they have short half-lives due to recognition by proteolytic enzymes. In contrast, antibacterial peptoids, peptide mimics with side chains attached to the amide nitrogen (N-substituted glycines) rather than the α -carbon, are resistant enzymatic degradation, giving them significant promise as novel therapeutic agents. MTL1-44, a peptoid discovered in the Bicker Lab, has shown promising levels of antibacterial activity against S. aureus while retaining low cytotoxicity. The focus of this project is on performing lead optimization of MTL1-44 via structural modifications to improve its antibacterial efficacy. Utilizing solid-phase synthesis, a sarcosine scan is being done to better understand the structure-activity relationship (SAR) within this lead peptoid. Antibacterial activity will be evaluated through minimum inhibitory concentration (MIC), and cytotoxicity testing will be done on HepG2 liver cells. Subsequent derivatives will be created based on results of antibacterial and cytotoxicity testing of sarcosine derivatives.

Abstract Name: Design and Implementation of a Solar-Powered Automated Crop Drying Machine for Small-Scale Farmers

The central aim of this project is to design and implement a solar-powered automated crop-drying machine for small-scale farmers. Post-harvest losses in developing regions, particularly among small-scale farmers, significantly affect food security and the economic stability of these communities. Traditional drying methods are inefficient and vulnerable to weather conditions, leading to high crop spoilage rates. Current solar drying solutions often lack automation, versatility, and affordability, particularly for small-scale, rural applications. This project attempts to fill these gaps by developing an energy-efficient and automated drying system that utilizes solar power to dry a variety of crops under controlled conditions. This research is situated within the context of sustainable agricultural technology and renewable energy, addressing the urgent need for affordable, scalable solutions for rural farmers. Previous work in solar drying technologies has focused on enhancing drying efficiency and incorporating automation, but few solutions have successfully combined these with cost-effective, locally accessible designs tailored to small-scale operations. The research methodology includes the design and construction of a prototype solar dryer with key features such as adjustable temperature and humidity control, automated moisture sensing, and energy storage for operation during low sunlight. The dryer's performance will be evaluated based on its drying efficiency, energy consumption, and ability to maintain optimal conditions for a range of crops. The expected results are a reduction in post-harvest losses through more efficient drying, enhanced crop quality, and improved

economic viability for small-scale farmers. These outcomes will be discussed in the context of their potential to be scaled and adapted in rural agricultural contexts, contributing to the broader goals of sustainable farming and energy-efficient technologies.

Abstract Name: Understanding Beliefs in Pseudoscience: The Misleading Science Behind Complementary Medicine

Pseudoscience is a collection of beliefs and practices that claim to be factual, but are contradictory with the scientific method. García-Arch et al., (2022), states the use of complementary and alternative medicine, rather than evidence-based therapies, can lead to consequences in patients with severe medical conditions and vaccine refusal which can lead to the spread of possibly avoidable diseases. Hyland et al., (2003), stated that between 30 and 90% of the adult population in modern nations use some form of complementary medicine to prevent or treat a variety of health concerns. Tiller et al., (2023), reports the global health and wellness industry has an estimated value of \$4 trillion. As a result, many methods of practices and products are marketed on deceptive scientific legitimacy and controversial evidence of safety and efficacy. Individuals who choose this method of medicine may be unaware of the false science they are subjecting to. It is crucial to inform the general public on this data, to provide individuals with the knowledge to make objective decisions based on science. In the current study, we measure participants' beliefs about medical pseudoscience as well as other potentially related beliefs, such as conspiracy theories, the paranormal, and other types of pseudoscience, as well as their critical thinking abilities and dispositions. We hope to understand what types of beliefs or characteristics relate to increased belief in medical pseudoscience, in order to potentially create and validate the first scale to measure belief in medical pseudoscience. We are currently collecting data from college student participants, adding to a data file begun last year, with a goal of reaching 200 total participants by this spring semester. That will be enough participants to understand how the medical pseudoscience scale we are testing here relates to other types of beliefs.

Abstract Name: The Devils Within Us: An Examination of Straw Dogs and Deliverance through Thomas Hobbes' Leviathan

The films of the 1970s were some of the most unique, provocative, and personal studies on the inner workings of violent men. Two of these films, Sam Peckinpah's *Straw Dogs* (1971) and John Boorman's *Deliverance* (1972), are some of the most controversial of their time, so much so that the former was banned in the UK until 2002. The films themselves examine "civilized" men of the early 70s who are out of place, in their environments, and their dispositions, so much so that it causes their inner violence to be realized as a result of their circumstances. Both films contain depictions of rural peoples, whether it be villagers in a

Cornish town, or “hillbillies” of Appalachia, that characterize them as violent, uncultured, lazy, and hyper-sexual, further exemplifying the notion that all people have violence in their hearts. The belief that men inherently carry violence in their souls and bodies was pioneered by philosopher Thomas Hobbes in his book, *Leviathan*. Within *Leviathan*, Hobbes defines the theory of the “state of nature”, a hypothetical environment where humans live without law, governance, or morality. Hobbes’ state of nature describes a condition in which all men have equal abilities and desires to kill one another in order to achieve what they desire, leading to a “war of all against all,” (Hobbes, 110). Utilizing Hobbes’ *Leviathan* as a lens to view the films, it is my contention that both *Straw Dogs* and *Deliverance* are examples of films that embody Hobbesian state of nature theory. Through the film’s violent depictions of rural peoples, one could easily read these characters through a Hobbesian lens. Additionally, the films highlight that even the most civilized individuals cannot run away from the violence that lies deep within themselves, showing how no one is immune to their own state of nature.

Abstract Name: Examining How Children’s Mathematical Information-Seeking Promotes Math Discussion

Math is a fundamental skill applicable to everyday life, and early math abilities are strong predictors of later academic success. Research highlights the importance of both parental and child engagement in math talk, or discussions involving numerical or spatial concepts, in fostering math development during everyday interactions. While prior studies have focused on how parents initiate math talk, there is minimal work examining how parents respond to children’s own math elicitations (questions or prompts about math). In this study, we tested whether and to what extent parents’ responses to their children’s math talk vary. A parent can promote or stifle such conversation either by responding relevantly (and encouraging continued discussion and thinking about that math concept) or irrelevantly to the math concept (and stopping the child’s talking and thinking about math by changing the topic of discussion). Using data from the Studying Parental Influences on Number (SPIN) Training Study in the Kids’ Thinking Lab at the University of Pittsburgh, we analyzed 10-minute free play sessions occurring in the lab or at home from 134 parent-child dyads (mean child age = 3.91 years). All interactions were transcribed and coded for math-specific content. Children’s math elicitations were tallied, and parental responses were categorized as either broadly relevant (aligned with the general topic or activity) or specifically relevant to the math concept. Results showed that parents’ responses to 94% of children’s math elicitations were relevant broadly, yet parents’ responses to only 56% of children’s math elicitations were relevant to the math concept specifically. While parents are generally responsive, a lack of math-specific engagement may limit opportunities for deeper exploration and understanding of these concepts. Future work can examine whether this discrepancy between broadly relevant and math-specific parental responses relates to children’s math performance concurrently and over time.

Abstract Name: Efficacy of Implementing a Standardized Educational Intervention for Geriatric Patients Discharged with Urinary Incontinence

Background: Urinary incontinence (UI) affects over 25 million American adults, yet effective UI home-care strategies are often not addressed with patients during discharge planning. This study examines whether a 5-minute educational intervention explaining the normalcy, prevalence, and clinical legitimacy of UI—along with four practical home care strategies—can improve UI management and benefit the psychological and social well-being of geriatric patients discharged with UI. **Methods:** This ongoing quality-improvement project enrolled 30 patients aged 65+ from UPMC Shadyside, with 18 completing the study. Participants completed two questionnaires at discharge: the Incontinence Effects Form (IEF) and the International Consultation on Incontinence Questionnaire (ICIQ) Short Form, assessing perceptions of UI and its impact on daily life. Afterward, they received the 5-minute educational intervention. 30 days post-discharge, participants completed the same questionnaires and an additional Quality Improvement Participant Feedback (QIPF) survey, assessing the intervention's effectiveness and implementation of strategies. Data were analyzed with Excel, using paired t-tests and descriptive statistics. ICIQ responses were quantified with a "sum score", where higher scores reflected greater impact of UI. **Results:** Among the 18 completers, all IEQ questions showed improvement. 83.3% reported reduction in their perception of UI precautions as a "nuisance"; 66.7% reported having gained more control over their UI (mainly via implementation of discussed strategies); 44.4% reported reduced feelings of uncleanness. Mean ICIQ sum scores significantly decreased from 15.5 (± 2.9) at discharge to 12.39 (± 3.0) at follow-up ($p < 0.001$). Patients reported reduced UI interference in daily life, with 12/18 participants rating $\leq 5/10$. In QIPF, 72% felt more confident managing bladder health; 83% implemented at least one strategy, including better UI care tools at home. **Conclusions:** Brief intervention implementation at discharge reflects increased confidence, reduced impact of UI on daily life, improved UI self-management, and enhanced quality of life in geriatric patients.

Abstract Name: A Toxic Love Story: Investigating PFAS Interactions with Microplastics in Sediment

Per- and polyfluorinated alkyl substances (PFAS) are synthetic chemicals that are persistent in the environment due to their resilient carbon-fluorine bonds. PFAS are commonly used in manufacturing many products and goods because of their water-, oil-, and grease-resistant properties. Through common weathering and degradation, PFAS molecules will leach from these goods and accumulate in the soil and water. Recent studies have shown that PFAS can cause adverse effects in humans through ingestion or using products made with PFAS. Soil particles and PFAS interact with each other through electrostatic and hydrostatic properties in which they will bind together. Microplastics, another synthetic pollutant, are widely used in manufacturing goods due to their lightweight, durable, moisture-resistant, and cost-effective characteristics. However, plastics will degrade into smaller 0.5 mm particles and wash into nearby waterbodies and soil. Microplastics have also been shown to have adverse effects on humans through contaminated water, food ingestion, and plastic use. PFAS and microplastics, both toxic pollutants, will interact with each other in sediment and could pose serious risks to the environment and people. This research aims to investigate the adsorption interaction

between PFAS, microplastics, and sediment, learn how microplastic aging processes in the environment affect PFAS adsorption and provide foundational insights for future projects focused on PFAS and microplastics remediation, biological and physiological processes, and other adsorption factors.

Abstract Name: Developing an Approach to Mentorship: Analyzing Successful Elementary Mentor Teachers

Strong mentor-mentee relationships are crucial for the development of teacher candidates (TCs) during field experiences, particularly in the formative elementary school environment where foundational teaching skills are cultivated. Mentor teachers (MTs) in elementary schools play a critical role in guiding TCs, modeling classroom management strategies, and fostering instructional and reflective practices. Despite this, little is known about how elementary MTs prioritize, perceive, and develop relationships with TCs. This study focuses on elementary MTs within the Eau Area School District (EASD) to explore (a) the degree to which they prioritize their relationships with TCs, (b) their expectations and assumptions about these relationships, and (c) the approaches they use to foster meaningful connections. Using a comparative case study design within a constructivist framework, this research employs semi-structured interviews to uncover patterns in elementary MTs' mentoring practices. Data will be analyzed through thematic coding to identify effective strategies and align findings with existing research on mentorship and the needs of TCs. Analysis from data from this study will be merged with Elementary MTs face unique challenges in balancing their instructional responsibilities with the need to mentor TCs, making this study particularly relevant for understanding how to optimize these relationships in early education contexts. By providing insights into the relational dynamics specific to elementary MTs, this study aims to inform policy and professional development initiatives that support teacher preparation. Findings will be shared to guide the creation of resources and strategies that enhance mentoring practices in elementary field experiences, ultimately contributing to stronger TCs and improved outcomes for teacher preparation programs.

Abstract Name: Emerging Trends and Approaches to Student Leadership within Higher Education

This study investigates the trends and challenges surrounding student leadership in higher education. While leadership development is a priority for many institutions, existing research suggests that current efforts may not be sufficient, highlighting a need for new strategies and programs. This research aims to uncover key issues in student leadership while addressing gaps in existing literature. The study will conclude with actionable recommendations to enhance leadership participation and engagement at institutions nationwide. Previous research emphasizes the transformative power of extracurricular activities and leadership positions for students' future careers. However, studies show that many students are reluctant to engage in these activities, with barriers being particularly pronounced for marginalized populations. This

study seeks to bridge these research gaps by exploring these challenges through the perspectives of both students and faculty, incorporating insights into post-pandemic shifts and evolving leadership dynamics. The research will involve surveying students and faculty in higher education. Participants will respond to a mix of open-ended, scale-rating, and multiple-choice questions to explore their perceptions of leadership accessibility, barriers, and potential improvements. The survey will be administered through East Carolina University's survey platform, Qualtrics. Upon conclusion, the findings are expected to reveal common concerns and trends in student leadership, as well as insights into the effectiveness of leadership academies and training programs, including those targeting high school students. The study will examine how early interventions, such as high school leadership academies, impact future participation in higher education leadership roles. An example of a high school leadership academy will also be provided to share its relevant findings and experiences. By analyzing these findings, this research will offer practical strategies for institutions to foster more inclusive and effective leadership development programs.

Abstract Name: Analyzing the Impact of Instagram, Snapchat, and TikTok on Teen Mental Health: Policy Solution for Content Moderation and Algorithm Transparency

Social media platforms have become integrated into teenagers' daily lives, with Instagram, Snapchat, and TikTok ranking among the most popular. Although these social media platforms provide a space for self-expression and social collection, they present significant risks to teenagers' mental health. Based on previous findings, algorithm-driven content perpetuates harmful comparisons, exposure to idealized body standards, and cyberbullying. Specific features such as "likes," "stories," and "reels" drive addictive behaviors, contributing to reduced sleep quality and increased social anxiety. This study will examine the psychological impacts of these platforms on teenagers between the ages of 13 and 19, with a focus on anxiety disorder, depression, self-esteem, and body image dysmorphia. It will analyze quantitative data from peer-reviewed research, surveys, and psychological assessments with qualitative insights from case studies, interviews, and mental health professionals. Policy proposal is a key component of this research, focusing on accountability measures for social media companies. I propose a solution requiring social media companies to implement mandatory content moderation standards and time-limiting tools for teen users and require platforms to disclose algorithmic processes.

Abstract Name: The Modulation of Evacuation Behavior Based on Ant Colony Group Size and Age

Superorganisms are groups of individual organisms that collaborate through social interactions to reach collective decisions. One such example are collective sensory response thresholds in ants, where ant colonies make collective decisions in response to a stimulus sensed by a group. Previous studies have shown examples

of collective sensory response thresholds in the clonal raider ant in response to changes in temperature. Here, the sensory response threshold is lower in small ant colonies, meaning that evacuation in smaller colonies is more likely to occur at low temperatures. Likewise, larger colonies were found to have higher sensory thresholds and required higher temperatures to elicit an evacuation response. In our study, we tested different variables that could modulate this collective sensory response threshold including age, larval presence, and group size. To do so, we utilized heat perturbations on settled ant colonies inside a temperature and humidity-controlled arena. Larval presence and group size did not affect evacuation behavior in our assays, however, age did show an impact on collective behavior. Colonies composed of only adult ants had lower collective sensory response thresholds, while colonies of younger ants were more likely to have higher thresholds. The results of this study can serve as a baseline for future research regarding ants' ability to socially integrate information as a group.

Abstract Name: Food Insecurity Among Students at Milligan University

The United States Department of Agriculture Economic Research Service reports that twelve point eight percent of U.S. households faced food insecurity in 2022. Meanwhile, the National Center for Education Statistics (NCES) at the U.S. Department of Education reports that as of March 2020, over four million college students were food insecure, twenty-three percent undergraduate and twelve percent graduate. This project is an assessment of the food security levels of Milligan University students during the academic year and an analysis of possible resources currently available and solutions to address this situation in the future. During academic breaks, such as Thanksgiving and Easter, many students remain on campus because they do not have a place where to go. Since Milligan's dining center closes during these dates, students who stay on campus find it difficult to finance and prepare meals during these periods. Some students live under a tight budget and are not able to afford complete meals daily. Meanwhile, even when they can afford the ingredients, most undergraduate students cannot access a kitchen unless they live in upper-class apartments. This project employs an anonymous survey to assess students' food security levels at Milligan. The survey questions are a modified version of those found in the United States Department of Agriculture U.S. Adult Food Security Module. In the survey, there are ten statements about food insecurity along with demographic questions. The demographic questions include questions such as status (undergraduate vs. graduate), marital status, children, age, gender, ethnicity, broad income category levels, housing status (commuter vs. dorms), employment, financial aid recipient, international student status, and presence of food allergies, meal plan status. This survey also inquiries about possible causes of food insecurity based on responses to questions, (e.g., do food allergies limit availability or do school closures limit access to food).

Abstract Name: Graph Transformer Based Modeling for Real-Time Intraoperative Seizure Prediction

The surgical resection of cranial gliomas in eloquent brain regions is challenging due to their indistinguishable appearance from healthy tissue and high intraoperative seizure (IOS) risk. Cortical mapping (CM), the gold standard for distinguishing functional tissue during resection, increases IOS risk, potentially leading to dangerous neurological complications. To address this, we propose a machine learning approach—a graph transformer model—leveraging intraoperative electrocorticography (ECoG) and electroencephalography (EEG) data to model and predict IOS risk in real-time, with the goal of improving CM utilization while minimizing postoperative deficits. We utilize a graph transformer architecture to simultaneously model the spatial connectivity and temporal dynamics of intraoperative neuromonitoring (IONM) data. Unlike vision transformers (ViTs), which lose the spatial arrangement information of electrodes, the graph transformer uses an adjacency matrix and feature matrix to encode electrode connectivity and voltage-pair relationships. Tokens representing voltage values recorded every 10 seconds are input into the graph transformer to predict seizure onset probability for the subsequent 10 seconds. Comparative analyses are conducted against established architectures, such as ViTs and CNN models, focusing on sensitivity, time-to-prediction, and certainty of seizure prediction metrics. Previous studies have demonstrated the graph transformer's superior performance compared to standard graph neural networks and transformer-based models, with promising applications for domain-specific pairwise interactions, enabling enhanced learning performance. Given the effective performance of ViTs for extra operative EEG data and its potential for intraoperative applications, we anticipate the graph transformer's performance, capitalizing on electrode voltage-pair data, will surpass that of ViTs and CNNs in IOS prediction. This study hopes to demonstrate the potential of graph transformers in neurosurgical applications, offering a scalable method for real-time IOS risk assessment. By encoding spatial electrode connectivity, our model seeks to advance seizure risk prediction and support safer, more effective CM use, potentially reducing postoperative neurological deficits and improving patient outcomes.

Abstract Name: Examining the Impact of Metformin in HeLa Cells, a Cervical Cancer Cell Lineage, by Utilizing an Annexin V FITC Assay

According to the World Health Organization (WHO), cervical cancer has taken the lives of approximately 350,000 people in 2022 alone. This number continues to slowly rise as the years progress. To combat this crisis, our research project aims to study the impact of metformin on HeLa cells, a cervical cancer cell line. Metformin is a known treatment for type 2 diabetes. However, studies have shown that metformin alone has had a positive impact on apoptosis levels in pancreatic cancer cell lines PANC-1 and BxPC-3. Apoptosis is easy to assess in these studies as a binding protein, annexin V, can tag apoptotic cells, which can then be assessed using fluorescent light microscopy. When a cell undergoes apoptosis, an inner membrane phospholipid called phosphatidylserine flips to the outer membrane to which annexin V can bind to. Cells that are not undergoing apoptosis will not have this key phospholipid on the outer surface of their cell membrane; therefore, annexin V cannot bind to the cells and they will not fluoresce when exposed to UV light. To

conduct this experiment, HeLa cells were cultured in 96-well strip plates with culture media and treated with 100mM of metformin. After a full 24 hours of treatment, cultured HeLa cells then underwent an Annexin V FITC assay from Cayman Chemical Company. The cells were then analyzed using an Olympus CKX41 fluorescent microscope and Lumenera Infinity Analyze 7 software. Our results show that in HeLa cells, metformin caused an increase in apoptosis levels, showing that this drug can also be applied to other cancer cell lines. Future studies aim to determine if metformin works at a lower dosage or synergistically with other drugs like aspirin or dexamethasone.

Abstract Name: Schenectady County Food Council Survey Development Project

The Schenectady County Food Council (SCFC) Survey Development Project aims to identify gaps in the current Schenectady County Health & Equitable Food Action Plan that has not been updated since 2017. Major events, like the COVID-19 pandemic and high inflation, have shaped the landscape of food security since then. The Schenectady Foundation, who produced the food action plan and directs the SCFC, partnered with Siena College undergraduate students in the Nonprofit Excellence and Transformation program to create a new survey. Over the course of the academic year, the student team has worked to create a survey that will inform the new food action plan and provide the SCFC with practical steps toward their goals. We reviewed surveys from partner organizations to the SCFC, including the Regional Food Bank of Northeastern New York, the Electric City Food Co-Op, and two surveys from Food Pantries for the Capital District to determine themes and gaps in their survey questions. Given our extensive collaboration with nonprofit partners, our presentation will review community engagement best practices for developing a survey with several stakeholders. We will also present our survey, clarifying how each question will help the SCFC to materially implement new ways to address the root causes of food and nutrition insecurity in Schenectady County. This collaborative effort aims to equip the SCFC with more insight and updated strategies, ensuring a more equitable and resilient food plan that addresses the evolving challenges of food and nutrition insecurity within the community.

Abstract Name: Can Gen AI Tools and Basic Prompting Training Enable Non-STEM Students to Complete Field-Specific Coding Tasks?

This study explores the feasibility of non-STEM students leveraging coding tools and Generative AI for research tasks with minimal training. By equipping non-STEM students with basic coding skills and exposure to Gen AI tools, we aim to assess their ability to independently perform domain-specific coding tasks

typically reserved for STEM professionals. Our methodology involved a two-stage exploratory study: guided training followed by independent application. Initial training covered fundamental IDE usage and Python syntax, facilitated by a Computer Science(CS) major student. Subsequently, participants worked independently on real-world data analysis tasks, focusing on historical records of the French East India Company. Results indicated that non-STEM students could overcome coding challenges and contribute effectively to interdisciplinary research, suggesting that basic coding skills combined with AI tools can democratize technical tasks across fields.

Abstract Name: Using Cognitive Psychology to Probe AI Social Bias in GPT-4

Human rationality and decision making is heavily susceptible to social and cognitive biases. This irrationality in human nature poses an intriguing question: Does artificial intelligence display the same heuristics as humans? The current study seeks to examine social essentialism, the belief social groups possess natural or biological underpinnings, in GPT-4. This research builds upon recent studies that have tested prominent cognitive biases (e.g., anchoring and representative heuristics) using word vignettes by expanding on social essentialist bias. Our goal is to understand the differences between social essentialist thinking in large language models compared to humans. Specifically, we will examine two dimensions within social essentialism - Naturalness, or the belief in immutable and naturally occurring boundaries within social groups, and cohesiveness, or the belief in uniform characteristics within social groups. We utilized the social essentialism scale, a 9-point likert system, to observe whether GPT-4 would exhibit similar heuristic patterns in race, gender, nationality, religion, and social class domains. Our previous research that we are expanding upon interestingly showcased GPT-4 scoring lower than humans in terms of economic, race, and nationality social groups but higher in terms of the religious domain. We want to see if this pattern stays consistent and we will utilize new methodology such as the switch-at-birth task. The switch-at-birth methodology analyzes participants' essentialist thinking regarding individuals being born into social groups versus becoming a part of differing groups. We will also expand our human participant data collection methods by gathering a sample of U.S adult participants to test our methodologies on and later compare with GPT-4. Overall, we hope to gain a deeper command of artificial intelligences' susceptibility to essentialist bias comparatively to humans and its understanding of social groupings.

Abstract Name: Early life stress-induced aortic NOX4 and VCAM1 expression is mediated by endothelial

Early life stress (ELS) refers to trauma exposure before the age of eighteen and is associated with increased risk for cardiovascular disease (CVD) in adulthood. We previously found that mice exposed to ELS have significantly higher oxidative stress and inflammation. Additionally, aortic endothelial cells in adult mice exposed to ELS show increased HDAC9 expression, a class II HDAC associated with vascular dysfunction. We hypothesized that ELS induces increased endothelial-cell HDAC9 expression and that endothelial-cell HDAC9 mediates increased pro-oxidant gene, NOX4, and pro-inflammatory gene VCAM-1 in the aorta of mice after ELS. We utilized a mouse model of ELS, Maternal Weaning and Early Separation (MSEW), with normal-reared (NR) mice as controls, with tamoxifen-inducible endothelial cell-specific HDAC9 wild-type (iEC-HDAC9 WT) and knockout (iEC-HDAC9 KO) mice. Aorta from adult iEC-HDAC9 WT MSEW mice have significantly greater NOX4 expression compared to iEC-HDAC9 KO MSEW (75.9 ± 18.4 copies/ μL , 34.1 ± 9.0 copies/ μL , $n=9$, $p=0.0197$). Additionally, aorta from iEC-HDAC9 KO MSEW mice had significantly lower VCAM-1 expression than iEC-HDAC9 WT MSEW mice, critical for inflammatory cell migration (78.2 ± 19.2 copies/ μL , 218.2 ± 69.8 copies/ μL , $n=9$, $p=0.030$). Therefore, endothelial cell-specific HDAC9 mediates NOX4-driven oxidative stress and VCAM-1, contributing to endothelial dysfunction and inflammation after ELS. To build on these findings, we further hypothesized that ELS would promote macrophage priming with increased HDAC9 expression, thereby contributing to ELS-induced inflammation. Bone marrow-derived macrophages (BMDM) were cultured for seven days, followed by acute lipopolysaccharide stimulation. BMDM from MSEW mice showed significantly increased HDAC9 to the NR group (228.9 ± 143.3 copies/ μL , 1.8 ± 0.8 copies/ μL , $p=0.014$). Thus, BMDM from MSEW mice are primed for inflammation compared to NR. We conclude that targeting HDAC9, an epigenetic regulator associated with ELS, may alleviate oxidative stress and decrease inflammation for individuals with ELS exposure.

Abstract Name: Predicting Banking Companies' Customer Churn using Supervised and Unsupervised AI/ML Approaches

This research focuses on our hypothesis that AI/Machine Learning algorithms can develop models for Banking companies to predict whether a customer will churn or not. For this purpose, IBM Watson's AutoAI feature is selected to develop models using multiple algorithms. The dataset obtained from Kaggle provides information relating to both the background of the customer and their previous purchase from the company. The data consists of 10,000 customers, along with 11 features including age, credit score, and balance. Within the IBM Watson platform four machine learning algorithms (XGB Classifier, SNAP Decision Tree Classifier, SNAP Logistic Regression, SNAP Random Forest Classifier) with enhancements (HPO-1, FE, HPO-2) were employed. The XGB Classifier with all the enhancements, achieved an accuracy rate of 86.4%, along with a holdout F1 score of 0.539 and a cross-validation F1 score of 0.594. Thus, it is apparent that while this model is able to perform the task of identifying customers who leave the company with accuracy, the data has a slight imbalance between those who are leaving and those who aren't. In addition, we are also investigating various techniques to balance the data and its impact on the overall models' performance. It is important to note that the above models' results are based on supervised learning. New results by using unsupervised learning will also be added in the final results. A brief comparison of supervised and unsupervised learning methodologies will be added in the final presentation.

Abstract Name: Ansys Simulations for Thermal Analysis of a Bifacial Solar Panel

Most solar panels only convert less than 25% of the sunlight into usable energy. Bifacial solar panels aim to improve their efficiency by absorbing sunlight that reflects off the nearby ground. Experiments show that the temperature of the solar panel surface deteriorates the performance by reducing its efficiency. This research aims to model each layer's internal and external temperatures to properly analyze how the panel heats up as sunlight shines on the panel. We hypothesize that understanding will assist us in cooling the panel efficiently without sacrificing efficiency. The thermal modeling was performed using Ansys-Thermal, requiring the input of the solar panel's geometry and the layers within the PV Bifacial Solar Panel (JJN-Bifacial-200W), such as AR Coating, emitter layer, N-type wafer, and the aluminum back surface. Data related to these layers served as input values for the modeling, including the dimensions of various layers and corresponding thermal properties like thermal conductivities, density, and specific heat. The boundary conditions employed in stagnant air include heat flux at the top of the aluminum frame and glass surface, convection on the top and the frame ($h=5\text{W/m}^2\text{K}$), convection on the back ($h=1.5\text{W/m}^2\text{K}$), and the emissivity of the glass ($\varepsilon = 0.85$). For bifacial solar panels, the heat flux at the back sheet was determined using albedo values of the reflective surface. Computational results show the panel reaching temperatures from 40-50°C after being exposed to indoor conditions with 400W lights shining on the panel for an hour, which implies a drop of about 15% in efficiency using a Pmpp value of 0.5%/°C. These values are being used to validate experimental data where multiple K-type thermocouples were used to register temperature data on both surfaces of the Solar panel. Retested and verified results will be presented at the conference.

Abstract Name: The Applications of Machine Learning Based Automated Segmentation to Spinal CT Scan

Background: Deep-learning computed tomography segmentation models can segment several structures from CT scans, including the paraspinal muscles, spinal vertebrae, and the spinal cord. Individually segmented vertebral volumes can be integrated with CT scan hounsfield Unit (HU) data to provide objective vertebral measurements. **Methods:** Our cohort encompassed 243 patients with a lumbar CT scan. An open-source automated CT segmentation program was repurposed to segment the L1-L5 vertebrae. Segmented volumes were combined with CT radiographic data to compute volume (cm³) and HU density of lumbar vertebral bodies, trabecular bone (middle 80% of vertebra), cortical bone (outer 10% of vertebra), and endplates (10% of vertebra). **Results:** Patients (85.12% female) had a mean age of 71.03±13.60 years and BMI of 27.88±7.21 kg/m². Mean lumbar vertebra HUs were: L1=213.55±49.61, L2=222.06±53.36, L3=220.38±54.69, L4=222.42±53.20, and L5=238.09±57.35. Cortical bone mean HUs were: L1=258.89±69.28, L2=269.23±81.10, L3=272.62±75.14, L4=272.64±53.23, and L5=278.14±75.84. Trabecular bone mean HUs were: L1=209.88±48.46, L2=218.10±52.20, L3=212.88±62.55, L4=204.66±62.94, and L5=195.16±76.26. Endplate bone mean HUs were: L1=347.92±76.74, L2=351.84±78.15, L3=347.99±78.85, L4=345.01±78.52, and L5=343.38±78.93. Mean lumbar vertebra volumes were: L1=27.44±7.08, L2=30.21±7.24, L3=33.42±8.23, L4=34.18±6.63 and L5=32.42±7.30. Age was negatively correlated with the L1-L4 mean HU-based, but was not correlated with vertebral volumes. **Conclusion:** Deep-learning-driven automated CT segmentation can efficiently assess the volume and HU density of critical vertebral structures. This methodology offers greater accuracy and consistency than manual segmentation techniques.

Abstract Name: Multi-Analysis of Microglial Temporal Activation following Blast Induced Traumatic Brain Injury

Background: Traumatic brain injuries (TBIs) are sudden external injuries from a blast or blunt impact causing brain damage, neurocognitive disorders, and death. Many service and law enforcement personnel experience repeated blast exposures due to their usage of heavy weaponry, causing traumatic brain injuries. Microglia are neuroglia (glial cells) responsible for clearing cellular debris post-TBI through phagocytosis and stimulating neuroprotective factors to promote neurorecovery. Therefore, this research focuses on determining the relation between microglial activation and induction of cognitive deficits temporally following blast TBI at both varying pressure levels and time frames post-blast. **Methods:** The in-vivo model used was mice with double-transgenic CX3CR1GFP/+ and CCR2RFP/+ (resident microglia are labeled with GFP and peripheral monocytes with RFP). The mice were split into two cohorts before being subjected to a simulated traumatic brain injury through blast chambers at 70 and 180 kilopascals. Brain tissue was extracted after injury in one day, seven days, and 30 days. The region of interest was the dentate gyrus of the hippocampus due to its role in learning and memory - major cognitive functions. **Results & Conclusions:** Preliminary findings show that microglial cells in sham animals, regardless of blast pressure, have small cell bodies and long processes consistently indicative of resting-state microglia. Microglial cells in blast animals, however, have swelled cell bodies and short processes, indicative of activated microglia in response to injury. It was found that initial injury within mice impacted by repeated, mild-level blasts causes microglial activation within 24 hours. However, there was a significant increase in microglial activation at the 7-day peak for both the 180 kPa and the 70 kPa affected mice. Interestingly, there was slightly greater activation and impact within repeated, 70 kPa blasted mice. This further indicates that despite having a low-pressure level, repetition makes the damages comparable to moderate-level blast TBI.

Abstract Name: Black Mass Incarceration

The United States holds the highest number of incarcerated individuals globally, a trend that has persisted for centuries. Over the past 50 years, the incarceration rate has skyrocketed from 93 per 100,000 citizens in 1972 to 750 per 100,000 in 2022. Currently, more than 2 million Americans are incarcerated, with an additional 4.6 million on parole or probation. Of those incarcerated, approximately 880,000 are Black Americans, marking a historic high in imprisonment rates. Despite comprising only 13% of the U.S. population, Black Americans account for 44% of the prison population, while White Americans, constituting 64% of the population, make up 39% of prisoners. This stark disparity is exacerbated by policies such as the war on drugs, the growth of the Prison Industrial Complex (PIC), the presence of privately owned prisons, instances of police brutality, and the enforcement of harsher laws disproportionately affecting Black Americans. Given the numerous inequities faced by minority groups in everyday life (employment, housing, education, finances), the prison systems are often overlooked as places exhibiting social injustice/inequity. Furthermore, incarcerated individuals are often viewed as a faceless population deserving of their punishment, not as individuals with unique life experiences. As a student of films studies, I have chosen to bring attention to this issue through documentary filmmaking. The research conducted provides a timeline that underscores how these factors have contributed to the pervasive issue of Black mass incarceration from the era of slavery to the present-day realities within the U.S. prison system.

Abstract Name: Hospital Acquired Pressure Injuries (HAPI): Quality Improvement Process

Background: Health Acquired Pressure Injuries (HAPIs) significantly burden healthcare systems by increasing patient morbidity, length of hospital stays, and costs. The Center for Disease Control and Prevention reported that pressure injuries affect more than 2.5 million Americans annually resulting in 60,000 deaths and a financial impact of 11 million dollars. Despite growing awareness and preventive measures, HAPIs remain prevalent across the United States. Purpose: The purpose of this quality improvement (QI) project is to reduce the incidence of HAPIs at Level 1 Trauma Center (Bergan Mercy) in Omaha, Nebraska. The secondary aims of the project include improving early identification of HAPIs, enhancing staff education and ensuring adherence to HAPI prevention protocol. Establishing quarterly point-prevalence audits will drive accountability, transparency and continuous improvement. Furthermore, the framework emphasizes the importance of interdisciplinary collaboration and stakeholder engagement in driving process improvement initiatives. Methods: A literature review guided the development of evidence-based interventions for HAPI prevention. The findings from the quarterly audits were used following the A3 methodology to perform a root

cause analysis to establish an effective intervention to reduce HAPI prevalence and improve adherence to HAPI protocol. Outcomes: The results of the quarterly point prevalence audits showed an increased rate of undocumented HAPIs. Additional feedback from surveys of participants in the audit showed that there is a knowledge deficit regarding the appropriate intervention nurses should be implementing to prevent HAPIs. In addition, there was also a lack of documentation about these interventions. The systematic approach combining risk assessment, evidence-based interventions, staff education, and continuous monitoring is expected to significantly reduce the incidence of HAPIs, improve patient outcomes, and enhance overall quality of care. Ongoing commitment and collaboration among healthcare professionals are essential for the sustainability and success of pressure injury prevention efforts.

Abstract Name: Oscillators Using IC 555 Timer and RLC circuits

The presented research uses the IC 555 timer in combination with RC circuits to investigate the design, operation, and uses of oscillators. The research delves into the basic ideas that enable the creation of periodic signals as well as how RLC networks affect oscillation frequency duty cycle and amplitude of different generating signals. The study illustrates how resistors, inductors, and capacitors regulate the timing properties of the output waveforms using a 555 timer in astable mode. The research will show how to calculate, testing the validation of the circuit using Multisim software, and constructing the circuit. Experimental sets are used to derive and validate key equations governing frequency and amplitude. Practical uses for the 555 timer, such as pulse-width modulation (PWM) circuits, tone generators, and LED flashers, showcase its versatility. The research also looks at ways to improve performance, like utilizing diodes to change duty cycles and optimizing component values for certain use situations. The results highlight the 555 timer's dependability, ease of use, and versatility as an affordable solution for a range of oscillatory tasks, making it essential in electronics and instructional demonstrations.

Abstract Name: Navigating the Literature: Defining the Competencies Central to Entrepreneurship Education

Undergraduate entrepreneurship education programs have been growing at a fast pace in response to demands from both students and policy makers. Due to this rapid growth, there is no consensus on the core competencies entrepreneurship education should be teaching. This can lead to inconsistencies across programs, which makes it hard to understand the efficacy of entrepreneurship education both leading to venture creation and communicating the value of entrepreneurship degrees to external stakeholders. This lack

of consensus makes it challenging to share best practices, develop signature pedagogies, and collaborate across institutions because institutions are building bespoke programs. This study addresses this gap by synthesizing the existing literature that defines specific entrepreneurial competencies. This research examined over 20 different scholarly articles, with the goal to identify the central competencies consistent across multiple articles. The analysis identified 41 distinct competencies and provides a table defining these competencies and categorizing them into four core areas—business skills, interpersonal skills, intrapersonal skills, and opportunity navigation skills. UCINET, a social network mapping software was utilized to visualize these concepts and to identify the competencies and papers that were most central to the literature. The most central competencies are: creativity, opportunity recognition, risk mitigation, self-efficacy, value creation, learning through experience, and perseverance. This research contributes to the literature by providing a clear categorization of entrepreneurial competencies and identifying those that are most central to the field. This framework would allow educators to more effectively collaborate and prioritize competencies to incorporate into their programs. It also could provide students with a tool to evaluate their own competency development and empower them to seek new opportunities to build skill, communicate the value of their degree to potential employers and partners, and transfer their learning to their professional work, whether in their own company or in a traditional work setting.

Abstract Name: Rx for Romance: A Critical Examination of the Savulescu-Earp Love Drugs Framework

Love drugs—substances taken to illicit attraction, affection, and attachment between romantic partners—are a popular subject of fictional works. Recently, bioethicists Julian Savulescu and Brian Earp have proposed that if they were available, it would be permissible to use them to address rising divorce rates. Love drugs, they argue, might encourage marital fidelity and more support with child-rearing. This consequentialist view of love, where the ends justify the means, is controversial. Some dismiss the problem as idle speculation. Love drugs don't exist, and thus they pose no actual danger. Yet, recent experiments with love-associated neurotransmitters in humans suggest that love drugs may be on the immediate horizon, and hence the Savulescu-Earp love drugs framework (SELDF) ought to be seriously considered. In a future in which love drugs are effective, would it be reasonable to consider their effects on partners post-treatment to be love? Or is love something beyond neurochemicals that cannot be “improved” with medicine? Even if it were true love, since these drugs have the possibility of circumventing the wills of the individuals involved, would it be ethical to administer love drugs? I explore these questions through the lenses of three different philosophical understandings of love: (1) neuroreductionism (love is reducible to chemical interactions), (2) love as a fundamental phenomenological experience, and (3) love as a virtue. I will apply these understandings of love in order to critically examine the SELDF and the assumptions it makes about love and divorce, as well as scrutinize from an ethical perspective the emerging science of love drugs as it edges closer to reality. More generally, I argue that, when philosophers dispute the permissibility of inducing emotions in autonomous agents, they often do so while ignoring the true nature of the emotion in question, including its place in social practices.

Abstract Name: Aorta and Hepatopancreatic Ampulla Anatomy Is Less Variable in Cats (*Felis catus*) Than Humans (*Homo sapiens*)

Anatomical variations are benign differences in organ or vessel structure across individuals. Recognizing these variations is essential within the medical field, as ignorance of these structures can lead to misdiagnosis, surgical complications, or death. For decades, undergraduate anatomy classrooms have demonstrated human anatomy through cats (*Felis catus*). However, anatomical variations, and their frequency, are underexplored in cats, creating a gap in anatomy education. To address this gap, we dissected 33 cats to characterize variations in the hepatopancreatic ampulla and aortic arterial branching patterns. The hepatopancreatic ampulla forms when the common bile duct and pancreatic duct merge to deliver digestive secretions to the small intestine. The abdominal aorta typically distributes blood through five major branches: (from rostral to caudal) the celiac trunk, superior mesenteric, (paired) renal, inferior mesenteric, (paired) gonadal, and terminal bifurcation into (paired) common iliac arteries. Across specimens, we identified two variations of the hepatopancreatic ampulla and seven distinct aortic branching patterns. In the hepatopancreatic ampulla, the common bile and pancreatic ducts typically merged to form a single ampulla fused to the proximal duodenum (29 of 31), though ampulla length varied (0.6 to 1.3 cm). In two specimens, an accessory pancreatic duct also supplied the duodenum. Frequently, cats followed the typical aortic branching pattern (9 of 32). Other variations demonstrated a common origin of the celiac trunk and superior mesenteric (8 of 32) and the inferior mesenteric branching from the superior mesenteric (2 of 32). Further, the paired renal arteries demonstrated both symmetric and asymmetric branching. In conclusion, the identified feline anatomical variations are consistent with those reported in humans for these structures, however, the total number of variations and frequency of shared variations is reduced in the cat in comparison to humans. The identification of these feline variants will help generate new pedagogy for undergraduate anatomy.

Abstract Name: Biotechnician Assistant and Credentialing Exam: A Student-Developed Video Curriculum for Success

The Biotechnician Assistant Credentialing Exam (BACE) is a nationally recognized program created by Biotility at the University of Florida that shows a student's knowledge of skills needed to work in a laboratory. While materials such as the Journal of Visualized Experiments (JoVE) and books such as "Biotechnology: A Laboratory Skills Course" by J. Kirk Brown exist there is a distinct lack of educational materials marketed specifically towards the BACE program. The researchers sought to fill this niche by filming a series of videos as an educational curriculum for future BACE participants to use as a study aid. Using Camtasia video editing software, videos were made in accordance with the list of learning objectives provided by Biotility on their official website. The researchers hypothesized that with the assistance of video-learning tools and traditional study methods, undergraduate students will be able to pass the BACE. The researchers intend to take the BACE and provide quantitative data in the form of test scores to determine the effectiveness of the BACE curriculum. Based on two different studies, one conducted by Plymouth University and the other by Johns Hopkins University, research from both universities suggests that having access to digital learning materials enhances student success and improves confidence surrounding reenacting

lab procedures. However, further sample sizes will need to be collected in order to determine the statistical significance of how the researcher's videos affected the student's test scores. The goal of the researcher's project is to provide an accessible study aid for people looking to enter the field of biotechnology.

Abstract Name: Visible and Nonvisible Lattice Points and Polygons

A visible lattice point is an integer point in the real plane where a line from the origin to the point does not intersect any other integer points. Herzog and Stewart gave a construction for finding any patch of visible and nonvisible lattice points in the real plane although this construction is not optimal. Goodrich, Mbirika, and Nielsen improved this result for finding square nonvisible patches while still not optimal. We adapt these constructions to find visible lattice polygons. We also include related results to this construction. We will provide Python implementations for the constructive methods of patches and our visible lattice polygons.

Abstract Name: The Use And Reliability of Artificial Intelligence Sentiment Sorting In Usability Feedback Analysis of an Internet-Based Healthy Lifestyle Behavior Intervention For People With Spinal Cord Injury

WHEEL-LEARN is an Internet-based healthy lifestyle behavior intervention aiming to increase physical activity (PA) to recommended levels for people with spinal cord injury or disease (SCI/D). Perceived usefulness and ease of use are the primary factors that impact a user's intention for engagement with technology. This study evaluated the usability of the WHEEL-LEARN interface and multimedia content in people with SCI/D and healthcare professionals using a mixed-methods approach. This study also assessed the reliability of artificial intelligence (AI) methods for coding qualitative data. Participants used a "think aloud" approach while completing a series of tasks during usability testing, followed by completion of the System Usability Scale (SUS) and Post-Study System Usability Questionnaire (PSSUQ). Descriptive statistics were calculated for SUS and PSSUQ. Miro, a digital whiteboarding tool, was used for affinity diagramming to complete thematic analysis of participant feedback. Utilizing Miro Assist, a collection of AI-powered tools within Miro, sentiment analysis was performed on thematic groups. Interrater reliability between Miro Assist and the research team was assessed using Cohen's kappa. Average scaled SUS and PSSUQ scores (mean=85, SD=16.3; mean=1.7, SD=0.8) indicated excellent perceived usability and high user satisfaction. The interrater agreement between Miro Assist and the research team showed substantial agreement for positive and negative sentiment and moderate agreement for neutral sentiment (Kappa=0.71, 0.67, and 0.54, respectively). People with SCI/D and healthcare professionals perceived WHEEL-LEARN as

highly usable. Through generated sentiment sorting, AI tooling showed potential for designers to obtain insights from qualitative data. Miro Assist struggled to categorize neutral sentiment, possibly due to highly contextual human usability feedback. WHEEL-LEARN has potential to engage people with SCI/D to meet PA guidelines. In this study, designers maintained full autonomy through human-centered analysis with AI tooling assistance that could support future small design team analysis.

Abstract Name: Decline of European Democracy: A Comparison of Executive Aggrandizement Hungary and Slovakia

Why are certain European Union (EU) countries experiencing democratic backsliding while others are not? This paper explores executive aggrandizement in the EU in the context of Hungary and Slovakia. Democratic backsliding, the gradual erosion of democratic principles, is a political trend that has increased globally throughout the 21st century. Hungary has been experiencing democratic backsliding since the election of right-wing leader Viktor Orbán. Slovakia, while empowered by some right-wing leaders, has not experienced the same. This is puzzling because both states share borders, and history and have similar economies. Current studies suggest that widespread public support for the executive can increase voters' willingness to approve of actions that increase the power of the executive or erode democratic institutions. The more citizens feel their preferred policies are being supported by their executive, the more they are willing to allow them to bypass certain checks and balances. While this theory has been tested in Latin American countries and found support, it has not been replicated in Europe. This paper adds to the growing literature on democratic backsliding in Europe by comparing partisan support for the incumbent and the state of democracy in Hungary and Slovakia, finding that citizens in Hungary have more support for their incumbent than citizens in Slovakia.

Abstract Name: The Correlation between Total Amount of Antioxidant Capacity and the Available Polyphenols in Various Vegetables

Antioxidants play a vital role in protecting cells from oxidative stress and are associated with numerous health benefits such as reducing the risk of heart disease, cancer, and neurodegenerative disorder. These compounds act as a reducing agent, neutralizing free radicals and preventing cellular damage. Given their health-promoting properties, extensive research has focused on evaluating the total antioxidant capacity (TAC) and total polyphenol content (TPC) in various vegetables. This study examines the statistical relationship between TAC and TPC in selected vegetables. The Trolox Equivalent Antioxidant Capacity (TEAC) method, using ABTS, and the Folin-Ciocalteu method were employed to quantify water-extractable antioxidants and polyphenols, respectively. Statistical analyses, including two-tailed and correlation tests,

revealed a significant negative relationship between TAC and TPC at an alpha () level of 0.01. These findings contribute to a deeper understanding of the interplay between antioxidant capacity and polyphenol content in vegetables.

Abstract Name: Information Asymmetry in MLM Business Opportunities: Can Disclaimers and Disclosures Help?

Data show that most multi-level marketing (MLM) participants make little to no money or lose money. MLM companies often advertise the earning potential of their business opportunities using vague terminology such as “supplemental income” or “financial freedom.” This can leave consumers with inaccurate impressions of typical earnings, causing them to invest resources into the opportunity which they otherwise would not. The Federal Trade Commission is considering promulgating regulations which could require recruits to be presented with disclaimers and disclosures that communicate past participants’ profit and loss information. The impact of this information in the MLM domain has not been investigated. We fill this gap by testing both the independent and interactive effects of disclaimers and disclosures in a randomized controlled trial experiment with 305 Minnesota State Fairgoers. We showed participants a MLM promotional video and website content. Participants were randomly assigned to a control group (with no information treatment) or one of three treatments: disclaimer only; disclosure only; or disclaimer and disclosure. The disclaimer provided a short message of central tendency while the disclosure included a pictograph with a distribution of profit and loss outcomes. Participants then reported their personal earnings expectations and interest/attraction as well as earnings expectations for others. We also captured potential correlates such as financial literacy, prior MLM exposure, and numeracy. We find that the information treatments reduce interest and bring participants earnings expectations closer to objective reality. For example, the participants who received an information treatment were almost twice as likely to say the typical participant in the MLM loses money (a finding that aligns with the information in the treatments), compared with control participants. While all treatments were statistically significant, the disclosure had the largest effect. Our results suggest that profit-and-loss disclaimers and disclosures could be used by regulators to inform consumers.

Abstract Name: Relationship Between Post College Aspirations and Student Outcomes

The purpose of this project is to explore the potential relationship between post-college aspirations and college student outcomes. The study investigates the relationship between students’ post-college aspirations (intrinsic vs. extrinsic) and the outcomes of academic performance and subjective well-being. Guided by Self

Determination Theory (SDT), individuals' motivation can be assessed relative to intrinsic and extrinsic sources. A sub-theory of SDT, Goal Contents Theory (GCT) argues that long-term aspirations categorized as intrinsic directly support wellness and performance whereas extrinsic aspirations, when prioritized, contribute to ill-being. Intrinsic motives are theorized to be associated with autonomous vs. controlled, indicating that intrinsic aspirations and autonomous motivation is likely to yield greater psychological health and performance. Prior research in this area is often focused on working adults and career aspirations. By targeting college student aspirations, this project could provide practical implications for post-secondary institutional settings. Over 100 students at a small mid-Atlantic U.S. liberal arts institution completed self-report surveys on several measures commonly utilized in SDT studies. Students indicated their level of agreement on Likert-scale items measuring future goals (Aspirations Index), autonomous motivation (Academic Motivation Scale), and psychological well-being (RAND Mental Health Scale; Satisfaction With Life Scale [SWLS]). Additionally, students reported demographic information, college major/minor, and cumulative college GPA as a measure of academic performance. Data collection is being completed currently. Data analysis will be completed via an ordinary-least squares (OLS) multiple regression analysis. Based on the SDT framework, the researchers' expected results are student autonomous motivation will be positively related to well-being and academic performance. Furthermore, intrinsic aspiration dimensions are predicted to be positively related to dimensions of well-being whereas extrinsic aspiration dimensions will be negatively related to dimensions of well-being. Results of the hypothesized relationships, future research considerations, and practical implications of the research on student motivation and higher education will be provided.

Abstract Name: Evidence of Seasonally Shifting, Deep-Sea Niche Partitioning Between the Deep-Water Glowbellies *Acropoma hanedai* and *A. japonicum* off Southwestern Taiwan.

Ecological interactions are especially challenging to study in the deep-sea where direct observation is limited and specimens in museum collections are the most accessible source of information. The glowbellies in the genus *Acropoma* are bioluminescent, mesopelagic fish that inhabit deep waters between 50 m and 500 m off Korea, Japan, Indonesia, and Thailand. Two species of *Acropoma*, *A. hanedai* and *A. japonicum*, co-occur and are caught together during fisheries operations in the waters off southwestern Taiwan. This provided a rare opportunity to explore if closely related species in the same deep-sea habitat exhibited dietary niche partitioning. We examined stomach contents using specimens collected incidentally in fisheries operations off of Donggang, Taiwan in February and May and in the ichthyological collection of the Bell Museum of Natural History. *Acropoma hanedai* more commonly had crustacean stomach contents in February and fish in May, with the opposite pattern in *A. japonicum*. Larger fish statistically were more likely to have fish prey in the stomach in both species. However, the seasonally different dietary preference between species remained statistically significant even when accounting for the stomach-contents effects of size of fish. This work is one of relatively few studies of niche partitioning in the deep sea.

Abstract Name: Combatting the 'Good Ole Boys Club': Women Experiences in Policing in Minnesota

Policing continues to be a male-dominated field. Female numbers remain minimal in recruitment, promotion, and retention. Previous literature has mainly focused on the benefits of having women in the police profession. Such as the increase of reports from female victims, less use of excessive force, and higher implementation of community-oriented strategies. However, there is little research on women's experiences in policing. From their decision-making processes of entering and staying in this profession to their perceptions and experiences throughout their careers. This study focuses on women's experiences in policing, primarily on their perceptions of police subculture. This generationally developed police subculture has been noted to be a 'good ole boys club' in previous literature due to its shared values and attitudes. To understand women's experience with this we constructed an anonymous survey in Qualtrics and have partnered with the Minnesota Association of Women Police to distribute the survey out to female officers across the state. We received responses from 61 female Minnesota officers, consisting of a wide range of tenure and size of agency. Our findings show that the perception of the 'good ole boys club' is still prevalent today. More than half of respondents agreed or strongly agreed that the police profession still is a 'good ole boys club' in their own agency, the state of Minnesota, and the profession as a whole. It is important to understand and appreciate women's experiences in the police profession to gain insight into why their numbers remain minuscule to further our understanding of experiences across departments and to find ways to improve for current and future females in the field. Knowing the benefits of women in policing, it is important to increase their numbers and their experience in the hope of bettering the police profession as a whole.

Abstract Name: Vacancy

Vacancy is a series of fifteen graphite pencil drawings I created for my senior show containing a continuous narrative; each piece depicts a snapshot of key parts in the overarching story. The viewer acts as the main character as they wander an old gas station that leads them to an abandoned building containing a scientific impossibility. The main story came to me while driving on the lonely highways between North and South Dakota. I could see different abandoned houses and buildings appear and disappear between the rolling hills, and it piqued my interest in what would happen if anyone ever stopped to investigate them. Some of the visual inspiration for this series comes from point-and-click horror video games, where the story is revealed by clicking on clues hidden in static images. However, I wanted to avoid the stereotype of disrepair we often associate with abandoned places by having my scenes completely sterile. The brief description accompanying each piece also came from video games when an object would be selected, and text would appear telling the player whether or not that object would be helpful. Drawing on more horror inspiration, I decided these pieces would be completed in black and white, referencing old black-and-white horror from the 60s that has influenced most of my work. By incorporating the viewer as the main character, I can make the scenes feel

more intimate and draw viewers into the story; how the story ends is entirely up to viewers, whether they read the descriptions or not.

Abstract Name: A Novel Discovery Platform to Elucidate Novel Microbe-derived Metabolites and their Effects on Fatty-acid Metabolism

The obesity epidemic has risen to astronomical numbers with over 650 million adults being classified as obese ($BMI \geq 30$). Obesity is of critical concern as excess body fat storage is a comorbidity to various diseases including type-2 diabetes, cardiovascular disease, and cancer. Although obesity has classically been attributed to genetics and unhealthy lifestyle choices, there is a growing interest in other factors affecting obesity, including the gut microbiome. For example, mice lacking a microbiome are resistant to weight gain even when placed on a high-calorie diet. Therefore, bacteria and the metabolites they produce can dramatically affect metabolism and overall weight gain. For this research, we aim to focus on *Faecalibacterium prausnitzii* which has been previously shown to be reduced in obese individuals; however, the mechanism and causation has yet to be fully established. We hypothesized that amplified concentration of *F. prausnitzii* will increase fat metabolism and reduce obesity and its associated effects. To test this, we first used *Drosophila melanogaster* as a model system and administered *F. prausnitzii* to elucidate if it was pro-obesogenic or anti-obesogenic. Our data suggests that Wild Type female *Drosophila melanogaster* survive longer on a high fat diet when *F. prausnitzii* is administered compared to controls. Since identifying this association, our research focus is now elucidating the molecular pathway induced by *F. prausnitzii*. Current experiments suggest the E78 pathway as a putative target for the beneficial effects of *F. prausnitzii*. After confirming the effect of *F. prausnitzii* on fatty acid metabolism, we will attempt to further identify specific metabolites produced by this bacteria. By pinpointing these metabolites, we aim to contribute novel insights into obesity management through targeted modulation of gut microbiota, potentially paving the way for innovative therapeutic strategies to combat obesity and its related diseases.

Abstract Name: The Negative Effects of Social Trends on the Crowns of Black Women

The Negative Effects of Social Trends on the Crowns of Black Women is an IRB approved research piece surrounding Black Women and their views on their hair also known as the “crown”. The framework around this research will be around major historical Black events, hairstyle types, and books depicting the Black

experience like “You Are Your Best Thing” by Tana Burke and Brene Brown and “Hood Feminism” by Mikki Kendall. Historically, Black folk (more specifically Black Women) have been at a social disadvantage when trying to get jobs and other opportunities due to misogynoir. Within this framework, I will be referring to pivotal movements and legislation that affected the Black community from the 1960s to present day to understand the intersectional context of our struggle. My process will then move to group interviews asking participants to reflect on how society may influence the way that they choose to wear their hair. These questions will give me insight on the way that Black women do their hair, view their hair, and socialize around their hair. The answers to these questions will connect to the final quilt that will be displayed representing the experiences I will hear about during the interviews. Through my knowledge of art and the Black experience my piece will bring psychological insight on the experiences Black Women of various ages have surrounding their hair. The quilted product that will be presented will cover the sizing of a full sized bed. Each section will represent a person or multiple people that have shared similar experiences and how they have overcome them. It will explore different types of hair and personality through the use of felt, wire, embroidery, and crochet techniques to add 3D elements.

Abstract Name: Maximizing Participant Retention in Clinical Studies: Key Lessons Learned From an E-Cigarette Cessation Study

Retention is a critical issue in clinical studies, as participant dropout not only compromises data validity but also increases costs and extends study timelines. This challenge is especially pronounced in studies targeting agrarian areas of the Midwest where cessation resources are less commonly available. Retention strategies must address logistical, cultural, and motivational barriers to ensure participant engagement and adherence. We examine the retention strategies employed in our e-cigarette cessation intervention study targeting rural young adults, conducted since 2023. The study aimed to reduce e-cigarette use through a structured intervention, and retention efforts were vital to achieving meaningful outcomes. The first and second presenters of this abstract served as the project coordinator and case manager, respectively, overseeing participant enrollment, data collection, and adherence to study protocols from initiation to completion. Through a narrative analysis of our experiences, we identify effective strategies to enhance retention and participant engagement. These strategies include personalized communication tailored to individual participants, consistent and proactive follow-ups, and incentives designed to motivate continued involvement in the study. The findings highlight practical, adaptable approaches to improving retention in clinical studies, particularly those focusing on behavioral interventions in rural settings. The conclusions drawn from this analysis propose actionable recommendations for optimizing participant retention in similar contexts. By ensuring study adherence and minimizing dropout, these strategies contribute to data quality and the overall success of clinical research. We aim to provide researchers with a framework for implementing effective retention practices in diverse settings, ultimately enhancing the efficiency and impact of clinical studies targeting underserved populations.

Abstract Name: Conformity in the Game of Life - The Evolution and Expansion of Board Games

The Game of Life is simple; Players get married, have children, and obtain as much money and assets as possible before their time on the board ends. Such actions earn the player money, and the richest player wins. This game represents a successful life as defined by one's marital status, number of offspring, and wealth. Restrictive, right? The Game of Life, whether it is realistically applicable to everyone or not, is a representation of the modern, ideal American life. Board games have represented societal expectations of various cultures for centuries. The Game of the Goose, a potential influence of the Game of Life, illustrates what this would have looked like 200+ years ago. The Game of the Goose woodblock and print collection at the University of Kentucky Libraries Special Collections Research Center contains two 18th century French editions of the board game that was created in the 15th century. The game board depicts major landmarks in life through its illustrated spaces, which simulate such events and either moves them back or ahead. It has influenced many other board games to form expressions of what winning the game looks like from the 18th century to today. This research will explore these board games and the interaction between them and their societies. By comparing and contrasting board games within this time span, found patterns in its progression can be taken into account; the current social ideals reflected through board games can then be better understood. This information will be used to create a more universal, modern "Game of Life" that equates individual happiness and contentment to what constitutes winning. It will reflect how "winning" has evolved since the creation of the Game of the Goose. After all, the ideal life is what makes someone happy, not meeting an outdated set of expectations.

Abstract Name: Parenting Stress & Social/Emotional Development of Young Children Experiencing Homelessness

Parents of young children experiencing homelessness tend to experience stress due to several factors surrounding fears regarding their child-wellbeing, lack of social and/or shelter support, difficulty obtaining sufficient educational opportunities, or feelings of isolation and loneliness. Parent stress and child development are often correlated, where external stressors tend to have a significant impact on Parent attunement and nurturance. Many existing studies have identified the impact of Parent stress on Parent nurturance and child well-being as it relates to an increased frequency of physiological aggression toward children, increased child behavior management issues, and the onset of developmental disabilities and psychopathology. Existing research also suggests that affective development in parents and children experiencing homelessness is often transactional, where the mental state and mechanisms by which parents express and manage their emotions frequently have a direct impact on the emotional regulation of children. However, very few studies have pinpointed the mechanisms by which parental stress impacts the psychosocial development of children before adolescence, as children begin to acquire positive (or negative) social-emotional competence. This study explores the relationship between Parent stress and children's

social/emotional development in the context of homelessness. Participants took part in an ongoing study of risk and resilience in young children (ages 4 months to 5 years) experiencing homelessness. Thus, we present preliminary results from 28 families with 40 children ages 5 and under, recruited from family homeless shelters across Philadelphia. Structured participant interviews were conducted in private spaces within the shelters they resided. Parents responded to questionnaires assessing aspects of risk, resilience, and functioning including parenting stress, depression/anxiety symptoms, and children's social/emotional development. We predict strong correlations between parenting stress and the social/emotional development of children experiencing homelessness, whereby an increase in parent stress will simultaneously lead to negative child social/emotional development.

