The National Conference on Undergraduate Research (NCUR)

What is NCUR?

The National Conference on Undergraduate Research (NCUR) is the premier annual event celebrating undergraduate achievement across all disciplines. Each year, thousands of students from institutions across the country gather to present original research, scholarship, and creative work. Unlike other conferences, NCUR is dedicated to celebrating undergraduate scholars from all institutions of higher learning from all disciplines. NCUR offers a unique platform where students can share their work with peers, faculty, and professionals from a wide array of fields.

The NCUR experience offers more than visibility—it provides a transformative experience where students:

- Build confidence and communication skills.
- Receive meaningful feedback from peers, faculty, and professionals across disciplines.
- Engage in cross-disciplinary learning by attending sessions beyond their field.
- Expand their academic and professional networks with mentors, collaborators, and recruiters.
- Discover new pathways through the Future Fair.

NCUR also supports the growth of institutions by equipping faculty, staff, and administrators to:

- Celebrate and mentor the next generation of researchers.
- Connect with colleagues to exchange best practices in undergraduate research.
- Stay informed on emerging trends and innovations in student scholarship.

NCUR began in 1987 at the University of North Carolina at Asheville with more than 400 students in attendance. In 2010, NCUR officially merged with the Council on Undergraduate Research (CUR), joining forces to advance undergraduate research on a national scale. Since then, it has grown into the largest undergraduate research conference in the world, with more than 4,000 in attendance.

For questions or further information about NCUR, contact NCUR@CUR.org. To learn more about upcoming conferences, visit CUR.org/NCUR.

About These Proceedings

This document features a comprehensive list of student presentations from this year's NCUR, organized by the primary presenter's last name. Each entry includes:

- Presenter's name
- Their institution (with state)
- Discipline of the presentation
- Additional authors (if applicable)
- Title of the presentation
- Abstract

This information was submitted by the student presenters during the NCUR application process.

Abstract Name: The Ripple Effect: How Tourism Affects Marine Debris

"Each year 180 million Americans make 2 billion visits to beaches –more than twice as many as to all national and state parklands combined" (Center for Conservation Biology). As more tourists travel to the beach for leisure, the negative impacts on beach and coastal ecosystems worsen, particularly through waste production. This research examines the environmental consequences of tourism, focusing on waste generated by beachgoers. The study employs a mixed-methods approach, including surveys of beachgoers and expert interviews with environmental professionals and beach management authorities. The surveys explore the types of waste produced, the frequency of littering, and the influence of transportation choices—such as personal vehicles and public transit—on waste patterns. According to the US Environmental Protection Agency, "Tourists produce up to twice as much waste than residents." The findings highlight the role of consumer behaviors, particularly the use of single-use plastics and non-biodegradable items, in contributing to waste accumulation on beaches. The study also examines how different travel methods, such as driving or flying, influence the overall environmental impact. To address these issues, the study suggests several strategies to reduce consumerism in beachgoing behavior. Ultimately, the findings aim to foster a shift toward more responsible and eco-conscious behavior among beachgoers to protect fragile coastal ecosystems and reduce the environmental footprint of tourism.

Abstract Name: Spatial Variation in Structural Lumber Strength: Experimental Testing and Probabilistic Model

The natural growth of wood leads to significant variation in the mechanical properties of structural lumber among an ensemble of boards and within a single board. As such, the safe and efficient use of wood in structural applications requires a process to assess the probabilistic nature of wood properties. Current processes neglect within-member variation and utilize uniform design properties for a given species and grade. This paper presents a framework for a high-fidelity treatment of within-member strength variation to enable higher precision uncertainty characterization of strength. The model incorporates clearwood strength variation and the strength reduction of knots. The model is adapted to incorporate two distinct functions for knot strength reduction, providing information for the comparison of the two calculation methods and demonstrating the model's adaptability as knot interaction continues to be studied. Simulated boards are graded by knot frequency and locations, and comparison is made between modelling results by grade and published experimental design values. The modelling method is also compared to experimental data of beams in bending to demonstrate the modelling process. Experimental failure of beams in bending is compared to the modelled failure location. The developed framework can be employed in computational analyses, such as reliability studies, to support improved material efficiency of structural lumber and large engineered wood products, like cross laminated timber. The tensile strength models were calibrated to Eastern hemlock but

could be applied to other softwood species of interest. Incorporating a high-fidelity description of material variation in the fabrication of mass timber products could support material efficiency and promote the use of traditionally low-value wood species in high-value structural applications.

Abstract Name: Examining Effects of Indole-3-Acetic Acid And Phosphorus Deprivation On Root And Shoot Growth In Brachypodium Distachyon

The world of the study of plant growth is vast and full of potential for research, namely the effects of different hormones on plant growth. One such plant hormone, indole-3-acetic acid (IAA), has existing but limited information about its usefulness in reinforcing plants against removal of phosphorus, an essential plant growth mineral. To remedy this gap in research, the focus of this study was to discover the potential of plant growth when assisted by IAA under different conditions. Over the course of several weeks, Brachypodium distachyon, a model grass plant with a simple genome and short growth period, was monitored within EcoFABs under varying conditions. Ecosystem Fabrications, or EcoFABs, are devices used to simulate an ecosystem without the use of soil, thereby maximizing visibility of plant roots. To test the effectiveness of IAA, a research question was put into action: “Can (IAA) protect against phosphorus loss in plants?”. The rescue group (treated with phosphorus removal and IAA at 0.2µg/µL) was successful in growth capacity of roots compared to plants grown in phosphorus deprived media and plants treated only with IAA, having an average percent increase of 50.19%. Additionally, the IAA treated group showed significant growth in shoots, with an average 32.62% increase. In future studies, the true growth potential of IAA must be pursued. While it was useful in helping with B. distachyon growth, there are many avenues future studies could focus on, such as various IAA concentrations used on a variety of other plants. The general increase of growth in groups treated with this hormone supports future studies to fully understand the growth potential of IAA on plants in distress. Overall, this success has many unrealized pathways to be explored for the sake of global environmental support in a rapidly changing agricultural environment.

Abstract Name: Implementing Strong Thinking in The Classroom

Strong thinking is asking students to look at an art piece and not only critique it, but to use their own imagination as to what they think the piece is saying. By observing the piece, working through the purpose it was created, and exploring what the artwork means to them, they are able to think of what the artist may be

trying to say to them. Strong Thinking is a tool that can be used in any classroom setting. Our research was compiled on an art classroom setting. We will take you step by step through the strong thinking process. Teachers can use strong thinking to help students critically assess their own work as well as their peers. This challenges them to create meaningful art and allows them to use art as a voice of advocacy.

Abstract Name: Developing Patient-Centered Educational Tools for Wisdom Tooth Pain Management

The current study addresses the design and development of evidence-based education materials on pain following surgery, which is the first phase of a to-be-implemented preemptive cognitive analgesia strategy for oral surgery patients. The purpose of this study is to educate the patients on the types of pain they can expect following surgery, to mitigate preoperative anxiety, enhance preparation for the procedure, and boost compliance with postoperative care. Data was collected from 10 patients who were going to undergo wisdom tooth extraction. Patients were asked to keep a pain diary after surgery, as well as engaging in a post-study interview to assess their narrative experiences in dealing with their pain, including strategies that were effective in reducing pain, and factors that led to increased pain. These responses were used to create written education materials. Materials were fashioned to be visually appealing and linguistically at an approximately eighth grade level, employing infographics, outlines, and case scenarios for engagement. Refinements were made in response to feedback from dental practitioners and patient focus groups to ensure clarity, accessibility, and usefulness. The current study serves to underscore the potential significance of preoperative education about pain in reducing psychosocial barriers to effective pain management, reducing pain related fear, thereby enhancing the patient experience. This project illustrates the need to incorporate educational strategies into the practice of dentistry- especially for procedures that are associated with high anxiety levels and significant pain. This study underscores the importance of integrating patient-centered educational tools into clinical dentistry to enhance procedural outcomes and patient well-being.

Abstract Name: The Effects of Antibiotic-Oxytocin Interactions on Social and Motivational Behavior

Oxytocin is a neuropeptide that plays a role in many parts of the body; and is well known for its role in social behaviors. Antibiotics are a staple in the modern world, with nearly 50 million yearly prescriptions given to people under the age of 20 (Center for Disease Control, 2024). To date, no studies have examined the drug interaction of oxytocin and antibiotics and its effect on social motivation. Mice were used as model organisms to study these behavioral effects. The experimental groups included both sexes and four drug groups: saline (control), oxytocin, antibiotics, and oxytocin with antibiotics. After 14 days of drug administration, 3

behavioral assays were conducted to examine social motivation effects. The results of this study found that the oxytocin-antibiotics group had lower social avoidance than the other groups. No sex effects were found in any social behavior analysis and no social approach differences were found between groups.

Abstract Name: The Effects of the Devaluation of the Egyptian Pound on AUC Student Happiness

The aim of the research project was to investigate and understand if there is a significant relationship between paying the full tuition fees at the American University in Cairo (AUC) or being on financial aid/ scholarship and happiness with the current devaluation of the Egyptian Pound. The researchers conducted a literature review that consisted of thirteen sources and they found that there are five key determinants for the happiness of university students such as financial satisfaction, academic performance, leisure time, social support, and high levels of self-confidence and esteem. The researchers used these five factors in their conceptual framework as well as the utility theory. This study was executed through an online Google Forms survey that the researchers sent out to students on WhatsApp and Facebook groups, as well as by going around campus with a QR code of the survey for students to scan. The survey consisted of questions from the PERMA Survey, the Student Life Satisfaction Scale, the Student Academic Scale, and the Financial Satisfaction Scale. The researchers used the Statistical Package for Social Sciences (SPSS) to analyze whether there is a significant relationship within the data, to determine which category of students from the two is happier with the devaluation of the Egyptian Pound. The results of SPSS exhibited no significant relationship between either category of students and happiness

Abstract Name: Photochemical Generation of Benzyne

Benzyne, a highly reactive strained cyclic intermediate, is instrumental in the synthesis of a variety of complex molecules, such as natural products, materials, and pharmaceuticals. Benzyne generation is commonly approached through the Kobayashi method which relies on a fluoride base and prevents the use of functional groups that are unstable to fluoride, making the development of alternative methods desirable. Furthermore, the current method for photochemical generation, photolysis of N-acetyl-N-methyltriazene

benzoic acid, results in the extrusion of two equivalents of gas and limited substrate scope due to the broad range of functional groups activated by harsh UV light. The purpose of this project is to develop a new method of benzyne generation using o-phenylsulfonyl benzoic acid as a readily synthesized starting material. o-Phenylsulfonyl benzoic acid was successfully synthesized from iodobenzoic acid and sodium benzenesulfinate through a dual photoredox/nickel-catalyzed cross-coupling reaction. NMR analysis confirmed product formation. We are developing a photochemical reaction using visible light, a transition metal, and o-phenylsulfonyl benzoic acid to generate benzyne and subsequently trap with a diene in a Diels–Alder reaction. We will be using various iron (III) species to coordinate to the carboxylic acid and become excited by light to undergo ligand-to-metal charge transfer (LMCT). Experimental conditions, including solvent choice, reagent ratios, and light wavelength, will be varied to optimize the process. This method is expected to be tolerant to a wider range of functional groups and minimize gas production, allowing for broader use in complex molecule synthesis and offering a safer alternative to current methods.

Abstract Name: Investigating the Catalysis and Substrate Specificity of Guanylurea Hydrolase

Metformin is a widely used drug for treating type 2 diabetes, but patients excrete a large amount of it and its byproduct, guanylurea (GU), which enter wastewater treatment plants as pollutants. Guanylurea is more toxic than metformin, negatively affecting the reproduction and growth of aquatic organisms. The degradation pathway of metformin as it is currently understood, reveals that the enzyme Guanylurea hydrolase (GuuH), plays a key role in converting guanylurea into guanidine, a harmless compound commonly found in living organisms. Research on the biochemical mechanism and substrate specificity of GuuH is essential for potential environmental applications, specifically to engineer this enzyme to degrade pollutants similar to guanylurea. One such pollutant is biuret, which is toxic to plants and commonly found as an impurity in fertilizers and pharmaceuticals. Biuret is structurally similar to guanylurea, differing only by an oxygen atom replacing one of GU's nitrogen atoms. However, the molecular determinants that enable GuuH to distinguish between guanylurea and similar compounds like biuret are not well understood. This project aimed to investigate how mutations in the substrate binding site of GuuH affect its ability to differentiate between guanylurea and analogs like biuret. Site-directed mutagenesis was used to create two GuuH mutants, N141K and E211Q, which were purified through affinity chromatography. Ammonia release assays were conducted to assess the activity of the wild-type and mutant enzymes with both guanylurea and biuret. The N141K mutant exhibited activity similar to the wild type for both substrates, while the E211Q mutant showed no significant activity, indicating that the E211 residue is crucial for guanylurea binding. Future research will focus on exploring the combined effects of a double mutant (N141K, E211Q) on the activity of GuuH, with the ultimate goal of enhancing its potential for environmental applications.

Abstract Name: BportGo: Efficacy of a Campus Navigation Mobile Application for SUNY Brockport

SUNY Brockport campus currently offers only a high-level PDF map of all buildings on campus. It is time consuming for new students, faculty, staff or visitors to accurately locate the correct room in the correct building. BportGo, a campus navigation mobile application, aims to address the challenges by supplying its users with an indoor and outdoor navigation system. This work takes advantage of Flutter, an open-source UI SDK created by Google, which is used to develop cross-platform applications from a single codebase. For outdoor navigation, the app leverages location services to provide real-time directions across the campus using the Google Maps API, ensuring accessibility. The app incorporates an improved search bar created using the Google Places Autocomplete API which provides an enhanced prediction algorithm to search for locations. For indoor navigation, university's static floor plans are made interactive using Mappedin to provide effortless navigation and optimized time management. Although the basic indoor and outdoor navigation in the app is complete, I plan to integrate more features for better accessibility options such as the implementation of artificial intelligence for better accuracy and real-time updates. The AI can process real-time data from the Wi-Fi infrastructure of the campus to adjust routes, provide prompt updates, and determine better routes for users with mobility challenges. I also plan to introduce voice navigation to assist people that are visually impaired or have other disabilities. The expected result will be a fully functioning app that can help users navigate indoors and outdoors, reducing the need for physical maps and improving campus mobility. BportGo represents a step toward a more technologically integrated campus environment, facilitating both routine navigation and special event logistics. Lastly, to determine if students will adopt to BportGo, I plan to conduct a usability testing for user feedback through an iterated design approach.

Abstract Name: Genetic Barcoding of darters in Middle Tennessee

In a world where freshwater ecosystems as well as biodiversity are in jeopardy, understanding the genetic diversity of hyper diverse darter species can help us properly strategize conservation efforts. Darters play an essential role in their habitats being integral to the stability of freshwater ecosystems as these organisms can reflect the overall condition of habitat as indicator species. With darters, these organisms are crucial in stability of biodiversity and setting a foundation for future studies. Loss of these species would also remove a vital system for studying evolutionary processes and development of species rich lineages. Our study around genetic analysis of preserved darter species which came from local Middle Tennessee waters is incredibly important for providing insight in revealing to evolutionary history within the south. We sequenced the genetic barcodes of darter species and will be generating genetic profile for the darters to be placed in database in our study. We will also compare these genetic barcodes to morphological features for each darter, and we hypothesize though gene sequencing that we will see a correlation in barcode sequences between variation and distinct morphological patterns used as comparative analysis in these darter species. To achieve this, DNA was extracted from 48 preserved darter samples to analyze their genetic makeup. We then used PCR to amplify part of the cytochrome oxidase I gene, followed by PCR clean up. Results of the current study are still pending. The project will undergo series of measuring expected band products, and determining size of DNA fragments to nucleotide sequence.

Abstract Name: Capturing Lived Experiences of Chronic Pain through a Listening Experience Model

Approximately 51 million Americans (more than 1 out of 5 Americans) suffer from chronic pain. Chronic pain patients often have symptoms that lack a clear cause of identifiable physical pathology, and traditional pain assessment methods, which focus on clinical history and physical examinations, tend to overlook the unique lived experiences of these patients. These experiences encompass the daily challenges, routines, personal needs, and aspirations disrupted by chronic pain. Current documentation practices, including clinician notes and patient-completed medical intake forms, offer a limited perspective and fail to capture the patient's voice fully. Similarly, patient-reported outcomes may not genuinely reflect the patient's experience, potentially omitting vital information relevant to their clinical status and overall well-being. Although clinicians desire to capture this patient information, it has remained impractical to collect, analyze, and summarize all the salient information of a patient's lived experiences. However, emerging machine learning technologies, such as Natural Language Processing (NLP), show promise for examining the language and expression used to describe their pain and allow for efficient analysis over large datasets. This method could provide insights often overlooked by traditional documentation, promoting a holistic and patient-centered approach. The objective of this ongoing study is to collect and analyze first-hand narratives of patients' lived experiences with chronic pain using NLP. This research aspires to foster better communication between patients and healthcare providers, ultimately leading to more personalized and effective pain management strategies.

Abstract Name: Silicon cell retrieval from bifacial and mono-facial solar panels

This study presents methods for silicon cell recovery from both mono-facial and bifacial panels. While pyrolysis has proven effective in removing encapsulant (EVA) and back-sheet films from photovoltaic (PV) modules, silicon cells often emerge broken due to several factors, including mismatches in the coefficient of thermal expansion, gas build-up from EVA, rapid heating rates, and sample collection methods. This paper also discusses various sample preparation methods, thermal treatments under anaerobic and vacuum conditions, and the measurement of emitted gases such as HF and acetic acid. To minimize damage, sample preparation techniques such as water jet cutting and hot knife removal of back-sheets and EVA films are applied. In the present research, we focus specifically on bifacial solar panels and the extraction of silicon cells. For this, we employ water jet cutting to separate each individual cell, followed by exposure to a muffle furnace for thermal treatment. This approach enables us to extract intact silicon cells without breakage. Thermal treatments are designed to assess crack formation and gas release dynamics, revealing key insights into stress alleviation and reduced emissions under controlled heating rates and vacuum conditions. Pyrolysis

experiments further confirm the optimal conditions for organic material removal, allowing for the successful retrieval of undamaged silicon cells.

Abstract Name: Assessment of neurodegeneration in the cerebellum of Slc39a14-Knockout mice

Over the last decade, several clinical reports outlined cases of autosomal recessive mutations of the manganese transporter gene SLC39A14 in humans resulting in elevated blood and brain concentrations of manganese and childhood-onset dystonia-parkinsonism. However, the pathophysiology of this disease has yet to be fully delineated, and it is our lab's goal to do so. Previous pathophysiological studies done by our lab using Slc39a14-Knockout (KO) mice have found that this genetic murine model of the human disease is associated with a dysfunctional but structurally intact nigrostriatal dopaminergic system. They have also proven that these changes happen early on in life, with no progression by aging. However, the presynaptic deficit in dopamine release is unlikely to explain the totality of symptoms of the behavioral phenotype and points to the involvement of other neuronal systems and brain regions in the pathophysiology of the disease. To delineate this idea further, a histological characterization of microglial populations was performed. In the brains of Slc39a14-KO mice, there was an overall increase in microglia density in select parts of the hindbrain in the context of highly elevated cerebellar manganese levels. Additionally, a Sholl analysis assessing the morphological activation of the cerebellar microglia demonstrated an increase in activation within the Slc39a14-KO mice. Lastly, when investigating the expression of cleaved caspase-3 (cCASP3), a biomarker of cell apoptosis, immunofluorescent staining revealed significantly elevated cCASP3 levels within the Purkinje cell layer of the cerebellum in Slc39a14-KO mice, indicating the presence of neurodegeneration within this area. In conclusion, this data begins to suggest that neurodegeneration is in fact occurring within the cerebellum of Slc39a14-KO mice, allowing us to better understand the pathophysiology of manganese-induced dystonia-parkinsonism. My specific contributions to this project were colony maintenance, genotyping, tissue slicing, brain perfusions, assistance with immunohistochemical staining, and the Sholl analysis.

Abstract Name: Copper-Induced Gene Expression in *Shewanella oneidensis* MR-1: Investigating the role of mtrC and mtrF in Bioremediation

Bioremediation is utilizing biological processes of microorganisms to transform environmental contaminants into harmless compounds. *Shewanella* sp. is a facultative anaerobic bacteria that has been confirmed to be able to reduce heavy metals such as copper under anaerobic conditions. In this experiment, *Shewanella oneidensis* MR-1 is used to investigate the mtrC and mtrF gene expressions in 2& 4mM copper acetate wastewaters 24h after bioremediation process. This experiment aims to determine whether there is a significant change in gene expression due to the bioremediation process. The results showed that mtrF and mtrC expressions increased ~4-6 times as compared to the original expression rate, indicating that these genes are actively involved in copper bioremediation process.

Abstract Name: Analysis of mtr Gene Expressions in *Shewanella oneidensis* MR-1 during Copper Bioremediation Process

Shewanella sp. can remove heavy metal pollutants like copper from industrial wastewater. In situ bioremediation process starts after the bacteria accept electrons from the anoxic media. The electron is then transported and released within the intracellular oxidative catabolic reactions to the terminal electron acceptors through the extracellular electron transfer (EET) pathway. Studies on *Shewanella oneidensis* MR-1 have implicated genes within the mtr cluster. Cytochromes, particularly type c, are well-established in bioremediation, especially MtrC and MtrF. These outer membrane cytochrome proteins are essential in electron shuttling and heavy metal ion reduction. In this study, we first identified the presence of the genes through PCR amplification. Next, we analyzed the mtrC & mtrF gene expressions through qRT-PCR analysis 24h after the bioremediation process of wastewaters at 2& 4 mM concentrations of copper acetate. The $\Delta\Delta C_t$ (delta-delta Ct) analysis revealed significant changes in gene expressions following 24 hours of treatment with wastewaters containing 2& 4 mM of copper acetate. The expression of mtrC increased six-fold after exposure to the wastewaters (2& 4mM), indicating a robust transcriptional activation in response to these treatments. Both concentrations of copper acetate contributed to this upregulation, suggesting that mtrC is highly sensitive to the specific conditions or components present in the wastewater. A distinct pattern of upregulation was also observed for mtrF, with its expression increasing four-fold at treatment with 2mM and five-fold with 4mM concentration of copper acetate. This differential expression hints at possible variations in the way mtrF responds to the distinct chemical or biological nature of the two wastewater components. These findings suggest that both mtrC & mtrF are responsive to environmental stimuli from wastewater treatments, with varying degrees of transcriptional activation. This information could provide valuable insights into the roles of these genes in stress response mechanisms or metabolic adaptation to wastewater exposure.

Abstract Name: How Bat Activity is Affected Based on the Quality of Urban Habitats.

This study investigates the effects of urban habitats on bat activity in the Houston metro area. Six different transects (Pasadena/Deer Park, Galena Park, 1-Inner 610 West, 2-Inner 610 West, Inner 610 Southeast, and Inner 610 Northeast) were driven twice within seven days to collect acoustic data using an Echo Meter Touch 2 PRO Active Bat Detector. Each transect was rated 1-3 based on characteristics such as green space, water presence, building density, industrial factories, and tree canopy. It is hypothesized that bat activity increases in higher-rated urban habitats (e.g., more water, green space, canopy cover, etc.). Preliminary results suggest differences in bat activity with respect to habitat quality (i.e. habitat rating). Data showed that bats were statistically more active at transect 1 (Inner 610 W) than at transect 3 (Pasadena/DP/Galena Park). However, no difference was found between transect 1 and transect 2 (Inner 610 SE/NE), and there was no difference between transect 2 and transect 3. Acoustic data collection will continue through 2025. Further research is needed to understand better how bats use urban landscapes such as the Houston metro.

Abstract Name: Δ 8 -THC Use Among Young Adults: Patterns, Perceptions, and Effects

Delta-8 THC, a psychoactive cannabinoid marketed as a milder, legal alternative to Delta-9 THC, has surged in popularity among young adults following the 2018 Farm Bill, which legalized hemp and its derivatives containing less than 0.3% Delta-9 THC. Despite its growing popularity, research on Delta-8 remains sparse, with little understanding of its safety, effects, usage, and societal perceptions. While some studies have explored consumer data and public opinion, this is the first to focus exclusively on adults aged 18–30, the largest demographic of Delta-8 users, and to directly compare their perceptions, usage patterns, and attitudes toward Delta-8 and Delta-9 THC. An online survey of 191 participants aged 18–30, primarily from universities in the American South, Southwest, and West Coast, was conducted. The survey included 61 questions and employed statistical analyses such as chi-square tests and Fisher's Exact Test to evaluate gender differences, reported effects, and legalization support. Key findings revealed significant gender differences in Delta-8 usage, with females more likely to report use than males ($\chi^2(1, 96) = 5.24, p = .022$), while no such difference was observed for Delta-9 usage. Participants reported both positive (e.g., relaxation, euphoria) and adverse (e.g., dry mouth, fatigue) effects of Delta-8, reflecting a nuanced user experience. Although many respondents correctly distinguished Delta-8 from CBD, uncertainty about its safety relative to Delta-9 THC was common, and the majority perceived Delta-8 as less socially acceptable. Support for legalization was

significantly higher for Delta-9 THC than Delta-8 THC ($p = 0.021$). These findings underscore the urgent need for public health education and evidence-based guidelines, particularly as Delta-8 products remain largely unregulated across the United States. As the first study to comprehensively examine Delta-8 THC use in this key demographic, this research provides critical insights into its effects and sets the stage for clinical trials to investigate its safety, efficacy, and broader policy implications.

Abstract Name: Crystals and Light Waves: The Structural Color of the Colonial Pearl

Perla del Mar Oriente (Pearl of the Orient Seas) is the title the Spaniards gave the Philippines during their colonial reign. It paid tribute to the archipelago's lands, biodiversity, and culture, all of which were soon dulled by Spanish exploitation. The pearl-diving industry, which once held a thriving position in the Philippines' economy, faced significant decline due to overharvesting and habitat destruction. Pearls manifest as layers of iridescent nacre gradually coat irritants within a mollusk. This gorgeous result is a form of natural resistance, a testament to the power of withstanding invasive, outside forces. In this way, its process feels resonant with peoples who struggle as a result of colonization. Crystals and Light Waves is a body of animated work examining the pearl through research in collection practices, colonized histories, and current art institutional dialogue. Each of the six pieces is a 10-to-32 second looping animation of a well-known pearl. To create them, preparatory research focused on the six pearls' historical records, as well as pearl-centric texts, from laws and treatises to poetry and fiction. Many of the resultant animations are timed to Morse code, reflecting both maritime traditions and the shaping influence of language on pearls. Other animations, digital effects, and visual elements are tailored to the personal origins of each gem. These 'new' pearls simultaneously reveal exoticized, false narratives while also reminding us that resistance is a beautiful power. Crystals and Light Waves was created to take on various presentation formats, like installations, GIFs, and single-channel videos, encouraging the barrier-breaking, action-focused initiatives that museums and related institutions are currently implementing. In doing so, it invites viewers to reimagine the role of art in healing, resistance, and the reclamation of histories.

Abstract Name: Examining disease in NEFL+/E396K and NEFLE396K/E396K mouse models of CMT2E

Charcot Marie Tooth (CMT) is one of the most common inherited neurological disorders with a prevalence of ~1:2,500. There are several types of CMT (1-7 and X) that are associated with mutations in many different genes. The two primary types of CMT Type 1 and Type 2 are associated with defects in the myelin sheath or

axonal degeneration, respectively. The focus of these studies concerns CMT2E, that is a result of mutations in the neurofilament light (NEFL) gene that encodes the NF-L protein. CMT2E gives rise to defects in peripheral axons and is clinically classified as an axonopathy. Patients typically present with distal weakness, muscle atrophy, sensory loss, and foot deformities with near-normal motor nerve conduction velocities (MCV) but with reduced compound muscle action potentials (CMAP) upon electrophysiology examination. There are currently no approved CMT2E therapeutics. In order to evaluate therapeutic efficacy, we generated a novel CMT2E mouse model based on the NEFLE396K patient mutation, the most common CMT2E mutation. Initially, we characterized our neflE396K mouse model and these studies are described below. While the mode of NEFLE396K inheritance is autosomal dominant, we evaluated nefl+/E396K and neflE396K/E396K mice to determine whether there were differences in disease pathology that could be leveraged for evaluating therapeutic efficacy. Assessments included fitness (lifespan and weight), motor function assays, electrophysiology measurements, and disease pathology (motor neuron, nerve and muscle). Our results show that nefl+/E396K and neflE396K/E396K mice develop disease phenotypes consistent with CMT2E clinical symptoms. Interestingly, neflE396K/E396K mice demonstrate disease pathology earlier than nefl+/E396K. Progressive muscle atrophy and nerve degeneration are detected that are consistent with decreased mobility. We are able to demonstrate clear differences in electrophysiology recordings between wild-type and nefl mutant animals early in disease pathology.