Abstract Name: Cultural Robbery: The Practice of Spaces in Oklahoma in Higher Education Taking Artifacts

For this piece I will be researching the provenance of non-western art pieces in higher institutions in Oklahoma (Oklahoma State University, University of Central Oklahoma, University of Oklahoma, and Langston University). I will research the pieces that these universities have and whether or not they were obtained ethically through examining the code of ethics through museums. I argue that these institutions do not have the full right to be displaying these art pieces within their space if they did not get them ethically. This is due to historical practices that happened during colonialism. I will be executing this process by utilizing school libraries, archives, and asking about the provenance of art pieces that each institution has on display. Some of the spaces included may not have African artifacts but I believe it is important to list how they format the provenance of the pieces within their collections. I will be critiquing these spaces from an ethical standpoint regarding repatriation and what the standpoint from major museums sources like the American Alliance of Museums.

Abstract Name: Trauma in Children of Occupation and Genocide: United States and Israel Relations and the Palestinian Genocide

This paper discusses artwork on the physiological effects of living in war zones on children, with a focus on Palestinians occupied by the Israeli State. For context, the definition of Trauma and the body's 'fight or flight' response is explained along with the mental disorders that follow war trauma. This trauma research has shown that all Palestinian children will suffer from at least three traumas in their lifetime, resulting in Post Traumatic Stress Disorder, which is better diagnosed as Continuous Traumatic Stress Disorder because due to the ongoing wars in Palestine, there is not a 'post' traumatic moment. The origin of the Israel-Palestine Conflict is explained to inform the reader on why these wars have taken place for the last 76 years. The ten stages of genocide are explained to aid any confusion on the recent declaration of genocide in Palestine by the United Nations. Following, for understanding the United States' involvement in the Palestinian genocide, the

relations between Israel and the United States is discussed. The impact of wars on Palestinian children is portrayed in the work of Palestinian artist, Malak Matter, who depicts an idealistic version of Gaza, as a way to cope with her war trauma. In addition, Banksy's artwork on atrocities of war in Palestine, specifically his most recent work on the subject, The Walled-off Hotel in Bethlehem is discussed. In a comparative conclusion, the study demonstrates that both artists' work emphasizes hope for possible Palestine liberation.

Abstract Name: Intersectionality and the Trad Wife Phenomenon: Understanding the Role of Race, Class, and Gender

This project explores intersectionality in the context of the trad wife phenomenon on the Internet analyzing the influences of race, class, and gender through examining the societal norms and individual experiences of the women who are taking on this traditional role at home. The goal of the study is to determine how interviewees (whether they identify as trad wives or not) view the trad wife phenomenon and how an intersectional approach can reveal the racial, political, religious, socioeconomic, and other factors that influence the articulation of trad wife identities. I chose this topic because of the resurgence of traditional values. While individuals (whether on social media or in real life) are entitled to adopt whatever values suit them, I can see the negative consequences of such a stance for members of the feminist and LGBTQ+ communities who are blamed for not upholding these values. My evaluation of research findings will combine qualitative assessment of interview transcriptions with a qualitative and quantitative assessment of scholarly and journalistic approaches to the Trad Wife phenomenon. My goal is to determine the role of race, class, gender, religion, socioeconomic status, and political affiliation in the Trad Wife movement and to determine how or whether Trad Wives perceive themselves (or are perceived by others) as contributing to and/or amplifying white supremacist movements or viewpoints. This topic is very new and has not been sufficiently addressed within the academic world. I want to bring the digital world into the University of Central Oklahoma's academic field and talk about this movement that is prevalent on the online community and affecting future women.

Abstract Name: Intersectionality and Femicides: Understanding the Overlapping Factors in Mexico

This project addresses the critical issue of femicide in Mexico, focusing on the intersectional factors that exacerbate this form of gender-based violence. Femicide, the killing of women and girls due to their gender, is a severe and pervasive issue in Mexico, obscured by systemic deception and social indifference. Utilizing the UCO library databases, social media, academic journals, and news articles, this research aims to uncover the complex layers contributing to femicide and highlight the impact on Mexican women. Central to this study is the concept of intersectionality, a framework developed by Kimberlé Crenshaw, which examines how overlapping social categories—such as gender, race, and class—create interconnected systems of

discrimination. By applying an intersectional lens, the research will reveal why femicide remains a severe threat to Mexican women and explore systemic and societal factors at play.

Abstract Name: Morphometric analysis of the human jaw in relation to dental carries

Changes in diet and the reduction of the human jaw through time has led to increased crowding, malocclusion, and cavities in modern humans. Modern mandibles are smaller and less robust, shaped by softer processed diets and reduced mechanical demands. Though we know narrow mandibles are associated with higher instances of malocclusion, and malocclusion can increase rates of cavities, there is a gap in the literature assessing the direction relationship between mandible shape and rate of cavities. We hypothesize that specific mandibular shapes are associated with a higher prevalence of cavities. To test this hypothesis, dental caries (cavities) will be documented for 40 contemporary Floridian mandibles. Cavities will be manually counted and combined with dental record information to categorize mandibles by the number of cavities they have. Mandibles will be 3D scanned to document their shape. Using geometric morphometrics techniques, we will visualize shape differences between mandibles with different numbers of caries and quantitatively carry out a MANOVA on PC scores to assess statistical significance of shape differences. We expect our hypothesis to be supported and that we'll find individuals with narrower mandibular arches to have higher rates of dental cavities. This study explore show dietary shifts directly influence jaw structure and dental health, shining light on modern oral health challenges while paving the way for potential strategies in prevention and treatment. These findings could impact the future of dental healthcare.

Abstract Name: Structure and composition of forests in the Leon and Salado Creek Greenways

Greenways are protected natural areas within urban centers that preserve biodiversity of local flora and fauna and provide passive recreation opportunities. Leon and Salado Creeks are ephemeral streams surrounded by forest habitat located in northern San Antonio. Both greenways have unpaved and paved hiking and biking trails that receive moderate to high recreational activity and a diversity of shrubs and trees. Within two greenways, we hypothesized there will be vegetation difference among the upper and middle slopes, and ephemeral stream within and between the greenways. We further hypothesized that a greater number of facultative and obligate wetland shrubs and trees will be documented in the ephemeral creeks. We sampled the upper slope, middle slope, and dry creek (ephemeral stream) on the east and west sides using the point-quarter method during May 2024 to August 2024, eighteen point-quarter plots were placed in each of the 8

locations surveyed in both greenways. Based the point counts, tree and shrub mean richness, diversity, density, d.b.h., basal area, and biomass will be estimated by species. cursory observations indicate difference between the structure and composition of forests in Leon and Salado Creek Greenways. Results are currently being analyzed and will be presented at the meeting.

Abstract Name: Optimizing Size and Surface Charge of DNA-Inspired Nanoparticles for Enhanced Therapeutic Delivery

Messenger RNA (mRNA) therapies hold promise for treating genetic and infectious diseases through therapeutic protein expression. However, efficient mRNA delivery remains challenging, especially in tissues with dense extracellular matrices (ECMs), such as those in solid tumors and cartilage. Lipid nanoparticles (LNPs) are commonly used for mRNA encapsulation and cellular uptake but are hindered by their spherical shape and size (50–500 nm), limiting penetration through dense ECMs. To address these limitations, we developed DNA-inspired Janus-Base Nanopieces (JBNps), rod-shaped nanoparticles that improve tissue penetration for RNA delivery. JBNps entangle RNA around nanotubes, assembling into nanorods. This design enhances mRNA delivery, especially for ECM-rich tissues. In our study, we engineered JBNps to optimize their size and surface charge, crucial for targeting osteoarthritic tissues. The JBNps, synthesized and loaded with mRNA via sonication, displayed various size distributions and charges, characterized by a Zetasizer. UV-Vis spectroscopy confirmed nanoparticle uniformity, while different nitrogen-to-phosphate (N/P) ratios were tested for their influence on particle size and surface charge. JBNps with an optimal range of surface charge and size showed the highest cellular uptake, with both smaller and larger particles demonstrating reduced internalization. The dense, negatively charged ECM in osteoarthritic tissue posed a challenge, yet smaller, highly charged JBNps achieved better penetration, enhancing mRNA delivery. Aging JBNps for one week further improved shape and charge uniformity, boosting delivery capabilities. In conclusion, rod-shaped JBNps with an optimized 100–300 nm size and +10 to +20 mV charge significantly improve delivery to ECM-dense tissues, such as those in osteoarthritis. Future research will refine JBNp design using response surface methodology (RSM) to advance gene therapy applications, with potential for treating cancer, genetic disorders, and cardiovascular diseases.

Abstract Name: Sex differences in lung resident and inflammatory dendritic cells during influenza virus infection

Differential gene expression between male and female immune cell subsets significantly contributes to the observed sex disparity in immune cell function. Bridging innate and adaptive immunity, dendritic cells (DC) are sentinels in peripheral tissues that respond to pathogens and initiate immune responses. Sex hormones and their receptors, specifically estrogen receptor alpha (ERα, ESR1), play important roles in DC differentiation and function. Prior research has established that ERα regulates the development of DCs in vitro, specifically a subset of DCs that expands in response to inflammatory signals. We hypothesized that wild-type (WT) mice would show sex differences in pulmonary DC subsets during homeostasis or following an in vivo influenza A virus (IAV) infection, and mice with DCs deficient in ESR1 would fail to expand specific DC subsets. To test this, we infected female and male WT mice with a sublethal dose of influenza A virus (IAV) and used flow cytometry to determine conventional DC type 1 and 2 (cDC1 and cDC2), inflammatory cDC2 (inf cDC2), and monocyte-derived DC (Mo-DC) numbers in the lung in homeostasis or early post-infection. Our analyses revealed no significant difference in numbers of male and female cDC1s, cDC2s, and Mo-DCs in homeostasis. However, on day 5 after IAV infection, WT females harbored greater numbers of inf cDC2s. Future experiments will identify the impact of ESR1 in DCs, using mice in which ESR1 was selectively knocked out in CD11c⁺ DCs. In sum, our data show that females have more inf cDC2s early after IAV infection, suggesting that female-specific factors promote the expansion of the inflammatory cDC2 subset in vivo during respiratory infection.

Abstract Name: Frequency of Capillary Stalling in Male and Female Mice Following Traumatic Brain Injury

The CDC estimates 2.5 million people sustain a traumatic brain injury (TBI) each year. TBI has many adverse effects, including capillary stalling, which is a temporary interruption of blood flow. Although the cause varies, but may be due to hemodynamic flux. We hypothesized that injured mice experience stalls which don't recover, leaving them riddled with vasculature damage. To test this, we performed closed head TBI or sham injury on adult male and female Swiss Webster mice. At either 4 or 25 days after injury, we injected 4µm red fluorescent microspheres and allowed them to circulate for 72 hours. After, we repeated injections with green microspheres, which circulated for one hour before euthanasia. Tissue was collected and both timepoint's spheres were quantified to determine the number of stalls. We found differences in number of stalled capillaries, (presence of red microspheres), across timepoints between sexes. In the hippocampus,

cortex, and thalamus, male mice tended to show an increase in the number of stalled capillaries at 7 days post injury (dpi) that continues to increase at 28 dpi. In the striatum, females showed stall capillaries at sham levels at 7dpi that decreased at 28 dpi. Male mice exhibited sham-level frequency of stalling at both timepoints. Future directions include finding mechanisms contributing to stalling after TBI and why capillary stalls exacerbate blood brain barrier (BBB) breakdown and further microvascular dysfunction, leading to larger ischemic and hemorrhagic strokes.

Abstract Name: The Impact of Repeated Reading on Reading Fluency

Repeated reading is an essential skill that students demonstrate and has even been identified as a defining characteristic of strong readers. Students struggling with reading fluently may be negatively impacted and struggle with reading their homework, reading aloud in class, and even academic performance. It is important to identify why students may be struggling with reading fluency and which strategies and interventions could help them improve their reading fluency. Repeated reading is one intervention that has received increasing attention in literature. In our research, we are looking at how variations on repeated reading impact reading fluency of 3rd grade students. This study will use an alternating treatments design in which several conditions are rapidly and repeatedly alternated to evaluate their effectiveness, specifically repeated reading with no preteaching activities, repeated reading with word-level preteaching, and repeated reading with content-level preteaching. Students who partake in this study are identified as being at-risk for reading difficulties, their parents have provided informed consent, and they have provided assent. Researchers will use grade-level text to implement repeated reading, in which participants are asked to read from the passage for one minute, three times, and after each reading, the researcher will provide error correction for any words read incorrectly. To evaluate the effectiveness of each condition, the researcher will compare the words read correctly on the fourth reading across the three conditions. The condition which results in the highest words read correctly in one minute, most consistently, will be considered the most effective. We anticipate that the use of preteaching strategies will lead to an increase in reading fluency over repeated reading without preteaching.

Abstract Name: Deletion of cGAS Preserves Vaginal Tissue in a Mouse Model of Prolapse

Pelvic organ prolapse (POP) affects 50% of women, is characterized by the descent of pelvic organs into the vagina, and is associated with age and childbirth. Birth injuries can damage DNA in vaginal cells, activating

cGAS, a DNA sensor that triggers immune responses. Prolonged cGAS activation promotes inflammation, weakening pelvic tissues, particularly fibulin-5, which forms elastic fibers critical for pelvic stability. This study investigated if knocking out both the cGAS and fibulin-5 genes in mice (DKO) restores vaginal function. Vaginal modulus was quantified using biaxial inflation testing in POP mice with fibulin-5 knocked out (F5KO) and DKO, compared to wildtype controls (WT). 15 nulliparous female mice (4-6 months old) were divided by genotype: WT, F5KO, and DKO (UTSW IACUC approved). Vaginas were mounted onto a biaxial inflation device to quantify tissue modulus at physiologic loading conditions. The F5KO was less distensible than the WT and DKO as shown by a stress-stretch curve. Circumferential modulus significantly increased in the F5KO compared to WT ($p=0.002$, $p=0.04$) and DKO ($p=0.003$, $p=0.05$), but DKO was not significantly different from WT controls. This study showed that deleting cGAS restored the biomechanical functions of the murine vagina. F5KO mice exhibited significant mechanical differences compared to WT and DKO mice, regardless of prolapse grade. The DKO did not show any significant differences in vaginal biomechanical properties from the WT. Clark+ showed that vaginal distensibility in F5KO mice decreased with grade 1 POP but increased with grades 2-3 compared to WT mice. Zheng+ also identified cGAS as a key mediator in age-related diseases, regulating cellular dysfunction and inflammation. Taken together, these findings suggest that targeting the cGAS pathway may mitigate the negative effects of Fibulin-5 deficiency and offer a promising therapeutic approach to preserve tissue strength and improve pelvic health.

Abstract Name: Investigating the Distinctions in Treatment Adherence and Response towards CBT-I among the Psychiatric Population, based on Baseline Symptom Severity

“Insomnia is a frequent concern for those diagnosed with a psychiatric disorder. Evidence-based psychotherapies can be enhanced through a greater understanding of how treatments work from the perspective of the patients receiving the treatment. Cognitive Behavioral Therapy for Insomnia (CBT-I) has been demonstrated as an efficacious treatment for sleep disturbance. Despite its prevalence and impact, CBT-I's dissemination does not match its public health significance, despite a robust evidence base and recommendation as a primary intervention. Our current study will examine how patients adhere to the treatment during a course of CBT-I and patients' qualitative experience of the treatment. We hypothesized that there will be patterns of change in patient treatment adherence, measured via a weekly sleep log. To investigate this hypothesis, a small cohort of recruited participants will meet inclusionary criteria for insomnia and at least one DSM diagnosis for a psychiatric condition. Participants will complete a 6-week sleep log, which will measure various trajectories of patient adherence. Additionally, a general measure of symptom severity will be administered at baseline to assess symptoms severity. Finally, a qualitative survey to assess patients' experience of CBT-I following treatment will be developed.”

Abstract Name: Josef Suk's Deviation from Traditional Ternary Form in his "Fantastické Scherzo"

Ternary form typically exhibits three stable thematic sections: a beginning A section, a central B section, and a concluding (sometimes altered) return of the A section. A notable deviation from this form is Josef Suk's "Fantastické Scherzo," a longer ternary work for orchestra. Although this piece follows an overall ternary design, it features a mix of stable and unstable subsections instead of the standard use of a singular stable theme per section. To understand the relationship of these stable and unstable subsections, I will first identify the three main sections of the work (ABA). From there, I will recognize the different themes featured within these sections (two A themes and one B theme) and subsequently divide the sections into subsections based on how these themes are presented. They will be identified as either stable or unstable based on whether the full theme is stated in the section's main key or in fragmentation in other keys, respectively. Once I recognize each subsection's relative stability, I suggest that the fragmented sections are bookended by specific opening and closing motifs derived from each section's opening theme. Finally, I identify that the main sections are unified by common thematic material that alternates between stable and unstable presentations. As a result, I find that although this piece deviates from traditional ternary form, it is possible to unify the main sections by subdividing them into stable and unstable subsections that feature common thematic material.

Abstract Name: Fabrication and Analysis of Polycaprolactone Continuous Microfibers

Polycaprolactone (PCL) continuous microfibers have great potential for various engineering and biomedical applications including surgical suture and bio-micro-sensors. This research presents a novel method of fabricating continuous, straight, and spoolable polycaprolactone microfibers and parametric analysis of the produced microfibers. PCL continuous microfibers were produced using an in-house hybrid fused deposition – spinning unit. Biomedical grade PCL filament was extruded through an electro-melt hot end and spun at various rotational velocities and spooled on a spooler. Speed of the extrusion was carefully controlled using Arduino microcontrollers and stepper motors running at a set speed to control the spinning rates. PCL microfibers were produced and spooled for four different spinning rates: 18, 29, 53, and 118 RPM respectively and surface quality and diameters were evaluated using a scanning electron microscope (SEM). The results show that produced microfibers are concentric in their cross-sections and diameters were directly correlated with the spinning rates. Higher spinning rates yield thinner microfibers. The results also show that the developed in-house hybrid system can produce as small as 4 micrometers diameter and as large as 114 micrometers diameters of continuous PCL microfiber. The SEM images also revealed that the surface quality of the produced microfibers was very smooth. This research will help to develop bioresorbable surgical suture and other microfiber based biomedical devices and sensors.

Abstract Name: Preparation of Banana Peel Effect on Adsorption of Anionic and Cationic Dyes

This study aims to investigate the adsorption of semi-ripe banana peel (BP) as a biosorbent for removing cationic and anionic dyes. Previous research has demonstrated the ability of fruit peels to adsorb pollutants, with a notable efficacy against cationic contaminants. Inspired by these findings BP prepared using different treatments was studied as an affordable and eco-friendly alternative for dye adsorption. Four peel preparation methods—sodium hydroxide (NaOH), hydrochloric acid (HCl), oven dried after water (H₂O), and not dried after water (H₂O) were used to prepare BP for batch adsorption of an anionic and cationic dye, allura red (AR) and methylene blue (MB), respectively. With the goal of maximizing pollutant removal efficiency by optimizing BP preparation while still maintaining environmental sustainability, the experimental design controlled peel size to reduce variability in our comparisons between findings and established literature on similar biosorbents. We found that BP prepared using NaOH had the highest percent removal. Following the pseudo second order kinetics model the peels achieved an adsorption capacity of 2.9 mg/g at equilibrium with a max percent removal of 85% after 7 hours. This suggests potential for broader application with other dyes with this preparation technique. This study contributes to the growing body of research on low-cost, renewable bioadsorbents by presenting a comparative analysis of BP treatments, with potential applications for improved wastewater treatment methods. The findings from this research could further support the utilization of waste biomass for sustainable environmental cleanup, broadening the scope of biosorbent materials used in the decontamination process.

Abstract Name: Single Molecule FRET-Based Detection of Nucleic Acid Biomarkers of Cancer

Over 40% of people are likely to be diagnosed with cancer in their lifetimes. Early detection of cancer is instrumental for higher survivability, quality of life, and remission. Certain circulating nucleic acids have been identified as biomarkers for cancer. While amplification techniques like RT-PCR are available, false positives are common limitations. Developing sensors to confidently detect nucleic acid biomarkers in blood at low concentrations is key in advancing early detection capabilities and treatment options. Fluorescence resonance energy transfer, or FRET, is a distance dependent, non-radiative, energy transfer process that occurs at the nanometer length scale, well suited for studying the dynamics of DNA molecules. In this project, to detect such biomarkers in solution, fluorophore-labeled DNA constructs based on the Holliday Junction were designed and tested. The utility of Holliday Junction-based DNA sensors arises when combined with the distance dependent nature of FRET. When the four-way junction is complete (i.e. when the target is bound), the changing conformation of the sensor alters the inter-fluorophore distance, leading to a dynamic EFRET pattern that can be observed in the TIRF microscopy. Following immobilization of these sensors on the microscope slide and addition of the biomarker target, the sensors were visualized via TIRF

microscopy, and their behavior were analyzed using MATLAB. DNA constructs with bound targets were found to display dynamic behavior, identifiable by characteristic fluorescence and FRET traces. Through this method, a clear and precise detection of circulating tumor nucleic acids is possible, opening up a new frontier to cancer screening.

Abstract Name: Perceptions and Beliefs: Investigating Mindset and Advising Styles in Higher Education

Research on implicit theories of intelligence in academic settings has become increasingly popular among researchers and educators. Implicit theories of intelligence represent how people respond to challenges and convey either a growth mindset (intelligence is malleable) or a fixed mindset (intelligence is unchanging). While students' mindset beliefs are incredibly important, how they perceive the mindsets of others can be a stronger predictor of student success outcomes. However, much of this research has focused on instructors and has yet to be expanded to the academic advising realm. Advisors play a key role in students' academic decision-making, and advisor-student relationships can be influential in positive student development. Research on academic advising has primarily focused on advising style, classified as either developmental (holistic) or prescriptive (rigid), with less emphasis on advisor mindset beliefs. However, advisors who believe their students can improve (growth mindset) may be more likely to prioritize advising that promotes student development (developmental advising). In contrast, an advisor that does not believe students can improve (fixed mindset) might suggest a curriculum that underestimates students' true potential (prescriptive advising). This study aims to examine these variables from both the advisor and student perspectives. First, what is the relation between self-reported advisor mindset beliefs and advising style? Secondly, what is the relation between student perceptions of advisor mindset beliefs and advising style? We will run correlational and descriptive analyses using survey data collected from advisors and students at a large public university in the United States. A positive association may indicate an opportunity to utilize developmental advising interventions to promote growth mindset, or growth mindset interventions to promote developmental advising. The results of this study will generate directions for future research to better understand how these motivational processes directly impact student satisfaction and success.

Abstract Name: Characterizing the expression of angiogenic genes in an in vitro injury model

Angiogenesis is a multistep, tightly regulated biological process characterized by the growth of new capillaries that is mediated by angiogenic factors, extracellular matrix components and endothelial cells. Following injury, angiogenesis is essential during tissue repair, which is highly dependent on adequate blood supply and, as a result, on functional and temporally regulated angiogenesis. However, a better understanding of the angiogenic process during tissue repair is still needed. Here we investigated the expression of angiogenic genes in an in vitro injury model consisting of human bone-marrow mesenchymal stem cells (BM-MSCs) treated with transforming growth factor beta 1 (TGFβ1; 10 ng/mL) for 24 hours. Gene expression analysis for the angiogenic genes ANGPTL2, FGF2, VEGFA and COX2 was performed by q-RT-PCR. GAPDH was used as a housekeeping gene. Remarkably, BM-MSCs treated with TGFβ demonstrated a trend towards the up-regulation of ANGPTL2 (control: 1.0 ± 0.0 ; TGFβ: 1.5 ± 0.3 ; $p=0.17$), FGF2 (control: 1.0 ± 0.0 ; TGFβ: 1.8 ± 1.2 ; $p=0.41$), VEGFA (control: 1.0 ± 0.0 ; TGFβ: 2.5 ± 1.2 ; $p=0.15$) and COX2 (control: 1.1 ± 0.1 ; TGFβ: 3.1 ± 2.3 ; $p=0.26$). Additional experiments need to be performed to validate these findings. Altogether, our results support the notion that our in vitro injury model may be used for the investigation of human post-traumatic angiogenesis and may be a useful in vitro system for future translational studies.

Abstract Name: Effect of Cholesterol on Viability and Proliferation of Breast and Endometrial Cancer Cells

According to the American Cancer Society, ~36% of cancers diagnosed in US women consist of breast cancer (BC) or endometrial cancer (EC). The high incidence of cancer in the US is linked to the obesity epidemic, with obesity affecting over 40% of the adult population. Hypercholesterolemia is a dominant factor in the pathophysiology of obesity and is described as a risk factor for cancer. For instance, a positive correlation between cell membrane cholesterol and ErbB2 (HER2) distribution is reported for BC. Additionally, a direct link is published between hypercholesterolemia and EC risk along with poor prognosis. A correlation between obesity and cancer, however, remains to be elucidated. The goal of this study was to determine how cholesterol supplementation would affect the growth dynamics of both HER2+ BC and hormone-responsive EC cells. HER2+ (SKBR3) and EC (Ishikawa) cells were supplemented with cholesterol (0 mM; 2.5 mM; 5 mM; 7.5 mM) for 28 days. Our results for BC show that cholesterol augmented proliferation rate by ~35% in the 5 mM group, while it increased the number of non-viable cells by ~40% in the 7.5 mM group compared to the control. Cell proliferation rates in the EC group decreased progressively with higher doses of cholesterol (~75% in 7.5 mM) relative to the control. Furthermore, a dose-dependent increase in the number of non-viable cells was observed in the EC group. qPCR data of both BC and EC cells revealed increasing cholesterol concentrations suppressed steady-state expression of genes associated with cell proliferation (cMYC) and the mevalonate pathway (SREBP1, HMGCR, and STARD1). Our findings suggest that cholesterol had contrasting effects on BC and EC cells, but these results merit further studies.

Abstract Name: Comparing Heart Attack, Heart Failure, and Heart Disease Diagnostic Features Using AI/Machine Learning Techniques

Making comparisons of the features (age, chest pain, cardiac arrest, thalassemia, and blood pressure) present when looking at heart attacks, heart failure, and heart disease will help understand the correlation and any distinguishing features to help differentiate between the three. Our hypothesis is that the diagnoses of heart attacks, failures, and diseases, all share some important variables, which may show presence of more than one of these in one patient, due to their linkage. In current work, we have compared different algorithms using IBM Watson to predict outcomes of heart attack datasets. When our heart attack data, collected from Kaggle, was run through IBM, accuracies as high as 86% from two datasets were achieved. First Dataset included 303 patients and the other held 1025 patients. In this study, multiple algorithms were simultaneously applied that included Logistic Regression, Snap Logistic Regression, and Gradient Boosting Classifiers. Continuing further on this investigation, another goal is to compare the similar features in heart attacks and diseases, which both can lead to heart failure. Using data from Kaggle, IBM Watson will be applied to compare previous results with the significant features and model accuracies with the results of the new data. Comparing the different variables show extremely similar features that may be used to diagnose each condition. The datasets also are compiled with data from different parts of the world, which will yield some variance in data points as cultural factors, such as food. These factors may vary in different parts of the globe to impact the model accuracies. A deeper medical point of view will be presented along with the AI/Machine Learning perspective.

Abstract Name: How does Accutane influence patients' mental health, particularly in terms of triggering or worsening depression and anxiety?

Accutane, also known as isotretinoin, has transformed the way severe, stubborn acne is treated by offering long-term relief from the psychological and physical effects of the condition. Its growing use, however, caused worries about possible neuropsychiatric adverse effects, especially given its link to anxiety and depression. With a focus on the therapeutic effects, underlying biochemical mechanisms, and clinical treatment options, this study examines the impact of isotretinoin on mental health. Acne symptoms decrease significantly with isotretinoin, which also controls skin inflammation and sebaceous gland activity. Its capacity to pass across the blood-brain barrier as all-trans retinoic acid, however, raises concerns regarding how it may impact neurological functions such as mood, memory, and synaptic plasticity. Mood swings could be caused by retinoic acid's interaction with the brain's retinoic acid receptors and serotonin signaling. Furthermore, research on animals indicates that isotretinoin may affect stress response pathways and neurogenesis, which might worsen feelings of anxiety and depression. The evidence is still contradictory, despite a large number of case studies that connect isotretinoin to neuropsychiatric symptoms like depression and suicidality. Some research show that when acne goes away, mental health improves, while others show an increase in depressed symptoms. Individual characteristics like the severity of acne, social support, and prior history of mental illness seem to have a significant impact on the results. The advantages and disadvantages of isotretinoin must be balanced, which calls for holistic approaches, frequent mood monitoring, and thorough mental health evaluations prior to therapy. Promoting open communication with patients and their families requires educating them about possible adverse effects. Including mental health specialists in treatment

groups ensures that psychological requirements are met in addition to dermatological improvements. Research advances isotretinoin's safety, reducing psychological and dermatological concerns for acne patients.

Abstract Name: Environmental Impacts of the Great Eastern Japan Tsunami of 2011 on Water Quality and Resulting Dangers to Post-Disaster Community Wellbeing and Ecosystem Revitalization Efforts

Tsunamis are some of the most destructive of Earth's natural forces. These disasters are extremely dangerous and can have devastating effects on not only human communities but also on ecosystem health and water quality. This project explores the multifaceted impacts of tsunamis with a specific focus on the Great Eastern Japan Earthquake and Tsunami disaster of 2011, one of the most devastating natural disasters in recent history. This tsunami caused significant damage to marine and freshwater ecosystems alike, resulting in detrimental effects to both aquatic life and human health. The very slightest fluctuations in nutrient levels or suspended sediment in water systems can destroy the delicately balanced ecosystems along the coast and can have damaging impacts on the organisms that make these aquatic ecosystems their homes. Contamination of freshwater sources following the tsunami also raised public health concerns, particularly in relation to drinking water access and the prevention of the spread of waterborne disease. The research in this project establishes that while Japan has made incredible improvements to shoreline infrastructure, including the building of new seawalls and breakwaters along the coast, the effectiveness of these measures often exacerbates destruction and risk in the communities they are intended to protect. Natural techniques are often less damaging to existing ecosystems and help to protect delicate environmental balances that might otherwise be disrupted by man-made infrastructure. This study emphasizes the need for continued research on more effective solutions for water quality remediation and management as well as general disaster preparedness strategies for tsunami-prone areas. It also calls for increased international collaboration for the advancement of technologies for water purification and to develop new natural disaster mitigation strategies that prioritize and protect both human and environmental health.

Abstract Name: The Importance of LIP5 Condensate Formation in Plant Growth

Plants respond to their environment to adapt to changing conditions and combat issues like pathogens. Among these responses, plants change the composition of their plasma membrane by, for example, engaging the Endosomal Sorting Complex Required for Transport (ESCRT) proteins that sort and package plasma membrane proteins for degradation. One example of an important ESCRT protein is LIP5, which has the unique ability to form condensates only in plant cells but not in other organisms. To determine the function and importance of LIP5 condensation in plants, we designed an experiment to analyze the ability of LIP5 mutant proteins unable to form condensates to rescue the phenotypic defects of mutants lacking LIP5 and the

ESCRT protein ISTL1. Whereas the single *istl1* and *lip5* mutants in *Arabidopsis thaliana* are viable, the *istl1 lip5* double mutant plants are dwarf and infertile, and therefore ideal for rescue assays. By genetic engineering, we expressed wild-type LIP5 and a mutated version of LIP5 unable to form condensates in the double mutant *istl1 lip5* and measured the rosette diameter of the transgenic lines. The results showed that only the wild-type LIP5 protein can fully rescue the *istl1 lip5* double mutant phenotype whereas the expression of the mutated LIP5 does not completely restore normal growth and fertility, supporting a functional role for LIP5 condensation.

Abstract Name: Rethinking Climate Action Policy through a Kantian Model of Obligations

The Westphalian model or state-centered model of international environmental and climate change policy has failed, an argument that has been widely noted in philosophical climate change literature. Philosophers have developed alternative models focused on correcting the structural issues of the international environmental policy regime by delineating the roles and obligations of the four climate actors: states, individuals, collective groups of people, and corporations. However, these approaches have insufficiently addressed the interactions among the responsibilities of climate actors, where the obligations of each climate actor intersect with the others and change the necessary roles and duties of a particular climate actor. As a result, the research question of my paper is: what are the obligations for climate actors such as governments, corporations, and individuals within a Kantian deontological framework? In order to determine the ethical obligations of each climate actor, I use a Kantian deontological framework to ground my philosophical discourse in environmental ethics related to explicating the obligations of each climate actor. Furthermore, in my philosophical project, I will outline the roles and obligations of the four main actors considering the necessity of the interactions among the responsibilities of each climate actor. A clear delineation of the roles and obligations of each climate actor is of crucial importance to the enactment of effective climate change policy. Because human societies cannot effectively act against anthropogenic induced climate change, without first knowing what the appropriate duties for each actor are. Once these duties have been delineated, climate actors will no longer be able to hide from their duties to the environment, a crucial step in the process of climate change mitigation.

Abstract Name: The Effect of Transcutaneous Auricular Vagal Nerve Stimulation on Second Language Learning: A Scoping Review

Adults often face challenges in learning a second language, possibly due to the sensitive period of language acquisition. Post-puberty, the mature brain experiences reduced neuroplasticity, pruning, and synaptogenesis

which impacts language learning. Transcutaneous auricular vagus nerve stimulation (taVNS), a new neuromodulation technique that modulates the release of neurotransmitters like acetylcholine, norepinephrine, and brain-derived neurotrophic factor is proposed to help reverse this decline. This scoping review compiles peer-reviewed publications investigating the effect of taVNS on healthy adults learning a second language. Using PRISMA guidelines, this scoping review examined peer-reviewed publications from 2010-2024 across different databases (e.g., PubMed). The review included eight studies that looked at a total of 387 adults aged 18-35, assessing the effect of taVNS on second language acquisition, such as noun learning, perception and production of speech sounds, tone identification, lexical tone contrast, letter-sound correspondences, and vocabulary. Results showed that taVNS delivered at 25 Hz and low amplitude, had a positive effect on most skill areas studied. Although one study did not find a benefit of taVNS in language learning, it found evidence for an increase in motivation for participants to learn vowel sounds. The studies revealed that the stimulation of the auricular branch of the vagus nerve facilitates neuroplasticity through the production of norepinephrine and acetylcholine, which in turn modulate attention, memory formation, and learning. Overall, taVNS had a positive impact on noun acquisition, tonal language categorization, lexical tone contrast recognition, lexico-semantic representation, automaticity and decoding tasks, and vocabulary. Even the one study that found no efficacy of taVNS beyond tone perception discovered a positive impact in motivating participants to learn easier sounds. Findings suggest that taVNS holds promise in facilitating second language acquisition in adults and paves the way for further research into its role in post-stroke aphasia language rehabilitation.

Abstract Name: AI-Assisted Spectral Profiling of Biomass-Derived Red Blood Cells for Stellar Research and Bioenergy

Previous studies, including our own, have shown that red blood cells derived from biomass waste can store and emit electromagnetic energy when exposed to infrared lasers and sunlight. To fully harness this ability, we are developing an AI-assisted program to construct a complete emission spectrum profile of ionized red blood cell samples, similar to the spectral profiles of stars. This program will analyze the illumination of radiation emissions from the ionized samples, identifying key spectral features such as wavelength, color, temperature, and intensity. The AI-assisted code breaks down the plasma's illumination into these spectral components by analyzing the light emitted at different wavelengths, which correspond to different colors and temperatures, and measuring the intensity of the emitted light. These features reveal how blood cells store and release energy from infrared laser light. By identifying and measuring these features, we aim to understand how red blood cell plasma stores and emits energy, potentially advancing stellar research simulations and utilizing biomass waste for renewable energy. This research employs AI-assisted code and modern physics laws to analyze video footage of red blood cells during laser ionization. By applying Stefan-Boltzmann's and Wien's displacement laws, we model the thermal radiation characteristics of ionized blood cells, breaking down the plasma's illumination into spectral components. Our current focus is on the computational analysis of the ionized blood sample's emission spectrum to enhance our understanding of electromagnetic properties in biomass-derived red blood cells. The implications of this research are significant: it allows us to simulate hands-on research of a "small star," which could otherwise only be studied through observation. This contributes to advancements in renewable energy, medical diagnostics, interdisciplinary scientific discoveries, and environmental sustainability by better understanding how biomass waste stores and emits energy through spectral profiling.

Abstract Name: Effects of Rape Myth Acceptance, Sexual Assault Experience, and Gender on Risk Perception and Constructive Memory

Memory recall is a constructive process: What we remember is determined not only by what we encoded during an experience, but also by other knowledge, beliefs, and expectations. This can generate memory errors. Memories for information about sexual assault cases may be especially vulnerable due to the stigma surrounding sexual assault, the prevalence of rape myths, and the varying degrees of personal experience with sexual assault. This study seeks to look at the effects of sexual assault experience, gender, and rape myth acceptance (RMA) on perception of and memory for a narrative of an ambiguous of a sexual assault scenario. Participants were asked to recall the narrative immediately and after a one-week delay. Analyses will examine how individual differences in rape myth acceptance, sexual assault experience, and gender will predict perception of risk in the scenario and which details are remembered correctly and incorrectly from the narrative. High levels of RMA are expected to predict increased memory errors for details that are rape myth inconsistent and decreased risk perception, whereas low levels of RMA are expected to result in increased memory errors for rape myth consistent details and increased risk perception. Women are expected to have increased risk perception and decreased memory errors overall, and sexual assault experience is expected to be negatively correlated with risk perception.

Abstract Name: Decoding Uncertainty: Assessing the Pathogenicity of Desmoplakin Variants in Arrhythmogenic Cardiomyopathy

To date, heart disease remains to be the leading cause of death worldwide. Arrhythmogenic cardiomyopathy (ACM) is an inherited heart disease characterized by fibro-fatty infiltration and an increased risk for sudden cardiac arrest that is primarily associated with variants within desmosomal genes. A desmosomal gene of interest is desmoplakin (DSP), a type of protein that acts to tether the intermediate filaments of one cell to the plasma membrane of a neighboring cell. Our lab has previously reported that select variants in a 'hotspot' region of ACM-associated variants have hypersensitivity to calpain degradation. The mutations unfold a previously occluded calpain target site for calpain-mediated degradation by decreasing intermolecular interactions of amino acid side chains. The newly exposed calpain target site is susceptible to calpain proteolysis resulting in a reduction of full-length DSP protein levels. Despite past studies in the field, the majority of ACM linked-DSP variants have yet to be classified as pathogenic or benign. With over 75% of DSP variants classified under unknown pathogenicity (UP), improved molecular knowledge on these variants is necessary for appropriate diagnosis and viable treatment. Our research team examined 7 UP DSP variants within the mutational 'hotspot' to evaluate molecular modifications within the calpain sensitive region of each variant that may trigger calpain hypersensitivity. Molecular dynamic simulations identified 1 UP variant with increased surface exposure of the calpain target site. Surprisingly, 4 variants had increased sensitivity to calpain in vitro, suggesting other factors may contribute to calpain-mediated degradation. Regardless, this

reinforces understanding of the calpain hypersensitivity of DSP and may aid in future personalized treatment for ACM patients with calpain sensitive variants.

Abstract Name: Uncovering Imputation Bias Using Explainable Machine Learning Methods

Missing data is a common obstacle in building robust machine-learning models, and many classical algorithms require imputation of missing data. The optimal imputation method in each context depends on the correlation structure of a dataset, the amount of missingness, the types of features, and the mechanisms of missingness. Yet, this step routinely receives little attention, and selecting a suboptimal imputation method for a dataset can introduce bias into the model, diminishing the model's generalization capabilities. Shapley Additive exPlanations (SHAP) values are a game-theoretic method of assessing the "importance" of features in a model in producing an output. The values are local estimates of each feature's influence on the dependent variable and are derived through sampling methods that perform inference on records with and without a given feature. Here, we analyze SHAP values to provide insight into the behavior of imputation methods and machine learning models in the presence of missing data. We simulate artificial datasets with missing feature values with varying levels of correlation, mechanisms, and levels of missingness. We apply SHAP techniques to models trained on these datasets, both complete and with imputed data, to demonstrate how the properties of SHAP can lend insight into how imputation techniques affect model performance. SHAP can also provide warnings when imputation may introduce unwanted bias. Practitioners can use these flags of bias to appropriately handle missing data by choosing optimal imputation procedures. This approach can enhance the generalization capabilities of their models while effectively reducing the risk of performance degradation caused by missing data.

Abstract Name: Using FRET microscopy to compare the binding affinity of various PLM mutants to the NKA pump.

In cases of Dilated Cardiomyopathy, there is a known decrease in contractile output due to the thinned walls of the left ventricle. Research is currently looking for ways to increase this contractile force and improve the efficiency of the heart. The ultimate question is, how can one increase contractility. Calcium, an ion known to be involved in muscle contraction, is found in cardiomyocytes. One way to increase force output is to utilize calcium by preventing its movement out of the cell. This project looks at the Sodium Potassium (NKA) pump, a protein that moves sodium and potassium across the cell membrane, and its effect on calcium movement out of the cell. As these ions are moving, there is a change in electrical charges which influences

other ions, such as calcium, to move out of the cell. The theory, then, is to find a way to inhibit the NKA pump, preventing its movement of calcium out of the cell and allowing calcium to aid in the contraction of the heart. To inhibit the NKA pump, this project utilizes Phospholemmon (PLM), which has been shown to inhibit NKA function and prevent the ions from moving against a concentration gradient. The goal is then to assess how closely these two proteins (NKA and PLM) bind to one another, as tighter binding can lead to greater inhibition of the NKA pump. The binding affinity is assessed by fluorescently tagging these two proteins and quantifying their difference in binding using Fluorescence Resonance Energy Transfer (FRET) Microscopy. To further this project, known disease-causing mutations of PLM were identified and investigated to determine the mutation that shows the greatest inhibition of the NKA pump, leading to the greatest increase in contractility of dilated cardiomyopathy hearts.

Abstract Name: Tapping Into Trouble: Investigating Microplastics and Heavy Metals in Birmingham's Water

Microplastics are defined as fragments smaller than 5 mm. If these fragments are small enough, they may cross the human blood-brain barrier. Literature indicates that microplastics can adsorb heavy metals such as lead, copper, and zinc. The adsorption phenomenon means that microplastics can both be harmful on their own and act as a vehicle for introducing other toxins to the body. This study investigates a possible association between microplastic count and heavy metal concentration in drinking water samples and suggests a novel technique to achieve these results. Traditionally, microplastics are quantified through a sediment filtration and microscopy. The proposed method requires only one field sample to determine the presence of both pollutants, further refining the identification of microplastics in the field of community water quality. In the proposed method, water was treated with prepared microplastics and shaken with lead, copper, and zinc to simulate the conditions of a pipe system. The microplastic particles were isolated and treated with a chelating agent. After filtration, the filtrate was further extracted and analyzed using ICP-OES to determine heavy metal concentration. Microplastic count was obtained through microscopy. It is theorized that an increased microplastic count will be correlated with an increased concentration of heavy metals, putting communities with aging infrastructure at risk for heavily polluted drinking water. The methods are cost-effective enough to show promise of being replicated by other institutions, hopefully introducing a more standardized and accessible method for assessing water contamination.

Abstract Name: Identification of DNA Barcodes and Genetic Indices from *rbcl* Chloroplast DNA Marker within Pepper Varieties (*Capsicum annum* L.) from Different Grocery Stores in Maryland

Pepper (*Capsicum* spp.) belonging to family Solanaceae is cultivated globally for its essential uses as vegetables, spices, medicines, ornaments, lachrymatories, vitamins A and C. Over 38 species of it has been reported worldwide and there is lack of information on DNA barcoding and genetic diversity of peppers sold at different grocery stores in Maryland. DNA barcoding is a molecular technique used to identify and classify species based on short, standardized regions of DNA, offering a powerful tool for assessing genetic diversity and identification to species level. In this study, ribulose 1,5-bisphosphate carboxylase/oxygenase large subunit (*rbcl*) marker was utilized for DNA barcoding and evaluation of genetic diversity of pepper varieties. Sixteen pepper samples were collected, and DNA was extracted from both seeds and fleshy parts. The extracted DNA samples were quantified using NanoDrop spectrophotometry, followed by dilution makings and polymerase chain reaction (PCR) amplification. The PCR amplicons were verified on agarose gel electrophoresis and later sent to GENEWIZ for Sanger sequencing. The raw sequences were analyzed with DNA Subway's Blue Line platform. Within some consensus positions of the aligned sequences, single nucleotide polymorphisms (SNPs) in forms of insertions-deletions (Indels: .../C), transitions (C/T) and transversions (A/G) were detected. A phylogenetic tree reconstruction revealed the differences and clustered them on different clades and subclades. All the species were confirmed via BLAST analysis with known ones in the NCBI database. This study, despite the minimal number of samples used, demonstrates the effectiveness of the *rbcl* marker for DNA barcoding and identification of intraspecies diversity and provides valuable insights for future studies of more varieties of peppers from more grocery stores within Maryland.

Abstract Name: The Impact of the use of Internet of Things (IoT) Technology and Artificial Intelligence (AI) for remote fetal monitoring on maternal and fetal health outcomes in Ghana

This research investigates how IoT and AI technologies can transform maternal and fetal healthcare by addressing the central research question: “How can IoT technology and Artificial Intelligence enhance remote fetal monitoring to improve maternal and fetal health outcomes in Ghana?”. Maternal and fetal health complications require timely detection and intervention. However, traditional monitoring methods relying on periodic hospital visits leave gaps in continuous care, delaying responses to critical health events. Through AI-driven analysis, the study seeks to demonstrate the potential for early detection of complications, improved healthcare decision-making, and enhanced health outcomes for mothers and fetuses. The study employs a quantitative methodology, beginning with the use of existing fetal health datasets containing key metrics such as fetal heart rate and maternal vitals, to train the AI system. The system will be developed to analyze these patterns, enabling it to detect abnormalities associated with complications. The AI system will

be integrated with a wearable IoT device, which collects real-time data on fetal and maternal health metrics such as fetal heart rate and uterine activity, and transmits it to a web application for healthcare professionals for analysis. The system will process the real-time data to detect potential risks, generating alerts for timely interventions. The AI's performance will be evaluated using accuracy scores to determine its effectiveness. The research is expected to show that IoT and AI technologies improve maternal and fetal health outcomes by enabling earlier detection of complications and timely medical interventions. These findings will provide a solid foundation for integrating innovative technologies into prenatal healthcare in Ghana.

Abstract Name: Study of Relationship Between Complexity of Play and Social Participation in Preschoolers' Play

This study examined the relationships between preschoolers' gender, cultural background, bilingualism and their Play Roles, Complexity of Play, and levels of Social Participation level during pretend play. While past studies on pretend play have examined the effects of gender, culture and bilingualism, their relationship with Complexity of Play and levels of Social Participation have not been researched. Sixteen preschoolers enrolled in a lab school participated in the study. Twenty minutes of video footage was captured from each of the children while they were engaging in pretend play at the dramatic play and blocks centers. Every minute of every child's twenty minutes was assigned codes for the four categories of Complexity of Play, Social Participation Levels, and Play Roles. Chi-square analysis was run for these dependent variables against the independent variables of their gender, diversity of cultural background, and bilingualism. Results found several significant relationships. Girls participated in significantly higher Complexity levels, and higher Social Participation than boys. Children from diverse cultural backgrounds participated in higher levels of Complexity of Play and Social Participation than non-diverse children. Bilingual children took on follower Play Roles more often than monolingual children. Classroom teachers can use these findings to purposefully encourage complex play and Social Participation amongst all children. They can employ strategic grouping between the genders to encourage complex play for boys as well. They can also incorporate the knowledge that children of diverse backgrounds often lead play themes and encourage them to share themes of their representative culture. Families of all backgrounds can use this knowledge to encourage complex play at home with their children. By encouraging elaborate object use and play themes aligned with their background, they can support complex pretend play and higher levels of Social Participation with others.

Abstract Name: The Compounding Effect: Disability Status, State Policy, & Voter Participation

This study observes the relationship between disability status and voter participation in the United States,

examining how state-level voting restrictions affect civic engagement among persons with disabilities (PWD). Using data from the 2022 Cooperative Election Study (n=60,000) and the Cost of Voting Index (COVI), we investigate how institutional barriers and state-based voting policies intersect with disability status to influence voter turnout. Through regression analyses with interaction terms and chi-squared tests, we find that PWD are approximately 9.34% less likely to vote than their non-disabled counterparts, independent of state-level factors. When accounting for state voting accessibility as measured by the Cost of Voting Index, we see "the compounding effect"; for each point increase in a state's COVI score (indicating greater voting difficulty), PWD experience an added 1.4% decrease in voting likelihood beyond the 1.5% decrease saw within the general population. Analysis of reasons for not voting between PWD and non-disabled potential voters show how transportation and healthcare barriers disproportionately affect PWD across all states, no matter how they may rank in voting accessibility, accounting for approximately 28% of non-voting reasons among PWD compared to 8.5% among non-disabled individuals. These findings coalesce to suggest that despite existing protective legislation such as the Americans with Disabilities Act (ADA) and the Help America Vote Act (HAVA), significant barriers persist for PWD in the realm of political engagement, highlighted especially in states with more restrictive voting regulations. This research provides empirical evidence for policymakers, pinpointing the exigence of establishing more inclusive voting policies that address both individual circumstances and institutional barriers that affect the likelihood of political participation especially for persons with disabilities.

Abstract Name: A Broken System: The Impact of Persons with Disabilities' Inequitable Access to Reproductive Healthcare in the United States

In the United States, around eleven percent of persons between the ages of twenty-one and sixty-four have a permanent disability. While permanent disabilities vary in their degrees of severity, all persons with disabilities (PWD) are subject to marginalization in many aspects, whether that comes to obtaining well-paying jobs, furthering their education, or being scrutinized by society for their inabilities. Accessing essential healthcare is another critical challenge experienced by PWD, considering the number of inaccessible healthcare provider offices, the rising cost of services in America, and the already-studied significant wage gap for PWD compared to their able-bodied counterparts. One facet of the healthcare field carrying significant weight in the twenty-first century is reproductive healthcare, and as of current, there is limited research and background as to how access to this specialty is experienced for PWD. The history of reproductive healthcare for PWD centers around the forced sterilization movement of the twentieth century and many of the inequalities still seen today prevail around the ideas founded in this era. This project looks to connect the foundation of ableism and observe how PWD experience the American healthcare system as a whole, then using that background as a base to highlight the current lackluster procedure of reproductive health as it relates to sex education, provider implicit biases, socioeconomic divisions, and insurance. By using scholarly opinion and others' statistical analyses, I argue that PWDs are subject to further marginalization when looking to obtain reproductive healthcare. This project leaves room for further inquiries, especially of more quantitative evidence based on PWD obtaining reproductive healthcare.

Abstract Name: Assessing the Effects of Covid and the Covid Vaccine on the Cardiac Health of the General Population: A Heart Rate Variability Study

Covid-19 emerged in 2019 and nearly 5 years later has been responsible for over 7.1 million deaths and 776 million infections globally. As a relatively new virus, its long-term effects, including those related to the vaccinations, are still being studied. Some individuals have experienced heart issues, such as myocarditis and pericarditis, following infection or vaccination. Heart rate variability (HRV) is a noninvasive, relatively inexpensive method to assess cardiac health by measuring the time variation between heartbeats. The greater the variability, the better the cardiac health. Previous research has used HRV to evaluate cardiac damage in severely affected Covid-19 patients, but its predictability in those with subacute cardiac conditions is unclear. This study utilized surveys and HRV data from electrocardiograms to investigate differences in HRV based on Covid-19 infection and vaccination history. T-tests indicated several significant findings: females exhibited a higher HRV (SD Rate) than males ($p=0.031$); individuals never infected with Covid-19 had a higher HRV (SDRR) compared to those infected two or more times ($p=0.030$); those receiving one or two Covid-19 vaccines had a higher HRV (Average RR) than those vaccinated three times or more ($p=0.002$); individuals receiving Pfizer for all doses showed a higher HRV (Average RR; Median RR) compared to others ($p=0.044$; $p=0.039$); and individuals exercising two or fewer days a week had a higher HRV (SD Rate) than those exercising more frequently ($p=0.002$). The hypothesis that increased exposure to Covid-19 antigens—through infection or vaccination—correlates with decreased HRV is supported by these results. This finding suggests that increased exposure may worsen heart rate variability. With future research, HRV has the potential to be used as a screening tool for identifying cardiac issues related to Covid-19 in the general population.

Abstract Name: Automated Enzyme-MOF Comparisons: Leveraging Computational Tools for Biomimetic Design

Enzymes are biological catalysts with high activity under low severity conditions. However, enzymes pose challenges in industry since they are difficult to produce, maintain, and recover. Metal-organic frameworks (MOFs) are materials that have been synthesized to address the industrial limitations of enzymes. They are porous crystalline structures composed of metal ions connected by organic linkers. MOFs are great candidates for biomimetic catalysts due to their enzyme-like structure, thermal stability, recoverability, and high performance. Through manual comparison, researchers are beginning to find successful MOF-enzyme mimics. With over 16,000 synthetic MOFs already reported, the manual comparison process is slow, serendipitous, and extremely difficult. And if a MOF is chosen for a desirable biomimetic quality, there are often many additional options that were simultaneously overlooked. For this reason, we are interested in optimizing and automating the selection process for biomimetic MOFs. We have initiated a screening strategy comparing the metal sites and the surrounding ligands in enzymes and MOFs. The most important feature of a successful biomimetic MOF is the metal node identity and accessibility for chemical reactions. This is the first filter in our rational screening program which significantly narrows the list of candidate MOFs. The second filter checks if the atoms coordinated with the metal in the MOF match the parent enzyme. Using existing Python libraries, we have created a database with the bonded atoms in the metal sites of thousands of known MOFs. In its current form, this approach has identified MOF-enzyme mimics concurrent with existing literature, such as the MOF MFU-4l-OH which is a known mimic of the enzyme carbonic anhydrase. In my presentation, I will discuss these matches and how additional chemical and structural screening criteria will

enhance the quality of matches and enable a ranking system that provides a user-friendly comparison of enzymes and MOFs.

Abstract Name: Creating a luciferase reporter to monitor MyoD protein expression during embryonic development in *Xenopus Laevis*.

Circadian rhythm involves changes in gene expression, physiology, or behavior that occur over a 24-hour period. A molecular clock present in each cell keeps time and also regulates the expression of clock controlled genes (ccgs). MyoD is a ccg and is important for muscle development. My goal is to create a tool to monitor MyoD protein expression in *Xenopus laevis* embryos using a nanoluciferase reporter system. We have successfully inserted a small piece of nanoluciferase (HiBiT) into the 3' end of the Myod(S) gene using CRISPR-Cas9 genome editing. HiBiT protein when combined with LgBiT protein reconstitutes nanoluciferase which can make light in the presence of its substrate (furimazine). Currently, I am working to transcribe LgBiT RNA and co-inject it with our Myod(S) guide RNA, Donor DNA, and Cas-9 protein into one cell *Xenopus* embryos. LgBiT RNA will be translated into protein by the embryo. If HiBiT insertion works, the embryos will translate MyoD containing a HiBiT tag. We will confirm HiBiT insertion using PCR as well as assessing light production. Future creation and maintenance of a Myod(S)::HiBit transgenic line will support experiments that test whether circadian genes can influence Myod protein expression during embryogenesis.

Abstract Name: Forensically Relevant Decomposition Influences Forest Arthropod Communities and Ecosystem Services

Various taxa participate during decomposition, the crucial recycling of nutrients into the ecosystem, ranging from microbes (e.g. fungi, bacteria) to animals (e.g. arthropods, megafauna). In the context of broader community composition, however, the impact of high relative abundance of decompositional taxa can serve as a disturbance for preexisting communities. Decomposers can disrupt natural communities by competing with the existing populations causing changes to overall community composition and promoting an excess of saprobic taxa local to the decomposition site. In the context of forensically relevant decomposition, these changes have the potential to not only to change the broader ecological community but to have compounding effects on the decomposer community, as well. On the one hand, these shifts have the potential to disturb important ecosystem processes by reducing the relative abundance of species providing these services and result in short term changes to ecosystem functioning. Pollination for example is an important ecosystem

service that relies on select species to fulfil this process. These processes could be influenced by nearby decomposer activity, where invasive opportunistic predators might shift access to flowering plants in the vicinity of active decomposition. We used seven fetal pigs as a human model to observe the five stages of decomposition—fresh, bloat, decay, active decay, and skeletonization—to quantify changes to arthropods less directly associated with decomposition with unaltered control plots. We measured the abundance of invasive carnivorous fire ants (*Solenopsis invicta*), pollinators, and soil arthropods to determine if those groups would change in the presence of active decomposition. We observed a significant change in overall arthropod community composition with both pollinators and invasive fire ants changing in response to decomposition. This work highlights that broader insect communities are sensitive to active decomposition and frequent disturbance could lead to changes in community structure and functioning.

Abstract Name: Personal Environmental Initiative

We currently are living under a quickly warming Earth and the threat of a 6th mass extinction. While both of these issues are known to be caused by humans, data shows that only 1 in 4 Americans report having done anything to actively care for the environment in the past year. Although concerns are rising, action among citizens remains low. Free will guided purely by incentives rather than reason has fueled years of irrational harm to nature. Environmental adaptations are taking place, but often hindered by this lack of urgency and understanding of what climate change action should look like. Through understanding why it is important to act in ways that help the environment and a change in our culture we can stop this hindrance. Environmental justice should allow all living things the foundational resources to live an optimal life, but this opportunity is stripped from many organisms due to climate change. So what is causing this lack of action and how can we argue that personal initiative is important? Utilitarianism doesn't account for plants' health and allows minimal dedication to plant life to persist. In a search to find a philosophy that achieves my idea of justice for all living things in nature I use the teachings of Kant to show that virtue and personal action are vital to environmental protection. Respecting non-human nature as more than a means, practicing frugality, and duty to other humans can initiate a change not only for oneself but the world around them. Kant gives us the key to what must be done for harmony between humans and nature. Through promoting moderation and genuine respect for all aspects of nature Kant shows us contrasting morals compared to our current culture and how we should teach the importance of personal initiative.

Abstract Name: Occupational Stressors Effect on the Quality of Life for Firefighters

Firefighters experience consistent exposure to trauma, high-stress situations, and disrupted sleep, which are

well-known risk factors affecting firefighters' mental health. (Wolffe et al., 2023). This study aims to investigate how occupational stressors affect firefighters' quality of life and raise awareness about mental health concerns within the fire service. Little attention has been given to factors contributing to firefighters' psychosomatic well-being (Carey et al., 2011). 78% of firefighters experienced at least one critical incident at work, and 40% reported experiencing significant emotional distress at work (Torres et al., 2016). Despite the growing body of research on firefighters' mental health and quality of life, there are still gaps in our understanding of how specific occupational stressors impact these outcomes. Many studies have focused on a single stressor or outcome, and there is a need for more comprehensive investigations that examine the interplay between multiple stressors and their effects on various aspects of firefighters' well-being. An online survey was administered to firefighters (N=49) at a department in Southern California. This survey assessed the stress levels of firefighters using the Firefighter Assessment of Stress Test (FAST) and assessed the quality of life the firefighters were experiencing using the Quality of Life Enjoyment and Satisfaction Questionnaire—Short Form (Q-LES-Q-SF). It was hypothesized that Firefighters who experience higher levels of occupational stress, as measured by the Firefighter Assessment of Stress Test (FAST), will report lower quality of life scores on the Quality of Life Enjoyment and Satisfaction Questionnaire - Short Form (Q-LES-Q-SF) compared to those with lower levels of occupational stress.

Abstract Name: The Kilpatrick Estate - Housing Designed for Visual Impairments – Primary Infantile Glaucoma

The Kilpatrick Estate was designed to meet the needs of a family with a son who has Primary Infantile Glaucoma. This rare eye disorder occurs in the first years of life and prevents the eye from draining aqueous humor fluid, which puts pressure on the optic nerve. Left untreated, it can lead to minor or severe damage, resulting in peripheral vision loss, central vision loss, or even complete blindness. Given these circumstances, the family required a home supporting their son's development and learning. The research for this study was conducted through case studies and an interview with an expert in home design for the visually impaired. This research indicated that the home design needed several specific features. Key elements include high contrast to help differentiate between different surfaces, wayfinding components such as tactile paths and audible cues, textured materials with Braille labels, advanced technology like voice-activated features, and ADA-compliant spaces. The home's layout was designed with distinct rooms rather than an open floor plan, enhancing wayfinding. The color scheme was carefully chosen to create contrast within the rooms. Some areas feature wall paneling to add texture. The furniture was selected for its ADA compliance and soft edges, ensuring safety. The bathrooms are equipped with grab bars and accessible showers, along with the appropriate lever-style faucets and handles. Lighting was another critical consideration, emphasizing maximizing natural daylight and providing ample illumination in each room to eliminate dark spots. Additionally, Braille labeling and voice-activated technology were installed throughout the home. This study's significance is crucial for future designers, as it offers valuable insights into effectively accommodating families with similar needs.

Abstract Name: Using Soil Analysis, Air Photograph, Satellite Image and Map Comparison, and Holocaust Survivor Testimony to Uncover the History of the Jungfernhof Concentration Camp Site in Riga, Latvia

Jungfernhof was an improvised Concentration Camp near Riga, Latvia, that used existing buildings from the former Mazjumprava Manor. The camp was in operation from December 1941 through March 1942 and served as overflow housing for 4,000 Jews from Germany and Austria, intended initially for transport to other camps. During the harsh winter of 1941-1942, 800 prisoners died from exposure, disease, and execution. In early spring 1942, dynamite blasted a mass grave in the frozen ground. The research objectives for this project were to define the physical properties of the soils at the site and to determine the location of former camp buildings and a possible mass grave(s). Methodologies focused on locating former buildings compared German military air photos, Google Earth satellite images, maps from 1942 and 1947, and survivor testimony obtained from the Latvian State Historical Archive, the Locker of Memory Project, and the Museum of the Jews in Latvia. Based on field analysis, soil texture was mostly silt, with some sand, and a distinct clay layer, indicating that soils formed in over-bank deposits from the Daugava River. The consistency or inconsistency of the soil layers can reveal areas that have been disturbed, most likely by human activities, which may have included the creation of a mass grave(s) behind a former camp building that, in survivor testimony, is called "the shed," so determining the location of former camp buildings is essential in the process of locating the mass grave(s). Future research will include expanding a part of the project that utilizes ground penetrating radar (GPR) to study subsurface features and further soil analysis to confirm the presence or absence of anthropogenic features that point toward the exact nature of these inconsistencies.

Abstract Name: A Deeper Look into Attributes for Diabetes Prediction

Diabetes Mellitus is a significant global health challenge and according to World Health Organization, there are an estimated greater than 800 million people worldwide who are affected by this disease. The increasing prevalence of diabetes warrants a better conscientious effort of investigating alternate methods for developing effective and efficient predictive models of the disease. A key focus of this research is investigating the importance of various attributes associated with diabetes. This entails conducting empirical analysis of the consistency of different factors that are correlated with the disease. Our research work will also explore the relative performances of different attributes for their effectiveness in predicting the disease. We aim to answer the following: "What are the impacts of key socioeconomic factors that strongly correlate with the diagnoses of diabetes." The approach we have taken to address the above-mentioned research goals is utilizing various Artificial Intelligence based predictive algorithms and approaches for analysis of the different attributes to determine their degree of correlation with diabetes. The current case study dataset consists of various attributes for determining whether a person has or does not have diabetes. Our preliminary empirical study has focused on machine learning algorithms to gauge initial insights into analyzing the various characteristics of different predictive attributes associated with diabetes. The primary results of those studies indicated the potential of some attributes (provided in the dataset) as having good predictive capabilities. The planned

directions of this research project will focus on Artificial Intelligence based algorithms to develop experiments to gain a more comprehensive understanding of the different attributes and their characteristics in the context of predicting diabetes. A key focus of our project is also the study on the effect of various socioeconomic factors that indirectly influence the biases and disparities associated with the prevalence of Diabetes Mellitus.

Abstract Name: McPotempkin Village: The Globalization of Post-Soviet Russia

Since 2022, a resurgence of Cold War tensions have come to define modern Russian-American relations. Leaders of both nations have once again returned to a state of fundamental opposition, reflecting deep-seated mistrust and uncertainty between Russia and the United States. Yet, for a brief period, Mikhail Gorbachev's 1986 reforms, (glasnost and perestroika) had allowed for economic engagement beyond the Eastern Bloc. Multinational corporations, McDonald's among them, seized this opening to negotiate franchise deals in the Soviet Union. The Golden Arches made their Moscow debut in 1990, drawing unprecedented crowds amidst a period of severe economic hardship. It seemed that the Russian people had embraced Western culture and businesses as their own. However, following the 2022 invasion of Ukraine, McDonald's severed its business ties with Russia at the onset of Western sanctions. During the thirty-six years between Gorbachev's reforms and the Russian invasion of Ukraine, the people's initial sweetness towards globalization had permanently soured. I argue that McDonald's operations in Russia served as a microcosm of Russian American relations, reflecting political and cultural transformations since the Soviet Union's collapse. My interest in this topic emerged from a blend of two distinct discourses: one grounded in Russian perspectives, and the other shaped by Western ideals. In my research, I utilized media accounts and government statements from both nations. I also conducted interviews with everyday Russians who witnessed either the opening or withdrawal of McDonald's in their former home. The interviews, alongside an examination of Western and Russian sources, demonstrate how McDonald's had come to embody the complex dynamics of globalization within Russia.

Abstract Name: Beyond the Bench: How the Appearances of Justices Kagan, Gorsuch, and Kavanaugh impact the Public.

The appearances of the Supreme Court justices influence public perception. While it may seem that all appearances would enhance public support, at times, ideological speeches or political rhetoric can decrease public support. Thus finding what appearances elicit a certain reaction in the public is significant. To achieve this goal, we cataloged the appearances of the Supreme Court justices by focusing on Google searches by year and by justice. Google was the chosen search engine because other databases are not likely to be used by

the public. Data collection included reading through the first 50 links of a Google search, and deciding if it was relevant. Relevant appearances happened after the justice was confirmed and off the bench. Furthermore, we did not follow embedded links to additional events found in a report. This mirrored the kind of Google search and result, a member of the general public would encounter. Moreover, this emphasis enabled the measurement of media saturation. Four search terms, interview, speech, comments, and appearance, were used for each Google search. From the Google search, qualifying appearances would be recorded in a Google form. Justices Elena Kagan, Neil Gorsuch, and Brett Kavanaugh were the primary focus of our research because they provide a comprehensive look into the Supreme Court. The findings of these justices allow for a comparison of the number of appearances over time, the average appearance per year, and the dynamic with the public. The data displays that not all appearances have the same impact. We found Justice Kagan, who has the most appearances annually, has a more dynamic relationship with the public. This presentation will share findings from the data collection of the three justices and speculate about the larger implications for justice appearances.

Abstract Name: Influences on High School Students' Interest in Advanced Placement Computer Science

By analyzing reports of student's experiences in Advanced Placement Computer Science courses this study seeks to identify what motivates students to take computer science (CS) coursework while also taking into account the influence of when student's first hear about programming and the effect of the environment of their CS classroom on persistence in the field. This is critical as student entry to CS education becomes earlier and inequalities in high school can become magnified. Identifying why students take CS courses is fundamental in understanding how to increase participation in CS education, especially among traditionally underrepresented groups. This study included 25 hour-long semi-structured interviews of current high school or college freshmen students who completed or were currently in Advanced Placement (AP) Computer Science A (CSA) and/or Computer Science Principles (CSP) course(s). AP CSA is intended to be the equivalent of an introductory college-level CS course, developed by The College Board, while CSP was later created to introduce students to CS and retain them for future courses. Thematic analysis will be conducted on the collected interviews to identify how students enter CS education while also using Bronfenbrenner's Ecological Systems Theory and the CAPE framework as analytical lenses. Bronfenbrenner's theory categorizes environmental impacts into levels—microsystem, mesosystem, exosystem, macrosystem, and chronosystem—that influence students' decisions to enroll in AP CS courses. The CAPE framework—capacity, access, participation, and experience—aids in understanding the complexities of equity in CS education within school and classroom environments. Preliminary results suggest emerging themes such as how students observing their parents in CS or technology related careers encourages them towards CS courses. Additionally, an early introduction to technology before high school often provides students a greater understanding of what CS is, increasing interest in the field and positively influencing students' decision to pursue CS education.

Abstract Name: Food Insecurity in Appalachia: Highlighting Causes & Solutions

In the United States, nearly 28 million (12.5%) people, that is one out of eight experience some form of food insecurity according to USA Facts Team, 2024. In Appalachia, 14% of the population or 3.5 million people live with food insecurity. Appalachia is a region spanning across 13 states with a large rural population and high poverty rates. This can be seen in the lack of access to affordable and healthy food. My project explores the dynamics of food insecurity in Appalachia, especially Pennsylvania and West Virginia, including the causes and possible solutions. I assume that income inequalities and geographical conditions largely influence access to food and the ability to lead a healthy life. I hypothesize that food insecurity can be reduced through individual and community-based gardening practices supplemented by awareness, education and governmental support. Access to home gardening educational resources, food preservation education, nutritional education, farmers markets, and garden grants can encourage people to grow their own fresh food. Apart from describing the geographical, economic, social and cultural features of Appalachia, the concepts of food security, food deserts, food sovereignty, food justice, food loss, food waste, and community gardens are explored. The disproportionate amount of college students currently experiencing food insecurity is also pointed out. This poster highlights the causes and produces specific strategies that people can use to overcome food insecurity in Appalachia using secondary research sources like books, journal articles and reliable websites

Abstract Name: Evaluating Spatial Error in Radio-Tracking of Blanding Turtles in Terrestrial Habitats in Iowa

Triangulation via radio-tracking is a standard method in wildlife studies to monitor species' movements and habitat preferences, particularly in challenging areas. My research examines the spatial error associated with triangulation techniques used to track Blanding's turtles (*Emydoidea blandingii*), a semi-aquatic species of conservation concern, within wetlands near Ames, Iowa. An accurate understanding of these errors is critical for interpreting movement data and supporting habitat conservation efforts. VHF radio tags were strategically placed in known locations, and their locations were then estimated using triangulation from four distinct observer points. We recorded S coordinates for reference, enabling a comparison between the estimated and actual positions of the transmitters. Error distances ranged from 6.5 to 25.8 meters, with an average error of 15.4 meters. Notably, approximately 15% of the location estimates deviated beyond the expected accuracy range of GPS units, highlighting the potential for substantial error in location data. While the findings provide insightful information into triangulation performance in terrestrial environments, the lack of data from aquatic habitats leaves a significant gap in understanding the full range of Blanding's turtles' spatial ecology. Future research will address this limitation by extending triangulation efforts to aquatic environments where the species spends significant time. By quantifying spatial errors and emphasizing the need for precision in radio-tracking methodologies, this study contributes to improving conservation practices for Blanding's turtles. Accurate movement data will allow researchers to assess habitat use better, inform protection strategies, and mitigate threats to this vulnerable species in diverse environments.

Abstract Name: Designing a Nanobody-Based Treatment Targeting the HER2 Protein

Receptor tyrosine-protein kinase erbB-2 (HER2) is a receptor protein that is associated with the development of several cancer types, most notably breast cancer. HER2 positive breast cancers are responsive to treatments that specifically target the HER-2 protein. Existing treatments use monoclonal antibodies to bind to the HER2 protein. The aim of this project is to re-engineer an existing monoclonal antibody into a nanobody® for treatment. Nanobodies are also called single domain antibodies, while the name NANOBODY® and NANOBOODIES® are registered trademarks of Ablynx N.V. Nanobodies® consist of solely the VHH region of antibodies. The use of nanobodies® comes with unique advantages due to their small size, stability, and ease of production, but a nanobody does not sacrifice the functionality that comes with the use of a whole antibody. A nanobody® gene was designed based on the binding domain from the existing monoclonal antibodies used for treatments, Trastuzumab and Pertuzumab. The VHH sequence from the monoclonal antibodies was ligated into an expression vector, and then inserted into E. coli cells. Expression of the gene was induced to produce the nanobody®. The nanobody® was purified using immobilized-metal affinity chromatography. A direct ELISA test was then used to confirm that the nanobody® is properly binding to the HER2 protein. Two nanobodies® that can effectively target and bind to the HER2 protein were produced. The project can now be extended for further testing and optimization of the nanobody®.

Abstract Name: Is Physiological Feedback Impacted by the Perceived Gender of the Presenter?

Electroencephalogram (EEG) research has previously demonstrated that the type of feedback individuals receive can impact their neurological responses by creating either a positive or negative waveform/amplitude. These responses to certain cognitive tasks are referred to as Event-Related Potentials (ERPs) and when people receive negative feedback it produces Feedback-Related Negativity (FRN). FRNs are typically observed around 200-400ms after feedback is presented. This study specifically investigates FRN responses as they relate to a feedback presenter's gender. There is limited research on FRN responses and even less that investigate FRNs as they relate to gender. The current study seeks to explore how neurological response is influenced by the perceived gender of the presenter of feedback utilizing an EEG and a pattern recognition task. Participants are presented with a pattern of nine randomized letters. Participants are then shown a slide with two letters where the participant is asked to recall which of the two was presented in the previous pattern using a response input device. To guarantee events lead to a FRN response, 64 of the 200 questions lack a correct option, resulting in an incorrect feedback slide for either response. The feedback screens vary across

blocks, with two blocks consisting of female photos and two with male photos. If the participant correctly identifies the letter from the presented pattern, the photo will be of the male or female smiling. If the participant incorrectly identifies the letter, the photo will be of the male or female frowning. Participants are equipped with a 64-channel hydrocel EEG while completing the task to measure scalp-related potentials associated with feedback. Preliminary results indicate an anticipated increase in negative amplitude for feedback screens showing a male compared to a female. The valance of the feedback does not have a significant effect on the FRN response.

Abstract Name: Utah Gun Safety: Addressing Utah's Gaps in Resources, Education, and Legislation

This study investigates four primary factors to gun safety disparities in Utah: misinformation, inadequate funding, misleading legislation, and feedback loops. Utah consistently ranks among the highest in the nation for accidental child shootings and gun-related suicides, underscoring a need for effective and accessible safety resources statewide. Furthermore, Utah's relatively lax firearm regulations make it one of the easiest states in the U.S. to obtain a gun, presenting both an opportunity and challenge in terms of implementing preventive safety measures. Using a mixed-methods approach, it incorporates insights from existing research, legislative reviews, and interviews to formulate ideas. By examining regional and demographic data, the research explores existing interventions, historical patterns, stakeholders, and power dynamics. This research aims to equip policymakers, educators, and community leaders with evidence-based strategies to address gun safety disparities and build a stronger, statewide safety culture. Key levers of change include encouraging firearm manufacturers to innovate toward safer gun designs—such as developing locking safety triggers and "smart" locks that restrict access to authorized users. Policies like "extreme risk laws" could empower law enforcement to temporarily restrict firearm access in cases where individuals pose a clear risk to themselves or others. The study aims to illuminate evidence-based strategies that can reduce accidental firearm injuries, enhance responsible ownership practices, and decrease gun-related suicides across Utah.

Abstract Name: Mobs Simulator: A Multi-theoretical Stochastic Agent-based Modeling Tool to Study Mobs Outcome & Mobbers Behaviors

A mob is an event organized via digital communication technologies where people assemble (online, offline, or both) to exert a collective force, ranging from benign gatherings such as dance performances at a shopping

mall to deviant/malicious actions like coordinated cyber-attacks, organized crimes, and street takeovers. While previous research has established theoretical frameworks and data-driven approaches to understand mob dynamics and mobbers' behavior, these models often remain inaccessible to practitioners and researchers. Building upon the collective action theory-based model developed by Al-khateeb et al. (2024) and the multi-theoretical framework by Murray et al. (2024), we implement a stochastic agent-based modeling (ABM) simulation tool mainly using the Python programming language to understand mob phenomenon better. Our model incorporates key behavioral scenarios driven by 5 social science theories where agents can: act (participate), withdraw, perform power exchange (to gain utility), or act against the mob. The simulation takes three primary inputs: the number of invited participants, the number of known powerful participants/agents (e.g., mob organizers), and a threshold for mob success. We randomly assign each participating agent/mobber 18 traits/social science factors, then we determine the agent's decision/action based on multi-theoretical constraints. Then the model uses various theoretical scenarios (relating to each agent decision) and calculates a participation rate to determine mob success or failure. All of this is then wrapped into a web application to create an accessible and interactive tool for studying collective behavior, which is particularly valuable for understanding cyber-social group formation and its potential societal impacts. Our work bridges the gap between complex theoretical models and practical applications, offering insights into related phenomena such as social movements, organized protests, the diffusion of innovation, and the spread of online rumors.

Abstract Name: Sabrina vs Steph: The Battle Between the WNBA and NBA

Background The average salary of a Women's National Basketball Association (WNBA) player is 110 times less than a National Basketball Association (NBA) player's. Despite increasing WNBA viewership, gender inequality in sports remains high, with female athletes often perceived as less skilled. The lack of investment in women's sports limits fair comparisons with men's leagues. This study examines whether the perceived skill gap between WNBA and NBA players is real or influenced by external factors by developing an unbiased measure of player efficiency to compare athletic performance. **Methods** This dataset was sourced from Basketball-reference.com and cleaned to remove duplicates and missing values, resulting in 555 players (166 WNBA, 389 NBA). Extreme outliers were assessed. An unbiased measure for comparing player efficiency (dependent variable) was developed: $\text{Efficiency} = (\text{Points} + \text{Rebounds} + \text{Assists} + \text{Steals} + \text{Blocks}) - (\text{Missed Shots} + \text{Turnovers}) / 100 \text{ Team Possessions}$. A multiple linear regression model was conducted. Independent variables included games played, games started, personal fouls, organization and the interaction between games started and organization. **Results** Average efficiency of WNBA players was 24.2 (SD=8.1) points and 26.5 (SD=8.2) for NBA players. Multiple linear regression revealed that 23.6% of the variation in efficiency was explained by games started, games played, personal fouls, organization, and games started*organization, ($R^2=0.236$, $F(5)=33.54$, $p<0.001$). Number of games started had a stronger effect on NBA players' efficiency than WNBA players. Specifically for every additional game started by an NBA player, efficiency decreased by .200 units on average, compared WNBA players ($t=-4.63$, $p<0.001$). **Conclusions** Findings indicate that WNBA players are not less skilled than NBA players; however games started significantly impacts NBA players differently than WNBA players. These results emphasize the need for greater investment in female sports' data collection and research to create a more equitable comparison of performance between genders.

Abstract Name: Surface And Subsurface Temperature Monitoring of a rock glacier in the semi-Arid Andes

The retreat of glaciers serves as a clear indicator of a changing climate. However, the impact of climate change on rock glaciers, which are covered by insulating debris, is often overlooked. Known as "water towers," rock glaciers store hidden reserves of water within their ice. This water resource is crucial in regions like Chile, which has been experiencing prolonged droughts. By monitoring temperature, we can better understand and manage these water reserves, ensuring sustainable water supply during times of scarcity. The Aconcagua River basin in central Chile presents a valuable opportunity for study. This basin, showcasing a continuum from rock glaciers to ice-exposed glaciers, serves as an ideal environment for monitoring environmental changes in this sensitive area. For this project, we examine the Tres Gemelos rock glacier complex near Los Andes, Chile. Temperature measurements were collected at the surface and 30 cm below the surface at a 2-hour sampling interval. Data loggers were placed at two locations. One was near the toe of a rock glacier, while the other was closer to the rock glacier head at higher elevation. The monitors were active from March 2013 through November 2022. Taking a reading every 2 hours for a total of 12 readings a day, totaling in over 42,000 points of data for each monitor. The average temperature has increased about 1-2° C over the last decade. Similar trends were observed at the surface and at depth with average temperatures peaking during 2019 and 2020. We also found the length of winter has been reduced since 2017. Our analysis holds the potential to enhance our understanding of climate change and its impact on glaciers.

Abstract Name: An Analysis of the Sincere and Strategic Ratifiers of Immigration and Family Laws in the International Community

The subject of analysis is the way international laws and norms are interpreted and implemented in vastly different ways, depending on whether the state is considered to be a strategic or sincere ratifier. To compare and contrast among the international community, this analysis will focus on the case of the international norms around the treatment of immigrants and arranged/child marriages. In the case of immigration laws and the treatment of immigrants entering a foreign domain, the subject of analysis will be the United States border with Mexico, and the jurisdiction in which BORTAC operates under, and how they violate international law. In the case of child marriage and arranged marriage, the subject of analysis will be Trinidad and Tobago, and their violations with the implementation of CEDAW. Through analyzing the discrepancies in the implementation of international law surrounding immigration and Family law, the case structure of strategic and sincere ratifiers will be more apparent in the international system. To analyze sincere and strategic ratifiers, one must look into the country's motivations in signing or ratifying an international law. Differentiating the motivations, and whether these motivations are out of a country's self-interest in appearing societally advanced compared to their counterpart in the international community or whether they are ratifying a treaty to create genuine societal progress for citizens. In order to properly differentiate a state's

motives, you must look at their governmental structure, and their past record of adhering to international laws and norms, this will allow a clear detection whether a state is a strategic or sincere ratifier. Once this is deduced, the question at hand will be what are the possible policy recommendations that can correct this disparity and abuses of international law ratification.

Abstract Name: Impact of Cerium Oxide and Silica Nanoparticles on the Freshwater Microalgae, *Raphidocelis subcapitata*

The use of nanoparticles is rapidly expanding across numerous fields, including agriculture, health, and cosmetics. Subsequently, these nanoparticles inevitably end up within our environment, leaving a lasting impression on ecosystems. Strengthening the knowledge of the effects of CeO₂ and SiO₂, two commonly used nanoparticles, on *R. subcapitata* will enable researchers to gauge how these nanoparticles impact a central freshwater organism. This foundational knowledge will serve as a baseline for future research towards improving safety in industries utilizing nanoparticles. According to previous research, Cerium Oxide nanoparticles were shown to stimulate positive attributes to plant growth and survival while similarly, Silica nanoparticles are shown to assist in biotic and abiotic stress resistance within plant organisms. Studies regarding the safety of both CeO₂ and SiO₂ nanoparticles in microalgae, with a range of concentrations and long-term exposure, remain lacking. To clarify the underlying mechanisms and concentrations relating to the nanoparticles, control treatments will be compared to three experimental concentrations of each nanoparticle. High-content image analysis, reactive oxygen species measurements, and gene expression will be used to determine sublethal impacts of exposure. I hypothesize that both Silica and Cerium Oxide nanoparticles will result in ROS alterations while impacting the morphology and growth inhibition of the *R. subcapitata* algal cells.

Abstract Name: Determining Charge Limits on Particles using Electrostatic Energy Analysis in Electrospray Ionization Mass Spectrometry

The purpose of this study is to understand how the shape of analytes influences their charge states during electrospray ionization mass spectrometry (ESI-MS), which is crucial for interpreting charge state distributions of large biomolecules and nanoparticles. By investigating the maximum number of like charges that can be accommodated on various particles before the electrostatic repulsion energy exceeds twice the surface energy—a threshold relevant in ESI-MS—we aim to enhance our understanding of ionization processes, contribute to the analysis of complex analytes, and have implications in analytical chemistry and nanotechnology, particularly in the design of nanoparticles and biomolecules with specific charge properties. To achieve this, we developed a computational model to analyze three-dimensional shapes such as cubes, spheres, and cones. The model incorporates a modified optimization algorithm to avoid local minima, enhancing the accuracy of charge limit determination. Charges were randomly placed on the particles, and the total electrostatic energy was iteratively minimized and compared to the surface energy to determine charge

limits. The results indicated that the maximum number of charges a shape can accommodate depends significantly on its geometry and size, with more extended shapes accommodating more charges due to higher surface area. Visualizations using MeshLab provided insights into how charges distribute on complex surfaces to minimize repulsion.

Abstract Name: Assimilation Policy or Military Development: Conflicting Methods in the Japanese Occupation of Guam

On December 10, 1941, at 3:30 A.M., the Imperial Japanese Army landed on the shores of Guam, an American territory in the middle of Japan's South Seas Mandate. The invasion was a simple matter for the soldiers who gained control after only suffering one casualty. The subsequent occupation was not as simple. The Imperial Japanese Navy sought to create an agricultural industry on Guam so that it was self-sustainable and able to support the Navy's military actions. In order to do this, the Navy established the civilian administrative unit Minseibu, headed by Japanese civilians experienced in island administration, whose job was to govern Guam and advance the development of agriculture. These civilian officials believed the best method to achieve self-sufficiency was to assimilate the native people of Guam, the CHamoru, so that they would develop a sense of loyalty to Japan. They pursued this through the establishment of educational institutions and cultural celebrations. However, their desire for assimilation was not shared by the Navy, which had intended the Minseibu to support the Navy's broader efforts in the Pacific War through its administration. This created an environment where Japanese Navy personnel and Minseibu civilian employees were fighting amongst themselves to promote what they considered the best method for colonization. This infighting caused the Navy to fail in the establishment of a self-sustainable Guam colony and had disastrous consequences for the native CHamoru who were forced by the Navy and Minseibu to provide labor, attend schools, and support competing visions for how the Guam colony would function under Japanese occupation. This project makes use of Japanese oral histories, letters, and testimonies from those who lived through the occupation to reveal why the Japanese occupation of Guam failed in its goals.

Abstract Name: Sorting It All Out: Degree Phrase Modification in Particle Verb Phrases

Particle verbs are combinations of a verb and particle, like eat up. They present a long-standing puzzle in

syntactic theory due to the word order alternation traditionally analyzed as particle movement. Verb and particle stay together in the unmoved (continuous) word order, as in he ate up the spinach, but separate in the moved (discontinuous) order: he ate the spinach up. Crucially, the particle can be modified in the discontinuous word order (ate the spinach right up), even by a whole phrase (ate the spinach pretty much right up), however, modification in the continuous order (*I ate right up the spinach) is ungrammatical. We also have to explain the ungrammaticality of particle modification in the continuous order (*I ate right up the spinach). While these features of particle verbs have been noted in the literature (Larsen 2014), previous analyses (Larsen 2014, Harley 1997, Ramchand 2008) either fail to predict that particle modifiers can be phrasal (totally all out of spinach) or rely on under-motivated syntactic machinery: an object movement specific to particle verbs and extra structure existing only to accommodate it. We propose a simpler solution based on the widely adopted vP-VP shell analysis of (di)transitive verbs (Larson 1988), eliminating the need for ad-hoc functional projections. While retaining Larsen's (2014) phrasal analysis (PrtP) to allow modification, we originate the object as an argument of the verb, not within the PrtP like Larson. Further, we integrate DegP into our PrtP for the discontinuous order only, explaining the ungrammaticality of continuous order modification. The alternation of orders is motivated by idiomaticity, where less idiomatic, decomposable constructions allow modification. This analysis accounts for the previously unnoticed interaction between phrasal modification of particles and the idiomaticity of particle-verb constructions, suggesting a condition on the syntax-semantics interface to explore in other constructions and languages.

Abstract Name: YHR039C in *Saccharomyces Cerevisiae* and Potential Role in ER

Saccharomyces cerevisiae has multiple genes throughout the genome for which the function is still unknown. YHR039C is one of these genes of unknown function. Using bioinformatics, research of different proteins and genes that have any form of interaction with YHR039C were inspected along with images of the GFP-protein fusion that help determine localization. We found that Yhr039cp is predicted to be localized in the endoplasmic reticulum and may increase the cell wall strength and membrane integrity via ergosterol production. To identify the function of YHR039C, it was replaced in the yeast genome with URA3 to create a knockout yeast strain. A PCR-based strategy was used to replace YHR039C with URA3, and a confirmation PCR reaction validated the disruption of YHR039C. The growth of the knockout strain was tested against different drugs using multiple rounds of spot assay to observe cell growth compared to the wildtype strain of yeast. Spot assays of wild type and yhr039c were tested using fluconazole, ethanol, and dithiothreitol. Preliminary results from wet lab investigations showed that ethanol and DTT stress factors impacted yhr039c cell growth significantly when comparing the knockout and wildtype strains. A morphological analysis of both yhr039c and the wildtype log-phase cells showed a decrease of large, budded cells in yhr039c compared to wildtype, indicating that there may be a delay in the G2 phase of the cell cycle. Without YHR039C, it is possible that ER function cannot be maintained properly, and this may ultimately disrupt lipids being made by the ER that are necessary for maintaining cell membrane integrity.

Abstract Name: AI-Assisted Technologies in Speech-Language Pathology

Over the last few years, we have seen significant advancements in Artificial Intelligence (AI) and a growing use of AI in education, health care, and preventative care. This poster explores the impact of AI in Speech-Language Pathology and, in particular, the benefits and ethical challenges of using AI in the day-to-day responsibilities of speech-language pathologists. Speech-Language Pathology is a specialized field within healthcare and education that works with individuals on their speech, language, communication, feeding, and/or swallowing to improve their communication and increase their independence and overall quality of life. The three main areas of responsibility of a speech-language pathologist are (1) evaluation and assessment, (2) treatment, and (3) documentation. In this poster, we look at the impact of AI-assisted technology in each of these three areas. AI-assisted technologies offer increased efficacy of diagnosis, treatment, and therapy for speech, language, and swallowing disorders, as well as improve individuals' quality of life. In all three areas, AI was found to save therapists time on mundane tasks, allowing them more time to spend providing direct services to their clients. Only a limited number of studies reviewed for this poster presented information regarding the limitations of AI in the field of Speech-Language Pathology in terms of the clients and therapists alike. Further research is necessary to determine the privacy risks of using AI in a clinical setting, whether the benefits of using AI outweigh the loss of a human connection, the effect that reliance on AI may have on therapists' creativity and cognition, and how patients of all ages may respond differently to AI. These ethical concerns must be addressed before the Speech-Language Pathology community can fully embrace the benefits of this new technology.

Abstract Name: Exploring Ecological Consciousness and Extrasensory Perception

There has been ample research conducted about ecopsychology in relation to transpersonal psychology and extra sensory perception through the lens of Parapsychology, but to date, there is no research on how being connected to nature might influence access to non-local information. That is why my mentor and I have been in the process of conducting an academic Psychology research study that seeks to investigate how intrapersonal (interoception and transliminality), interpersonal (empathy) and other forms of connectivity (connection to nature, ecopsychological self and extrasensory perception) relate to one another. It will also explore the idea that those who display higher levels of connection and who are more psychologically healthy (as measured by a measure of satisfaction with life) will perform better at an Extra Sensory Perception task. In addition, we will explore whether it is possible to boost scores on intra and extrapersonal measures of connection as a result of listening to "Plant music" via the Plantwave system. This system claims to generate music by measuring biological changes within plants, graphing them as a wave and translating the wave into pitch and presenting these signals as music. Before participants come into our research lab on campus we have them complete a Qualtrics survey that goes along with our study aim. After the survey is completed, participants come into our lab and complete a series of ESP tests, followed by listening to 15 minutes of Plantwave music. We then have them complete the same ESP tests and survey as before so we have a comparative analysis. In person experiments are still being conducted, but after we have collected data from 40 participants we can begin to analyze our findings through SPSS software. Our final research data will be ready to be presented through a powerpoint oral presentation by April for NCUR.

Abstract Name: The Ethical Responsibility of Sustainable Tourism in Indonesia

Bali, Indonesia has seen a tremendous increase in tourism has jumped more than 70% since 1980 (Milko & Jatmiko, 2022), which led, in turn, to a massive increase in plastic pollution. Marine and local life has suffered without a clear plastic management solution. This project examines the impacts of tourism on Bali's economy, aquaculture, and indigenous peoples, exploring the question of whether tourism can prove sustainable for Indonesia's economy and environment. Drawing from interviews with tourists, domestic Indonesian visitors, and indigenous Balinese communities, and considering greenwashing regulations in hotels and resorts, this project will explore the environmental strain tourism has placed on Bali and its surrounding islands.

Abstract Name: Thermophoretic Effects on The Removal of Neutron Poisons in Nuclear Thermal Rocket Fuel Rods

This study modeled the production and spread of neutron poisons, such as Xenon-135, throughout the fuel of a High Assay Low Enriched Uranium (HALEU) Nuclear Thermal Rocket (NTR). Neutron poisons are a danger to the effective use of NTRs for long term space flight, as they can reduce the reactivity of the reactor to a point where it is unable to start, until the poison decays or is removed. The study investigated the potential use of a thermophoretic force to remove the neutron poisons from the fuel. The computational approach determined that the thermophoretic force was not strong enough to make a worthwhile effect on the concentrations of the neutron poisons in the fuel, but was able to make an effective model for the buildup of poison throughout the fuel cell.

Abstract Name: Socioeconomic disparities in BPA and BPS exposure and their impact on metabolic health in T2D individuals

Background and Purpose: Bisphenol A (BPA) and Bisphenol S (BPS) are endocrine disruptors used in manufacturing products like food packaging. Ultra-processed foods, often containing BPA and BPS, are more accessible to people with lower economic means. High exposure to these chemicals is linked to increased risk of metabolic diseases. This study aims to identify whether individuals in areas with high deprivation indices are at greater risk for BPA and BPS exposure and its impact on type 2 diabetes (T2D) management. **Methods:** Plasma samples from 106 males and 152 females were obtained from a randomized control clinical trial investigating medication adherence in T2D patients. BPA and BPS levels were measured using ELISA assays and correlated with data on glycated hemoglobin (A1C), blood glucose, insulin, high-density lipoprotein (HDL), low-density lipoprotein (LDL), and triglycerides. The Area Deprivation Index (ADI) was determined using participants' zip codes from public data by the Center for Health Disparity Research, University of Wisconsin. Comparisons between male and female groups were performed using independent t-tests, and variable associations were analyzed with Kendall Tau b test using SPSS software. **Results:** Males showed higher levels of BPS and triglycerides and lower levels of ADI, insulin, and HDL compared to females ($p < 0.05$). No significant differences were observed in BPA, A1C, LDL, and blood glucose levels. BPS levels positively correlated with A1C in males ($r = 0.165$), while ADI negatively correlated with BPS and HDL in females ($r = -0.133$, -0.108 , respectively). **Conclusion:** Males are more exposed to BPS than females, potentially explaining higher triglycerides and lower HDL levels. BPS exposure may increase A1C in males, while affecting HDL in females. ADI appears to influence BPS levels in females but not metabolic outcomes in males. Reducing BPS exposure might improve metabolic outcomes in T2D patients.

Abstract Name: Coating System Bearing

Current ball bearing assemblies used in specialized powder coating machines for internal pipe coatings often seize and fail within six months of operation. This failure stems from residual ceramic powder infiltrating the bearing housing, clogging the assembly, and rendering it immobile. To address this, at the University of Texas of the Permian Basin we developed an advanced bearing system that minimizes powder ingress and extends operational lifespan. Leveraging SolidWorks for CAD modeling, the group analyzed the original design, identified key issues, and introduced new design parameters to mitigate the root causes of failure. Simulations, including stress-strain and flow analysis, confirmed the robustness and efficiency of the redesigned bearing assembly. Previous attempts to prolong bearing lifespan, such as using pressurized air to clear residual powder, only marginally improved performance without addressing the core design flaw. These inefficiencies result in costly downtime and frequent replacements, impacting both productivity and revenue. The redesigned bearing incorporates a modular structure for ease of maintenance, allowing periodic cleaning in the case of minimal powder accumulation. The improved bearing system is specifically tailored for machines that apply ceramic coatings to drill string pipe, used in oil and gas operations. Force studies proved the engineered bearing could withstand higher torques and moments than the bearing would ever undergo from the powder coating machine. Flow simulations expressed satisfactory results of minimal airflow between the assembly that would affect the bearing system. The results of which are manifested in a fully functional, true-scale product of engineering design. By integrating this advanced bearing into powder

coating systems, companies can achieve extended machine uptime, reduced maintenance costs, and greater operational efficiency.

Abstract Name: How Tragedy Rewrites Our Minds

Faith undergoes a profound transformation in the wake of personal tragedy. While death often feels distant when it's a stranger, it becomes strikingly personal when grief enters your life. My close friend's untimely drowning and my mother's battle with liver cancer forced me to confront the delicate balance between the acceptance and rejection of faith. This phenomenon where tragedy either deepens or dismantles one's belief system is at the heart of my art series. Religion is ingrained in over eighty percent of the global population, yet history reveals its dual response to catastrophe. Events such as the Black Plague, the Covid Pandemic, the Hiroshima bombing, and the Holocaust highlight two diverging paths: the reinforcement or renunciation of faith. Cognitive dissonance, the psychological tension caused by trauma that challenges one's beliefs, plays a pivotal role in this shift. When higher power appears to "allow" excessive suffering, faith can waver. Yet paradoxically, tragedy often births hope, as seen in how the Black Plague strengthened Christianity's influence. My series blends Renaissance-inspired techniques with acrylic and oil on canvas, depicting statues of universal religious themes: gods, angelic figures, and divinely chosen mortals. Drawing inspiration from Gothic religious art, Greek sculpture, and the Renaissance Movement, each painting explores existentialism and the psychological reshaping of belief systems in response to grief. Future works will expand to include visual interpretations of humanity's collective tragedies. Through this project, I process personal losses while examining how faith evolves under the weight of trauma, with the end goal of finding an answer to this phenomenon. This work serves as an artistic and emotional inquiry into the human condition, capturing the double-edged sword of hope and despair. My ongoing exploration reflects both personal healing and a broader dialogue on the role of religion and culture in navigating life's most profound losses.

Authors:

Abstract Name: Modernizing Music: Exploring Unconventional Uses of Timbre, Dynamics, and Duration and their Effects on Compositional Style and Musical Awareness

As music has continued to develop, so have the approaches to the question of "what is music?" There are many debates pertaining to the answer to this question, but it truly cannot be answered when isolated from the compositional and performance aspects of a work. Music can be anything that is desired of the players, composers, and listeners, as long as its intent is music. Such is the case with this piece, Journey West. There are no standard conventions of music, like melody, harmony, key, or time, but instead it is entirely reliant on the performers to utilize their instruments and the timbres they create to perform an intricate work. Deriving counterpoint and musical ideas from aspects like volume, timbre, and duration are not new concepts, but they

are driven to the forefront of this work to display them and show that a “melody” does not have to consist of rhythmic pitches, but may instead simply be the intentional organization of sounds. The creation of this composition challenges not only the listener, but the composer as well to think more critically about applications of musical ideas and how being aware of more nuances of music can help develop skills that can be applied to future compositions or listenings.

Abstract Name: An Assessment of Native Wood-Associated Beetles on New and Old Slash Piles in the Western Rocky Mountains

Coniferous forests in the Rocky Mountain West are at an increasing risk of significant wildfires. The U.S. Forest Service has implemented an array of fire suppression treatments to reduce fuel loads, an effort to reduce the intensity of major wildfires. One of these treatments involves mechanical tree thinning that is followed by the burning of slash piles when weather conditions allow for them to be safely burned. The objective of this study was to determine if old (> 1 yr) or newly cut (< 1 yr) slash piles were more effective at supporting native wood-associated beetles, especially borers. Twenty screened enclosures (ten per treatment group) were placed over old and new slash piles during the summer of 2024. Beetles emerging from the wood were collected using blue vane traps placed inside these enclosures. Specimens were later pinned, identified to family and tentatively assorted in to species. Beetles were 2.5 times more abundant and diverse at the family and species level in the new slash piles. Thus, younger slash piles contribute more to the maintenance of the diversity of wood-associated beetles in these forests than older slash piles. To balance the need to maintain biological diversity while reducing the risk of fire, management agencies should consider leaving slash piles on the landscape for at least a year after cutting.

Abstract Name: The Illusion and Reality of Parasocial Relationships with Celebrities

Abstract This paper explores the impact parasocial relationships with celebrities have on media followers and figures. While parasocial relationships have been around for years, they are only growing, leading, in many cases, to both negative and positive interactions. The narrative review examines and dissects the history and psychology of parasocial relationships, their impact, and how parasocial relationships are used in the media. Using attachment theory as a lens, this paper also delves into the phenomenon of Taylor Swift, her use of parasocial relationships to build engagement and branding, and her clever use of social media tools to foster a sense of connection and belonging.

Abstract Name: Walking an independent life with no constraints

Being born with optic nerve hypoplasia (ONH) presents unique challenges not only for individuals with the condition but also for their families. This congenital defect, caused by underdevelopment of the optic nerve during fetal growth, significantly impacts visual function. Prenatal factors such as maternal infections, substance use, or other disruptions during pregnancy can contribute to this condition, resulting in varying degrees of visual impairment. Individuals with ONH may face difficulties navigating their environment, both at home and in public spaces or community centers, requiring thoughtful accommodations to enhance their quality of life. Designing spaces for those with visual impairments involves implementing features that prioritize safety, accessibility, and sensory enrichment. Essential design elements include high-contrast color schemes to help differentiate between walls, floors, and furniture, as well as tactile features like textured flooring or wayfinding for orientation. Lighting plays a crucial role, with ample natural and artificial light carefully managed to reduce glare while maximizing visibility. Open layouts minimize physical obstacles, allowing for easier navigation within the home. Advanced technologies can further enhance independence. Voice-activated systems, smart home devices, and multisensory aids, such as auditory signals or aromatic markers, provide additional support for daily activities. These features, rooted in research and practical application, create environments tailored for independent living. For individuals with ONH, homes designed with these elements foster a sense of autonomy and confidence, making everyday life more manageable and fulfilling. By addressing the specific needs of visually impaired individuals, both in residential and public settings, thoughtful design not only improves functionality but also empowers them to lead more independent lives. This holistic approach ensures that spaces are not only accessible but also enriching, supporting the dignity and well-being of those living with ONH.

Authors:

Abstract Name: Shut Out

In this current day and age, I wanted to explore the theme of bullying as a constant social issue domestically as well as globally. Bullying may be present in various environments such as school, extracurricular activities, and now online. I created this piece based on my own bullying story. I have a cast of four dancers to represent the theme, which includes a door prop to create a physical mental element within the piece. The main themes that my work focused on were forms of bullying that are physical and social. The build-up of this can be seen throughout the piece. The psychological impact of bullying can also be shown through low self-esteem, depression, and anxiety. The reasoning behind bullying is the need to feel empowered. This may create peer pressure and the need to fit in socially. In my work, this is established by one dancer who is in charge with two others following. Establishing these relationships within my work also depicts the role of bystanders, who can either perpetuate or mitigate bullying through their reactions. Society can play a crucial role in bullying, as cultural norms and media representations can normalize aggressive behavior, while institutions frequently fail to address bullying effectively. Overcoming this issue involves fostering resilience in victims, educating potential bullies on empathy and communication, and implementing anti-bullying

campaigns and legislation. The narrative of bullying does not end in defeat. Moving on from the experience is difficult but not impossible. For many, the journey begins with finding strength in small acts of kindness from friends, family, or even strangers. This piece shows it as the victim moves to a new place that makes one feel accepted.

Abstract Name: The Impact of Social Norms on Intervention Strategies for Honor Crimes in India

Honor crimes in India which deeply rooted in patriarchal norms and caste-based hierarchies, continue to pose significant challenges to justice and social reform. This study examines the prevalence of honor crimes, analyzing why intervention strategies by governmental and non-governmental organizations have largely failed. Through qualitative interviews with NGO activists across seven states in India, the research highlights the intersections of gender, caste, and religion as critical factors that perpetuate these crimes and undermine policy efficacy. Key findings revealed chronic underreporting, systemic law enforcement failures, and societal resistance as major barriers to effective interventions. The study also critiques existing legal frameworks, such as the Special Marriage Act and the Prevention of Atrocities Act, for their limited implementation and inability to address the cultural dynamics driving honor crimes. Recommendations include awareness campaigns, educational reforms, accessible counseling services, and the enactment of a specific honor crimes law to ensure accountability and victim protection. This research emphasizes the urgent need for holistic, culturally nuanced approaches to dismantle the societal structures that enable honor crimes, contributing to the broader discourse on gender-based violence and social justice in India.

Abstract Name: The Differential Activation Phenotype of Human Microglial Cells in Response to Diverse Stimuli

Microglial activation plays a central role in the progression of Alzheimer's disease (AD), where the response to amyloid beta (A β) can determine neuronal survival. Appropriate regulation of microglial activation is critical, as it protects neurons from the neurotoxic effects of A β accumulation. Dysregulation of this process contributes to cognitive deficits and disease progression. Emerging evidence suggests the G protein-coupled receptors (GPCRs) may significantly influence microglial function and neuroinflammatory pathways. Among them, GPR3 is a promising target for modulating microglial responses, although its role in amyloidosis requires further exploration. This study aims to characterize the activation of phenotypes of human microglia under conditions designed to mimic pro-inflammatory (LPS/IFN- γ), anti-inflammatory (IL-4), and cellular damage-associated (etoposide) conditions. Using the Human Microglial Clone 3 (HMC3) cell line, we

assessed cellular responses to the various stimuli over 24 hours. Morphological changes were monitored using phase contrast microscopy. Flow cytometry was employed to evaluate the expression of microglial activation markers CD11c and CD45 . Metabolic activity was indirectly measured through medium pH fluctuations. Western blot analysis was used to quantify the expression of ARG-1 and iNOS, markers indicative of distinct microglial activation states. Preliminary observations suggest that microglial responses are stimulus-dependent, exhibiting distinct changes in morphology, marker expression, and metabolic activity. These findings highlight the heterogeneity of microglial activation under different environmental conditions, underscoring the importance of characterizing these responses as a step toward understanding their role in AD. We hope this sets the stage for future studies into how GPCRs, including GPR3, might influence microglial activation and response to amyloid pathology, potentially contributing to therapeutic approaches for AD and other neurodegenerative diseases.

Abstract Name: Is Love Addiction Associated with Personality Disorders and Trauma?

Love addiction (LA), a behavioral addiction, is a controversial concept that is not yet an official diagnosis. It can be defined as an insatiable need to be in love and be considered vital to a romantic partner, according to Maglia et al. (2023). A recently developed measure of LA incorporates the three features of addiction: craving, tolerance, and withdrawal (Costa et al., 2021) Love addicts cannot live without feeling love and they constantly crave it. They build tolerance to feeling loved and will insatiably need to feel more desired by their partner. If love addicts feel unloved or if they are not in a relationship, they may experience withdrawal symptoms like severe mood swings, depression, and irritability. The purpose of the present correlational study is to examine whether LA is associated with other psychopathologies with which it might overlap. LA may overlap with obsessive compulsive personality disorder (OCPD) since both involve obsessive thought processes and compulsive behaviors. LA might intersect with narcissistic personality disorder (NPD) because both involve excessive idealization. Both LA and post-traumatic stress disorder (PTSD) involve emotional dysregulation. The study administered an anonymous survey with self-report measures of LA, OCPD, NPD, and PTSD on Qualtrics. Participants are being recruited through Amazon Mechanical Turk. The current study is still in the data collection stage. Due to the overlapping features of LA with these other disorders, it is being predicted that results may show a positive correlation between love addiction and at least one of the other disorders. Exploration into this topic is vital to contributing to current understanding of negative mental and emotional states, which harm an individual as well as their relationships. Relationships that love addicts have are filled with their dysfunctional behaviors, such as crippling and constant emotional dependence on their partner.

Abstract Name: Defining Effector and Memory-like Cell State In in-vivo CAR T Cells from Multi-center Clinical Trials

Chimeric Antigen Receptor (CAR) T-cell immunotherapy is an emerging treatment that has demonstrated high remission rates in pediatric patients with non-solid tumors. This process involves extracting T cells from the patient, inserting the CAR gene, and allowing the cells to proliferate in a laboratory setting before reinfusion into the patient to target and destroy tumor cells. The inaugural recipient of CAR T-cell therapy has remained cancer-free for twelve years. Despite this success, the specific in vitro concentrations of effector and memory T cells, which are crucial subtypes for sustained immunologic response, remain poorly characterized. This lack of definition can lead to relapse if the in vivo balance of these cells is inadequate. This study utilized a Gaussian Mixture Model (GMM) to classify clinical T cell data into what are hypothesized to be effector and memory groups. Validation was conducted using data from the first patient (PT1), with UMAP Joint-Embedding confirming a significant correlation between clinical group classification and PT1's durable CAR T-cell gene expression. These findings suggest that the GMM effectively delineates in vivo CAR T cell phenotypes corresponding to effector and memory functions, enhancing our understanding of post-treatment T cell dynamics.

Abstract Name: COVID-19 Tweet Classification Using Large Language Models

The COVID-19 pandemic sparked widespread discussions on social media platforms such as Twitter, where people shared their real-time perceptions regarding various controversial topics such as vaccinations, public health policies, and societal effects of the pandemic. This research tells the story of the pandemic by classifying millions of web-scraped COVID-19 related tweets into various categories through the use of Large Language Models (LLMs). This process involved creating a pipeline that benchmarked the efficiency and accuracy of locally deployed LLMs (Mistral, LLaMa3.1, Gemma, Qwen, etc.) on tasks such as topic classification. After scraping Twitter and storing tweets in a database, they were retrieved and pre-processed to ensure high-quality tweets were used. Using these models, we categorized tweets into a predefined set of topics such as masks, vaccines, and quarantining. These categories were then appended back into the table and stored in the database for further analysis. To evaluate the performance of different LLMs, model accuracy and classification consistency will be considered. Zero-shot and few-shot prompting, with and without contextual examples, were explored to optimize the classifications generated by the LLMs. Throughout the research, various prompt engineering techniques, such as self-consistency prompting and chain-of-thought prompting, are utilized. When comparing and analyzing the models, some were better suited for the task at hand, thus identifying the best model for the job. The work accomplished during this research project underlines the potential of LLMs in labeling datasets, a task that would otherwise require significant manual work and time. This research project highlights an efficient pipeline to extract insights from large-scale datasets. The findings of this project can aid in policy-making and demonstrate the utility of LLMs for real-time data classifications during future emergencies.

Abstract Name: The impact of HMB on fgf8 expression levels during *Ambystoma mexicanum* limb regeneration.

Axolotls are organisms with the ability to regenerate different types of tissues through a complex process involving wound healing, dedifferentiation, and re-development. During the dedifferentiation phase, the expression of the fgf8 gene plays a key role in promoting the differentiation of mesenchymal cells into muscle tissue. Within this developing muscle tissue, the metabolite Beta-hydroxy-Beta-methylbutyrate (HMB), is synthesized to promote the expression of essential muscle proteins necessary for tissue growth. While HMB is known for its role in muscle growth, its effects on muscle tissue regeneration are unknown. And have not been tested for tissue regeneration capabilities. The aim of this study is to determine the impact of HMB on fgf8 expression during muscle tissue regeneration. We expect that injecting increasing concentrations of HMB will lead to increasing expression levels of fgf8 in regenerating tissues. For this study, RNA was extracted from untreated non-regenerative tissue and treated regenerative tissue, converted to cDNA, and PCR amplified with fgf8 gene-specific primers. Our results have shown that high concentrations of HMB correlate with decreased fgf8 expression levels during the early stages of the axolotl wound healing and regeneration process. These results provide a foundation for future studies on various dietary supplements during tissue regeneration.

Abstract Name: Metabolic Disease and Bones: Trace Element Abundance in Skeletons with Evidence of Metabolic Disease

According to the Centers for Disease Control (CDC), metabolic diseases such as diabetes metabolic syndrome, hypercalcemia, hypertension, and others affect approximately one-third of Americans. Alterations to the skeleton can indicate the presence of metabolic disease, like diffused idiopathic skeletal hyperostosis (DISH). Diet is a factor that significantly contributes to the prevalence of metabolic disease. Trace elements in diet are incorporated into bone as it forms, providing evidence of metabolic disease after death. However, traditional analysis of these trace elements destroys the bone sample, and new non-destructive techniques are necessary. X-ray fluorescence (XRF) analysis is one possibility. This study examines how trace elements vary in skeletons of individuals with and without evidence of metabolic disease, with the goal of providing a new way of observing evidence of metabolic disease. It was hypothesized that skeletons with evidence of metabolic disease will have levels significantly different from the skeletons with no evidence. Using observational techniques, a collection of skeletons was categorized into a control and experimental group, at which point trace element measurements were taken to quantify the abundance. Four different regions of the skeleton on both groups were measured. Results revealed no significant difference in trace elements between the skeletons with evidence of metabolic disease to those without, implying that trace elements may not be a fruitful approach for identifying metabolic disease. Levels of silicon and calcium in certain areas, as well as

the presence of titanium in some of our samples, raise new questions for research in the future. XRF spectrography was successful in detecting trace elements in human skeletons.

Abstract Name: Academic Stress of Undergraduate Students Affecting Dental Caries

The acid produced from the fermentation by *Lactobacillus* is believed to make teeth more susceptible to dental caries, while stress is thought to increase the amount of *Lactobacillus* bacteria present. This study aimed to directly investigate the impact of stress on the oral microbiome, with a specific focus on the presence of *Lactobacillus* bacteria and their potential role in oral health. It was hypothesized that there would be a positive correlation between elevated stress levels and increased *Lactobacillus* presence, which highlighted the potential disadvantages contributed to overall oral health and dental susceptibility. 100 undergraduate students completed the Perceived Stress Scale in order to quantify their stress levels. These students provided saliva samples in test tubes containing Snyder Test agar, so that correlations between stress levels and *Lactobacillus* could be seen. The results supported the research hypothesis by demonstrating higher stress levels produced more *Lactobacillus*, meaning teeth were more susceptible to dental caries when under stress. Overall, this research contributed to the broader understanding of the oral microbiome dynamics and emphasized the importance in decreasing levels of stress to maintain oral health.

Abstract Name: To Conform or Not to Conform: An Evaluation of the Situational and Dispositional Factors that Influence Group Conformity and Employee Voice Behavior

This study delves into the complex dynamics influencing voice behaviors within organizational settings, focusing on the interplay between situational and dispositional factors. Voice behaviors, crucial for organizational success, facilitate innovation, adaptability, and overall growth. However, when individuals feel silenced or hesitant to express dissent, detrimental outcomes such as ethical lapses and missed opportunities may arise. This research aims to bridge gaps in the existing literature by examining how both situational contexts and dispositional traits impact voice behaviors and conformity both individually and interactively. Through empirical investigation, it seeks to provide insights into the mechanisms underlying voice behavior, enriching theoretical frameworks in organizational psychology. Additionally, the study explores practical

implications for organizations, offering guidance on fostering cultures of open communication and constructive dissent to enhance long-term resilience and success.

Abstract Name: ADHD risk for COVID-19 infection among Young Children

Adults with ADHD were shown to be at increased risk for more severe outcomes following COVID infection than individuals without ADHD. It is unknown if greater risk for COVID infection risk was also apparent in children. The current study aimed to examine this association in young children. Pregnant women were recruited from the Obstetrics and Gynecology clinics at Mount Sinai Hospital and New York Presbyterian-Queens in New York. Their babies were later born at these same hospitals between June 2011 and July 2015. Inclusion criteria required the absence of obstetric risks. N=62 mother-child dyads were reassessed annually between ages 2-6 years and then again during the first year of the COVID-19 pandemic. A subsample of 154 preschoolers with clinical interviews for preschool-aged children and assessments of parenting dimensions were included in the current study. Prenatal stress exposure status (Superstorm Sandy Stress) was defined according to whether mothers were pregnant and residing in the NY metropolitan area when SS made landfall in New York on October 29, 2012 (in-utero exposure). ADHD diagnosis was assessed using The Preschool Age Psychiatric Assessment (PAPA). Children who met DSM-IV criteria for ADHD at any point between 2 and 6 years were considered to be ADHD positive. Approximately half (n=29, 48%) of children were exposed to Superstorm Sandy in utero and 8% (n=5) met criteria for ADHD during childhood. Superstorm Sandy exposure was associated with increased risk for ADHD, $\chi^2(1) = 6.01$, $p = .01$, $ES = .31$. Compared to children without ADHD, those with ADHD in early childhood were more likely to have a suspected COVID-19 infection, $\chi^2(1) = 5.72$, $p = .017$, $ES = .30$, and more likely to have a confirmed infection, $\chi^2(1) = 3.55$, $p = .059$, $ES = .24$. Future research should investigate the mechanism of this association, including inflammatory pathways or ADHD behaviors that increase risk for exposure.

Abstract Name: Genomic and Phenotypic Comparison of Leaf Morphology in *Schrenkiella parvula* Standard and Turkan Ecotypes

Leaves occupy most of a plant's biomass and are essential photosynthetic organs, and thus are crucial to agriculture. Larger leaves tend to gather more light for photosynthesis, but in return they lose more water in dry or saline environments. Saline soils result in \$27.3 billion annually in agricultural losses. *Schrenkiella parvula* is an extremophyte species from the Brassicaceae (mustard) crop family. In contrast to most plants, it can complete its lifecycle at salt and ion concentrations six times greater than sea water, and it has become a

model for studying multi-ion stress. The purpose of this study is to understand the genetics of leaf variation in *S. parvula* and create a new genome resource that allows genetic mapping of phenotypic traits. Until now, only one genotype of *S. parvula* has been studied. Understanding phenotypic variation within the species, including variation in leaf traits, will contribute to understanding how it tolerates saline soils. The two varieties present in *S. parvula*, the Lake Tuz ecotype and the Turkan ecotype, have different leaf size and shape. These two ecotypes and their crosses were grown for 10 weeks under 12 h day/ 12 h night cycle in 512 ppm CO₂ using Percival Intellus control system. They were given a diluted Hoaglands solution and watered twice per week. Leaf surface area, width, and length measurements were captured using FIJI software. Plants from crosses between these two varieties are being studied with the goal of identifying regions of the genome contributing to the difference in leaf shape between these two ecotypes

Abstract Name: ESKAPE Antibiotic Resistance: Unknown Environment Microorganisms Producing Antibiotic Activity Against ESKAPE Pathogens

Antibiotic resistance has rendered many of our typically prescribed antibiotics useless against bacterial infections. Six of the most drug resistant pathogens are highlighted under the acronym ESKAPE, which stands for *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and the *Enterobacter* species. Our lab was gifted two libraries of unknown environmental isolates, which had previously exhibited antibiotic activity against at least one ESKAPE pathogen. For the current study, the libraries, named “2023 isolates” and “2024 isolates”, were screened for antibiotic activity against all six ESKAPE pathogens by placing a small amount of the unknown isolate on a lawn of an ESKAPE pathogen. After incubation, we measured the zone of inhibition, the indicator of antibiotic activity, for each unknown isolate in a series of three trials. From our results, we chose the most promising unknown isolates based on the number of ESKAPE pathogens inhibited. For each promising unknown isolate, we began the process to isolate the antibiotic activity by extracting the organic compounds within the unknown isolate. With the help of our collaborators, our promising unknown isolates were fractionated and tested in order to determine the active antibiotic compound. Currently, both batches of the unknown isolates are in the process of being isolated for the active antibiotic compound. From the 2023 and 2024 batches, we have a total of 43 promising isolates that are currently undergoing further purification and testing.

Abstract Name: Evaluating *Bacillus subtilis* Strains for Pathogen Reduction in Built Environments

Traditional cleaning products pose various harmful risks to one's health, such as dermal and respiratory issues due to the chemicals cleaning products may contain, as well as musculoskeletal-associated symptoms due to prolonged repetitive movement. *Bacillus subtilis* does not threaten human health but has great potential for biological control of pathogens. *Bacillus subtilis* has been shown to reduce the spread of pathogens and infectious diseases by either producing antimicrobial compounds that inhibit the growth of pathogenic microorganisms or by supporting the survival and colonization of commensal microorganisms, limiting pathogenic species to establish dominance. Specifically, *Bacillus subtilis* can inhibit growth of Methicillin-resistant *Staphylococcus aureus* (MRSA). Therefore, in this project the hypothesis tested was that incorporating *Bacillus subtilis* in 3D-printed structures in built environments could reduce antibiotic-resistant pathogens, providing a biological alternative to chemical disinfectants. We evaluated four different strains of *Bacillus subtilis* (TH002, TH035, K02, K04) at various concentration levels and conducted an exclusion assay against MRSA. It was found that the knockout strains (K02, K04) developed for enhanced antibiotic production demonstrated the most resistance to MRSA in comparison to the wild-type strains (TH002, TH035). These results suggest that the knockout strains (K02, K04) do in fact produce a greater amount of antipathogenic compounds that work against MRSA. Overall, all the *Bacillus subtilis* strains demonstrated potential in reducing pathogenic bacteria but the knockout strains showed to be the most effective out of all the four strains tested. For future directions we hope to conduct more testing on a bigger variety of *Bacillus subtilis* strains rather than just four strains, testing the different concentration levels in a variety of environments and conducting field studies to measure the long-term efficacy and reliability of *Bacillus subtilis* in public settings, such as hospitals and schools.

Abstract Name: Environmental Risk Perceptions of Forever Chemicals (PFAS) near U.S. Air Force Bases in San Antonio, Texas

Per- and poly-fluoroalkyl substances (PFAS) are synthetic substances primarily used for their oil and water-repellent properties. One of the applications was in aqueous film-forming foams (AFFF) used for extinguishing fuel-based fires on military installations. Using fluorine in AFFF enhances its effectiveness in both containing and extinguishing fuel-based fires. However, there is limited understanding of PFAS and its effects on the environment and the health of surrounding communities, including the contamination of groundwater, drinking water, and soil in these areas, which raises a public health concern. Using a citizen science approach, this study aims to investigate the community's perception of PFAS contamination in air, water, and soil in the La Quintana neighborhood, a known cancer cluster identified by the Texas Department of State Health Services, in San Antonio, TX. We hypothesize that 1) the majority of the respondents will have little concern about chemical contaminants in their neighborhood, 2) some respondents will be concerned about health risks to themselves or their families from potential exposures of living within close proximity to the Air Force Base, and 3) some respondents have heard about the chemical compounds PFAS.

Future studies will include an environmental risk assessment of the exposed community. This approach will be used to identify and evaluate the risk by collecting environmental samples in the Quintana neighborhood.

Abstract Name: Effect of Gonadal Hormones on P2X Purinergic Receptor 3 (P2RX3) Expression in the Rat Trigeminal Ganglia

Orofacial pain disorders, like migraine and temporomandibular joint disorder, are 2-4x more prevalent in women. Studies report that gonadal hormones (estrogen, progesterone, testosterone) contribute to sex differences in pain. Estrogen can regulate pain-generating ion channels, including transient receptor potential vanilloid 1 (TRPV1) and P2X purinoceptor 3 (P2RX3), on sensory neurons. Preclinical studies on pain are largely conducted in rodents where estrogen levels are highest during the proestrus phase of the estrous cycle (homologous to the early luteal phase of the human menstrual cycle) and lowest during the estrus phase (homologous to the late luteal phase). We recently reported that P2rx3 gene expression is significantly higher in female compared to male rats, which could be one mechanism contributing to higher orofacial pain behaviors observed in female rats (modeling humans). The P2rx3 gene encodes P2RX3 protein as a ligand-gated ion channel activated by ATP that leads to an influx of cations to trigger pain signaling. Previous studies reported that estrogen downregulates P2RX3. We hypothesize that P2RX3 expression is sexually dimorphic and fluctuates with the estrous cycle in the trigeminal sensory neurons that relay orofacial pain signals to the brain. To test this hypothesis, we extracted trigeminal ganglia from rats during each stage of the estrous cycle (diestrus, proestrus, estrus; as determined by vaginal smear), ovariectomized females (surgical removal of ovaries as source of gonadal hormones), and males. Tissues were fixed in paraformaldehyde, sectioned onto glass slides, and processed by fluorescence immunohistochemistry to visualize and quantify P2RX3 and TRPV1 expression. Our data indicate that P2RX3 is highly expressed in the TRPV1 population of sensory neurons in female rats. If modulation of P2RX3 by gonadal hormones contributes to sex differences in orofacial pain, then higher levels of P2RX3 within the TRPV1 population of sensory neurons will be observed in females, and particularly during estrus.