Abstract Name: Cybersecurity Resistance and Small Businesses in the NJ/NY area

Small businesses are vulnerable to cyber threats due to limited resources; therefore, strong cybersecurity measures are necessary to protect their digital assets. Kean University's Center for Cybersecurity offers these assessments free of charge to small businesses in the NJ/NY region. However, the uptake has been limited. Hence, this study seeks to evaluate the motivating factors that influence small business adoption of cybersecurity assessment. With the use of the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT), the study examines the effects that performance expectancy, social influence, facilitating conditions, trust, perceived risk, and ease of use have on the decision-making of small businesses taking on these assessments. Survey data will be collected from local businesses, using a Likert scale to test the relationships of these variables vis-a-vis the perceptions of the entrepreneurs, as shown in the conceptual model below: The survey will be distributed in December and January using a multi-pronged distribution strategy, including email, social media, in-person events, and partnerships with regional chambers of commerce. The target is 300-400 responses. The data will be analyzed using partial least squares structural equation modeling (PLS-SEM) and SMARTPLS 4.1 software to assess the hypothesized relationships. The results will identify potential opportunities for data-driven interventions to reverse cybersecurity adoption resistance in small businesses.

Abstract Name: Relationship between overconsumption of Short-Form Video and Attention Impairment through Behavioral Data

The rise of clinical depression worldwide has emphasized the importance of promoting pathways to improve quality of life. Among common symptoms like persistent low mood, decreased interest in things once pleasurable, and a lack of energy, people with depression also exhibit significant cognitive impairments in executive functioning. Research has indicated that excessive consumption of short-form videos is associated with higher rates of mood disturbance, poorer memory, and a hindered ability to concentrate. However, many of those findings are solely based on participant's self-report. Our study aims to further explore the link between prolonged short-form video content consumption and poor mental health. This study recruited students from the City College of New York. Participants completed a modified version of the social media use questionnaire, the Depression, Anxiety, Stress Scales DASS survey, the adult ADHD self-report scale (ASRS v1.1). After completing the surveys, participants completed a series of modified Erikson Flanker tasks to measure their selective attention on a computer. The reaction time participants took to respond to each trial and their accuracy in identifying the direction of each target stimulus were recorded. This study will split participants into a high TikTok use group and a low TikTok use group by taking a median split from participant's scores on the modified social media use survey. Then, the study plans to compare the amount of TikTok usage with reports of depression using a simple t-test. To further understand the effect of prolonged TikTok use on possible depression-related attention deficit, this study plans to compare the difference in the adult ADHD self-report scale among the high and low TikTok-use groups. To investigate the behavioral differences among high and low TikTok use groups in their accuracy performance between negative stimulus trials and neutral stimulus trials.

Abstract Name: Predict, Prevent, Protect: AI's Role in Epidemic Control

Artificial Intelligence (AI) is an emerging topic in society today. AI can simply be defined as the theory and development of computer systems able to perform tasks that typically require human intelligence. Most importantly, AI can be used in healthcare around the world. AI can be used in the early detection of epidemics and overcome the challenges faced by weak health systems. AI can detect epidemic signals much earlier than traditional disease surveillance. AI systems such as ProMED-mail, HealthMap, BlueDot, Metabiota, and EPIWATCH can be used to constantly monitor areas for emerging diseases. AI has aided public health delivery via spatial modeling, risk prevention, misinformation control, public health surveillance, disease forecasting, pandemic/epidemic modeling, and health diagnosis. In addition, Blockchain can be paired with AI to allow for faster, more efficient analysis and communication of information. Blockchain and AI can be used to analyze outbreaks, detect and analyze diseases, develop vaccines, and predict future outbreaks. Blockchain enhances AI's epidemic control capabilities by ensuring secure, tamper-proof data sharing

between healthcare organizations, enabling real-time analysis of disease spread. AI can analyze Blockchain medical information and then distribute that information to clinical labs, hospitals, network operations, social media, and patients. Blockchain works alongside AI to address challenges like data accuracy, privacy, and communication in epidemic management. It makes it an ideal way to record information on how many people are affected by a disease, communicate that information, and then take action to stop the spread. Integrating AI and Blockchain can lead to earlier disease detection, faster outbreak responses, and improved resource allocation to strengthen global epidemic preparedness.

Abstract Name: The Intersection of Identity and Economy

In bell hooks' *Where We Stand: Why Class Matters*, hooks explores the intersectionality of race, class, and gender, demonstrating how privilege and oppression shape our modern societal structure. As she draws on her personal experiences as a young working-class black woman, she critiques the societal structures that perpetuate inequality. This presentation aims to examine the key themes in hooks' work, such as systemic racism and gender-based discrimination, and how these issues present themselves personally and institutionally. As well as addressing the historical roots of these inequalities and their modern manifestations in society today. In the discussion of these challenges, this presentation also addresses interventions, such as DEI and Vivid Counterstereotypic Scenarios need to evolve to successfully bring these issues to an end. It is through reimagining these interventions that we can work to better address these complex intersections and work towards a more just society. This brings us to the creation of the Bias in Action program that would take the form of open dialogue and reflection. By promoting the open exchange of reflection and challenges, the program can confront these issues and address them collectively. Unlike the Vivid Counterstereotypic Scenario and DEI, thus implementing regular check-ins and group tasks to ensure accountability and facilitate growth personally and professionally. This would envision a future where bias is challenged, diversity is celebrated, and individuals feel they can live.

Abstract Name: The Art of Inquiry: Exploring Artistic Approaches to Research

By definition, arts-based research is a multifaceted field that explores various methods and techniques for researching to expand artists' knowledge and experience of their artwork. While art-based research is often seen as less academic than STEM research, the main distinction lies in that artists aim to learn and discover during the research process rather than proving a specific idea or theory. More specifically, a survey performed at the University of West Florida found that 69% of art and design students had never heard about research opportunities available, however, 71% were interested in doing research. With this in mind, this project aimed to dispel the stigma around arts-based research and mend the knowledge gap by defining how artists conduct research and creating educational materials for students to understand how they can be

involved with arts-based research. Our central research question was “What is Arts-based research, and how can we make conducting Arts-based research more accessible for students at the University of West Florida?” Answering this involved doing in-depth literature reviews and interviews with the University of West Florida Art and Design faculty to grasp what the art research process looked like for different faculty artists. The interview’s qualitative data was then used to design a zine intended for undergraduate students to better understand arts-based research, what components an art research project should have, and opportunities to get involved in research at the University of West Florida. Although no conclusive results have been measured so far, it is expected that research programs hosted through the university, such as the Summer Undergraduate Research Program, will see a rise in art-based student researchers based on students’ better understanding of how to start an art-based research project.

Abstract Name: What is the “Perfect” Woman?

With the rise of the Barbie (2023) movie, more and more individuals are beginning to recognize the role and journey of women that are faced in the United States, but this is not the first form of media to tackle this issue. The portrayal of women in television has significantly evolved over the 1960s to the 2000s, reflecting gender roles, feminist movements, and societal ideals. Through this paper, it examines how key female characters from shows spanning these decades- Laura Petrie from The Dick Van Dyke Show (1961), Maude Findlay from Maude (1972), Clair Huxtable from The Cosby Show (1984), and Claire Dunphy from Modern Family (2009)-- embody the change of the “perfect” woman. Through these characters, television reflects and challenges the definition of femininity. Characters like Laura envisioned the ideal housewife yet also challenged gender roles with her independence and cleverness in the 1960s. Then as the women's movement progressed, Maude confronted social issues, such as abortion, in the 1970s. The 1980s and 1990s saw Clair take back her role as an individual redefining femininity through her success in her career and family. While Claire in the 2000s highlighted the complexities and challenges faced by modern women going through contemporary society via motherhood, marriage, and the workforce. Through analyzing these characters, this paper argues that the representation of women on screen has significantly shaped the role of public perceptions of gender and societal ideals, demonstrating the “ideal woman” is continuously evolving rather than fixed. In conclusion, the portrayal of women in television opens the discussion on feminism and the complexities of womanhood.

Abstract Name: Comparison of Two Three-Dimensional Imaging Approaches for Fluorescence Microscopy

Microscopy is the scientific study of using microscopes to capture magnified images of objects and details too small to be seen by the human eye. Three-dimensional (3D) subjects are difficult to capture because not

all regions can be in focus at once. I researched two different methods of obtaining 3D images of a fluorescent subject (that reflects light), using a ZEISS Axio Imager.Z1 microscope enabled by the ZEISS ZEN software for data acquisition and processing. My presentation will assess both methods using data I acquired from imaging a brine shrimp sample. In widefield microscopy, a 3D image of a subject is captured by taking multiple 2D images using a conventional light microscope focused on different axial depths within the sample. These images include emitted light from all regions of the sample, causing the output to appear blurry. The 3D image is modelled by the 3D convolution of the microscope's point-spread-function and the fluorescence light emitted by the sample. The convolution process is then reversed by performing a deconvolution operation, which makes the images sharper because out-of-focus light is removed and light is reassigned to the location that it originates in the underlying sample. This provides a better approximation for the 3D object. In contrast to widefield deconvolution microscopy, structured illumination microscopy (SIM) is performed by capturing multiple images for each axial depth; each image has a structured illumination (SI) pattern with a different phase projected onto it. The SI pattern modulates a portion of each axial depth, allowing better detection of in-focus light, and in this way it improves the information that can be captured. The ZEISS ApoTome device I used enables capturing and processing of optical-sectioning SIM images, which leads to final images with reduced out-of-focus light at each axial depth in the 3D subject.

Abstract Name: Authentic Identity and Brands: A Cross-Cultural Exploration into Brand Authentication and Brand Loyalty

Brand preference is primarily determined by a congruence between self-image and symbolic brand-image. Moreover, brand loyalty contributes to a sense of self by creating a brand community that a consumer may identify as part of their “true” self. This study explores how cultural differences in self-construal (whether a culture is collectivist or individualist) influence how individuals use brands to express their “true” identity in two distinct social and cultural regions: the U.S. and China. This study builds upon the authenticity literature by examining social and personal identity performance in two distinct cultures. Furthermore, this study is increasingly important in the era of globalization by laying the foundation to explore how certain social groups may transcend cultural lines allowing social groups to form based on shared meanings ascribed to certain brands. Using survey data collected from a nationally representative sample of individuals in the U.S. and China this study evaluates the levels of personal authenticity, collectivist and individualist orientations, and the degree to which one authenticates oneself through brands and brand communities. Findings indicate that the U.S. and China are culturally distinct in terms of individualist orientation and brand authentication. Unexpectedly, Chinese respondents report greater individualism, and both individualism and collectivism positively predict all forms of brand authentication. Findings also suggest that Chinese respondents are more likely than U.S. respondents to authenticate through brands based on self-image congruity and the brand's ability to express the social self. Additionally, accepting external influence significantly predicts brand authentication through brand communities. By introducing brand authentication as a framework, this research offers a new lens to understand consumer engagement and the broader societal impacts of globalization, particularly how shared meanings ascribed to brands can bridge cultural divides and shape global consumer dynamics.

Abstract Name: Honey as a Natural Preservative Against Lipid Oxidation in Meat

Preserving and extending the shelf life of meat products remains a key concern for producers, retailers, and consumers alike. This study investigates the effectiveness of various honeys—local beekeeper honeys, commercially available grocery honeys, and Manuka honey—in inhibiting lipid oxidation in beef, a process that leads to rancidity. Fresh beef samples were treated with honey and sodium tripolyphosphate (STPP) on the day of acquisition, and lipid oxidation levels were measured over four days using Peroxide Value and TBARS assays. Results from the Peroxide test revealed that M-256 honey exhibited the highest lipid oxidation inhibition (74.63%), outperforming the synthetic preservative STPP, which achieved 71.64% inhibition. Other honeys, including 23H-50 and 23H-76, demonstrated moderate inhibition levels at 59.70% and 40.30%, respectively. TBARS assay results showed that G-19 honey provided substantial inhibition of lipid oxidation (80.75%), with NJ-15 and SA-31 offering moderate inhibition at 52.07% and 46.73%, respectively. Although STPP exhibited a higher inhibition rate of 95.7%, its use is associated with health risks such as kidney failure and gastrointestinal issues, raising concerns for prolonged consumption. These findings suggest that high-bioactivity honeys could serve as a natural and safer alternative to synthetic preservatives in meat, effectively inhibiting lipid oxidation and potentially extending shelf life without adverse health effects.

Abstract Name: How Social Media has affected the Mental Health of First-time Student Voters in this year's Presidential Election

"How Social Media has affected the Mental Health of First-time Student Voters in this year's Presidential Election" Social media has vastly affected the United States youth in many ways, including how we convince our youth into voting. The methodology for this research consists with a thematic analysis of research articles and interviews of first-time voters pending IRB approval. The timeline for this research is actively being determined. University of South Florida published a research article about voter opinions on inflation, impact of politics on mental health, election distrust and social media use (Johnson, 2024). This study gives this growing field an understanding of the impacts social medias politics has on youth mental health. If social media negatively affects voters' mental health, this is going to deter these voters from attending the voting polls, and it is likely that they will continue to not vote. As of January 31, 2024, "More than a quarter of respondents (26%) say that they rely on social media 'a great deal' to stay informed about politics and current events, while another 34% say that they rely on it at least "a little." (Johnson, 2024) The study showed that "Social media users chose decidedly negative terms to describe the political discussions they meet on social media." With this research, we could harness the power of social media to positively affect first- time voters' mental health and get more young voters involved in the elections. University of Oregon Eden Henry conducted research on An Evaluation of Well-being in College Voters During Election Cycles. This research was a mixed-method approach using literature review as well as case study gathered via social media. One of the results showed "With most students reporting greater stress levels, the distribution of answers shows a considerable skew towards higher stress.

Abstract Name: Antacids Buffering Capacity (BC): A measure of effectiveness

Stomach upset, indigestion, and acid reflux occur when the body produces an excess of HCl, which travels to more delicate tissues, causing burning and painful sensations. Antacids, which are mainly basic, are taken to buffer the acid and reduce these effects. This research created a simulated acid environment of 0.1M HCl and a fourteen (14) number. brands of antacids bought over the counter (OTC) and online were used. The pH of the HCl buffered with the antacid was read using the OHAUS PH meter at intervals of 10 minutes for 90 minutes. and subsequent addition of 5 ml of 0.1M HCl at each interval. The rate of the pH change of the resulting solution was measured, and the buffering capacity was calculated. It was shown that some (OTC) antacids had a lower buffering capacity as against the standard of 3.5 for an extended period. This finding will create awareness among the masses and the regulatory bodies on the quality of the commonly sold antacids.

Abstract Name: In Vitro Evaluation of the Antimicrobial Efficacy of Manuka Honey Against *Bacillus cereus* and *Escherichia coli* Using Kirby-Bauer Disk Diffusion Assay

Antimicrobial resistance (AMR) is a significant global health threat, with pathogens such as *Bacillus cereus* and *Escherichia coli* becoming increasingly resistant to conventional treatments. This study investigates the antimicrobial effects of Manuka honey against *E. coli* and *B. cereus* and compares its efficacy to penicillin and tetracycline. Manuka honey was applied to agar plates using filter paper disks, and zones of inhibition were measured after 24 hours of incubation. The results demonstrated that Manuka honey effectively inhibited the growth of *B. cereus*, indicating its potential as an antimicrobial agent, particularly against Gram-positive bacteria like *B. cereus*, which are more challenging to treat.

Abstract Name: Mechanistic Investigation of Substrate Docking in a Traceless Tether Catalyst

Our lab has designed a novel, regioselective dock and release system for one-pot C-H functionalization, aimed at producing polysubstituted aromatics more efficiently. We designed a “traceless tether” based on triazolopyridine (tripy) to provide catalyst stability and the correct geometric alignment for substrates to react. Designed catalysts were synthesized and tested for activity under a variety of conditions. In nearly all cases, the desired catalytic reaction was not observed. We then sought to determine the reason for catalyst failure. Equilibrium and kinetic properties of our dock and release system were measured via Fluorine-19 NMR reaction monitoring. We were successfully able to determine the concentrations of our reactants and products at different times during the reaction. Results indicate that the dock/release step of the reaction proceeds successfully with sufficient yields and rates. However, using a pre-formed palladium catalyst, we observe large amounts of metallic palladium even at low temperatures indicating that tripy ligation was not stable enough. Results obtained in this study have pointed us to second-generation systems with more robust metal-ligand binding modes.

Abstract Name: Deciphering the Past: Examining Patient Records of the Second Minnesota State Hospital through Paleography and Analysis

This project investigates how ethics and personal beliefs played a role in the diagnosis, description, and treatment of mentally ill patients at the Second Minnesota State Hospital in the 1880s. We analyzed patient records of the “insane” from the first 76 unclaimed patients. These patients are buried at Rosemont Cemetery, a location that is still unknown. We delved into additional primary sources such as the superintendent’s reports and newspaper articles relating to the treatment of mentally ill patients. Knowledge on mental illness, let alone how to treat mentally ill patients properly, was lacking. The absence of definitive guidelines for diagnosing patients caused disputes between neurologists and superintendents because the diagnoses given were rarely based on research. The superintendent believed that potential treatments included: (1) physical labor for meager pay or incentives, with clear disparities between male and female tasks; (2) the use of restraints; and (3) certain medications, such as potassium bromide. Ultimately, we discovered that caretakers at the Second Minnesota State Hospital deemed patients mentally ill based on their ethical judgment and morals, rather than distinctly-proven, scientific facts. With this research, we hope to shed light on the unmarked 76 people at Rosemont Cemetery—who were unfortunately born at a time lacking scientific rigor on the study of mental illness—and the mistreatment they received during their time in the Hospital.

Abstract Name: Paws, Hooves, and a Whole Lot of Poop: A Multi-Animal Parasite Study

Zoonotic diseases, caused by parasites transmitted between animals and humans, are a significant public health concern, especially in environments where animals and humans interact closely. Among domestic animals, cats (*Felis catus*) are of particular interest due to their frequent proximity to humans, both as pets and as free-roaming populations. Parasites in feline feces can pose health risks through direct contact or environmental contamination, making it critical to understand their role as potential reservoirs of zoonotic diseases. This study primarily focuses on the prevalence and diversity of parasites in stool samples from cats while also examining samples from chickens (*Gallus gallus domesticus*), sheep (*Ovis aries*), horses (*Equus caballus*), and cows (*Bos taurus*). Standard parasitological methods were employed to identify and categorize parasites. Cats, as close companions to humans, represent a key species for zoonotic transmission pathways. Investigating the parasites they harbor can provide valuable insights into the risks they pose to human health, especially in urban and rural settings. This research highlights the importance of regular parasitological surveillance in feline populations to guide public health policies and develop effective measures for reducing zoonotic transmission.

Abstract Name: A Study of the Boston Dynamics Spot Robot in Extraterrestrial Environments

In planetary exploration, one of the greatest challenges faced by researchers is understanding how rovers will navigate extraterrestrial environments, especially in rocky, unstable terrains and low-gravity systems. Quadruped robots are studied for this reason, as they are better equipped to navigate such terrain much more effectively than wheeled rovers. Methods of virtual simulations using the Boston Dynamics Spot robot, an agile quadruped robot, can be used to test how robotic systems can function in alternate conditions. This project aims to create an open-source code package for the Spot robot's simulation and navigation using the latest versions of ROS2 (Robot Operating System) and Ignition Gazebo, a newer and more advanced robotic simulation software, on rocky terrain that mimics a lunar and/or Martian surface. Basic reinforcement learning (RL) techniques using a preconfigured Proximal Policy Optimization (PPO) algorithm utilized the data collected from experiments conducted in a simulated uneven terrain to enhance the understanding of the robot's navigation in similar extraterrestrial conditions. In future applications, applying this RL algorithm to a simulation of the Spot robot on an accurate lunar will enhance researchers' understanding of quadruped navigation in complex environments

Abstract Name: Recursive Formula of Constrained Joins in Partitions Lattice

In the lattice of partitions P of a finite set X with n elements, the set of atoms is divided into two groups: red and blue, with m atoms in the red group. In this project, we focus on counting the number ps_j of partitions at the j -th level of P_n that can be expressed as the join of exactly s and m or $s = m$ red atoms. To this end, we propose a recursive formula for ps_j . To derive this formula, we consider the graph G whose vertex set is X , where two elements are connected by an edge if they form a red atom. Then, counting the desired partitions is equivalent to counting the spanning subgraphs of G that satisfy certain additional conditions. This reduction allows us to leverage graph-theoretic techniques to effectively address the lattice-based counting problem. Applications of our formula to reducing the search space associated with consensus problems for partitions, particularly cluster ensemble problems in the context of clustering algorithms, are formally investigated.

Abstract Name: Physician Availability and Social Vulnerability to Disasters in Puerto Rico using the US Census Bureau Community Resilience Estimates (CRE)

Puerto Rico, a U.S. territory susceptible to natural disasters, has been in a crisis due to hurricanes, infectious disease outbreaks, a prolonged economic recession, and more. The situation has contributed to severe shortages of medical professionals, worsening health conditions on the island, and leading to socioeconomic instability. A new measure created by the US Census Bureau, the Community Resilience Estimates (CRE), captures social vulnerability to disasters throughout Puerto Rico. This study aimed to explore how the availability of physicians is associated with this CRE measure by county. We conducted different data analyses using R, including descriptive statistics and simple linear regressions, to reveal if there was a significant correlation between physician availability and community resilience in Puerto Rico. Our results showed that municipal areas of Puerto Rico with fewer physicians exhibited lower levels of resilience, which could worsen the impact of disasters. The findings of this study underscore the crucial role of physician availability since medical professionals are essential for improving health outcomes and enhancing the resilience of the island to respond to natural disasters. To protect the well-being of its residents and mitigate the impacts of future crises, the Puerto Rico health system should prioritize improving physician availability, especially among municipalities with more socially vulnerable populations.

Abstract Name: History of Femicide and Transfemicide in Mexico

One major issue Mexico has continued to combat is the ongoing cases of both femicide and transfemicide. Within the last few years, there is still an uprising in cases where both women and transwomen are intentionally being killed by their perpetrators. As a result, this has brought major concerns among citizens and experts regarding the government's attempts to resolve and provide solutions to reduce the violence against women and transwomen. This study will examine the history of both femicide and transfemicide by analyzing different elements that contribute to this issue. To further examine this issue one method that will be applied for this study would be secondary data analysis including statistical data, academic journals, books, and websites to obtain more information on the number of deaths of these victims as well as finding other elements that potentially contribute to this ongoing violence against women and trans women. Once gathering this information, the goal is to raise awareness about this issue so other individuals can be informed not only about their rights but the potential resources available to them. Most importantly providing this information could help individuals in detaching themselves from any teachings and behaviors that contribute to both patriarchy and machismo.

Abstract Name: Echoes of 1978: A Comparative Analysis of Personal Narratives and Media Coverage During the 1978 World Cup in Argentina

This project explores how six interviewees' collective memories surrounding the 1978 World Cup align with Argentine newspaper reports from 1975 to 1980. During the late seventies, Argentina faced political repression under a military dictatorship while hosting the World Cup. By examining the connections between the tournament and the political climate reflected in newspapers, my research will contribute to existing literature on the socio-political implications of Latin American football. Through comparing recurring themes across personal narratives with Argentine newspaper articles, this research aims to build on previous findings about Latin American football's expansion beyond mere sport. The data will consist of collective narratives from a series of six virtual interviews with individuals who lived in Argentina during the events of the 1978 World Cup. Further investigation will include thematic coding from twenty Argentine newspaper articles covering the World Cup. The findings may reveal gaps between interviewees' collective memory and newspaper reports, offering contradicting accounts of a pivotal moment in the history of football and politics. Ultimately, this research seeks to allow individuals to share their stories and assess the correspondence to Argentine newspapers reporting on the 1978 World Cup.

Abstract Name: Comparison of Macroinvertebrate Taxa and Stream Quality Determinations for Samples in Varying Microhabitats

This study aims to compare differences in macroinvertebrate taxa between freshwater stream microhabitats. Macroinvertebrates are bioindicators used to determine levels of pollution within certain habitats. Microhabitats within streams vary by position, flow, and vegetation and these can affect what benthic macroinvertebrates can live within them. Using a modified protocol derived from the Illinois Riverwatch Citizen Science Program; a low effort sampling strategy using dip nets were taken from 2 sets of 4 different microhabitats, including undercut banks, riffles, snags and macrophytes in Lily Cache Creek in Plainfield, IL. Taxa richness, EPT (insect orders Ephemeroptera, Plecoptera, Trichoptera) taxa richness, Macrobiotic Indices (MBI), Shannon Diversity Indices (SDI), EPT/nonEPT and pollution intolerant/pollution tolerant individuals collected were analyzed to determine if differences existed within as well as between microhabitats. Data from each individual microhabitat was analyzed separately then data for each paired microhabitat was combined for comparisons. Paired microhabitats that were most similar in EPT/nonEPT were the two undercut banks, and the two macrophytes; and for between microhabitats, undercut banks and snags. Pollution intolerant/pollution tolerant comparisons for both paired microhabitats were significantly different, and between microhabitats as well, except undercut banks/riffles. MBI were variable, as were stream quality determination, ranging from good to poor. SDI were similar for most macrohabitat samples, but lowest for macrophytes and a smaller snag. Taxa richness was similar between microhabitats with macrophytes and undercut banks having the lowest EPT taxa. Scuds (C. Crustacea, O. Amphipoda) dominated all microhabitat samples except for riffles. Different microhabitats display variability in macroinvertebrate taxa and stream quality characteristics, likely related to physical factors such as velocity and substrate characteristics, but even similar microhabitats can vary as well. These considerations are important in making accurate assessments of stream quality and macroinvertebrate characteristics.

Abstract Name: The Dynamics of Parental Acceptance, Intimacy, and Differential Treatment: Implications for Sibling Delinquency in Mexican-Origin Families

Previous research highlights the role of parental acceptance and warmth in promoting adolescents' psychological well-being and reducing engagement in risky behaviors. Parental warmth, particularly when combined with open communication and consistent involvement, buffers the influence of deviant peers. However, dynamics such as differential treatment based on birth order and sex can negatively impact sibling relationships, leading to resentment, lower self-esteem, and increased delinquent behaviors in the less favored child. Building on this framework, my research examines the contributions of perceived maternal and paternal acceptance, parental intimacy, and parental differential treatment on older and younger siblings' delinquent behavior. Using a preliminary sample of 84 Mexican-origin families in Northern Indiana, we explore how predictors of delinquent behavior may differ for siblings aged 12–18. In alignment with familismo, which emphasizes strong family bonds, we hypothesize that higher parental acceptance and

intimacy will be associated with lower delinquent behaviors, while greater parental differential treatment will correlate with higher delinquent behaviors. Mothers, as primary caregivers, may have their acceptance perceived as more emotionally salient, potentially making differential treatment more impactful for youth. Conversely, fathers, traditionally seen as breadwinners and authority figures, may express less overt acceptance but still exert a powerful influence due to cultural values like *respeto*, which could validate adolescents and reduce risky behaviors. While maternal acceptance has been extensively studied due to mothers' caregiving roles, research on fathers' relationships with their children remains limited, especially in cultural contexts like Mexican-origin families. Preliminary findings suggest that the predictors of delinquent behavior vary between younger and older siblings. Understanding these culturally specific dynamics will inform family-centered interventions tailored to Mexican-origin families, promoting healthier adolescent development and family relationships.

Abstract Name: Developing the Natural Fiber Welding Process for Keratin Fibers: A Study on Wool from a Valais Sheep

Natural Fiber Welding (NFW) is a process where ionic liquids are used to fabricate higher-order, functional biocomposites from biopolymer materials. In this study, we evaluate for the first time how NFW can be applied to weld keratin-based wool fibers. Starting with an industrially-cleaned fleece from a Valais sheep, we first use chemical processes (i.e, soxhlet extraction, base treatment) to remove internal lipids from the fiber surface. Then a series of NFW experiments are performed, systematically exploring the effectiveness of four welding solvents with and without sodium sulfite. Each step of the process is evaluated using scanning electron microscopy, infrared spectroscopy, and thermal gravimetric analysis.

Abstract Name: External Debt and Economic Growth: A Cross-Country Analysis on South Asia

This study investigates the relationship between external debt and economic growth in six South Asian countries: Pakistan, India, Bangladesh, Nepal, Sri Lanka, and Maldives. Given the region's distinct economic challenges and high external debt levels, understanding this relationship is critical. A panel data regression analysis was performed using data sourced primarily from the World Bank to assess whether external debt

influences economic growth negatively or non-linearly. A rigorous literature review provided a basis for hypothesizing a negative association, which the regression analysis supports. Findings further reveal that in most of the selected countries, external debt correlates with reduced economic growth, offering valuable insights into regional economic dynamics and policy implications.

Abstract Name: Enhancing CAR-T Cell Function Using Precision Particles

Advancements in cancer research have highlighted the immune system's potential to be used as treatment. Specifically, T cells can be modified to Chimeric Antigen Receptor (CAR) T cells that are engineered with receptors that recognize, bind to, and kill target cancer cells. However, this approach still faces challenges as patients who receive CAR-T cell therapy often relapse and cancerous cells reappear due to CAR-T cell count dropping in vivo. Here, we developed precision biodegradable particles, with antigen and co-stimulation signals attached to the particle surface via DNA scaffolds, which offer a potential route to cell-extrinsic manipulation of CAR-T cells, given optimized stimulation to promote proliferation while reserving their effector function. T cell expansion is also dependent on a third immunomodulatory signal, interleukin-2 (IL-2), a growth and signaling cytokine. We have developed a second particle with IL-2 attached to the surface to dose functional biomaterials to promote T cell expansion in CAR-T cell populations in vitro. Future steps aim to use animal models for in vivo experimentation. Particles will be used to deliver immunomodulatory signals to CAR-T cell populations through a vaccine approach.

Abstract Name: Looking into Biomechanical Solutions to Help Improve Intractable Diplopia Induced by Strabismus Surgery in Adults

Intractable diplopia is a side-effect of long-term strabismus misalignments being corrected with strabismus surgery. These long-term strabismus errors end up creating Anomalous Retinal Correspondence (ARC) that creates intractable diplopia for the patients. Additionally, treatment forms like prisms, intraocular opaque lenses (IOLs), Botulinum toxin, and fresnel prisms, among others are popular forms of treatment. The purpose of this research is to propose alternative non-invasive and invasive biomechanical solutions as well as evaluate previous solutions and then speculate their effects and success on patients with intractable diplopia. The first theory is a proposal of using prism diopters to recreate ARC in patients who are displaying symptoms of intractable diplopia after undergoing strabismus surgery. Additionally, the topic of implementing this theory into the daily lives of patients is accounted for along with potential drawbacks and benefits. However, with typical prisms there comes an issue of thickness, which can be solved through various methods. The second proposed solution is analyzing the usage of Gradient Refractive Index (GRIN) Materials in cataract IOLs and the usage of Diffractive Optics in multifocal IOLs and relating them to potential

intractable diplopia treatment. The third proposed solution looks at more nuanced technologies like metamaterials and holographic optics and how they could be potential solutions for patients displaying ARC with intractable diplopia through prism deviation recreation. Metamaterials enable precise control over light propagation, which allows for the creation of ultra-thin designs that still have the enhanced deviation capability of thicker prisms. Holographic optics are capable of allowing dynamic, multifocal corrections in lightweight and adaptable formats. The end goal of this paper is to speculate and propose solutions with the intent of these being incorporated into clinical applications in the near future.

Abstract Name: Advancing Human Security Through UNICEF's "Let Us Learn" Initiative

This research examines UNICEF's "Let Us Learn" initiative, launched to provide educational opportunities for children in marginalized conflict-affected regions, with a focus on Afghanistan. The study explores how this initiative contributes to human security by addressing educational inequalities worsened by sociopolitical instability and restrictive policies imposed by the Taliban. Contextually, the research situates the initiative within broader human security frameworks, emphasizing its role in integrating protection and empowerment to mitigate gender-specific vulnerabilities. The methodology involves a qualitative analysis of key program interventions, including Community-Based Education, Accelerated Learning Centers, gender-sensitive teacher training, and financial assistance programs. These interventions are designed to overcome barriers such as cultural constraints, security risks, and economic insecurity, which disproportionately impact Afghan girls' access to education. The study also examines advocacy efforts that amplify the voices of Afghan girls and influence policymaking at local and international levels. The expected findings highlight the initiative's dual impact: restoring educational access for Afghan girls while fostering resilience, economic stability, and gender equality within communities. By addressing systemic barriers and promoting education as a fundamental component of human security, UNICEF's efforts demonstrate how targeted programs can achieve measurable outcomes even in restrictive and unstable contexts. This research contributes to ongoing debates about the intersection of education and human security, presenting evidence that localized interventions can serve as effective tools for social progress and conflict mitigation. The findings underscore the importance of sustained international support and adaptive strategies in advancing education and gender equality in regions affected by persistent instability.

Abstract Name: Beyond the Binary: Gender and Space in the Art of Helen McNicoll

Explorations of gender and space in nineteenth century French art has been a nexus of flourishing art historical scholarship for decades. However, within recent burgeoning discourse, many scholars have urged for a reworking of its examination, as the binarism perpetuated by separate sphere ideology has led to a lack of nuanced and complex understandings of the relations between gender and space. It is within this context

that my paper is situated as I examine the work of Canadian Impressionist Helen McNicoll (1879-1915) to suggest how her images of female rural laborers break down the rigid, dichotomous nature of gender and space. Scholars on McNicoll have begun exploring this strain of analysis, considering how the depiction of working class women exposes the indeterminate spaces they operate within as a result of their labor. This paper builds upon the scholarship by suggesting further that McNicoll's images of rural working class women complicate the rigid, binary ways of thinking about the spaces that men and women of the nineteenth and early twentieth century occupied. Through a focused examination of her market scenes, I argue that McNicoll breaks down the dichotomy of gendered spaces through her depiction of women exercising their social and economic agency in a space otherwise traditionally deemed as public and for men. Through visual analysis, critical feminist art theory, primary sources, and secondary scholarship, this paper establishes that McNicoll's market scenes collapses the binarisms present in the public/private and urban/rural debates, necessitating a nuanced understanding of how the boundaries and thresholds of spaces are more fluid than we may think.

Abstract Name: Effect of Hot-Leg Height with Varying Collector Angle on Thermosiphon Performance

A thermosiphon is a passive water heating system that utilizes maintained temperature differences to provide a constant water density gradient within a closed volume of fluid to drive cyclical flow. This, in turn, generates a reservoir of high-temperature fluid that could be used for heating applications or energy production. The efficiency and simplicity of these systems offer advantages in highly populated or developing regions. This design also avoids the use of mechanical or electrical components. The effect of hot-leg height with a variable collector angle on collector efficiency was explored in the current research. Collector efficiency was defined as the energy absorbed by the working fluid relative to the total energy input to the collector. Key testing parameters included collector angle, variable input power to simulate various levels of sunlight, cold leg height, and hot leg height. Previous research identified local maxima and minima in the collector efficiency as the collector angle varied but research was limited to a single hot leg height. The previous results have important implications to the "latitude rule", which states the collector angle should be set to the collector's installation latitude for fixed collectors. The current research extends the previous research by investigating the effect of different hot leg heights on collector efficiency when the collector angle and input power are varied. This research is needed since some thermosiphon systems have the hot fluid reservoir mounted on top of the collector, or in other words no hot leg height, while other systems have a specified hot leg height. The results of the current research show maxima in the collector efficiency as the collector angle is varied, which indicates it may be beneficial to deviate from the latitude rule to optimize the performance of the thermosiphon.

Abstract Name: Expanding an AI Model for Pulmonary Vasculature Segmentation in Robotic Lung Surgery: Application to the Left Lower Lobe

Introduction: Intraoperative vascular injuries during lung resections, particularly those involving the pulmonary artery, can lead to serious complications. Accurate segmentation of pulmonary vasculature is crucial for minimizing these risks. This study expands upon our prior work on pulmonary artery segmentation in the right lower lobe (RLL) and left upper lobe (LUL), testing the model's ability to generalize to the left lower lobe (LLL) for broader clinical applicability. Methods: Robotic lobectomy video clips, focusing on the pulmonary artery and inferior pulmonary vein, were used for training. The XMem model was trained on RLL annotations to generate segmentation masks. The dataset was split into 80% for training and 20% for testing. The model's generalizability was evaluated using unseen LLL pulmonary artery data and inferior pulmonary vein annotations. Performance was assessed using the Mean Intersection over Union (mIoU) metric. Results: The model was trained on 9 RLL pulmonary artery cases, each with approximately 300 frames. It was tested on 6 LLL cases, which contained fewer frames but effectively tested its adaptability. Despite the smaller dataset, the model achieved an average mIoU of 74.8%, with scores ranging from 64.5% to 87.4%. The model performed best with clear anatomical landmarks, while accuracy slightly decreased in frames with occlusions or complex anatomy. Additionally, the model successfully segmented the inferior pulmonary vein, demonstrating its flexibility for multiple vascular structures. Conclusion: This study shows that our AI model, originally developed for RLL and LUL pulmonary artery segmentation, successfully generalizes to LLL pulmonary artery segmentation. These results highlight its potential to enhance intraoperative decision-making by accurately identifying pulmonary vasculature across lobes. Future efforts will focus on refining the model and expanding the dataset to improve its clinical utility

Abstract Name: Mathematical Analysis of kaleidoscopes in at least 2-Dimensions

This research explores the intersection of mathematics, art, and computer science by examining 2D kaleidoscope generation through the lens of abstract mathematics. It investigates how mathematical principles—such as matrices, group theory, and reflection symmetries, can be applied to create dynamic, visually captivating patterns. Central to the study is the use of geometric group theory, which informs the creation of reflection rules for manipulating and transforming images. The project translated these mathematical concepts into a functional Java program that enables users to upload an image, adjust the angle of reflection, and control the resulting kaleidoscopic effect. The program leverages advanced programming techniques, including pixel manipulation and dynamic reflection methods, to generate intricate and symmetrical patterns. By applying reflection symmetries and matrix transformations, the program allows for the real-time generation of kaleidoscopic visuals, which can be tailored to the user's specifications. The research demonstrates how computational tools abstract mathematics can bridge the gap between them and visual art, offering new perspectives on how mathematical structures can shape digital art. The results underscore the synergy between mathematics, computer science, and artistic creativity, illustrating the potential of computational methods in both artistic expression and educational applications. This work not only contributes to the growing field of mathematical art but also opens up possibilities for further exploration in both creative industries and interdisciplinary education.

Abstract Name: Optimizing Reactive Molecular Species and Immunogenic Cell Death Correlation in Lipid Nanoparticle-Enhanced Photodynamic Therapy

Cancer remains one of the leading causes of death worldwide, highlighting a need for innovative treatment approaches. Photodynamic therapy (PDT), a light-based modality, has gained attention for its ability to treat cancers by generating reactive molecular species (RMS) through photosensitizers activated at specific wavelengths. These RMS induce stress in the tumor microenvironment (TME), triggering immunogenic cell death (ICD) and initiating an immune response. This study examines the correlation between the production of RMS using our photosensitizer and the ICD response. The process that allows safe delivery of our photosensitizer (BPD-PC), is by encapsulating it within Lipid Nanoparticles (LNPs). A key component of the first portion of the study is monitoring Heat Shock Protein 70 (HSP-70) and Calreticulin, which are ICD markers. Under stress from PDT, these proteins relocate to the cell membrane, where helps activate immune

responses. We will measure the levels of expression to assess the ICD response using various LNP formulations, including BPD-PC 20:0, BPD-PC 16:0, BPD-Cholesterol, and Free-BPD. The second portion of the study focuses on measuring the RMS released during PDT. The two main types of RMS produced are hydroxyl radicals and singlet oxygen species. These two RMS are produced in different quantities depending on the LNP formulation. The purpose of this portion is to measure the production for each formulation. Using these two experiments, the data produced from each portion is randomly correlated according to the level of concentration used to induce ICD (IC25, IC50, IC75). The data will then be tested for significance, to determine a relationship between the ratio of RMS produced and the level of ICD induced. The findings will allow us to ascertain which ratio of RMS is the most effective at producing an ICD response, which would result in choosing a formulation that most closely matches that ratio.

Abstract Name: Predicting ICU Length of Stay with Admission Data Using Neural Networks

This research aims to predict the length of stay (LOS) for patients in intensive care units (ICUs) using only admission data. The central question guiding this study is: Can admission data be utilized effectively to predict ICU LOS and improve resource planning in critical care? Using the MIMIC-IV dataset, the model captures demographic information (e.g., gender, age), admission details (e.g., type and location), and initial diagnoses. Additionally, it includes patient history and dependencies between providers and resources, as well as explore time-series data for dynamic predictions during a patient's stay. Initial results highlight the potential for enhancing the accuracy of LOS predictions, particularly through the integration of provider-resource relationships. This study contributes to predictive healthcare analytics by showcasing the potential of machine learning to address critical operational challenges in healthcare settings.

Abstract Name: Retour à l'Authenticité: Traditional Nationalism, Re-Invention, & Post-Colonial Power

Across the African diaspora, political elites have used traditional nationalist rhetoric, personal representation, and policy to display their allegiance to citizens. However, these representations are still poorly understood. Therefore, this paper seeks to answer the question: why do Togolese political elites act as traditional nationalists, whilst having policies, values, and associations that contradict that representation? This question has been answered using post-structuralist analysis in two approaches. Firstly, this project has analyzed official speeches, campaign videos, reporting of events, and a comic book from Togo's National Library. By analyzing these materials—meaning utilizing subject positioning to map the discourses—this study contributes to our understanding of how authoritarian leaders legitimize themselves. The second approach includes an interview component with Togolese citizens. Interviews were conducted through the snowball

sampling method to determine modern interpretations of Togolese traditional and cultural values and whether citizens see those values reflected in their representatives and the political campaigning that occurred in the 2024 election. This data has been supported by the interviews of political candidates that ran for the 2024 election. Ultimately, these interviews demonstrate the fluidity of Togolese traditional values and that a Togolese politician can be viewed positively as a traditional nationalist whilst still being perceived as an authoritarian. Together, these two approaches advance the claim that all Togolese presidents have had traditional representations at one point during their tenure, though their differing method of displaying this representation—pan-Africanist language, personal representation, traditional associations, and policy—serves to strengthen varying desired overall characterizations, for example, savior, pacifist, and even modernizer.

Abstract Name: Interrogating the Effects of Circadian Genes on Mesoderm Induction and Metabolism Using an Antagonist of REV-ERB α

Intrinsic to every mammalian cell is the circadian clock which consists of transcriptional-translational feedback loops to time 24 hours and influence multiple cellular processes such as metabolism and cellular division. We are interested in the role circadian genes play in early cell fate decisions of the embryo where they are less understood. Early in development, cells are pluripotent and can become any cell type of the embryo; when cells receive instructive signals they differentiate into specific cell types (induction). Circadian genes are expressed but do not oscillate in pluripotent embryonic stem cells, and oscillations only begin as cells differentiate, accompanied by a shift in metabolism. The circadian gene, Rev-erb α , coordinates circadian oscillations with metabolism in differentiated cells. We are seeking to understand if it plays a similar role during early development through use of an antagonist drug, SR8278. We examined somites (precursor cells of skeletal muscle of mesoderm) in *Xenopus laevis* embryos, as REV-ERB α affects myogenesis and depletion or overexpression of other circadian genes (nocturnin) can affect somite size and number. We injected 10nL of a 10 μ M SR8278 solution into one cell of two cell embryos, allowing for comparison of uninjected versus injected somite size and number within the same embryo throughout development using fluorescence microscopy. We observed that injected cells had less defined somite boundaries. Separately, embryos were cultured to blastula stage before animal caps were removed and induced to form mesoderm (muscle) with activin and a 10 μ M SR8278 solution. Gene expression and metabolic activity were assessed for 24 hours using a luciferase-based reporter gene and assay, respectively. We observed decreased nocturnin expression and decreased metabolic activity in the presence of SR8278. Originally, we predicted that nocturnin expression would increase, leading us to conclude that the drug may target a different repressor in an indirect pathway.

Abstract Name: Development of an Efficient and Low-Cost Quantitative Electrochemical Method to Fast Screen Titanate-Based Bioscaffold Candidates for Tissue Engineering

Titanate nanofibers exhibit unique physiochemical properties, making them valuable in biomedical engineering and tissue regeneration. However, evaluating bioscaffold performance through in vivo or in vitro methods remains costly and resource-intensive. This project seeks to develop a rapid and low-cost quantitative electrochemical method to predict bioscaffold bio-performance, bridging the gap between material synthesis and application. Specifically, titanate nanofibers doped with valve metals or coated with materials like molybdenum disulfide, boron nitride, or reduced graphene oxide will be analyzed for charge transfer and diffusion properties using cyclic voltammetry and electrochemical impedance spectroscopy. By synthesizing doped/coated nanofibers using a hydrothermal method and characterizing their structure through SEM and XRD, this study ensures consistency in material morphology. Electrochemical techniques will quantify critical parameters, such as bulk resistance, charge transfer resistance, and mass transfer diffusion coefficients, which are key indicators of biophysical properties. Parallely, in vitro tests using C2C12 cell proliferation will validate the correlation between electrochemical data and cellular behavior, including cell distribution and tissue integration. This innovative approach offers a fast-screening alternative for pharmaceutical and biomedical industries, potentially expediting the development of efficient tissue engineering scaffolds. Expected results include a robust correlation between electrochemical parameters and biological performance, providing a predictive model for long-term bioscaffold functionality. This work represents a significant contribution to nanotechnology and biophysical chemistry, paving the way for scalable, low-cost evaluation techniques in biomedical applications.

Abstract Name: Exploring the Role of Bacteria in Snail Health and Trematode Infection

Snails are critical hosts for trematode parasites, which can severely affect their health, survival, and ecological functions. These infections disrupt snail populations and have cascading impacts on ecosystems, influencing nutrient cycling and the transmission of diseases to other hosts, including humans and animals. While trematode infections are well-documented, recent research has identified the microbiome of snails as a potential factor influencing their ability to resist or tolerate parasitic infections. Microbial communities, particularly bacteria associated with uninfected snails, may modulate host immunity or directly affect parasite viability. However, the mechanisms governing these interactions remain poorly understood, leaving significant gaps in our knowledge of host-parasite dynamics. This study investigates the role of bacterial communities from uninfected snails in influencing the health, survival, and development of trematodes. By isolating and analyzing bacteria from uninfected snails, the research seeks to determine whether these microbes can impact the lifecycle and success of trematodes. Understanding this interaction may provide insights into the ecological and evolutionary dynamics of parasite-host relationships, as well as the broader role of the microbiome in disease resistance. To explore these interactions, a combination of microbiological techniques, experimental infection trials, and molecular sequencing analyses will be employed. This study has significant implications for both basic science and applied fields. It could inform the development of microbial-based strategies for controlling trematode infections, which are responsible for various diseases in human and animal populations. Moreover, these findings may contribute to a growing body of research on the importance of microbiomes in mediating complex ecological interactions, advancing our understanding of host-parasite-microbiome systems.

Abstract Name: Investigating the Role of Tau in Astrocyte Reactivity and Astrogliosis

Astrocytes are the most abundant type of glial cells in the brain, and they play a role in the immune response. Tauopathies, like Alzheimer's disease (AD), are diseases where tau, a microtubule-associated protein, hyperphosphorylates and misfolds causing it to unbind from microtubules and form aggregates. Astrocytes have a low endogenous expression of tau, and this endogenous tau is thought to affect the reactivity state of astrocytes. Preliminary work from the Link Lab at University of Colorado Boulder has demonstrated that tau knockout astrocytes produced similar gene changes to those seen when wildtype astrocytes undergoing astrogliosis due to exposure to exogenous cytokines. This shows that knocking down tau in astrocytes might cause them to undergo astrogliosis. Whether the similarities in these observations were due to an endogenous immune response initiated by the knockout of tau is unknown. My research proposal is to identify whether astrogliosis markers are present upon tau knockdown in fetal human astrocytes (FHA) and using Sholl analysis to quantify morphological changes. This will aid future treatment developments in regards to the suitability of knocking down tau as a target therapeutic.

Abstract Name: Understanding Tuberculosis: Health Literacy and Perception Among Unhoused Individuals in Shelters Guide the Development of an Education Program

Tuberculosis (TB) is a treatable infectious disease that is on the rise globally. Although unhoused individuals are at a higher risk for contracting TB and the rates of homelessness are on the rise nationally, federal funding for TB detection programs in shelters is decreasing. This study, through interviews with shelter staff, aims to understand current TB protocols in shelters as well as the accessibility of the residents to healthcare services. The data will be analyzed using reflexive thematic analysis. Themes pertaining to perceived risk of TB, attitudes toward seeking healthcare services, access to healthcare services, and prevalence of TB education resources will be analyzed alongside the staff's role. The results of the study will be used to develop an educational program in partnership with the TB Clinic in Denver and the Colorado Coalition for the Homeless, organizations which have recognized the urgent need for an educational program to counteract the increasing TB incidence with the rapid increase in people experiencing homelessness.

Abstract Name: Peptide-based Therapeutics Targeting Amyloid Beta for Alzheimer's Treatment

Alzheimer's Disease (AD) is a neurodegenerative illness characterized by a decline in cognition and memory. In the USA, an estimated 6.7 million adults aged 65 and older are currently affected, with projections of 13.8 million by 2060 if the trend continues. AD-related deaths surged by more than 145% from 2000 to 2019. Shockingly, the CDC ranked Alzheimer's as the 7th leading cause of death in 2019, and it rose to the 5th leading cause in 2023. The Amyloid-Beta ($A\beta$) hypothesis proposes that the accumulation of Amyloid-Beta ($A\beta$) peptides in our cerebral cortex causes the formation of senile plaques leading to neuronal cell death. This research aims to develop potent analogs by modifying previously tested peptides for their ability to bind and inhibit the 1-42 Amyloid-Beta ($A\beta$) peptide. For synthesizing several linear and cyclic peptides, a CEM Liberty Blue peptide synthesizer was utilized to synthesize solid-phase peptides following standard Fmoc procedures and cleaved with 95% trifluoroacetic acid. Peptide characterization was then performed using a mass spectrometer. The peptides in this study were then measured for their binding affinity with Amyloid-Beta ($A\beta$) using selected ion monitoring (SIM) based mass spectrometry assay. The dissociation constants (K_d) for $A\beta$ -peptide interactions were estimated based on the dose response by fixing the $A\beta$ concentration while varying the concentration of the linear and cyclic peptides. The three best linear peptides showed the K_d values of 299, 37, and 8.6 nanomolar (nM), respectively. Moreover, the best cyclic peptide demonstrated a K_d value of 49 nanomolar (nM). This study showed that both linear and cyclic peptides show promise to be excellent therapeutics in inhibiting amyloid beta. Additionally, amyloid fibril formation was significantly reduced once these peptides were incubated with amyloid-beta peptide as measured by ThT (Thioflavin T) fluorescence assay.

Abstract Name: What changed on the journey? How Chinese food carries culture and its adaptation to the American Market.

This project investigates how cultural products, practices, and perspectives are shaped and evolve through intercultural experiences over time, with a specific focus on Chinese cuisine in the United States. It addresses two central questions: (1) why and how did earlier immigrants adapt Chinese food to cater to the American community? and (2) what is the current development of Chinese cuisine in the U.S., and how does this evolution reflect broader cultural development? The study employed an exploratory approach, combining survey, interview and field observation in a museum. Through a survey of 35 students at a mid-sized Midwestern university and in-depth interviews with 8 Chinese foreign exchange students at the same institution, findings revealed a strong link between food and culture, highlighting how migration and intercultural exchange foster the evolution of traditional practices in a new environment. The findings echo/align with four key themes from existing literature: the impact of food culture, the role of modern innovation, the influence of cultural identity, and the significance of cultural adaptation. The findings illustrate how Chinese cuisine in the U.S. has transformed over time, reflecting a blend of preservation, adaptation, and innovation. This process not only meets local tastes but also challenges perceptions of authenticity in food.

Additionally, the study emphasizes how the creation of hybridized culinary traditions contributes to cultural identity while promoting dialogue between different cultural groups. By examining the historical and contemporary transformations of Chinese cuisine, this research sheds light on the broader dynamics of cultural exchange, globalization, and the role of food as a vehicle for cultural connection and evolution.

Abstract Name: Is this generation too tired? The cultural impact of Tang Ping and its reflection in western culture.

This study examines the impacts of two cultural practices—tǎng píng (躺平, lying flat) in China and Quiet Quitting in the United States—and their implications for younger generations. Specifically, it investigates how these movements influence college students and educators in both countries. The research explores how American college students perceive and engage with Quiet Quitting and how American teachers and professors interpret, understand, perceive, view) its impact on students' futures. Similarly, it analyzes Chinese college students' views and interactions with tǎng píng (躺平lying flat), as well as Chinese teachers and professors' perspectives on its long-term effects. Adopting an exploratory research design, the study incorporates surveys, interviews, and a comprehensive literature review to investigate whether these trends reflect generational shifts, cultural differences, or a combination of both. By examining attitudes and analyzing the interviewees' view on work-life balance, ambition, and societal expectations, this research sheds light on the cultural and generational dynamics shaping students' transitions into the workforce. Findings reveal significant similarities between tǎng píng (躺平lying flat) and Quiet Quitting, including a shared resistance to traditional notions of success and work ethic. These trends reflect deeper concerns about burnout, disillusionment with societal pressures, and a desire for alternative lifestyles. However, the study also uncovers cultural distinctions in how these cultural concepts/practices are perceived and acted upon in their respective contexts. This research highlights the importance of understanding how these movements impact not only the individual futures of students but also broader societal and workforce trends. It is relevant to students, educators, and those interested in the evolving attitudes of the current generation toward work, education, and societal norms. By drawing connections between these cultural phenomena, the study contributes to the ongoing dialogue about generational change and its implications for global society.

Abstract Name: What About the Fans? The Impact of Conference Realignment on Fan Engagement and Loyalty

For over 100 years, the Pac-12 was one of the premier conferences in the United States collegiate sporting world. The west-coast-based conference, consisting of some of the nation's preeminent public and private institutions, won more National Championships collectively than any other conference. However, starting in 2022, media rights uncertainty led to a mass exodus that saw ten of the twelve schools leave the Pac-12 for one of three other major conferences: the Atlantic Coast Conference, Big 10, or Big XII. Within a two-year period, the conference transitioned from an elite athletic powerhouse of the NCAA to the brink of complete dissolution. With it being such a historic conference that represented western America on the national stage and produced figures that transcended sport, the Pac-12's impending demise was certain to leave a mark on the conference's fans, who had no say in any of the proceedings that brought its fall. To better understand the underrepresented, yet crucial perspectives of the fans, I conducted semi-structured, recorded interviews at the final Pac-12 Men's Basketball Tournament in Las Vegas in March 2024. This work is a part of a larger documentary to uplift the voices of the fans, the supposed "lifeblood" of sport. In these interviews, I asked for their histories with the conference, why the Pac-12 mattered to them, what they thought the ramifications of this abrupt change could look like, and other relevant topics of interest. Before the first game tipped, it was clear that many, even if ultimately optimistic, are uncertain about the future of their schools and college sports as a whole and will sorely miss the conference once dubbed "the Conference of Champions." Now, as the landscape of American sport nationwide is more unsettled than ever, understanding the potential implications of seismic shifts such as this is vital.

Abstract Name: Gene variants MAOAuVNTR and 5-HTTLPR as possible indicators of Non-Suicidal Self-Injury (NSSI) and differential expression between Hispanic/Latino and Anglo-American adolescents

With an aim to assess potential genetic predispositions for the development of non-suicidal self-injury (NSSI) in non-Hispanic White and Hispanic/Latino adolescents, this paper examines differential expression of the genetic variants MAOAuVNTR and 5-HTTLPR in individuals from ages 12-18. NSSI, which was added to the Fifth Edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) in 2013, has been predominantly investigated through psychological and social lenses by scholars such as Olivier Campos and Kristina Eggermont, but very few examinations exist on the biological aspect of NSSI. This study analyzes Kaess et al.'s (2021) meta-analysis that conveys the possibility of NSSI as a result of variants of the MAOA and 5-HTT genes. Wester & Trepal's (2015) study is also investigated in order to determine which ethnicities currently display higher rates of NSSI. A close analysis of these sources revealed no longitudinal studies have been conducted to support the validity of those genetic variations as biological predictors of NSSI. Additionally, no information was found on the prevalence of these genetic mutations in different ethnic groups, likely due to the recent development of a biological approach to NSSI. Ultimately, this research proposes cross-sectional studies should be conducted to examine genetic variations to the development of NSSI in Hispanic and non-Hispanic White teenagers. Future research should aim to provide an optimal timeframe for the prevention of NSSI through therapeutic approaches by conducting additional longitudinal studies, especially due to the novelty of the issue in biology.