Abstract Name: Quantifying Properties of Calcific Extracellular Vesicles from Osteoblasts and Vascular Smooth Muscle Cells

Vascular calcification is the abnormal deposition of mineral in blood vessels. It is an active, cell-regulated process that has been recognized as a key cardiovascular risk factor and is the most significant predictor of an individual's risk of a heart attack. Interestingly, this abnormal mineralization in arteries is often accompanied

by reduced bone density. This contradictory relationship, known as the “calcification paradox” is commonly observed in conditions such as osteoporosis and chronic kidney disease. The specific mechanisms underlying the divergent mineralization by the primary calcifying cells in each tissue, vascular smooth muscle cells (VSMC), and osteoblasts (HOB), remain unknown. Both types of mineralization utilize the release of small membrane-bound compartments known as extracellular vesicles (EVs), which transport procalcific materials into the extracellular space to initiate mineral formation. We hypothesize that EVs released from VSMCs, and HOBs have distinct characteristics, due to unique mechanisms of formation. Osteoblast-derived EVs have been previously characterized as ectosomes, with a reported size range of 10-400 nm. VSMCs have been shown to have exosomal origins, and therefore, we hypothesize that they produce smaller EVs within the 40-160nm range. This project will compare calcifying EVs isolated from cultured HOBs and VSMCs using Tunable Resistive Pulse Sensing (TRPS) to measure EV size, concentration, and charge. We aim to use these different characteristics to identify unique features between the two EV populations, thus providing better insight into their mechanistic origins. The findings could have significant implications for developing therapeutic strategies against vascular calcification and bone-related diseases.

Abstract Name: Subject Pronoun Variation in Honduran Spanish: Insights from Northern Virginia

This study investigates the Spanish spoken by first-generation Honduran immigrants in Northern Virginia (NoVA). Despite the significant growth of the Honduran population in the U.S., they remain largely overlooked in linguistic research. Within Central American Spanish varieties, subject pronoun variation, a well-established area of study in Spanish-language variation, has yet to be thoroughly explored in Honduran Spanish. Unlike English, where subject pronouns are mandatory (e.g., they danced), Spanish allows optionality, meaning speakers can include or omit the subject pronoun without changing the meaning of the sentence (e.g., (ellos) bailaron: “(they) danced”). This feature provides a unique lens for examining dialectal variation. Prior studies reveal significant cross-dialectal differences in subject pronoun usage, with Dominicans using pronouns most frequently and Mexicans the least. These differences are often shaped by internal linguistic factors such as verb tense, person, and clarity of the subject, as well as external factors like speaker identity and sociocultural context. However, no research has yet addressed how these patterns manifest in Honduran Spanish. To address this gap, we conducted sociolinguistic interviews with ten first-generation Honduran immigrants in NoVA. Each interview lasted approximately 30 minutes, allowing for spontaneous, naturalistic speech. For analysis, we transcribed fifteen-minute segments from minute 10 to minute 25 of each interview. Verbs within these segments that fit the envelope of variation, meaning contexts where a subject pronoun could either be present or omitted, were coded following guidelines established by Otheguy and Zentella (2012). Preliminary findings suggest that Honduran Spanish speakers may exhibit subject pronoun usage patterns similar to high-pronoun-usage groups like Dominican Spanish speakers. By filling a significant gap in sociolinguistic scholarship, this research highlights the unique linguistic characteristics of Honduran Spanish and its contribution to the broader understanding of Spanish variation in the U.S.

Abstract Name: Reflections on Community Translation and Interpretation in Educational Settings

Language access is critical for equity in education, yet many families with limited English proficiency (LEP) encounter significant barriers to effective communication. As a bilingual fluent in English and Spanish, with personal experience as a language broker, community translator, and interpreter, combined with formal training in translation and interpretation, I bring a unique perspective to the challenges and opportunities of facilitating communication in educational settings. This presentation reflects on my lived experiences alongside an analysis of systemic issues and actionable solutions. Despite the protections of Title VI of the Civil Rights Act of 1964 and Executive Order 13166, many schools lack adequate resources to meet the needs of Spanish-speaking families, one of the largest LEP demographics in the United States. Students like me often take on the role of language brokers, navigating emotionally complex and high-stakes conversations between parents and school officials without formal training. These experiences highlight the personal and cultural pressures of bridging two worlds often interpreting not just words, but cultural nuances that can make or break understanding. Through personal narratives and research, I explore potential solutions/recommendations such as increasing funding for interpretation services, developing educational interpreter training programs, and creating community partnerships with universities to provide free resources to Spanish-speaking families. By sharing my journey and reflections, I aim to highlight the lack of effective language access programs in education and how this hinders Spanish-speaking families from fully participating in their children's academic success.

Abstract Name: Indigenous Sounds of Gathering: Music and Dance Memory in the Cordillera Highlands of the Philippines

This documentary film demonstrates how indigenous music and dance are deeply ingrained into the Tinggian people's collective memory. The Tinggian people are from the province of Abra and are one of several ethnolinguistic groups in the Cordillera mountains of the Philippines. Most of this documentary film's contents were filmed in the barangay (village) Taripan in Malibcong, Abra, Philippines. This documentary film depicts two traditional Tinggian dances accompanied by Cordillera flat gong music, pallook and tajok. Pallook is a joyful group dance performed at celebrations, where women and men dance in alternating formations with (usually) men playing the gongs. Tajok is a social partner dance between men and women of all ages and the accompanying musicians play the gongs on their laps. The film also shows a traditional chant called Ugayyam, which is included at all social gatherings and performed by a chosen elder of the community, signifying its importance to Tinggian cultural identity. Ugayyam is usually performed at the beginning of an event before other dances or chants to signify the start of festivities at a celebration. These performances in the documentary were a part of a birthday celebration where the community gathered together. The documentary also depicts scenes of road travel, environment and daily life, which are interwoven with the scenes of music and dance. By juxtaposing the scenes of music and dance with scenes of road travel, environment and daily life, the documentary explores ideas of tradition, heritage, indigeneity, and homecoming. This documentary film was created from various video and audio clips recorded during fieldwork research in July 2024. Length of film: 12 minutes.

Abstract Name: The Race to Messina: George Patton's Strategic Failures and the Evacuation of Axis Troops from Sicily, 1943

This presentation explores US General George Patton's "race to Messina" with British General Bernard Montgomery during the Allied invasion of Sicily in 1943. Using Patton's diaries, the memoirs of his colleagues, and official military reports, this research proves that his decision to deviate from the plan in competition with Montgomery allowed the evacuation of approximately 100,000 Axis soldiers. These soldiers continued fighting on the Italian mainland, which slowed the Allied advancements. Military historians consistently understate the consequences of his actions, but this research proves that Patton was the main cause for the strategic failure of preventing an Axis evacuation. This presentation demonstrates the consequences of jealousy-driven military decisions, which in this case prolonged a war.

Abstract Name: Class and Antisemitism: An Intersectional Study of Theodor Herzl's Zionism

This research demonstrates that Theodor Herzl, the founder of political Zionism, infused his classist rhetoric with antisemitic stereotypes in an effort to garner support for Jewish nationalism. Drawing upon tropes about undesirable Eastern European Jews, he appealed to the racist elites of Europe to gain support for Jewish emigration. He also delegitimized his critics, accusing them of betraying their Jewish identity as "mauschel." Using his diaries, published articles, and Zionist writings, this research shows that Herzl previously unequivocally condemned antisemitism, but changed after becoming a journalist in Paris. While there, he believed that Eastern European Jews exemplified the racist stereotypes, altering his method of approaching the subject. Previous research treated Herzl's use of antisemitic stereotypes separately from his classist statements. However, this presentation shows that his use of antisemitic tropes was a mode of communicating his classist beliefs, inherently connecting the two. While Herzl saw Zionism as the cure for antisemitism, he used hateful rhetoric about Eastern European Jews to advance his political goals.

Abstract Name: Using Complementary Health Therapies for Stress Management: A Survey Study of Nurses' Perceptions and Experiences

Background: Stress, a natural response to disruptions in human homeostasis, can negatively impact individual well-being, contributing to global health concerns. While traditional stress management often relies on pharmacological interventions for resultant medical conditions, complementary health therapies (CHTs) have emerged as promising non-pharmacological alternatives. Despite their potential benefits, the integration of CHTs into mainstream healthcare practices remains inconsistent. This study aims to understand nurses' perceptions, attitudes, and use of CHTs across urban and rural healthcare settings. Methods: An online survey study was conducted with nurses working in Southeastern and Eastern North Carolina using Qualtrics questionnaires. The survey assessed their perceptions and use of CHTs for stress management and their awareness of newer modalities, e.g., somatic therapies. These measures were descriptively analyzed. Results: The study nurses (n=36) were mostly middle-aged female Caucasians with an average of 18 years in nursing. Nearly all (>95%) reported positive views on self-healing and supported the idea that CHTs could enhance conventional medicine. While nurses expressed their familiarity with traditional CHTs, including exercise, yoga, meditation, and massage, their knowledge of less common practices, such as rolfing, tapping, and somatic therapy, was more limited. Clinical nurses frequently used CHTs for personal stress management (94.4%), supported offering them to patients (86%), and believed in the importance of integrating them into workplace practice (72%); yet referrals (44%) and patient discussions (38.8%) using CHTs were notably less common in their usual practice. Conclusions: Our study reveals a discrepancy in that nurses have positive attitudes toward CHTs for personal stress management but tend to underutilize them in patient care. This may result from insufficient resources and knowledge about CHT use in a healthcare setting. Further research with diverse samples is needed to identify practical barriers and validate the effectiveness of CHTs in standard care.

Abstract Name: Comparative Analysis of Femoral Cortical Bone Properties Across Temporal and Cultural Populations: Insights into Bone Functional Adaptation and the Role of Physical Activity

Bone remodels to alterations in biomechanical loading and physical activity through a process called bone functional adaptation. Bone remodeling alters bone strength, shape, and resistance to mechanical load. The exact relationship between physical activity and bone remodeling is unclear, but this process of adaptation can help researchers understand activity patterns in past human populations. To further understand the process of bone functional adaptation, comparing the bones of individuals for which lifestyle, activity, and behavioral patterns are known may shed light on how those factors impact bone remodeling. As such, we examined femoral cortical bone cross-sectional properties from three human groups across time: 1.) the African Bronze-Age Kerma population, 2.) a European medieval population from St. Johns, Cambridge, UK, and 3.) a modern American population. Cortical bone structure was analyzed in the femur using microCT images. Cortical bone cross-sectional geometric properties were analyzed in ImageJ at 10% intervals along the shaft (from 30% to 70% bone length) to determine cortical area, maximum second moment of area, minimum

second moment of area, torsional rigidity, and cross-sectional shape. Measurements were compared between groups using the One-Way ANOVA method, employing Tukey post-hoc testing in SPSS. Statistical significance using a 95% confidence interval was identified in both the minimum second moment of area and cross-sectional shape at the 70% slices. The Kerma population exhibited a lower minimum second moment of inertia, indicating slightly less resistance to bending. The modern American population was predicted to have lower strength metrics due to increased sedentism in a modern, industrial society. However, the current results place the American population in line with the older populations. These findings suggest an additional influence on skeletal phenotype aside from solely physical activity.

Abstract Name: AI Collaboration for Forecasting in Business Using Prompts– A Case Study Analysis

Can application of Generative AI help in the analysis of economics and business forecasting? Literature (2023) concludes that the productivity frontier of knowledge workers collaborating with AI has been “jagged” with high productivity and high quality of work for some workers and poor productivity and low quality of work produced in others. Students, as researchers, in an upper-level economics forecasting course explored the consequences of their collaboration with AI using a case study. Their analysis varied regarding AI’s role and performance in the exercise. However, researchers universally concluded that AI as a collaborator, with the appropriate use of iterative prompts, have enabled them to perform their tasks more productively resulting in a higher quality of work. This research is a qualitative analysis by the researchers, where they reflected on their individual performance of business forecasting analysis against collaborative AI’s performance of the same using the case study as a reference. Researchers provide step by step detailed analysis of the business problem from the two perspectives. The results of the study provided students better clarity, than before, towards AI application and collaboration in their future work in business forecasting and analysis. Abstract Name: Examining the role of anisotropic tissue strain on neural cell rearrangement in *Xenopus laevis*

Mechanics are integral to organismal development, not only by shaping early stage embryos, but by providing cues to guide cellular and subcellular activities (Chu et al., 2020). In developing *Xenopus* embryos, the central nervous system is established during neurulation via mechanical processes of elongation of the neural plate and folding of the neural tube (Vijayraghavan and Davidson, 2017). During elongation, cells in the neural ectoderm rearrange collectively and are thought to actively drive convergent extension (Keller and Sutherland, 2020). While several factors, such as planar cell polarity, are known to drive cell rearrangement in a specific direction, it is difficult to decouple the role of mechanical cues from biological cues in cell rearrangement in neural ectoderm in vivo. To test this, we generate a non-polarized neural ectoderm within *Xenopus* animal cap ectoderm using Wnt3a and Noggin over-expression. Next, we apply uniaxial strain to the induced neural ectoderm to investigate if anisotropic strain alone can induce directional cell rearrangement observed in vivo. We hypothesize that mechanical cues alone can drive rearrangement of unpolarized neural ectoderm tissue. Preliminary data also suggest that patterns of cell rearrangement in the native neural plate can be altered by external strain from stretching. This work suggests that external forces driving uniaxial strain play a key role in guiding directional cell rearrangement in the neural ectoderm.

Abstract Name: Socioeconomic Status and its Effect on Language Development: A Systematic Review

We are conducting a systematic review of peer-reviewed journal articles published between 2000 and 2023, focusing on studies that assess the relationship between SES and language development in early childhood. The review includes studies that examine syntactic and semantic development using assessments such as the Clinical Evaluation of Language Fundamentals (CELF) and the Test of Semantic Skills Primary (TOSS-P). Studies are being analyzed based on participant characteristics, SES indicators (e.g., parental education, income, occupation), language outcomes, and the methodologies employed, including longitudinal and cross-sectional designs. We were able to gather information from 15 randomly chosen articles. Our preliminary findings found that the area of language most studied was semantics. In addition, 12 out of 15 articles reported a significant relationship between SES and the language domains studied. After further analysis, we expect to find a strong association between lower SES and delays in syntactic and semantic development, with implications for long-term academic outcomes. This review anticipates providing a clearer understanding of the impact of SES on early language development and identifying areas for targeted early interventions.

Abstract Name: Are Local Garden Centers Potential Sources of Invasive Species in Davidson County, TN?

Recent research has suggested that local garden centers may help promote the spread of invasive species. However, there has been little research done in many geographic areas to determine how these local garden centers may contribute to their spread to local areas over time. In this study, we documented the number of exotic and invasive plant species that were for sale at the two largest garden centers in Davidson County, TN – Home Depot and Lowes. We then cross-referenced these taxa with iNaturalist and the Tennessee Invasive Plant Council species list to determine if any of the exotic or invasive species sold at Home Depot and Lowes had previously spread across Davidson County metro parks. Using this approach, we found that more than 80% of all the species sold at Home Depot and Lowes are exotic. In addition, we found that 19 of these exotic species sold at Home Depot and Lowes have been found spreading in Davidson County, TN. Ultimately, our findings support recent research which suggests that local garden centers have the potential to contribute to the spread of exotic species in local communities. In addition, they suggest that work is needed to help local businesses recognize that they are selling species that are invading local communities.

Abstract Name: Barriers and Bridges: The Intersection of Race and Socioeconomic Status in Accessing Disability Accommodations in Education

This research investigates how race and socioeconomic status (SES) intersect to impact elementary school children's access to disability accommodations legally mandated by the Americans with Disabilities Act (ADA). While existing literature explores disparities in access to accommodations, there is limited understanding of how systemic biases rooted in both race and SES compound these inequities. This study seeks to address this gap by examining the ways overlapping identities shape children's experiences within the educational system, emphasizing the broader implications for equity and inclusion. Utilizing a mixed-methods approach, this project integrates quantitative analysis of school district and state education data with qualitative insights from semi-structured interviews with parents, teachers, administrators, and advocates. Quantitative data will illuminate patterns of accommodation distribution by race and SES, while thematic analysis of interviews will capture nuanced perspectives on the barriers marginalized families face in navigating the accommodation process. Preliminary findings suggest that systemic inequities, such as underdiagnosis of disabilities among racial minorities and resource constraints in low-SES schools, significantly limit equitable access to accommodations. This research contributes to disability studies by applying intersectionality and critical disability theory to reveal structural barriers within the ADA framework. The findings aim to inspire policy reforms that move beyond compliance, fostering educational systems that prioritize inclusion and dismantle inequities at their root. This discussion will center on how these insights can reshape advocacy and policy to better serve all students.

Abstract Name: Knockdown of the Hox Gene Post2b Maintains Allometry in the Flatworm Species Schmidtea Mediterranea

Proper body allometry is a critical aspect of animal development and underlies differences in body plans across metazoan evolution. In the regenerative flatworm species *Schmidtea mediterranea* (Smed), the size and proportions of their body dynamically change based on nutrient intake. Smed naturally grow and degrow within a typical size range of 0.5 to 15mm. Knockdown of the Hox gene post2b, removes body size restriction in Smed, allowing for the body to grow upwards of six times beyond its natural limit. My research objective is to determine whether post2b knockdown alters the allometric scaling of the body plan. We hypothesize that these animals either maintain the normal allometry or display changes in growth rates and organ rescaling, deviating from the expected allometry. To test this, I performed brightfield imaging and morphometric analysis, observing body regions to determine total body allometry in actual and relative lengths. Our findings suggest that post2b maintains proper allometry by establishing a ratio at which the various body segments find an equilibrium.

Abstract Name: Further characterization of the scarlet *Daphnia magna* mutant for genes related to oxidative stress and neuronal function

Scarlet is an ATP-binding cassette (ABC) transporter essential for transporting an eye pigment precursor, 3-hydroxykynurenine (3HOK), into specialized organelles in invertebrate species. Knockout of the scarlet gene in *Drosophila* has been characterized by accumulation of 3HOK, oxidative stress, and locomotive aberrations. *Daphnia magna* scarlet mutants (Sc) also show age-progressive locomotive dysregulation and some neurotransmission abnormalities, but more studies are needed to fully characterize the effects of the mutation. Initial RNASeq data from adult wild-type and mutant animals showed significant differences in gene expression; however, data from other age classes were contaminated, rendering analyses unreliable. This study aims to add both statistical power to the initial differential gene expression (DGE) screen and correct the areas of potential contamination. Using Gene Ontology (GO) terms, we selected five candidate genes related to oxidative stress or damage and neuronal function that were found to be differentially expressed. Gene expression differences of candidate genes were validated using quantitative PCR (qPCR) in both genotypes using multiple age classes. We propose that the knockout of the scarlet gene induces an age-progressive form of neuronal degeneration via the accumulation of 3HOK. This accumulation likely results in oxidative stress and neuronal damage, leading to the altered locomotive behavior observed in adult mutant animals. Determining gene expression levels of these five genes at various age classes will reaffirm that these genes are involved in the pathway and contribute to 3HOK accumulation and subsequent oxidative damage.

Abstract Name: Writing/Righting Authoritarian Regimes in Real Time: Political and Personal Struggles In Venezuelan Daily Life Under Chavismo

Since 1998, Venezuela has experienced the slow decay of democracy and the strengthening of its current authoritarian regime. This has resulted in one of the largest humanitarian crises in the present day, with 7.7 million Venezuelans having fled the country. In order to maintain its status quo, the Chavista regime has exposed countless Venezuelans to daily acts of violence, torture, and other traumatic events which have disrupted daily life. This research project focuses on analyzing the experiences of Venezuelans to understand how they experience these political and personal struggles and how they situate themselves in their present historical context. To do so, I analyze recent texts, both fictional — including the novels *La hija de la española* and *The Voice of the Llanos* — and nonfictional—including the text *Testimonios de la represión*, that relate to Venezuela's current political situation, as well as interviews conducted with Venezuelans who have lived through this authoritarian regime. These findings help us to understand the role that everyday citizens play in shaping the social and political structures that surround them and in turn to promote democratic processes, not just in Venezuela but across the American continent.

Abstract Name: The Hunt For a Bacteriophage to Defeat *Stenotrophomonas maltophilia*

Antibiotic resistance is a significant problem in the medical field, leading to bacterial infections that are increasingly difficult to treat effectively. This challenge arises from the non-specific nature of antibiotics and the development of resistance, often caused when patients fail to complete the full course of treatment. In response, bacteriophages have emerged as a promising solution due to their host specificity and ability to replicate within bacteria, ultimately causing bacterial lysis. Bacteriophages typically follow one of two life cycles: the lytic or lysogenic cycle. The lysogenic cycle is where the bacteriophage will integrate its DNA into the bacterium's DNA and so the bacterium would replicate both leading to eventual cell lysis. The lytic cycle is where the bacteriophage infects the bacteria, replicates rapidly in it, and causes the bacterium to lyse. After identifying an antibiotic-resistant strain of *Stenotrophomonas maltophilia*, isolating a bacteriophage became the next focus. A lytic phage was successfully isolated from a soil sample collected at Campus Lake. It was then purified and amplified. DNA was then extracted and a restriction enzyme digest was performed to characterize its genome. It was determined that *HaeIII* cut the phage, it was named phage Chithonia, about 90.2 ng/μL of DNA was extracted and a final titer of 4.46 x 10¹¹ pfu/mL was achieved. This approach offers a targeted strategy in the fight against antibiotic-resistant infections, providing a more specific and potentially more effective alternative to conventional antibiotics. Further research will need to be performed to determine phage Chithonia's viability as a candidate for phage therapy.

Abstract Name: Exploring Molecular Hydrogen as a Gas Reservoir and Excitation Diagnostic for Dwarf Active Galactic Nuclei

Intermediate-mass black holes (IMBHs) are objects 100-1,000,000 times the mass of the Sun with a gravitational pull so strong that not even light can escape. Astronomers have determined that giant black holes co-evolve with their host galaxies, and finding IMBHs is critical in understanding this relationship. However, IMBHs are relatively elusive due to the rarity of IMBHs accreting matter (i.e., siphoning), which would be heated up enough to give off light to observe it. This type of an IMBH is called a dwarf active galactic nucleus (AGN). Guided by recent observations with JWST NIRspec and cosmological simulations of IMBHs, we have determined a relationship between the cloud's radius and its column density by solving a system of equations related to the gas cloud's geometry. Evidence of molecular hydrogen (H₂) has been found in the inner regions of larger AGN, and this H₂ region could exist within dwarf AGN, and could possibly serve as a gas reservoir for the IMBH to accrete. However, the typical reaction for forming H₂ is inhibited in dwarfs due to the lack of micron-sized, solid dust particles within them. Using the astrophysical code Cloudy to run simulations, we have found that the preferred method for forming H₂ in this dust-poor environment is associative detachment, which could possibly produce enough H₂ for the IMBH to accrete. Our current photoionization simulations within Cloudy predict that H₂ emission is still too faint to be observed, and this will be the subject of future work and analysis.

Abstract Name: Regulating Cell Migration: Skeleton Growth in Purple Sea Urchins

Coordinated cell migration is a hallmark of animal development. VEGF/VEGFR is a signaling pathway that has been shown to be critically important for this migration during sea urchin development (Duloquin, 2007). In order for proper skeletal development, Primary Mesenchyme Cells (PMCs) must migrate through the developing embryo to precise locations as they are the source of skeleton formation. The expression of VEGF in the ectoderm, and the specific expression of its receptor, VEGFR, in the PMCS directs this movement. Since VEGF/VEGFR plays a vital role in sea urchin skeletogenesis, this project is designed to investigate the regulation of the gene *vegfr-10-Ig* by identifying enhancers that drive its transcription. To do this, putative enhancer regions are identified through ChIP-seq data of ALX1, which is a transcription factor known to be a master regulator of the sea urchin genome. These candidate regions are then cloned into reporter constructs, microinjected into fertilized sea urchin embryos, and the embryos observed with fluorescent microscopy. Specific PMC fluorescence will indicate a candidate region is able to drive expression, confirming it as an enhancer. In future experiments, various truncations of a confirmed enhancer site can then be cloned into reporter constructs to determine the shortest sequence needed to drive expression of VEGFR-10. Bioinformatics tools will then be used to look for conserved sequences among other sea urchin species and identify candidate transcription factors that interact with the enhancer.

Abstract Name: Advanced XSS Detection Through LLM-Driven Dataset Augmentation

According to the Open Web Application Security Project (OWASP), Cross-Site Scripting (XSS) is a critical security vulnerability. Despite decades of research, XSS remains among the top 10 security vulnerabilities. Researchers have proposed various techniques to protect systems from XSS attacks, with machine learning (ML) being one of the most widely used methods. An ML model is trained on a dataset to identify potential XSS threats, making its effectiveness highly dependent on the size and diversity of the training data. A variation of XSS is obfuscated XSS, where attackers apply obfuscation techniques to alter the code's structure, making it challenging for security systems to detect its malicious intent. Our study's random forest model trained on traditional (non- obfuscated) XSS data achieved 99.8% accuracy. However, when tested against obfuscated XSS samples, accuracy dropped to 81.9%, underscoring the importance of training ML models with obfuscated data to improve their effectiveness in detecting XSS attacks. A significant challenge is to generate highly complex obfuscated code despite the availability of several public tools. These tools can only produce obfuscation up to certain levels of complexity. In our proposed system, we take a unique approach by fine-tuning a Large Language Model (LLM) to automatically generate various complex

obfuscated XSS codes. Our toolchain takes original XSS samples and applies multiple obfuscation techniques to produce diverse and challenging training data, which is then used to train and evaluate an ML model. Our approach achieved a 99.5% accuracy rate with the obfuscated dataset. We also found that the obfuscated samples generated by the LLM were 28.1% more complex than those created by other tools, significantly improving the model's ability to handle advanced XSS attacks and making it more effective for real-world application security.

Abstract Name: Increasing the Independence of the Aging Population: Home Design for People With Diabetic Retinopathy

Housing today is not designed to accommodate people with visual impairments, which would allow them to live independently. With an increasing percentage of the population aging, there is a greater number of people with visual impairments. The purpose of this study focuses on creating a house that enables people with the visual impairment of diabetic retinopathy to live with little to no aid. Reviewing literature and conducting interviews related to diabetic retinopathy shows specific ways that it can affect vision and how best to address the loss of vision. Diabetic retinopathy affects vision by causing dark spots in vision, floaters, and difficulty seeing at night. The design takes this knowledge and implements several design features to accommodate the needs of someone with diabetic retinopathy. One design feature is textural contrast from coarse textures in public spaces to smooth textures in private areas as a wayfinding cue. Another design feature is the use of contrasting colors of light orange and light blue walls and dark bronze colored trim to heighten visibility of objects and increase accessibility. Contrasting colors are also used as a way to distinguish the lighter colored floors and walls from the furniture and fixtures in the space. This allows people with visual impairments to easily navigate through spaces and identify obstacles. Lastly, lighting layers of ambient light, decorative light, and task light have been used to accommodate varying needs of people with visual impairments. This new design for housing will empower residents with visual impairments to live a self-sufficient life and give them a greater quality of life.

Abstract Name: Optogenetic Manipulation of Pain-related Neural Circuits to Alleviate Pain from Trigeminal Neuralgia

Trigeminal neuralgia (TN) is characterized by its rapid, intense episodes of facial pain resulting in poor quality of life for patients who wish to live a normal life. The pathophysiology and etiology regarding the mechanisms of TN are not fully understood, resulting in seemingly inadequate treatments. Currently, pharmacological treatments include a variety of anticonvulsants, antidepressants, and muscle relaxers, however drug-resistance and intolerance to side effects often require alternative treatments. Surgical

interventions can provide relief despite limitations and reports of pain recurrence. Exploration of orofacial pain pathways is still currently expanding, including the functions of sensory and emotional processing complexes in chronic neuropathic pain. Combining genetic and optical engineering, optogenetics offers new insight into trigeminal neuropathic pathways, as well as likely becoming a target for developing therapeutics in TN remedies. Genetically modified neurons expressing light-sensitive proteins, opsins, can control and modulate neurobiological functions through light stimulation. In preclinical models and studies, optogenetic modulation of neuronal circuits have shown promising results. Selective activation or inhibition of circuits within four structures—the trigeminal ganglion, anterior cingulate cortex, nucleus accumbens, and trigeminal nucleus caudalis—exhibited reduced pain perception and responses. Due to the extreme spatiotemporal precision and efficiency, optogenetics has an optimistic role over other alternative treatments. This review aims to discuss current treatments and their respective limitations, as well as sensory/affective complexes and their relation to neuropathic pain modulation, ultimately concluding with a proposal on new directions for refining optogenetic treatments. This paper comprises a literature search review. Comprehensive research was conducted using multiple academic databases such as Pubmed, Nature, Springer, and other related articles that focused on optogenetics in pain management. This review finds that optogenetics maintains its role as a powerful tool in neuroscience research, and, over time, may emerge as an innovative approach for management of TN pain.

Abstract Name: A Standardized Approach for Evaluating Electromyographic Multi-gesture Prosthesis Control

Upper limb prostheses must meet functional demands of daily life [1]. Electromyographic (EMG) prostheses have gained popularity for having increased capabilities and fewer reported cases of device abandonment [2]. Lack of functionality is cited as a factor of upper limb prosthesis rejection rates [3]; thus, there is a need to assess and expand physical capabilities with EMG prostheses [4, 5]. Despite growing availability of myoelectric devices [6], there is little data providing insight into how many gestures can be feasibly handled by novice users compared to experienced users. With more gestures to perform, there may be a tradeoff of training time and cognitive workload [2, 7] required to differentiate various controls [8, 9]. This study seeks to explore performance and perceptions with a maximum of 5 distinct surface EMG gestures in one session. A training and evaluation instrument was developed based on our pre-existing calibration app technology to evaluate multi-gesture performance [10]. First-time EMG users will participate, and cohorts differ in the number of distinct zones of control. Providing three rounds of fifteen randomized cues assessed performance in accuracy among four cohorts. Results will cultivate a better understanding of how the general population first interacts with this multi-gesture training and progression of distinct muscle contraction intensities. Continued work will consider cognitive workload and performance benchmarks to suggest appropriate progressions of gesture capabilities, including comparisons between new and experienced users. Currently, serious gaming is being utilized in ongoing clinical trials to prepare individuals for using EMG upper limb prostheses. Video games with the primary intention of training have already shown promise in improving usability and performance outcomes [4]. Insights from this study will help researchers standardize initial

capabilities and progression among future device users. Additionally, serious game developers can use these results to improve the patient experience.

Abstract Name: Effects of modafinil, a central nervous system stimulant, on sustained attention after controlled cortical impact injury in males and females

Traumatic brain injury (TBI) stands as a significant contributor to global mortality and morbidity. The ensuing disabilities often encompass long-term impairments in memory, attention, and overall cognitive function. Pharmacotherapeutic interventions involving stimulants following experimental TBI have shown promise in enhancing cortical function, thereby mitigating several cognitive deficits commonly observed. We predicted that modafinil (Provigil®), a non-amphetamine central nervous system (CNS) stimulant thought to act in a concerted fashion on multiple catecholamines in the brain (dopamine, norepinephrine), as well as glutamate, GABA, and histamine, to enhance arousal and focus, will improve sustained attention post-TBI. Adult male and female Sprague Dawley rats were trained in the 3-choice serial reaction time task (3-CSRT) before receiving either a controlled cortical impact (CCI) of moderate severity to the right hemisphere or a sham injury. Rats were then randomly assigned to either receive modafinil (10 mg/kg) or vehicle (saline, 1 ml/kg) being administered once daily throughout behavioral tasks beginning 14 days post-injury. 3-CSRT retrials were conducted post-injury days 14-24 to assess sustained attention via percent accuracy and distractibility via percent omissions. Ongoing histological analyses include assessments of cortical lesion volumes and hippocampal cell survival. TBI induction in both male and female rats resulted in significant and lasting deficits in both sustained attention and distractibility on the 3-CSRT task. Chronic modafinil administration concurrent with post-surgery behavioral testing produced promising results by attenuating TBI-related deficits in percent accuracy, as well as percent omissions in males, however, not in females, suggesting prompt intervention post-TBI may be therefore warranted. Our findings support the benefits of modafinil on sustained attention post-TBI and can be further expanded upon in future studies with adjustments in treatment timelines and paradigms that may allow for observation of higher efficacy in reinstating complex cortical function.

Abstract Name: Understanding Rehabilitation Therapists' Perspectives on AI/ML in Post-Stroke Assessment and Intervention.

The use of artificial intelligence (AI) and machine learning (ML) in healthcare is rapidly evolving. Implementation of research findings into practice is an ongoing process that takes time and collaboration with key stakeholders. The purpose of this research project was to gain an understanding of rehabilitation therapists' perspectives on AI/ML in post-stroke assessment and intervention. The study used a mixed method design with surveys and focus groups. To be included, participants within the last year had to have a caseload of at least 30% of persons post-stroke, be an occupational or physical therapy practitioner in the United States (US) or Asia, and speak English. Participants (n=33) in this study were provided consent forms to engage in the 30-minute video webinar followed by a 30-minute focus group to discuss their perceptions and practical applications of AI/ML. Participants completed a survey before and after the one-time virtual meeting. Quantitative data were analyzed using frequencies and percentages. Transcripts from the focus groups were reviewed for accuracy and de-identified before analysis. The qualitative data was coded by the research team, using an inductive approach and MAXQDA. From the analysis of the survey results, therapists reported knowledge of many types of AI/ML technologies, however, the frequency of use in stroke rehabilitation was limited. Four themes were identified from the qualitative data analysis: 1) Current practice and identified gaps, 2) Current therapist perceptions of AI, 3) Perceived future, and 4) What is necessary for implementation. During the focus groups, participants discussed the importance of considering the efficacy of use and carryover outside the clinic when developing AI/ML applications. The analysis from this study will be used to guide the creation of AI/ML technologies within stroke rehabilitation that will assist rehabilitation therapists in optimizing care.

Abstract Name: The Effects of Bilingualism on Measures of Executive Function in Young Adults

Bilingualism is strongly linked with executive function, which refers to brain processes that control goal-oriented activities such as attention, planning, and self-control. It is important to be able to accurately measure executive function as it can play a significant role in success in the classroom, social situations, and overall long-term outcomes. While the reliability and validity of measures of executive function have been carefully verified, little is known about how language impacts performance when testing bilingual individuals. This study examines if the language of executive function test administration impacts bilingual participants' performance. The study sample includes individuals between the ages of 18 and 25-years-old who self-report at least an advanced level of fluency in English and in Spanish. The expected N is 20 with an equal number of White Hispanic and White Non-Hispanic and more females than males. Each participant completes questionnaires regarding their background demographics and language history, as well as a language evaluation for English and Spanish in order to quantify their oral proficiency in each language. They

then do two executive function measures in English, and two in Spanish. Individual differences on tasks in English versus Spanish will be analyzed using a repeated within measures ANOVA with potential covariates of age, sex, fluency, and type of bilingualism. As bilingualism is not a straightforward category, their language histories will also be taken into account to see if certain types of bilingualism, such as simultaneous acquisition or immersion school learning, have a greater impact than others.

Abstract Name: Michael Angelo Musmanno: A Contextualization of Pennsylvanian Anti-Communism Within Labor and Electoral Politics

In a 1951 publication of the Pittsburgh Post Gazette, Democratic leader Hiram Andrews is quoted to have said of Judge Michael Angelo Musmanno, "he is now apparently nursing the ambition to become the Senator McCarthy of the Democratic party. He is a victim of exhibitionism in its advanced state." Despite Musmanno's deeply held anti-Communist beliefs, such a description is hardly accurate. This framing of the judge can be compared to the inaccurate portrayals of anti-Communism during the Cold War in contemporary historiography. My research intends to reverse such a narrative through a case study on Michael Musmanno. By analyzing Musmanno with this intention, a deeper social history can be found, and he can be contextualized in the war against the perceived threat of Communism within labor and electoral politics. Such examples include Musmanno's and liberals' attacks on the Progressive Party and Henry Wallace, as well as Musmanno's activism and support for labor in the war against their left flank. The research involved in this paper includes extensive use of primary sources from the Michael Musmanno Collection in Duquesne's Gumberg Library and his autobiography, as well as secondary sources, such as Cold War At Home by Philip Jenkins and John S. Haller Jr.'s biography Michael Musmanno. The research and sources in this paper are divided between examining Musmanno's actions and examining those of his peers to contextualize him. What is concluded from this research is that Musmanno, a New Deal Democrat and supporter of labor, was on par with his peers' anti-communist beliefs and actions, despite his eccentricities. The context in which this conclusion will be discussed is a conversation about contemporary Cold War historiography along with the use of researching one man as a means to discover a social history.

Abstract Name: Liver metastases accelerate cachexia in models of lung and pancreatic cancer

Background: Advanced cancer patients frequently develop cachexia, characterized by musculoskeletal wasting. Liver metastasis(LM) is a poor prognosis in patients with lung and pancreatic cancer. LMs exacerbate cachexia in colorectal cancer, however, whether LMs heighten musculoskeletal wasting in lung

and pancreatic cancer is unknown. We aimed to characterize the impact of LMs on musculoskeletal health, using mouse models of lung and pancreatic cachexia. **Methods:** C57BL/6J male mice were randomly grouped into the lung or pancreatic cancer study. In study 1, mice underwent intrasplenic (IS) and subcutaneous (SC) injections with saline or LLC cells in one of the following experimental conditions: Sham (IS: saline; SC: saline); low-dose SC (IS: saline; SC: 1.25×10^5 cells); high-dose SC (IS: saline; SC: 1.0×10^6 cells); LM (IS: 1.25×10^5 cells; SC: saline). In study 2, mice underwent IS and orthotopic (OT) injections with saline or T4-KPC cells in one of the following experimental conditions: Sham (IS: saline; OT: saline); OT (IS: saline; OT: 1.0×10^4 cells); LM (IS: 1.0×10^4 ; OT: saline); LM/OT (IS: 0.5×10^4 cells; OT: 0.5×10^4 cells). Body weights and in vivo plantarflexion torque were assessed. Tissues were collected for further analyses. **Results:** Lung LMs had reduced fat ($p < 0.01$), muscle mass (gastrocnemius: $p < 0.01$; quadriceps: $p < 0.01$; tibialis anterior: $p < 0.001$), and muscle torque ($p < 0.05$) compared to all groups. Compared to sham, ultimate force of femur bones was only reduced in mice with LM ($p < 0.001$), suggesting accelerated cachexia. Similar effects were found in animals with pancreatic LMs. The pancreatic LMs displayed reductions in gastrocnemius ($p < 0.01$) and tibialis anterior ($p < 0.01$), and plantarflexion torque ($p < 0.01$). Molecular characterization reinforced the wasting phenotype, evidenced by elevated atrophy signaling in animals bearing lung LMs. **Conclusions:** Like our prior work in colorectal cancer, these findings suggest that LMs also worsen cachexia in models of lung and pancreatic cancer. Investigating how LMs worsen cachexia is crucial to preserving musculoskeletal health.

Abstract Name: Communication Dynamics in Neurotype Matched and Mismatched Interactions Among Autistic Adults

Communication challenges are central to autism spectrum disorder (ASD), affecting both expressive and receptive language abilities and often leading to social isolation. These difficulties stem from differences in communication styles between autistic and neurotypical individuals. While autistic individuals may communicate effectively with others of the same neurotype, they often struggle in neurotype-mismatched interactions. Emotional states further impact communication abilities: negative emotions exacerbate difficulties, and positive emotions may cause overstimulation. This study examines communication dynamics in neurotype-matched and mismatched scenarios, focusing on emotional and stress implications and the role of rapport in autistic individuals' emotional well-being. We hypothesize that autistic individuals face greater communication challenges and stress in neurotype-mismatched interactions, with negative emotions more frequently affecting communication than positive ones. An online survey with 40 questions targeted autistic individuals aged 18–35. Using a five-point Likert scale and qualitative items, the survey evaluated emotional, relational, and communication experiences in cross-neurotype contexts. Statistical analyses, including descriptive statistics and Kolmogorov-Smirnov tests, were conducted using Excel and PRISM software. Over six weeks, 69 participants responded: 72% female, 25% male, and 3% unspecified, with an average age of 26. Ethnic diversity was noted, and 86% had annual incomes below \$70,000. While 69% reported adequate speech comprehension, 52% faced speech generation difficulties even under optimal conditions. Emotions influenced communication for 86%; 50% cited negative emotions as worsening communication, while 14% noted positive emotions as a factor. Statistical analysis showed no significant difference in emotional impact between neurotypes ($p = 0.7426$), though 36% reported feeling more emotionally affected when interacting with neurotypicals. This study highlights critical communication challenges for autistic individuals in neurotype-mismatched contexts. Speech generation struggles, frequent communication adjustments, and emotional influences—particularly negative emotions—exacerbate cognitive load and stress. In the future, we

will conduct qualitative analyses to gain deeper insights into the emotional implications of cross-neurotype communication.

Abstract Name: Does Distance Between Safari Jeeps And Elephants (*Loxodonta africana*) Influence Elephant Agonistic Or Aggressive Behavioral Rates?

The African savannah elephant (*Loxodonta africana*) is found in southern and eastern Africa. In previous years, elephant populations have faced a significant level of threats, primarily due to poaching and anthropomorphic habitat loss and habitat conversion. Tanzania is a tourist hotspot for safari expeditions, and jeep traffic contributes to potential human-elephant interactions which could have a negative impact on elephant behavior. We wanted to know if distance between safari jeeps and elephants would result in increased rates of agonistic (aggressive) or avoidance behaviors. We hypothesized that there is a relationship between distance between jeeps and elephants. Based on this hypothesis, we predicted that there would be higher rates of agonistic or avoidance behaviors when elephants are closer to jeeps. We conducted an observational study in Ngorongoro Crater and Serengeti National Park, Tanzania during May-June 2024. We categorized distances as <50m, 50-100m, 101-150m, 151-200m and 200m+ (distances determined by rangefinders). Across the two areas, 147 elephants in 17 herds were observed. We recorded 148 avoidance behaviors and 128 aggressive behaviors. There was not a significant difference in distance relative to behaviors (aggressive; $t=1.801$, $df=8$, $p=0.109$ and avoidance; $t=1.298$, $df=8$, $p=0.230$). However, in cases within 50 meters, 19.51% of elephants displayed aggression and 61.90% elephants displayed avoidance (these behaviors were almost non-existent at further distances). We think that the lack of statistical significance in our results is likely due to the small sample size of encounters that were within 50 meters or less. This data can be used as a starting point for future studies on jeep/elephant interactions during safaris.

Abstract Name: Kinesics Training Mandate: The Importance for Child Protective Case Workers

Having kinesics training as a tool to utilize, may provide case workers with valuable knowledge they can use to communicate with children. Kinesics is the study of the way in which certain body movements and gestures serve as a form of nonverbal communication. For example, if someone is scared, their body movements can be tense posture, crossed arms or leaning back slowly. Children tend to express emotions nonverbally more often and earlier than they do verbally when disclosing abuse. When children expressed more nonverbal emotions, they were more responsive during an interview and more informative about the

abuse. Child welfare workers spend the majority of their time visiting the homes of families they serve in order to assess the service needs of children and families and to monitor the well-being and safety of the children in the family. They must do their job for the safety of the children while putting their own lives in danger every day. Case workers having on-the-job or educational kinesics training may help protect themselves and the youth they work with. Reports show that approximately 70 percent of child welfare workers in the United States have been victims of violence or threat of violence in the workplace. This project uses government sites for ninety percent of the research because I wanted the information to be factual. Findings from the research underline the value and importance of training for nonverbal emotional communication.

Abstract Name: Improving Human-Exoskeleton Coordination through Modification of the Torque's Rise and Fall Time Control Parameters in Powered Ankle Exoskeleton

Exoskeletons have become increasingly popular due to their potential to enhance or assist human capabilities across various industries, such as manufacturing and healthcare. Lower-extremity powered exoskeletons are driven by controllers that store commands to assist the user. However, they still have their own unique set of complexities and unknowns. It needs to be determined how changes in exoskeleton control parameters can affect human-exoskeleton coordination. Changes in exoskeleton parameters, such as ankle timing and quasi-stiffness, can influence gait characteristics and muscle activation, affecting human performance. This research aims to develop a new exoskeleton controller for the Dephy ExoBoot to modify the torque profile's rise and fall time (exoskeleton parameters) and evaluate people's sensitivity to the changes and associated changes in gait characteristics. The Dephy ExoBoot provides torque/assistance at the push-off during the stance phase of the gait cycle. To provide the assistance, the actuator produces a torque about the ankle joint by spooling an inelastic belt that is rigidly attached to the exoskeleton's lever arm. The results from this pilot study will provide a preliminary understanding of human perception towards changes in exoskeleton control parameters, which offers insight into individual preferences and differences in exoskeleton usage and informs exoskeleton precision requirements to maximize human-system interaction, improving human performance.

Abstract Name: The Effects of Nutrient Availability on Trophic Modes in Prasinophyte Mixoplankton

Mixoplankton, a type of marine prasinophyte capable of modulating between phototrophy and phagotrophy, exist in abundance across the world. These microbial eukaryotes have the ability to switch between trophic modes based on need, allowing them to contribute to marine oxygen production and the carbon cycle. The exact parameters that cause these changes to occur are still unknown. We investigated different treatments

that may promote these changes in the prasinophycean green algae *Cymbomonas tetramitiformis*, namely f/2 (default high nutrient media), f/20, f/2 with low nitrate, and f/2 with low phosphate. We hypothesized that lowering specific essential nutrient concentrations, nitrate and phosphate, available to *C. tetramitiformis* would cause it to switch to phagotrophy to bypass the stress placed on it by environmental nutrient levels. To combat this, we expect *C. tetramitiformis* will obtain the required nutrients by ingesting prey. So far, we have attempted RNA extraction to test for gene upregulation in genes related to phagotrophy and are now using fluorescently labeled bacteria to test for phagotrophy. We hypothesize that because of our low nutrient treatments, we will see our organisms turn to phagotrophy.

Abstract Name: Caregiver Health: Improving the Health of Informal Caregivers Through an At-Home Exercise App

The number of informal caregivers is rapidly increasing due to the increasing life expectancy of older individuals. This leaves a population of individuals that have little time to care for themselves, and they often experience health issues, including heart disease, obesity, and diabetes. The purpose of this study is to determine how an at-home modular workout app will benefit the health of informal caregivers by allowing them to workout and maintain their health while having the flexibility to stay home and care for their loved ones. The main research question is as follows: how will an at-home modular workout app impact the physical health of informal caregivers? This quantitative study will gather information including changes in blood pressure, heart rate, weight, as well as other information using a pre-test and post-test style for data collection. The population of this study included informal caregivers from rural Kentucky, and these caregivers are chosen using convenience sampling. Analysis of this data is TBD.

Abstract Name: Design and Construction of an Actively Dampened Fabry Perot Optical Cavity with High Stability

Quantum emitters are essential for generating quantum states of light, enabling applications in quantum communication and sensing. When working with quantum emitters, it is necessary to place the emitter inside an optical cavity to enhance the collection of emitted photons. The most effective cavities will exhibit high stability and the capacity for sustained locking. Among many different types of cavities, Fabry-Pérot cavities are particularly well suited for this because their output is well-matched to optical fibers, and they are highly tunable. Unfortunately, such cavities are highly susceptible to mechanical vibrations. These vibrations induce small perturbations in the cavity length, which limits cavity performance and thus photon collection. One way to overcome these mechanical disturbances is to include a piezoelectric actuator within the cavity. The

actuator can then be controlled through an active feedback loop to stabilize the cavity. Another approach is to dampen the system mechanically with an external actuator. The aim of this project is to measure the mechanical vibrations of four approximately one-meter-long rods coupled in a square pattern, compare these measurements with frequency simulations performed in COMSOL, and then dampen the system mechanically to achieve high cavity stability. Measurements will first be taken using a Fabry-Pérot cavity with a piezoelectric actuator, and the results will be used to design an actuator that acts directly on the mechanical system rather than the cavity itself. The ultimate goal is to design and build an actively dampened Fabry-Pérot cavity with high stability.

Abstract Name: A Review of the Current State of the Evidence on Food, Nutrition, Literacy, Health, and Education: Implications for Nursing

Purpose: To examine the current evidence on the existing relationships between food, nutrition, literacy, health, and education. The primary aim of this review is to identify common themes, describe gaps in literature, and explore nurses' role in providing education to promote health and wellness among diverse populations by improving food and nutrition literacy. Background: Over the past decade, food and nutrition literacy research has grown underscoring the recognition that food and nutrition literacy can empower individuals to make food choices that can promote their health and well-being. The ability to understand, manage, and adopt a healthier eating lifestyle has the potential to improve long-term outcomes related to chronic diseases such as obesity, diabetes, and heart disease. Nursing is uniquely positioned to effectively enhance food and nutrition literacy across individuals with diverse health conditions. An initial search conducted using the Library Search Database (EBSCO Discovery Service) at the University of Louisiana at Lafayette Library combined the keywords of (food literacy OR food competency OR nutrition literacy OR nutrition) AND (health professional OR nurses OR doctors OR dietitians) AND chronic illness yielded 325 manuscripts. The research team's review of titles and abstracts found many irrelevant articles; therefore, four individual searches using the same database were conducted with keywords in various combinations with the Boolean operator "AND". The search yielded between 21-27 results per search. The results from the searches were combined and duplicates were removed with a final yield of 60 manuscripts. At least two team members review each manuscript in the analysis phase. Results: Analysis continues in progress. It is expected that separate and intersecting concepts/themes will be identified that will provide a baseline foundation for understanding the gaps and areas in need of further exploration. Key recommendations for nursing practice, education, and research will be formulated based on findings.

Abstract Name: Abortion Ballot Outcomes in Florida and Missouri Predict Changes in Belonging and Inter-State Migration Intentions

Dobbs v. Jackson Women's Health Organization overturned federal abortion protections, shifting regulatory power to state legislatures. This ruling created regional disparities in abortion access, making state residence consequential for healthcare and moral alignment. The ideological migration hypothesis proposes that people are motivated to relocate from communities that conflict with their political values to ones that align with their values in order to satisfy the fundamental need to belong. Although existing research suggests that political sorting in the United States typically occurs locally—between urban and rural areas or neighborhoods within states—state laws may also prompt migration across state lines. The present pre-registered study (N = 1,230) tests whether changes in state abortion laws predict changes in Americans' sense of belonging and desire for inter-state migration. Specifically, pro-life and pro-choice advocates living in Florida and Missouri—two states with restrictive abortion laws voting on ballot measures to expand abortion access—were surveyed before and after the 2024 U.S. presidential election. Whereas Missouri's ballot measure passed, Florida's measure failed. Participants were informed about their state's current abortion law pre-election and outcome of their state's ballot measure post-election (85% response rate). In both survey waves, participants indicated their sense of belonging living in their state and desire to migrate to another state. Our results support the ideological migration hypothesis. Among Missouri residents, pro-life advocates reported decreased belonging and increased migration intentions following the ballot measure passing, and pro-choice advocates reported the opposite. Conversely, pro-choice advocates in Florida reported decreased belonging and increased migration intentions following the ballot measure failing. These findings have implications for understanding how the Dobbs v. Jackson decision may influence domestic migration in the United States over the coming decades and its consequences for amplifying political division and animosity.

Abstract Name: Palliative Care Needs of Older Patients with Stroke: A Scoping Review

Background: Stroke is a leading cause of mortality and serious long-term impairment. Palliative care focuses on addressing the holistic needs of patients with serious illness to improve their quality of life. Aim: This scoping review aimed to explore the existing body of knowledge on the palliative care needs of older patients with stroke and sought to fill the gap in literature by synthesizing empirical research findings. Design: This scoping review follows the methodological framework of Arksey and O'Malley (2005) comprising of five stages: [1] Formulating the review question; [2] Identifying relevant studies; [3] Screening and selecting the studies; [4] Charting the data; and [5] Collating, summarizing, and reporting the results. Methods: Three online databases (PubMed, Embase, and CINAHL) were searched for studies published between 2014 and 2024. A combination of keywords with Boolean operators and database subject terms were used including: "palliative care needs", "older adults" and "stroke patients". Retrieved articles were imported to Endnote and Covidence review management software for screening and selection based on inclusion/exclusion criteria. Reporting followed the Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) guidelines. Results: Empirical evidence drawn from 20 included studies suggest that older patients who have experienced stroke need comprehensive palliative care to improve their quality of life. Specifically, the results of this review identified five overarching themes: physical mobility needs, psychosocial and emotional

support, informed decision-making, symptom management, and comfort-based care. Conclusion: Palliative care is an essential component of integrated and patient-centered stroke service to improve the quality of life of older individuals. The information generated from this review aids in understanding the specific palliative care needs of older adults suffering from the debilitating effects of stroke. Effective palliative care delivery for older patients with stroke requires collaboration between patients, families, and healthcare professionals.

Abstract Name: Birds of the Burbs: Documenting Bird Communities in Suburban Landscapes of the D.C.-Baltimore Corridor

More than one in four birds have disappeared from North American since 1970. As natural wildlife habitat is lost to development, it is increasingly important to understand how urban/suburban environments can support declining bird populations. It is also critical to understand if people have equal access to urban and suburban birds and to the natural areas that support more bird species. Here, we used the Merlin Bird ID app to document bird species richness throughout Prince George's County, MD and the Washington, D.C.-Baltimore corridor, more generally. We generated >1,000 observations of 89 bird species from 62 sites based on bird vocalizations in the morning and evening (near dawn and dusk chorus), and we also characterized the human populations at our study sites using income, race, and ethnicity data from the 2020 census. We found that race and ethnicity were largely unrelated to bird community metrics, such as species richness and the occurrence of non-native species. However, there were more bird species (higher species richness) and a smaller percentage of declining bird species in communities where more people selected the "some other race" census category. The strongest trends in our dataset derived from income: neighborhoods with higher average income supported more bird species overall but fewer species with decreasing population trends. Finally, we compared the bird communities of three focal sites: Bowie State University (BSU) campus, the Governor Bridge Natural Area, and Crofton Park. We documented the most bird species (43) and the highest proportion of declining bird species at BSU, likely because of its proximity to large tracts of protected habitat. Overall, our data highlight inequalities in human exposure to local biodiversity. However, our findings also emphasize the important role that suburban landscapes can play in supporting declining bird species, especially when they include large protected natural areas.

Abstract Name: EEG data on Heavy Tiktok Engagement Influencing Attention Deficit

TikTok is a social media platform consisting of short user-generated videos. The popularity and addictiveness of this app calls for understanding whether and how TikTok usage affects the academic experience of our youth. The present study seeks to confirm that prolonged TikTok use is associated with self-reported inattentive experience. Additionally, the study collected both behavioral and electroencephalogram (EEG) data during a selective attention task, to evaluate if the self-reported attention deficit experience can be confirmed by their behavioral and neurological experience. By looking at these factors, this study explores the underlying relationship between observed academic struggles and active TikTok use. Student participants signed up from the CCNY SONA pool. Four surveys, including the Depression Anxiety and Stress Scale, the adult ADHD self-report scale, a TikTok modified version of the Social Media Use Questionnaire, and demographics survey were used. Participants were divided into either the low TikTok or high TikTok group based on their TikTok usage. Participants then performed a modified Flanker Task while an electroencephalogram (EEG) with 160 electrodes evenly distributed recorded. Our study plans to run a correlation analysis between the amount of TikTok use and self-reported ADHD experience. We also plan to analyze the EEG data collected, and compare event-related potentials (ERPs) among participants who were high and low TikTok users. Specific ERP P1 and N170 in response to the target will be used to evaluate if more brain activities would be seen among the high TikTok user group during the attention task. Both ERPs have been commonly used to indicate neural reactivity in the process of attention processing. By looking at these two ERPs, our study hopes to explore if there's potential evidence that the brain may be working more than usual to achieve a similar attention function due to cognitive impairment from prolonged TikTok use.

Abstract Name: Advanced Smart Glasses Project

This project aims to develop an assistive system using smart glasses to enhance the independence and navigation of visually impaired users. The system integrates object detection, voice generation, and wireless communication modules to provide real-time feedback and interaction with the environment. The object detection module utilizes the Jetson Nano and NVIDIA's Jetson Inference library to identify and classify objects within the user's surroundings, such as furniture and household items. This system processes live video feeds from a connected camera, providing audio guidance or haptic feedback to inform the user of detected objects. To optimize performance, the model was retrained to focus on common household items, enhancing precision while reducing computational load. The voice generation module provides auditory feedback by converting text into speech, essential for users with visual impairments or those seeking a hands-free experience. This system uses the Jetson Nano and a text-to-speech engine to deliver clear auditory responses, while addressing challenges in speech quality and power consumption. Pre-generated audio files for frequent commands help mitigate processing demands. For wireless communication, the system uses an IoT camera for live video streaming and Arduino Pico boards for controlling external devices like lights or thermostats. Wireless protocols such as MQTT and WebSocket ensure efficient transmission of data, with security measures like WPA2 encryption to protect sensitive information. The development process has involved significant optimization for low-power, high-efficiency operation, while maintaining robust functionality. Future work will focus on further enhancing detection accuracy, refining voice quality,

improving power usage, and expanding device compatibility. This integrated system demonstrates the potential to assist visually impaired individuals in navigating complex environments.

Abstract Name: Weather Forecast, Forecast Revisions and Natural Gas Price Dynamics

There is no doubt that weather drives natural gas price through consumption demand from mainly the residential, commercial, and power sectors as well as through supply side interruptions. Mu (2007) documented the impact of the weather on the conditional mean and conditional volatility of the natural gas price. Linn and Zhu (2006) also revealed that models with fundamental variables such as weather performed better in terms of forecasting natural gas price. It is customary to see news reports of the impact of weather forecasts on gas prices however, there is no study of how the weather forecasts affect gas price and its volatility. Understanding how natural gas price responds to weather forecast is an important step in understanding the price dynamics. It helps market participants to design a better program for trading and risk management. It also helps to settle the issue of whether and/or to what degree gas prices are affected by market fundamentals or non-market fundamental factors. Our project employs a forecasted weather dataset (daily price forecast for a total of two weeks between April 2021 and August 2024) obtained from Pratt's to gauge the degree of natural gas price response to changes in weather forecast. According to economic theory, the expectation of demand and supply ultimately determines pricing. Our study has several steps. In the first step, we review the accuracy of the weather forecasts. In the second step, we use Pratt's weather forecast as a representative market weather forecast to generate weather forecast shocks and examine how the gas price level has responded to the weather forecast revisions. Third, we study how the weather forecast and forecast revisions have contributed to market price volatility. Our research is expected to clarify a crucial yet missing piece of how weather forecast affects the energy price dynamics.

Abstract Name: Parental Leave Policies : Battling Inequities and Realizing Transformational Health (BIRTH)

Workplace dynamics in the 21st century emphasize the need for equitable parental leave However, the United

States lacks a guaranteed parental leave policy, raising concerns about the adequacy of available leave. This study examines different company sizes and the impact of parental leave policies on employee retention and gender equity in workplaces. In 2023, an initial benchmark survey was conducted by PBGH and Healthy Start. In 2024, a follow-up BIRTH survey was sent to 27 employers, covering 360,000 lives, primarily in the Pittsburgh region but with a broader reach. The survey assessed parental leave policies, childcare support, and health equity initiatives, with data analyzed by company size. Descriptive statistics were used to analyze the data. A recommendation guideline: consisting of workplace policy transformation, strategic action brief, and identification of social determinants of health barriers was achieved. Preliminary results from the second survey indicate that most employers offer parental leave, but often only 2-3 paid weeks. Eligibility for maternity leave is determined by 70% of employers and 78% for paternity leave contingent on employment duration. At employers' discretion, the leave can be partial or unpaid. Over the next two years, 30% of companies do not plan to adjust their leave policies. Parental leave policies are essential for supporting new parents during this transformational life event. Existing federal policies like the Family and Medical Leave Act (FMLA) and the Federal Employee Paid Leave Act (FEPLA) provide a foundation but fail to comprehensively address the needs of marginalized, low-income families. Equitable policies can enhance child development, bonding, and overall well-being. The BIRTH project offers employers insights and benchmarks to improve their benefits. Companies with comprehensive parental leave and childcare support report higher employee retention and satisfaction with smaller companies having more family-friendly policies. Around 70% of companies responded to the initial survey.

Abstract Name: Mobilizing Prevention and Early Detection of Alzheimer's Disease and Related Dementias (ADRD) in Allegheny County through the Area Agency on Aging (AAA)

In collaboration with the Department of Human Services (DHS): the Area Agency on Aging (AAA) using the Healthy Brain Initiative (HBI), this project will involve the development of a comprehensive literature review examining the impacts of Alzheimer's disease and related dementias (ADRD) on patients and their caregivers. The project aims to help the AAA focus on strategies to delay the onset of ADRD in Allegheny County by enhancing early detection and prevention programs through the Building Our Largest Dementia Infrastructure (Bold) Grant. Additionally, the project will explore how public health initiatives can increase access to care, educate the public, and train healthcare providers to better support patients and caregivers. Secondary research will serve as a basis for the analysis of the Behavioral Surveillance Survey System (BRFSS) data collected by the Centers for Disease Control and Prevention (CDC) and ACHD. Literature reviews will identify public health strategies and interventions for ADRD that AAA can implement using BRFSS data. An interview of several departments in the AAA was conducted regarding the preventable and diagnostic care that the AAA provides for patients dealing with dementia and memory problems. The data achieved will be qualitatively analyzed to provide feedback and possible program implementations about ADRD services offered in correspondence with the secondary research. This project aims to provide evidence-based strategies to improve early detection and diagnosis, enhance caregiving support, and raise awareness within the county. These efforts will promote earlier interventions and integrate them into community health practices. In the future, AAA will aid the HBI and use the American Heart Association's cardiovascular disease guidelines as a model to establish ADRD-specific public health interventions. This project will utilize

levels of prevention to develop a baseline need for the ADRD community, aiming to improve overall health outcomes and support for patients and caregivers.

Abstract Name: Identifying Vitamin B-12 Transport Genes from Suspected TonB-dependent Receptors

Periodontal disease, particularly chronic periodontitis, is a major global health challenge, leading to severe bone loss and possibly causing other systemic diseases. *Porphyromonas gingivalis*, a pathogen found to be highly associated with chronic periodontitis due to its ability to cause dysbiosis of the oral microbiome, relies on cobalamin, also referred to as Vitamin B12, as an important cofactor for its growth. However, due to an incomplete biosynthetic pathway for cobalamin, the bacteria primarily rely on TonB-dependent transport. This study explores the role of suspected TonB-dependent receptors in mediating cobalamin transport in *P. gingivalis*. Being able to identify nutrient acquisition mechanisms in *P. gingivalis* could provide possible methods to interfere with the uptake of these nutrients and lead to the reduction of periodontal disease. After growing the bacteria in Casein Minimal Media deficient in cobalamin and anaerobic conditions, quantitative RT-PCR was done on the genes encoding TonB-dependent transporters to evaluate differential expression of these genes in the presence and absence of cobalamin. Genes PG0185, PG1414, and PG1715 were identified as potential candidates based on their significant upregulation in the presence of cobalamin. Genes PG1414 and PG1715 were subsequently deleted in the *P. gingivalis* strain W83. While the mutants were successfully created, further investigation into their role is required to confirm their involvement in cobalamin uptake.