Abstract Name: Investigating the dietary sources of nutritive and caloric content in nonhuman primates: Evaluating current practices to determine the potential for obesogenic weight gain in macaques (*Macaca mulatta*).

Foraging opportunities are designed to encourage species-typical behaviors, provide cognitive stimulation, and promote the welfare of captive macaques. However, concerns about healthy body weight in captive primates highlight the need for careful dietary management, as foraging enrichment has the potential to introduce additional calories that may not be effectively measured. This study examines the dietary sources of nutrients and caloric content in nonhuman primates to assess whether current feeding practices contribute to obesogenic health trajectories. Currently diets in captive primates include the following 4 sources: nutritively balanced chow titrated to the individual based on body condition, and veterinary evaluation comprises the majority of the diet (adult ~100 kcal/kg), foraging opportunities containing food informed by delivery schedule and suggested portion sizes, treats given when observing animals (e.g., peanuts, raisins), and oral veterinary medicine disguised in a fruit roll-up or yogurt. Our previous research studied chow and enrichment as dietary sources; we will extend these findings to include analysis of all four sources. This expanded approach will provide a more comprehensive understanding of caloric contributions from all dietary sources. We will compare animals identified as clinically at-risk for obesity to sex- and age-matched control animals of normal body weight. By examining the sources of caloric content and how they contribute to overall caloric load, we aim to determine if we can identify sufficient conditions that may act as tipping points to trigger weight gain. This research will be instrumental in shedding light on key drivers of obesogenic health trajectories.

Abstract Name: Developing a Nuclear Magnetic Resonance (NMR) Spectroscopy Protocol for Qualitative and Quantitative Analysis of Drugs

Drug analysis has many interdisciplinary applications, from forensic chemistry to pharmaceutical analysis as well as medical testing and diagnostics. In forensic chemistry, substances suspected to be illicit drugs are frequently analyzed to confirm their identity and amount. Findings from such analyses are often applied to criminal cases to determine charges, drug origins, and physical characteristics of new drugs. Paired chromatographic and mass spectrometry techniques are widely considered as the industry standard and as such, many other instrumental methods are not commonly explored. In the present work, we explore the use of Nuclear Magnetic Resonance (NMR) Spectroscopy in drug analysis and create a standard operating procedure using NMR as the main instrumentation. The research work analyzes five over-the-counter drugs, namely, Acetaminophen, Ibuprofen, Naproxen, Aspirin, Caffeine and also mixtures of these drugs. The drugs were first dissolved in deuterated acetone and were analyzed using a Bruker NMR Spectrometer equipped with a topspin data analysis software. Individual samples of each drug were analyzed, and the resulting carbon and proton spectra were employed as references when working with unknown samples. The carbon and proton spectra of individual drug samples and drug mixtures were used to determine identity. Furthermore, integrated proton spectra were used for quantitative determinations. Overall, a standard NMR protocol was developed for both qualitative and quantitative analysis of drugs.

Abstract Name: Examination of Latency in AR Guided Skull Base Surgery

BACKGROUND: The integration of Augmented Reality (AR) in surgical workflows offers potential advantages in surgical efficiency and accuracy. While traditional surgical workflows maintain sterility through dedicated personnel managing non-sterile interfaces, implementation of AR technology could enhance surgeon autonomy. The hands-free virtual interface manipulation enables surgeons to directly control surgical systems and displays without intermediaries, potentially reducing operating room personnel requirements and streamlining workflow efficiency. In practice, system latency – understood as the delay or time it takes for data packets to travel from the sender to the receiver across a network - may impact AR practical implementation in the operating room. **METHODS:** This study evaluated the impact of AR headset latency when used to project endoscopic views during skull base procedures. In a controlled cadaveric study, trained skull base surgeons performed identical procedures (exposure of the sella, carotid, and vidian nerve) using both conventional endoscopic displays and AR-projected holographic displays. Performance was assessed through the comparison of procedure duration and video analysis. Qualitative reflections from the surgeon participants were recorded. **EXPECTED RESULTS/FUTURE IMPACT:** The learning curve for basic AR system proficiency proved manageable, with surgeons typically achieving comfortable operation within 1-3 hands-on experiences under direct guidance, suggesting feasible implementation in surgical practice. Results demonstrated that while system latency was generally negligible, specific conditions - particularly those related to wireless network instability - negatively impacted surgical performance. Beyond validating the basic feasibility of AR integration in the surgical environment, this study establishes a foundation for expanding AR applications in surgical workflows. There is great potential for future applications of integrating additional surgical information systems, imaging data, and controls into the AR environment, enabling surgeons to have immediate and direct control over multiple surgical systems during complex surgical procedures.

Abstract Name: Bacteriophages: The Champions Rivaling Antibiotics

Antibiotics have long been the treatment of choice against bacterial infections. However, the rise of resistance to antibiotics is occurring so quickly that it has been referred to as the “silent pandemic.” It is crucial to find

alternative treatments to address this growing crisis. This is where bacteriophages come into play. Bacteriophages are viruses that target, infect, and effectively kill bacteria, including antibiotic-resistant variants. This study aims to increase public awareness about phages, a shortened term for bacteriophages, and to actively contribute our own phages for future clinical applications. A variety of biological samples, such as animal feces, soil, and water from different parks in the Houston area, were gathered. Samples were homogenized and phages were isolated using centrifugation, filtration, and chloroform emulsions to obtain high-quality samples free from impurities. A double-layer agar assay was then performed by mixing a low-percentage agar solution with purified phage samples. To this, 100 µL of the target specimens, namely *E. coli*, *S. aureus*, and *K. pneumoniae*, was added. The assays were incubated overnight at 37°C and checked for plaque formation the following day. When positive results were observed, the samples were retested at smaller bacterial concentrations to confirm that the previous positive results were not false positives. A total of 27 samples have been tested, of which six tested positive against *E. coli*, while one showed a possible positive result against *S. aureus*. Moving forward, samples will undergo further purification, serial dilution analysis, and evaluation for lytic efficiency. Full genome sequencing, along with electron microscopic imaging, is planned for spring. If any of the isolated phages are found to be unique, their genomes will be added to a global database, contributing to the expanding field of bacteriophage research and potentially being used against drug-resistant infections or as eco-friendly bio-sanitizers.

Abstract Name: What does the text want to say? Hans-Georg Gadamer's hermeneutical philosophy as a remedy for the originalist/pragmatist split in legal interpretation

Present-day interpretations of the U.S. Constitution are deadlocked in a debate between self-styled “originalists” and “pragmatists” over the appropriate context for textual interpretation: either the authors’ original intent (emphasis on historical context) or the demands of present-day society (emphasis on context of present-day application). Hermeneutical philosopher Hans-Georg Gadamer (1900 - 2002) offers a radical challenge to this apparent dilemma, by problematizing the conventional contrast between the legal historian’s task of understanding the law and the jurist’s task of applying the law. As Gadamer instead emphasizes, these interpreters tacitly presuppose one another’s work, such that the legal historian’s attention is already directed by a sense of the law’s application, while the jurist’s concern with the law’s application is always directed by a sense of historical context. In applying Gadamer’s emphasis on “the hermeneutical priority of the question” to an analysis of the Sixth Amendment (on the right to a fair trial), I will demonstrate the ways in which both originalist and pragmatist ways of interpreting the amendment fall short. On Gadamer’s analysis, “originalist” interpretation, for all its purported objectivity, involves a heavy interpretive bias, since its commitment to an “original” meaning imposes a traditionalist agenda that is not in the text itself. Likewise “pragmatists,” for all their emphasis on the evolving demands of the present moment, also operate with a significant pre-understanding, in treating the text as something completely understandable and applicable in terms of the known “social facts” and intended outcomes of the present time. As I show in my project, Gadamer’s emphasis on “the question” both diagnoses and prescribes a path beyond the deadlock between these two approaches, and opens a way for jurists to appropriately exercise their responsibility to both the text and the people in front of them.

Abstract Name: The Effect of Exercise and Vagus Nerve Stimulation on PD Patients with Different BDNF Polymorphisms

Parkinson's Disease (PD) is the second most common neurodegenerative disease and has no known cure (Marsden, 1994). Currently, medications are used to manage symptoms but produce significant side effects (Hayes, 2019). Aerobic exercise, an alternative to medications, has been shown to improve PD symptoms by increasing the production of Brain Derived Neurotrophic Factor (BDNF) (Liu, 2020). Additionally, Vagus Nerve Stimulation (VNS) has potential to improve symptoms through increased BDNF production (Follesa, 2007). A BDNF single nucleotide polymorphism (SNP) can result in decreased BDNF, potentially limiting the benefits of exercise and VNS. Understanding how each individual responds to these treatments, depending on their genotype, can lead to personalized treatment plans for those with PD. 20 participants with PD were randomly assigned to receive 15 minutes of either active or sham non-invasive VNS followed by 30 minutes of exercise, 3 times per week over 4 weeks. Baseline, post-treatment, and four-week follow-up assessments of motor and cognitive function will determine treatment effectiveness. DNA was extracted from participants' blood to assess for the Val66Met polymorphism and its potential effects on participant response. The BDNF SNP at 11p14.1 causes a single amino acid substitution, resulting in three genotypes: Val/Val, Val/Met, or Met/Met, with the Val/Val genotype producing the most BDNF. The hypothesis is that participants who are Met/Met and Val/Met are less likely to produce BDNF compared to Val/Val which would hinder the response to the exercise and VNS. Results regarding the participants' progress through the VNS and exercise can be used to evaluate if they are alternatives to medications. These findings can be used to treat other neurodegenerative disorders by emphasizing exercise that increases factors that nourish neuron health. Information about each genotype's effects on treatment response can be used to create personalized treatment plans according to genotype.

Abstract Name: Role for KMT2C mutation in endometrial cancer pathogenesis

Endometrial cancer (EC) is the 4th most common cancer to be diagnosed in women. Although EC has reasonable survival rates, there is a disparity gap for African American (AA) women, who are twice as likely to succumb to metastatic EC. They are more likely to develop the more severe subtype, uterine serous

carcinoma (USC), and high-grade EC. HER2-positive USC can be treated with Trastuzumab, but response varies. The KMT2C gene encodes a lysine methyltransferase involved in histone modification and transcriptional coactivation. Through a meta-analysis of multiple datasets, we identified KMT2C as highly mutated in High Grade Serous Endometrial Cancer (HGSEC) tumors from AA patients when compared to Non-Hispanic White patients. KMT2C was the top gene mutated when comparing differential mutation rates from this data. To explore the relationship between KMT2C and EC, we transfected 12Z endometrial epithelial cells with KMT2C siRNA to induce transient knockdown and performed western blots with the transfected protein lysates. Additionally, we transfected cells with plasmids containing green fluorescent protein (GFP), Cas9, and 3 different guide RNAs targeting KMT2C to generate stable knockouts. Flow cytometry isolated the GFP+ cells. Using those isolated 12Z CRISPRCas9 knockouts, we performed another western blot. KMT2C knockdown showed decreased HER2 expression. KMT2C knockdown increased Arid1a expression and minimally increased Snail and Slug expression. GFP expression confirmed successful transfection. CRISPR KMT2C guide 1 silenced some isoforms of KMT2C. Patients who have KMT2C mutations would likely be less responsive to Trastuzumab due to reduced expression of HER2. Arid1a is mutated in about 10% of human cancers and Snail and Slug are markers of epithelial to mesenchymal transition (EMT) so their overexpression in the KMT2C knockdown may have serious implications. More testing should be done related to EC patients with KMT2C mutations and alternate treatment plans need to be explored for this vulnerable subpopulation.

Abstract Name: Improving Plant Health in Lunar Regolith Using Plant Root Microbes

Interest in space exploration has been rising over the past decades. A sustainable life without plants is impossible; growing healthy plants in the space environment is essential for long-term space missions. However, plants are exposed to unique stresses in space, like lack of gravity and high-energy space radiation. Additionally, Mars and Moon regoliths, soil like dusty material found on the surface of Mars and Moon, lack organic matter that plants would need to grow. On Earth, plants exist together with their specific microbiome that helps them to thrive in various environments. Plant-associated microbes can provide nutrients to plants and improve their tolerance to biotic and abiotic stresses. In this project, we are exploring the potential of plant-root microbe interactions to improve plant health in the Lunar and Martian regoliths. *Brachypodium distachyon* and *Setaria viridis* plants, inoculated with a bacterial synthetic community, were grown in Lunar and Martian regoliths and plants were evaluated for their biomass. We observed how a small synthetic community can improve plant health in the Lunar and Martian regoliths to support their growth. We expect our results to contribute to finding practical solutions to improve plants' health in space.

Abstract Name: Leveraging Multimodal AI for Medical Image Diagnosis through LLM's and Visual Question Answering

Artificial Intelligence (AI), particularly large language models (LLMs), has significantly advanced medical diagnostics, especially in interpreting medical images. This research explores the application of the LLaVa (Large Language and Vision Assistant) model for medical visual question answering (VQA) in analyzing chest X-rays, with a focus on COVID-19 diagnoses. Accurate, automated diagnostic tools are crucial in healthcare, where rapid and precise analysis is often life-saving. Chest X-rays, essential for diagnosing conditions like COVID-19, require expertise and time to interpret. This study investigates how LLaVa can augment or partially automate these processes, generating accurate responses to clinical queries using LLMs. LLaVa integrates natural language processing and computer vision to generate text responses from image inputs. Leveraging its ability to learn from image-text pairs, LLaVa was fine-tuned for medical VQA to analyze chest X-rays. We utilized the LLaVa 1.5 model, known for its dynamic high-resolution capabilities, enhancing its perception of intricate medical details. To enhance the performance of LLaVa, we extracted mask features of the images using a convolutional neural network (CNN) and integrated these features into the model, enabling it to better capture structural details and improve diagnostic accuracy. A dataset of 7,146 chest X-ray images paired with detailed doctor notes was used for model training, refining LLaVa's ability to associate visual cues with clinical findings. Training spanned 10 epochs on two NVIDIA RTX 3090 GPUs. Hyperparameters, such as learning rate, were optimized to improve accuracy, while a test set of 2,114 images evaluated the model's performance. Preliminary results demonstrate LLaVa's potential in identifying pulmonary infections and handling complex clinical questions. However, challenges remain with nuanced cases and ambiguous visual cues. Further refinement is necessary to improve robustness and accuracy. LLaVa's integration into medical VQA systems shows promise in supporting healthcare professionals, enhancing diagnostic accuracy, and improving patient outcomes.

Abstract Name: Synthesis of a Novel Quinazolinone as a Potential RAD51 Inhibitor for Cancer Treatment

Homologous recombination (HR) is an important DNA repair pathway for DNA double strand breaks (DSB) and inter strand cross links. RAD51 recombinase is a major HR protein involved in DNA strand exchange and forms nucleoprotein filament on single stranded DNA (ssDNA). The nucleoprotein filament promotes strand exchange between ssDNA and dsDNA called D-loop which serves as a primer and a template for DSB repair. RAD51 is overexpressed in many cancers and its high expression is correlated with high resistance to chemo & radiation resistance and poor patient outcome. There have been a few RAD51 inhibitors reported in the literature but none of the reported candidates inhibit RAD51 potently with good drug-like properties suitable for clinical translation. Recently a quinazolinone derivative have been reported as a RAD51 inhibitor. However, the reported lead candidate contains unfavorable groups such as iodine and free benzyl units. In this regard, we have carried out a structure activity relationship study of a pyridyl quinazolinone and replaced them with pharmacologically favorable structural units. Currently, in vitro biological studies are being carried out.

Abstract Name: Unveiling Campylobacter Jejuni's Pathogenicity: Insight into AspA Enzyme and Potential Therapeutic Targets

Campylobacter jejuni is a widely recognized pathogenic bacterium responsible for foodborne illnesses globally. The bacteria are typically acquired through consumption of raw or undercooked poultry, contact with animals, untreated water, and other contaminated foods such as seafood, meat, and produce. C. jejuni commonly causes gastrointestinal symptoms, including diarrhea, cramping, abdominal pain, and fever. This project focuses on the enzyme AspA, which is integral to C. jejuni virulence. The objective is to elucidate its catalytic mechanism by substituting potential active site residues. We created mutants using Phusion Site-Directed Mutagenesis and extracted the enzyme through Fast Protein Liquid Chromatography. We are currently purifying recombinant proteins T101, S140, T141, and S319. Characterizing these variants aims to enhance our understanding of C. jejuni's metabolism of L-aspartate. The underlying hypothesis is that if these active sites are critical for enzyme function, their inhibition could hinder the bacteria's energy acquisition. This research seeks to advance our comprehension of C. jejuni pathogenesis and may facilitate the development of novel inhibitors targeting AspA activity.

Abstract Name: Multi-Electrode DBD Plasma Torch Design with Drug Delivery Option for Wound Healing and Sterilization

Due to its non-thermal properties, Dielectric Barrier Discharge (DBD) plasma has been increasingly utilized in medical applications, particularly for accelerating wound healing and sterilization. DBD plasma jets are generated using a dielectric tube equipped with two electrodes separated by a dielectric material. By applying high voltages (5 kV–10 kV at 30–50 kHz), gases such as helium (He) or argon (Ar) are ionized within the plasma torch to produce a plasma jet. When mixed with air, this jet generates reactive oxygen and nitrogen species (RONS), which play a critical role in promoting accelerated wound healing. Traditional DBD plasma torches, however, face limitations, particularly in controlling RONS production. To address this, a new multielectrode plasma torch was designed and tested. This innovative design incorporates multiple outer electrodes, enabling the modulation of plasma characteristics without altering gas flow rates (~10–15 slpm), thereby offering precise control over RONS generation. Comparative analysis of emission spectra (e.g., nitrogen second positive system, helium, and oxygen lines) demonstrated that the plasma properties vary significantly with the positioning of outer electrodes. The electrode closest to the torch exit exhibited the strongest emission spectrum and highest gas temperatures, while the farthest electrode resulted in weaker emissions and lower temperatures at a constant operating condition. Additionally, the new plasma torch includes a feature for introducing water droplets via a syringe, enabling liquid droplets to pass through the plasma. This functionality explores potential applications in drug delivery directly to wound surfaces while plasma treatment is being performed. The study investigates how droplet size and ejection rates impact

plasma conditions. High-speed imaging was employed to visualize droplet trajectories through plasma, facilitating accurate measurement of droplet sizes under varying operational conditions. Comprehensive experimental results and analyses will be presented at the conference.

Abstract Name: The Role of Human Alpha Defensin 5 (HD5) in Disrupting Desmoplakin Mediated Epithelial Wound Closure in Crohn's Colitis

Wound healing is a complex biological process requiring the coordinated function of multiple proteins. In chronic inflammatory bowel disease (IBD), particularly Crohn's Colitis (CC), this process is dysregulated, leading to delayed tissue repair and increased disease burden. Prior studies indicate that Human Alpha Defensin 5 (HD5) is over-expressed in the colonic epithelium of CC patients, yet its impact on wound healing remains poorly understood. Our laboratory has identified that HD5 may impair wound healing by modulating key structural and regulatory proteins. Preliminary findings suggest that HD5 reduces the expression and function of desmoplakin, a critical desmosomal protein essential for maintaining epithelial integrity and promoting wound closure. Utilizing an assortment of biological techniques, including wound healing assays, quantitative polymerase chain reaction (qPCR), and Western blotting, we aim to elucidate the mechanistic relationship between HD5 and desmoplakin in epithelial wound healing using NCM460D cells as a model system. We hypothesize that increasing concentrations of HD5 down-regulate desmoplakin protein and mRNA expression, compromising its ability to mediate cellular adhesion and epithelial repair. This disruption is predicted to result in reduced wound closure and impaired epithelial barrier restoration in HD5-treated cells compared to untreated controls. Understanding the interaction between HD5 and desmoplakin provides a novel perspective on the molecular mechanism of IBD-associated epithelial cell damage. This research may lead to the development of targeted therapies aimed at targeting colonic HD5, thereby improving wound healing and reducing disease burden in CC patients.

Abstract Name: Fusing PhuZ with GFP and mCherry Fluorescence Proteins Using AI Modeling

Microtubules play a crucial role in cell division and comprise a major drug target for many cancers. However, studying microtubules is challenging as they are hard to cultivate in bacteria like E.coli. PhuZ is a self-assembling, tubulin-like protein found in bacteriophages. It serves as a model system for mammalian microtubules because it's easy to isolate and it has a comparable function in phage replication to microtubules in cell division. By making mutations in PhuZ, we can study which amino acid positions affect the polymerization properties of the protein and apply that knowledge to understanding microtubule dynamics. The current method to track PhuZ's polymerization involves using a chemical fluorescent tag. However,

fluorescent tags are unreliable because they might alter the binding properties of PhuZ. Here, we've engineered a method to track the polymerization of PhuZ without the use of fluorescent tags by fusing a fluorescent protein (GFP and mCherry) to the N-terminus of PhuZ. Using AI-powered molecular modeling, which recently won the Nobel Prize for chemistry, we designed an optimal linker sequence that allowed for attaching the fluorescent protein without hindering PhuZ polymerization. The GFP-PhuZ fusion polymerized with a similar critical concentration as the wild type, making it usable for future testing. MCherry-PhuZ fusion polymerized differently than observed previously, warranting further study. These results demonstrate that making fusions with PhuZ is possible without inhibiting polymerization. Currently, we are working to apply this method to fuse PhuZ with periplasmic binding proteins. The aim is to modify the assembly trigger of PhuZ to respond to a diverse range of molecules and engineer a "plug-and-play" biosensor system where ligand binding is linked to polymerization. In the future, we hope to successfully produce and test PhuZ fusions with an array of periplasmic binding proteins.

Abstract Name: The Forgotten Lives of Rochester State Hospital

This project investigates the history of Rochester State Hospital and the unmarked Rosemont Cemetery, where the hospital buried many of the initial patients who passed away during their treatment from 1879 to 1886. While the hospital originally marked their graves with white wooden crosses, these markers were lost or displaced over time. The central research question focuses on the steps needed to locate, mark, and recognize the lost Rosemont Cemetery in order to address both the historical neglect and the ethical importance of this work. Using primary sources such as patient case records, hospital superintendent reports, and newspaper articles, this research shows the stories of patients whose backgrounds as immigrants or marginalized individuals often determined their treatment. To locate Rosemont Cemetery, we explore techniques like Ground Penetrating Radar and draw on examples from other successful gravesite recognition projects, such as the Remembering with Dignity project. By combining historical analysis and modern technology, this study aims to show the importance of memorializing those who were overlooked and to bring awareness and respect for these patients.

Abstract Name: Scoping review of the effects of breathwork in women with breast cancer

Patients with breast cancer experience distress, treatment-related discomfort, and fear of recurrence. This study aimed to assess the effects of breathwork interventions on the mental health and quality of life of breast cancer survivors. We searched multiple databases for randomized controlled trials involving breathwork interventions in patients with breast cancer. Of the 5,909 items screened, 16 studies involving 1,726 participants met the inclusion criteria. Breathing interventions included yoga (n=8), qigong (n=4), and other breathing techniques (n=4). Interventions were prescribed daily or weekly, lasting from one week to two years. Outcomes included treatment side effects, fatigue, sleep, quality of life, biomarkers (e.g., inflammatory markers), psychosocial factors, anxiety, and depression. Although positive outcomes were reported in some domains, the wide range of interventions and outcomes complicates firm conclusions. Future research should standardize interventions and outcome measures and include longer follow-up periods to evaluate survival and recurrence.

Abstract Name: Effects of Temperature Resistant Buffer Solutions on Biomedical Research Samples

Storing research samples at cryogenic temperatures has become an important part of preserving biomedical research samples because of its ability to halt chemical reactions and prevent protein degradation. Using subzero temperatures to maintain stable proteins is vital to obtaining accurate results from data; however, low temperatures can cause changes in equilibrium, which leads to changes in pH and harms proteins. In order to prevent proteins from denaturing, buffers are incorporated in biomedical research samples because they maintain equilibrium and a stable pH by shifting neutralizing acids and bases according to what is present in excess to the solution. Although buffer solutions resist pH change, some are more effective than others. To continue using cryogenic temperatures for research samples, the most temperature resistant buffer solutions should be found to reduce the shift in pH and better preserve protein structures. By establishing the potential of different buffer solutions to diminish pH changes, the stability of proteins within a solution can also be determined. To measure the effectiveness of different buffer solutions' capability to protect proteins, this paper examines ten peer-reviewed sources on experiments pertaining to buffer solutions' ability of protecting proteins from denaturation. From the ten reviewed experiments, data was narrowed down and the most optimal buffer solution for preserving proteins at cryogenic temperatures was found. The results from analyzing the sources showed that the HEPES buffer is the most resourceful, followed by the carboxylic acid and potassium phosphate buffer, all of which maintained a pH between 6-8 throughout most experiments. Although this paper finds a practical buffer solution, there is still more research to be done to determine an effective buffer solutions that maintains protein stability at a wider pH range.

Abstract Name: Titania-Silica Hybrid Aerogel-Like Materials for Catalysis Applications

The widespread use and development of aerogels for catalysis applications is due to their characteristically high surface area. However, the synthesis of typical aerogels is costly and time-consuming, and the need for supercritical drying compounds both these issues. This study serves to further modify our novel synthesis to chemically control binding sites to increase surface area. Our original synthesis involved doping fumed silica with titanyl sulfate hydrate followed by drying and calcining at high temperatures to remove any water and organic molecules. The proposed modification of this procedure involved doping fumed silica with a second, smaller compound prior to adding titanyl sulfate to chemically promote binding at sites away from naturally occurring pores in the fumed silica. Characterization through scanning electron microscopy, BET surface area analysis, and BJH pore size distribution showed that doping the fumed silica prior to adding the titanyl sulfate did result in substantially larger surface area and an increase in nanopores. As surface area is intrinsically tied to catalysis, further developments in high surface area materials results in more efficient catalysts

Abstract Name: Norm Adherence and Perceived Solidarity in Online Communities

There is currently a gap in understanding how we can research the effectiveness of communication in online communities. This study seeks to understand the relationship between norm adherence and solidarity in online communities. Quantitative discursive analysis and qualitative ethnographic analysis are used in tandem to study the levels and regularity of norm adherence, and its correlation with overall community cohesion and group solidarity. This is done by using ethnographic data to determine the norms of three different online communities, then track their adherence/transgression through quantitative content analysis, the results of this analysis are then compared to survey data on feelings of community cohesion. This study hopes to provide a framework for measuring solidarity in online communities in a way that is lacking in the current literature.

Abstract Name: Comparative Analysis of Gut Microbiome Diversity Across Three Clades of Rodentia: Species, Gender, and Age-Dependent Variations

This research investigates the variations in gut microbiomes based on sex and age across three rodent species: *Mus musculus* (common mice), *Meriones unguiculatus* (gerbils), and *Acomys* spp. (African spiny mice), which have remarkable regenerative abilities. Gut microbiota plays a vital role in health, affecting metabolism, immune responses, and behavior, but the influence of sex and age on microbiome composition remains underexplored, especially in rodent species with differing physiological traits. Fecal samples and rectal swabs were collected from male and female subjects at juvenile, adult, and senescent stages in each species. We utilized 16S rRNA gene sequencing to profile bacterial communities and perform comparative analyses to uncover significant variations in microbial diversity and composition among the groups. We

hypothesize that sex and age significantly influence gut microbiota composition, with potential variations between species that exhibit regenerative capabilities. Understanding these differences could shed light on how gut microbiota contribute to health and disease, offering new perspectives for regenerative medicine and age-related health conditions. Our study aims to enhance the field of comparative microbiomics, providing insights into how evolutionary adaptations shape gut microbial ecology and informing future research into microbiome-based therapeutic strategies.

Abstract Name: Differences in the Male and Female Brain: An opportunity for Modern Medicine Advancement

In the past, sex differences in the brain were used to justify the supremacy of one sex over the other. In modern times, this idea has been largely shunned by the scientific community, leading to a general ignorance of sex differences in science so as to avoid the pushback of being considered sexist. However, the literature consistently points towards differences in the brains of men and women. These differences do not imply certain capabilities of men and women, but are statistically significant enough to make a difference in how medicine is developed and prescribed. The evolutionary psychology perspective is used to identify why there are sex differences to begin with. Then, neuroimaging studies, lab experiments, and quantitative research is used to pinpoint the various ways in which the male and female brain differ. They are different in structure, function, hormonal influences, emotional processing, and neurotransmitter systems. Most shockingly were the significant tendencies towards specific mental illnesses. Men are 4-5 times more likely to be diagnosed with autism. They are also more likely to develop schizophrenia and obtain drug addictions. Simultaneously, women are twice as likely as men to be diagnosed with depression. New technological research has pinpointed specific genes that operate differently depending on the sex. Understanding how these genes react under different circumstances can help scientists tailor medicine to more accurately meet one's needs. Prescribing the same medicine to different people will likely promote side effects that alter depending on the sex. This work promotes the idea that medicine could and should be modified further to accompany the brains that they work on, which could be an alteration to medicine that makes a remarkable impact.

Abstract Name: Digging in a Galaxy Far, Far Away: Colonial Archaeology in Star Wars

Disney's expansion of the Star Wars universe created an outlet for many artists to explore their political expressions beyond George Lucas' original vision. Star Wars Rebels, a four-season series, includes many institutions and practices meant to parallel our world. This comprehensive media review focuses on the anthropological and archaeological practices depicted in Star Wars Rebels, particularly Grand Admiral Thrawn's cultural analyses and the archaeological dig portrayed in Season 4 Episode 12 "Wolves and a Door", as the portrayals follow real-world examples of colonial control over cultural artifacts. Following

Lynn Meskell and Maria Starzmann's claim that archaeology has long been used as a tool within the context of colonial domination, particularly in the Middle East, motivated by religion, security, and the Western concept of civilizing "barbaric" societies, this study highlights contemporary cases of physical occupation of heritage sites, usage of archaeological findings to justify territorial claims or cultural dominance, and implementations of securitization developed for purpose of archaeological discovery. Findings indicate strong parallels between the Star Wars Galactic Empire and real-world colonial powers such as the U.S., the U.K., and Israel. By surveying both Star Wars portrayals and contemporary conditions of archaeology, this study extends the discussion of mere depictions within Star Wars to the broader role of archaeology in shaping historical narratives and cultural identity under imperial occupation.

Abstract Name: Understanding Yemeni American Voting Patterns in Alabama

This research explores Yemeni American voting patterns in Alabama, a demographic often overlooked in national political discourse. Recognizing the gap in data, a grassroots census was conducted to estimate the population and voter-eligible Yemenis in Alabama, revealing approximately 1,000 individuals. The study utilized bilingual surveys to assess voting behavior, preferences, and the issues driving voter decisions, comparing responses from English-speaking and Arabic-speaking community members. Pre-election surveys indicated significant generational and gender-based differences: younger, English-speaking women leaned toward third-party candidates, citing dissatisfaction with the Democratic Party, while older, Arabic-speaking immigrants favored Vice President Kamala Harris due to concerns about former President Donald Trump's policies. The study identified Gaza and the economy as top issues influencing Yemeni American voters. Post-election surveys further revealed voter turnout trends, final candidate preferences, and community reflections on the election process. The study concludes with strategies to increase voter engagement and addresses how Yemeni Americans can amplify their political voice in future elections. By providing data-driven insights into this underrepresented community, this research contributes to broader discussions on Arab American voting behavior and highlights the importance of culturally specific outreach in the electoral process.

Abstract Name: Maximal Expression of the FOXR1 Gene Promoter Requires Positive Transcription Factor Interaction

During cellular transcription, specific gene regions are copied into a complementary RNA molecule, acting as the genetic blueprint for creating proteins. The transcription process begins at the promoter region, which

controls how much a gene is expressed by providing binding sites for RNA polymerase and other transcription factors. Foxhead Box R1 (FOXR1) is a housekeeping gene that has been found to play essential roles in cellular and developmental processes in the brain. Though the involvement of FOXR1 in regulating stress pathways and neural development has been proven, its underlying transcriptional regulatory mechanisms remain elucidated. To understand transcriptional regulation, mapping the transcription start sites and transcription factor binding sites of FOXR1, will help determine the positive regulators of the FOXR1 promoter. Bioinformatics of the FOXR1 promoter identified a CpG island, associating FOXR1 as a housekeeping gene, predicting it will have a dispersed promoter with multiple transcription start sites. FOXR1 promoter region was directionally cloned into pGL3 basic, a promoterless vector containing a multiple cloning site (MCS), ampicillin resistance gene, and luciferase component to establish which transcription factor binding site is the main positive regulator of FOXR1 gene expression. Deletion constructs of the promoter region will then be developed through site-directed mutagenesis (SDM) to identify the positive regulator by transiently transfecting into human embryonic kidney cells (HEK293T) cells and using a dual luciferase assay to determine where gene expression is positively regulated within its promoter region. Understanding how gene regulation occurs can help guide genomic solutions such as genetic therapies to prevent cancer or neurological diseases associated with this gene.

Abstract Name: The Impact of Executive Dysfunction on Brain Activity During Postural Control in Older Adults

Executive functioning is critical for maintaining physical performance in older adults, yet its impact on brain activity during postural control, particularly under dual-task conditions, remains underexplored. This study examined the relationship between executive dysfunction and brain activity during postural control in older adults under both normal and dual-task conditions. We hypothesized that older adults with impaired executive functioning would demonstrate decreased alpha power during dual-task standing, as alpha power is linked to executive function. Eighteen participants (age: 73.2 ± 4.5 , 11 female) without executive dysfunction and six participants (age: 82.5 ± 7.3 , 5 female) with executive dysfunction were recruited. Executive dysfunction was defined by a TMT B completion time exceeding 90 seconds. Electroencephalogram (EEG) assessed brain activity, while APDM inertial sensors recorded postural sway metrics during quiet and dual-task standing conditions. The Timed Up and Go (TUG) test assessed mobility. An Independent t-test compared EEG alpha power, mobility, and postural sway outcomes between these groups. The results indicated that individuals with executive dysfunction had significantly lower alpha power while standing quietly ($p=0.01$) and dual-task standing ($p=0.02$). Those with executive dysfunction took longer to complete the TUG test ($p < 0.001$) and had greater postural sway area during quiet standing ($p < 0.001$) and dual-task standing ($p = 0.03$). These findings suggest that executive dysfunction in older adults is associated with decreased alpha power and impaired postural control. Further research is needed to investigate the neurophysiological mechanisms underlying these observed relationships.

Abstract Name: Wavelength-Dependent Photopolymerization of Ethyl Lipoate: Optimizing Conversion Efficiency and Exploring Photoinitiator Effects

The wavelength dependence of the photopolymerization of ethyl lipoate was investigated to elucidate its photochemical behavior and optimize conversion efficiency. UV-visible spectroscopy revealed that bulk ethyl lipoate absorbs light in the range of 220–540 nm, with a maximum absorption (λ_{max}) at 333 nm and an extinction coefficient of $\epsilon_{\text{max}} = 146 \text{ (cm}^{-1} \text{ M}^{-1})$ in both ethyl acetate and tetrahydrofuran. Radical ring-opening polymerization was studied using six monochromatic light sources (380 nm, 405 nm, 425 nm, 450 nm, 475 nm, and 525 nm) at 25 °C. Equilibrium conversion was highest (~85%) at 425 nm, while longer wavelengths yielded lower conversions, likely due to reduced initiation efficiency and slowed depolymerization. To improve polymerization performance at longer wavelengths, camphorquinone, a photoinitiator with $\lambda_{\text{max}} = 470 \text{ nm}$ and $\epsilon_{\text{max}} = 37 \text{ (cm}^{-1} \text{ M}^{-1})$, was incorporated. This addition significantly enhanced both conversion and polymerization kinetics, particularly at 475 nm, resulting in the formation of gel-like polymers. The molecular weights of the resulting polymers ranged from 4,000 to 140,000 g/mol, with dispersity values (M_w/M_n) spanning 1.6 to 18.0. Proposed termination mechanisms include disproportionation of thiyl radicals, yielding thiol and thioaldehyde end groups, as well as radical coupling to form cyclic disulfides. This study highlights the critical role of wavelength selection and photoinitiator choice in optimizing photopolymerization efficiency. Future research will investigate the effects of ester chain length, layer thickness, and biodegradable crosslinkers on polymer properties, alongside the potential of alternative photoinitiators and cationic polymerization systems to enhance reaction dynamics. These findings contribute to advancing the understanding of disulfide-based polymers, emphasizing their degradability and potential applications in sustainable materials and biomedical fields.

Abstract Name: Monoid Motivated by DNA Origami

DNA Origami provides a method to create DNA nanostructures, which have been proposed to be used as scaffolds for nano-electronics and as means for drug delivery systems that can naturally interact within cell environments. Various structures have been experimentally created, including 2D arrays and 3D curves and meshes. However, a mathematical framework and theoretical understanding of DNA Origami shapes and structures is still lacking. A DNA Origami structure consists of a single long cyclic strand called a “scaffold” and numerous short strands complementary to various locations of the scaffold called “staples.” By designing precise annealing locations for the staple strands, the scaffold may be forced to fold into a desired shape. We propose an algebraic system to describe varying staple arrangements within a rectangular fold of the scaffold. For each arrangement, we associate an element of the algebraic system, which we name the Origami monoid, and design its operation to represent concatenation of graphical representations of the origami shapes. We construct the monoid by doubling the generators and relations of the well-studied Jones monoid, then adding relations that describe plausible modifications to DNA Origami nanostructures. We prove several algebraic properties of the Origami monoid, including restrictions on the forms of its elements, facts about its Green’s

classes, and we find and prove an unexpected occurrence of contextual partial commutation between certain generators of the monoid. Besides possible applications to DNA Origami, our approach also provides new ways to build and study algebraic structures.

Abstract Name: Preparation of Alginate Beads for Coliform Bacteria Detection

Each year diarrheagenic strains of *Escherichia coli* cause about 111 million illnesses and 63 thousand deaths worldwide. Total coliforms, a generally harmless and large group of bacteria, are used as initial indicators in water management for determining the presence of such harmful pathogens. Drinking and recreational waters harboring fecal coliforms like *E. coli* imply fecal and sewage contamination that threatens human health. In high numbers, total coliforms also suggest the presence of pathogenic bacteria that cause typhoid fever, shigellosis, bacillary dysentery, cholera, and parasites. Current laboratory detection methods are based on growing bacteria in agar petri dishes, which take at least 24 hours to complete. This renders field detection infeasible, causes overtime, and delays public health response. For decades, few innovative coliform detection methods were standardized for testing drinking water samples and incubation time remain too long for same day results. Those that do significantly reduce time and provide field testing capabilities are unaffordable, especially for regions suffering the highest water sanitation challenges that would benefit the most. In this study, we developed a technique that uses alginate microbeads for the selective detection and identification of coliform bacteria in water. Using a syringe needle system, we prepared microbeads to encapsulate the bacterial cells. We further incubated the bacterial beads under a nutrient medium containing differential dyes. This allows for differentiation of coliform bacteria species by observing the color changes in the microbeads. Preliminary results showed that color change will be observable in 5 hrs. The results can also be scanned using a microplate reader to achieve fast and sensitive detection. We expect that the microdroplet method could improve environmental monitoring for effective disease prevention and advance microbiology research.

Abstract Name: Parasite Communities in Fish Populations of Northern Wisconsin

Fish parasites are vital to aquatic ecosystems, serving as indicators of water quality and ecosystem health while revealing environmental stressors. However, parasites also harm fish health and quality, which can negatively impact the stability of commercial and recreational fisheries. I expect lake size will impact the

intensity of parasites in the fish. I predict that smaller lakes will have a greater intensity of parasites since there could be a greater fish density facilitating parasite transmission. Using traditional hook and line methods, I collected four species of game fish, including *Sander vitreus* (Walleye); *Micropterus salmoides* (Largemouth Bass), *Micropterus dolomieu* (Smallmouth Bass), as well as *Esox lucius* (Northern Pike) from three lakes in Northern Wisconsin. Because of the unpredictability of catching only game fish, I also opportunistically harvested panfish (*Lepomis macrochirus*, Bluegill; *Lepomis gibbosus*, Pumpkinseed; and *Perca flavescens*, Yellow Perch) to obtain an accurate census of fish parasites in these lakes. In addition to the capture location, I also documented environmental characteristics including water temperature and clarity. Overall, I dissected 31 game fish and 22 pan fish (Pike=17, Turner=23, and Amik=13). I recovered parasites from every fish in this study. Among the lakes, most parasite taxa were shared in gamefish; however, intestinal helminth abundance varied (Pike=69.08, Turner=91.2, and Amik=44.88). Contrary to my prediction, the smallest lake had the lowest intensity of parasites per gamefish. A commonality among the three lakes was the presence of the dominant parasite *Neascus* spp. (Blackspot). Furthermore, *Neoechinorhynchus* sp. was a dominant intestinal helminth observed at all three lakes. Further analysis will focus on resolving the parasite community for each fish species. Establishing an initial parasite community for these lakes can be used to help track how communities fluctuate in the future in response to changes in external factors.

Abstract Name: Computational Fluid Dynamics Modeling of FRESH 3D Printing Mature Adipocytes

Introduction: Livestock farming is one of the largest consumers of land and fresh water globally. The production of lab-cultured meat is a growing industry with potential to solve this issue. Widespread adoption of lab-cultured meat would allow for a 99% reduction in agricultural land use and a 96% reduction in water consumption. Printing fat for cultivated meat has proven difficult due to the large size, fragility, and buoyancy of adipocytes. Here we use fluid flow simulations to optimize Freeform Reversible Embedding of Suspended Hydrogels (FRESH) 3D printing parameters to generate lipid laden tissue. Increased pressure and shear stress during printing results in cell rupture and decreased average cell diameter. Thus, it is necessary to optimize printing parameters (nozzle diameter, bioink viscosity, print speed) using CAD and CFD software. **Methods:** Several simulations were run in SolidWorks CAD and CFD with varying parameter values: 1) Inlet Speed – 4mm/s, 10mm/s, 16mm/s, 2) Bioink viscosity (a function of alginate concentration) – 1%, 4%, 6%, 8%, 10% alginate, and 3) Nozzle diameter – 18-gauge, 22-gauge, 26-gauge. A 3mL BD Syringe was used as the base model for fluid flow CFD. Laminar flow was assumed due to small pipe diameters, low fluid flow speeds, and high viscosities involved, resulting in a low Reynolds number. **Results:** It was found that increasing the inlet speed of the printed bioink led to a linear increase in average shear stress and pressure, while increasing the printing needle gauge and bioink viscosity resulted in a much faster growth of average shear stress and pressure. **Conclusion:** By varying different printing parameters and bioink properties, FRESH 3D printing can result in high fidelity prints that minimize shear and bulk stresses experienced by adipocytes during extrusion, allowing high cell viability to be maintained.

Abstract Name: Bimetallic Core-Shell Nanoparticles as Promising Photocatalysts

Nanoparticle structures have become a cornerstone of modern nanoscience and technology due to their tunable properties, which make them highly adaptable for specific needs in the chemistry industry. Their unique ability to undergo controlled surface chemistry enables nanoparticles to function as effective photocatalysts. This process, known as photochemistry, offers a new approach in the petroleum industry and helps mitigate CO pollution. Traditional fuel production methods are energy-intensive and rely heavily on resources like water and CO₂, the latter of which contributes to environmental harm. These methods often exploit and damage the environment, making them inefficient in material usage. The analysis of nanoparticle structures, such as Gold and Titanium Nitride (TiN), reveals a more sustainable and cost-effective way to produce fuel, in contrast to conventional methods. Photocatalysts, activated by light, offer a more energy-efficient alternative, consuming less available energy. The process also yields non-harmful products, with reactions like CO oxidation and CO₂ hydrogenation producing water, methane, and CO₂, all less harmful than CO. These catalysts provide a promising pathway for a greener and more selective approach to chemical production, reducing the consumption of valuable resources. This project investigates the use of viable elements with reliable nanoparticle structures, focusing on bimetallic core-shell nanoparticles with Titanium Nitride as the core metal. Ruthenium, rhodium, and nickel have been used as shell metals in these core-shell structures. The core-shell nanoparticles enhance the catalytic properties of the plasmonic cores due to their unique characteristics. These nanoparticles are synthesized and washed using centrifugation. Microscopy techniques, such as Scanning Electron Microscopy, Energy-dispersive X-ray Spectroscopy, Transmission Electron Microscopy, and Ultraviolet Absorption Spectroscopy, are used to analyze the samples. Future data is expected to demonstrate that photocatalysts offer a more efficient and sustainable alternative to traditional methods in the chemical industry.

Abstract Name: Bibliometric Analysis of Satoyama

Satoyama lacks a consensus definition, encompassing everything from traditional Japanese village-managed landscapes to modern parks. It has captured the interest of many different actors over time, such as social scientists, biologists, and educators. Satoyama ideas shape major policies like the Satoyama Initiative, which promotes sustainable land use and addresses global challenges such as habitat degradation, climate change, and resource overuse. To improve understanding of satoyama as a concept and driver of action, we conducted a bibliometric review of 704 bilingual sources to clarify its historical development and reflection in public policy. Using qualitative analysis, we manually classified English abstracts to identify frequent keywords indicative of integral themes and translated these keywords to automate the classification of Japanese

abstracts. Subsequently, we performed quantitative analyses to examine temporal trends in these themes, resulting in a timeline that captures how conversations around satoyama have shifted from forest management techniques to local and global conservation policies. This analysis will permit collaborators to discuss the literature in connection to shifts in policy and actor engagement over the past 75 years.

Abstract Name: Le Chlordécone

Les Antilles sont un archipel de belles îles tropicales qui périclitent de l'intérieur. Un pesticide poudreux blanc, le Chlordécone, s'est infiltré dans le sol, l'eau de la rivière, et les cultures entre 1972 et 1993, provoquant des effets cancérogènes dans les générations multiples des îliens. Le gouvernement français n'était pas seulement consciente des effets dévastateurs, mais a continué de permettre l'utilisation du Chlordécone dans les bananeraies d'îles comme la Guadeloupe et la Martinique même lorsque c'était interdit sur le continent. Au début du 21^e siècle, la France a finalement mis en place des plans pour financer la recherche et de compensation pour les travailleurs agricoles affectés, mais est-ce trop tard de 30 ans? Cette présentation examinera les propriétés chimiques du Chlordécone, expliquant pourquoi il a des effets destructeurs sur l'environnement ainsi que ses conséquences à long terme sur le corps. En plus, nous porterons un regard plus profond jusqu'à la fin de l'histoire de la mise en œuvre du pesticide, l'arrêt de l'utilisation dans les autres pays, les effets en Guadeloupe et en Martinique, et une discussion sur ce que le gouvernement Français fait aujourd'hui pour améliorer la situation.

Abstract Name: Diffusible and membrane-bound amyloid- β oligomers in early and late stages of Alzheimer's disease

Amyloid- β (A β) plaques are a neuropathological hallmark of Alzheimer's disease (AD). A β plaque deposition involves polymerization of diffusible A β oligomers (A β O), primarily involving the aggregation-prone A β 42, into insoluble A β fibrils. The status of presumably neurotoxic A β O during early and late AD stages is not well understood. Commercial ELISA kits were used to assay concentrations of total A β O and soluble A β 42 in occipital cortex from 25 autopsy cases in groups with AD neuropathologic change low (non-AD controls, n=8), intermediate (AD-mild/ADm, n=7), and high (AD-severe/ADs, n=10). Sequential fractionation produced PBS-soluble (diffusible A β) and Na₂CO₃-soluble (membrane-bound A β) fractions. We observed strong associations between PBS- and Na₂CO₃-extracted A β O ($r^2=0.79$, $p<0.0001$) and A β 42 ($r^2=0.61$, $p<0.0001$). A β O concentration was higher in PBS than Na₂CO₃ extracts in controls, while the opposite

was seen in both AD groups. A β 42 was near assay detection limit in both fractions from controls, while in AD groups it was >10-fold higher in Na₂CO₃ compared to PBS extracts. Relative to the ADs group, the ADm group showed significantly higher A β 42 in Na₂CO₃ extracts and higher A β O in both extracts. PBS:Na₂CO₃ ratios for A β O and A β 42 were high in controls and low in the AD groups. These results support a preponderance of membrane-bound vs. diffusible A β O, particularly A β 42, in AD. Highest concentrations of A β O appear to accumulate in cell membranes during early AD, while lower levels in late AD may be due to fibrilization and sequestration of A β O into plaques. Thus, targeting A β O directly may be an efficient therapy strategy only in early AD.

Abstract Name: Impact of Estrogen-related receptor gamma (Esrrg/ERRg) Modulation on Activity-dependent Gene Expression in Drd1 & Drd2-expressing SPNs: Implications for Huntington's Disease

Introduction: Current treatments for Huntington's disease (HD) focus on reducing huntingtin protein (HTT) expression, but this may not suffice to address the cellular effects of HTT repeat expansion. Additional research is needed to explore neuroprotective strategies. Studies on transcriptional regulation show that the transcription factor ERR-gamma (ERRg; encoded by Esrrg) can modulate HD-related gene expression in spiny projection neurons (SPNs). Esrrg/ERRg overexpression in dopaminergic neurons enhances mitochondrial mass, boosts genes for respiration and autophagy, reduces synuclein inclusions, delays neuronal loss, and preserves axonal terminals in synucleinopathy models (relevant to Parkinson's disease). These findings suggest that understanding ERRg's roles in SPNs could inform potential therapeutic approaches in HD. **Methods:** In this study, we evaluated the influence of ERRg knockdown or overexpression on the expression of putative ERRg target genes in SPNs. One robust and reproducible response was for Egr1, an activity-dependent gene, which was reduced with ERRg overexpression and increased with ERRg deletion when measured by rt-PCR in homogenates of striatum. To determine whether the transcriptional changes were happening specifically in SPNs, tissues from both groups underwent small molecule fluorescence in situ hybridization (sm-FISH) protocols to amplify Egr1 in cells positive for Drd1 and Drd2 mRNA signal to define specific SPN populations. Cell Profiler software is utilized to automatically identify the amount of Egr1 expressed in either Drd1 or Drd2 cell types in confocal images. **Results:** While ERRg overexpression was capable of inducing subsets of genes involved in mitochondrial function and protein clearance, it caused a reduction in Egr1 expression. In contrast to overexpression, ERRg deletion caused an increase in Egr1. **Conclusions:** This finding could be explained by ERRg-mediated recruitment of transcriptional co-repressors to the promoter. Future experiments will explore the biology underlying the transcriptional effects of Esrrg/ERRg overexpression to determine whether ERRg activation could be neuroprotective in HD.

Abstract Name: Model Studies to Guide Cleanup of Clandestine Methamphetamine Labs: Reproducibility of Wipe Sampling

Clandestine methamphetamine production labs (“Clan Labs”) are found in residential dwellings, motel rooms, garages, automobiles, etc. Law enforcement and first responders remove gross quantities of hazardous materials, but property owners do further remediation. Decontamination processes for residual chemical materials can vary, and the most effective cleaning method is unknown. Dr. Karen R. Caldwell’s research aims to understand how surface properties and interfacial chemical reactions govern the effectiveness of cleaning methods and determine the best method. In our research, a typical sample is obtained by wiping a 10-cm x 10-cm square to which a known quantity of a model compound was applied uniformly. Then, a chemical analysis of the wipe will be performed. Previously, we developed a simple template that prevents leakage of applied solvent when performing the wiping procedure. We also found that wipes based on laboratory filter paper are the best to ensure that all material on the test squares is ultimately analyzed. Preliminary results: (1) Not all material applied is routinely recovered – 60-65% recovery is typical, and (2) Variability of up to 30% recovery is observed when different workers carry out the identical wipe procedure. Current research focuses on what causes these differences. We continue using a model compound that can be analyzed via UV-VIS spectroscopy. Modern computational chemistry approaches are being explored, as is the potential influence of surface roughness on the reproducibility and accuracy of this surface-wiping procedure. Once a well-characterized wipe test protocol is developed, a compound more closely related to methamphetamine will be synthesized and subjected to standard wipe testing and analysis. Progress towards this end will be reported.

Abstract Name: The Aesthetics of the Graphic Novels of Guy Delisle and Riad Sattouf

Graphic novels, as a literary genre, teach how to combine text and images effectively. French graphic novels, in particular, explore relatively unknown genres in multiple formats without pagination. They experiment with graphics and narratives with original tones, styles, and content. The research endeavors to examine portrayals of Eastern and Western cultures, linguistic aspects of the French language, and artistic choices in the Francophone world through a comparative analysis of graphic novels by two prolific authors: Guy Delisle, a French Canadian, and Riad Sattouf, a French Syrian. Guy Delisle's graphic novels explain his life in Quebec (his birthplace) and other countries (those he visits for work). On the contrary, Riad Sattouf describes his experiences living in France, Syria, and Libya. The research concludes with the possible biases that the works may have based on the upbringings of the authors and the way that these biases alter the perceptions that the readers have of these countries based on the media.

Abstract Name: Effect of Caregiver Stress on Perceived Stress of Adolescents with and without Clinical High-Risk for Psychosis

Adolescence is a period of rapid development with changes in brain structure and functions, body, and environmental factors. It is also known as a period during which the risk for psychosis increases and the first episode of psychosis occurs. Perceived stress has emerged as a critical contributor to increasing vulnerability to developing psychosis by worsening psychotic symptoms among adolescents with clinical high-risk for psychosis (CHR-P). CHR-P is identified with the presence of attenuated psychotic symptoms, such as unusual thought content, grandiosity, delusion, hallucination, and disorganized communication, and within 2 years, 20-35% of adolescents at CHR-P may transition to psychosis. A number of studies have indicated that adolescents' relationships with their parents may impact their stress, which plays an important role in psychological outcomes. However, less is known about how caregiver stress influences the relationship quality and perceived stress level of youth with and without CHR-P. Low caregiver-adolescent relationship quality may explain the effect of caregiver stress on adolescent stress. To fill in this gap, the present study examines the effect of caregiver stress on the caregiver-adolescent relationship, as well as perceived stress of adolescents at CHR-P and low-risk controls. It is hypothesized that for all adolescents, (1) higher caregiver stress will be negatively associated with both adolescent and caregiver reported relationship quality, and (2) lower relationship quality will be associated with higher adolescent stress. We will also explore differences in effects between CHR-P and low-risk adolescents. Approximately 30 adolescents (15 CHR-P, 15 controls) and their caregivers will participate in the study. Caregiver stress levels, caregiver-adolescent relationship quality, and adolescent stress levels will be assessed using self-report questionnaires. Findings will advance

knowledge of mechanisms contributing to perceived stress in adolescents at high- and low- risk for psychosis and could inform effects to develop dyadic therapeutic interventions for adolescents and their caregivers.

Abstract Name: Exploring Teacher Educators' Practices and Challenges in Preparing Preservice Teachers for Emergent Bilingual Students

Emergent bilingual students in K-12 classrooms face unique linguistic and cultural challenges, requiring teachers to employ specialized instructional strategies. Despite this need, teacher preparation programs often lack sufficient emphasis on equipping preservice teachers to effectively support these learners. Vomvoridi-Ivanovic and Chval (2014) observed that many teacher education programs fail to adequately integrate content and language instruction, leaving preservice teachers underprepared to meet the needs of linguistically diverse classrooms. Similarly, Echevarria, et al. (2004) emphasized the importance of structured models, such as the SIOP framework, which are often absent in teacher education curricula. García and Kleifgen (2010) further noted that deficit views held by some teacher educators toward multilingual learners hinder the adoption of inclusive and equitable practices. This multiple case study employs comparative analysis to examine how teacher educators integrate pedagogical language knowledge, strategies, and assessments to prepare preservice teachers for emergent bilingual students. The study focuses on three teacher educators teaching foundational education courses at three teacher preparation programs in the Midwest. Through interviews and syllabi analysis, the research explores key areas, including differentiation, curriculum planning, assessment practices, and professional development. The comparative analysis reveals variations in practices and identifies common gaps between educators' current efforts and their aspirations to fully integrate culturally and linguistically responsive approaches into their courses. Additionally, the study investigates challenges educators face in aligning their teaching with these goals. Findings will incorporate identity-informed perspectives from the researchers, blending insights from both a teacher candidate and a teacher educator. These findings emphasize the importance of intentional planning, the development of bilingual teaching strategies, and fostering advocacy for emergent bilinguals in teacher education courses. By leveraging a comparative analysis approach, this study aims to advance equitable and inclusive practices for diverse learners while promoting the ethical development of preservice teachers as advocates for social justice.