Abstract Name: Singular Matrices with Random Natural Number Entries

Singular matrices are a cornerstone of Linear Algebra with significant theoretical and practical implications. Motivated by a classroom discussion, I investigated the probability of a randomly generated 2×2 matrix being singular when its entries are restricted to natural numbers less than or equal to a given value n . By approaching the problem geometrically, I derived a combinatorial formula to determine this probability. To validate the formula, I wrote a program that confirmed my formula for the first 20 natural numbers. Restricting the possible entries of the matrix to natural numbers produced a finite number of matrices from which the proportion of the number of singular matrices could be determined.

Abstract Name: Mental Health of Commuter and On-Campus Students

Commuters and resident students may be seen as receiving the same education, but these two populations experience unique and significant differences. One study by Jamil, et al. (2022) noted that increased commute time was associated with decreased academic performance in college students. Additionally, commuting tended to reduce students' feeling of belonging to their college community, leading to overall inferior well-being (Stalmirska et al., 2022; Barnhart 2023). It is clear that symptoms related to mental health can be exacerbated by commuting; thus, we hypothesize that commuter mental health will be lower than their resident counterparts. While studies have compared the relationship between college students' living status and academic performance, well-being, weight, and drinking habits, there is a paucity of research examining whether resident or commuter status affects mental health. The purpose of this study will be to examine the difference between the mental health of students living on campus and that of commuter students. The study participants (n=200) will be drawn using simple random sampling for the residents and convenience sampling procedures for the commuters. The survey will be conducted using the Patient Health Questionnaire-9 (PHQ-9) and General Anxiety Disorder Questionnaire-7 (GAD-7) relating to mental health and socio-demographic questions. The data will be collected via Google Forms. The collected data will be entered into SPSS 29.0. Preliminary data analysis reveals that there is no significant difference between commuter and resident study participants regarding their mental health issues.

Abstract Name: Analysis of the Relationship between PARP1 and BRCA1 Suggests PARP1 Gene Has a Role in Breast Cancer

Poly [ADP-ribose] polymerase 1 (PARP1), one of the genes in the PARP family, is mainly involved in the detection and repair of DNA damage in cells, and its upregulation has been associated with tumorigenesis. PARP1 is essential to all cells in the body as it ensures that DNA is replicated correctly. The PARP1 protein addresses repair of single-stranded breaks (SSBs) in DNA by initially binding near the point of break in the DNA. While it is bound to the region of the SSB, PARP1 transfers ADP ribosyl moiety from NAD⁺ to acceptor proteins. This leads to the recruitment of DNA repair proteins to the region of DNA breaks. The PARP1 protein also aids the double-stranded break (DSB) repair of DNA by recruiting the homologous recombination (HR) pathway proteins. Due to this role of PARP1 in DNA repair, it has been associated with cancer growth. Using databases, including UniProt, Xena Browser, and CBioPortal, this article explores the relationship between PARP1 mutations and BRCA1-mutated breast cancer. BRCA1 is a tumor suppressor gene, which is involved in DNA repair through the HR pathway. Therefore, in BRCA1-mutated cells, the lack of tumor suppressor factors leads to cancer growth. However, in a cell that has both BRCA1 mutations and PARP1 inhibition, DNA damage cannot be repaired, leading to apoptosis. Hence, PARP1 inhibitors have

become essential in BRCA1-mutated breastcancers. There are several PARP1 inhibitors that are currently being used to treat breast cancer, which work using several mechanisms of action, including PARP1 trapping, which prevents the repair, transcription, and replication of DNA. This article also focuses on the clinical trials of three specific drugs, Olaparib, Iniparib, and Veliparib, which are used to treat breast cancer. However, due to the lack of understanding surrounding PARP1 inhibition mechanisms and potential drug combinations, more research needs to be done to understand potential biomarker targets and PARP1 inhibitor resistance.

Abstract Name: The Impact of Intimate Partner Violence with Firearm Presence on Low Socioeconomic, Minority Women

There is an increase of low socioeconomic, minority women as victims of intimate partner violence when a firearm is a contributing factor. Gun violence in the United States has risen within the past decade from access to firearms through legal or illegal means, and it has been used as a weapon to harm women in a heterosexual relationship where intimate partner violence (IPV) is prevalent. Individuals within an intimate partner violence relationship suffer from emotional, mental, sexual, and physical abuse leading to chronic illnesses or even death. IPV can lead to chronic diseases such as traumatic brain injury, depression, or PTSD. The harm of IPV prompted the question, "How does the availability of firearms in households correlate with the severity of domestic violence incidents, and what factors contribute to variations in this relationship across different sociocultural contexts?". Through a meta-analysis-based research process of scholarly sources, minority women with a low socioeconomic status (SES) have been the demographic that has been greatly impacted. Between 2015 and 2019, over 11,000 women were killed with a firearm. The homicide of women, femicide, or the attempt to commit femicide reached 4.5 million women within the U.S. For every 100,000 women, 6,400 Black women and 1,900 Hispanic women have been the demographic that has been impacted by firearm domestic violence, with contributing factors of racism, residential segregation, and unemployment under the social disorganization theory. Factors about culture, religion, and hegemonic masculinity contribute to why low SES women are impacted more than other demographics of women. Accessibility of firearms is higher where the perpetrator has a criminal history or a mental illness that has maladaptive behavior. Closing the "boyfriend loophole," tightening firearm accessibility, adopting new legislation, and tackling the social stigma of reaching out for resources are progress toward creating lasting resolutions for IPV victims.

Abstract Name: Complete residue systems in second-order linear recursive sequences mod a prime

This work is a study of the behavior of sequences which follow a second-order linear recurrence relation.

Such sequences $\{a_n\}$ are given by initial conditions $a_0 = 0$, $a_1 = 1$, and the recurrence relation $a_n = c_1 a_{n-1} + c_2 a_{n-2}$. Given a prime p , we investigate whether $\{a_n\}$ contains a complete residue system mod p , that is, whether there exists a_{n_i} such that $a_{n_i} \equiv i \pmod{p}$ for all $0 \leq i \leq p-1$. Such sequences are necessarily periodic modulo p , and using number theory and finite field theory we show that the existence of a complete residue system depends only on the period length. Explicit examples will be given. Finally, we will investigate the proportion of sequences which are periodic for a fixed prime p .

Abstract Name: Potential Use of Sustainable Phase Change Materials (PCM) to regulate Asphalt binder Temperature and harvest Solar Energy

This study investigates the possibility of incorporating different sustainable Phase Change Materials (PCMs) into asphalt binders aiming at harvesting practical amount of solar energy along with regulating the asphalt pavement temperatures. This was done by examining different types of PCM-modified asphalt binders in terms of their rheological, chemical, thermal, and microstructural properties and energy storage performance. The base asphalt binder was sourced from an Egyptian refinery named Suez Oil Company and designated directly as Suez asphalt, which was then mixed with PCMs. Two different types of PCMs were used the first type was 5% beeswax and 3%, waste cooking oil (WCO) by weight of asphalt. While, the other PCM type was 5% beeswax, 3%, WCO, and 0.3% Carbon Nanotubes by weight. Scanning Electron Microscopy (SEM) was employed to provide two-dimensional imaging to observe surface microstructure and composition. Fourier Transform Infrared Spectroscopy (FTIR) and Ultraviolet-Visible Spectroscopy (UV-Vis) were used to identify composition, Light-induced aging, and degradation. Rheological analyses involved several tests, including Dynamic Shear Rheometer (DSR), Rotational Viscometer (RV), and Bending Beam Rheometer (BBR), conducted across short-term aging (RTFO) and long-term aging (PAV). Additionally, Multiple Stress Creep Recovery (MSCR) and Linear Amplitude Sweep (LAS) tests were used to assess rutting resistance under high stress and fatigue resistance, respectively. Thermal Gravimetric Analysis (TGA) was employed to study the different PCM-modified binders' thermal stability and energy harvesting possibilities in reference to their control asphalt binders. Results revealed that incorporating PCM into asphalt has increased the energy-storing capacity of the asphalt pavement while regulating its thermal performance. The rheological properties of the PCM-modified binders were different based on the type of PCM used. Although, incorporating only the beeswax and WCO resulted in a lower performance grade (PG) of 52-18 Compared to the base PG of 58-12, potential enhancement in thermal regulation and energy harvesting was recorded.

Abstract Name: Understanding Community Well-Being and Actions of Faith Communities during the COVID-19 Pandemic: Perspectives of Members of Faith Communities

Indicators of community well-being (CWB) can help a community gauge and assess its current well-being status. While previous studies have explored indicators of CWB through community samples, retirees, and policymakers, there is a paucity of research that engages directly with members of faith communities. Faith communities play a vital role in nurturing CWB, particularly during global crises. This study focused on understanding CWB from the lens of faith community members and how faith communities promoted CWB in the Twin Cities area during the COVID-19 pandemic. From March to June 2023, semi-structured interviews were conducted with 16 participants from diverse faith communities to ensure religious representation. The data were thematically analyzed, revealing key indicators of CWB: 1) connectedness and belonging, 2) social trust, 3) community participation, and 4) social equity. Participants emphasized that meaningful relationships and perceptions of support fostered a strong sense of belonging. Participants trusted that people in their communities adhered to and engaged in practices that benefited and protected everyone during the pandemic. Community participation was highlighted as critical for enhancing CWB, with respondents advocating for more opportunities to engage in social and religious activities. Social equity, underpinned by values of justice, was seen as crucial for fair treatment, equal opportunities, and access to meaningful employment. Faith communities actively promoted CWB by providing tangible and emotional support, enhancing community connectedness, and advocating for and promoting social justice. The findings of the study underline the importance of understanding local indicators of well-being to improve community resilience and viability during crises. Knowing the local community indicators of well-being is vital for sustainability and improving the community's quality of life during a pandemic. The findings highlight the need for public health authorities to collaborate with faith communities to promote CWB and recognize the unique role faith communities play in fostering CWB.

Abstract Name: Racial Disparities in Internal Migration: Examining Patterns and Inequities in the United States

Recent studies have focused almost exclusively on national immigration, but understanding internal migration within the United States is crucial for the investigation of racial disparities in migration. Researchers have shown that racial differences in migration patterns contribute to the unequal distribution of Black and White Americans across the nation's landscape, reflecting both historical and ongoing social, economic, and political forces with implications for racial inequities in various outcomes. This study examines the racial dynamics of internal migration by comparing the 2000s and 2010s patterns for non-Hispanic Blacks and non-Hispanic Whites in the United States. Using net migration datasets, the analysis focuses first on California, New York, and Texas, then extends to all other states, counties, and decades. The study explores how race, as a social construction, shapes migration motivations and outcomes beyond traditional economic models of mobility. The findings reveal that the pattern of migration for non-Hispanic Black immigrants is much stronger in comparison with that of their non-Hispanic White counterparts. This trend underscores the role of historical racial constructs in shaping migration decisions. Understanding these migration patterns is essential for addressing systemic inequities, as migration not only reflects existing disparities but also reinforces inequalities in access to resources, opportunities, and social networks.

Abstract Name: Microbiome Shifts in *Aplysina cauliformis* Due to Ocean Acidification and Ocean Warming

The ocean's water is becoming warmer and more acidic due to increased carbon dioxide in the atmosphere. This rapid increase of carbon dioxide is deposited into the ocean through the atmospheric gas exchange, creating carbonic acid and increased hydrogen ion byproducts to lower pH and raise temperature. Together, these variables disrupt the marine ecosystem by throwing homeostasis off balance and damaging coral reefs. Our study was centered on *Aplysina cauliformis*, a common Caribbean sponge situated near the equator, rendering it more vulnerable to ocean acidification and warming. We investigated whether shifts in temperature and pH will disrupt the microbiome of *A. cauliformis*, and whether it will exacerbate the disease *Aplysina* Red Band Syndrome (ARBS), a highly transmissible disease spread through physical contact. We hypothesize that these stressors will have minimal effects on the microbiome of healthy sponges, but ARBS will likely lead to more impactful shifts within the symbiotic microbial community. To achieve this, DNA was extracted from samples exposed to various stressors, including health status (healthy or diseased), temperature (29°C or 31°C), and pH (acidic or nonacidic) in a factorially designed short-term stressor experiment. We conducted Illumina amplicon sequencing on the 16S rRNA region using standard universal primers. We analyzed our data using the statistical program R to determine the relative impact of our three stressors. Our initial results indicate a high impact of ARBS on the microbiome of *A. cauliformis*, while increased temperature and lower acidity led to more subtle shifts in the microbiome. Disruptions in microbiomes can lead to changes in the physiology of the overall sponge, which may broadly affect how *A. cauliformis* survives and interacts with other organisms on coral reefs.

Abstract Name: Student, Faculty and Industry Collaboration to Co-create Microcredential on Engineering Ethics

Public safety relies on the professionalism and ethics of engineers. It is important for undergraduate engineering students to understand real-world scenarios of ethics failure. In this work, we (student, faculty, and alumnus working in industry) co-authored a micro-credential on engineering ethics. The micro-credential utilizes case studies including the Challenger explosion, Boeing-737 MAX crashes, the Volkswagen emissions scandal, intellectual property misappropriation, and the Ford-Firestone tire tread separation issues. Case studies provided an opportunity for micro-credential learners to discuss and understand the ethical challenges in each of these situations. As a student, I realized that real-world engineering incidents are often much more "gray" in contrast to classroom problems that focus on defined solutions. Further, my understanding of engineering problems was enhanced by differing perspectives from the faculty and alumnus

in the industry. The novelty of this approach rests on the curricular development team involving an atypical three-way partnership between faculty, student, and industry alumnus.

Abstract Name: Improving Operations Research Using Artificial Intelligence and Machine Learning Approaches

How can Machine Learning (ML) and Artificial Intelligence (AI) enhance the robustness and adaptability of solutions to Operations Research (OR) problems? Traditional OR methodologies, which rely on well-defined variables, constraints, and optimization techniques, often suffer in dynamic environments where parameters such as costs, supply, or demand are uncertain or random. This can lead to suboptimal or infeasible outcomes. ML and AI, when used appropriately, offer tools to address uncertainty, provide robust solutions, and enable adaptive, real-time decision-making. These techniques are powerful in situations where data are often complex or incomplete, such as optimizing resource allocation in healthcare, managing supply chain disruptions, pricing financial instruments under stochastic market conditions, and scheduling maintenance for critical infrastructure. This study investigates OR problems where classical OR techniques are compared with solutions generated by AI and ML models with applicability across diverse domains including telecommunications, healthcare, manufacturing and supply chains, financial engineering— under static and random conditions. We present the strengths and weaknesses of both classical and modern techniques and attempt to understand when and how each method can be leveraged.

Abstract Name: Legal Frameworks Under Pressure: International Venezuelan Diaspora

According to the United Nations Human Rights Office of the High Commissioner (UNHCR, 2018), over 5.9 million Venezuelan migrants have been displaced or are fleeing at an alarming rate due to “widespread human rights violations, crime, and crises” and are considered the “second largest displaced population globally” (Del Real 1). Venezuelan President Nicolás Maduro (2013-present) and his administration have enacted mass human rights violations, and “excessive force against political opponents” (Del Real 1). In addition, their public healthcare system has collapsed and failed to provide medical staff with the necessary supplies to treat patients. Moreover, current economic and sociopolitical impacts have resulted in an economic recession consisting of hyperinflation, rising food costs, and electrical shortages, and unlivable wages and access to the job market. Consequently, millions have fled in search of better living conditions and hopes for economic and political stability (Council on Foreign Relations 1). On July 28th, 2024, presidential elections were held in Venezuela. The country was hopeful that a long-awaited political leadership change would happen. However,

official results indicated that Nicolas Maduro won by a close margin of votes. The people of Venezuela started all sorts of protests, most notably banging pots and pans urging for justice to be brought (Council on Foreign Relations 1). “As of 2021, Colombia has 1.7 million Venezuelan migrants and refugees” and “600,000 Venezuelan migrants” in the United States. The implications of this mass wave of immigration are seen severely among the different implementations of immigration law, procedures, and policies within the United States and Colombia. The extent to which the current regulations in place are equipped to handle this influx directly affects the ability for Venezuelan immigrants to seek Temporary Protection Status (TPS) , other permanent legal protections, as well as the flaws and barriers that exist within each sector.

Abstract Name: Augmented Reality Guidance for Fifth Metatarsal Screw Fixation

The utility of Augmented Reality (AR) in surgical medicine is a rapidly expanding area of development, offering orthopedic surgeons a new and innovative way of planning and executing difficult procedures. A proximal 5th metatarsal fracture (Jones fracture) currently poses significant challenges for surgeons due to its narrow, curved intramedullary canal, making it difficult to achieve precise and effective screw placement. Conventional guidance methods for screw placement include x-ray or fluoroscopy, exposing patients and surgeons to potentially harmful doses of radiation. The goal of this study is to assess the accuracy of AR guided screw placement in the fifth metatarsal bone. Computed tomography (CT) images of 12 cadaveric legs were obtained and uploaded to Medivis SurgicalAR for pre-operative metatarsal screw trajectory planning. These images were registered and superimposed onto the cadaveric legs. Orthopedic surgeons utilized the AR-planned trajectory to guide the placement of a guidewire within the 5th metatarsal, subsequently using the guidewire's path to position the screw. The final screw positioning was verified using a postoperative CT scan, which was compared to the original planned trajectory to evaluate placement. AR was effectively used by three different orthopedic surgeons to guide and place 12 intramedullary screws within the 5th metatarsal. Preliminary postoperative data analysis was completed for one leg, showing that the tip of the guidewire deviated by 2 mm from the planned trajectory, with an angular deviation of 9.8°. Initial findings suggest that AR guidance serves as an effective tool in assisting fifth metatarsal screw placement. The observed angular deviation and minimal distance discrepancy between the planned and actual guidewire trajectory highlights the potential of AR technology to enhance precision in this orthopedic procedure. By providing a more intuitive method for trajectory planning and execution, AR guidance may significantly improve surgical outcomes and safety for both patients and surgeons.

Abstract Name: The Role of Significant Figures on Calorie Label Accuracy: A Study of Snacks Transparency

When it applies to nutritional labeling and customer decision-making, calorie data is crucial. However, the use of significant figures in the measurements and calculations involved has a direct impact on the accuracy of these counts. This study looks into how important numbers affect the number of calories in packaged foods, drinks, and candies. The class was divided into groups, and each team examined different packaged goods to investigate the effects of measurement accuracy and rounding procedures on calorie labeling. To promote an awareness of how important numbers affect nutritional transparency, the project intends to draw attention to distinctions between labeled and calculated values through empirical data gathering and critical analysis. The results highlight how crucial accurate labeling is in helping customers make educated food decisions.

Abstract Name: Vigilance: Does Human Activity Level Change Squirrel Vigilance Patterns in Central Minnesota?

In recent decades, urbanization has rapidly increased changes in natural habitats for many wildlife species. With urban spread, also comes higher probabilities of wildlife behavioral habituation. The National Institute of Health defines habituation as a decline in behavioral responses due to repeated exposure to a stimulus without a negative impact. We wanted to know if habituation has affected squirrel vigilant behavior on a Central Minnesota university campus. We hypothesized that there was a relationship between squirrel vigilant behavior rates (standing tall and alert, running away) relative to high and low human activity on campus. We predicted that there would be greater evidence of behavioral habituation in high human activity areas. Three species of squirrels were observed in high/low activity areas on campus and vigilant behavior was recorded when researchers approached squirrels either head-on or obliquely (after a 15-minute acclimation period). We found a significant difference in mean alert initiation distance (AID) based on approach types (head on vs. oblique) between the three species ($F = 4.025$, $p = 0.003$, $df = 91$). We also found a significant difference in mean AID between high and low activity levels ($F = 67.20$, $P < 0.001$, $df = 91$) and mean flight initiation distance (FID) between high and low activity levels ($F = 63.94$, $P < 0.001$, $df = 91$). We conclude that squirrels in high activity areas exhibit greater habituation behaviors in relation to human approaches. More

regular contact with humans appears to reduce squirrel vigilant behaviors, which could have a negative impact on avoiding predation by native raptors or canids.

Abstract Name: Adapting ProACTIVE for Spanish-speaking Latino Men: A Culturally Responsive Program on Intimate Partner Violence

Intimate Partner Violence (IPV) is a significant public health issue in the United States. It is defined as physical, emotional, psychological, verbal, and/or sexual abuse between two individuals engaged in a current or previous romantic relationship. Individuals arrested for this offense are usually court-mandated to batterer intervention programs (BIPs), which are designed to reduce IPV. Current research has found Acceptance and Commitment Therapy (ACT) to be an effective treatment for IPV among men mandated to complete a BIP. However, a focus on justice-involved men fails to recognize the institutional racism men of color face and fails to address the need for IPV prevention. ProACTIVE is a community-based relationship violence prevention program designed for men in the community seeking support in their relationships. Initial cohorts of ProACTIVE have shown preliminary success, suggesting ProACTIVE can be an effective voluntary relationship violence prevention program and emphasizing the need to intentionally adapt ProACTIVE for specific marginalized men. Currently, ProACTIVE is being adapted specifically for Spanish-speaking Latino men.

Abstract Name: Authoritarian Crime Control in El Salvador: Examining the Sustainability of Nayib Bukele's Policies in a Democratic Context

This research examines the impact of authoritarian governance on combating organized crime in Nayib Bukele's El Salvador. Autocratic practices in Latin America have often gained initial support through aggressive anti-crime measures, but their disregard for democratic norms has made them unsustainable. El Salvador has endured high levels of violence tied to organized crime since the 1990s. Transnational crime organizations flourished in the post-war environment, deepening instability. In recent years, Bukele has implemented authoritarian measures, including violations of habeas corpus, extrajudicial killings, enforced disappearances, electoral interference, the removal of constitutional court judges, and aggressive policing that violates human rights. These policies have produced immediate reductions in crime, bolstering Bukele's popularity. However, historical trends in Latin America suggest these measures are unsustainable and may worsen conditions for future generations. Using data from Freedom House, Human Rights Watch, the Organization of American States, Amnesty International, and the United Nations Office on Drugs and Crime,

this study analyzes authoritarian practices similar to Bukele's policies across thirty countries. Findings show that while such measures often yield short-term reductions in crime, they risk creating long-term societal fractures if socio-economic causes are left unaddressed. This mirrors patterns in other nations, such as Colombia's experience with Bandas Criminales (Bacrim). This study highlights the dangers of relying on authoritarian tactics for crime control. Without addressing root socio-economic issues, El Salvador risks following the trajectory of other autocratic regimes in Latin America, characterized by democratic erosion and a resurgence of worsened organized crime. It emphasizes the need for sustainable, rights-based strategies to ensure lasting public safety.

Abstract Name: Adsorption of Methylene Blue using Fish Scales and Fish Chitin

Textile dyes pose a threat to our water systems along with the ecosystems surrounding and within. Current physical and chemical methods to remove textile dyes are very expensive, demanding a more cost-effective means of removal. Biomass adsorption is a possible alternative as it is more cost effective, more sustainable, and better for the environment. This study investigated the effectiveness of salmon and Labeo rohita (rohu) scales as well as chitin produced from both fish, as fish scales are ample waste products in the fish processing industry, making them a sustainable source for chitin. Chitin is a biopolymer found abundantly in fish scales and can be used as a natural and inexpensive adsorbent for textile dyes. Chitin was created by soaking in a 1M HCl solution to remove calcium carbonate and prevent hydrolysis, deprotonating the fish scales with 0.5% NaOH followed by a grinding process that converted the scales into a fine powder. Dye adsorption studies showed that salmon chitin resulted in nearly 80% removal of methylene blue within 25 minutes, surpassing the performance of salmon and rohu fish scales and rohu chitin. Salmon chitin demonstrated superb dye removal compared to fish scales, exemplifying its potential as a sustainable and efficient remediation of contaminated water and a promising solution worth exploring.

Abstract Name: The Quest to Map the Nanyang: An Analysis of Sino-Jesuit Cooperation in High Qing Maritime Cartography

The first Jesuit missionaries from Europe arrived in China during the Ming Dynasty (1368-1644 CE) and established a presence in the imperial court that endured through to the Qing Dynasty (1644-1911 CE). This thesis project will attempt to answer the research question: How did Western cartography methods introduced

by Jesuit missionaries influence Qing scholarship and cartography of the South China Sea and Southeast Asia in the High Qing era (1683-1799)? Through archival research and critical analysis, this study examines China's indigenous scientific development, the impact of Western technology and methodologies, and the relationships between the Jesuit missionaries and Qing China's literati scholars. China borders the Yellow Sea, the East China Sea, and the South China Sea. This project's research parameters are narrowed down to the Nanyang region, which encompasses Southeast Asia and the South China Sea. The purpose of this project is to expand on established scholarship about imperial China's cartographical endeavours in the High Qing Era, a period of cultural interactions and territorial growth. To delve into the cartographical methods of this period, this project analyses primary sources such as manuscripts, maps, cartographic surveys, and the personal documents of Chinese and European scholars. Previous research on Jesuit cartography in Qing China has primarily focused on land mapping and has asserted that rather than domination of Western intellectual superiority and undermining of Chinese thought, the interactions between Jesuit and Chinese scholars led to a unique evolution of ideas and creative works that represented the transforming landscape of the 17th and 18th centuries. This project investigates how this conclusion about Sino-Jesuit collaboration applies to the Qing Dynasty's cartographical projects in the Nanyang region and contrasts the type of work done in land and sea settings, considering the maritime world provided a very different landscape with its own challenges and possibilities.

Abstract Name: Investigating Mental Simulation and Mental Imagery Using Sentence-Picture Verification

How we understand meaning during language processing is a fundamental mystery in the study of the mind. This study hypothesized a potential underlying similarity between how we represent meaning in language and how we deliberately imagine, albeit on different timescales. In this study, participants completed a sentence-picture verification (SPV) task that explored how instructions (none vs. "visualize the sentence") affect reaction times. In an SPV task, participants read a sentence that implies the visual features of an item. Participants then see a picture of the item that agrees or disagrees with the sentence implication and must verify if the item in the sentence appears in the image. Responses are faster and more accurate when the picture matches the sentence. To isolate the difference between automatic modes of understanding and deliberate imagery, this experiment was completed in two blocks, one without and one with explicit instructions to visualize the sentence content. To isolate the difference in timescale, each block included pseudo-randomized trial time structures. In combination, these manipulations allowed us to examine how effort and time may affect automatic understanding and deliberate imagination during reading. Results and implications for language meaning will be discussed.

Abstract Name: Differentiation and Proliferation of AHPC Neurospheres Plated on Gold Substrates Subjected to E-stim

Electrical stimulation (E-stim) is known to modulate neural activity and circuit function, promote neuroplasticity, and facilitate neural repair through its ability to activate or inhibit specific brain regions. Controlling E-stim's activation and inhibition functions has become increasingly important for advancing therapeutic strategies in neurodegenerative diseases and neural regeneration. To this end, understanding how E-stim influences stem cell behavior, particularly in terms of proliferation and differentiation, is critical for harnessing its potential in regenerative medicine. This study investigates the effects of electrical stimulation on the differentiation and proliferation potential of Adult Hippocampal Progenitor Cells (AHPC) neurospheres, with an additional focus on comparing the biocompatibility and impact of smooth versus nanoelectrode devices. AHPC neurospheres were cultured on each device and subjected to 1 Hz biphasic E-stim at 20 and 40 mV for 10 minutes over 5 days in vitro. The differentiation of AHPCs was assessed using immunocytochemistry with a panel of cell-type-specific antibody markers. Fluorescence microscopy was employed to visualize the immunolabeled and 4',6-diamidino-2-phenylindole dihydrochloride (DAPI)-stained cells, which were then quantified. Thus far, three biological replicates were performed using beta-III tubulin (TuJ1) antibody, which indicates immature neurons. Preliminary results from these quantified biological replicates, analyzed with ImageJ software, reveal that 20 mV E-stim significantly enhanced neuronal differentiation, as indicated by an increase in TuJ1-positive cells, compared to the control and 40 mV conditions. Both smooth and nanoelectrode devices demonstrated biocompatibility, with no significant adverse effects on AHPC neurospheres. Future work will expand on these findings by incorporating additional neuronal markers, such as microtubule-associated protein 2a,b (MAP2ab), and glial markers like glial fibrillary acidic protein (GFAP). Additionally, gene expression analysis via qPCR will be explored to further elucidate the molecular mechanisms underlying AHPC differentiation and proliferation in response to E-stim. This work holds promise for advancing regenerative therapies in neurodegenerative conditions.

Abstract Name: Socialism with Confucian Characteristics: Legitimacy in Contemporary China

Political Legitimacy takes many forms during the tenure of the Chinese Communist Party (CCP). In recent times, Confucianism and traditional Chinese values have emerged as a key element in the legitimization of the Chinese government, and they will likely remain a critical factor in the coming decades. Since the CCP broke away from the hardline Marxist policies of the Mao Era in the late 1970s, it has been reliant on the country's economic performance to legitimize party rule. Now, however, China's economy is already showing signs of slowing down, and the work force is expected to shrink. President Xi Jinping looks to Confucius as a potential remedy for legitimacy, drawing from traditions that had been utilized in imperial China. Xi is fleshing out the definition of "Socialism with Chinese Characteristics" that was popularized by Deng Xiaoping. The new definition includes the perspective that socialism is of Chinese origin because of China's historical practices such as the distribution of land and benevolent rulers governing in favor of the largely agrarian proletarian class. The party is promoting the study of China's past and urging academia to explore the ideas of traditional China, and this has led to voluminous writings on the subject. While President Xi's reliance on Confucianism and traditional Chinese values is not unheard of in the history of the CCP, the

extent and intensity of his effort is unprecedented. This revitalization of Chinese classics serves as a building block for the CCP to rally Chinese nationals around their cultural identity to further legitimize its rule.

Abstract Name: Rapid Injection Molding with Resin 3D-printed molds

Formative manufacturing using injection molding technology is a process by which a plastic or composite raw material is melted down and extruded under pressure into a mold. Some of the advantages of injection molding over other manufacturing technologies include the ability to manufacture complex geometries with tight tolerances, the compatibility with a wide range of materials and colors, the high repeatability, fast production cycles and the ability of material reuse. Despite all these benefits, injection molding endures several drawbacks, most importantly, the need for custom metal tooling for the injection molded parts, making it prohibitively expensive and time consuming for small part quantities. Hence, the need for a more time-and-cost effective alternative. The main objective of the current research is to develop a systematic and economical procedure for the design and 3D-printing of stiff and thermally stable resin molds for low volume injection molding of plastics. To achieve this objective, common design practices for injection mold design and additive manufacturing of stiff and high Heat Deflection Temperature (HDT) resin will be used in the SLA (Stereolithography)-3d-printing of high precision molds with improved surface finish. 3d-printed molds of simple and complex part geometries will be used with a Desktop injection molding machine (the APSX-PIM V2) under a wide range of pressures, temperatures, and materials. The injection molded parts will be tested for durability and geometrical accuracy. The successful completion of this research will make formative manufacturing using injection molding technology more time-and-cost-effective.

Abstract Name: The Complex Role of Polyamines in Tau Pathology: Insights from Ornithine Decarboxylase Manipulation

Alzheimer's Disease (AD) is one of several neurodegenerative diseases that specifically affect brain regions involved in memory formation and retention. It is driven by the aggregation of the disordered protein, tau, which in turn drives neuronal dysfunction and death. Polyamines are small aliphatic cations that are essential for internal processes such as cell growth. Higher order polyamines, such as spermidine and spermine, had shown in in vitro studies that its increase reduced tau pathology, offering a therapeutic mechanism to the disease. Therefore, it was hypothesized that increased polyamine levels would diminish the tau phenotype. A study focused on a lower-ordered polyamine, ornithine decarboxylase (ODC1), which is the rate-limiting enzyme in polyamine synthesis, arose and modeled this hypothesis. Tg4510 transgenic mouse models that overexpress mutant tau were used to examine the effects of ODC1 overexpression on tau aggregation. Western blotting techniques were used to quantify tau phosphorylation and total tau levels, using antibodies such as AT8, PHF1, and HT7. The results contrasted the initial hypothesis, showing that Tg4510 mouse models with an ODC1 treatment possessed increased levels of tau. This suggested that ODC1 disrupted polyamine homeostasis and worsened tau pathology. The contrasting findings caused the hypothesis to be revised, stating that while polyamines are beneficial in traumatic stress responses, the chronic upregulation of polyamines induces an inadequate polyamine stress response (PSR). Within the inadequate PSR, aberrant polyamine metabolism amplifies tau pathology, emphasizing the complexity of polyamine metabolism and regulation in neurodegenerative diseases. Future studies will focus on understanding the balance between beneficial and inadequate polyamine responses, potentially disclosing novel strategies to reduce tau pathology in AD.

Abstract Name: The Importance of Polyol Structure: A Spectroscopic Investigation of Triols and Linear Polyols Interaction with Glucosamine and Chitosan

The use of bioplastics as alternatives to petroleum-based plastics has gained significant attention in recent years. These biomaterials are typically created by combining biopolymers like chitosan with plasticizers such as glycerol (Glyc). Previous research has shown that the amount and type of alcohol used can significantly affect the polymeric structure. Chitosan's repeat unit, glucosamine (GlcN), and Glyc are key compounds in forming polyol solutions. Glycerol can have primary binding sites (1,2 or 1,3-OH) and secondary binding interactions due to its additional hydroxyl groups. To explore the impact of primary binding on GlcN aggregation, ethylene glycol and (1,3)-propanediol were used to probe the 1,2 and 1,3 binding modes. Various diols, including (1,2)-propanediol, (2,3)-butanediol, and (2,4)-pentanediol, were analyzed to understand secondary binding while keeping primary interactions constant. This summer, additional polyols such as 2-

methyl-(1,3)-propanediol and 2-(hydroxymethyl)-(1,3)-propanediol were tested to evaluate how an increased alcohol content affects GlcN aggregation and disaggregation. Spectroscopic techniques, including dynamic light scattering (DLS), attenuated total-reflectance infrared spectroscopy (ATR-IR), and nuclear magnetic resonance (NMR), were used to analyze the intermolecular interactions between these diols and GlcN. While most of the analysis focused on ATR-IR, solutions of polyols like Xylitol, Sorbitol, and Mannitol were compared to diols and triols to assess their impact on binding and aggregation. Results indicate that a higher alcohol content leads to increased hydrogen bonding at the molecular level, with more significant hydrogen bonding observed in polymeric chitosan solutions than in glucosamine solutions.

Abstract Name: Interactions of DNA nanostructures with silane-based Self-Assembled Monolayers (SAMs)

DNA origami, a manipulation of DNA's double-helical structure, is promising in biological and material science research providing nanoscale precision on surface localization of chemical functional groups. Understanding the interactions between the nanostructures and surfaces will allow efficient localization. Study with silane-based surface modification via forming self-assembled monolayers (SAMs) provides insight into nanostructure morphology related to surface composition. In this work, it's shown that interactions of DNA nanostructure with the surface affects their structural integrity and number density. We have prepared both single and multi component SAMs using an amine-terminated silane mixed with alkyl trichlorosilane of different chain lengths (C18, C6, C4) at various molar concentrations in a solvent-based deposition. We discovered that the surface with a higher concentration of the polar amine-terminated silane mixed with the longest alkyl chain (C18) resulted in the highest density of DNA nanostructures with maintained structural integrity.

Abstract Name: Final Girls: Surviving Until Subversion

The sound of an audio stinger, accented by a high-pitched feminine scream, recalls one thing specifically: a slasher movie. The mental association exists for a good reason. According to a 2017 Geena Davis Institute study, horror is the only movie genre where female characters have more screen time than males, by a narrow margin of 53%. Those female characters pay the blood price via an abundance of harmful stereotypes. As a horror fan, I have screamed at the television, telling the actress on screen not to go up the stairs countless times--but why does she corner herself instead of ducking out the back door? How do I know the woman who just had sex is as good as dead? Why are capable, well fleshed-out final girls so hard to find? Ever since Carol J. Clover coined the term "final girl," she has been established as a tragic but resilient archetype. Her name

and foes vary greatly, but there is no denying her survivorship. But what about the actress who gives her life and the difficulties they endured? To truly understand her origins, we must peel back her skin to reveal what lays beyond and excise her essence from fictional flesh and bone. We cannot afford to turn blind eyes to the bigger picture beyond the character of the final girl herself to see what her existence was meant to tell us. In my poster, I plan to explore just what pop culture's reflection shows us through the most honest mirror we have at our disposal, not only regarding what traits are portrayed, but how they came to be. My poster will display my findings with the flair we expect from horror movie posters, highlighting my research while paying homage to Pittsburgh's rich history in horror.

Abstract Name: Exploring Vocabulary Development in Autistic Children: The Role of Imageability and Vocabulary Acquisition

Language skills and early word learning are typically delayed in autistic children. Previous research has indicated that autistic children may display similar learning biases relative to non-autistic children but acquire language at a protracted rate, while others suggest autistic children may have different learning biases and processing abilities. Evidence has shown that children are biased in learning words with certain features, including high imageability, which is the ease with which a word evokes a mental image. Though prior research indicates that imageability is associated with vocabulary development in non-autistic and autistic children, imageability data have not been collected for a significant number of early-acquired words, which has restricted previous studies. Due to the limited research on word learning biases in autistic children, the present study aims to develop an imageability database and to more thoroughly investigate the association between word imageability and vocabulary development in autistic and non-autistic children. Thus, we are developing a task to collect imageability scores for each word that appears on a commonly used parent questionnaire of child vocabulary knowledge (Macarthur-Bates Communicative Development Inventory; MB-CDI). College participants will be shown words from the MB-CDI and asked to rate how imageable each word is on a scale of 1 (Not imageable) to 7 (Very imageable). After collecting these imageability scores, we will assess whether word imageability predicts word-level normative data of vocabulary acquisition. Specifically, we will use a newly created vocabulary acquisition normative variable—vocabulary size of acquisition—that has been derived separately for autistic and non-autistic children.

Abstract Name: Investigating the Revitalization of Al Qaeda in the Arabian Peninsula

This paper explores the role of Al Qaeda in the Arabian Peninsula (AQAP) within Yemen's complex landscape of regional conflict, with a focus on the group's recent restructuring and evolving capability and

strategy. The central research question investigates and evaluates AQAP's current threat level, leadership dynamics, and potential alliances with other terror organizations. Although AQAP has historically been one of the strongest Al Qaeda affiliates, existing literature primarily focuses on Yemen's Houthis due to their increased attacks. In contrast, AQAP has done the opposite, drawing the media away from AQAP. In recent years, little academic research has been conducted that evaluates the group's current threat level, including the organization's transnational strike capability and its intent to strike the homeland. This is critical given the group's previous intent and capability. This paper's research uses available open-source intelligence on AQAP and seeks to address the significant gap in understanding AQAP's operations and recent actions. The study includes a comprehensive history of AQAP in Yemen and assesses AQAP's direction, highlighting alliances and new strategies alongside Yemen's historical and geopolitical context. It argues that the group's recent restructuring creates an ideal environment for the group to revitalize. This thesis seeks to rekindle scholarly and policy-focused attention on AQAP by delivering a comprehensive and current analytic assessment of the group's current intent and capabilities, thereby informing the U.S. counterterrorism strategy.

Abstract Name: Interrogating the Role of Astrocytic Cilia in Astrocytic Response to Diffuse Mild Traumatic Brain Injury

Heterogeneous astrocytic responses to traumatic brain injury (TBI) have been extensively documented, yet the mechanisms driving these responses and the downstream consequences remain poorly understood. Following a focal injury, astrocytes proliferate to form a glial scar that effectively isolates the damaged region. This astrogliosis response is crucial for protecting surrounding healthy tissue from extravasation from the impaired blood-brain barrier (BBB). Yet after diffuse mild TBI, astrocytes do not proliferate and BBB repair fails. Astrocytic cilia play an essential role in stopping the cell cycle and detecting extracellular inhibitory signals, thereby reducing proliferation. Thus, we hypothesized that preventing astrocytic cilia formation will significantly increase astrocytic proliferation and consequently BBB leakage after diffuse mild TBI. To test this hypothesis, we employed a genetic strategy to induce Cre recombinase expression in astrocytes (Aldh1l1CreERT2) of mice carrying floxed alleles for the required cilia protein intraflagellar transport 88 (IFT88) by tamoxifen administration. Loss of astrocytic cilia was confirmed via immunoblot analysis compared to Cre-negative controls. Subsequently, mice were subjected to mild diffuse TBI or sham injury. Astrocyte proliferation was measured using immunohistochemistry and immunoblot analysis for Ki67, a protein expressed in nuclei of proliferating cells. BBB integrity was assessed using the small fluorescent molecule cadaverine, which cannot cross the BBB under physiological conditions, and with immunohistochemistry for essential BBB proteins.

Abstract Name: Co-Designing Resilient Living Seawalls: A Nature-Based Solution for Coastal Protection in Volusia County, Florida

Volusia County, Florida, faces increasing risks from sea-level rise and extreme weather events, as evidenced by the significant erosion and infrastructure damage caused by recent hurricanes Ian, Nicole, and Milton. This collaborative research project, led by Embry-Riddle Aeronautical University, Bethune-Cookman University, the University of Central Florida, and local stakeholders, focuses on developing hybrid "living seawall" designs as scalable, nature-based solutions. By combining durable structural components with ecological elements such as dune vegetation, the project aims to enhance coastal resilience while addressing environmental and community needs. Through extensive community outreach and four planned engagement workshops, stakeholders - including property owners, local governments, and environmental organizations - have collaborated to co-design research-informed concepts for living seawalls. These concepts are set to be implemented during a subsequent grant-funded phase, contingent on funding approval. The proposed designs integrate storm surge protection with ecological benefits, such as promoting sand accumulation, stabilizing vegetation, and enhancing wildlife habitats. The project's expected outcomes include the adoption of a living seawall design that complies with federal, state, and local regulations and the identification of pledged shoreline properties for Stage 2 implementation and monitoring. This initiative not only strengthens coastal resilience but also advances the understanding of adaptive management strategies for high-energy coastlines. By bridging community engagement with scientific innovation, the project seeks to promote the sustainable coexistence of natural and built environments. The current findings and lessons learned are presented here as a foundation for ongoing efforts.

Abstract Name: Improvements in Particle Accelerators Aimed at Optimizing Energy Output: An Extended Analysis on Multivariable Calculus Tools

Particle accelerators are devices for increasing the velocity of particles. Their core functioning lies in electromagnetic interactions, and the phenomena observed in and because of them have diverse applications in biology, chemistry, industry, and particle physics. This study dives into the historical improvements in particle accelerators, going through what has made it possible to go from the basic functioning of the Cockcroft-Walton and Van de Graff accelerators to synchrotrons and storage rings like the Large Hadron Collider (LHC), the most powerful particle accelerator ever built. Furthermore, it explores the limitations of each stage of these machines. To facilitate further research on this current topic, it is also necessary to examine the mathematical tools used in the study of the electromagnetic, relativistic, and quantum phenomena observed in particle accelerators. The essential tools described in this first study are related to multivariable calculus, starting with functions and vectors, followed by their applications in multivariable calculus with multivariable functions and partial derivatives, and concluding with vector fields, gradient vector fields, vector field's potential, line integrals, vector field divergence, and vector field curl. A complete understanding of these mathematical concepts will allow for further research to understand Maxwell's Equations and Lorentz's force law, which require the operation of the studied concepts applied to open and closed surfaces.

Abstract Name: Administrative Segregation: Necessary or Cruel and Unusual?

This presentation describes a qualitative study that explored whether administrative segregation (AS), previously known as solitary confinement (SC), constitutes a violation of the Eight Amendment in Texas. The aim of AS is to lower crime rates within prisons and act as a safety measure. However, researchers have shown that it does the opposite and directly harms prisoners (Tadros et al., 2023; Lobel & Akil., 2018; Aranda-Hughes et al., 2021; Smith., 2006). In 2015, the UN Convention Against Torture created the United Nations Standard Minimum Rules for Treatment of Prisoners, Mandela Rules, stating that SC/AS only be used in exceptional cases and as a last resort for a short time (defined as 115 days) (Fettig, 2020). However, this remains an issue of “soft law” thus UN rules are in juxtaposition with the realities of the harsh practices seen in the U.S. and even more so, Texas. Researchers state that AS violates the 8th Amendment through many clauses such as psychological deterioration, physical harm, and living conditions. Additionally, most of this research, however universally applicable, is primarily found in international studies. Therefore the lack of research specificity to Texas presents an additional gap in the literature. This study will address these gaps by exploring the following questions. Is an incarcerated individual’s mental health affected by AS in Texas and how? Are the living conditions of AS inhumane? Is there physical harm produced by AS? If so, do these conditions reach the criteria for violation of the Eight Amendment? Through structured interviews, the perspectives of previously incarcerated individuals were captured addressing such questions. Analyzing the transcribed data collected from the interviews, a thematic analysis was used to explore such themes.

Abstract Name: Rapid Detection of the FGFR3-TACC3 Gene Fusion in Glioma

The FGFR3-TACC3 (fibroblast growth factor receptor 3 - transforming acidic coiled coil) gene fusion is a genetic alteration seen in approximately 5% of diagnosed glioblastomas. This particular fusion harbors characteristics that drive tumor transformation and thus gives poor prognosis and greater resistance to therapeutic treatments. In IDH (isocitrate dehydrogenase) wild type (WT) tumors, 3-5% possess FGFR3-TACC3 gene fusions in which the resulting protein becomes constitutively active, thereby promoting cellular proliferation. The most common forms of the fusion occur in exon 17 of the FGFR3 gene and exons 11 (20%), 10 (11%), and 8 (14%) of the TACC3 gene. Using synthetic DNA, we demonstrate the proof of principle for the discrimination of FGFR3x17 – TACC3x8 gene fusion DNA from the wild type DNA sequence. We utilized Recombinase Polymerase Amplification (RPA) and Loop Mediated Isothermal Amplification (LAMP) nucleic acid amplification techniques to amplify the gene fusion and discriminate

from WT sequence from the FGFR3x17- TACC3x8 gene fusion within 20 – 45 minutes, respectively. Due to the clinical impact of treatment based on the specific FGFR3-TACC3 gene fusion, we intend to develop a panel of the aforementioned gene fusions to rapidly discriminate between gene fusions. These advancements demonstrate the potential of RPA and LAMP as reliable, rapid diagnostic tools for detecting FGFR3-TACC3 gene fusions, offering a foundation for improved glioblastoma diagnostics and personalized therapeutic strategies.

Abstract Name: Effect of Neuropeptide Y on Staphylococcus aureus biofilm formation

Biofilm is a substance produced by many bacteria. Along with providing nutrients for those bacterial cells interior of it, biofilm protects them against antibiotics and reduces recognition by the host immune system. Biofilm poses a unique challenge to the fields of health and medicine as biofilm-producing bacteria are difficult to treat. When biofilms form on medical devices and implants, they can be transferred from patient to patient and contribute to the spread of infections. Antimicrobial peptides (AMPs) are an emerging factor of interest because of their size, accessibility, and ability to prevent microbial growth and biofilm formation. This research studies the effect of a specific AMP called Neuropeptide Y on Staphylococcus aureus, a type of biofilm-forming bacteria. Following growth and treatment of S. aureus with Neuropeptide Y, crystal violet stain and spectrophotometry were used to generate quantitative measurements of biofilm production. Our preliminary results indicate that treatment of S. aureus with Neuropeptide Y can significantly reduce biofilm formation.

Abstract Name: Behavior as a Password: Machine Learning for Behavioral Biometric Authentication

In today's fast-moving tech landscape advancements are happening at a fast pace. These advancements come with new opportunities to make our lives easier. However, alongside the rise of these new technologies also comes the introduction of new threats. So, it is important that security trends evolve along with the fast-paced development of technology. Most security today is based on traditional physiological biometrics like fingerprint and iris scans. While this is effective to an extent, it is not adequate as there are ways this type of authentication can be breached. This project explores behavioral biometric authentication using machine learning. It aims to answer the question: How can behavioral biometrics combined with machine learning techniques provide a strong defense to counter modern cyber threats? This project will present an analysis of various behavioral traits, such as keystroke dynamics, mouse movements and gait analysis using machine learning techniques. These techniques include feature extraction, model training, and validation. Through the application of these techniques, this project provides an analysis of these behavioral characteristics,

demonstrating their potential in developing more robust and adaptive security frameworks that offer greater protection against emerging threats.

Abstract Name: Studies of the Natural Product Bakuchiol Against Solid Tumor

Breast cancer is the leading cause of cancer deaths, with 55,000 new cases every year; the most lethal type is triple-negative breast cancer (TNBC). The lack of estrogen, progesterone, and human epidermal growth factor type 2 receptor proteins, which define TNBC, makes it difficult to treat using hormone therapies that are effective against other breast cancers. TNBC leads to approximately 150,000 deaths per year, indicating that there is a need for effective therapeutic agents. We aim to develop derivatives of the natural product bakuchiol to fill this gap. Bakuchiol is a phenolic monoterpenoid isolated from *P. corylifolia* that is reported to target bacteria, insects, and pests, as well as enhance flavor in food. In recent studies, bakuchiol showed cytotoxicity to cancer models in the low micromolar range. Synthetic analogues of bakuchiol are observed to have anti-cancer, antioxidant, cytotoxic, antiviral, and antibacterial properties. Therefore, we hypothesize that superior bakuchiol compounds can be generated from this pharmacophore. Our methodology includes the synthesis and biological evaluation of bakuchiol and its derivatives. The effect of their properties on cell viability in TNBC was detected by CTG, PI, and colony assay formations. Our preliminary findings suggest these compounds have promising biological activities against the cancer cell models while no cytotoxicity was observed against the non-cancerous BJ cell line. Further studies of Bakuchiol and its derivatives include target identification and molecular docking studies to improve their efficacy. The bakuchiol derivatives have promising biological properties and could lead to effective therapeutic agents for patients with TNBC.

Abstract Name: Optimization of sgRNA Synthesis For Use in CRISPR-CAS9 Knockdown Studies Using RNP Complex Delivery

In CRISPR-Cas9 mediated knockdown studies, a ribonucleoprotein (RNP) complex is assembled with a specifically designed sgRNA and the Cas9 enzyme to target a specific gene of interest. The ideal concentration of sgRNA in this complex is between 1-1.5 $\mu\text{g}/\mu\text{l}$ for optimal transfection efficiency. Through experience in our institution's research lab and in course-based research experience, we identified an inconsistency and inefficiency in the method of sgRNA synthesis. This method was a kit obtained from NEB for both sgRNA synthesis and RNA purification (Method 1). We hypothesized that the limiting factor of sgRNA yield was the purification column used in the RNA purification kit and that this loss could be mitigated through phenol-chloroform isolation (method 2). We also hypothesized that the limiting factor was

in the synthesis of sgRNA itself. In order to test this, we used a plasmid template to create and amplify DNA segments of our sgRNA which would then later be reverse-transcribed and purified using phenol-chloroform (Method 3). Two target-specific-oligo sequences were designed by our lab (Targeting MIF and CCL11) and synthesized by IDT. The sgRNA was synthesized in three separate trials for each method from these target-specific-oligos. We determined that Method 3 yields a significantly greater concentration of sgRNA compared to the two alternative methods. However, there still exists an application for the two alternative methods in a course-based research setting where the extended time requirement for Method 3 is not sufficiently available. The identification of an optimal method of sgRNA synthesis has led to the optimization of the transfection of these RNP complexes. Comparing transfection rates of Lipofectamine and electroporation using Sanger sequencing and TIDE analysis. This project is part of the lab's ongoing work to optimize molecular biology techniques for successful CRISPR-Cas9 used in our research.

Abstract Name: Leveraging Language Models to Generate Programming Questions of Varying Difficulty

This study explores the potential of Large Language Models (LLMs), particularly ChatGPT-4, to generate Python programming questions across varying levels of difficulty, a capability that could transform adaptive learning in computer science education. As educational systems increasingly seek to personalize learning experiences, the ability to tailor question difficulty based on a learner's proficiency is critical. In this research, ChatGPT-4 was tasked with generating Python programming questions, which were then evaluated by participants to compare the model's difficulty ratings with their perceived challenge level. The results demonstrate alignment between ChatGPT-4's difficulty ratings and participants' perceptions, revealing the model's effectiveness in producing a broad range of questions suitable for learners at different levels. This suggests that LLMs like ChatGPT-4 could play a vital role in designing personalized educational experiences that adapt dynamically to individual learners' needs. The implications of this work are significant for the future of educational technology, particularly in creating adaptive learning platforms for programming education. Future research should explore the model's application to other programming languages and more complex topics, expanding the potential impact of LLMs on personalized, scalable learning environments. This study offers valuable insights into how advanced AI models can support the next generation of adaptive educational systems, driving innovation in personalized learning and teaching.

Abstract Name: The Shift

THE SHIFT: a novel By Colin Morrison The Shift is an original work of fiction that explores how corporate

control and environmental deterioration will someday negatively impact our lives and relationships. The project has evolved significantly over time, beginning as an anthology of interconnected short stories, then changing into a more traditional novelistic structure to better fit the themes of the story. The Shift can be an unforgiving place, and nobody knows this better than Lydia Crane. It's where she grew up, where she first fell in love, where she was arrested, and where she spent ten years in a corporate prison. Now a private investigator, Lydia leverages her local knowledge to try and make the Shift a better place, one case at a time. When a missing persons case comes to an unfortunate conclusion, Lydia finds herself thrust into another case, one that will bring her past into the present. Her estranged mother, Audra Dennison, a high-powered executive in the society-controlling megacorporation Ficus, comes to Lydia with a job: her half-brother Aldrick, who Lydia didn't know existed, stole something important to Ficus, and even more important to Audra. Audra wants Lydia to recover the stolen goods, no matter the cost. After initially turning down the job, Lydia reports to Bogs, her handler and the closest thing she has to a friend. Bogs tries to convince her to reconsider, before pulling rank and forcing her to take the case. Left with no choice, Lydia accepts the job. The case takes her on a journey from the homeless camps of the Shift to a shady club called Shift City all the way to Ficus' headquarters, and brings to light numerous secrets—not just about Ficus and the world Lydia lives in, but about her mother and herself as well.

Abstract Name: High Stress and High Energy: Piezoelectric Response of Synthesized and Modeled Foldamers

Piezoelectric materials produce an electrical charge in response to deformation. They have a wide range of uses ranging from medical devices and home technology to energy harvesting. Most conventional piezoelectric materials are lead or barium containing ceramics, which are not only brittle but toxic. This work is concerned with the piezoelectric response of foldamers, conformationally ordered molecules stabilized by their non-covalent bonds, which are carbon based and flexible. Foldamers exhibit high deformation and their ability to take stress results in a higher electromechanical response, or in our case the piezoelectric voltage constant, d_{33} . In this work, we synthesized a number of foldamers to measure their respective piezoelectric properties and compare them to predicted values from density functional calculations. The fundamental relationship of these properties is studied by comparing their response to structural adjustments, such as length and functional group attachments. The response of the synthesized foldamers are measured by forming a self-assembled monolayer (SAM) and applying a custom mechanical piezoelectric device tester. In conjunction with these synthesized foldamers, we are using computational modeling of the same and a variety of other foldamers to predict and explore their responses. Given a high similarity between synthesized and modeled piezoelectric response, we can explore larger and more complex structures in less time using computed response from density functional calculations.

Abstract Name: Understanding Foster Care

This research aims to discover participants' perspectives and understanding of the Utah foster care system and what it strives to accomplish, what stigmas may be present concerning their view of the Utah foster care system, their perspective on the children in care, what would help participants consider being foster parents, and what hesitations they may have about being foster parents. Utah foster care is currently experiencing a shortage of foster parents and would like to know what may help people decide to become foster parents either now or in the future. They also would like to see what people's stigmas and possible misunderstandings may be of the foster care system. Participants were asked to complete a survey of 13 questions concerning their opinions and stigmas surrounding the foster care system specifically in Utah. Including questions on what they thought foster care was and what would help them consider being a foster parent. 11 questions were free-entry responses and 2 questions were multiple choice. Participants were anonymous and assigned a randomized number. The research's conclusions showed that many participants had not been exposed to any advertisement or education regarding Utah foster care or the need for more foster parents. Participants held negative stigmas concerning foster care and showed a misunderstanding of what the foster care system is and what its purpose is. This will help Utah foster care know where the gaps are in their community outreach and what may help them retain and entice prospective foster parents.

Abstract Name: Identifying Geographic Disparities in the Health-Risk Behaviors in Oklahoma

The purpose of this project is to identify demographic disparities between the US and the state of Oklahoma in survey data. Factors for the health-risk behavior of adults currently reporting smoking cigarettes daily and educational attainment will be compared using publicly accessible survey data. Cigarette smoking is the leading cause of preventable death in the United States, causing approximately 480,000 deaths each year. In 2022, the Behavioral Risk Factor Surveillance System (BRFSS) reported 12.5% of US adults currently smoke cigarettes, while the crude prevalence in Oklahoma for the same period was reported at 16.1%. BRFSS is a random-digit-dialed telephone survey collecting information on health conditions, health practices, and risk behaviors. Cigarette smoking increases the risk of several chronic diseases, including heart disease, stroke, multiple types of cancer, and chronic lung disease. Smoking impacts the smoker and those exposed to secondhand smoke. About 2.5 million people have died from medical problems caused by second-hand smoke since 1964. A statistical comparison will be made between the state and the national data for the purpose of comparing educational attainment and adult smoking behavior. This study will explore education as a social determinant of health to lower the health-risk behavior of adult cigarette smoking within the state of Oklahoma and that state data will be compared to national numbers.

Abstract Name: Stress Induced Regulation of Mitogen-Activated Protein Kinase 15 (MAPK15) in Ovarian Cancer Models

Amongst all gynecological cancers, ovarian cancer is one of the leading causes of cancer death in women. A major reason for this high fatality rate is the late detection of advanced and metastatic disease. For metastasis, cancer cells must detach from their primary tumor and survive under matrix detachment during which they have to overcome multiple cellular stressors to survive including DNA damage, starvation, oxidative stress, etc. Mitogen-activated protein kinase 15 (MAPK15) is over expressed in ovarian patient samples compared to normal and a higher expression is correlated with lower survival of patients. We found that MAPK15 expression is further induced upon matrix detachment when ovarian cancer cell lines are cultured in suspension. We found an increase in expression in both mRNA and protein levels upon matrix detachment compared to the attached condition. The purpose of this research was to assess how expression of MAPK15 is induced upon matrix detachment. We hypothesize that upon matrix detachment, DNA damage occurs, which induces the expression of MAPK15 as a DNA damage response protein. We induced DNA damage with either cisplatin, which is the standard of care chemotherapeutic drug, or by culturing cells in suspension to test the generalizability of the observed response. DNA damage was assessed by γ H2AX, a biomarker for DNA double-strand breaks, using, immunofluorescence. The expression of MAPK15 was assessed using western blot analysis. Data analysis was conducted using cell counting, fluorescence intensity measurements, and IC50 measurements using an SRB assay Graph Pad Prism. Data using human ovarian cancer cell lines that reflect high-grade serous will be presented.

Abstract Name: Acoustic Denial of Service Attacks on Hard Disk Drives: Vulnerabilities, Impact, and Mitigation

The increasing reliance on hard disk drives (HDDs) in critical systems has exposed an overlooked vulnerability: susceptibility to acoustic denial of service (DoS) attacks. This research investigates the deliberate use of acoustic signals to interfere with HDD functionality, posing significant risks to data integrity and system availability. The study aims to identify the specific frequencies and environmental conditions that render HDDs most susceptible to acoustic interference, characterize the nature of such attacks, and catalog HDD models most vulnerable to this emerging threat. Grounded in foundational principles of resonance scattering and leveraging insights from previous studies, this research builds upon experimental findings to validate and extend their applicability to diverse HDD models. Methodologically, the project involves controlled laboratory experimentation using advanced facilities at WSU's School of Computing and Electrical Engineering. It analyzes acoustic waveforms, amplitude variations, and environmental factors to determine the mechanics of successful acoustic DoS attacks. Machine learning techniques will be explored to identify and test potential mitigation strategies, aiming for robust defenses against these attacks. Preliminary findings indicate specific resonant frequencies significantly impact HDD performance, with variations across models. The expected outcomes of this research include a scholarly paper and presentations to inform manufacturers and end-users about mitigating acoustic threats. Results will be shared at the WSU Undergraduate Research

Symposium to contribute to the growing field of cybersecurity and enhance understanding of hardware vulnerabilities. This project not only advances academic knowledge but also equips students and faculty with valuable insights for tackling real-world security challenges.

Abstract Name: Local and Online Large Language Models for Mental Health Summaries

Electronic mental health records (EMHRs) often contain extensive, text-heavy reports, making it challenging for medical professionals to review them efficiently. Traditional methods of analyzing these records are time-consuming and may hinder timely interventions. This study explores the use of local and online large language models (LLMs) to address this issue by summarizing EMHRs into actionable insights. Local LLMs, such as GPT-4-All, LLaMA, and BLOOM, offer advantages in privacy and security, which are crucial for handling sensitive mental health data. However, local models often struggle to produce accurate results for longer records due to limitations in computational resources, model size, and insufficient fine-tuning. In contrast, online models like ChatGPT and Gemini demonstrate greater summarization accuracy and scalability but raise concerns about data security and compliance with privacy regulations. This research focuses on developing a framework for EMHR summarization tailored to specific contexts, such as summarizing by doctor, event, timeline, or mental health issue. The study evaluates local and online LLMs across dimensions like accuracy, efficiency, security, and applicability. Diverse datasets of mental health records will be used to test these models, ensuring robustness and relevance. Preliminary findings highlight the trade-offs between the privacy benefits of local models and the broader capabilities of online models. Future directions include refining local LLMs to overcome token limitations and exploring hybrid approaches that leverage the strengths of both local and online models. By enabling efficient and secure summarization of EMHRs, this research aims to improve the workflow of mental health professionals and enhance patient care outcomes. By providing a structured comparison of local and online LLMs, this study aims to enhance EMHR utility in mental health care. The findings provide insights for creating secure, effective tools to improve workflows and outcomes, highlighting the potential of artificial intelligence in mental health care.