Abstract Name: Unwanted Passengers: Level of Influenza Inside College Bars

For many people, drinking and attending college bars is seen as an essential part of the college experience. Large amounts of people flow through these locations regularly, often carrying unwanted passengers (i.e., viruses) with them. Compared to the past, good hygiene and cleanliness are seen as imperative by modern society, and represent key public health interventions or responses that curb the spread of illness. Since the outbreak of COVID-19, good hygiene is an important part of societal health. However, some typical habits, including attending college bars and pubs, go against this focus on hygiene and safety from disease, inviting an increase in risky activities such as sharing drinks. Evidence suggests that there is often a plethora of pathogens found in public spaces (e.g., bars, recreational gyms libraries), however they do not explore college bars specifically, showing the need for studies to explore this location type. This project aims to examine the presence of influenza on several fomites, or surfaces that may contain pathogens, inside of bars and compared to other locations. Influenza may have been transferred to the bar surfaces through direct contact with human hands, or indirectly, through the air or from clothing contact with chairs. Example bar surfaces include handrails, chairs, tables, and toilets. The final results from the bar surfaces will be compared to similar surfaces inside two other locations (student gym, campus library). These locations were chosen because they will contain the same group of interest and are also high traffic. Samples from each bar surface will be compared to an analogous surface of the two other locations. Data collection is ongoing. The expected result is that there will be statistically more influenza present on surfaces inside bars compared to the other two locations. The results from this study can inform illness prevention initiatives in bars.

Abstract Name: Targeting the Menin-KMT2A Interaction with SNDX-5613 as a Treatment for Pediatric Medulloblastoma

Medulloblastoma (MB), an embryonal tumor arising from the cerebellum, is the most common CNS malignancy in childhood. Current treatments achieve a 75% five-year survival rate; however, they often result in significant complications or relapse, emphasizing the need for novel therapies. Recent research has identified the Menin-KMT2A interaction as a key driver of tumor progression in various cancers, including MB, making its disruption a promising therapeutic strategy. SNDX-5613, a small-molecule inhibitor, specifically targets the Menin-KMT2A interaction, offering a potential targeted treatment for this malignancy. This study explores the efficacy of SNDX-5613 in pediatric MB cells by examining its impact on cell proliferation, apoptosis, and molecular signaling pathways. D458 MB cells were treated with varying concentrations of SNDX-5613 and cell proliferation was monitored to determine the IC50. mRNA expression of Menin, MLL1, cMyc, and CDK6 was analyzed via RT-PCR, protein levels of key apoptotic and cell cycle regulators were assessed by Western blotting. Flow cytometry was used to evaluate cell cycle progression. Results demonstrate that SNDX-5613 has significant efficacy in targeting the Menin-KMT2A interaction and is accompanied by a decrease in the levels of both Menin and KMT2A individually. Furthermore, treatment not only increases the levels of P21 and other pro-apoptotic factors, but also induces apoptosis in MB cells, highlighting its dual role in inhibiting cell proliferation and promoting cell death. These findings collectively support the therapeutic potential of SNDX-5613 as a targeted treatment for pediatric medulloblastoma.

Abstract Name: Surveying and Visualizing Subsurface Anomalies with Ground Penetrating Radar at the Vilkija Cemetery in Vilkija, Lithuania

The Vilkija Jewish Cemetery in Vilkija, Lithuania has found itself in disrepair since the Nazi invasion and Soviet occupation of Lithuania in the 20th Century. The Karnofsky family were prominent Jewish community members in Kaunas, Lithuania when they fled to New Orleans in the early 1900s. In New Orleans, they met Louis Armstrong and developed a deep connection to the Armstrong family. This relationship has sparked international interest in preserving the Vilkija Jewish Cemetery to honor the legacy of the Karnofsky and Armstrong families. Recent community interest in the preservation of the cemetery has welcomed surveyors and researchers to collaborate at the site. Geographic research was conducted in the cemetery using a pulseEKKO Pro 500 MHz antennae ground penetrating radar (GPR) unit with 0.25 m step spacing to image the subsurface. GPR is a non-invasive imaging method that transmits electromagnetic pulses into the ground and reflects off disturbances in natural sedimentary stratigraphy. A Topcon RL-H4C self-leveling laser and receiver are used to rectify the GPR data. The GPR unit collects the data and transfers it to a digital video logger (DVL) to be stored for analysis. Three grids and one line were recorded, 13.5 x 22 m, 5 x 12 m, and 10 x 10 m. In the subsurface of these grids, consistent anomalies equidistant from one another were observed at -0.100 to -0.150 m, -0.300 to -0.350 m, and -0.850 to -0.900 m below the surface. Observed anomalies are yet to be identified though they are currently inferred to be the mourning room and the ritual purification building. Further research on this site will be required to fully image the subsurface and locate structures to satisfy the local Jewish community's desire to preserve local history.

Abstract Name: From Grief to Acceptance: Disabled Young Adults & the Transformation of Self

Disabled young adults often find themselves at crossroads in early adulthood, facing a unique set of challenges that can feel overwhelming. They face challenges with job retention, burnout, financial struggles for meds and mobility aids, socialization, and forming connections. Limited transportation and unsupportive environments add to their difficulties. For lifelong disabled individuals, young adulthood can feel like navigating a new world with intensifying disabilities. The lack of resources and economic stability can lead to grief, isolation, and withdrawal, causing frustration, hopelessness, and mental health decline. Unable to engage in past or new activities, they often experience a shift in identity and a sense of loss. I am a Black, disabled college freshman transitioning into adulthood. Inspired by my Psychology of Death and Dying

course, my project explores my experiences as a late-diagnosed, neurodivergent, and chronically ill individual. In my early 20s, these identity aspects became more pronounced, making life navigation harder. I transitioned from being a gifted child to severe burnout in late adolescence, worsening in early adulthood. My struggles with money, events, relationships, and distress led to grief, withdrawal, and a complicated self-relationship. While not universal, this experience is common among many young adults with disabilities. My research examines how childhood disabilities affect identity transformation, grief, mourning, and self-acceptance in young disabled adults. It explores the "death of a previous self" as disabilities worsen, referencing the 1969 Kubler-Ross Grief Model and the birth of a new transformed self. I will also interview seven affected individuals to substantiate my arguments. Through this oral presentation, I aim to provide a platform for sharing and understanding experiences, focusing on acceptance, adaptation, and self-advocacy.

Abstract Name: Creating Glypican-3 KO in human Glioblastoma cells using CRISPR

Glioblastoma (GBM) is a grade 4 tumor within the brain, commonly found in the frontal lobe. This form of cancer is challenging to treat due to the blood-brain barrier, the speed of growth, and the invasiveness of the tumor. Mammalian cells often contain six glypicans that operate in cell signaling and growth, the third glypican being the focal point of this study. Here, we have focused on creating a knockout glypican-3 in human GBM cells using CRISPR technology. To do this, we designed a single guide RNA (sgRNA) to guide the Cas9 enzyme to the glypican-3 gene. When doing this, a frameshift mutation will form that inhibits the function of the targeted gene. To obtain a clonal cell line containing the glypican-3 CRISPR edited knockout, we used clonal expansion cell culturing methods. We grew the CRISPR edited GBM cells in culture and diluted them to a concentration of 0.5 cell per 100 μ L in a 96-well plate to produce clones. Clones were grown over several months for harvesting of genomic DNA to determine glypican-3 knockout score in each clonal CRISPR edited cell line through Sanger sequencing. Having a glypican-3 CRISPR edited clonal cell line for GBM tumor cells allows us to examine the role glypican-3 has in GBM tumor progression.

Abstract Name: Effect of kiwi and tomato storage on Vitamin C content

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available products and food items using titration techniques. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the highest concentration of vitamin C, a crucial antioxidant that plays a vital role in human health. The experimental approach involves titrating the samples, employing 2,6-dichloroindophenol (DCIP) as the titrant, chosen for its ability to

exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. This study aimed to investigate the effect of food storage conditions on the vitamin C content of kiwis and tomatoes. Fruit were subjected to different storage conditions, including refrigeration, and room temperature storage. Samples were collected at regular intervals over some time, and the vitamin C content was analyzed using a standardized titration method.

Abstract Name: Photonic Integrated Circuits

Photonic integrated circuits (PICs) and free space frequency filters are essential components in modern optical communication systems. This report discusses the characterization of these two key elements, focusing on design principles and performance. Moreover, we will discuss the methods and techniques of PIC's. The characterization of PICs encompasses an analysis of the various building blocks, such as waveguides, splitters, and modulators, along with interactions in the integrated circuit. Several key parameters, including insertion loss and power efficiency, are evaluated to assess the performance of PICs and highlight their advantages and limitations. The characterization of free space frequency filters addresses the design considerations and implementation techniques for achieving precise waveguide filtering. There are various types of filters, such as Michelson Interferometers, Mach-Zehnder interferometers, grating-based filters, and other forms of free-space frequency filters. The characterization includes an analysis of key performance parameters, including the filter's bandwidth. Exploring the challenges associated with characterizing both PICs and free space frequency filters, such as the influence of fabrication imperfections, temperature variations, and environmental factors. By providing a comprehensive characterization of both photonic integrated circuits and free space frequency filters, our research aims to enhance the understanding of these components, facilitate their optimization, and enable their efficient integration into advanced optical communication systems. The insights gained from this work will contribute to the development of next-generation photonic devices and pave the way for improved performance and scalability in optical networks.

Abstract Name: Evaluating Acid Neutralizing Capacity (ANC) of selected antacids sold in grocery stores and online.

Heartburn is a symptom that results when the stomach produces too much hydrochloric acid, HCL. This condition, known as hyperacidity, is treated by antacids to neutralize the excess acid and reduce or stop the pain. Various commercial brands of antacids were bought from grocery stores in Maryland and online. A titrimetric method was carried out using 0.1 M HCL and 0.1 M NaOH. The number of moles of acid neutralized per amount of antacid and the cost analysis were calculated. The ANC of all the brands was calculated as the mEq/g. The ability of an antacid to have a high ANC is crucial in assuring its quality and efficiency.

Abstract Name: A Mouse, a Plumber, and You: How Disney and Nintendo Brought Japan and the United States Together Post-WWII Through Family Entertainment

Disney and Nintendo are two of the biggest companies in the world. Disney is responsible for a sizable amount of popular animated movies and champions theme parks globally. Nintendo has pioneered the video game market and has greatly influenced positive public perception on gaming. Though both companies market towards children and families, they've found large fan bases with adults. I will be examining the history of Disney and Nintendo, how they have helped the two countries heal animosity from the second World War, and how they have since helped construct the childhoods of Japanese and Americans alike. Disney first took off around the start of WWII when they released Snow White and The Seven Dwarves in 1937. The flood of American entertainment—such as Disney's Snow White and The Seven Dwarves being released in Japan in 1950—introduced a different kind of animation to Japanese children and adults alike. This created a new, thriving animation and entertainment industry in Japan, "anime," which has since been globally recognized. Following WWII, Nintendo (a playing cards manufacturer at the time) found growing success in this new entertainment industry after a striking a partnership with Disney in 1958 to produce disney-themed playing cards. As they moved into the 1970s and 80s, they took the world by storm with revolutionary gaming systems. Now, in modern days, they've come full circle, helping Disney branch into the gaming market by publishing on their consoles. I intend to visit the Tokyo Disney outlet store and Tokyo Disney. I will also visit the Nintendo Store in Kyoto and Super Mario World at Universal Japan. I will focus on a mixture of visitor behavior, interviews, and exhibits/offers/products.

Abstract Name: The Impact of Adverse Childhood Experiences on COVID-19-related Stress and Mental Health in Emerging Adults.

Adverse childhood experiences (ACEs) are defined as disruptive and harmful events that are typically chronic in nature taking place within a child's social environment. The COVID-19 pandemic introduced widespread disruption, particularly among emerging adults (18-24 years old), exacerbating mental health issues such as anxiety and depression. Literature suggests ACEs may amplify the impact of trauma experienced during the COVID-19 lockdowns. Enforced confinement may have triggered ACE exposure or painful reminders of past ACEs, increasing vulnerability to mental health concerns. We test the hypothesis: The COVID-19 lockdown serves as a predictive factor in shaping the current mental health outcomes of young adults, amplifying the influence of individual ACEs. Survey data was collected from 81 young adults (aged 18-24) from South Africa (n = 39) and the US (n = 42) using a Qualtrics cross-sectional survey. Respondents were surveyed on their ACEs, pandemic-induced stress, and mental health outcomes. Preliminary findings show the overall sample (44.3% male and 51.9% female) reported relatively low scores (M = 1.17, SD = 1.43) for total ACE burden (score range, 0-7). However, an independent samples t-test indicated that participants residing in South Africa reported significantly higher ACE scores (M = 1.54, SD = 1.68) compared to those residing in the United States (M = 0.83, SD = 1.06), $t(79) = 2.28$, $p = .026$, with a medium effect size ($d = 0.51$). Additionally, a linear regression also showed that ACEs significantly predicted mean negative emotions impacted by COVID-related stressors, showing a weak but positive relationship ($\beta = 0.14$, $t(79) = 2.81$, $p = .006$, $R^2 = .09$). Findings show that exposure to ACE serves as a predictive factor in determining COVID-19-related stressors in emerging adults. Preliminary insights underscore the importance of further research to explore the interplay between ACEs and pandemic-related mental health outcomes, particularly among emerging adults in diverse cultural contexts.

Abstract Name: That Dang Phone! How phone usage affects stress levels during and after a stressful event

A. This study was designed to assess stress levels during a break from a stressful event while doing nothing, using a smartphone, or practicing mindfulness. Previous research has shown that stress levels decrease while using a smartphone but has failed to reintroduce the stressor after phone usage ends. Reintroducing the stressor is important because many students use phones when stressed but eventually return to their stressor. This study investigated whether phone usage is an effective strategy to mitigate stress once phone usage ends. Sixty participants were told that the study was on job preparedness to keep them unaware of the nature of the study. Participants were connected to biofeedback equipment (Heart Rate Variability and Galvanic Skin Conductance monitors) throughout the experiment. Participants were given five minutes to prepare a speech on why they were the best candidate for a job and were told that their speech will be recorded as they give it from memory. Participants were then given a five-minute wait period in which they were randomly assigned to one of three conditions: doing nothing, free use of phones, or mindful breathing. Once the wait period ended, participants gave their speech to a camera and then completed surveys, including demographics, State/Trait Anxiety Inventory, Profile of Mood States survey, and questionnaires specific to their condition. Data has been collected and analysis will occur in January and February of 2025. I anticipate that phone use will temporarily reduce stress during the wait period, but stress levels will revert upon re-exposure to the stressor. Conversely, it is expected that mindfulness and inactivity will only slightly reduce stress during the waiting condition but result in lower stress levels upon stressor re-exposure. The findings aim to reveal the efficacy of phone use as a stress management tool through avoidance, particularly among college students.

Abstract Name: Impact of Brewing Temperature on the Available Antioxidant Amount in Coffee

Coffee is among the most widely consumed drinks worldwide, appreciated for its taste and caffeine content and its ability to promote health, notably due to its rich antioxidant levels. This study investigates the relationship between brewing temperature and the total antioxidant capacity of coffee, measured using the Trolox Equivalent Antioxidant Capacity (TEAC) assay. Two coffee types were analyzed: commercially available ground coffee and freshly ground dark-roasted coffee beans. Coffee beans were ground, sieved, and standardized to particle sizes between 0.35 and 1.00 mm, while commercially available coffee was sieved similarly to ensure uniform particle size. The coffee-to-water ratio was set at 5 g/L. Antioxidant levels were determined through %inhibition values at varying concentrations using serial dilutions, with the slope of %inhibition vs. concentration used to calculate the TEAC value. The developed color was measured at 735 nm using the Aquamate 8000 UV-Vis Spectrophotometer. Preliminary findings highlight brewing temperature as a critical factor influencing coffee's antioxidant capacity, with freshly ground coffee exhibiting a stronger temperature-dependent effect than commercial coffee. Detailed results and further insights will be presented during the conference.

Abstract Name: The impact of land use, discharge events, and plastic bag ordinances on anthropogenic litter abundance in suburban and urban headwater streams

Aquatic plastic pollution is an ever-growing issue with many negative ecological impacts such as harming the digestive health of aquatic organisms and being sources of heavy metals. Despite its substantial effects, few studies have investigated the distribution of macroplastics in riverine environments with even fewer focused in upstream areas. Understanding the sources of plastics to riverine environments could help society take meaningful measures to prevent its introduction, such as single-use plastic ordinances. We collected and categorized litter, including macroplastics (>4mm in diameter), from 20 headwater streams in southeastern Pennsylvania over 6 rounds of sampling from June 2023 to July 2024. Litter was collected along a 50-m longitudinal transect immediately downstream of stormwater outlets. Litter was categorized in accordance with the National Oceanic and Atmospheric Administration (NOAA) marine debris shoreline survey guide. Over 5,000 macroplastics were collected over the study period. Macroplastic totals were compared to potential controlling parameters such as relative land cover, population density, and socioeconomic variables in the upstream area as well as the frequency of high discharge events. We found positive statistically significant relationships ($p < 0.05$) between macroplastic totals and percent impervious surface cover and the number of buildings, as well as macroplastic totals and the frequency of high discharge events. Finally, we tracked the relative effectiveness of multiple municipal plastic bags ordinances in the study area. Our findings support the effectiveness of such policies and highlight other litter categories for similar measures.

Abstract Name: Eco-anxiety and pro-environmental behaviors in college students

Climate psychology is an emerging field that studies the impacts that climate change has on mental health. Eco-anxiety, a term used to describe anxiety about climate change and environmental destruction, is of growing concern because of its potential negative effects on pro-environmental behavior. Young people are particularly vulnerable to the effects of eco-anxiety, studies have shown. This study utilizes survey methods to examine relationships between eco-anxiety, pro-environmental behaviors, generalized anxiety, and a variety of demographic factors among the undergraduate population at Middle Tennessee State University. Our hypothesis was that those with low eco-anxiety will engage in fewer pro-environmental behaviors than

the moderate and high eco-anxiety groups, but due to the potential paralyzing effects of eco-anxiety, the moderate group will engage in more pro-environmental behaviors than the high eco-anxiety group. Our results showed that eco-anxiety has a significant positive relationship with pro-environmental behaviors as well as gender.

Abstract Name: Spectroscopic characterization of designed fluorescent probes for biomedical research

The development of turn-on fluorescent tools is critical for advancing cellular imaging and improving disease diagnostics. Oxidative stress, caused by an imbalance of reactive oxygen species (ROS), leads to carbonylation of biomolecules—a chemical process associated with cancer, neurodegenerative disorders, and diabetes. Detecting these modifications requires precise and robust tools. We synthesized small-molecule fluorophores capable of selectively targeting carbonyl groups in cells using click chemistry. These probes were designed with essential properties for effective imaging, including high stability, low toxicity, fast reaction kinetics, and favorable photophysical characteristics such as large Stokes shifts and reasonable quantum yields. By introducing these novel probes into cellular systems, we aim to visualize carbonylation processes in various cancer cell lines. This work contributes to understanding oxidative stress mechanisms, advancing diagnostics, and supporting the development of innovative tools for biomedical research.

Abstract Name: ARCHITECTING GLOCAL SCHOLARS: LEVERAGING THE POWER OF INTENTIONAL MENTORING IN UNDERGRADUATE RESEARCH

Embark on a mentor-student odyssey that takes you around the world. Dig deep into a plethora of topics by engaging with global scholars and community leaders to understand myriad problems and issues plaguing our world today. Dive into the wealth of a culturally knowledgeable mentor-scholar as you learn interviewing skills that empower your glocal research. In my teaching, I always strive to being an intentional mentor. Intentional mentoring is important for students in undergraduate research when what the students are doing in the classroom requires more than giving them topical readings to discuss in the classroom. In my case, I always work with students on a semester-long topic of their choice. When they pick their topic, they will stay with it the entire semester, completing different aspects of research. The research they embark on requires them to explore the world through the eyes of refugees, immigrants, international scholars, community leaders, and people from all over the world. This presentation will showcase how students use interviews to strengthen their research. We develop the interview tools together through my cultural knowledge that spans many countries, cultures, and languages. We work together to hone to hone interviewing skills suitable for people from other countries and local leaders working with organizations that serve global citizens. The result

of this is a well-crafted, thematic interview that gives insight on chosen research topics. Students will be present to give examples of some of the interviews they have conducted, and the themes and countries they have traversed while still on their campus. It is hoped that other mentors will gain insight from processes that mentors and students can use to conduct powerful interviews that in turn make undergraduate research more meaningful and robust.

Abstract Name: The Undergraduate Perspective: National Trends in the 2024 Presidential Election

The 2024 presidential election highlighted the growing importance of college campuses as centers of political engagement and mobilization. Despite increased attention to young voters, limited research examines how the unique environment of four-year college campuses influences undergraduate presidential vote choice. This study addresses this gap by investigating the interplay of demographic characteristics, perceived political issues, and campus culture in shaping undergraduate voting trends. Using a 21-question survey distributed through social media and professional networks, we collected 1,115 responses from students at 1,200 institutions over two-and-a-half months before the 2024 election. Preliminary analysis reveals significant demographic variations in voting behavior, with race, religion, political affiliation, and issue salience emerging as key factors. These findings suggest that the political incubation effect of college campuses not only shapes individual voting decisions but also has broader implications for understanding shifts in the electorate. By exploring these dynamics, this research contributes to a deeper understanding of the evolving role of young voters in American elections and the strategic implications for future campaigns.

Abstract Name: Targeting retinoid X receptor alpha (RXR α) in T-cell acute lymphoblastic leukemia

T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy, representing 10–15% of pediatric acute lymphoblastic leukemia (ALL) cases. Despite advances in treatment, the prognosis for relapsed or refractory T-ALL remains poor, with event-free survival rates below 10%. This underscores the need for novel therapeutic approaches. Retinoid X receptor alpha (RXR α), a nuclear receptor regulating gene expression in differentiation, proliferation, and apoptosis, has been implicated in cancers like acute promyelocytic leukemia (APL). However, its role in T-ALL remains unexplored. Analysis of 264 pediatric and young adult T-ALL samples (Liu et al., 2017) revealed RXR α mRNA upregulation in early T-cell precursor (ETP)-ALL phenotypes and pre-cortical maturation stage groups. Validation through quantitative

PCR (qPCR) and western blotting across seven T-ALL cell lines showed variable RXR α mRNA levels, with significant upregulation in KOPTK1 cells. Western blot confirmed RXR α protein presence across all lines, although transcript and protein levels were not consistently correlated. MTS assays using the RXR α agonist 9-cis-retinoic acid (9-cis-RA) demonstrated reduced leukemic cell viability in six T-ALL lines (KOPTK1, ALL-SIL, KARPAS45, JURKAT, LOUCY, PER117) in a dose-dependent manner. The treatment of the derived IC50 value revealed that 9-cis-RA treatment increased apoptosis. Combination treatments of 9-cis-retinoic acid (9-cis-RA) with standard and investigational T-ALL chemotherapy drugs demonstrated synergistic effects with Venetoclax, a Bcl-2 inhibitor, in multiple patient-derived T-ALL samples and cell lines, including LOUCY, ALL-SIL, PER117, and KARPAS45. These findings highlight the therapeutic potential of RXR α as a target in T-ALL treatment. Future research will evaluate the preclinical efficacy of additional RXR α agonists in combination with Venetoclax and investigate the underlying mechanisms contributing to the observed synergistic effects in preclinical models.

Abstract Name: The Impact of Home-Cooked Shrimp Flavors on Chitin's Effectiveness in Adsorbing Methylene Blue Dye from Wastewater

Dyes in wastewater have a negative environmental impact due to their toxicity. Many dyes, like methylene blue (MB), have complex chemical structures that resist breakdown, leading to their accumulation in water sources. These dyes pose significant risks to humans, microbial life, and the reduction of biodiversity. Shrimp shells offer a promising, eco-friendly solution for removing MB from wastewater. These shells contain chitin, a natural polymer known for its strong adsorption properties, making it effective for dye removal. Using shrimp shells, typically considered waste, provides a sustainable and accessible method for mitigating the impact of residual dyes. Previous research has found raw shrimp shell waste as an effective bio adsorbent, however, this use of raw material is not a realistic approach to sustainable wastewater treatment. This study aimed to assess the effectiveness of brown shrimp shells in removing MB-based preparation and seasoning from a home-cooked meal. Each group of shrimp in the experiment was prepared at home as a dish; boiled in a cilantro sauce (SSBC), grilled with a lemon pepper rub (SSGL), or boiled with no seasoning (SSB), then brought straight to the lab bench after the meal, they were thoroughly cleaned, treated with NaHCO₃, dried, and ground into chitin powder. Duplicate batch adsorption studies were conducted with MB. Results showed that SSGL had the highest percent removal at 35%, followed by SSBC at 30%, then SSB at 15%. This work confirms shrimp shells as a low-cost, environmentally friendly bio adsorbent and that home preparation impacts the efficiency in removing MB dye from wastewater.

Abstract Name: The State of Investing

Amid continuing economic volatility, according to the Aspen Institute, 44 percent of American workers are earning a median hourly wage of \$10.22. What are they going to do with that money is the next question. The theme of this research is to understand individuals' investment strategies. To this end, a 15 question survey was administered using Amazon turk to individuals 18 and older across the United States. The survey examined 150 respondents from a variety of backgrounds, income levels, gender, political party, education levels and age range. I tested two hypotheses. First, is there a significant difference between gender and investment strategy; and second, is there a significant difference between gender and obtaining a retirement account. I used IBM SPSS to analyze the data and found that there is a statistical significant difference in both hypotheses at the one percent level. I found that women are more risk averse, while men tend to be willing to take on more risky investments. For example, 33% of men said they would invest in crypto currency while only 10% of women would invest in this type of investment. Another key finding was that men seem to have a more proactive stance obtaining a retirement account compared to women. Overall, the results of this research look to compare key differences with how men and women think about investing and their exposure to different risk levels.

Abstract Name: Assessing Heavy Metals Contamination in Spices and Teas with X-Ray Fluorescence

Spices and herbs are globally utilized for consumption in everything from dishes cooked at home to fancy meals at five-star restaurants. Everyone from children to adults consume spices daily since spices and herbs have been made more readily available by industrialization. However, as our society has grown, the potential for carcinogenic or otherwise toxic materials showing up in our foods and other areas of our lives has increased. In fact, Consumer Reports did a study in 2021 that found around one-third of the products tested had high enough levels of arsenic, lead, and cadmium to pose a health concern. The current project aimed to determine whether or not certain brands and certain spices available locally in Greeley, Colorado contained these heavy metals. Using X-Ray Fluorescence, this project measured elemental concentrations of lead, cadmium, arsenic, and mercury. The spices tested included basil, black pepper, chili, cinnamon, crushed red pepper, coriander, cumin, curry, ginger, onion, oregano, paprika, thyme, and turmeric purchased within the Weld County area from a range of grocery stores and brands. 140 samples of spices and 20 samples of tea were tested for carcinogenic and other toxic inclusions. This study used the Artax software to qualitatively assess the presence or absence of each toxin. The results from this study found that there were no toxic levels of these heavy metals within any of the tested spices. Future studies may investigate nutrient profiles of spices to better understand how they are beneficial to human health and can be more inclusive of cultural health practices and medicinal alternatives while acknowledging the colonial practices that have impacted communities already practicing with this knowledge.