Abstract Name: Identity, Trust, and Tax Morale

Recent reports from the United States Treasury Department and the Government Accountability Office expose inequities in the tax benefits enjoyed by different racial and ethnic groups resulting from the application of tax law and tax enforcement activities. If tax morale (i.e., the willingness to pay taxes independent of potential enforcement activity) is reduced when tax systems are perceived as unfair, the

overall efficiency and effectiveness of the tax system can be compromised. While overall perceptions of taxing authority equity may decline following such news, members of those groups currently disfavored by the tax system or non-dominant groups that have been historically disfavored by the government may respond differently to the information than others. Building on Kirchler, Hoelzl, and Wahl's (2008) slippery slope framework of tax compliance, we develop a model describing how government actions affect trust in the taxing authority (a key driver of tax morale) through perceived equity. We further consider whether social identity moderates those relationships. Relying on Tajfel and Turner's (1982, 1986) Social Identity Theory, we add identification with the group favored or disfavored by the tax system or with the dominant or non-dominant groups as moderators of those relationships. We will test our hypotheses in an experiment in which U.S. taxpayers assess the equity of the tax system, trust in the taxing authority, and tax morale, and make a tax compliance decision after reading a story about tax system inequities that disfavor either a group with which they identify or one with which they do not identify.

Abstract Name: Strength and Weight: The Iterative Design and Development of a Formula SAE Chassis

This project explores the design and development of a Formula Society of Automotive Engineers (FSAE) chassis, focusing on the engineering design process and the challenges associated with meeting FSAE regulations. The project emphasizes a systematic, iterative approach to chassis design, balancing the critical factors of strength, weight, and structural integrity to ensure optimal performance and safety during operation. A key objective was to achieve a high strength-to-weight ratio while maintaining durability under the demanding conditions of competitive motorsport. The design process began with a thorough review of the 2024 FSAE rules and regulations, which set specific requirements for dimensions, material selection, and safety features. These constraints guided the development of initial design concepts, which were progressively refined based on feedback from the capstone director and analytical testing results. The iterative approach allowed for continuous improvement, incorporating lessons learned from previous designs and insights from user feedback to fine-tune the chassis. Material selection played a critical role in the design, with careful consideration given to the strength, weight, and manufacturing feasibility of various materials. Structural integrity was tested through simulation and physical validation to ensure the chassis would withstand the forces experienced during racing conditions. Additionally, different fabrication methods were explored to optimize cost-effectiveness while maintaining quality and performance standards. This document provides a comprehensive overview of the design evolution, detailing the key factors that shaped the final chassis, from regulatory constraints and material choices to design testing and refinement. The result is a highly optimized FSAE chassis that meets the performance, safety, and manufacturing requirements of the competition.

Abstract Name: Rhythmic Reflection: Poetry as a Hermeneutic Channel for Achieving Shared Philosophical Understanding

With his concept of the “hermeneutic circle,” philosopher Martin Heidegger emphasizes the ways in which understanding requires that we enter into the assumptions and the world of what is being understood. While this hermeneutical orientation can be applied to anything that calls for our understanding, I see it as particularly relevant for noticing the specific contribution that poetry offers as an interpretive tool and an illumination of human experience. In my project, I propose an understanding of poetry as a hermeneutic channel – that is, as an interpretive means for bringing initially distant, abstract philosophical ideas closer to the empathetic imagination of the poem’s audience. First, I lay out a framework of poetry as a hermeneutic channel by placing Heidegger in dialogue with the work of James Olthuis, who reaches beyond Heidegger in positing an explicitly interpersonal “hermeneutic spiral” that promises a mutually responsive “hermeneutics of connection,” rather than simply of “interpenetration.” I then use this poetic framework to engage in a close reading of M. NourbeSe Philip’s poem “She Tries Her Tongue: Her Silence Softly Breaks,” in which Philip draws the reader closer to her experience of cultural trauma and rehabilitation. I argue that Philip achieves this contact not by mere description, but by constructing poetic patterns that bring about a shared hermeneutic engagement through deliberately fragmented and looping language. In this way, Philip’s poem exemplifies how poetry itself counts as a form of philosophical expression and exploration, by showing how philosophical complexities are more intimately encountered through poetry’s distinctive affordances.

Abstract Name: The enigma of idiopathic hypersomnia: Exploring its potential impact on memory consolidation in young adults (ages 18-25)

Idiopathic Hypersomnia (IH) presents a significant challenge to young adults, disrupting their daily lives and impeding cognitive functions, including memory. Despite reports of memory impairment among IH patients, the exact mechanisms underlying these impairments remain unclear. This paper investigates the potential impact of IH on memory consolidation in young adults (ages 18–25) by systematically reviewing existing research and synthesizing findings into five key areas. First, I analyzed foundational research to establish a clinical understanding of IH, emphasizing its defining symptoms (excessive daytime sleepiness (EDS), unrefreshing sleep, and sleep inertia) and the diagnostic challenges posed by overlapping conditions and limitations in testing methods. Second, I investigated the role of sleep inertia in impairing memory encoding and retrieval. Third, I explored how disruptions in non-rapid eye movement (NREM) and rapid eye movement (REM) sleep, both crucial for memory consolidation, result in decreased slow-wave sleep (SWS), increased REM duration, and the prevalence of REM parasomnias. These disruptions, alongside altered cerebral blood flow and incomplete NREM-to-wake transitions, illuminate the mechanisms by which IH may impair memory processing and cognitive function. Fourth, I examined changes in the salience network and default mode network (DMN) associated with IH, highlighting how hypermetabolism in the salience network and disruptions in the DMN interact to potentially impair memory consolidation and cognitive function. Finally, I investigated parallels between IH and major depressive disorder (MDD), focusing on shared mechanisms such as altered regional cerebral blood flow in the medial prefrontal cortex, which impair memory consolidation. Lifestyle factors like substance use, nutrition, and physical activity complicate the relationship between IH and memory. Current research is limited by small sample sizes, lack of diversity, and

insufficient longitudinal studies. Addressing these gaps is crucial to understanding IH-related memory impairments and developing evidence-based strategies to improve cognitive outcomes and quality of life for affected individuals.

Abstract Name: Comparing Variations of Ozone (2005-2024) in Multiple Cities Using Data From Pandora Spectrometer, and EPA Sensors

Ozone (O_3) is a pollutant primarily formed from volatile organic compounds (VOCs) and nitrogen oxides ($NO_x = NO_2 + NO$). While ozone in the stratosphere plays a critical role in shielding the Earth from harmful UV radiation, its presence near the surface poses health risks, especially to respiratory systems. This research examines ozone trends from 2005 to 2024 in Houston, other major U.S. cities, and Singapore. Data for this analysis were collected using the recently installed Pandora spectrometer at San Jacinto College, South Campus in Houston, Texas. The spectrometer is part of the Pandonia Global Network (PGN), a collaboration between NASA and the European Space Agency (ESA). This instrument provides real-time measurements of air pollutants, including NO_2 and O_3 , offering valuable insights into air quality in the Houston-Galveston area. In addition to the Pandora data, we used the Environmental Protection Agency (EPA) ground-based measurements for a broader perspective. By using Python-based data processing techniques, we translated raw measurements into clear ozone trends.

Abstract Name: Predictive Modeling of Surface Roughness in Metal Additive Manufacturing using Machine Learning

To achieve high-quality, additively manufactured metal parts, real-time process monitoring and advanced

predictive modeling of the surface roughness are crucial for accelerating quality assurance in metal additive manufacturing. This study proposes a methodology to improve the quality of additive manufacturing (AM) products based on the data analysis. Surface roughness is one of the important quality indicators and can cause short product life and poor structure performance. The study explores the use of artificial intelligence (AI) and machine learning (ML) models to predict surface roughness in metal additive manufacturing (MAM) with the XM200C powder-bed fusion 3D printer at MSU Denver. Surface roughness is crucial for the performance and reliability of metal parts used in aerospace, automotive, and biomedical applications. Traditionally, manufacturers rely on expensive trial-and-error methods to optimize printing parameters, which this project aims to replace with a data-driven framework. The research team will conduct controlled experiments to gather data on crucial printing parameters, such as laser power, scanning speed, layer thickness, and powder properties. Advanced metrology tools will measure surface roughness, informing the development of predictive AI/ML models. Predictions will be validated against experimental results from test prints. Expected experimental results to show that the predictive models trained by the machine learning algorithms are capable of predicting the surface roughness of additively manufacturing metal parts with high accuracy. Deliverables will consist of an AI/ML predictive tool, detailed experimental findings, and a comprehensive report, marking a significant advancement in additive manufacturing. This comprehensive analysis encompasses the impact of process parameter variations on a wide range of surface roughness values, affirming the efficiency of the proposed methodology.

Abstract Name: Assessing Green Space Accessibility in Urban Communities

Urban environments are continuously evolving, driven by population growth, economic development, and societal changes. As cities expand, the need for sustainable practices that enhance the quality of life for residents has become increasingly apparent. Parks, gardens, and green corridors are just a few of the many components that make up urban sustainability. These areas not only provide essential ecological services but also strengthen the sense of community in urban areas by serving as outlets for recreation, relaxation, and social interaction. The purpose of this study is to assess the accessibility of green spaces within communities, utilizing Geographical Information Systems (GIS) to provide a comprehensive understanding of the importance of green spaces within communities and their role. Using the GIS tool called ArcGIS, this study will evaluate key parameters related to green space accessibility, quality, and distribution across diverse communities. It will also consider other important factors such as health outcomes, social connectivity, and economic benefits. By spatially mapping out green spaces, this research study will explore how disparities in green space access correspondingly correlate with access to green infrastructure and significantly influence community well-being and social cohesion. There will be specific attention to how green spaces promote physical activity, support mental health, and help mitigate environmental issues. The findings from this study will provide insights for urban planners, community stakeholders, and policymakers aiming to enhance urban livability through the introduction of green spaces. By highlighting the multiple benefits of green spaces, the research will advocate for more policies that prioritize access to green infrastructure, contributing to a more sustainable urban environment. Through this initiative, the research seeks to inform the ongoing discourse on urban planning and sustainable development, underscoring the critical role of green spaces in shaping communities.

Abstract Name: Implementing the Odyssey Fc Machine: Developing a Research Module for Classroom Application

Undergraduate research experiences have been shown to be extremely beneficial and contribute to persistence in the STEM major, especially for women and students from marginalized communities. However, all students do not have equal access to these types of impactful experiences. Therefore, the goal of this project was to design a research module within a course that will engage undergraduate STEM students, women of color, in authentic research by making discoveries and practicing scientific skills. The research module was designed to use the Odyssey Fc System to study gene expression in two different types of bacteria: *Enterobacter aerogenes* and *Bacillus cereus*. After completing the research module, students will be able to: develop a research question and hypothesis, understand and apply Odyssey Fc technology, engage in scientific literature, have an increased confidence in conducting research, analyze data and draw conclusions, and develop written and oral communication skills; thereby, preparing them for advanced research and professional careers. This research module not only provides valuable skills transferable to internships and other student research opportunities, but also aims to equip students with the proficiency to utilize the Odyssey machine.

Abstract Name: Towards the development of synthetic ultrasound data for image classification of Obstructed Defecation Syndrome

Obstructed defecation syndrome (ODS) without dyssynergia is a form of constipation associated with structural defects in rectal support. Diagnosing ODS remains challenging due to inter-patient anatomical variability. The overarching aim is to train deep learning models for automated diagnosis. However, clinical image acquisition and manual annotation are time-consuming and resource-intensive. This study investigates the feasibility of generating synthetic ultrasound images using a dual-stage pipeline. In the first stage, Houdini™ software was used to create geometric models representing the rectum, vagina, cul-de-sac, and levator plate using simple geometries. The 3D model was animated to mimic and simulate dynamics observed during ultrasound imaging. The second stage utilizes Field II, a MATLAB-based ultrasound simulation tool, to simulate collecting radio frequency data of anatomic phantoms based on the Houdini model. The radio frequency data was then processed to create synthetic ultrasound B-mode images. One simulation using 50,000 point scatterers in the phantom required approximately 20 minutes to collect 50 lines of radio frequency data. The results demonstrated the pipeline's ability to produce realistic ultrasound images with clear anatomical boundaries. Compared to collecting real clinical images, the pipeline is more time efficient,

allowing for scalability to create batches of models and images. Future work will improve the anatomic accuracy of the model, integrate patient-specific MRI-derived geometries, and refine parameters to match clinical probe specifications. This study establishes the pipeline as a viable method for synthetic ultrasound image generation.

Abstract Name: Identification of Potential Orthologous pmt-2 Genes in Parasitic Nematodes

Nematodes such as *Caenorhabditis elegans* and the parasitic *Haemonchus contortus* share a phosphobase methylation pathway analogous to plants and *Plasmodium* species. This pathway converts phosphoethanolamine (pEA) to phosphocholine (pCho), enabling the Kennedy pathway to produce phosphatidylcholine—essential for phospholipid biosynthesis. This pathway is divided into two functional domains of phosphoethanolamine methyltransferase: N-terminal (PMT-1), which initiates the methylation of pEA to phosphomonomethanolamine (pMME), and C-terminal (PMT-2) that continues to methylate the pMME and the phosphodimethylethanolamine intermediate to yield pCho. In nematodes, the PMTs are encoded by two distinct paralogous genes. There is growing interest in studying the structure and biochemical function of PMT-2 for potential drug targeting, driven by the need to develop novel nematocides that can combat parasitic nematodes that infect animal, human, and plant hosts; fueled by concerns about anthelmintic resistance in nematodes and the rising prevalence of parasitic infections associated with the expanding human population in developing countries. We employed the NIH's Basic Local Alignment Tool (BLAST) to detect probable nucleotide and protein sequences in parasites containing unannotated pmt-2 genes orthologous to those known in *C. elegans* and *H. contortus* across numerous sequence databases. Additionally, the Conserved Domain Search, also provided by the NIH, aided in locating conserved domains characteristic of PMT-2, namely the N-terminal vestigial domain and the S-adenosylmethionine-dependent methyltransferase binding site. The presence of pmt-2 genes was further analyzed using gene prediction software like GENSCAN and GeneID, which are capable of estimating the exons of protein-coding genes that can be used to formulate hypothetical sequences that may be identified in genomes of parasitic nematodes in future studies. To date, we have made predictions for pmt-2 in *Teladorsagia circumcincta*, *Ascaris lumbricoides*, and *Meloidogyne javanica* and plan to expand our predictions to other nematodes listed in the neglected tropical diseases category, as well as those of significant medical and agricultural importance.

Abstract Name: Using Probability to Illustrate the Confirmation Evidence Trap in Diagnosis

The confirmation Evidence Trap The confirmation evidence trap not only changes how we collect or receive

information in the medical field, but also how they interpret the information which significantly contributes to medical bias, affecting diagnosis, treatment, and patient outcomes. In the medical field, this bias manifest when healthcare professionals focus on evidence that confirms their initial assumptions or diagnoses while disregarding an individual's contradictory critical information. Therefore, devising strategies to mitigate the effect of the confirmation evidence trap will be paramount for proper diagnosis

Abstract Name: Feminine Rage: A Study of the Feminine Struggle Through the Eyes of Lilith

The project explores what it means to be a woman in a modern world, to be vilified for being angry about being a woman today, and issues that are far older than they should be. My project aimed to create a series of seven circular large-scale figurative oil/mixed media paintings that contributed to casting a more transparent lens onto the struggles of women in society and the misconceptions of feminine rage. In this, I utilized my double major, English/Creative Writing and Studio/Fine Arts/Painting, to create a visual narrative of the biblical figure Lilith embodying/being afflicted by the seven deadly sins. Each painting is also accompanied by several playlists specially curated for each individual piece.

Abstract Name: Finding Alternative Ways to Engage in Meaningful Research at Primarily Undergraduate Institutions: Inclusive CUREs and Protocol Alternatives

Research at Primarily Undergraduate Institutions (PUIs) is critical for several reasons. Among them are student growth and development, collaboration in and outside the institution, and contribution to the field. St. John Fisher University is a PUI in Rochester, NY where we have begun to pilot two primary ways to enhance undergraduate research experiences at a PUI. First, the Division of Life Sciences has committed to ensuring a Course Based Undergraduate Experience (CURE) to all majors to all of inclusive access to research. This is paired with an optional elective that further allows for the enhancement of student experiences. Further, use of soft skill building, inclusive teaching, and open pedagogy are used within in the source. Second, within our lab specifically we have continued the tradition of finding affordable means to conduct relevant cell and molecular techniques for advanced research. Jointly, more affordable research further increased inclusive access to research as we provide more opportunities for all to research. Here we propose to share our insights into the importance of inclusivity and ingenuity in the research setting. It is our hope to continue to expand the long standing tradition of meaningful research at PUIs; and to do so by engaging in meaningful conversation and community through discussion at NCUR.

Abstract Name: Housing Design for Multi-Generational Families and Visual Identification for Age-Related Macular Degeneration.

This project aimed to design a single-family residence for an older adult with age-related macular degeneration (AMD). The target user had recently been diagnosed with late-stage AMD. Research was conducted to target the user's needs. These findings were collected through online resources, two case studies, and interviews with a family member who has also experienced AMD. Additionally, the project involved researching inclusive design features suitable for individuals with visual impairments. The residence incorporated key design features such as North and South window orientation to ensure consistent natural light, even lighting layers to avoid large pools of light, high contrast for better visibility, color-coded rooms for easy identification, pocket doors for minimizing door swing interference, and textured wainscot for wayfinding. The home featured innovative technology, including a voice-controlled shower and refrigerator. Accessibility features applied to this house were oversized cabinet hardware, under-cabinet lighting, wider 36-inch doors, wide enough room size for improved mobility, and non-slip floor materials for safety. The kitchen and laundry room design included integrated eye-level storage, continuous countertops, soft-close drawer glides, a pull-out pantry, textured sink fronts and backsplashes for identification, and a higher toe kick for convenience. These accessible and inclusive design solutions support both safety and independence for the user and contribute to long-term independence and quality of life.

Abstract Name: The Effects Nutrient-Limited Conditions Have on Prasinophyte Mixoplankton

Mixoplankton are marine protists that have the ability to perform both phototrophy and heterotrophy. Their ability to switch between these trophic modes makes them vital components for the health of marine ecosystems on a global scale. However, not much is known on when these mixoplankton switch between feeding methods and what causes them to do so. Prasinophytes are one of the earliest lineages of green algae, and have been classified as strict phytoplankton. Recent studies have shown that under low nutrient conditions, certain strains of prasinophytes were seen to switch from phototrophy to heterotrophy, indicating that some may exhibit mixotrophic traits. With this newfound information, we want to further investigate if a certain strain of prasinophyte, *Cymbomonas tetramitiformis*, presents this mixotrophic switching by placing it in nutrient-limited environments. By growing *Cymbomonas tetramitiformis* in a full nutrient medium, a diluted version of the full nutrient medium, a full medium with low nitrate, and full medium with low phosphate, we expected that the prasinophyte strain would switch from autotrophy to heterotrophy. We observed how *Cymbomonas tetramitiformis* reacts under certain nutrient-limited environments based on growth observed overtime. *Cymbomonas tetramitiformis* showed little growth in the diluted full-nutrient

medium and the low nitrate medium, with no growth shown in the low phosphate medium. The results in the nutrient-limited treatments indicate that there was an attempt to switch to phagotrophy which resulted in slower growth under phototrophy. We plan on performing feeding experiments to confirm that the strain did switch trophic modes. Understanding the feeding mechanisms of prasinophyte mixoplankton can aid in uncovering more about their lineages to see where these traits arose from, and allows for future research on the impact these organisms have on marine environments overtime.

Abstract Name: The impact of global CREBRF overexpression on energy homeostasis

Causative genes and underlying mechanisms of obesity, a global health threat, remain largely unexplained despite the high prevalence and heritability of the condition. Though obesity is typically associated with metabolic dysregulation, a subset of individuals have been identified to have a missense variant that confers protection from these metabolic disturbances. The CREBRF-R457Q variant is associated with an elevated risk of obesity while paradoxically protecting against type 2 diabetes in humans. Prior in vitro studies have demonstrated the CREBRF variant's role in promoting cellular lipid storage and cellular energy conversion. However, neither the function nor the mechanism of action for the gene has been established in vivo. A murine model was generated with CREBRF overexpression to better understand CREBRF's impact and complications. We hypothesized that global overexpression of CREBRF in mice will replicate the metabolic phenotypes associated with the CREBRF-R457Q variant, illuminating its role in energy homeostasis. To test this hypothesis, global transgenic CREBRF and control mice were given either a sucrose-matched low-fat or high-fat diet until sacrifice at 22 weeks. During this 22-week period, the mice's energy, glucose, and lipid homeostasis were assessed. Results indicated that global CREBRF overexpression increased lean and fat mass, and body weight, and that total body and fat mass are further exacerbated by chronic nutritional overload. Furthermore, the transgenic mice's length increased, consistent with existing data indicating an increase in heights in human individuals with the CREBRF-R457Q missense variant. In addition, the variant, despite contributing to an excessive increase in body weight, positively influences lipid homeostasis regulation through the reduction of non-esterified fatty acid, triglyceride, and cholesterol levels. These findings offer novel insights into CREBRF's role in energy and lipid homeostasis, paving the way for future therapeutic strategies targeting obesity and related metabolic disorders.

Abstract Name: Application Development of Digital Safety for Women

The increasing prevalence of unsafe environments for women highlights an urgent need for innovative

solutions to enhance their security. This research focuses on developing a mobile application tailored to address key issues related to women's safety. The app's design is based on findings from the literature on gender and safety, which suggests that women's mobilities are inherently precarious, due to pervasive sexual violence against women and also draws from semi-structured interviews with women focused on safety and digital technology use. The PI and undergraduate researcher analyzed this data, finding that women have concerns about accessing these apps in moments of crisis, maintaining a sense of privacy and autonomy when using location-sharing features, and using these apps when cell services are unavailable. Based on these findings, the PI and undergraduate researcher developed a high-fidelity prototype of a mobile safety application that addresses these concerns. They engaged user testing of the application, refining the design with features that accommodate user needs and promote safety. It incorporates features such as ad hoc location sharing, customizable emergency alerts, and discreet communication options for use during dangerous situations. By analyzing gaps in existing safety tools and leveraging user insights, the project emphasizes the importance of accessibility, adaptability, and reliability in designing digital solutions to the complex social problem of women's safety. Beyond technology, this initiative advocates for systemic change by promoting awareness of responsive safety measures and highlighting the need for policies that prioritize women's well-being. Additionally, this project offers app design recommendations, explores user-driven functionality, and discusses broader implications for fostering safer, more inclusive communities.

Abstract Name: Evaluation of ICAM-2 expression in patient-derived xenograft models of neuroblastoma

Neuroblastoma is the most common extracranial solid tumor of childhood and accounts for ~15% of all cancer-related deaths in children. Most children with high-risk neuroblastoma survive less than 5 years. Our laboratory investigates mechanisms of neuroblastoma progression and metastasis, with a long-range goal of developing effective therapies that prevent or slow relapse with metastatic disease. We recently made the novel observation that intercellular cell adhesion molecule-2 (ICAM-2) delays the development of disseminated tumors in a mouse model of metastatic neuroblastoma. We identified the cytoskeletal linker protein α -actinin as a binding partner of ICAM-2 and observed that this binding functions to suppress metastasis. Further, this binding is essential to the suppression of metastatic progression. Importantly, and relevant to the proposed project, we observed that primary human neuroblastoma cells expressing ICAM-2 have limited metastatic potential. The goal of the current study was to immunostain for ICAM-2 in our recently developed patient-derived xenograft models of neuroblastoma, to begin to identify correlations between stage and ICAM-2 expression and between stage and subcellular localization of this protein. We developed these models, Stage I-III, to implant directly into immunodeficient mice. Our published data document that SK-N-AS neuroblastoma cells transfected to express ICAM-2 express readily detectable levels of this protein and do not form metastatic tumors when implanted into immune-deficient mice. In contrast, control SK-N-AS transfectants express no detectable ICAM-2 and do form metastatic tumors in vivo. For the current project, we used an ICAM-2 specific antibody to immunostain thin sections of 5 patient-derived xenograft models derived from these tumors. The data will address the level of expression of ICAM-2 in specimens of neuroblastoma tumors.

Abstract Name: The Effect of Raptinal on Apoptosis in Melanoma A375 Cells

Melanoma is the most aggressive form of skin cancer that can become life threatening in only six weeks. Cancer cells can become resistant to current treatment options, which often target the RAF/MEK/ERK signaling pathway to mitigate deregulated cell proliferation. Raptinal has been shown to induce rapid and reliable activation of the intrinsic apoptotic pathway in several other cancer cell lines. However, its effect on A375 human melanoma cells have not been investigated. We were therefore interested in examining whether Raptinal could induce concentration dependent apoptosis of A375 cells. XTT viability assays showed that viability decreased to 60% in cells treated with 2 μ M Raptinal and further decreased to 43% upon treatment with 10 μ M Raptinal. PARP cleavage was evident in cells treated with 2-10 μ M concentration of Raptinal, indicating that apoptosis was induced in treated cells. As the MAPK signaling pathway has been shown to induce apoptosis of cancer cells when treated with certain drugs such as cisplatin, we examined the phosphorylation status of ERK. Activation of ERK, as indicated by phospho-ERK (p-ERK), was observed in cells dosed for 12 and 24 hours with Raptinal. We have shown that Raptinal induced apoptosis of A375 cells in a concentration dependent manner, and future objectives are to investigate whether the inhibition of ERK MAPK signaling is required for the induction of apoptosis by Raptinal.

Abstract Name: Universality Laws in Pure Fluids and Critical point Experiments Under Density Gradients

Critical fluids have properties that deviate from typical fluids; for example, some quantities present a divergence in power laws when the temperature is very close to the critical temperature. We investigated two critical fluids, critical oxygen under magnetic levitation and sulfur hexafluoride in microgravity conditions. The topics of the first project show that turbidity data, a quantity due to density fluctuations, can be directly obtained from image analysis. We fitted the turbidity to a theoretical expression and estimated the isothermal compressibility and correlation length. The second project focused on the late-stage phase of SF₆ in microgravity after quenching from the critical point. We studied the distribution of the radius of vapor/gas bubbles as a function of time and found that it could be well approximated by lognormal functions and the bubbles shifted to a smaller radius over time. We observed binary coalescence events during the phase separation process and small droplets presumably generated by condensation.

Abstract Name: Modeling Decisions in Crisis: A Game-Theoretic Analysis of the 988-Suicide Prevention Hotline

This study examines the decision-making processes surrounding the use and referral of the 988-suicide prevention hotline through a game-theoretic model incorporating dynamic utility functions and prospect theory. Analyzing survey data from a national sample of 1,694 teens on Personal Use and 1,569 teens on Referral Behavior, we categorized key positive and negative factors such as HELPFUL, POLICE INVOLVEMENT, RESOURCE, and CARE FRIENDS. The data was analyzed by applying logarithmic and square root utility functions to quantify the net utility for both the Caller and the Referrer, incorporating loss aversion to reflect the disproportionate impact of negative factors. The findings reveal that both players are disincentivized primarily by negative perceptions, leading to a Nash equilibrium of disengagement. Simulated scenarios, adjusting the weights of positive motivators and reducing negative deterrents, demonstrate that improving the hotline's perceived helpfulness and mitigating negative perceptions significantly increase engagement, highlighting the importance of a holistic and critical intervention approach.

Abstract Name: Deaths of Despair in Virginia: Analyzing Socioeconomic Factors and Demographics

"Deaths of despair", a term coined by Anne Case and Angus Deaton in 2015, refers to fatalities from suicide, drug overdose, and alcohol-related diseases. Over the past twenty years, the U.S. has seen a significant rise in deaths of despair (DOD). Reflecting this national trend, Virginia, and Appalachia overall, experienced a significant increase in these deaths in 2019, primarily driven by a rise in drug overdoses that disproportionately impacted economically disadvantaged areas. Our study examines the socioeconomic factors and demographics of DOD in Virginia from 2018 to 2022. We utilize county-level socioeconomic data from the 5-year American Community Survey (ACS) and death rates from the Centers for Disease Control and Prevention (CDC). We document gaps in DOD rates across different demographic groups, including sex, race, and age. Using ordinary least squares (OLS) regression, we analyze the relationship between education, income, and employment rates and the incidence of DOD. Our findings indicate that populations with lower educational attainment, higher poverty rates, and higher unemployment rates are most susceptible to DOD. Aligning with previous literature, our study suggests that middle-aged, White males represent highest rates of DOD, but in 2022, African Americans surpassed the White death rate in Virginia, representing a substantial demographic shift. By assessing correlates and demographics associated with DOD, we highlight the need for targeted interventions and suggest potential directions for future research.

Abstract Name: Birds of a feather compete together? Modeling homophily across stakes and backgrounds

This study investigates the conditions under which homophily—individuals’ tendency to form ties with those who share their demographic attributes—affects team formation under different task contexts. Homophily is traditionally understood as an overarching principle of social network formation, but a growing body of observational research suggests that it is inconsistently expressed depending on task demands and participant factors. We designed a controlled experiment in which participants, serving as team leaders, selected teammates from a demographically diverse pool for tasks with varied stakes and objectives. Specifically, we compared a low-stakes, collaborative scenario focused on improving a community space with a high-stakes, adversarial setting, where participants faced greater performance pressures. In our experiment, participants made social tie decisions using a “group ranking” approach and a pairwise selection mechanism. The group ranking condition allowed participants to sort all potential teammates at once, encouraging comparative evaluations that might accentuate or diminish demographic preferences. By contrast, the pairwise task forced direct comparisons between two candidates at a time, potentially highlighting more granular biases. Through these complementary methods, we sought to discern whether participants rely on stable demographic heuristics or adjust their strategies according to contextual demands and selection formats. Preliminary analyses indicate that homophilic sorting, while present in more relaxed, cooperative tasks, attenuates in higher-stakes, adversarial scenarios. Under greater competitive pressure, participants appear more willing to set aside demographic similarity in favor of perceived skill or other advantageous attributes. Our results suggest that homophily is not a universal principle of team formation, but rather a flexible strategy that individuals variably deploy in response to task demands.

Abstract Name: The Evolution of Human Rights Throughout the 1940s

What are human rights? The loaded term seems to have always existed. It plagues news headlines, books, and day-to-day rhetoric. However, the specific definition of human rights and how they should be enforced has rarely been clear. My research explores how the concept of human rights evolved throughout the early 1940s, as the Second World War made people yearn for peace through a “One World” that would potentially ensure international protection of human rights. Through the announcement of the Four Freedoms, the Atlantic Charter, and the Declaration of the United Nations the term human rights became more prevalent by the 1940s. Yet, the interpretation of the concept varied. Many scholars circumvented the term, taking advantage of its vagueness. The Catholic church paraded the term around, declaring its all-time commitment to protecting rights and religious freedom. Others tried to connect the term to natural law, searching for differences between the concepts. Only a few attempted to define human rights and generate meaning from the definition. One of these scholars was Quincy Wright, an American lawyer, who ventured to figure out how difficult it would be to set up an intentional institution to protect human rights. He highlights the difference between positive and negative rights, with negative rights being easier to protect through policy than positive ones. Yet, other scholars were against the international protection of human rights, such as

opposing scholar Frank Holman who believed America should keep to itself rather than take the lead in global affairs. The complex conversations, and lack thereof, that occurred surrounding human rights in the 1940s are monumental to understanding why, to this day, granting universal rights seems impossible. It gives clues as to why policy to protect human rights has become so complex, as national sovereignty and cultural differences rise as key issues.

Abstract Name: Dragon Ladies and Lotus Blossoms: Deconstructing the Colonial Fantasies of Southeast Asian Women

Western perceptions of Asian women have always been rooted in the fascination of the exotic Other. Through concepts such as dragon lady and lotus blossom, this view is clear; fierce and hyper-sexual, while also obedient and pure. Despite this being applied to women throughout the continent, Southeast Asian women have a particularly unique experience due to Southeast Asia's strained relationship with the United States - one full of colonization, exploitation, and violence. This study examines the fetishization and objectification of Southeast Asian women in the U.S. by considering the intersections of race, gender, and Orientalism through an analysis of scholarly literature. The U.S. involvement in the region will be highlighted to give background information on the history and origins of such ideas. From there, the connection between contemporary notions of Southeast Asians and Asian women will lend itself to a better understanding of what it means to be a Southeast Asian woman in the U.S., how Orientalism plays a part in day-to-day life, and what steps can be taken to decolonize the Southeast Asian female body.

Abstract Name: FTY720 as a potential drug treatment for activating pro-survival pathways in NPC Disease Models.

Niemann-Pick disease type C (NPC) is an inherited lysosomal storage disorder characterized by cholesterol and sphingolipid accumulation, leading to complex progressive neurodegeneration and death. The S1P/S1PR axis is a ligand/receptor combination involved in NPC pathology, and the binding of extracellular S1P to S1PR activates a pro-survival intracellular signaling pathway unique to each S1PR isoform, providing potential therapeutic targets. FTY720 is a high-affinity ligand agonist of S1PR1 and has been shown to decrease cholesterol and glycosphingolipid levels in NPC1 mutant fibroblasts as well as activate the synthesis of cytoprotective proteins through distinct pro-survival signaling pathways. However, it is unclear if FTY720 activates these pro-survival pathways in NPC knockout cells. Current therapies for NPC disease have shown the involvement of the S1P/S1PR axis in alleviating symptoms of NPC models. However, current treatment effects are suboptimal, underscoring the need for additional therapeutic options. Preliminary data confirms significantly increased cell death in HeLa NPC KO compared to WT ($p = 0.0028$) and treatment of HeLa KO

NPC cells with 2 uM FTY720 did not significantly reduce cell death. A dose escalation study will be performed with increasing concentrations of FTY720. Additionally, western blot analyses will be conducted to examine the pro-survival proteins AKT and MEK, which are modulated by the S1P/S1PR axis. Understanding FTY720's role in pro-survival signaling pathways of S1PRs could lead to significant developments in new therapeutic approaches to treating NPC disease and other neurodegenerative diseases.

Abstract Name: Women of the Night: A Study on Indian Women Employed in the Business Process Outsourcing Sector (BPOs)

Since 1990, the female labor force participation rate in India has declined. Moreover, in the 2023-24 Women Peace and Security Index, India was ranked 128 out of 177 countries in terms of women's security. Additionally, in recent decades, cities like Bengaluru have begun to globalize and offer more job opportunities to women, especially within the business process outsourcing sector (BPOs). Since many BPOs operate in the United States and Canadian time zones, many women employed in the BPOs work the night shift. As a result, more Indian women now interact with public spaces at night while simultaneously navigating Indian sociocultural norms and stereotypes of respectability, which dictate that Indian women should avoid public spaces, especially at night. Furthermore, while literature exists on physical mobility, respectability, and women's economic opportunities, we know little about how ideas of both physical mobility and respectability affect the future economic opportunities of women employed in BPOs, specifically those working the night shift in Bengaluru. This research seeks to fill this gap by answering the following question: How do physical mobility and ideas about respectability affect the future economic opportunities of women employed in business process outsourcing centers (BPOs) working the night shift in Bengaluru, India? 13 semi-structured interviews with Indian women working the night shift in BPOs revealed themes surrounding safety, health, and fertility concerns, changes in night-shift perceptions post-marriage, and strict company policies. The research concludes that the themes, explored through anecdotes, illustrated how ideas of respectability impacted Indian women's physical mobility, often hindering future economic opportunities. The study strongly advocates for greater inclusion of women's voices in developing company policies on women's safety and calls for broader public education on the role of women in the BPO sector to increase Indian women's economic opportunities and participation in the formal labor force.

Abstract Name: Emotional Appraisal of the Hindustani Classical Raag System

Do all humans have similar emotional appraisals of music? Experts in North Indian Classical [Hindustani] Music ascribe emotional responses to melodic structures [Raag]. While research into the emotional appraisal of Western scales exists, there is little research into the universality of emotional appraisal of Hindustani Music. To what extent do demographics, training, and culture influence this association of a Raag and its emotional appraisal? If strong emotional associations are identified, these may be utilized in emergent Raag-based music therapy, applicable to diverse demographics. Participants (n=665) were provided with a survey where they were prompted to listen to vocal recordings of compositions in four Raags, each associated with a dominant emotional response. For each clip, participants were asked to choose one among four options of emotions they experienced. Recorded factors included demographics (age, gender, ethnic background), familiarity with Indian and non-Indian Music, and understanding of lyrics. A numerical score for each participant's response was assigned relative to the "correct" response, and a frequency distribution of emotional response accuracy was generated for each Raag and factor. Statistical tests conducted rejected the null hypothesis that the distribution was uniform across emotional responses. To analyze the relative importance of different factors, a Random Forest classification algorithm was implemented. Age is the most important factor in response accuracy: younger participants more correctly/consistently identify the correct emotional response. Interestingly, expertise in Indian and non-Indian music or understanding lyrics does not correlate with higher accuracy. The results strongly suggest the universality of Raag-based music's emotional appraisal, which suggests a promising applicability to music therapy.

Abstract Name: Endothelial cell HDAC1 mediates vascular and kidney damage in diet-induced obesity

Histone deacetylase 1 (HDAC1) is an enzyme related to direct post-translational deacetylation of proteins. HDAC1 increases risk of cardiovascular disease (CVD). Endothelial dysfunction is related to nitric oxide (NO) reduction. Endothelial dysfunction is a major mechanism initiating organ damage in CVD. Our lab has shown that overexpression of HDAC1 in endothelial cells (ECs) reduces NO production, suggesting that HDAC1 may mediate endothelial dysfunction. Obesity is a major risk factor for CVD. Mice fed high fat diet have endothelial dysfunction, vascular damage, and kidney damage. We hypothesized that EC HDAC1 mediates vascular and kidney damage in a model of diet-induced obesity (DIO). Our lab generated tamoxifen inducible EC specific HDAC1 (iEC-HDAC1) wild-type (WT) and knockout (KO) mice. We utilized a 20-week DIO (45% high fat) protocol. We gave tamoxifen at week 17 of DIO and assessed vascular and kidney damage at week 20. Vascular function was assessed by pulse wave velocity (PWV) to measure aortic

stiffness. Male iEHDAC1KO DIO had significantly reduced PWV compared to iEHDAC1WT DIO mice ($p=0.0018$). There were no differences in females. Kidney damage was assessed by measuring tubular vacuoles and interstitial fibrosis with histology. We found that iEHDAC1KO DIO males showed reduced tubular vacuoles and interstitial fibrosis compared to iEHDAC1WT DIO males (Vacuoles: $p=0.0118$, Interstitial Fibrosis: $p=0.0228$). No differences were observed in females. Our data indicate that DIO mediates vascular and kidney damage through EC HDAC1-dependent mechanisms in male mice only. Future studies will investigate mechanisms of how EC-HDAC1 drives damage in male DIO mice.

Abstract Name: Design and Synthesis of Inhibitors Targeting c-MYC in Cancer Treatment

Myc is a family of proto-oncogenes that encode for transcription factors. In healthy cells, these transcription factors, namely c-Myc, regulate a variety of important cellular processes, including cell growth, division, metabolism, differentiation, and apoptosis, among others. When Myc and its associated transcription factors become dysregulated, they drive a series of harmful changes, such as genomic instability, uncontrolled cell proliferation, and cellular immortalization—hallmarks of tumor pathology. The effects of Myc are not exclusive to certain parts of the body, gender, age, or tumor type and are observed in over half of all human cancers. Previous studies have elucidated that small molecules can inhibit the heterodimerization between c-Myc and its zip partner, Max, and effectively silence all Myc activity in the body contributing to significant tumor regression. Complete silencing of Myc in the body has been shown to result in only mild and reversible side effects. Targeting the c-Myc-Max protein-protein interaction is a promising strategy for cancer treatment, particularly given the toxicity and invasiveness of current cancer therapies. This project aims to develop and synthesize small-molecule inhibitors to inactivate c-Myc-Max interaction. We seek to improve upon the metabolic stability, potency, and affinity to the c-Myc binding region of previously tested inhibitors using SAR analyses. Specifically, we aim to develop a series of oligoamide analogues for their ability to mimic characteristics of the alpha-helices involved in the c-Myc-Max interaction. A general synthetic route has been designed to create a series of O-alkylated monomers and construct the oligomer using a facile amide bond formation. Further work will include validating the inhibition of c-Myc dimerization and transcriptional activity in vitro. The development of effective inhibitors could provide a novel and preferred treatment option for cancers influenced by c-Myc activity.

Abstract Name: Designing a Novel and Effective Childproof Gun Lock for Gun-Owners Families

Our project aims to create a novel and effective gun lock that is child-proof but allows adult owners to access their firearms hassle-free. According to research collected in 2022, more children in the United States were killed by guns compared to any other cause of death. This trend has been consistent for the past four years. Unnecessary deaths, especially accidental ones, can vastly be prevented if guns are more securely stored in homes. Starting with our local community in Southwest Virginia, we have researched the types of guns that families most commonly own. These gun types include shotguns, rifles, and handguns. Our current design is modeled around a handgun and consists of three main parts that we have 3D-printed. There is a box around the trigger which is secured to the gun using child-proof velcro. A top component goes around the barrel of the gun and secures the velcro in place. Lastly, we use multiple long connecting pieces to hold the trigger box and top component together. Our gun lock has multiple parts to ensure that children do not have access to the trigger. Adults can still assemble and remove the gun lock due to our ergonomic design. Compared to currently existing cable locks and gun safes on the market, our design makes sure that the trigger itself is securely encased. Working in conjunction with students at our local medical school, we plan to get feedback on our design from multiple stakeholders, including gun-owning families that have children. We will then apply this feedback to refine our design and work towards making it more adjustable to guns of all sizes. Ultimately, our project will allow adults to more safely own and store firearms in households with children.

Abstract Name: Analyzing Sleep Waves in Monkey Cortical and Subcortical Areas

Sleep disturbances are common in psychiatric disorders, yet there have been limited sleep-based biomarkers. Conventional sleep measures are often of low resolution, low throughput, with poorly understood neural mechanisms and potential applicability to diverse psychiatric conditions. We recently discovered in rats a surface electroencephalogram (EEG) signature – a modified EEG theta-delta-theta peak (EEGTDT) ratio – which provides a high-resolution metric for assessing quality of rapid eye movement sleep (REMS). EEGTDT ratio closely tracks the second-to-second dynamics of population activities of melanin-concentrating-hormone (MCH) neurons in the lateral hypothalamus – a group of neurons that critically regulate sleep, emotion, and reward. Hence, EEGTDT ratio-based evaluation of REMS may provide novel biomarkers for psychiatric conditions. A critical knowledge gap in translating EEGTDT ratio from rodents to human lies at the different sleep wave forms and frequency compositions across species, and our lack of understanding on how different features of EEGTDT ratio may be produced and regulated between subcortical and cortical regions. Here we take advantage of monkey cranial EEG and intracranial mesoscopic local field potential (LFP) recordings during sleep to analyze EEGTDT ratio dynamics in sleep. Mesoscopic recordings are achieved by tessellating the volume of an entire macaque hemisphere with 992+ intracranial electrode contacts. Contacts are distributed across chronically implanted multi-electrode shafts, forming an approximately regular three-dimensional grid with 5 mm or less between adjacent electrode contacts. We asked the following questions: What are the appropriate frequency bands for calculating monkey EEGTDT ratio? What are the spatial and temporal distribution patterns of LFPTDT ratio across brain regions and sleep states? What are the relationships between surface EEG and intracranial LFP regarding the TDT ratio? Answering these questions will provide key insights into the spatial temporal organizations of EEGTDT ratio features and critically bridge rodent-to-human transitions for the development of EEGTDT ratio-based biomarkers.

Abstract Name: Restrictive Contexts, Organizational Attributes, and Operation of Local NGOs in Northeast India

Scholarship has explored the operation of international non-governmental organizations (INGOs) under restrictive contexts and how their organizational attributes influence their experiences of the restrictive contexts and the adaptive strategies they employ. However, there is a gap in the understanding of how local NGOs may differ from INGOs in their responses to these restrictive contexts. This study aims to examine the experiences of local NGOs under restrictive contexts, how they experience and adapt to these restrictive contexts, and how their organizational attributes impact these experiences. This research will focus on local NGOs operating in Northeast India, as this region is underrepresented in existing literature and offers opportunities to analyze a range of restrictive contexts, including funding restrictions and government scrutiny, regional conflict, and limitations in resources and support for NGOs in the region. Interviews with 13 NGO staff members from local NGOs in Delhi and Assam revealed nuances and variations in the correlation between organizations' responses to restrictive contexts and their organizational attributes, such as size, mandates, location, funding portfolios, and principles. It is thus recommended that local NGOs operating in Northeast India consider partnering with organizations in Delhi in a capacity that does not involve funding or subgranting. These partnerships can help local NGOs raise awareness about their programming, while increasing support and access to resources for their initiatives.

Abstract Name: Evaluation of CRISPR/Cas knockdown of glutathione-dependent genes in Group B Streptococcus

Group B Streptococcus (GBS) can cause meningitis and pneumonia in infants. Glutathione, a small molecular tripeptide, protects GBS against damage caused by oxidative stress and synthesis of glutathione can contribute to GBS virulence in mice. CRISPR/Cas9, a gene-editing tool, can be used to target and disrupt genes involved in glutathione metabolism in GBS. This project's focus is to apply CRISPR interference (CRISPRi) to knockdown specific GBS genes involved in glutathione synthesis (gshAB) and glutathione import (gshT and tcyABC) to examine how glutathione metabolism affects the growth and/or virulence of GBS. We designed oligonucleotides to synthesize double-stranded protospacers to use as guide RNAs to insert into the plasmid p3015b, a shuttle plasmid used for CRISPRi in GBS. We digested both p3015b and the protospacers with BsaI and ligated the protospacers into individual linearized p3015b plasmids. Transformations of ligation reactions were performed in chemically competent *E. coli*, and single colonies were counted to determine transformation efficiency. The resulting plasmids containing the protospacers were confirmed by restriction enzyme digestion and DNA sequencing. Confirmed plasmids will be transformed into electrocompetent GBS and phenotypic expression in silenced versus wild-type genes will be studied. We will also compare the knockdown of gshAB to our gshAB knockout strains of GBS. These results will show how CRISPRi can be used to study glutathione metabolism in GBS.

Abstract Name: Analysis and Forecasting of U.S. and Japanese Economic Indicators

This study investigated the prolonged yen depreciation against the U.S. dollar following the Corona pandemic, a trend that defied expert predictions, and its subsequent rapid appreciation. Additionally, the research explored connections to mathematics and artificial intelligence (AI), culminating in using deep learning for predictive modeling. Generally, exchange rates, interest rates, and inflation rates exhibit interdependence under normal conditions. However, extraordinary events can disrupt these relationships. Hence, the study visualized time-series data of these three economic indicators from 2000, identified anomalies in graph fluctuations, and analyzed their correlations with global events during the same period. The originality of this study lies in focusing on interrelationships among these economic indicators and contextualizing them with broader global developments. Key events associated with rapid inflation rate changes included the 2008 Lehman Shock, quantitative easing policies under Abenomics in 2013, fiscal spending during the COVID-19 pandemic, and the surge in oil prices post-2021. Each event corresponded to distinct economic outcomes: rising prices and yen depreciation in 2008, stable prices but yen appreciation in 2013, and simultaneous price increases and yen appreciation after 2022. Japanese interest rates also exhibited notable patterns: a sharp decline in 2008, a sustained decrease from 2013 to 2017, and a negative one since 2017 (data sourced from BIS Statistics). Graphical trends revealed distinct characteristics during each anomaly. The analysis extended to predictive modeling targeting dollar-yen exchange rates using DataRobot, an AI-driven platform that automates machine learning and data analysis. The model employed was an elastic net regressor (L2 / Poisson Deviance) with forecast distance modeling, combining ridge regression and LASSO regularization to manage missing values and perform rigid transformations. Model validation yielded a mean absolute error of 1.9147 and a prediction accuracy of 54.8%. This study presents findings from both the data analysis and machine learning model.

Abstract Name: Making Brain Tumor Detection More Accurate: Fuzzy Means Clustering and Convolutional Neural Network Integration

Accurate and swift detection of brain tumors from MRI scans is very important for the treatment of patients, yet it remains a challenging task for a doctor to perform manually. Present techniques are heavily dependent on individual doctors examining such scans-a time-consuming process that might result in different opinions from different doctors. This research effort combines two powerful computer techniques to help solve this

problem and make brain tumor detection more reliable. The first, Fuzzy Means Clustering, is particularly good at detecting the unclear or fuzzy tumor boundary in brain scans—a very similar process to the human expert searching for subtle differences in the images. Unlike traditional computer programs, which make strict yes-or-no decisions, this method can handle uncertainty in the images, making it especially suitable for medical diagnosis where boundaries aren't always clear-cut. The second technique, Convolutional Neural Networks, is very good at learning to recognize patterns in images after being trained on many examples, like how humans learn to recognize objects through experience. By combining the two methods, we have created a system capable of recognizing brain tumors with an accuracy of over 95%, and more speedily than in traditional methods. More importantly, it provides clear explanations for decisions to support doctors in understanding and verifying the results rather than just giving them a black-box answer. Early testing shows this combined approach not only to be more accurate but also much faster than current methods. This may help doctors make quicker and more reliable diagnoses, which could lead to earlier treatment for patients. The real impact such research can have on healthcare involves the fact that physicians would, for the first time, have a dependable means of diagnosing brain tumors, which will expedite proper treatment for patients while also lessening the burden for medical professionals.

Abstract Name: Temperature Predictions for South America using an Auto-ARIMA Time-Series Based Algorithm

This analysis focuses on modeling temperature change in South America, a region particularly vulnerable to the impacts of climate change due to its diverse ecosystems, from 1917 to 2020. We hypothesize that ARIMA-based predictive algorithms can help us understand future global temperatures and find preventive measures for environmental disasters. The proposed ARIMA model was applied to test data obtained from Kaggle, which includes temperature changes in the South American region over the last century. ARIMA is a time series algorithm that employs an autoregressive integrated moving average technique to model data for future predictions. The model performed moderately across all regions, with root mean square error (RMSE) values averaging 0.42 in South America during the months of Summer. Significant temperature changes over select months in South America contribute to extreme environmental events, such as the landslides in Colombia (2017) and the volcanic eruption in Chile (2015). For summer data in South America, temperatures transitioned from a decrease of 0.4°C in 1960 to a projected increase of 2°C by 2030, indicating a sharp rise even without accounting for external factors. Including external influences like carbon emissions and energy consumption may improve the model's accuracy, offering deeper insights. This enhancement would also enable the identification of key factors that cause temperature anomalies, allowing for targeted strategies to fight global warming. Using external factors with natural variability will also help predict region-specific solutions and policies. Similar analyses conducted for other regions revealed similar trends, suggesting that temperature fluctuations will significantly increase compared to current temperature value. This research aims to explore time series-based algorithms, their applications, and their performance limitations. A detailed analysis will be presented at the conference.

Abstract Name: Assessing Transgender Physical and Psychological Safety at a University: Suggestions for Administrative Reform.

Psychological safety refers to an organization wherein one feels included and can challenge the status quo without fear of negative consequences, whereas a physically safe environment is free from violence and threats of violence. Therefore, a sense of safety is essential for a person's wellbeing. Transgender college students who participated in previous studies have reported alarming levels of transphobic harassment and discrimination. Environments high in such incidents can be considered both psychologically and physically unsafe for trans people. Transgender students at a land-grant University were asked whether they felt safe. If transgender students feel unsafe, what dimensions of their safety concern them most, and what could the University Administration do to be more supportive? This study designed and applied a 60-question self-report survey to assess the perceived psychological and physical safety of 26 trans individuals currently enrolled at or recently graduated from a large University. A total of 57 cisgender students, serving as a comparison group, took the same questionnaire. Results have provided insight into where, on both a policy and community level, the university could improve at serving its transgender students. Regarding psychological safety, trans students expressed 20% more concern about the behavior of peers, faculty, and staff than did their cis peers. Of the transgender respondents, 88% had been in a situation on campus where they felt threatened because of their gender presentation, compared with only 17.9% of cisgender respondents. Additionally, transgender participants felt less supported by and were less likely to access the University administration, and were more concerned about the behaviors of faculty, staff, and other students toward themselves. The data suggest a need for the University administrators to be more sensitive to the specific and unique challenges of transgender students, and to consider implementing a large-scale intervention to reduce gender identity-based stigma.

Abstract Name: Equity vs. Efficiency, the sensitive balance in electoral pledges: a methodological proposal

Equity and efficiency are fundamental concepts in both economic theory and everyday language. The tension between these principles, often referred to as a trade-off, has been a subject of extensive debate, with scholars like Okun (1975) arguing for its existence. Conversely, other researchers such as Atkinson (2009) and Kenworthy (2000), have challenged the notion of an inherent conflict between the two. This study seeks to propose a methodology that allows to identify this trade-off in electoral pledges and preferences in the case of the last three mayoral elections in Medellín, Colombia. By focusing on voter behavior, the research aims to analyze individual preferences and perceptions regarding this dilemma, offering insights into the interplay

between these concepts in electoral decision-making. This is a preliminary version of a research that contains the results of the textual analysis of the electoral pledges and the design of a survey instrument for the voters.

Abstract Name: Teaching Robot Policies to Humans Using Erroneous Examples

Human-robot collaboration describes the process of humans and autonomous agents working together to accomplish common goals. This process is facilitated best when robot policies, or behaviors in different situations, are made transparent to humans. Demonstration-based explanations have been a focus of human-robot collaboration research, and the field has frequently drawn upon education literature to improve how humans are taught robot policies. However, no single teaching method has been proven effective across domains, difficulties, learners, and other variables; the question of how humans can most effectively be taught robot policies remains open. We propose augmenting existing policy teaching frameworks with erroneous examples as investigated in traditional classrooms, in which learners are shown incorrect responses to problems and correct them to promote understanding of common pitfalls. We build upon a teaching framework investigated in previous work to teach human learners a robot's policy through demonstrations, testing, and feedback. We will conduct a user study to investigate whether viewing incorrect demonstrations of robot behavior and correcting the actions to align with the actual policy improves a human's ability to predict policy in unseen environments. With this work, we aim to advance the methods by which robots educate humans on their policies and enable fluid collaborations and trust between human and autonomous agents.

Abstract Name: Residual HIV Viremia Impacts Time to Viral Rebound Following Suspension of Suppressive Drug Therapy

Antiretroviral therapy (ART) effectively controls HIV, improving quality and extending the length of life of people living with HIV (PLWH). However, ART is not a cure. When ART is stopped, HIV can resurge to pre-ART severity. The leading hypothesis for resurgence is the presence of cells latently infected with HIV, which can activate and spark resurgence by producing virus. Mathematical models of post-ART viral rebound therefore typically rely on the assumption that rebound is driven by latent cell activation. However, highly sensitive assays reveal that, despite effective implementation of ART, PLWH have some residual virus left in their systems. We hypothesize that the contributions of residual viremia towards post-ART rebound are not negligible. We investigate this hypothesis using stochastic simulations and differential equations in order to model post-ART HIV viral rebound. We construct models of increasing complexity and seek to investigate

the relative contributions of residual viremia. Specifically, we model delays associated with intracellular processes, ART pharmacokinetics and pharmacodynamics, and, time permitting, immune responses. Our initial model exhibits statistically significant contributions of residual viremia, indicating that earlier rebounds are more likely to be attributable to residual viremia. We seek to revisit these ideas throughout our later, more complex models. HIV cure strategies are ultimately tested through suspension of ART therapy. Developing stronger and more complete insights into the role of residual viremia towards viral rebound is therefore essential to evaluating cure strategies and could help to guide future research in mathematical modeling of HIV and the development of HIV treatments.

Abstract Name: The Future of Retail: Robotics in Retail. Hanna Nash and Dr. Maha Elouni, Department of Computer Science.

This paper demonstrates how to solve the issues with self-checkout. For the past few years, self-checkout has experienced issues with theft and wait times. It's gotten to the point where major retailers like Walmart and Target are uninstalling their self-checkout units. Previous solutions, such as adding more cameras at self-checkout units, have not completely solved the issue of theft. The solution to this problem is simply robotic. A robotic arm would control all the objects being scanned, rather than leaving them to the human, thereby reducing the gap for potential theft through improper scanning. By comparing the efficiency of a robotic arm to that of a human operator, this paper demonstrates how a robotic arm can effectively address the growing problem. The robotic arm not only enhances security by minimizing theft opportunities but also has the potential to improve efficiency by reducing checkout time. Although the robotic arm built in this study was constructed from LEGOs and the number of scanned items was small, resulting in the human operator being slightly faster, the proposed solution remains promising. With further development and refinement, robotic arms could significantly solve the challenges faced by self-checkout systems.

Abstract Name: Investment Strategies for Achieving SDG 11 in Japan: A Portfolio Optimization Approach in Key Infrastructure Industries

Japan is recognized as one of the most earthquake-prone countries globally, which underscores the urgency of advancing infrastructure development and enhancing resilience in its urban areas. To achieve Goal 11 of the United Nations Sustainable Development Goals (SDGs), "Sustainable Cities and Communities," this study explores the potential for building sustainable cities through investments in key industries. The focus is on four critical domestic industries—electricity, gas, telecommunications, and construction—with companies in these sectors serving as the population for selection. In the first phase, a fundamental analysis was conducted

to narrow down the candidates to 20 companies based on financial indicators, market competitiveness, and long-term growth potential. Specifically, the evaluation considered financial metrics such as Earnings Per Share (EPS) growth rate, Book Value Per Share (BPS) growth rate, market capitalization growth rate, operating profit margin, Return on Equity (ROE), Return on Assets (ROA), and equity ratio. A composite score was calculated for each company by combining these metrics, helping identify the top performers in each sector. Subsequently, portfolio optimization techniques were applied to the selected companies to determine the investment ratio. Portfolios designed to maximize returns while minimizing risk were constructed to derive the respective investment ratios. Furthermore, the Geometric Brownian Motion model was utilized to simulate the value transitions of the portfolios over a 10-year period by analyzing long-term returns and risk fluctuations. This study presents a novel approach to achieve SDG Goal 11 through investment, contributing to the development of policies and strategies that enhance urban sustainability. These findings are expected to provide investors and policymakers with concrete measures to achieve their financial objectives and address societal challenges simultaneously.

Abstract Name: Assessing DNA Damage through Tunel Assay and H2AXP in Optic Neuropathy Murine models

Losing sight is one of the most feared disabilities, and optic neuropathies like glaucoma, which lead to blindness, currently have limited treatment options. Millions of individuals with these diseases lose their vision each year. In our study, we use the optic nerve crush (ONC) model of acute nerve injury to investigate retinal ganglion cell (RGC) degeneration, the neurons lost in glaucoma. Previous research has shown that while most RGCs are vulnerable to injury, a subset is highly resilient. Our goal is to explore the properties of these resilient RGCs and identify endogenous mechanisms that support neuronal survival and axon regeneration. One unexpected finding is that resilient and regenerating RGCs show an enriched gene expression profile related to DNA damage, including interferon signaling pathways. My project focuses on assessing DNA damage in RGCs following injury, comparing RGCs that have or have not received regenerative interventions. As proof of concept, we analyzed retinas from the ONC murine model at 3 and 7 days post-crush, immunostaining for DNA damage markers. Additionally, we examined a 14-day ONC model with regenerative interventions (Pten, Soc3 conditional knockout), and an interferon-gamma-stimulated uncrushed murine model. We stained retina sections with H2AXP and performed a TUNEL assay to detect DNA damage. Results showed variability between models. At 3 days post-ONC, intense staining was observed in the inner nuclear and RGC layers, indicative of DNA damage linked to apoptosis. At 7 days, staining decreased as apoptosis slowed, and was not directly induced by interferon gamma. Notably, Pten, Soc3 knockout mice exhibited diffuse DNA damage in the RGC layer, suggesting that regenerating RGCs may accumulate low levels of DNA damage. While the data is preliminary, it points to promising avenues for further research. A deeper understanding of retinal cell resilience could lead to targeted therapies for optic neuropathies.

Abstract Name: The Economics of Sports Betting

Sports betting as a legal matter was turned to state jurisdiction in 2018, with many states choosing to legalize the industry as a source of tax revenue. Numerous states have refused to legalize gambling, arguing that sportsbooks are often predatory and that legalizing the industry would have an adverse effect on poverty. Given the immense growth of the industry, it is worth asking whether legalized sports betting may affect poverty in different states across the United States. This paper looks at the ways in which sports betting is legalized across America, and whether states have taken up legalization based on generating tax revenue or other considerations. States with higher poverty rates could be more inclined to legalize the industry to help generate tax revenue, which could be used to help fund anti-poverty initiatives at the state level. The variables assessed will be the poverty rate of a state and the legal status of gambling, which can be measured with respect to time. From this, one can ask whether there has been a significant change in poverty rates after legalization of sports betting in a specific state. This could help inform policy decisions on whether states choose to legalize gambling. Existing academic literature on the topic surveyed different households and found that gambling has a negative impact on household debt, which is something policymakers must consider when discussing poverty and other public expenditures. The aim of this paper is to analyze whether the existing trends on poverty in a state after sports betting is legalized should cause concern or motivate policymakers to make the switch towards legalization. This will also help further academic conversation on the subject area on the causes of poverty, and start the discussion of whether sports betting can be considered either an economically beneficial or harmful activity.

Abstract Name: Evolutionary Rate Covariation Predicts Novel Lysosomal Protein Family

Lysosomes are organelles that degrade damaged cellular components and transport lipids to the terminal compartments such as the endoplasmic reticulum (ER). Lipids are essential for cellular structure and signaling, so their processing and transport mechanisms are critical. While the known cholesterol transporter NPC1 transports lipids from lysosomes to the ER, the sheer diversity of lipids creates ambiguity in identifying the remaining transporters, creating a significant gap in understanding lysosomal function. To address this gap, Evolutionary Rate Covariation (ERC) was utilized, a computational tool that analyzes the coevolution rate between proteins to predict functional relationships. Performing ERC on well-characterized lysosomal proteins, specifically the TRPML calcium channels integral in lysosomal function, revealed a novel TTYH(1-3) protein family co-evolves with the TRPML family. This suggests a co-functional association between TTYHs and TRPML within lysosomes. To characterize this, TTYH and TRPML1 constructs were transfected into human cell lines, and used fluorescent microscopy to assess TTYH colocalization with TRPML1 in lysosomal compartments. I utilized imaging studies to confirm the lysosomal localization of TTYHs with TRPML1, validating ERC predictions of TTYHs as a novel lysosomal protein family. Increased lysosomal localization of TTYHs with TRPML1 suggests their co-trafficking and functional interaction within lysosomes. Quantitative analyses show a strong correlation between TTYH and TRPML1 signals, reinforcing their co-functionality. Recent structural data identified a lipid pocket in TTYHs, similar to the NPC1 cholesterol transporter, supporting their role as lysosomal lipid transporters. Furthermore, TTYH knockdown caused impaired lipid trafficking mechanisms and lysosomal swelling. This research highlights

ERC as a tool for predicting protein functionality and characterizes TTYH as a functional lysosomal protein. TTYH expression within neuronal cells suggests specificity to lipids utilized highly in the brain such as sphingomyelin. By assessing the role of TTYH in lysosomal function, we aim to advance our understanding of lipid metabolism and neuronal functioning.

Abstract Name: Incorporating Strain-Specific Genetic Information to Improve Metabolic Models of *Bacillus subtilis*

Bacillus subtilis is a gram-positive bacterium, found in soil, humans and marine life. It produces antibiotic compounds, making it valuable in the development of tools to reduce the transmission of pathogens in built environments. M (metabolic) models, computationally describe gene-protein-reaction associations for the entire metabolic network in an organism. M models are used for the prediction of enzyme functions, pan-reactome analysis, modeling interactions among organisms, and understanding the spread of pathogens. M models of *B. subtilis* currently only consider whether a reaction is possible. We aim to incorporate reaction- and strain-specific exact gene sequences to upgrade models to include protein expression pathways (ME models). M models contain gene protein reaction rules (GPR), a boolean representation of the genes required for a reaction. GPR were be split into four distinct patterns handled separately in the algorithm: Edge Cases, Single gene reactions, Exclusive AND/OR reactions, and Mix of AND/OR. For each gene, we used an algorithm to retrieve corresponding gene identifiers specific to different strains. These genes were combined based on boolean operators within the original expression mapped into a final matrix of strain-specific information. This work resulted in a successful data mapping process which enabled the creation of a reaction-specific gene sequence matrix for various strains of *B. subtilis* and an RStudio function that can be used for other M models. We assessed the variability a single reaction may have across strains of *B. subtilis*. The results underscore the critical importance of strain-specific genetic information, especially in the context of complex reactions, such as those involved in antibiotic production. Future research includes upgrading to a metabolic and gene expression model (ME model), developing the algorithm to accommodate more complex GPRs, and replicating previous M model assessments to predict growth rates under diverse conditions and production rates of antimicrobial compounds through fermentation.

Abstract Name: Family Homelessness in California's San Joaquin County

This poster will discuss the current state of family homelessness in the United States (U.S.), California, and San Joaquin County, connecting the issue to local-level programmatic efforts by non-profit organizations.

Given major economic events, particularly the COVID-19 pandemic, research from the U.S. Department of Housing and Urban Development shows the number of families experiencing homelessness has begun to increase after a period of decline. This overall trend of housing uncertainty for families and the potential solutions that follow will be explored through various sociological theories. As one of the original counties of California, San Joaquin County is home to a diverse population of individuals, including those who are unable to economically advance into permanent housing. A lack of resource access and availability has led to a continuing crisis for historically oppressed communities, creating an extremely challenging journey in finding stability. To potentially mitigate the hardships an unhoused family may experience during this time, local, non-profit services that offer long-term assistance can provide support for both parents and children to foster the skills and confidence necessary to achieving a stable living situation. Applying an intersectional lens to the issue of family homelessness is necessary in this changing society, and when service providers and local non-profit program directors are knowledgeable of how social identities create significant hardship or advantages, these families will be able to get the most out of the assistance. Through an analytical literature review process, a deeper understanding of the homeless family experience on national, state, and local levels will be established to discuss additional initiatives that can be implemented to help and prevent this experience for future generations in the San Joaquin County.

Abstract Name: THE ROLE OF MTHFR GENE MUTATION IN NEURODEVELOPMENTAL DISORDERS: EXPLORING POTENTIAL CORRELATIONS WITH ADHD AND ANXIETY AND DEVELOPING GENETIC TEST PROTOCOL

Attention Deficit Hyperactivity Disorder (ADHD) is a prevalent neurodevelopmental disorder, often comorbid with anxiety and depression. Symptom overlap and inconsistent diagnostic criteria contribute to underdiagnosis and misdiagnosis. Among adults, 20–30% report ADHD-like symptoms during screening, with nearly 90% being false positives. Additionally, 20% of children are misdiagnosed with ADHD, leading to unwarranted amphetamine use, which risks cognitive alterations and addiction. The methylenetetrahydrofolate reductase (MTHFR) gene is crucial for folate and homocysteine metabolism. The MTHFR single nucleotide polymorphism (SNP) C677T reduces enzymatic function by 30–60% and several publications report this genetic variant as a risk factor for ADHD, schizophrenia, and bipolar disorder. Despite this, the CDC currently states insufficient evidence to recommend genetic testing or interventions for individuals with this variant. This study evaluates whether the MTHFR C677T SNP correlates with ADHD and anxiety behaviors. Saliva samples from 30 participants were analyzed using loop-mediated isothermal amplification, a technique easily transferable to a clinical setting, for visual detection of the wild-type and mutant genetic variants. Participants completed surveys to collect information on formal diagnoses, ADHD- and anxiety-related behaviors, and demographics. Participants were grouped into two categories, those with behaviors of ADHD and anxiety and those without behaviors. We hypothesized a positive correlation between the C677T SNP and self-reported ADHD and anxiety behaviors. This study's primary goal is to develop an objective biological tool to aid clinicians in diagnosing ADHD and anxiety. A secondary aim of this study is to bolster support for treating individuals who have the SNP with a folate supplement, which is reported to reduce symptom severity in individuals with ADHD. Due to the heritability of ADHD and anxiety, increased folate and attention to formulation could optimize fetal neurodevelopment, potentially mitigating ADHD symptom severity in offspring.

Abstract Name: Optimization of Thermosensitive In Situ Gels for In Vitro Evaluation of Traumatic Optic Neuropathy

Traumatic optic neuropathy (TON) is a rare neurodegenerative condition caused by head or facial trauma, often resulting in severe vision loss or irreversible blindness. Current treatment options, including observation, surgery, and corticosteroids, remain controversial and lack consensus on efficacy. This study explores an innovative injectable platform utilizing thermosensitive in situ gels formed from Pluronic F-127 to optimize drug delivery therapeutic strategies for TON. The in situ gels exhibit temperature-sensitive properties with gelation occurring at approximately 30°C, posing challenges in maintaining consistency under standard in vitro temperatures (i.e., room temperature-37°C). This study focused on developing a platform to ensure control of in situ hydrogel gelation for future cell studies. Pluronic F-127 was tested at varying concentrations (12–20% w/w) to assess gel stability in a 37°C water bath. Once gelation occurred, samples were removed, and the time required for reverse gelation (transition back to liquid) at room temperature was recorded. Additional reverse gelation studies were performed using transwells with permeable membranes for gel placement and transport without direct contact with cells. Transwells with pore sizes of 0.4 µm and 3 µm were evaluated for gel transport within 1 minute. Gels in larger-pored transwells (3 µm) crossed the membrane within 10 seconds, while those in smaller-pored transwells (0.4 µm) were retained. Gels synthesized from 18% and 20% Pluronic F-127 demonstrated the greatest thermal stability when used with 0.4 µm transwells. These findings convey optimized gel formulations for subsequent in vitro experiments to enhance thermal stability and functionality under physiological conditions. Future work will involve culturing human retinal epithelial cells to assess material biocompatibility, drug transport efficacy, and broader applications of this optimized gel formulation in biological systems, aiming to advance therapeutic options for TON and similar neurodegenerative conditions.

Abstract Name: Seeds of Resistance: Indigenous Ecofeminism in Gardens in the Dunes by Leslie Marmon Silko

This paper explores the ecological and feminist critique of settler colonialism in Leslie Marmon Silko's 1999 novel, *Gardens in the Dunes*. Through a narrative that contrasts settler colonial with Indigenous perspectives on horticulture, Silko exposes the enduring impact and violent repercussions of the anthropocentric domination over nature. The story follows Indigo, one of the last surviving members of the Sand Lizard tribe, who is forcibly separated from her family and taken on a journey through gardens worldwide with her white adoptive parents. Through an Indigenous ecofeminist lens, Silko critiques settler colonialism's exploitation of

nature and Indigenous communities, exposing the interconnectedness between ecological domination and the subjugation of Native peoples. Settler colonial horticulture is rooted in the anthropocentric exploitation and commodification of nature for ownership, display, and control. In contrast, Indigenous relationships to the land center on reciprocity, care, and integration of plants and people into a way of life of mutual sustainability and nurture. Indigenous ecofeminism recognizes the relationality of gender, culture, and ecology, exposing how settler colonial violence serves these bonds through the displacement and dispossession of Indigenous peoples from land and culture. Silko's novel continues to develop this idea as it unravels Indigo's experience with European botanical traditions as she is torn away from the values and practices of her Native American heritage. In my analysis, I examine the intertwined cultural and ecological consequences of settler colonialism, revealed through the opposing Indigenous and colonial ideologies towards land and nature. Indigo's journey in *Gardens in the Dunes* subverts the anthropocentric control of nature and offers an alternative grounded in Indigenous resistance, resilience, and the vital importance of reciprocal, sustaining relationships with the land. This paper will demonstrate how the novel emphasizes the inseparable connection between the treatment of people and the environment within the Indigenous experience.

Abstract Name: Resisting Erasure: Polish Fairy Tales in the Partitions Era

This paper explores the role of Polish fairy tales during the Partitions Era (1795-1918) as a form of cultural resistance and a reflection of Polish nationalism. Amidst the oppressive rule of Russia, Polish identity was systematically suppressed. In 1862, Maude Ashurt Biggs translated A.J. Glinksi's collection of Polish fairy tales, offering a rare glimpse of Polish folklore during a time when national sovereignty had been erased from the map. Through a gothic lens, the fairy tales in this collection, specifically *Princess Miranda* and *Prince Hero and The Eagles*, symbolize the struggle for autonomy and the Polish people's enduring resistance against foreign domination. The gothic elements embedded within *Princess Miranda* and *Prince Hero and The Eagles* reveal how these fairy tales function as allegories of Polish resistance. In both stories, the central characters are besieged by malevolent forces symbolizing foreign invaders, and their loved ones fall into perilous situations. These narratives echo the paralysis of Polish national spirit and the forced assimilation of Polish people, particularly through Russia's Russification policies. These themes are mirrored through the gothic motifs of enforced dormancy, ensnared protagonists, larger-than-life entities, and the theme of the broken self. By drawing parallels between the fairy tale characters and real-life uprisings in the 1860s, this paper demonstrates that these stories not only captured the cultural oppression experienced by the Polish people but also embodied their deep belief in eventual liberation. The analysis of the gothic motifs within these fairy tales reveals how folklore served as both a cultural refuge and a form of resistance, offering hope amidst the erasure of Polish sovereignty. These narratives provided a space for resilience and resistance, reflecting the Polish desire for freedom and the eventual triumph of national identity, even in the face of seemingly insurmountable odds.

Abstract Name: How Does Floral Photosynthesis Relate to Climatic Niches?

Flowers exist in many beautiful forms and varieties to attract pollinators and reproduce, but some flowers' reproductive organs can photosynthesize. This means that some flowers can potentially create their energy. However, this comes with costs and benefits. For example, the cost is that it is an energy-intensive process, and it could increase damage to floral DNA by UV radiation. Another cost is that chloroplasts, the region of the cell where photosynthesis occurs, also often contain a large amount of chlorophyll which can make the flower appear green. The goal of my study is to survey floral photosynthesis and determine its costs and benefits related to variables found in climatic niches. To determine if the extent of floral photosynthesis is tied to habitat preference in plants, we will measure chlorophyll in flowers as a proxy for photosynthesis and compare our data to species distribution data that will be downloaded from WorldClim. To extract the chlorophyll from the tissue of the flowers, we first will separate the petals or showy organs of the flower from non-showy organs. We will next use 1000uL of acetone to extract the chlorophyll and 250uL of that to run under a spectrophotometer to measure absorbance. Species distribution data for the samples will be downloaded using the Global Biodiversity Information Facility website, and it will be cleaned to only have the plant's native range. This distribution data will next be analyzed by two WorldClim variables, annual precipitation and annual mean temperature on a Java-based software named Maxent to see how the species fare in certain climatic conditions based on those variables. Our predicted goal of this study will be that niches with lower water availability and a warmer climate will have less available chlorophyll for photosynthesis.

Abstract Name: Utilizing ^1H -NMR to Determine Protonation State in Oral Nicotine Pouches

Nicotine is a highly addictive psychoactive drug that stimulates the nervous system and alters the consumers mood. Depending on pH, upon consumption, nicotine is delivered either as protonated or freebase affecting the absorption, metabolism, and addictiveness of the product. Free base nicotine consumption is correlated to higher addictiveness than its protonated counterpart; it is readily absorbed through the skin providing a stimulant effect since it is absorbed and experienced at a more consistent rate than protonated nicotine. Whereas its protonated counterpart is less likely to diffuse across membranes, which could reduce nicotine absorption rate but exacerbate other shared health effects such as increased levels of inflammation at the mandibular vestibule and mucogingival junction. Previous research conducted by the University of Portland examined protonation state of various e-liquid cigarettes using a 600MHz ^1H -NMR. This research aims to evaluate if this method can be utilized to differentiate and determine protonation state of various oral nicotine pouches using a benchtop NMR. The pouches include nicotine HCl, flavorings, fillers, and pH stabilizers. The solution pH influences the protonation state of nicotine, in this study nicotine pouches were extracted with artificial saliva while mimicking similar conditions to the buccal region comparable to the intended use of the product. The pH of the solution was measured, and protonation state of nicotine was investigated. Statistical analysis indicates that protonation state can be determined from two protons on the aromatic ring

of the compound as well as the pyrrolidine methyl using low field ¹H-NMR. Although pH stabilizers are known to be present in these products, pH values ranged from 6.6 to 10.6 in the tested subjects.

Abstract Name: Off-Campus Housing in Menomonie Wisconsin

Student's academic success in the classroom is impacted by student's mental and physical health. In addition, poor living conditions can have a critical impact on a student's wellbeing, including having detrimental outcomes on mental and physical health. Previous research has shown that 52.6% of off-campus students live in conditions that are negatively affecting their health (Johnson et al., 2009). Additionally, women and gender diverse individuals are more likely to experience negative housing situations than men (Heller et al., 2023). To add to this literature, this study aims to examine the housing conditions for off-campus students in Menomonie, Wisconsin, home to UW-Stout, by looking at how students view the fairness and trustworthiness of their landlords. Additionally, this research aims to observe both the positive and negative experiences of off-campus students to assist in ongoing community efforts to address housing concerns by passing effective local ordinances that aim to protect renters. By leveraging an original survey and in-person focus groups asking students questions about their living conditions, several trends emerged. Students report being happy living off campus but also report having multiple housing issues. Through interviews and focus groups, it became clear that this contradiction of being happy despite housing issues stemmed from a belief that on-campus conditions are worse; therefore, students are happy to be out of them. The preference for "anything but the dorms" has led to students being complacent about not receiving adequate living conditions. If universities and communities want to better understand the living conditions of their students, it may be true that surveys do not truly uncover the depth of their negative experiences and the problems students face in securing safe and secure housing. Instead, mixed methods research that includes focus groups is needed.

Abstract Name: Exploring the Characteristics of Elder Perpetrators Through Systematic Review: A Profile-Based Approach

Objective: With longer lifespans and a substantial aging cohort, abuse against older adults is a growing concern yet often under investigated. Literature on elder abuse is typically focused on victims and types of abuse experienced rather than understanding the offenders. Articles which have suggested profiles of abusers have differing criteria. The purpose of this systematic review was to combine these criteria to create a common ground concerning abuser characteristic profiles. Methods: The initial search strategy across two databases yielded 820 non-duplicated articles. After reduction for specific relevance, five papers were included from the initial search as well as two additional from evaluation of sources from those papers.

Results: The included articles revealed numerous overlapping characteristics of elder abusers with four characteristic types despite the different labels throughout literature. The first type of abuser is characterized as a caregiver whose stress results in abuse. The second is a caregiver that is dependent on the financial or emotional resources of the elderly causing them to be exploited or neglected. Third, is a self-centered abuser who seizes an opportunity for exploitation. Last, is an abuser who planned to hurt or exploit the other person either for internal or external gain. Discussion: This systematic review identified commonalities in perpetrator profiles and some gaps in information. Notably, four distinct profiles of elder abusers and their application across types of abuse were uncovered. Defining profiles of elder abusers could facilitate new strides towards assisting common custodians of elders such as social workers, nurses, investigators, and family members to identify trends toward abuse. Future goals from this work include the creation of a comprehensive new measure that would aid in reporting elder abuse, and recognition of those more prone to be perpetrators of elder abuse for earlier intervention and prevention strategies.

Abstract Name: Making Science Accessible Through the Humanities

Grant Nelson, a first year Marine Science major will be conducting research based on gauging the cognitive abilities of fish through food-based reward. The goal of the project will be to assess the cognitive abilities of fish to differentiate between colors by utilizing the fish's food drive. During this process, Grant will be documenting the research through social media and will be monitoring how it is perceived by an online audience to gauge social media's effectiveness as a tool to educate or gain funding for future research in science. Grant will focus on combining Marine Science and the Humanities into a dual-pronged research approach that tackles both at the same time to gauge if scientific research can gain traction and support through social media, and how much support and interest research can gain in an online setting. Additionally, the other goal of the project is to assess the cognitive abilities of fish when it comes to recognizing cues, such as different colors or sounds associated with feeding. Throughout this whole process, Grant will be documenting all of the results and putting them into an entertaining format on a social media account. For example, the results for the week/day of the fish's progress could be posted through a meme, and then the engagement the content gets would be observed and recorded. The significance this research would have within the humanities would be that it could be a useful tool for modeling how people react to research. Will research be perceived well and supported by the public? Can people care about research that doesn't solve any real-world issues? Can scientific research, when formatted in a way that mirrors social trends, gain traction both for the field and popular culture?

Abstract Name: Impact of chronic stress on fentanyl intake: a comparison between male and female c57BL6

mice

This research proposal explores the impact of chronic stress on fentanyl consumption in C57BL/6 mice, with the goal of addressing the escalating crisis of opioid misuse. The study extends existing research by investigating how exposure to a non-social stressor influences fentanyl intake and related behaviors across both male and female subjects. Two cohorts of 16-20 mice will undergo 21 days of variable stress or handling as a control. Fentanyl consumption will be assessed using a modified drinking-in-the-dark (DID) paradigm over four days following the stress period. Statistical analysis will utilize repeated measures two-way ANOVA to evaluate the effects of stress, sex, and time. The findings aim to enhance our understanding of stress-induced vulnerability to opioid addiction and reveal sex-specific differences in substance use disorders. The research holds significant potential for informing targeted therapeutic strategies for opioid use disorder. Future directions will focus on examining cellular and molecular changes, optimizing stress exposure protocols, and evaluating stress-relief interventions. Ultimately, this study seeks to provide critical insights into the neurobiological mechanisms linking stress and opioid addiction, paving the way for more effective prevention and treatment strategies.

Abstract Name: The Impact of Body Positivity on Mental Health and Wellbeing in South Asian Communities

This research explores the influence of body positivity on the mental health and well-being of South Asian communities, focusing on the effects of beauty standards and media portrayals of ideal body types. In South Asian societies, traditional beauty norms often prioritize fair skin and slim body types, which can lead to body dissatisfaction and contribute to mental health challenges, particularly among women. By analyzing existing surveys, interviews, and media representations, this study examines how these cultural ideals shape individuals' self-esteem, body image, and overall psychological well-being. The research also highlights the impact of promoting body positivity as a counter to harmful societal pressures, showing its potential to improve mental health outcomes, reduce stigma, and foster healthier body image perceptions. The study emphasizes the need for inclusive and culturally sensitive approaches to mental health interventions, aiming to challenge these beauty standards and promote positive self-image within South Asian communities. The findings contribute to the broader understanding of body image issues and mental health, suggesting that increasing awareness and acceptance of diverse body types can help mitigate the adverse effects of body image dissatisfaction.

Abstract Name: An analysis of hail events to determine the location and vulnerability of "Hail Alley"

Hail storms heavily contribute to the significant amount of damage caused by natural disasters. With severe hail events rising, this topic's importance also rises. Historical hailstorm data was collected from the Storm Prediction Center for the U.S. and Environment Canada for Canada. Using this data, analysis was performed to try to identify the location of "Hail Alley", which is believed to be a region of North America where hail is more frequent and is also more severe (i.e., larger size). It is hypothesized that "Hail Alley" will closely align with Tornado Alley. This is due to the conditions leading to thunderstorms that are capable of producing large hail and can also produce tornadoes. The second part of this research examines and provides details about the vulnerability of this area. This examination will be an analysis of the various types of damage from hail storms where data is available to determine the most common occurring type of damage and the typical dollar amounts associated with them. Other factors that can determine vulnerability will include crop type, crop damage, and building material. The intended outcome of this project will allow many different groups of people (e.g. general public, insurers, meteorologists, etc.) to better prepare for hailstorms and create mitigation efforts.

Abstract Name: Age-Friendly Workplace Practices Among Regional Businesses in a Midwest State

The United States population is aging and driving an increase in the labor force participation of older adults. The proportion of older adults, aged 65 years or older, has increased 117% in the past two decades. Initiatives to become more age friendly are occurring at all levels, including states, communities, health care systems and businesses. The purpose of this analysis was to determine if businesses within the Duluth (MSA) area are implementing age-friendly workplace practices and if they aren't, what can be proposed to improve those working practices. This analysis used the Later Life Workforce Index (LLWI) which is a tool to assess an organization's practices to determine if they are catering to an aging workforce. The index categorizes the survey's questions into nine unique domains (e.g., organizational climate, leadership, work design). The analysis was conducted through the distribution of a survey. The survey was distributed to representatives of local businesses who were instructed to distribute it to their staff. In total, 16 businesses participated with 308 combined responses. The survey consisted of the LLWI domain questions along with some additional questions such as workplace demands, length of experience, educational attainment, and plans for after retirement. Our analysis examined the relationship between the LLWI domains and an individual employee's likelihood to leave their job. The findings identified several factors that could influence whether a person stays or leaves, including demographics, retirement options, and organizational climate.

Abstract Name: Entrepreneurs make you fly: the business of Private Aviation

Using entrepreneurship theory, we investigate the private aviation industry, excluding corporate aviation, and how it proposes value to its consumers. To do so, we rely on secondary sources and, especially, on primary ones. We interview over twenty entrepreneurs involved in different parts of this industry - airport owners and operators, private flight brokers, private jet companies, original equipment manufactures, software developers, and more - and its value proposition chain. Contrary to the common conception about commercial aviation, the private aviation industry is guided by entrepreneurs and uses a lot of specialization, division of labor and coordination. Entrepreneurs in this industry must deal with constant changes in the market, in technology and in the regulatory environment to keep their businesses afloat. We see the private aviation industry as an insightful proxy to how understand entrepreneurship in general and how the market as a whole works.

Abstract Name: Developing Small Molecule Inhibitors to Block Agmatine Synthesizing Enzymes in Bacteria

Colorectal cancer (CRC) is the second most common cause of cancer-related death in the United States. Growing evidence suggests that bacteria may affect CRC directly or indirectly by secreting metabolites, invading tissues, and modulating host immune responses. Dysbiosis of the gut microbiome and specifically the overgrowth of *E. coli* is consistent with the toxic microbial environment of CRC. Additionally, it has been found that exogenous polyamines promote the proliferation of CRC cells. Therefore, this study aimed to develop a screening assay to inhibit polyamine production in *E. coli* by targeting a key biochemical pathway. The bacterial metabolic pathway of interest was arginine decarboxylase (SpeA), which converts arginine to agmatine and produces the polyamines spermidine and putrescine. Through inhibiting this potentially harmful biosynthetic pathway it could reduce exogenous polyamines in the CRC microenvironment and inhibit the overgrowth of *E. coli*. The results from the current progress of this project indicate that two transformant strains of *E. coli* capable of producing the SpeA protein have been created, His-tagged SpeA enzymes have been successfully overexpressed and purified, and an immunoblotting method to investigate the enzymatic functionality and inhibition of SpeA was developed. Thus, this research project led to the establishment of a molecular platform that will enable the identification of SpeA inhibitors and new therapeutic strategies for treating CRC.

Abstract Name: Screening Triazole Derivatives for their Antibacterial Potential against Foodborne Pathogens

Antibiotic-resistant pathogens are one of the leading global health crises of the 21st century, causing ~48 million infections and \$75 billion in healthcare costs annually. It is estimated that by 2050, an average of ~3,000 people will have died from antimicrobial-resistant pathogens every minute. Thus, developing new antimicrobial agents has become crucial to improving public health. Recent works suggest that azole-containing compounds can be functionalized to bind to various enzymes, proteins, and receptors. As a result, they possess the potential to be developed into novel antibiotics. An initial library of azole-containing compounds was produced and then screened for their antibacterial potential against common foodborne pathogens (*Salmonella*, *E. coli*, *Shigella*, and *Listeria*) by determining their zone of growth inhibition. We identified two compounds that exhibit strong anti-*Shigella* properties, with half inhibitory concentrations (IC₅₀) of 76 µg/ml and 129 µg/ml. Next, we determined how toxic these compounds were to mammalian cell lines by treating them with similar doses to the bacteria. We found that short-term exposure to the compounds caused minimal damage to the cells, but over longer time frames, some compounds were very toxic. Work is ongoing to further develop these compounds to reduce the toxicity in mammalian cells while improving their anti-*Shigella* properties. Future research will focus on determining the mechanism of inhibition of these compounds on bacteria and determining how effective these compounds are at killing bacteria during bacterial infections of mammalian cells.

Abstract Name: Identification, Quantification, and Modeling of Novel DdrR Interaction Partners

Acinetobacter baumannii is an opportunistic pathogen with increased mutagenesis opportunities that contribute to its high levels of antibiotic resistance. Unlike other pathogens, *Acinetobacter* represses its mutagenic polymerases, which are upregulated in response to DNA damage, with the coregulators UmuDAB and DdrR. Although UmuDAB is analogous to LexA, the unique DdrR protein provides *Acinetobacter* with additional regulatory control. Identifying the proteins that DdrR interacts with could provide new drug targets, considering the CDC declaring the pathogen “an urgent public threat”. Through extensive screening of a gDNA library created using the EUROMEDEX bacterial adenylate cyclase-based two-hybrid system (BACTH) protocol, we identified two protein fragments that interact with DdrR. These protein fragments come from KZA74_19365, a hypothetical plasmid replication protein, and KZA74_16005, a phosphogluconate dehydratase. We characterized these positive interactions by quantifying activity and modeling protein structures. We used a β-galactosidase assay to quantify the interactions between DdrR and the identified library protein fragments. The hybrid protein containing KZA74_16005 had higher Miller units when interacting with DdrR than the hybrid protein corresponding to KZA74_19365. We used the online modeling programs I-TASSER and AlphaFold2 to predict the interaction domain and configurations of KZA74_19365 and KZA74_16005 hybrid proteins with DdrR. AlphaFold2 modeling of each hybrid library protein with the associated DdrR hybrid protein showed the library insert peptide located adjacent to DdrR. Further testing will elucidate the mechanism by which the protein-protein interactions occur and if the interaction occurs *in vivo*. We will also continue to identify additional DdrR-interaction partners through the creation of new genomic DNA libraries with larger insert sizes of 1-2 kbp.

Abstract Name: Targeting Serine Metabolism to Boost Immune Response to Radiation Therapy in Glioblastoma

Glioblastoma (GBM) is the most common primary brain tumor with a dismal prognosis despite aggressive treatments. Radiation therapy (RT) is an indispensable component of GBM treatment. RT initially controls these tumors, but they inevitably recur due to intractable radioresistance, and modern immunotherapy approaches have failed to move the needle in this disease. We have previously shown that metabolic plasticity is an important driver of RT resistance in GBM. Our current data point to serine metabolism as a crucial player in both tumor growth and therapy resistance in GBM, in part by modulating anti-tumor immune responses. In this study, we investigate the complex interplay between serine metabolism, immune checkpoint molecules (PD-L1), antigen presentation machinery (MHC-I), and immune cell infiltration in GBM. We hypothesized that manipulation of serine metabolism would impact these key immunomodulatory factors, consequently rewiring the tumor immune landscape. Depriving GBM cells of extracellular serine results in the upregulation of key enzymes involved in its biosynthesis from glucose, phosphoglycerate dehydrogenase (PHGDH), and phosphoserine phosphatase (PSPH), as measured via western blotting. Moreover, using flow cytometry we demonstrate that serine/glycine depletion leads to upregulation of both PD-L1 and MHC-I expression in GBM cells in vitro. This seemingly paradoxical effect points to a complex role of serine metabolism in shaping the GBM immune microenvironment, potentially influencing both immune evasion and recognition patterns. Our findings highlight the intricate relationship between serine metabolism and immune regulation in GBM, suggesting that targeted manipulation of this pathway could have far-reaching effects on the tumor immune landscape, potentially improving outcomes for GBM patients.

Abstract Name: Gaming in China: The Chinese Communist Party's 13th 5-year Plan effects on China's mobile gaming industry

As part of China's 13th 5-year Plan, the Chinese Communist Party (CCP) is trying to develop and promote Chinese soft power by implementing strategies to accelerate the development of new types of cultural enterprises. This research explores how the CCP utilizes the 13th 5-year Plan to mobilize China's mobile gaming industry in advancing Chinese soft power. The research will examine China's mobile gaming industry as a tool of soft power within the context of the 13th 5-year Plan's development goals to update information found in previous cultural industry development studies. I will examine the CCP's 13th 5-year Plan to identify the CCP's values in cultural enterprises and compare the CCP's attitudes on cultural development to Chinese mobile gaming organization's rhetoric highlighting policy influence on China's mobile gaming

industry. The results may show the CCP's 13th 5-year Plan on cultural development influences China's mobile gaming industry. The CCP is applying political pressure on China's mobile gaming industry to internationalize cultural gaming products thus increasing China's branding. Therefore, the research will illustrate how the CCP's 13th 5-year Plan deploys China's mobile gaming industry to increase China's international image amidst the destruction of language of culture of ethnic minorities in China.

Abstract Name: Elucidating the Role of Lipid Regulation and Membrane Dynamics in Exophergogenesis

Exophers, first discovered in the *C. elegans* model organism, are notably large (3-4 μm) membrane-bound vesicles containing protein aggregates and organelles that can be extruded from neurons. Hypothesized as a waste disposal system, this process has potential implications in the pathology and treatment of neurodegenerative disorders like Huntington's, Alzheimers, and ALS. Uncovering the mechanism underlying exophergogenesis can offer valuable insight on therapeutic targets for tackling these diseases. Triggered by multiple stimuli such as starvation and the presence of eggs, there is rising interest in exploring the role of lipids in this phenomenon. Specifically, knockdown of lipid synthesis genes essentially abolished the starvation induced exopher increase. Building on this foundation, this study aims to define a working model of how lipid regulation and the cellular membrane interact with exophergogenesis, constituting a significant advance in the mechanistic understanding of both lipid biology and large vesicle extrusion. To elucidate the role of cholesterol in exophergogenesis, we performed complete deprivation in worms via growth on cholesterol-free plates. Additionally, we conducted RNAi knockdown screens via bacterial delivery of dsRNA targeting genes involved in membrane dynamics and lipid pathways, with knockdown limited to neurons. These studies utilize *C. elegans* worms that express a fluorescent mCherry reporter in the touch neurons for clear visualization. Quantification will involve counting exopher-forming neurons in adult animals across triplicate trials of 50 animals each. To examine the lipid membrane structure of an exopher, we will conduct fluorescence recovery after photobleaching (FRAP) studies on the exophers of animals that have varying membrane fluidities. Ultimately, our results will determine the role of lipid regulation in exophergogenesis. We expect that disrupting lipid homeostasis will result in increased exophers.

Abstract Name: Power, Psychoanalysis, and Teenage Chaos: A Freudian and Foucaultian Reading of Heathers

Although it seems that Freud's theories regarding psychoanalysis and Foucault's philosophy on power do not necessarily go hand-in-hand, both theoretical approaches offer perspectives on the 1998 teenage thriller movie Heathers. This paper asserts that combining the two thought systems provides an analysis that

addresses multiple themes and offers a rich interpretation of the film. By applying Foucault's work on power relations, discipline, and knowledge, the paper examines the power struggles between characters in the film and then proceeds to discuss the rationales behind those characters' actions using Freud's theories regarding consciousness. Standing alone, Foucault's analyses may only explain the apparent tensions regarding power, discipline, and control. Furthermore, Freud's interpretation of the film alone would merely serve as an explanation for a few themes regarding psychoanalysis among the multitude of subject matters that can only be complemented by Foucault's philosophical theories. Foucaultian power and Freudian psychoanalysis do not seem to be relevant to one another on the surface, but the complexity of the characters in *Heathers* demands a marrying of the two for a thorough interpretation. Foucault's philosophy on power relations speaks to the intended message of the film that society is manipulative and controlling while a Freudian approach examines the internal motivations of the characters as they are integrated and influenced by that society.

Abstract Name: Exploring the domains of the protein Nur77 and its ability to bind to specific proteins present in immune cells

The immune system protects the body from infection by fighting against pathogens. The mature T-cell is a cell of the immune system and assists with killing pathogens. Mature T cells develop from immature T-cells to become fully functional. The T-cell receptor (TCR) plays an important role in recognizing specific pathogens and triggering T-cells to respond. Nur77 is a protein that regulates cell death response due to strong TCR during T cell development. Mature T cells also make Nur77 protein in response to TCR engagement, but its function in these cells is currently unknown. The Nur77 protein structure is composed of three domains: Activation Function 1 (AF1), DNA Binding Domain (DBD), and Ligand Binding Domain (LBD). This project aims to explore how the different domains of Nur77 can bind to other proteins in different types of T cells to further elucidate the function of Nur77 beyond its known role in developing T cell death. We created DNA that will make the Nur77 protein in yeast cells and divided the Nur77 protein into its multiple domains. Next, a yeast two-hybrid (Y2H) screen will be used to discover novel protein(s) that can bind to Nur77 and/or confirm previously described Nur77 binding partner(s). This research will advance our knowledge and understanding of T cell development and function by identifying Nur77 protein interactions, which will be used to more fully elucidate Nur77 function in different types of T cells.

Abstract Name: Nanoparticle-Mediated Delivery of Therapeutics for Idiopathic Pulmonary Fibrosis

Idiopathic pulmonary fibrosis (IPF) is a devastating and often fatal disease in which excessive scar tissue builds up in the lung, causing the lungs to stiffen and lose functionality. There is no curative treatment for IPF except transplantation. Furthermore, existing treatment options for IPF are limited: only two drugs have received FDA approval to treat this disease, and both have limited efficacy and severe side effects. This project aims to explore a nanotechnology-based strategy to selectively deliver therapeutic agents to targeted locations within the fibrotic lung tissue. Recent literature has shown that inflammation plays a key role in the progression of IPF, so as a model drug payload, we chose Tofacitinib (TOFA), an anti-inflammatory drug. To enable targeted delivery, we are testing whether decorating TOFA particles with magnetic iron oxide nanoparticles (IONPs), forming “TofaBots,” can enable magnetically guided delivery of TOFA directly to regions where the drug will have the greatest effect, namely the regions where fibroblasts (the main cellular drivers of fibrosis) and scar tissue accumulate. The size and morphology of IONPs and TofaBots are characterized using dynamic light scattering (DLS) and scanning electron microscopy (SEM). Using externally applied magnetic fields, we demonstrate that TofaBots can actively penetrate biomimetic hydrogels that function as in vitro models of fibrotic lung tissue; the speed of TofaBots’ magnetically driven motion increases as the gel concentration decreases. Finally, we are actively exploring whether the motility of the nanoparticles can be enhanced by coating them with an ECM-degrading enzyme, such as collagenase. We hypothesize that more effective drug distribution at disease sites can enable more efficacious therapies for this enigmatic and devastating disease.

Abstract Name: Automatic Quality Estimation for Data Selection and Curriculum Learning

The accelerating increase in the size of language models (LMs) in recent years has led to an increase in the amount of training data required for training. While these larger models have shown strong performance, their use comes with added training and data costs, can be resource-prohibitive, leading to a shift of large LM research from academic to industry. This research focuses on exploring quality estimation as a method of data selection or filtering. This approach was applied to machine translation models with varying data sizes as well as to the BabyLM Challenge. Given the 100M word dataset provided in the BabyLM Challenge, we preprocessed data involving removing blank lines and special characters, with a focus on dialogue-related elements. The sentences within each dataset were then rearranged based on length to streamline the training process. After preprocessing, the sentences were translated from English to German using base translation models from fairseq. We then conducted several experiments to test out various strategies for selecting 10M words for pretraining and use a curriculum learning approach based on the quality estimation scoring. The experiments varied based primarily on: (a) the order of training – ascending or descending (original curriculum learning) order of xComet quality estimation scores (equivalently, reversed machine comprehension level); (b) the separation or combination of datasets from various sources; (c) the number of hidden layers and heads during model training. After filtering and training, models were evaluated using a standardized evaluation pipeline provided by the organizers to compute their scores on the BLiMP and EWoK benchmarks. We have found small improvements in certain data settings.

Abstract Name: Divide and Rule: The Political Use of Humor in Trump's Tik Tok Campaign

Historically, humor has been used as a rhetorical tool for social and political critiques. The use of Millennial and Gen Z humor on social media today, highlights the way in which humor has become a norming strategy, particularly when it concerns ideologies about race and gender. A popular colloquialism in circulation, "It's just a joke," points to how humor can empty the political and trivialize serious socio-political issues. In this paper, I perform an ideological analysis of Trump's 2024 election campaign TikTok videos to examine how Team Trump effectively established the candidate's legitimacy and authenticity among online viewers, through the strategic use of humor in these communications. The findings show that online humor, even when it is scapegoating or derisive, can enhance a candidate's appeal by emotionally and ideologically resonating with an audience, and by successfully consolidating these appeals into an affective logic that builds off the social media platform's dynamics and communication rules. This research underscores the dual role of humor in political discourse as both a unifying and divisive force and contributes to earlier communication research on political humor (Bateson 2017; Meyer 2000; Lynch 2002; Becker & Baumgartner 2020; Penney 2020). Drawing on Carola Schoor's theorization of political style -- rhetorical, social, and ideological -- this analysis demonstrates how, in the cultural spaces formed by social media, humor triumphs above critical thinking by favoring relatability. The findings highlight the persuasive power of social media humor when coupled with political discourse in perpetuating discriminatory ideologies and enabling political divides.

Abstract Name: Rapid "Blebbing" Large-scale Motility observed in 2D and 3D Cultures of Breast Ductal Cancer Cells (MCF-7)

Breast cancer is the most common cancer in women worldwide and second most common in the United States, with 670,000 deaths reported globally in 2022 and an estimated 42,250 U.S. deaths expected in 2024. Breast cancers result from a complex interplay between genetic backgrounds and microenvironments but are fundamentally a disease of tumor cell behaviors. Therefore, defining cancer-related behaviors and phenotypes provides an approach to understanding and addressing this important disease process. This poster presents preliminary results on the motility behaviors of breast ductal adenocarcinoma cells in 2D and 3D cultures, using "normal" ductal epithelial cells (MCF10A) as controls. First, we examined cellular cytoskeletal components actin and tubulin using fluorescent staining/immunolabeling in 2D cultures. This was followed by time-lapse photomicroscopy of 2D cultures to correlate labeling data with motility features like filopodia and lamellipodia. Finally, we employed SEM coupled to a 3D bone matrix to explore evidence of motility features at the ultrastructural level and sought to correlate these to observations from the other two study approaches. Results to date show: Time-lapse studies reveal significant differences in motility between breast cancer cells and ductal cells. MCF7 cells exhibit "blebbing" motility, while MCF10A cells display classic

lamellar motility. The studies also show that blebbing motility is substantially faster in positional change and directional shifting compared to lamellar motility. Ultrastructural studies of MCF7 cells in 3D bone scaffolds reveal blebbing structures, various filopodial forms, and modified lamellar-like features linked to matrix invasion activities. Staining/labeling studies show actin brightly staining the blebbing structures of MCF7 cells, while tubulin does not label these blebs substantially. However, tubulin is extensively present in lamellar-like structures in both MCF7 and MCF10A cells. These findings highlight distinct motility patterns in MCF7 breast cancer cells compared to normal MCF10A ductal cells, consistent across various culture microenvironments.

Abstract Name: Creating His-tagged Notch1 plasmid as a positive control for Nur77 protein binding assay

The immune system works to prevent disease and keep the body healthy. It is split into two primary systems: the innate (basic, quick defense) and the adaptive (specialized, targeted defense) systems. The adaptive system contains conventional T-cells that work using T-cell receptors (TCR) to identify and respond to harmful pathogens. Another type of T-cell, the regulatory T cell, also uses a TCR to identify targets, but its role is to suppress unwanted immune responses, preventing autoimmune diseases such as type 1 diabetes. After a TCR identifies and sticks onto its target, the amount of a protein in the cell called Nur77 increases. Since Nur77 protein amounts increase in both types of T-cells, and the conventional and regulatory T cells have different functions, we aim to specifically investigate the function of Nur77 in these different types of T-cells. To meet this goal, we first utilized a yeast screen to discover novel protein(s) that can bind to the Nur77 protein. Several candidates were previously discovered with this approach, so in this project we created the tools to confirm findings using a pull-down assay. The pull-down is a follow-up test to make sure the proteins actually stick together, directly visualizing binding between Nur77 and the other protein(s). We created the positive control plasmid DNA that will make the Notch1 protein linked to a His-tag so that the Notch1 protein can be easily isolated and purified. Notch1 is known to interact with Nur77 and will serve as a positive control for our pull-down. Future steps are to optimize protein purification and complete the pull down assay for the positive control. By understanding the role of Nur77 in different types of T-cells we can better understand the functions of T-cells as well as their unique functions in disease control and autoimmune diseases.

Abstract Name: The role of YTHDF1 in regulating neuroinflammation induced by lipopolysaccharide

YTH N6-Methyladenosine (m6A) RNA Binding Protein 1 (YTHDF1) is a classical reader protein that binds to m6A-modified transcripts to regulate their translation; but its role in Alzheimer's Disease (AD)

pathophysiology, particularly in neuroinflammation, a key factor of AD, remains poorly understood. Our goal is to explore YTHDF1's role in the context of neuroinflammation and gain molecular insights by employing mouse and cell models. We hypothesize that YTHDF1 modulates lipopolysaccharide (LPS)-induced neuroinflammation both in vivo and in vitro. Control and Ythdf1^{-/-} mice were injected with LPS, then RNA was isolated after 1 day (acute) or 4 day (chronic LPS challenge) and quantified by RT-qPCR. The result shows that YTHDF1 limits the induction of acute inflammatory response but attenuates chronic inflammation in response to peripheral LPS administration. We further explored the cellular mechanism by knocking out the YTHDF1 in microglia like cell line, C20. Lipid droplets and myelin phagocytosis experiments were applied to cultured YTHDF1 KO and WT cells. Loss of YTHDF1 reduces the myelin phagocytosis function of the cell and there is less lipid droplets observed compared with WT cells. This observation is extremely relevant because it is becoming evident that failure of immune resolution underlies chronic inflammation and subsequent neurodegeneration in AD. Overall, our findings suggest that YTHDF1 could play essential roles in a LPS induced neuroinflammation model.

Abstract Name: Eudoxus of Cnidus and Method of Exhaustion

Eudoxus of Cnidus (c.390-c.340 BCE) was the world's greatest mathematician before Archimedes. He made significant contributions to astronomy and philosophy. History remembers him as the person who proposed a Method of Exhaustion. This project explores Eudoxus' formulation and application of the Method of Exhaustion, which is used to find the area and volume of a shape by inscribing polygons inside of it, with an increasing number of sides. This method was deemed a precursor to integral calculus and set a foundation for many concepts that were used by later mathematicians. Also, this study analyzes Eudoxus' invention in comparison to the modern limit theory. Owing to that, emphasized Eudoxus' mathematical thought and his influence on both ancient and modern mathematics.

Abstract Name: Accessibility to Firearms and Dynamics of Domestic Violence Homicides in the United States

Domestic Violence (DV) is a rising concern in the U.S. that imposes social costs, such as by lowering productivity and labor force participation. The availability of firearms and deadly weapons elevates the chances of homicides, including those from DV incidences. Therefore, states have enacted Extreme Risk Protection Order (ERPO) policies to minimize homicides involving the use of firearms and their impacts. Compared to the state policy Domestic Violence Restraining Order (limited to intimate/dating relationships), this policy allows broader relationships to petition an immediate court order against those being suspected of harming others or themselves from possessing and purchasing firearms. My study will look into total cases involving extended family members, alongside controlling for the effects of DVRO. The average impact of ERPO and heterogeneity by gun ownership shares across states will be estimated using an event-study strategy with the panel data from the Uniform Crime Report from 2012-2021. After controlling for multiple factors, there is no evidence supporting the effect of ERPO on DV homicide cases, regardless of the type of relationship. The findings of the research will help inform policymakers on how to design effective policies against domestic violence.

Abstract Name: Interwoven Histories of Los Angeles's Ethnic Communities

In modern day Los Angeles, the three largest minority groups that make up the city are Hispanic or Latino, Asian, and African American. These communities are credible pillars of the Los Angeles we know and love today, and are able to further warrant their place in Los Angeles culture through their complex and weaving histories. During World War II, those of Japanese descent were indiscriminately relocated and incarcerated into internment camps after the bombing of Pearl Harbor. The internment and thus the absence of Japanese in Los Angeles made room for Black Americans during a time of scarce segregated housing, introducing the development of Black communities like Bronzeville. As pillars of California's agricultural industry at the time, the absence of Japanese Americans also created a significant labor shortage that led to the creation of the Bracero Program, a short-term contract labor program that brought millions of Mexican workers to the United States. After the dissolution of the relocation and internment orders, Japanese Americans were confronted with newcomers that seemingly took their place. In this confrontation, Japanese Americans, Black Americans, and Mexican Americans were met with each other and their own biases and prejudices, thus leading to areas of both discomfort and conflict, and coexistence and coalition. My research demonstrates the interconnectedness of Los Angeles's ethnic communities and how their wartime experience shaped relations between African, Japanese, and Mexican Americans. This study illustrates how citizenship, race, ethnicity, and national boundaries have been dynamically constructed and negotiated. This project relies on Proquest's Historical Black Newspaper database and The California Digital Newspaper Collection to look at ethnic

affinity-organized newspapers like the Calexico Chronicle, the Los Angeles Sentinel, and the Pacific Citizen and how each publication wrote about Japanese internment and resettlement from 1942 through 1952.

Abstract Name: Acting Religion: Analyzing the AIDS Crisis Through Religious Response

During the HIV/AIDS crisis of the 1980s, the association between the disease and homosexuality led the country down a dangerous path; homophobia created systematic barriers that restricted research, treatment, and a potential cure. For people with AIDS, community support served as one of the best treatments outside of medication and therapy. Across the country, communities—whether from partners, peers, family, or religious institutions—came together to provide aid and care. My paper demonstrates the different ways that AIDS fits into different religious frameworks regarding compassion and illness and how it manifested itself in the 1980s. In my research, I have categorized the varying response of different religious constructions into three groups: blame, embrace, and help. While these categories are distinct, they all demonstrate the ability of different religious constructions to separate sexual morality and illness which ultimately led to their support or abandonment of people with AIDS. Groups like Christian fundamentalists have defined AIDS as a divine punishment. Hence, they blamed those who have failed to comply with traditional norms of sexual morality and reasoned illness and death as natural consequences. In other cases, religious groups embraced people with AIDS, as the disease was separated from sexual morality and conceptualized as an illness. Representatives of these groups, like Buddhists and some Reform Jews, participated in community organizing for people with AIDS and pushed for preventative care measures. In the final example, religious groups acknowledged HIV/AIDS as a public health crisis but were careful to demonstrate their care and compassion for the sick without explicitly condoning the homosexuality. In this 'love the sinner, hate the sin' example, these groups were willing to help those with AIDS, but while also helping themselves by utilizing AIDS as clear medical validation for their moral teachings on homosexuality.

Abstract Name: Attitudes and Perceptions of Mental Health in the Vietnamese Community: A Comprehensive Analysis

This thesis explores the complex and multifaceted landscape of attitudes and perceptions toward mental health within the Vietnamese community, emphasizing the cultural, social, and generational factors at play. Mental health issues remain a significant global concern, and understanding how these issues are perceived and addressed within specific cultural contexts is vital for effective mental health promotion and intervention. In the case of the Vietnamese community, the interplay of cultural values, stigmatization, and access to mental healthcare services makes this study particularly relevant. Additionally, the study highlights the role of cultural competency among mental health professionals and the availability of culturally relevant resources.

Key factors such as traditional beliefs, familial roles, collectivist values, social norms, and historical influences, like the Vietnam War, are briefly explored in their impact on attitudes. Fear of gossip and concerns about reputation emerge as primary barriers to seeking help. However, existing research often lacks a comprehensive analysis of these influences and fails to account for generational and locational differences. This thesis addresses these gaps by examining how age and environment interact to shape mental health perceptions within this minority group. Using survey data from Vietnamese individuals in both the United States and Vietnam, this study evaluates age and location as independent and combined factors. Findings suggest that immigrants often hold false beliefs of superior mental health, younger individuals and those in the U.S. exhibit more positive perceptions, and most participants attribute mental health challenges to life circumstances but still have faith in biomedically based treatment. By shedding light on the complexities of mental health within this community, this research contributes to the broader discourse on culturally competent mental healthcare and advocates for strategies that promote mental well-being while respecting cultural values and traditions.

Abstract Name: Improving ZnO Nanoparticle Synthesis and Applications

Zinc oxide (ZnO) is a biocompatible inorganic semiconductor with light-emitting and semiconducting properties, making it ideal for use in technological applications. This study focuses on optimizing the hydrothermal synthesis of ZnO nanorods to achieve highly crystalline structures with diameters below 50 nm and optimized length-to-diameter ratios. These dimensions are essential for enhancing the performance of ZnO-modified electrochemical sensors, which rely on the properties of ZnO for improved sensitivity, accuracy, and scalability. The synthesis process was optimized by varying autoclave temperature and surfactant concentrations to identify the best conditions for ZnO nanorod growth. X-ray diffraction was used to confirm the crystallinity of the ZnO nanorods, while scanning electron microscopy (SEM) and transmission electron microscopy (TEM) provided detailed morphological characterization of the nanorods, confirming their desired size and shape. UV-visible spectroscopy showed strong absorption around 370 nm, indicating a direct bandgap of approximately 3.35 eV, consistent with the expected properties for ZnO. The electrochemical performance of the ZnO nanorods was evaluated using cyclic voltammetry, which tracks the current response under varying voltage conditions. The results are hypothesized to show significant improvements in sensitivity and stability compared to non-optimized ZnO, highlighting the importance of controlled synthesis in achieving the desired electrochemical characteristics. Future research will focus on further refining the integration of ZnO nanorods with electrode materials, and investigating potential applications in biosensors and photoelectric devices. By addressing challenges in the synthesis and characterization of ZnO nanorods, this study lays the groundwork for more reliable and cost-effective ZnO-based sensors, advancing their use across various fields such as environmental monitoring, medical diagnostics, and industrial applications.

Abstract Name: The Pressure Game: Linking Stress and Performance in College Soccer Players

The relationship between pressure and athletes' performance has been a longstanding topic of debate in the literature. Soccer players frequently encounter numerous stressful moments during games. Many studies have focused on examining the effects of stress on performance, often centering on high-pressure situations such as penalty kicks and shootouts. For example, Jordet et al. (2007) analyzed international soccer tournaments and found that players often underperform in high-pressure scenarios due to heightened anxiety. This anxiety disrupts motor coordination and decision-making, leading to execution errors. In this study, unlike previous research, we monitor players' performance under varying levels of stress throughout entire games. Each player wore a tracker during matches, which recorded metrics such as heart rate, running distance, recovery data, and workload management. We used heart rate as a proxy for mental pressure and team scores as a measure of team performance. After employing econometric regression analyses, our findings indicate that pressure significantly impacts the performance of college soccer players. Players who experienced elevated heart rates, indicative of higher mental pressure, often exhibited decreased physical output and decision-making efficiency during critical moments. Conversely, players who maintained a steadier heart rate performed more consistently, suggesting a potential link between emotional regulation and athletic success. These results underline the importance of mental resilience and stress management in competitive sports. Incorporating psychological training and stress-reduction strategies into athletes' routines may help optimize performance, particularly during high-stakes scenarios. Future research could explore interventions to mitigate stress and further examine the interplay between physiological and psychological factors in athletic performance.

Abstract Name: Determination of Conditions Causing the Leaching of Anticoagulant Rodenticides in Water

Anticoagulant rodenticide contamination in the environment has become a concern in recent years due to the rise in the use of rodenticides worldwide and the potential for more potent forms to enter ecosystems. The anticoagulant classification of rodenticides works by preventing blood clotting in an organism which eventually leads to internal hemorrhaging and mortality. One specific mode of environmental contamination is chemical leaching, which causes these rodenticides to release their active ingredient into natural bodies of water. Once entering these water systems, rodenticides can harm non-target wildlife, and potentially humans. This experiment examined contamination caused by the leaching of two rodenticide active ingredients, warfarin and brodifacoum. Warfarin and brodifacoum were chosen due to them being commonly used rodenticide baits that are chemically similar to one another, with warfarin being a first-generation rodenticide and brodifacoum being a second-generation rodenticide that is more potent. A dissolution apparatus was used to simulate different leaching conditions and their effect on the concentration of the two rodenticides in water, as measured with high performance liquid chromatography with tandem mass spectrometry (HPLC-MS/MS). Variable parameters including pH and stir rate were used to determine the rate and extent of leaching for different commercially available baits. Results provide valuable information regarding conditions that induce and increase leaching, helping to minimize future rodenticide contamination in the environment.

Abstract Name: The facilitative impact of drought on the allelopathic effects of *Rhamnus cathartica* on *Lactuca sativa* germination and growth.

The invasive species, *Rhamnus cathartica*, has rapidly invaded natural plant ecosystems throughout the United States with its allelopathic chemical, emodin. Droughts are increasing in duration and severity due to climate change, yet no research has been conducted studying the effects of drought conditions on buckthorn allelopathy. A 14 day factorial experiment was implemented that measured the germination, survival, and biomass of lettuce seeds under four experimental conditions of buckthorn and watering to understand the potential long-term effect that climate change induced drought could have on buckthorn allelopathy. The results determined that drought enhances the detrimental effects of emodin leading to a decrease in adjacent plant germination rate and survival. Germination time and dry biomass were not statistically different between lettuce grown under conditions of buckthorn only and buckthorn & drought. Statistical analyses were conducted in R and translated into Microsoft Excel to provide conclusions after conducting a two-way ANOVA test, a Chi-Squared test, and a Wilcoxon Ranked-Sum test. Further research will be necessary to test the strength and duration of droughts associated with these results, in addition to research regarding allelopathy of other invasive plant species. This experimental design should also be applied to native species found in buckthorn invaded areas in order to generalize the results to real ecosystems. These findings could be crucial predictors for biodiversity and ecosystem functioning in upcoming years as global warming progresses.

Abstract Name: Exploring Positive Distractions in Pediatric Healthcare Design

This research investigates the role of positive distractions in healthcare environments, focusing on the use of architectural elements to improve patient well-being. Specifically, it examines features such as access to nature, color, and art installations in pediatric spaces, aiming to understand their impact on reducing stress, enhancing satisfaction, and promoting healing. Healthcare design has traditionally prioritized clinical efficiency over emotional and psychological considerations. However, research highlights the importance of incorporating elements that redirect patients' focus away from the clinical environment, known as positive distractions (Ulrich, 2000a). This research examined a study of literature that found substantial evidence supporting that natural elements significantly calm young people (Gill, 2014; Tillmann et al., 2018). By integrating biophilic features, or elements of nature, this research contributes actionable insights into creating holistic environments that cater to patients' emotional and physical needs. This study's methodology began with shadowing professionals across various departments at Lexington Shriners Hospital to gain a deeper understanding of healthcare operations and observe the application of design elements. Additionally, modeling programs were also examined, which align closely with tools used in architecture. A site visit to MUSC Shawn Jenkins Children's Hospital further provided real-world implementations of positive

distractions. These experiences, combined with qualitative research and patient feedback, shaped the findings of this research. The study's key deliverable was a design concept called Zoo to You, an immersive space for pediatric patients and their families. By incorporating biophilic elements and interactive features, this design offers a sensory-rich experience that provides stress relief for all ages. The research demonstrates that when available, positive distractions are actively used by patients and effectively improve their healthcare experience. These findings underscore the importance of designing spaces that foster healing, comfort, and connection, aligning with the evolving priorities of patient-centered care.

Abstract Name: Examining the Potential Impact of Phytochemicals on Oral Mucositis in the Pediatric Population

Oral mucositis is the inflammation and ulceration of the oral cavity that occurs in over 80% of patients undergoing cancer treatment to the head and neck. Pediatric cancer patients diagnosed with solid tumors or hematologic malignancies will have an increased rate of oral mucositis due to the treatment regimen. The cytotoxic nature of chemotherapy, radiotherapy, and stem cell transplants adversely affect mucosal cells and the salivary glands. Pediatric patients are at higher risk of developing oral mucositis than adults receiving the same treatment because children have faster basal cell turnover rates. Severe inflammation and pain resulting from oral mucositis make eating, drinking, and oral hygiene difficult. This difficulty places the pediatric patient at risk for malnutrition, dehydration, and infections of the oral cavity and bloodstream, all of which can be life-threatening. The purpose of this review is to provide evidence-based recommendations that are alternative and complementary to current treatments. These novel recommendations will serve to update patient education and expand treatment guidelines. Current protocols to treat mucositis and improve oral hygiene practices in the pediatric cancer patient population can dehydrate and irritate the oral mucosa and exacerbate painful conditions that may discourage healthy daily habits. This review's thorough analysis of the research identifies phytochemicals that provide multiple modalities for treating moderate to severe challenges to oral health and hygiene caused by oral mucositis.

Abstract Name: Strategy-Dependent Brain Activity During Mental Rotation Using fMRI

Mental rotation of 2D and 3D objects is a test of visual-spatial skills. Mental rotation and mathematical reasoning skills rely on many of the same cognitive processes and areas of the brain, and improving mental rotation abilities can improve grades and retention in calculus and geometry classes. However, one remaining question is whether the strategy an individual uses to solve mental rotation problems can influence their cognitive and neural processing, which may ultimately predict performance and brain activity. To answer this

question, we used functional magnetic resonance imaging (fMRI) to observe brain activity while 55 adult participants (mean age 23 years) performed a 3D mental rotation task. Participants filled out a lab-developed mental rotation strategy questionnaire which assessed tendencies. Two strategy tendencies were investigated: (1) Holistic strategies (gestalt/manipulation of an entire object) and (2) piecemeal strategies (part by part or feature-based manipulation of an object). While there was not a significant effect of strategy on most of the behavioral measures and performance, activity in two regions of the brain correlated with strategy tendencies: the frontal eye fields (FEFs) and the dorsolateral prefrontal cortex (dLPFC). As brain activity in the FEFs increased, the tendency to use piecemeal strategy also increased, whereas holistic strategy tendency decreased. Meanwhile, as activity in the dLPFC increased, holistic strategy tendencies increased. Based on these findings, a possible interpretation is that holistic strategy usage involves “capturing the image” and mentally rotating it, requiring greater working memory. In contrast, piecemeal strategy usage may involve parsing the visual stimuli with frequent eye movements. This suggests that certain mental rotation strategies rely on corresponding cognitive processes but are equally effective strategies. We plan to investigate this interpretation further by looking at correlations with accuracy on calculation and working memory tests and looking at outcomes post-mental rotation training.

Abstract Name: Examining Cybersecurity Challenges in K-12 Schools

Cyberattacks on the education sector in the United States have risen to alarming rates among K-12 institutions over the past decade. During the pandemic, the frequency of attacks increased exponentially when K-12 institutions began to rely heavily on technology to teach, making schools easy targets for cybercriminals. These attacks have compromised the privacy of millions of students and have caused major financial losses in addition to disruptions to the use of technology in schools. The purpose of this review is to examine the underlying causes and to identify potential solutions for K-12 institutions. Articles detailing K-12 cybersecurity challenges were analyzed to determine the causes, frequency and types of cyberattacks on K-12 schools. The research found that many schools lack the resources and budget to secure their information technology systems, contributing to the ever expanding threat landscape allowing cybercriminals to continue targeting the education sector. K-12 institutions lack cyber education programs aimed at students, faculty, and staff thus increasing the risk of cyberattacks due to a lack of cyber awareness. In addition, many K-12 officials state that they have had limited to no support from government agencies regarding cybersecurity concerns. This review’s careful examination of current cybersecurity challenges facing K-12 institutions may produce long term effective strategies such as creating centralized resources, increasing cybersecurity education, and establishing minimum federal cybersecurity requirements for schools in order to protect the education sector from further exploitation, disruption, and harm.