Abstract Name: The F Word: An Intersectional Analysis of the FaT GiRL Zine Anthology

This project explores the layered identity, expression, and demographics of the zine collection FaT GiRL and its contributions to the fat liberation movement of the 1990s. I will examine the intersection of identity within the seven-issue series, specifically related to gender, sexuality, and weight. Additionally, I will position the zine series alongside the influence of the pop culture of the time to understand the purpose of the language within the text. Through literary analysis, I explore the common theme within FaT GiRL and reference relevant social history that could contribute to its conceptual framework. With the shift of priority in the Third Wave feminist movement, advocacy goals grew into something different: attempting to be more intersectional in a growing culture of consumerism. FaT GiRL was created out of frustration with mainstream queer culture by self-identified "fat dykes" who wanted to voice issues that were not recognized. Thus, this literary collection that was active from 1994 to 1997 was unashamed as a "zine for fat dykes and the women who want them." There are strong themes of sex positivity that are subversive and attempt to empower the fat, queer readership. Each copy contains information about fat liberation, lesbian personals, sensual writing, and fetish photography, which all challenge the assumption that the demographics featured are not sexually attractive. Upon a surface-level observation, these works emphasize the power of utilizing their readers' intersectional identities to build community. These zines will be accessed from the virtual FaT GiRL Archive, and I will showcase their themes with detailed discussion points and featured artistic imagery from the collection in my presentation.

Abstract Name: Maternal Child Health Nurses' Experiences Performing Screening With the Edinburgh Postnatal Depression Scale

Postpartum depression (PPD) affects many new mothers, stemming from multiple intersecting factors including hormonal changes, genetics, and environmental factors. Many women, especially those with increased risk factors, go unrecognized. Undetected cases pose severe risks to both mothers and their newborns. Maternal consequences include disturbed relationships with their partner, increased pain, physical limitations after birth, and poor bonding with their infants. Consequences for the newborn range from failure to thrive, poor sleep quality, development of behavioral issues, and increased risks of developing childhood illnesses. Nurses play an essential role in screening for PPD symptoms using the Edinburgh Postnatal Depression Scale. This reliable screening tool consists of 10 questions with higher total scores indicating a greater possibility of depression. However, this tool is not consistently and systematically used in nursing practice. This leads to missed opportunities for identification, intervention, and prevention of poor maternal and infant outcomes. In turn, this may lead nurses to experience distress and yet this critical information is missing in the literature about this experience. Filling this gap is important as it may help us understand systematic and structural issues maternal child health (MCH) nurses face screening for symptoms of depression. Therefore, the purpose of this qualitative phenomenological study is to describe the lived experiences of MCH nurses performing screening of antepartum and postpartum women for symptoms of depression using the Edinburgh scale. We conducted semi-structured interviews with 10 MCH nurses working in a Magnet hospital. Data analysis for this study will be guided by Giorgi's phenomenological descriptive 4-step model. Our presentation will include forthcoming results of our study, and may assist in the development of new tools and/or new processes for screening that may help nurses screen for depressive

symptoms early in order to address the needs of antepartum, and post-partum women who are most vulnerable.

Abstract Name: Environmental Influence on Social Hygiene Practices in Ants

Ants practice social hygiene via corpse removal and refuse/waste management. Previous studies on their behavior have highlighted that these practices have resulted in an increased survival rate for the colony. Understanding this type of collective decision making in response to environmental changes can help inform policymakers and act as a model for resource allocation during disaster management. In this study we examined the effect of local humidity on collective decisions about nest architecture executed by a colony of *Tetramorium immigrans* “pavement ants”. Colonies were housed in hexagonal 3D printed modular nest sections with interchangeable lower reservoirs to easily alter the colony’s environment. We expected that our subjects will prefer a colder and drier environment for waste storage, possibly with a draft of wind to circulate the area to limit mold and bacterial growth. Future work will involve switching the location of entire cells and reservoirs while recording their movement to observe their response to changes in their environment. In addition, we will note the placement of larvae and pupae relative to humidity differentials within the nest. The success of ant social organization can serve as inspiration to improve the resiliency of our societies to environmental change.

Abstract Name: Institutional Memory in Student Politics: A Study of the Written Recordkeeping Practices of Student Governments

This project focuses on the written recordkeeping practices of student governments and establishes the extent to which they kept written records. In addition to analyzing which records were created and preserved, I looked at the policies, procedures, and positions which governed the creation and preservation of written records. Student governments are unique in the sense that they have naturally high turnover rates which makes knowledge preservation practices and institutional memory especially important. This research involved searching through finding aids, websites, governing documents, and corresponding and meeting with members of several student governments. It also explored the practices of student governments used in the absence of or alongside written recordkeeping such as the use of oral histories and student newspapers to preserve knowledge. Among my findings I identified that while a variety of recordkeeping practices were used, most student governments lacked extensive and consistent records. Student governments which did implement formalized and consistent recordkeeping practices were often larger in their membership. Smaller student governments, and smaller schools, often only maintained minutes, governing documents, a

recordkeeping position, and an organizational email. Those schools which did have archived collections within their university archives did not receive frequent updates. Few student governments had specified procedures to consistently commit records to their university archive. It was observed that practices such as preserving correspondence, using an organizational email, and creating/preserving reports allow for students to continue pursuing policy goals despite the effects on institutional memory due to high turnover.

Abstract Name: The Effects of Audiovisual, Visual, and Orthographic Input on Language Learning in College Students

The study compares three conditions of watching a documentary, audiovisual (AV), visual and text (VT), and audiovisual and text (AVT), to determine the highest incidental vocabulary acquisition, the correlation between existing vocabulary skills and vocabulary learning, and the differing perspectives of the documentary based on the three conditions. College students were recruited, and a series of tests were given before and after participants watched a 25-minute selected documentary clip. Currently, the data from 44 participants are getting organized and scored. Data analysis will be performed using repeated measures ANOVA and processed using the SPSS software. Preliminary analyses reveal increases in gain scores after watching the documentary, but there have been no changes in language learned among the three conditions with fill-in-the-blank scores. There have also been preliminary gains in writing definitions of the unfamiliar vocabulary from the pre-test to the post-test.

Abstract Name: Artificial Intelligence: A New Platform to Influence Elections

Since its inception in 2022, artificial intelligence has impacted education, social relationships, job markets, and politics all while using a system of machine learning through algorithms. The creation of artificial intelligence comes at a pressing time for the United States as this November will be the first presidential election in American history with the presence of artificial intelligence. Some political and business leaders have expressed concerns over artificial intelligence and its lack of regulation and potential to spread misinformation. My research aimed to study the relationship between text-based artificial intelligence programs and voter behavior while monitoring the 2024 United States presidential campaigns. Based on literature and other research conducted, I expected the responses to reveal certain political biases when informing users. To test this relationship, I gathered a random sample of twenty participants in a controlled setting to measure their political views on salient issues of the campaign before and after using ChatGPT through two Likert scale surveys. In between both surveys, participants were each given a booklet with both

presidential candidate's stances on each issue according to ChatGPT. A reading comprehension quiz followed the second survey to incentivize participants to read the booklet. The experiment yielded three results: respondents who follow politics loosely were swayed by ChatGPT, ChatGPT polarized respondents with strong political beliefs, and the language used by ChatGPT tended to favor Joe Biden more than Donald Trump. This research strives to illuminate the biases of artificial intelligence to prevent the spread of misinformation and political polarization.

Abstract Name: Aid and Democracy in Southeast Asia: Comparing the Impact of U.S. and Chinese Foreign Assistance

This paper examines the differential impacts of U.S. and Chinese foreign aid strategies on democratization trends in 11 Southeast Asian countries. Understanding how these competing aid approaches affect recipient domestic politics is becoming more important as China's influence in the region grows. This research will use a mixed-methods approach to analyze the complex relationship between foreign aid and democratization, building on established theories that highlight the role of linkage and leverage, donor intent, and institutional strength. It draws on panel data on democratization scores, foreign aid from the U.S. and China, and indices for domestic institutional strength and donor alignment from 2000 to the present. It will incorporate country-fixed effects and time lags for aid variables to address potential endogeneity. These findings will be supplemented by comparative case studies of Myanmar, Cambodia, the Philippines, and Thailand, which can provide an in-depth evaluation of the specific mechanisms by which aid interacts with various domestic political contexts. I hypothesize that U.S. aid may have a more positive association with democratization, especially in countries with stronger democratic institutions, while Chinese aid may have a negative impact on democracy, potentially entrenching authoritarian institutions. This research contributes to the ongoing debate on foreign aid effectiveness and democracy promotion in Southeast Asia. This study seeks to inform more effective aid policies that benefit humanitarian goals and strategic interests in an increasingly complex and competitive geopolitical landscape by analyzing the connections between donor strategies, recipient institutions, and democratization scores.

Abstract Name: Genetic Mosaicism in Appalachia: Geographic Patterns and Their Implications for Cancer Outcomes

Somatic mutations refer to mutations that arise after birth. When a cell acquires a somatic mutation it can expand and give rise to genetic mosaicism, the presence of genetically different cell populations in an individual. Research shows that individuals with detectable clonal mosaicism in their blood are at a higher

risk for hematological malignancies and chronic diseases, while cancer patients with mosaicism tend to have poorer outcomes. Previous studies have linked age and sex to mosaicism rates but often lack geographical data, hindering our understanding of how these rates vary across different populations. This knowledge gap limits our ability to identify US regions with higher mosaicism rates, which may correlate with increased cancer incidence and mortality. Identifying these differences and their molecular causes is essential for improving risk assessment and cancer prevention strategies. This project focuses on studying genetic mosaicism in diverse geographic populations to determine if differences in mosaicism rates mirror cancer incidence rates across these regions. We will use blood sequencing data from the ORIEN network, which includes ~19,000 samples from 16 US states, notably Kentucky, which has the highest cancer rates. We will compare mutation rates across US states adjusting for age, sex, and smoking. We will also contrast mosaicism rates in the Appalachian population of Kentucky to the non-Appalachian Kentucky population. We postulate that the burden of genetic mosaicism will differ across these geographically defined populations, mirroring the cancer burden in these populations. We postulate that samples from high cancer burden populations will have elevated rates of genetic mosaicism due to increased carcinogenic exposures and/or increased rates of inherited cancer risk mutations. The goal is to explore the molecular drivers of cancer disparities in Appalachian Kentucky and enhance our understanding of clonal mosaicism as a biomarker for cancer risk assessment and early cancer detection.

Abstract Name: Augmented Reality Data Exploration with Large Language Models via a Conversational Interface

The progression of large language models (LLMs) has enabled natural language data-driven interfaces, but their integration with augmented reality remains largely unexplored. This intersection is important because data enables informed choices, and presenting information in an immersive way can reduce the difficulty of making those choices. To address this need, we introduce ARChat, a speech-based data analysis tool using LLMs that blends the real world and data – allowing for natural language commands and responses while providing seamless overlays to the real world. ARChat addresses questions that often arise with real-world objects, including tables and graphs, that cannot be answered through visual analysis alone. This allows the user to understand all information related to an object, including information that may be difficult to gather just by observing the object, such as cost, brand, ingredients, mean, confidence interval, etc. The process begins with the user loading a database or scanning their environment. Then, based on a natural language question provided by the user and combined with the context of the user's environment, ARChat develops a natural language response for the user, displaying additional information as an overlay where necessary. As an example of ARChat's efficiency, it was tested on a dataset of 13 common household items, achieving an accuracy of approximately 91% in interpreting user questions of varying complexity, ranging from simple questions like 'Do users like this product?' to more complex prompts such as 'With a 10% tax, how much will this item cost?'. These results are significant because they show that ARChat can parse object information based on the context of the user's environment with a high degree of accuracy. Ultimately, since ARChat is designed for flexibility, we anticipate it will serve as a foundation for more sophisticated augmented reality-based data exploration tools with potential applications across various disciplines.

Abstract Name: Advancing Mars Image Classification: A Comparative Study of CNN Models with Interactive Applications

This study leverages AI to investigate Convolutional Neural Networks (CNNs) for classifying Martian geological images, focusing on a comparative analysis of EfficientNet and VGGNet architectures. These models were tested on two specific NASA datasets. The HiRISE orbital dataset comprises 3820 grayscale images of Mars captured from orbit, categorized into six landmark types. The Mars Science Laboratory (MSL) surface dataset contains over 6,000 images of Martian landscapes classified into 24 categories. This research aims to determine the optimal CNN model for Martian image classification by comparing accuracy, efficiency, and computational requirements. To make these findings accessible, we developed a web application using the Python-based Django framework. The application enables users to interact with the AI models and datasets, fostering a deeper understanding of AI's role in image classification. Users can test the EfficientNet and VGGNet models, explore classification results, and examine evaluation metrics. The application also includes the HiRISE and MSL datasets, allowing users to analyze the data that shaped the models' training and testing processes. A unique feature of the application is an interactive game, "Classifier Clash" Users can challenge the models by attempting to classify Martian images and compare their accuracy against that of the CNN/AI models. This engaging feature helps users understand AI's capabilities and limitations. This innovative project bridges advanced AI research and public engagement, highlighting the importance of deep learning in planetary science. Integrating Django ensures a seamless user experience, transforming complex research into an accessible educational tool. Beyond Martian image classification, this study lays a foundation for using CNNs in broader scientific image analysis tasks. Through its interactive and educational approach, the project promotes understanding and application of AI technologies, preparing users for the expanding role of machine learning in science and beyond.

Abstract Name: Participation in and Perception of a University's Counseling Services

Universities have a responsibility to provide services to help students succeed. This may include mental health services as college students are more likely to develop mental health issues due to the pressures and stresses of being a college student. Counseling services have been shown to have a positive impact on a student's mental health and increase their likelihood of academic success. Past studies have found relationships between participation in counseling and demographic characteristics that point towards

underutilization and disparity based on race and sexual orientation. A total of 289 undergraduate students completed an online survey that assessed their use and perceptions of the services offered by the Center for Health and Wellness. Participants were asked questions about their demographic characteristics, their perception of counseling in general and the university's counseling services specifically, their usage of counseling services, and opinions on potential services offered at the university. It was found that 42% of students currently use or have used the free counseling services at some point, but 30% no longer utilize the services. Underutilization by students who could benefit from counseling was found, but disparity of use within social minorities was not. The results indicated that participants thought counseling could be beneficial for others, but few thought it could be beneficial for themselves. The university's counseling services were found to be beneficial with only 11% of students reporting that services were not beneficial at all. Some of the suggested ways the services could improve were adding more counselors and having more availability for appointments. Based on the results, universities should consider adding counselors to increase appointment availability, improve communication, and add other services and events to benefit a wider range of students, while continuing to monitor for inequities in usage and outcomes based on race and sexual orientation.

Abstract Name: Dance, Meditate, Recover: The Role of Integrated Mind-Body Practices in Enhancing Stress Resilience via RSA Modulation

Respiratory sinus arrhythmia (RSA) is a physiological index reflecting autonomic nervous system flexibility, crucial for resilience to stress. High resting RSA and rapid post-stress recovery are linked to enhanced emotional and physiological regulation, which are core aspects of positive emotions and resilience. This study investigates the effects of a combined dance and fitness meditation practice on stress resilience, as indicated by RSA measures. Participants with sustained engagement (2 years or more) in a structured dance and fitness meditation program were considered in this study. Their RSA was monitored using the Biopac MP160 system, which tracked heart and respiration rates during baseline, high-stress, and low-stress tasks. In the high-stress task, participants learned and performed a 16-measure dance routine, first with video instruction and then independently. Following this, a guided five-minute meditation served as the low-stress task. It is hypothesized that individuals with prolonged involvement in dance and fitness meditation will display elevated baseline RSA values and accelerated RSA recovery following stress exposure compared to their peers without the 2+ years prolonged involvement. These indicators suggest greater autonomic flexibility and heightened resilience to stress. This study makes several contributions to psychological research. It investigates the long-term effects of integrated mind-body practices on RSA, contrasting with most existing research focused on short-term or isolated interventions like yoga or mindfulness. The findings may demonstrate how sustained participation in such practices promotes lasting autonomic and stress-regulation benefits. Moreover, it emphasizes the role of consistent lifestyle habits over temporary interventions in mental health and resilience. Should dance and fitness meditation reliably enhance RSA and resilience, it could offer a dynamic, accessible tool for preventive mental health care and stress management. By addressing the gap in research on prolonged engagement in integrated practices, this study broadens the understanding of their potential for fostering resilience and well-being.

Abstract Name: Ethical Implications of Gender Disparities in Healthcare Research: A Psychology Approach

Overall, this research aims to analyze the ethical implications of gender disparities in healthcare research while highlighting the physiological and psychological consequences. While examining these disparities, this project advocates for more inclusive medical practices that align with ethical principles, such as justice, beneficence, and nonmaleficence. Despite the plethora of medical advancements, women remain predominantly underrepresented in medical-based trials. This leads to overwhelmingly biased data and gaps in diagnosis, treatment plans, and outcomes. Furthermore, healthcare research historically prominently favored male participants, leading to a uniform approach when treating patients. This uniform approach resulted in treatments that are not as effective for women and, in some cases, even harmful. These disparities bolster systemic inequality and inequity while also negatively impacting women's physical and psychological well-being. This project utilizes a multidisciplinary approach by incorporating analysis of existing statistical data, literature, and case studies to examine the consequences and relevance of gender disparities in healthcare research. The research primarily focuses on cancer treatments, cardiovascular diseases, and mental health, in which disparities are the most significant. This project includes insight from psychological, bioethical, and medical perspectives to examine the integration of these frameworks and their relation to healthcare. Furthermore, this research concludes that gender disparities in healthcare research lead to unequal treatment and negate ethical principles. These disparities have profound psychological effects, for example, a lack of trust in medical institutions by female patients, increased levels of anxiety, and feelings of neglect. This project advocates for more gender-inclusive research in clinical trials and analysis of sex-based treatment differences. By implementing a more inclusive, equitable healthcare system, underserved populations' physical health and psychological well-being can improve.

Abstract Name: The Psychological and Cultural Legacy of Systemic Racism

This project examines the intersectionality of race, colonialism, and personality to investigate racism within the context of cultural, systemic, and historical factors. It addresses the question of how systemic racism and colonial legacies shape psychological and social constructs within post-colonial societies. It influences an individual's cultural identity, mental health, and personality development. Utilizing cultural-psychological theories and frameworks, this research seeks to analyze the impact of racial hierarchies that were imposed during colonialism and its impacts on marginalized individuals. This study offers a broader discourse, indicating racism as an institutional and systemic phenomenon, instead of the understanding that racism is merely based upon individualistic racial biases and viewpoints. Significant research focuses primarily on overt racist actions, less specified attention is given to how institutional and systemic racism can affect an individual's mental health and personality. Colonial ideologies permeated modern psychological and social constructs, reinforcing generational traumas and inequality. Examples from the United States and South Asia

demonstrate how societies with colonialist pasts indicate racialized experiences, which affect mental health . The methodology in this research draws from cultural psychology, empirical studies regarding the psychological outcomes of racialized experience, historical analysis and reasoning. Analyzing concepts such as systemic racism, intergenerational traumas, and cultural resistance, this project delves into the adaptive traits that may emerge as a result of systemic oppression and dehumanization. This research offers a deeper understanding of the psychological and cultural impacts in post-colonialist societies while discussing insight into social progress for marginalized communities. This research exposes how colonial ideologies create patterns of inequality and trauma, which impacts personality development in marginalized communities. The findings of this research illustrates how resistance and resilient personality traits act as adaptations towards systemic oppression. This study contextualizes the cultural and historical hierarchies, while also aiming towards providing social progress in post-colonial society.

Abstract Name: Effects of Race, Gender, and Skin Tone on Perceptions of Exonerees

The present research aims to examine the effects of race, gender, and skin tone on perceptions and support for exonerees. Past literature reveals that in 2010, 75% of post-conviction exonerates belonged to a minority group and spent 13 years on average, behind bars for a crime they did not commit. Exonerees—individuals who are wrongfully convicted of a crime and later proved innocent—continue to experience stigma post-incarceration. Further, prior research has found racial and gender biases in stigma experienced by exonerees. For example, landlords are less likely to rent to Black exonerees and participants are more willing to push for integration when exonerees are White. However, prior literature on exonerees is limited since it usually examines race and other social identities (e.g., gender) as independent variables, failing to account for their interaction. Therefore, the present study aims to build on earlier research by applying an intersectional approach to examine the influence of race, gender, and skin tone on perceptions of exonerees. Participants will be presented with news stories discussing the exoneration of individuals who were wrongfully imprisoned for a crime they did not commit. The exoneree's race, gender, and skin tone will vary for each story. Participants will provide character judgments, guilt assessments, support for reintegration services, and the amount they are willing to donate to support exonerees. We predict that perceptions and support for exonerees will vary based on race, gender, and skin tone such that participants will report more positive perceptions and support for White women exonerees relative to all other groups. Further, we predict that light-skin women exonerees, regardless of race, will receive more positive perceptions and support. The implications for the criminal justice system and society at large will be discussed.

Abstract Name: A Novel Role for Mediator in Gene Regulation Through its Association with CNBC

Gene regulation is a complex process that takes place through multiple mechanisms with transcription being the primary site of gene regulation. The human Mediator, which consists of 30 tightly associated proteins, is the most critical coactivator complex involved in the regulation of all protein-coding genes. Mediator exerts its main function by bridging enhancer-bound activators with promoter-bound general transcription factors as well as RNA Polymerase II. We recently identified Cellular Nucleic Acid Binding Protein, CNBC, to co-precipitate with the Mediator complex. This protein is involved in various cellular processes including DNA replication, RNA binding and processing as well as transcriptional and translational regulations. Importantly, this protein regulates oncogene expression and promotes cellular proliferation. It can also inhibit apoptosis and its overexpression is associated with tumorigenesis and poor prognosis in cancers. We hypothesize that Mediator directly interacts with this protein to regulate proper cellular processes and aberrant interactions will lead to oncogenesis. In this proposal, we will recombinantly generate CNBC and its mutant forms in a eukaryotic environment and check whether or not they directly interact with the Mediator complex. We will use the eukaryotic Sf9 insect cells for protein expressions so that protein foldings as well as post-translational modifications will be more physiologic. Observing a direct interaction between the Mediator and CNBC will open avenues toward identifying potential interaction surfaces to design inhibitors for future therapeutics

Abstract Name: The Brilliant Mind Behind Calculus—Isaac Newton: His Struggles, Victories, and Legacy Behind the Mathematical Discipline

In science and mathematics, interconnectedness has been evident throughout history. Sir Isaac Newton was heavily influenced by Ancient Greek mathematicians and philosophers (namely Archimedes, Eudoxus, and Pythagoras, among several others) in the same way William Herschel, Michael Faraday, and Albert Einstein's contributions to STEM were all shaped by Newton. This sharedness among the pioneers of STEM shows how theorems, concepts, and disciplines start with one mind and then continually evolve to become a body of foundations as time progresses. The irony is that while he had a group of influences, Newton's solitude played a significant role in the conception of calculus. Newton first devised theories of calculus as a student at Cambridge, where he largely kept to himself and had minimal social interactions. Later, he would finalize the foundational concepts of calculus during the Great Plague of London, where he quarantined and isolated himself in his family home, Woolsthorpe. Derivatives, definite and indefinite integrals, rates of change, infinite series, and many more were the outcomes of the years he spent alone, a testament to the power of individual creativity. Despite Newton working alone when developing calculus concepts, Gottfried Wilhelm Leibniz was actually on the other side of Europe publishing his version of calculus. Although friendship and collaboration would have been expected between similar minds, there was a rivalry and dispute regarding credits instead. This shows how Newton's upbringing and personal struggles drove him to shut himself off from potential companionships. Ultimately, Sir Isaac Newton proves that even in solitude, a single mind can shape the foundations of human knowledge and inspire future generations.

Abstract Name: Comparative Analysis of Muscle Characteristics and its Correlation to Maximal Power Output

Our muscles are composed of several different muscle fiber types, in this research we focused on Type I, Type IIa and Type IIx. To assess the muscles contractile properties, Tensiomyography (TMG) can be used as a non-invasive and accurate method. Type I fibers are abundant in endurance athletes such as cross-country runners. On the other hand, Type IIa and Type IIx are abundant in power athletes such as powerlifters. To record someone's max power output, a Wingate test can be performed. A Wingate is a stationary anaerobic ergometer that measures maximal power output and anaerobic capacity alongside other factors. Previous research has been done within muscle fiber types, the use of TMG, and the use of Wingate but lack of research was seen with the use of both and its correlation. The purpose of this research is by knowing the correlation between muscle characteristics and maximal power output, we're able to determine if an individual has reached their full potential or has room for improvement. In this research 25 participants (8 female and 7 male) ages 18-45 from the general public participated in this study. Participants had their rectus femoris first tested on the TMG followed by a 30 second Wingate test. Results showed statistically significant correlations among power metrics and between body weight and maximal displacement. Highly significant correlations ($p < 0.01$) were found between Peak Power and Average Power as well as Td (Delay Time) and Tc (Contraction Time). As said before, these findings enable us to develop a training regimen that can help determine whether an individual has reached their full potential or if there is room for improvement. This method is not only effective but also simple, fast, and non-invasive.

Abstract Name: Gender Non-Conforming Voices in Speech Perception

Traditionally, gender has been understood as a binary construct with categories of man/masculine versus woman/feminine, a concept reflected in various fields of study, including linguistics. Speech perception research typically adopts this framework, assuming that a speaker's gender is processed as a binary variable. Similarly, studies have shown that listeners hold preconceived notions about what voices associated with specific genders should sound like. However, such research largely overlooks gender non-conforming (GNC) individuals, leaving gaps in our understanding of how GNC voices are perceived. This study explores how listeners' understanding of and experiences with non-binary genders influence their perception of speech produced by GNC individuals. Participants complete 3 tasks: a voice similarity rating task, a questionnaire, and a brief exit interview. Each listener's perception of gender in speech is measured implicitly via the voice similarity rating task and explicitly via the questionnaire. This quantitative data is supplemented by the exit interview, which gathers qualitative data regarding the listener's personal experiences and perceptions of gender. We expect that listeners with more diverse gender experiences will exhibit a less binary understanding of gender, which may be reflected in their individual cognitive perceptual spaces. The findings aim to shed light on both the implicit categorization of GNC voices and the impact that societal factors may have on this process. This research contributes to the growing body of linguistic work that recognizes a more nuanced understanding of gender, ensuring that the field accurately represents the lived experiences of diverse individuals.

Abstract Name: Antinociceptive Effects of Morphine:Ketamine Mixtures in Female Rats

Pain management is a critical aspect of patient care, with opioids being the gold standard treatment for moderate to severe pain. However, opioids have adverse effects such as abuse, dependence, and overdose. One strategy to mitigate adverse effects of opioids is combining them with non-opioid analgesics. For example, our laboratory previously showed that the NMDA receptor antagonist ketamine selectively enhanced antinociceptive effects of the opioid morphine in adult male rats. The present study aimed to extend our previous findings in male rats to female rats (n=8, Sprague Dawley). A warm water tail withdrawal was used as an assay of pain, and all rats received morphine alone (1.7 – 17 mg/kg), ketamine alone (5.6 – 56 mg/kg), and morphine:ketamine mixtures in ratios of 3:1, 1:1, and 1:3 where the rats received six cycles of injections each session. The first cycle was always saline followed by tail immersion test 13 minutes later. Then another injection was administered after two minutes and repeated for 6 cycles total. Antinociception was assessed using a tail immersion test in water temperatures of 40°C (negative control), 50°C, and 55°C (positive control). Results indicated that both morphine and ketamine, individually and in combination, significantly and dose-dependently increased tail withdrawal latencies in 50°C from approximately 5 sec to 15 sec, with morphine having greater potency as compared to ketamine. Morphine:ketamine mixtures demonstrated comparable efficacy in pain relief to the individual drugs. These findings suggest that morphine:ketamine mixtures may be a viable alternative for pain management, however, its adverse side effects compared to either drug alone are still unknown.

Abstract Name: Assessing Differences In Healthcare Experience Of All of Us Research Program Participants With Autoimmune Disease Across Income Levels

Individuals with autoimmune diseases, often managing chronic and unexplained symptoms, are met with unique challenges in healthcare settings. They frequently report feeling as if they are being unheard or dismissed by their providers, and socioeconomic barriers may further compound these difficulties. This study aims to explore the healthcare experiences of those with autoimmune diseases and how they may vary between different socioeconomic levels, utilizing data from the All of Us Research Program, a National Institutes of Health initiative. Partnered with over 800 institutions across the country, this program aims to collect biomedical data from 1 million individuals across diverse backgrounds. Information collected from participants includes electronic health records, surveys, and fitness trackers. In this study, survey data (n=413,360) were analyzed to assess perceptions of healthcare experience across three income groupings of participants with autoimmune diseases and the rest of the All of Us participants. Findings revealed that participants with autoimmune diseases, regardless of income, were more likely than other participants to feel that healthcare providers were not listening to them. However, only autoimmune participants with annual household incomes below \$100,000 were more likely to perceive that their providers were considering them as less intelligent. This suggests that while the overarching challenge of feeling unheard is universal among

those with autoimmune diseases, lower income levels intensify specific experiences within this group. By identifying low-income individuals with autoimmune diseases as a vulnerable population, this study emphasizes the need for interventions to improve physician-patient relationships and promote equity in healthcare experiences. These findings further evidence the challenges that those with autoimmune diseases face in healthcare settings and also underscore the interactions that occur between healthcare experiences and the social determinants of health.