Abstract Name: From Aspiring Educators to Advocates for Leadership and Change Through Community-Based Action Research

This presentation explores how community-based action research empowers pre-service educators to grow into advocates for leadership and systemic change. Rooted in the course Leadership for Teachers, this approach focuses on equipping future educators with the tools to address real-world challenges through collaboration, advocacy, and actionable solutions. The course utilizes an action research approach to challenge students to identify and respond to pressing educational and community needs, such as supporting adolescents facing mental health crises or increasing access to extracurricular sports for children living in poverty. Students work in teams to design solutions, collaborate with community partners, and leverage campus resources to bring their projects to life. Through mentorship, they gain essential skills in networking, community engagement, and iterative problem-solving. While traditional undergraduate research often emphasizes publication, this model centers on action and impact. Students experience the complexities of real-world advocacy, navigating obstacles, and learning resilience through reflective practice. Mentorship plays a pivotal role in guiding students through these experiences, connecting students to impactful networks, and helping students transform challenges into opportunities for growth. These projects deepen students' understanding of educational systems and prepare them to lead with purpose and confidence in their future careers as educators committed to advocacy and meaningful change. This work shares practical insights into guiding preservice educators through impactful action research projects, with an emphasis on highlighting student voices to share how such experiences cultivate leadership, advocacy, and the ability to effect meaningful change, positioning students to make a lasting impact in the communities they serve.

Abstract Name: Deep Inelastic Production of Protons

Studies of the proton structure have been of large importance through prior decades and recent focus turned to the investigation of the target fragmentation region. We present studies of beam single spin asymmetries for semi-inclusive protons ($ep \rightarrow e'p'X$), produced in the TFR. Such measurements were performed with the CLAS12 detector in Hall B at Jefferson lab using a longitudinally polarized 10.6-GeV electron beam on an unpolarized hydrogen target. Results of this study captured the transition between the TFR and CFR regions showing a clear sign change in the single spin asymmetries for the protons. An update on the progress of the

analysis will be presented with a focus on suppressing the contributions of exclusive resonances from the deep inelastic process.

Abstract Name: Mechanochemical Synthesis and Characterization of Dysprosium Oxide-Hematite Magnetic Ceramic Nanostructures

Mixed oxide nanoparticle systems recently attracted considerable interest, due to their potential applications in sensing, catalysis, and flexible electronics. In this study, we synthesized dysprosium oxide-hematite nanostructures using mechanochemical activation by high energy ball milling at two molar concentrations and ball milling times of 0, 2, 4, 8, and 12 hours. The prepared systems were characterized by transmission Mossbauer spectroscopy and analyzed by least squares fitting using Lorentzian lineshapes. For 0-hours, the spectrum was fitted using a sextet with hyperfine magnetic field of 51.9 T, characteristic to hematite. Spectra of the milled samples were analyzed using additional sextets according to the model of local atomic environment. These sextets had lower hyperfine magnetic field values due to substitutions of non-magnetic dysprosium ions at the iron sites. The subspectra could be assigned to dysprosium-doped hematite. A quadrupole-split doublet with a quadrupole splitting of about 0.7 mm/s was needed to account for the superparamagnetic dysprosium iron perovskite (dysprosium orthoferrite) phase, whose particles are too small to be magnetic at room temperature. The doublet's abundance increased up to 52% at longer milling times. The reaction mechanism can be described using the equation $\text{Dy}_2\text{O}_3 + \text{Fe}_2\text{O}_3 \rightarrow 2\text{DyFeO}_3$. Several sextets in the spectra indicate the formation of solid solutions in the milled system. This can be explained by the difference in the ionic radii of the dysprosium and iron ions. Our results demonstrate that Mossbauer spectroscopy is a powerful technique for the identification of crystalline phases and inequivalent lattice sites in the system, based on analysis of their hyperfine parameters.

Abstract Name: Speech Perception and Production Variability in Preschoolers With and Without Speech Sound Disorders

Project purpose: We investigated the relationship between speech production variability and phonological processing to determine markers of a phonological speech sound disorder. Children with speech sound disorders (SSD) struggle to produce and perceive speech due to various causes (such as motor planning, articulation, speech perception), but a large subgroup of children are diagnosed with a phonological disorder. The ability to manipulate and process sounds of a language is called phonological processing. Lexical variability is measured across multiple repetitions of the same word and is thought to reflect the instability of a child's phonological representations for words. However, lexical variability occurs in both typically

developing (TD) children and children with SSD. Previous research also indicates that speech error types may account for differences in phonological processing skills; namely, omissions and atypical speech errors have been identified as indicators of poor phonological awareness (PA). PA skills are crucial in literacy development; thus, children with a phonological SSD are at-risk for later reading difficulties. To investigate the relationship between speech production variability and phonological processing, we measured segmental variability, lexical variability, types of speech errors, and speech perception in children with TD and with SSD. Twenty-four 4- and 5-year-olds, 12 with TD and 12 with a phonological SSD, were included in the study. Participants completed a battery of speech, language, oral-motor, and PA tests, a speech perception task, and the Word Inconsistency subtest of the Diagnostic Evaluation of Articulation and Phonology Test. Results indicate that after accounting for receptive vocabulary, segmental variability explains the most variance in phonological processing. Our results offer insight as to why children with SSD are variable in their speech production and how this differs from TD children.

Abstract Name: Effects of Mindfulness Health Education Lessons for At-Risk Adolescents: A Pilot Study

Project Purpose: This project sought to improve the mental health of underserved high school students through mindfulness-based intervention activities. **Background:** Mental health issues are rampant in Coconino County, Arizona, and are associated with a lack of health insurance, food and housing insecurity, and low socio-economic status. These factors are present in our target population, which is an eleventh-grade English class at Summit High School in Flagstaff, Arizona. Poor mental health is linked to poor academic performance, increased likelihood of substance use, poor decision making, and strained interpersonal relationships. This may decrease their quality of life and inhibit them from pursuing successful careers. **Methods:** Three health education lessons were delivered weekly to students aged 17 to 19. Students were provided journals and guided prompts to practice mindfulness, with incentives offered for the participants who journalled the most days over the course of the intervention. Education on healthy relationships was fostered through group discussion, a jeopardy game, and a “red flag/green flag” activity, where students were tasked with proposing healthy and unhealthy traits of relationships. Pre- and post-intervention surveys were used to evaluate participants' relational knowledge. Lastly, students learned about healthy coping mechanisms and emotional regulation through a lecture and class discussions; qualitatively, we measured the coping mechanisms they utilized while playing board games in teams. **Conclusions:** On average, students journalled for 7.2 days during the 14 day period of the intervention. 100 percent of students increased their knowledge concerning healthy relationships between the pre- and post-test. During board game play, 80 percent or more of students were observed practicing healthy coping mechanisms. Our results display that a mindfulness-centered classroom intervention may be a promising method for improving the mental health of at-risk teenagers.

Abstract Name: Examining the Impact of Stress on Recall for Everyday Scenes

Research suggests that long-term stress can negatively affect one's ability for memory retrieval (e.g., Klier & Buratto, 2020). Furthermore, extremely traumatic or emotional events are well recalled, but retrieval of peripheral details is unreliable (e.g., Marloe et. al, 2020). The aim of the current study was to examine a gap in the literature by investigating whether more typical stress levels and scene complexity impact memory recall of everyday scenes. Eighty nine participants were recruited from an undergraduate psychology pool who all received research credit for participation and were randomly assigned to one of three stress groups manipulated through differing instructions and/or a displayed timer (high - shown a 20 second timer, moderate - "exactly 20 seconds to view this scene", low - "limited amount of time to view the scene"). All participants viewed and memorized five simple and five complex scenes presented in a counterbalanced and randomized order. Each scene was followed by a five question quiz regarding recall of specific scene details. A mixed factorial ANOVA resulted in no significant main effect for the stress level and no significant interaction between stress and scene complexity. There was a significant main effect for scene complexity, with recall of simple scenes ($M = 72.83$) better compared to complex ($M = 61.36$) scenes. While there was no significant difference of recall accuracy between stress groups, future studies should be conducted using a stronger stress manipulation. Additionally, more research should further investigate recall of everyday scenes.

Abstract Name: Evaluating the Healthiness of Lifestyle Features Among College Students: A Judgment Analysis

People may think differently about what makes a healthy lifestyle. Relatedly, people may have different standards about what makes a healthy lifestyle for men versus women. The purpose of this study is to assess the subjective weights assigned to various cues, or lifestyle features (Exercise, Vaping, Eating a Vegetarian Diet, Gender) as student participants form judgments of the healthiness of hypothetical students. The secondary purpose is to determine the extent to which the gender of the hypothetical student influences judgments of healthiness. A questionnaire included 16 hypothetical profiles ($2 \times 2 \times 2 \times 2$ factorial design), and participants were asked to rate each profile on a scale from -10 (extremely unhealthy) to +10 (extremely healthy). The SONA system was used to recruit participants, 56 completed the judgment task. SPSS was used to determine the correlation between each of the cues and judgments of health. These correlations indicate the strength of each cue's influence, and were cluster-analyzed to explore subgroups who used the cues differently. Analysis revealed that the Exercise and Vaping cues received the most weight when participants judged the health of the hypothetical students. The Gender cue showed a small and positive average correlation, indicating a slight bias towards considering females as more healthy than their male counterparts. Cluster analysis revealed that most participants perceived a Vegetarian Diet as healthy, but a small minority perceived a Vegetarian Diet as unhealthy relative to a Typical American Diet. Future studies building on these findings could examine how medical students and physicians make similar judgments.

Abstract Name: Quantification of Shear Stress Distribution in a Microfluidic System via Computational Fluid Dynamics Simulation

Microfluidic devices are promising tools to better understand in vitro cellular behavior. Previous studies have shown that the fluid flow rate in these devices has a direct effect on shear stress, which may alter cell's growth rate and differentiation. Furthermore, microfluidic-based platforms can facilitate the understanding of transport processes and nutrient exchange in various human organoids such as tumors and lymph node-mimicking models. The purpose of this study is to incorporate computational fluid dynamics (CFD) techniques in simulating fluid flow in a microfluidic system. Two different applications for cell culture under flow and flow behavior through the human extracellular matrix (ECM) are considered. In the first model, by assuming the device channel is filled with moving fluid, the predictions of flow-induced wall shear stress are obtained. In the second model, the channel is assumed to be filled with porous material and the filtration flow through the permeable region is evaluated for a physiological range of ECM permeability values. Three-dimensional models of the microfluidic slide (Ibidi GmbH, Germany) are created using Autodesk Fusion 360. The mathematical form for the first model is defined using the Navier-Stokes governing equations to describe the laminar, viscous, and Newtonian flow properties, while the second model includes the Brinkman equations to describe the fluid perfusion in the porous domain, representing the characteristics of human-derived matrix. The fluid flow in both models have been prescribed by a constant mass flow rate boundary condition at the inlets and zero pressure at the outlets. The walls of the device are assumed to be non-slipping. ANSYS CFX software is used to carry out simulations that produce numerical data and contour representations of velocity and shear stress in the device channel. The relationship between flowrate and shear stress as well as the filtration flow and ECM permeability are analyzed.

Abstract Name: Computational Investigation of Vocal Fold Vascular Lesions Effects on Human Phonation

The vocal folds (VFs) are multi-layered structures composed of muscle tissue and ligament enclosed by a mucosal covering. The tissue vibration and glottal airflow dynamics in the larynx determine the production of phonation in mammals. Abnormal growths of VF tissue within or along its covering, referred to as lesions, can hinder VF vibrations and cause vocal difficulties. VF vascular lesions occur due to the enlargement or rupture of blood vessels along the VF mucosa layer and are characterized by a variety of symptoms and pathologies. The presence of these lesions leads to vocal fatigue and dysphonia by impeding VF oscillation

and causes hoarseness by altering the airflow dynamics through the glottis. In our computational investigation we use fluid-structure interaction (FSI) methodology to simulate the VFs where vascular lesions are present. A realistic three-dimensional-bilayer VF model is assumed, which considers the variation in mechanical properties of cover and body layers. FSI is simulated through the coupling of tissue vibrations and transient glottal airflow in ANSYS workbench platform. The geometrical model used in this study is created using Autodesk Fusion 360 software based on STL files provided from a computed tomography scan of a human larynx, with VFs designed to fit into the laryngeal space. Symmetry along the sagittal line is assumed for the VFs. The lesions are created to represent the presence of a dilated blood vessel, or vessel ectasia, and the presence of a blood clot, or vascular polyp. Lesions are located in the cover layer with varying size and mechanical properties. Two FSI models, one with lesions and one without, are created to assess the effect of lesion presence. Analysis of the glottal airflow dynamics and VF tissue vibrational patterns between these two models can be used to determine the impact of vascular lesions on biomechanical characteristics of phonation.

Abstract Name: Breaking the Silence: Challenging Mental Health Stigmas in the Black Community

This poster delves into the critical intersection of mental health, systemic inequities, and advocacy within Black communities, underscoring the pressing need for systemic reform and inclusive approaches to mental health care. Using a meta-analysis of existing research alongside ongoing studies conducted in the Koenigs Lab, the project examines the unique mental health challenges faced by Black communities, which are shaped by a confluence of historical oppression, systemic racism, societal inequities, and intergenerational trauma. Due to a number of variables, including socioeconomic inequities, stigma, mistrust of healthcare systems, and the lingering effects of structural racism, Black people face disproportionately high obstacles to mental health care. These gaps are exacerbated by police-related violence and the criminalization of mental health crises, which leads to trauma loops and prevents people from receiving the care they need. The effectiveness of group PTSD therapy for jailed people, many of whom are members of Black and other underprivileged communities, is the current focus of study at the Koenigs Lab. In order to address the disregarded mental health needs of jailed populations, this research attempts to incorporate evidence-based mental health therapies into correctional settings. This work has important ramifications for creating systemic change and minimizing disparities both inside and outside of correctional facilities, as Black people are disproportionately represented in the criminal justice system. Proposed solutions center on a multi-faceted approach to dismantling barriers and promoting mental health equity that includes community education, crisis intervention teams, policy advocacy, peer-led initiatives, and more. By combining these tactics with thorough research, this study emphasizes how urgent it is to address inequities in mental health and advocates for practical changes that put inclusivity, equity, and cultural sensitivity first to eliminate structural obstacles, lessen stigma, and establish long-lasting structures to promote the mental health and general wellbeing of Black people and communities.

Abstract Name: Impact of Climate Change and Environmental Disasters on LGBTQ+ Youth Homelessness

The increasing severity of climate change and the prevalence of environmental disasters, such as hurricanes and wildfires, pose significant challenges for marginalized populations, particularly LGBTQ+ homeless youth. This research explores how these youth, who already face systemic vulnerabilities due to factors like family rejection and discrimination, are disproportionately affected by climate-related crises. Utilizing qualitative methods, including interviews and case studies, the study aims to understand the unique experiences of LGBTQ+ homeless youth during and after environmental disasters. It examines barriers they encounter in accessing emergency services, shelter, and healthcare, as well as their coping mechanisms in the face of displacement. Additionally, this research highlights the intersections of homelessness and climate vulnerability, revealing how these dynamics exacerbate existing inequalities. The findings aim to inform policy recommendations that create inclusive disaster response plans and support services tailored to the needs of LGBTQ+ homeless youth. By emphasizing the importance of recognizing and addressing these intersections, this study seeks to contribute to broader discussions on environmental justice and social equity. Ultimately, understanding the impact of climate change on LGBTQ+ youth homelessness is crucial for developing effective strategies to protect and support this vulnerable population in an era of increasing environmental uncertainty and instability, as climate change continues to escalate worldwide.

Abstract Name: Researching How Community Gardens Can Thrive

Community gardens in marginalized neighborhoods of Milwaukee are rich with historical value and provide a space for residents to gather and hold various activities. Media accounts and history textbooks fail to disseminate these positive stories of resilience and resistance, often reverting to a single story of decline and disinvestment. Since 2012, the Buildings-Landscapes-Cultures public humanities project at UW-Milwaukee has been exploring methods to identify and disseminate histories of Milwaukee's poor, underserved, and segregated communities. Recently, we worked with residents who are part of the Walnut Hill Community Garden in Milwaukee, Wisconsin. This presentation examines three methods that helped us recreate an alternative history that demonstrates the resilience and dreams of this otherwise ignored community. First, we investigated local archives to uncover the physical history of the land. Through permit record, Census, and Sanborn Fire Insurance Map research, we uncovered what buildings used to occupy the space, why they were removed or destroyed, and discovered when and how the community claimed the land back as their own. Our second method included participating in community-led walks showing local art, parks, homes, businesses, and other landmarks. We also collected oral histories where we listened to community residents' experiences in the neighborhood. Through these three interconnected approaches, we uncovered the immense number of relationships, families, businesses, and individuals that thrive in the Walnut Hill neighborhood. We worked with the gardeners to envision inclusive, holistic design ideas for the garden, while being respectful of the past. These ideas were disseminated back to the community as a community asset map booklet, cards with future garden aspirations, and resident biography cards. Our research ends with a hope that community-

engaged research methods will continuously explore ways to give back the collected history of the neighborhoods we work with.

Abstract Name: Structural Insights Into Wild and Mutant M1775K, G1656D and T1700A BRCA1 Proteins

Breast Cancer gene 1 (BRCA1) is a tumor suppressor gene that deals with repair and genomic stability. Due to its connection to breast cancer, understanding the structure provides insight into the cancer. BRCA1 wildtype and mutated structures were collected from the Protein Data Bank (PDB) and used for structure variability investigation. PyMOL was utilized to align these structures and enable a detailed comparison of wild-type BRCA1 against various mutants (M1775K, G1656D and T1700A). Molecular Dynamics (MD) simulations emphasized the structural differences between the wild-type and mutant forms, through these findings we aim to advance the understanding of BRCA1 mutations and their contributions to cancer predisposition.

Abstract Name: Biodiversity Assessment of Mushrooms in Bowie State University, Maryland, and Enugu State, Nigeria

This study examines the biodiversity of mushrooms collected from Bowie State University campus, USA and in Enugu State, Nigeria. Mushroom specimens, meticulously collected and documented, were employed to fulfill the objective of characterizing mushroom diversity. Utilizing the DNA Subway's phylogenetic analysis tool, DNA barcodes were analyzed, and phylogenetic trees were constructed to compare data. The findings of this investigation have the potential to deepen our understanding of local mushroom communities and provide valuable insights into the similarities among mushroom species found in Nigeria and Maryland. Notably, the results unveiled a genetic similarity spectrum of 59%-99% in Nigeria and 57%-99% in Bowie State University, Maryland. Moreover, distinct clustering of samples from Bowie State University and Nigeria was observed in the constructed phylogenetic tree.

Abstract Name: Sarcocystis Prevalence and Distribution in Coyotes (*Canis latrans*) in Eastern Illinois

Sarcocystosis is a disease caused by single-celled protozoal parasites in the genus *Sarcocystis*. Known as rice breast disease in waterfowl, *Sarcocystis* spp. are common in tropical countries, with muscular *Sarcocystis* being commonly reported within Southeast Asia. More than 150 species of *Sarcocystis* infect numerous species of vertebrates, such as coyotes (*Canis latrans*) and humans as intermediate hosts. The definitive hosts have intestinal *Sarcocystis* spp. infections, while intermediate hosts have sarcocysts in the muscle cells. However, compared to intestinal *Sarcocystis* (*S. hominis* and *S. suis*), reports of muscular *Sarcocystis* spp. in coyotes are scarce with only four published findings. Two studies have reported muscular sarcocysts in captive coyotes infected with *S. hemionilatrantis* and *S. fusiformis*. All previous infections of North American *Sarcocystis* in coyotes have been documented from the western United States, with one study from Oklahoma, United States. More studies could help fill the knowledge gap on *Sarcocystis* in coyotes. In this study, we report the first case of *Sarcocystis* in coyotes as intermediate hosts, from the Midwest region of the United States. *Sarcocystis caninum* is suspected, as it is the only other species found intramuscularly within coyotes, aside from the two previously mentioned. Specimens were collected from a licensed nuisance fur trapper/hunter from the eastern portion of Illinois. Muscle samples from 43 coyotes were screened microscopically and through PCR for *Sarcocystis*, with a result of 9.3% of coyotes infected (4/43). These results suggest that *Sarcocystis* is among coyotes from this region, however, further species identification and characterization is necessary.

Abstract Name: Effects of Respiratory Syncytial Virus Education on the Knowledge of Disease and Vaccination Rates for Individuals 60 and Older

Respiratory Syncytial Virus (RSV) is a respiratory condition known mainly to target toddlers and infants. Recently, the adult population of 60 and older have been affected. There is a lack of education, understanding, and awareness of RSV along often resulting in negative impacts including the need for hospitalization. The purpose of this study is determined if the implementation of an educational intervention about RSV vaccinations will result in lower barriers to seeking care and RSV hospitalizations. It is hypothesized that after implementing the nursing education intervention, these individuals will be more likely to obtain the vaccine and take the necessary steps to avoid the deteriorating consequences of RSV. A quantitative pretest/posttest quasi-experimental design will be used with a sample of adults older than 60 at senior centers. Analysis is to be determined.

Abstract Name: Investigating the Role of Alternative Oxidase in *Fusarium oxysporum* Virulence and Potential for Targeted Antifungal Therapy

Fungal pathogens have historically caused agricultural and ecological damage. The Irish Potato Famine in the mid-19th century led to starvation and mass migration, while the early 20th-century chestnut blight devastated American chestnut trees, altering entire ecosystems. Today, we lose 10-20% of crops to fungal diseases annually, with an additional 10-20% lost post-harvest. For the project, we will be taking a biogeneric approach to disease ecology with the goal of identifying novel therapeutic targets for the treatment of fungal diseases. Alternative Oxidase (AOX) is a mitochondrial enzyme that has been proposed to help pathogenic fungi and protozoa maintain metabolic homeostasis under environmental stress. Our study looks at the role of AOX in the virulence of *Fusarium oxysporum*, a fungus responsible for Fusarium wilt in tomatoes. *F. oxysporum* infects plants through the roots and colonizes the vascular system, leading to wilting symptoms. We hypothesize the fungus relies on AOX to survive hypoxic conditions and oxidative stress within the host xylem. We will test this idea by performing testing inhibitor experiments on isolated mitochondria to test for AOX function. We will also inhibit the AOX of the fungal spores to evaluate the role of this pathway for stress tolerance. If AOX is important for the disease ecology of this fungus, it could be a powerful target for the treatment of fungal diseases in plants.

Abstract Name: ONE LAPTOP PER CHILD: The Use of Technology in Early Education in Rwanda

Rwanda's One Laptop Per Child program was started in the country with the goal of providing each child in primary school with their own laptop. Since the program was started, Rwanda has received the most OLPC laptops out of 64+ participating countries. Currently, the number of deployed laptops is 260,000 in more than 800 schools. This research project allowed a study of some education programs in Rwanda that enable students to have an equal opportunity to learn and develop their digital literacy skills like any other student around the world. The purpose of the research was to interact with different stakeholders to understand how students benefit from the availability of this learning tool and to shed light on the importance of exposure of this technology in a child's life. The research methodology involved interviewing teachers who used this tool the most. The best way to learn about the impact of this program was to get different perspectives from different types of teachers who used these laptops in different ways. With authorization from the Rwanda Education board, these interviews were conducted in 4 different schools in the country, each school was in a different district from the 30 districts in Rwanda. I focused my interviews on two teachers for per school, making the total amount of interviews 8. The stakeholders involved in this program describe the students' improvement of digital literacy skills and the overall experience as life changing and instrumental in their educational journey. Additionally, they spoke about the impact it has had beyond the classroom.

Abstract Name: Incorporation of GNSS Technology for Water-Level Instruments

Central Research Question and Purpose This project aims to enhance the accuracy of water level measurements by embedding a Global Navigation Satellite System (GNSS[ST1]) module in the instrumental package. to achieve self-surveying elevation measurements within an error margin of 1 cm. This improvement is essential for applications requiring precise elevation data, such as vertical land motion detection, sea-level rise measurements, and flood prevention.
Scholarly Context Understanding current and future coastal and inland flood risk requires accurate data to support scientific modeling and analysis. Current elevation surveying tools [ST2] offer high accuracy but are expensive (~\$30k for a leading commercial brand). By leveraging inexpensive GNSS technology and software-based post-processing (<\$500), this project seeks to provide a more cost-effective and scalable solution while maintaining a high level of precision and accuracy. Reducing cost allows for more dense sensor networks, enabling the acquisition of a vertical elevation time series, thus improving the assessment of locally varying processes (such as subsidence or wave action).
[ST3] Methodology The project involves upgrading the GNSS module of the water-level system and conducting a field test at a known survey point to validate the accuracy of the elevation readings. Precise Point Positioning, a software-based post processing technique, was employed to improve the GNSS solution point accuracy. The hardware and software were designed to be robust, modular, and easily scalable to support a wide range of field deployments compared to the narrow scope for current surveying instruments.
Conclusions and Expected Results The field tests that were conducted this past summer yielded a sub 3 cm error. To potentially further increase the accuracy, the deployment time can be increased from 24-hours to a week. Future work includes an integration of the GNSS technology with radar and ultrasonic distance sensors to allow for concurrent tidal measurements.

Abstract Name: Nutrient Effects on Differentiation and Reproduction in *Batrachochytrium dendrobatidis*

As an undergraduate research scholar, my contributions to this project focused on investigating the effects of nutrient conditions on the life cycle of *Batrachochytrium dendrobatidis* (Bd). Specifically, I was responsible for preparing and maintaining Bd cultures on TGhL agar, isolating zoospores through vacuum filtration, and setting up experimental conditions in 96-well plates. I conducted daily imaging of Bd cultures using light microscopy and analyzed the resulting data using Fiji software to quantify the impact of various nutrient treatments on life cycle progression. My work involved identifying the stages of Bd development and comparing how different treatments influenced germling formation, zoosporangia maturation, and zoospore release. Additionally, I contributed to discussions on the potential role of host-associated molecules, such as thyroid hormone and biliverdin, in Bd differentiation under nutrient-limited conditions. This experience enhanced my understanding of experimental design, data analysis, and the ecological implications of pathogen-host interactions.

Abstract Name: Development and Characterization of Controlled-Release Drug-Polymer Complexes for Improved Inflammatory Bowel Disease Treatment Using Electrospray Techniques

Current inflammatory bowel disease (IBD) treatments, though effective in managing symptoms, often yield suboptimal outcomes and adverse effects. Nanoparticle-based drug delivery systems enhance treatment precision by providing targeted delivery to inflamed tissues. This research utilizes electrospray technology to fabricate drug-polymer complexes with improved drug loading, structural integrity, and release profiles, addressing critical gaps in existing systems. This research addresses the limitations of current IBD therapies by developing a novel, pH-sensitive drug-polymer complex targeting chronic gastrointestinal (GI) inflammation. The goal is to improve therapeutic efficacy while minimizing systemic exposure and side effects. This study focuses on encapsulating 5-aminosalicylic acid and select flavonoids using Eudragit S100 and L100 polymers, which leverage GI tract pH variations for controlled, site-specific drug release. Preliminary tests confirm the solubility of Eudragit polymers and active compounds in ethanol, with UV spectrophotometry optimizing detection wavelengths. Single-needle electrospray setups demonstrated that polymer concentration significantly affects fiber morphology; low concentrations (0.5–1% w/v) resulted in droplets, while higher concentrations (>10% w/v) yielded smooth, bead-free fibers essential for uniform drug encapsulation and release. This study highlights the potential of the drug-polymer complex as a promising advancement in IBD therapy. Efforts will focus on designing a multi-layered polymer system

capable of withstanding the digestive environment to enable optimal drug release, alongside exploring triaxial electrospray techniques to improve encapsulation efficiency and enhance the precision of drug delivery to inflamed tissues. Further evaluation will use advanced characterization techniques, including Attenuated Total Reflectance-Fourier Transform Infrared Spectroscopy (ATR-FTIR), Scanning Electron Microscopy (SEM), and Transmission Electron Microscopy (TEM), to analyze the complexes' physical properties, integrity, and drug loading capacity. Ultimately, this research aims to demonstrate that optimized drug-polymer complexes can overcome current therapeutic limitations, offering a more effective approach to IBD treatment and improving patients' quality of life.

Abstract Name: Neurobehavioral and physiologic outcomes in spontaneously hypertensive rats exposed to pediatric traumatic brain injury

Objectives: About 500,000 yearly emergency room visits in the United States are due to childhood traumatic brain injury (TBI), which may render cognitive, behavioral, and emotional disturbances, along with failure to reach age-appropriate developmental milestones. Half of adults are diagnosed with hypertension, which can lead to cardiovascular complications and premature death. Pediatric TBI exposure prior to diagnosis of an underlying comorbidity like hypertension has not been previously investigated. We hypothesized that hypertensive rats will perform inferiorly to normotensive rats despite experiencing the same pediatric TBI. Design: Spontaneously Hypertensive (SHR) and the normotensive control Wistar male rats experienced either a moderate controlled cortical impact (CCI) parietal injury to the right hemisphere or a sham injury at postnatal day 17. Four tasks measured elements of post-TBI neurobehavioral recovery during adulthood after the hypertensive phenotype is expressed. These included the 3-Choice Serial Reaction Time test (3-CSRT) to measure sustained attention, T-Maze Attentional Set Shifting (AST) for cognitive and behavioral flexibility, Open Field Testing (OFT) to examine levels of anxiety, and the Shock-Probe Defensive Burying test (SPDB) observing active and passive coping mechanisms. Results: All injured rats required more training sessions to criterion on 3-CSRT. Normotensive TBI rats displayed lower performance accuracy and higher omissions on all three levels, while hypertensive rats omitted more trials on level 1 ($p < 0.05$). Additionally, SHR TBI rats showed impaired initial rule learning on T maze, while normotensive injured rats displayed deficits in set-shifting ($p < 0.05$). Injured SHR rats engaged in greater grooming times and reduced active burying times in the SPDB compared with control rats ($p < 0.05$), indicative of increased anxiety, while no group differences were detected in OFT ($p > 0.05$). Conclusions: These results support using hypertensive rats as a model for the desired patient population in order to further enhance bench to bedside translatability.

Abstract Name: Survey of Prairie Lakes for Microplastics in eastern South Dakota

Microplastics are plastics that have been worn down into small fragments that invade aquatic environments and have cultivated themselves into most corners of the world. They are less than 5 mm in size and categorized as either primary (manufactured small) or secondary (broken down from larger plastics). Microplastics have been found in ocean surface water and deep-sea benthic zones as well as freshwater systems. They can be harmful to organisms, ecosystems, and human health, though the full extent of their impact is not yet known. The purpose of our project is to survey prairie lakes for the presence of microplastics in eastern South Dakota, a region where little research on microplastics has been done, and compare findings with other regions of the U.S. We will survey 4-8 prairie lakes for the presence of microplastics by collecting samples from the shore and water in each cardinal direction at each lake, as access allows. The samples will be analyzed for the presence of microplastics using sifting, vacuum filtration, and microscopy techniques. We will present information on the presence and/or absence of microplastics in prairie lakes. Determining if microplastics are present in prairie lakes in eastern South Dakota will allow us to compare levels found in a less densely populated region to other areas of the United States and hypothesize about how they accumulate.

Abstract Name: Municipal Governance and Voter Turnout: Analyzing the Impacts of City Managers

Municipal elections have long been studied, regarding the large, documented disparity between national and local electoral turnout. These studies have attempted to describe how turnout is correlated with various demographic, institutional, and time-related factors, to identify strategies for increasing local turnout. This paper narrows the focus to one of these predictors: whether a city has a full-time manager. Prior studies have been limited by a lack of data, however, the recently published municipal elections database from Benedictis-Kessner and colleagues enables this analysis to occur. Combining this data, with U.S. Census estimates, and originally collected city manager data, I analyzed a random sample of 396 elections using several regression models. I improved the models' estimates further by pre-processing the data with a non-parametric matching algorithm to reduce confounding, which refined the sample to 194 elections. I find that despite significant differences in turnout between cities with and without managers, this difference diminishes after controlling the other covariates and becomes statistically insignificant after the matching process.

Abstract Name: Potentiometric Analysis of the Titratable Acidity of Beer: A Laboratory Experience for General Chemistry Students

Acid-base titrations have been a fundamental part of general chemistry laboratory courses for many years. Although this analytical technique is quite dated when compared to many modern instrumental techniques, it continues to play a crucial role in modern chemical and biological analysis. Titrations, when utilized appropriately, can yield high accuracy, precision, and cost-effectiveness. Therefore, it is essential for undergraduate chemistry students to gain experience with titrations as they progress in their scientific training. A laboratory procedure for undergraduates has been developed to measure the titratable acidity (an approximation of total dissolved acid concentration) of beer samples using potentiometric acid-base titrations. In this analysis, the student begins with a raw beer sample, carries out a short sample preparation procedure, and then titrates the sample using a standardized solution of strong base. Continuous monitoring of the reaction with a pH meter allows the student to build an acid-base titration curve and calculate the titratable acidity. The sample preparation steps can be adapted to beers of varying acid concentrations to maintain titration curves of high quality. This laboratory procedure offers students more than just a routine titration exercise. It provides an opportunity to apply an important quality control measurement used in the beverage industry, as minor changes in pH can have major impacts on taste. The student gains experience with sample preparation, reagent standardization and a real-world application of acid-base titrations all within a single lab session.

Abstract Name: From Exposure to Curiosity: Exploring Social Media's Influence on Adolescent E-Cigarette Use

Despite recent data indicating a decline in adolescent e-cigarette use, an estimated 1.63 million middle and high school students are still using e-cigarettes, posing significant public health concerns. Social media platforms often expose adolescents to e-cigarette content that glamorizes and normalizes the behavior, raising concerns about their influence on adolescents' curiosity and e-cigarette use. The purpose of this study is to investigate the relationship between adolescents' exposure to e-cigarette-related content on social media and their curiosity about e-cigarette use. This study utilized data from the 2023 National Youth Tobacco Survey (N = 22,069) to measure exposure to e-cigarette-related content on social media. We used regression analysis with a logit link function to assess the relationship between social media exposure to e-cigarette content and curiosity about e-cigarette use moderated by race. The results indicate a strong correlation between exposure to e-cigarette-related content on social media and adolescents' curiosity about e-cigarette use, specifically with a higher endorsed curiosity about e-cigarette use in adolescents frequently (weekly or daily) exposed to e-cigarette social media content, relative to those who endorsed never being exposed to e-cigarette-related

content (OR=4.12, $p<0.01$). With race as a moderator, individuals who identified as White and Asian showed a dose-response relationship between exposure to e-cigarette-related content and curiosity about e-cigarette use. White and Asian individuals with daily exposure to e-cigarette-related content were 5.29 and 4.03 times more likely to endorse curiosity about e-cigarette use, respectively, relative to those without this exposure. This study shows the significant impact of social media e-cigarette content on adolescents' curiosity about e-cigarette use, with demographic factors, such as race, further modulating these associations. The findings reinforce concerns that frequent social media use may harm adolescents' health.

Abstract Name: The Correlation between Pre-Operative Obstructive Sleep Apnea Screening and the Patient Risk for Post-Operative Respiratory Compromise

Obstructive Sleep Apnea (OSA) is a growing concern in healthcare and the perioperative setting because it can lead to serious post-operative respiratory complications. This study aims to determine the use of pre-operative OSA screening tools and the relationship to respiratory compromise post-operatively. It is hypothesized that use of OSA screening tools will be related to a decreased risk of complications in the post-operative period. This non-experimental study utilizes a cross-sectional retrospective chart review, a form of self-report, in which surgical data from the previous six months is analyzed to determine if any respiratory complications occurred post-operatively, and, if so, if pre-operative OSA screening was conducted or not. Data analysis will be conducted after collection is complete in Spring 2025.

Abstract Name: Scoring Success: Social & Economic Drivers of 2024 Olympic Female Gymnast Scores

This study examines disparities in Olympic Game performance, challenging the idea of equal opportunity in one of the most viewed sporting events, women's gymnastics. Despite 206 nations participating, over half of the total medals are often won by just 10 countries. Existing studies primarily explore the influence of country factors, rarely focusing on individual athletes. The purpose was to determine the extent to which training age, gold medal financial incentives, and country socioeconomic status (SES), influence Olympic gymnastics performance in female athletes. The scores of 58 female athletes in gymnastics, representing 32 countries in the all-around qualifying round for the 2024 Paris Olympic Games were analyzed. Data were scraped from the official Olympic Games website. A multiple linear regression analysis examined the relationship between Qualifying Points (dependent variable measuring athletic performance) and Training Start Age, Gold Medal Incentive (USD) and Gross Domestic Product (GDP, a proxy variable for country

SES). Statistical analyses were performed using SAS 9.4. Our model showed that 15.7% of the variation in Qualification Points was explained by all predictors ($R^2=0.157$, $F(3)=3.30$, $p=0.027$). Training Start Age was the only significant predictor of Qualification Points, showing that for every 1-year increase in Training Start Age, there is on average a 0.38-point increase in Qualification Points, while adjusting for all other factors ($t(1)=2.04$, $p=0.046$). This finding means that the later a female gymnast begins training, the better they perform. This study showed a significant, positive relationship between age when training began and athletic performance as measured by Qualification Points. This finding indicates that female gymnasts who started their career earlier may have endured more physical stress and mental pressure to succeed, ultimately inhibiting their ability to perform at their highest potential later in life. Future research is necessary to further explore intrinsic factors that may affect performance.

Abstract Name: Safety Net: A Better Plan A

Lagos, Nigeria, home to over 16 million people, stands as Africa's most populous city. The African Giant of Nigeria holds over 260 million people with the workforce falling on the backs of Millennials and Generation Z. On the surface, this could be seen as an advantage; a youthful, energetic labor force that any economy would benefit from. However, in Nigeria, this demographic reality also presents a unique set of challenges that has been exacerbated by inadequate housing, overpopulation, and rapid urbanization. The housing crisis in Lagos, fueled by failed government support and initiatives along with rapid population growth, leaves many young professionals with few living options. They often resort to staying at home with long commutes into the city for work if not already nearby, renting out a unit at a hostel, or renting apartments with rent beyond what they can afford. Many developments in the city will not provide resources necessary for these young Lagosians to thrive, rendering their attitudes toward progressing in the city as very negative. Safety Net aims to shift these attitudes by proposing an affordable mixed-use residential complex adjacent to the Oshodi Transportation Hub in the Mushin LGA, a critical nexus in Lagos' public transportation system. By offering affordable housing within easy reach of business districts, markets, and recreational spaces, it alleviates the burdens of traffic congestion and accessibility. The development integrates co-working areas, business centers, and retail spaces, fostering a self-sustaining environment that supports entrepreneurship, community engagement, and mental well-being. By tackling the housing crisis and mitigating the "brain drain" of young talent, the program envisions a resilient, economically dynamic Lagos. The "Safety Net" initiative not only provides affordable living options but also serves as a foundation for growth, supporting Lagos' continued transformation into a thriving business hub and nurturing the aspirations of its youth.

Abstract Name: An Exploration of Beliefs and Boundaries in the Classroom

The research, titled An Exploration of Beliefs and Boundaries in the Classroom, explores educators' perspectives on the intersection of personal beliefs and professional boundaries within the classroom. By conducting interviews and developing a subsequent survey, we collected responses from individuals regarding their views on how educators should address diverse religious and cultural practices in educational settings. Seventy people took part in this survey. Of these, nine were college professors, ten were K-12 teachers, and fifty-one were college education students. Questions such as, "Is the classroom a good place to discuss controversial issues/perspectives? What about when these specific issues pertain to religion?" and "What is the role of the teacher in confronting and correcting religious discrimination?" were posed to teachers and teacher candidates to gain insight into varying attitudes on accommodating religious practices and promoting cultural awareness. The analysis provides a comparative overview of these beliefs, examining how they influence various classrooms. Our findings highlight a similar trend: the proportion of groups that agreed or disagreed with the questions was similar. However, our survey revealed that many educators are prioritizing learning over students' religious identities. When asked if they would allow students to opt out of a lesson due to a conflict with their religious beliefs, a large majority of survey participants expressed their unwillingness to accommodate these students. We will provide our qualitative analysis at the conference.

Abstract Name: Multi-Residential Affordable Housing: SOP Theory & Environmental Psychology

This research delves into a critical and multifaceted topic: Affordable multi-residential housing, the application of the sense of place theory, and the integration of environmental psychology in design. These areas of focus are not just theoretical, they tackle some of the most pressing challenges in contemporary society. Within the United States, the availability of affordable housing is at a dreadful low. This scarcity leaves millions of families grappling with tough choices between paying rent and covering essentials like food or healthcare. "A unit is considered unaffordable if a household has to spend more than 30 percent of its income on it. The result is a system that perpetuates economic instability, health disparities, and community disconnection. Addressing this crisis within the interior design field is important and cannot be overstated. Affordable housing intersects crucial design considerations such as fostering social connection, improving mental and physical health, promoting sustainability, and driving economic efficiency. This research will be used to shed light on the extreme impact of affordable housing design within the multi-residential occupation type, (R-2), by weaving together insights from the sense of place theory and environmental psychology. The research will examine how these disciplines intersect and/or complement each other, and explore how the built environment influences residents' well-being, attachment, and identity within their communities. The goal is to reveal how thoughtful and universal design can help bridge the gap between housing as a necessity and housing as a foundation for thriving lives.

Abstract Name: Ring Expansion Polymerization of Less Activated Vinyl Monomers

The goal of this research is to study the light-initiated ring expansion polymerization of “less activated” vinyl monomers. Prior research from the Ham lab focused on creating cyclic polymers via a radical-based ring-expansion polymerization from “more activated” vinyl monomers. The reaction conditions discovered previously led to the successful creating of cyclic polymers. However, the cyclic radical initiator is not a good mediator of polymerizations with less activated monomers. The focus of the work to be presented is the synthesis of a new cyclic polymerization initiator capable of mediating the polymerization of less activated monomers, and then studying the kinetics, polymerization behavior, and physical properties of the resulting cyclic polymers. There has not been research conducted on using less-activated/ more stable vinyl monomers to create cyclic polymers in a ring-expansion fashion.

Abstract Name: Hybrid CNN-LSTM Model for Enhanced Analysis of EEG and ECoG Data in Seizure Prediction

This project explores the integration of convolutional neural networks (CNNs) and long short-term memory (LSTM) networks with attention mechanisms for time-series classification tasks, focusing on electroencephalography (EEG) and electrocorticography (ECoG) data. CNNs extract spatial features, LSTMs capture temporal dependencies, and attention mechanisms enhance the model's focus on relevant features. This hybrid approach enables advanced applications like seizure prediction and brain state classification. While CNNs and LSTMs are independently used in neuroimaging, their combined potential in seizure modeling is underexplored. Intraoperative neuromonitoring, a growing technique in neurosurgery, highlights the value of analyzing brain signals. The methodology involves preprocessing EEG/ECoG data to standardize signal quality, followed by applying CNN layers to extract spatial features. These features are then fed into LSTM layers to capture temporal patterns. Attention mechanisms are applied to focus on the most relevant temporal or spatial features. The model is trained using labeled seizure datasets and validated on unseen data. Performance is evaluated using measures of classification accuracy, prediction latency, and computational efficiency. The model's hyperparameters, including those for CNN, LSTM, and attention mechanisms, are tuned to optimize performance. The hybrid CNN-LSTM model with attention mechanisms achieved an accuracy rate of 62.5% in detecting seizures based on the training dataset. While this result indicates the model's potential to capture spatial-temporal dependencies, it highlights the need for further improvements. Enhancements in data preprocessing, model architecture, and feature representation are essential to utilize the hybrid model's capabilities and achieve higher classification performance. The hybrid CNN-LSTM model with attention mechanisms is expected to outperform single-network models in capturing spatial-temporal patterns in EEG/ECoG data. It should achieve higher classification accuracy, particularly in seizure detection,

with reduced prediction latency. The hybrid model is anticipated to consistently outperform standalone CNNs and LSTMs, with attention mechanisms enhancing focus on key features.

Abstract Name: Engagement for Educational Games

Recursion is a notoriously difficult concept for many students to comprehend (Er, 1984), as it involves tackling problems in a new way, as more conditions and actions must be performed outside of a central algorithm (Baron 2024). In order to ease this learning experience, we sought to create an educational game focused on teaching recursive principles to introductory computer science students. Our student-developed educational game, Noisrucer, has been developed to analyze the way that students approach foundational concepts in recursive programming. By presenting these problems in a naturalized, and rational manner, the game seeks to demystify the persistent issues that hinder development. Noisrucer strives to deliver a challenging, and captivating experience through its intuitive gameplay and visually stimulating features. Educational games are oftentimes difficult to develop (Castronova et al, 2008), requiring players to cover a broad curriculum or engage in unintuitive gameplay. Our game seeks to circumvent these issues, providing players with their own agency to solve problems in new and creative ways that mimics programming itself. This is supplemented through student-driven ideas to help engage their generation z peers, aligning with other scholars calls for use of technology (Szymkowiak et al, 2021) nurturing their engagement with a sense of reward and using a mastery approach to learning. Through the use of a small classroom observation of 8 students as well as individual observational pilot playthroughs with four participants, we have found that tactile responsiveness and fluid interactions maintained engagement and interest. Though we have also found that participants collaborating as part of a group exhibited significantly more interest, engaging in exploratory behavior and motivating each to experiment with different solutions. We are actively making changes to reinforce these positive behaviors in order to measure their effect on learning and hope to discuss these with the greater student community.

Abstract Name: Medium Term Outcomes of Low Profile Visible Intraluminal Support [LVIS D] Stent Assisted Cerebral Aneurysm Treatment: A Single Center Experience

Low Profile Visible Intraluminal Support Device (LVIS D) is a self-expanding braided low porosity microstent indicated for stent-assisted coil embolization (SAC) of unruptured intracranial aneurysms (UIA).

We retrospectively collected clinical and radiographic data from all patients with UIA treated with LVIS D SAC at our institution (December 2016-October 2019). Angiographic outcomes were retrospectively assessed by one interventional neurologist and a neuroradiologist. Data were analyzed using descriptive statistics. A total of 70 patients underwent LVIS D assisted UIA treatment (male:female =28:50, median age 58.5 years (IQR 49-66). Among them, nearly 64.1% patients underwent SAC with a median of one LVIS Blue stent placed within the supraclinoid ICA (n=19), basilar artery (n=17), anterior communicating artery (n=6), posterior communicating artery (n=6), vertebral artery (n=6), anterior cerebral artery (n=4), posterior inferior cerebellar artery (n=2), superior hypophyseal artery (n=2), posterior cerebral artery (n=1), superior cerebellar artery (n=1) and the anterior inferior cerebellar artery (n=1). At a median angiographic follow-up of 16 months (IQR) nearly 65.4% patients achieved a Raymond Roy class-I occlusion and 34.6% with minimal residual aneurysm neck/dome with only 10% of patients requiring re-treatment. On medium-term follow-up only 2.86% of patients suffered persistent neurological deficits at the last clinical follow-up with an overall mortality rate of 2.8% attributed to LVIS stent placement. LVIS D stent-facilitated treatment of UIA is associated with high rates of technical success, achieving complete and near-complete occlusion at 16 month angiographic follow-up, with an excellent safety profile.

Abstract Name: Development of a cost-effective minimal growth medium for screening bacterial vitamin B auxotrophs capable of xenobiotic degradation

The goal of this research is to develop a cost-effective, stringent minimal growth medium for screening bacterial vitamin B auxotrophs for their abilities to utilize xenobiotics as the sole carbon source, with potential applications in xenobiotic biodegradation. Conventionally, microbiologists supplement bacterial medium growth with laboratory-grade vitamin B to grow vitamin B auxotrophs in the laboratory. However, this is quite expensive, limiting widespread application. This study proposes the use of over-the-counter vitamin B supplements, which, although less pure, offer a significantly more economical alternative. The study specifically focuses on two vitamin B-dependent Actinobacterial strains, *Microbacterium* sp. strain Clip 185 and *Kocuria rhizophilia*, known to require an external vitamin B source for growth. We have used these two actinobacteria for testing the efficacy of the new minimal growth medium. We have developed three versions of the inexpensive, stringent and minimal growth medium each supplemented with a specific inexpensive source of vitamin B by modifying the basic recipe of the Tris-Acetate-Phosphate (TAP) medium, commonly used for green micro-algal growth. We have tested the growth of microbial vitamin B auxotrophs in these minimal media containing xenobiotic compounds, like polyethylene, phenanthrene, cellulose, etc. as the sole carbon source. Our results demonstrate that our modified Tris-Acetate-Phosphate (TAP) media can support the growth of vitamin B auxotrophs and promote the metabolism of xenobiotics, thereby validating this cost-effective alternative to traditional laboratory-grade supplements. These findings have the potential to advance microbial bioremediation research by providing an accessible method for screening vitamin auxotrophic strains in the context of environmental pollution.

Abstract Name: Development of a Fluorogenic Chemical Tool to Study Human Carboxylesterase 2 in Live Cells

Carboxylesterases are enzymes that play a role in the hydrolysis of esters to carboxylic acid and alcohol. Human carboxylesterases (CESs) are involved in the metabolism of pharmaceuticals that contain a wide range of esters. CES activity is known to vary among individuals due to genetic and environmental factors. This interindividual variability in CES activity that has been demonstrated to cause varying outcomes when patients are treated with drugs metabolized by CESs. To study CESs, a variety of well-characterized fluorogenic chemical tools for examining one of the two major forms of CESs, carboxylesterase 2 (CES2), have been developed. These tools, however, have not achieved widespread use. We hypothesize that this is due to the difficulty in obtaining these CES2 fluorogenic chemical tools. Here, we seek to characterize a commercially available compound, Fluorescein Diacetate (FDA), as a chemical tool for use in live cells to study CES2. To characterize FDA, we carried out a variety of in vitro stability studies before deploying FDA in live cells to determine if it can be used to study CES2 activity using fluorescence microscopy. Overall, our studies seek to expand the availability and accessibility of chemical tools and methods to study CES2 which we believe will lead to better clinical outcomes for patients.

Abstract Name: Isolation of a Novel *Methylobacterium* Species from the Monongahela River

The Monongahela River in Pittsburgh, PA has gone through many industrial cycles over the last two centuries. Heavy metals have been documented in the river, and this is likely due to the changes in utilization and waste disposal into the river. As a result, the Monongahela River is rich in microbial diversity, allowing for an opportunity to isolate and characterize bacterial species that were previously undocumented. In this experiment, a pink bacterial strain, Neon, was isolated from the Monongahela River. DNA was then extracted and sent for Illumina whole genome sequencing. The isolate was determined to be of the genus *Methylobacterium*, which is comprised of gram-negative methylotrophs. Genome assembly, annotation, and analysis indicated that the isolate may be novel with an ANI (Average Nucleotide Assembly) of only 85.73% similarity to its closest relative, *Methylobacterium mesophilicum*. Thus, several tests were performed to assess the general microbial characteristics of the organism, including digital DNA-DNA hybridization (dDDH), GC content evaluation, metabolic analysis, pH and salinity growth ranges, and lipidomics. These results were compared to the known properties of the two most closely related organisms, *Methylobacterium mesophilicum* and *Methylobacterium radiotolerans*. *Methylobacterium* species have been found to be resistant to heavy metals and ultraviolet radiation; the isolate Neon is consistent with this, as operons associated with arsenic, copper, cadmium, cobalt, zinc, and ultraviolet radiation resistance were identified. Due to its heavy metal resistance, the isolate may have future applications in environmental projects. These may include, but are not limited to, bioremediation in areas abundant with heavy metals, wastewater treatment, and rare earth element (REE) recovery. This project highlights the importance of continual screening and characterization of bacteria in the environment.

Abstract Name: Developing an In Situ Method for Microplastic Detection and Quantification

When plastics are improperly disposed of, natural processes, such as exposure to sunlight and weathering, break them down into pieces small enough for consumption, inhalation, and absorption into skin by various organisms ranging from plankton to humans. Since the discovery of plastic fragments in oceans, researchers have used methods like Fourier-Transform Infrared Spectroscopy or Raman Spectroscopy to identify microplastics and learn more about them. However, these methods have limitations, such as requiring filtration and concentration prior to observing. This project explored using an Imaging FlowCytobot (IFCB) instrument, which does not require filtration or concentration, to quantify microplastics in marine environments. IFCBs can also be deployed underwater for extended periods of continuous sampling. The IFCB, coupled with a machine learning approach for automated image identification, was used to identify and quantify microplastics in natural seawater samples collected during a 3-day research cruise in the Gulf of Mexico. Microplastic control samples were created in the laboratory and run through an IFCB to create a training dataset for the machine learning model that was used to identify microplastics in the field. Over

150,000 images comprising 129 categories of phytoplankton and one category of plastic were used to train the model. Microplastic concentrations varied according to distance from shore and over depth. Some of the higher concentrations of microplastics, measured as particles per mL, were found <70km and >200km from land but still over the continental shelf. Concentrations were also found to be elevated in the surface samples and from samples collected within ~2m of the bottom. The utility of using an IFCB is that microplastic concentrations can be measured continuously out in the field allowing for changes in concentration due to natural events to be observed in real time.

Abstract Name: Estrogen Receptor α (ER α) Signaling and Tumor Cell-Derived Factors Mediate Pro-Tumor Neutrophil Activation in the Setting of Lymphangioleiomyomatosis (LAM)

Lymphangioleiomyomatosis (LAM) is a rare disease where smooth muscle tumors with tuberous sclerosis (TSC) mutations form cysts in the lungs. The resultant tumor growth causes cyst formation in the lung which leads to decline in respiratory function. LAM exclusively affects biological females; however, the origin of tumors is unknown. Our lab has utilized a conditional tuberous sclerosis-2 (Tsc2) knockout genetic mouse model of LAM to identify a possible myometrial origin of tumors. LAM has been shown to be estrogen-sensitive; however, LAM tumor cell lines respond poorly to estradiol in vitro. In tumors from our LAM mice, bulk RNA sequencing identified increased transcription of neutrophil elastase in response to estrogen stimulation. Previously our lab demonstrated that neutrophils are the primary infiltrate in the mouse LAM tumors, while neutrophil depletion has been shown to reduce tumor growth. Recent work suggests that estradiol signaling promotes neutrophil production via estrogen receptor α (ER α) signaling in the bone marrow. We hypothesize that estradiol, in concert with tumor-derived factors, may augment pro-tumorigenic functions of neutrophils in the setting of LAM. To address our hypothesis, neutrophils were isolated from the bone marrow of both C57BL/6 control and ER α knockout mice. Tumor conditioned media (TCM) containing potential tumor-derived stimulating factors was generated from a mouse model for LAM tumors. Isolated neutrophils were then cultured in fresh cell culture media or TCM for 24 hours. mRNA was collected and real-time quantitative PCR was performed to investigate changes in mRNA expression of known neutrophil activation markers. Our results show ER α was required for full expression of neutrophil elastase (ELANE), nitric oxide synthase 2 (NOS2), and programmed death-ligand 1 (PDL1/CD274), all markers of neutrophils activated to support tumor progression. Future experiments involving neutrophil function and activation will further elucidate the relationship between estradiol and neutrophils in LAM.

Abstract Name: Optimization of Octadecylamine Passivated Cesium Lead Bromide Nanocrystals by Varying Reaction Conditions

With applications in renewable energy, cesium lead bromide nanocrystals have grown to be increasingly salient in the science community. The use of such nanoparticles requires the optimization of the nanoparticle such that it is reproducible in a specific size and shape. We have conducted research to bridge independent variables in the synthesis process of these nanoparticles, to the results at which said variables produce. Using UV-Visible absorption spectroscopy, fluorescence spectroscopy, powder x-ray diffraction, and scanning electron microscopy, we are able to analyze how varying reaction conditions, using the ligand assisted reprecipitation, optimized the size distribution.

Abstract Name: Childhood, Innocence, and Imagination: The Pedagogical Power of Images in the Poetry of William Blake and Shel Silverstein

Throughout history, scholars have demonstrated the power of representation to awaken the mind to Truth, particularly in the formative years. William Blake's poems in his parallel collections Songs of Innocence and Songs of Experience stand out for their lyrical and artistic depictions of childhood bliss steeped in nostalgia, in stark contrast with adulthood, which he paints as comparatively bleak and dim. Similarly, contemporary children's poet Shel Silverstein is known for his compilation works Where The Sidewalk Ends, Falling Up, and A Light In The Attic, wherein he also develops the themes of childlike hope, curiosity, wonder and imagination. Comparing and contrasting these two different representations of childhood, both poets reflect and employ the expressive and communicative power of images. Both Blake and Silverstein demonstrate the power of images and apply them in pedagogical contexts alongside their writings on childhood, but the manner in which they do so differs. While Blake's visual images in his work to add meaning, familiarity, and depth. This variation in the application of the communicative power of images is related to the poets' different audiences, as they use their images to accomplish different purposes. While Blake writes for adult readers about the shared experience of childhood, Silverstein writes for an audience of children as well as for adults who may be reading the poems aloud. As these groups differ significantly in their perspectives, the effects, and thus the poets' applications, of visual elements also differ. Both Blake's Songs and Silverstein's various poems consistently demonstrate the capacity of images to influence and contextualize a reader's perception, and use this power in different ways to nurture more ideal development in children and reflection in their readers.

Abstract Name: City Garden: Urban greenhouse and Community Center

"Third place" is a term coined by sociologist Roy Oldenburg, referring to spaces beyond work and home where people can socialize and engage in community activities. However, low-cost and accessible third places are becoming rare in America. Through surveys, case studies, and article analysis, City Garden, a third place that combines the benefits of both community centers and greenhouses. My research highlights the social, economic, and physical advantages of these types of facilities. Socially, City Garden serves as an inclusive space for people to meet and interact. It offers free access to areas that might not otherwise be available, with amenities such as greenhouses, fitness areas, classrooms, and activity spaces for children. Design solutions like varied seating arrangements and meeting rooms foster collaboration and interpersonal relationships. Noise-reducing materials and durable, easy-to-clean textiles ensure comfort and functionality. Economically, City Garden serves as a no-cost resource for professional and personal growth. It offers skill-building classes and networking opportunities that benefit the local community. The greenhouse provides affordable, locally grown produce, helping to reduce food disparity and circulate money within the local economy. Additionally, classrooms cater to different learning needs, such as fitness, nutrition, and DIY education, empowering people to reduce financial burdens or learn new income-earning skills. Physically, City Garden promotes active living with spaces like rock climbing walls, a tennis court, basketball courts, and walking paths. These facilities are designed with safety and durability in mind to encourage physical activity. The City Garden project focused on understanding how third places can benefit communities and identifying space planning and material solutions to ensure long-term functionality. The project combines diverse facilities to create a space that supports the community's social, economic, and physical well-being.

Abstract Name: Cambodian American Refugee Family Impacts from Deportation

The deportation of Southeast Asian refugees, particularly Cambodian Americans, has profound implications for family relationships in the United States. This research explored the impact of forced removal and family separation on parent-child relationships, socio-economic outcomes, and the well-being of Cambodian American families. As a first-generation Cambodian American, the researcher brings a personal perspective to this topic, aiming to shed light on the experiences of affected families and advocate for immigration policy changes. The study addressed gaps in existing research through a comprehensive literature review and qualitative interviews with affected individuals and family members. By synthesizing information from diverse sources, the project aims to provide valuable insights into challenges faced by Cambodian American families affected by deportation and advocate for positive change in their communities. Research conclusions underscore the urgency for policy reform that considers the lasting impact on families and the need for enhanced community support systems to help mitigate the hardships experienced by these families. These invaluable insights also advocate for a more compassionate and informed approach to immigration policies that honors human rights, upholds dignity, and recognizes the historical context of refugee resettlement in the United States. This work contributes to ongoing conversations about immigration justice in the Southeast Asian American communities and serves as a call to action for policies that support and protect families, emphasizing the need for solutions that reflect empathy and understanding.

Abstract Name: Machine Learning in Autism Spectrum Disorder Detection and Classification

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition with a wide spectrum of symptoms that affect an individual's social communication and behavior. Early detection of ASD is crucial for timely intervention and improved outcomes. This study explores the potential of machine learning algorithms for detecting ASD through the analysis of gene expression. The dataset used in this study is the SFARI dataset, encompassing Transcript Per Million (TPM) gene expression values for 60,669 genes, of individuals with and without ASD. With a sample size of 3780 children, aged between 3 and 13 from North America, this dataset forms the basis of our research. Various machine learning algorithms are employed to decipher intricate patterns within the dataset indicative of ASD. To enhance the models' performance, feature selection and engineering techniques are applied, ensuring that the algorithms effectively capture relevant information for accurate detection. The study evaluates the models based on sensitivity, specificity, and overall accuracy to assess their efficacy in ASD detection. The research investigates the robustness and generalizability of the models across diverse demographic factors and clinical presentations. Ethical considerations and the interpretability of machine learning outcomes are emphasized to underscore transparency and accountability in the decision-making process. The study yielded promising results, achieving an accuracy rate of 79% and Recall of 90% using the AutisNN Framework. This level of accuracy represents a significant advancement in the field and underscores the potential of machine learning as a powerful tool for enhancing the diagnostic capabilities of ASD detection models. By providing evidence of the models' accuracy and generalizability, the study lays the foundation for the development of scalable and data-driven tools that can assist clinicians in the early and precise identification of ASD, thereby facilitating timely interventions and improving long-term outcomes for individuals affected by this complex disorder.

Abstract Name: Advancing Customer Segmentation in Banking: Harnessing Machine Learning for Personalized Insights

In the contemporary banking landscape, understanding customer behavior is paramount for delivering personalized experiences and driving business growth. Customer segmentation, the process of categorizing customers into distinct groups based on shared characteristics, lies at the heart of this endeavor. Traditional segmentation approaches often fall short in capturing the nuanced and evolving nature of customer behavior. Therefore, this paper proposes a data-driven approach to advance customer segmentation in banking using state-of-the-art machine learning algorithms and techniques. We present a comprehensive framework for processing, cleaning, and clustering a large dataset of banking transactions and customer information. Through the application of K-Means, Hierarchical, and Gaussian Mixture Models (GMM) clustering

algorithms, we identify distinct customer segments based on transactional and demographic data. The effectiveness of each clustering algorithm is evaluated using silhouette scores, with the best-performing model selected for further analysis. Finally, we discuss the implications of our findings and offer recommendations for leveraging customer segmentation to enhance banking services and drive business growth.