Abstract Name: Indole Treatment of *C. elegans* Rescues Illness Induced by the Opportunistic Pathogen *Cronobacter sakazakii*

Necrotizing enterocolitis (NEC) is a severe and often life-threatening inflammatory condition of the intestine primarily affecting premature infants. The opportunistic pathogen *Cronobacter sakazakii* (Cs) has been implicated in NEC. While activation of the ligand-dependent transcription factor aryl hydrocarbon receptor (AhR) has been shown to prevent NEC in a mouse model, its potential as a therapeutic target for established NEC remains unclear. We hypothesize here that the AhR ligand indole can reverse Cs-mediated illness in the model organism *Caenorhabditis elegans*. Our results demonstrate that exposure to live Cs, but not heat-killed Cs, significantly impaired worm motility, demonstrating Cs is an effective pathogen of *C. elegans*. Treatment of Cs-infected worms with indole improved motility and enhanced survival under heat stress. These effects were dependent on *ahr-1*, the *C. elegans* ortholog of the human AHR gene. Finally, wild-type worms infected with Cs maintained higher motility scores and heat stress survival rates than their *ahr-1* knockout counterparts, even with no exogenous indole supplied but fed a diet of indole-producing commensal *Escherichia coli* prior to Cs infection. Our findings indicate that indole enhances health outcomes in Cs-exposed worms, suggesting a potential therapeutic avenue for NEC. Further investigation into AhR ligands could reveal new treatment strategies for managing NEC in premature infants.

Abstract Name: 23andMe and Rhetorical Identity

The research question informing my presentation is how does genetic testing alter how a person identifies themselves, particularly in a rhetorical sense. Specifically, I will examine this question by rhetorically analyzing 23andMe testimonials and interviews regarding ancestor genetic testing. The texts will be analyzed through the lens of Kenneth Burke's theory of identification. Other theorists have drawn on identification theory and Burke to study the links between genetic testing and identity such as Michael Peterson, an English professor at Utah Tech University, who wrote his dissertation on identification theory in family history writing. Another such researcher is Wendy Roth, who has done multiple studies on the link between genetic testing and identity, particularly in the way participants identify themselves before and after receiving their

results. Informed by identification theory, my presentation will examine testimonials and interviews of individuals participating in 23andMe genetic testing. This theory posits that audiences see themselves in the rhetoric they consume. Rhetors can also cultivate that connection with their audience. This provides researchers the opportunity to study how interconnected the rhetor, rhetoric, and audience are. Specifically the connection of identity and how rhetoric can shape and adjust it through the exchanged mentioned above. In the context of these 23andMe testimonials and interviews, I expect to learn that participants will express changes in how they perceive themselves. I also expect to see the testimonials as having been written in a way that will be simple and relatable to encourage readers to identify with the people providing these testimonials to possibly persuade them to participate in a genetic ancestry test as well. The interviews I expect to be more informal while being more detailed. The analysis of these 23andMe testimonials will provide insight into the role that genetic testing plays in the forming of rhetorical identity.

Abstract Name: Constraining the nature of the electron distribution in the X-ray corona of active galactic nuclei

During the accretion process, black holes produce abundant radiation, especially in the X-ray band. A lot of this radiation is created in the corona, a region of hot electrons located at the accretion disk's center close to the black hole, where X-rays are being produced through the Compton scattering of accretion disk photons. It is believed that the powering of the corona and its emission from the X-ray continuum are important for the energy balance during the accretion process. But, there is still not much information about the nature and origin of electrons in the black hole's X-ray corona. Over the years, evidence has emerged in black hole X-ray binary systems suggesting that electrons have a hybrid nature, meaning that most of the electrons follow a thermal distribution while the minority follow a non-thermal power-law-like distribution. To date, there are no constraints on the existence of a hybrid corona in accreting supermassive black holes at the center of galaxies. In the work presented here, we placed constraints on a possible non-thermal contribution to the electron distribution by investigating the indirect effects of the enhanced hard X-ray production in the non-thermal case on the interaction of the X-ray continuum with the accretion disk in the X-ray reflection process. To achieve this, we studied the X-ray spectra from two accreting supermassive black holes. Our results are the first constraints of the nature of the electron distribution in accreting supermassive black holes.

Abstract Name: Media Portrayals of Haitian and Ukrainian Immigrants in America

This paper compares and contrasts media portrayals of Haitian and Ukrainian immigrants in the United States. The coverage spans eight years (2017-2025) and two administrations, Presidents Donald Trump and

Joseph Biden. Haitian and Ukrainian immigrants have fled considerable political turmoil in their home countries and received temporary protected status (TPS), allowing them to legally immigrate to America. Despite these similarities, the portrayals of these groups in mainstream media diverge significantly, reflecting broader cross-cultural and political biases. To explore this disparity, this paper focuses on how Haitian and Ukrainian immigrants are covered in the New York Times, one of America's most influential newspapers. My central research questions are: How does the New York Times cover Haitian and Ukrainian immigrants? What do the similarities and differences in coverage reveal? This analysis tracks the Times' coverage by examining the number of articles written about these groups, their placement in the paper, their length, the language used, and the journalists who wrote them. It highlights patterns of bias and their impact on shaping public perception. For instance, the Times tends to characterize Ukrainian immigrants favorably, emphasizing both their escape from the war and their integration into American society. However, Haitian immigrants are described in ways that align with harmful stereotypes, often concentrating on poverty and social chaos. These portrayals perpetuate distinct narratives: Ukrainian immigrants are seen as more deserving and compatible with American values, while Haitian immigrants are framed in a problematic light. In some cases, the Times uses nativist and dehumanizing language towards Haitian immigrants (but never towards Ukrainian immigrants). This affects how these groups are perceived, reinforcing unequal assumptions about their contributions to American society. By unpacking these biases, this paper sheds light on the media's role in perpetuating myths about immigrant groups and shaping public perception.

Abstract Name: A Comprehensive Review of Deepfake Detection Methods Using Machine Learning

Deepfake technology, driven by advancements in machine learning (ML) and deep learning (DL), has emerged as both a creative tool and a significant threat to privacy, security, and societal trust. While its potential for innovation in fields like entertainment and education is undeniable, its misuse raises critical ethical and practical concerns. This paper offers an in-depth exploration of the evolving field of deepfake detection, synthesizing insights from 40 leading studies conducted between 2020 and 2023. It critically examines the comparative strengths of ML-based detection techniques, which prioritize accessibility and computational efficiency, against DL-based approaches that deliver superior accuracy but require substantial resources. The analysis focuses on key factors like detection accuracy across different datasets, adaptability to real-world scenarios, and resistance to tricks designed to fool detection systems. However, the research also reveals significant challenges. These include a lack of high-quality and diverse training datasets, making it harder for detection systems to perform well across different situations. Another issue is scaling these tools for widespread use, as many methods require powerful computers and advanced technical setups. Additionally, as deepfake techniques grow more advanced, detection systems must evolve to keep up. This research brings together these findings to identify gaps and suggest ways to improve. It offers clear recommendations for creating systems that are accurate, easy to use, and able to handle real-world demands. The ultimate goal is to ensure trust and authenticity in digital content, protecting people from the risks of deepfakes while encouraging the responsible use of this technology.

Abstract Name: Apollonian Assimilation at Greek Cultural Sites: A Trend in Hellenization

Ever since Fontenrose's revelations on early mythical theory at Delphi, classical scholars have carefully examined the most minute details, both textual and archaeological, to gain covert knowledge regarding heroic origins of Apollo sanctuaries but none have provided a cultural narrative for Apollo's arrival at these sites. I argue that these cases form ubiquitous patterns throughout the Greek world and in doing so elucidate fundamental cultural trends in the construction of a Pan-Hellenic identity. Archaeological evidence including epigraphy from the surrounding areas of Parnassus indicates the presence of local hero cults which Apollo assimilated in both the Late Helladic and Iron ages. Oracular implements at Delphi prior to the introduction of Apollo to the region evidence the long-standing religious heritage of the site. In reexamining texts of Strabo, Pausanias, and Homer, I reveal in this paper a fundamental religious trend towards Olympian pan-Hellenism at Trikala, Delphi and Thusa, a trend which is symptomatic of a larger identity revolution in the north-eastern Mediterranean.

Abstract Name: The Tate Phenomenon: Examining Social Media Influencers through the Lens of Max Weber and Sigmund Freud

Though the role of social media influencer is a new phenomenon, its theoretical foundation is not. Since technology now enables a person to become an overnight celebrity through charismatic displays in videos, this kind of fame can be explained through older concepts established by Max Weber and Sigmund Freud. The case of Andrew Tate, a kickboxer turned social media influencer, is illustrative. Despite his misogynistic and discriminatory claims, Tate's radical statements and cult-like following echo Weber's nineteenth-century description of how a charismatic authority and their followers function. While the label of charismatic authority is a start, Weber's theories alone do not sufficiently explain some questions of why anyone would adhere to Tate's claims and how he gained popularity. Fortunately, Sigmund Freud's pleasure principle describes an instinctive desire that is in contention with the reality principle of societal rules. Tate's countercultural statements create a space for people to freely engage under the pleasure principle, making his behavior attractive to many. Further interpretation of the Tate phenomenon can be built through what Verena Wieser, a Weberian sociologist, calls charismatic entrainment. Charismatic entrainment argues that the interaction between a brand leader, consumer-followers, and consumer-critics creates prominent charismatic authorities. Through an online platform, Hustler's University, Tate, the brand leader, allows his immediate fans, the consumer-followers, to spread his message and engage in discourse with others. This discourse often invites those who disagree with Tate, the consumer-critics, to bash Tate for his statements, but these protests produce only more publicity for Tate. These aspects of Tate's rise to fame reflect charismatic entrainment, explaining his rapid popularity. Andrew Tate is not the first influencer to engage in this process, but he will definitely not be the last. Thus, society must understand these processes to halt a more detrimental influencer in the future.

Abstract Name: Epithelial-to-Mesenchymal Transition and Other Effects of Vape Aerosols on A549 Lung Cancer Cells.

Lung cancer is one of the leading causes of cancer deaths worldwide, primarily caused by smoking. E-cigarettes and vaping have been advertised as a healthier, safer alternative to smoking and is often used as a smoking cessation tool. If a lung cancer patient or undiagnosed individual begins vaping, this may cause a benign tumor to become metastatic. This project is to determine if vape aerosols will cause lung cancer cells to undergo epithelial-to-mesenchymal transition (EMT) which is indicative of metastasis, and whether differing amounts of nicotine content influences the number of changes seen. Human lung cancer cell line (A549) was grown in DMEM media supplemented with 10% fetal bovine serum and 1% penicillin/streptomycin. The media was exposed to vape aerosols of differing concentrations then applied to

the cells which were observed over the following 72 hours. Results show that cells exposed to any concentration of nicotine vape aerosols caused cell morphology changes indicative of (EMT).

Abstract Name: Advanced Deep Learning Integration of YOLO v11 and SAM2 for Precise Detection of Missing Cochlear Hair Cells

Accurate detection of cochlear outer and inner hair cells is essential for diagnosing auditory impairments. This study presents a deep learning approach that integrates the object detection capabilities of You Only Look Once (YOLO) v11 with the segmentation proficiency of the Segment Anything Model 2 (SAM2) to identify missing cochlear hair cells in high-resolution microscopic images. YOLO v11 features an enhanced backbone and neck architecture that improves feature extraction for precise object detection. Its optimized design achieves a higher mean Average Precision (mAP) on the COCO dataset while utilizing 22% fewer parameters than its predecessor, YOLO v8m, thereby enhancing computational efficiency without compromising accuracy. In this study, YOLO v11 is employed to detect and localize existing cochlear outer and inner hair cells within microscopic images, providing bounding boxes that indicate the presence and positions of these cells. To identify missing hair cells, SAM2 is applied directly to detect regions where outer and inner hair cells are absent. SAM2 extends the capabilities of its predecessor by incorporating a per-session memory module that captures information about the expected morphology of hair cells, enabling it to identify gaps or abnormalities in the cellular arrangement. This architecture allows SAM2 to handle complex visual data through a unified, promptable model that supports real-time processing and zero-shot generalization. By generating precise segmentation masks of missing areas, SAM2 facilitates the direct identification of regions affected by hair cell loss. Experimental results demonstrate that the integration of YOLO v11 and SAM2 significantly enhances the accuracy and efficiency of detecting missing cochlear hair cells. The combined approach leverages YOLO v11's real-time object detection capabilities and SAM2's proficiency in identifying absent structures, providing a comprehensive tool for auditory research.

Abstract Name: Exploring Elesclomol as a Potential Therapy for Copper Insufficiency

Menkes disease in humans is a genetic disorder that impairs the body's ability to absorb and distribute copper, leading to severe developmental and systemic issues including lethargy, frail bones, and persistent seizures. This disease is caused by a mutation at the ATP7A gene. A comparable mutation in *C. elegans* is located at the CUA-1 gene and mirrors many aspects of copper metabolism dysfunction, making it a valuable model for studying potential treatment options. Through our study, we identified an antibiotic, Elesclomol, that significantly improves the survival and physiological outcomes of mutant *C. elegans* that are exposed to copper. Without this intervention, the mutants exhibited a pronounced stress response, causing dauer formation, a reduced brood size, and lethargic behavior. It seemed that administration of the antibiotic alleviates these phenotypes suggesting that it may redirect copper metabolism pathways or mitigate the toxicity it presents. This was affirmed by the use of the antibiotic on wild type *C. elegans*, as it may cause an overwhelming uptake of copper, killing most of the population. The use of this antibiotic may present an avenue for considering therapeutic strategies for Menkes disease and similar disorders. Further research will focus on determining the specific mode of action of the antibiotic and its potential application in higher organisms.

Abstract Name: Exploring the relationship between alcohol use and disordered eating attitudes and behaviors in college students.

Intro: The relationship between problematic alcohol use and disordered eating attitudes and behaviors has been noted in college age women. 'Drunkorexia' is a relatively new term used to describe the restriction of food or other eating behaviors that compensate for the calories consumed from alcohol, or alternatively with the intention to optimize the effects of alcohol. Much of the previous research has focused on these relationships in women; this study includes college students of all genders and utilizes updated assessment measures validated in all genders to explore the relationships amongst disordered eating attitudes and behaviors and alcohol consumption in college students to better understand the underlying motivational connections among high-risk behaviors. Methods: Participants are over 300 UW-Whitewater students who completed a Qualtrics survey that included disordered eating attitudes and behaviors questions from the Eating Pathology Symptoms Inventory (EPSI), alcohol frequency and binge drinking frequency measures, and eating behaviors related to alcohol consumption from the Compensatory Eating and Behaviors in Response to Alcohol Consumption Scale (CEBRACS). Students were recruited through email, organizations, professors, social media and posters around campus. Results: Data collection continues through December of 2024; analyses will be conducted in Spring of 2025. Analyses will examine differences amongst genders on all measures. It is predicted that disordered eating attitudes and behaviors will be associated with the use of such behaviors to compensate for calories from alcohol and the enhancement of alcohol effects. It is hypothesized that binge eating will be associated with binge drinking. It is also predicted that bulimia associated behaviors and restriction will be associated with use of eating behaviors to enhance alcohol effects across genders. Results can potentially inform future intervention efforts.

Abstract Name: SSRI's Effects on Reproductive Health and Behavior

Sex is an important part of life; one's sexuality, relationships, and libido are all components of the sexual human nature. Fulfilling sexual desires can provide a sense of emotional, physical, and social wellbeing. The loss of one's sex drive can negatively impact one's quality of life and overall sexual satisfaction. The first line of treatment for major depressive disorder as well as anxiety disorders are selective serotonin reuptake inhibitors (SSRIs). One of the most prevalent side effects of SSRIs is sexual dysfunction. Sexual dysfunction is a disturbance in one's ability to experience sexual pleasure, drive, and/or arousal. The importance of sexual wellbeing is given little attention in the field of clinical psychology, thus eliciting the need for more treatment options for sexual dysfunction. Most mental health professionals (psychologists, psychiatrists, etc.) do not encourage discussions of sexual health with their clients, let alone specialize in sexual dysfunction treatment. Consequently, the lack of treatment for sexual dysfunction due to SSRIs may influence the high rate of non-adherence due to their sexual side effects. This study serves to investigate the prevalence of sexual dysfunction among patients prescribed SSRIs and understand the impact that SSRIs have had upon one's quality of life that leads to non-adherence. There is a critical need for more discussions about sexual discussions and treatments for sexual dysfunction in the field of clinical psychology in order to improve the sexual-wellbeing of patients.

Abstract Name: The Pharmacology of Lamotrigine in Crickets

Neurons are specialized cells that are responsible for sending electrical signals throughout the body. The action potential is the mechanism in which there is a temporary change in voltage within the resting membrane potential due to sodium influx and potassium efflux. The electrical firings of action potentials from neurons are crucial for neuronal functioning and cell to cell communication. Depolarization is an event in which the voltage of the membrane increases and this allows voltage gated sodium channels to open and allow the flow of sodium into the cell. This event is crucial for the start of an action potential as it is considered dichotomous, or an "all or nothing event". If the threshold for depolarization is not reached then an action potential will not occur. Lamotrigine (Lamictal) is an anticonvulsant and prescribed as a mood stabilizer. Lamotrigine is an inhibitory 5-HT receptor antagonist. Through its inhibitory and antagonistic effects on voltage gated sodium channels, its mechanism of action decreases the firing rate of a neuron by inhibiting depolarization from occurring, thus regulating 5-HT levels in the synaptic cleft. Neurophysiological experiments were conducted on *Acheta domesticus* (brown crickets) in which extracellular neuronal firings were recorded before and after the administration of Lamotrigine in order to understand the pharmacodynamics of Lamotrigine on neural firing activity. Lamotrigine consistently displayed lower action potential firing rates in comparison to the control trials, thus supporting the hypothesis that Lamotrigine functions as an anticonvulsant and mood stabilizing by impeding the depolarization of the membrane potential and thereby blocking action potentials.

Abstract Name: Impact of bidentate ligands on photocatalytic C-N coupling reactions using BODIPY and nickel

Access to affordable medicine is essential for many people's healthy lifestyles. Among numerous medicines, the C-N bond formation is a fundamental step in drug synthesis. A promising new approach for C-N bond formation involves using light as an energy source. Currently, the state-of-the-art method employs a nickel catalyst alongside an iridium photocatalyst. Under light exposure, the photocatalyst transfers energy or electrons to the nickel center, activating the catalytic process. However, iridium is expensive, which can drive up the cost of medications. Moreover, the energy or electron transfer between iridium and the nickel center is inherently inefficient due to the nature of the intermolecular interaction. To address these challenges, we developed a "two-in-one" nickel complex, where an organic photocatalyst (BODIPY dye) is chemically linked to the nickel (II) complex. We hypothesize that this integrated complex will be more efficient than the nickel/iridium combination. Our findings revealed that the ligands used to form nickel complexes significantly influence the C-N cross-coupling between aryl halides and morphine. We plan to present the mechanism of the C-N coupling and explain why bidentate ligands inhibit the photocatalytic reaction. Abstract Name: Comparative Genomics across Ganoderma Species to Identify Secondary Metabolite Clusters with Cytotoxic Properties

Fungi in the genus *Ganoderma* have been widely studied in Chinese culture for their medicinal properties and promoting overall health and longevity. Our prior work on eight *Ganoderma* species showed that they contain Secondary Metabolite Clusters (SMCs) that code for multiple terpenes, betalactones, and ribosomally synthesized and post-translationally modified peptides (RiPPs). These compounds are well known for their cytotoxic and anticancer potential. A specialized bioinformatics analysis tool, antiSMASH1, was used to identify and annotate SMCs that produce anticancer compounds in the eight *Ganoderma* genomes. To test the results obtained from the bioinformatics analysis, fungal extracts were prepared from *G. lucidum* and *G. tsugae* by air-drying and powdering the mushroom fruiting bodies, mixing them with 95% ethanol, followed

by lyophilization. Different dilutions of these extracts are being used for proliferation assays on two cancer cell lines, PN528 (Proneural) and patient-derived GSC20 (Glioblastoma stem cells) to assess the cytotoxicity potential of the fungal compounds. Cell counts will be performed along with the assessment of stem cell and apoptotic markers with an expectation that the stem cell and apoptotic markers will be elevated in treated cells. Survival analysis will be performed to evaluate and compare the survival rates of cells over time. In addition, comparative transcriptomic analyses will be performed to identify differentially expressed genes/pathways followed by qRT-PCR. The promise of this study lies in establishing the pharmaceutical and nutritional role of natural products from the genus *Ganoderma* and creating opportunities to develop market-ready health products.

Abstract Name: Uridine Homeostasis is Impaired in Obesity and MASLD and Affects Fatty Acid Metabolism

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a common chronic liver disease associated with obesity and diabetes. Disruption of uridine homeostasis has been linked to both obesity and the onset of MASLD. However, the role of uridine in regulation of lipid metabolism remains poorly understood. Our project goal is to elucidate how uridine influences fatty acid metabolism during obesity and MASLD development. Methods: Bioinformatics analyses of omics data was performed with AI-based platform Yotta (DeepSpace Biology). Male C57BL/6 mice fed a chow or obesogenic high fat, fructose, cholesterol (FFC) diet for 8 weeks, received uridine (50 mg/kg) or vehicle for 3 weeks. Metabolic phenotype, liver injury, and tissue homeostasis were analyzed by multi-omics analysis, histological and molecular assays. Results: Unbiased bioinformatics analysis of spaceflight liver metabolomics data revealed a significant enrichment of fatty acids ($p < 0.03$) and depletion of uridine ($\text{LogFC} = -0.85$, $p < 0.02$) in flight vs. ground control mice. Concomitantly, liver expression of uridine 5'-monophosphate synthase (UMPS) was significantly downregulated in flight mice. UMPS was downregulated in human MASLD compared to normal livers ($p < 0.002$). Targeted metabolomics analysis confirmed a significant time-dependent decrease of liver uridine in diet-induced MASLD mice. In vivo, uridine-treated FFC mice exhibited increased metabolic activity without changes in food and water intake, as compared to vehicle-treated FFC mice. In FFC mice, uridine reduced body, liver, and adipose tissue weight, protected from liver and muscle steatosis, and reduced intestinal inflammation, as confirmed by histological assessment. Liver phosphoproteomics analysis identified differential phosphorylation of proteins associated with mitochondrial fatty acid metabolism in FFC mice. Conclusions: Our findings indicate that UMPS downregulation and uridine depletion occur early in MASLD/obesity development and impair fatty acid oxidation, leading to lipid build-up over time. Further elucidation of uridine metabolism may uncover potential novel targets for obesity/MASLD treatment.

Abstract Name: Interfaith Informatics

Religious misunderstandings often stem from a lack of interfaith awareness. This ignorance leads to conflicts among different religious groups. When people are limited to only one perspective, it could lead to stereotypes and make it hard to find common ground on critical topics; such as abortion, gun control, same-sex marriage, etc., which causes further division. Sharing perspectives, on the other hand, allows people to see the beliefs that guide different communities and identify the overlap between religions. In this project, we bridge the knowledge gap and provide a common perspective between the different religious communities such as Christianity, Hinduism, and Islam. Our platform, Interfaith Informatics, is a user-friendly web interface that helps people explore the perspectives of different religions on different topics. While existing literature has some work done in sharing perspectives on different religions, it is often limited in considering comprehensive data points and not able to provide a better perspective. In this project, we provide three primary features: 1) Information, which displays an overview of our comprehensive dataset that includes multiple sacred texts across religions; 2) Sentiment Analysis, which analyzes the general sentiment of a selected religion on a given topic; and 3) Comparison, which identifies the similarities and differences of the perspectives from two selected religions on a given topic. We used generative AI as a supporting resource for the interpretation and analysis of sacred texts. Finally, we conducted preliminary experiments to demonstrate the efficiency of our tool, which is developed using Web 2.0 and MySQL technology.

Abstract Name: Synthesis of 1-(Diphenylamino)-2-propanone and 1-(phenyl(p-tolyl)amino)propan-2-one for Radical Arylation Studies.

In this study, the synthesis of 1-(diphenylamino)-2-propanone as a model compound for radical arylation studies was carried out. The synthetic pathway involved a multi-step approach, where diphenylamine was reacted with 3-chloro-2-methyl-1-propene in a substitution reaction. Subsequent oxidation was carried out using osmium tetroxide and sodium periodate, providing an efficient route to the desired ketone. The crude product was then purified via column chromatography and characterized using NMR, and GC-MS. This method proved advantageous over alternative synthetic routes because it produced the highest yield of desired product. The synthesized diphenylamino ketone will be used to carry out radical arylation studies to form indoline derivatives, which are basic motifs found in antitumor agents. Although the syntheses of indoline derivatives via the radical arylation of diphenylamino epoxides have been extensively studied, a study on the radical arylation of diphenylamino ketones to form indoline derivatives could also serve as an alternative and synthetically useful pathway. The same synthetic approach was applied to produce 1-(phenyl(p-tolyl)amino)propan-2-one, which will potentially be used to further investigate the regioselectivity of radical additions to arenes.

Abstract Name: Sentiment Analysis in Software Engineering: Evaluating Generative Pre-trained Transformers

This study investigates the efficacy of transformer-based models in performing sentiment analysis within the domain of software engineering (SE). Recognizing the limitations of traditional sentiment analysis tools in handling the technical and context-specific language of SE, the research systematically compares bidirectional transformers, such as BERT, with generative pre-trained transformers, specifically GPT-4o-mini. The study explores the interplay between dataset characteristics and model performance by evaluating these models on datasets from GitHub comments, Stack Overflow, Jira, Oracle code reviews, API reviews, and App reviews. The methodology involves fine-tuning the GPT-4o-mini model using SE-specific datasets, adhering to established benchmarks for consistency. Performance metrics, including precision, recall, and F1-scores, are assessed across sentiment categories (positive, neutral, and negative). The findings reveal that fine-tuned GPT-4o-mini matches or exceeds BERT's performance on balanced datasets like GitHub and Jira. Notably, it achieves a macro-averaged F1-score of 0.93 on GitHub and near-perfect scores of 0.98 on Jira. However, on the linguistically complex and imbalanced Stack Overflow dataset, the default GPT-4o-mini model outperforms its fine-tuned counterpart, achieving an 85.3% accuracy compared to 13.1%. The study concludes that generative models like GPT-4o-mini offer significant advantages in SE sentiment analysis, particularly when fine-tuned for structured datasets. However, the challenges posed by imbalanced datasets highlight the need for tailored strategies to optimize model generalization. These findings contribute to the growing understanding of the application of advanced natural language processing tools in SE, providing actionable insights for researchers and practitioners aiming to enhance sentiment analysis accuracy in this specialized domain. The implications of these results emphasize the importance of aligning model architectures with dataset properties to achieve optimal performance.

Abstract Name: COVID-19: Retelling the Story Through Topic Modeling and Sentiment Analysis

The COVID-19 pandemic, spanning late 2019 to late 2022, caused global disruption, resulting in over 700 million infections and 7 million deaths, while also greatly impacting economies, healthcare systems, and social life. During this period, social media sites such as X (formerly Twitter) became critical spaces for people to voice their thoughts and opinions concerning the pandemic. The objective of this study is to analyze the evolution of public sentiment and key topics over time using text data from X related to COVID-19. This will be achieved through topic modeling and sentiment analysis, creating a data-driven timeline of public opinions during the pandemic. The first phase of this study is the data collection phase, in which a

containerized web scraping Python program will hydrate tweet IDs from a database to collect millions of COVID-19-related tweets. The second phase focuses on understanding the data through topic modeling and sentiment analysis. Topic modeling will utilize LDA and BERT to identify key topics people discussed and how they developed and changed over time. Sentiment analysis will utilize Vader and Stanza to determine whether people felt positive, negative, or neutral regarding the pandemic and other subtopics. The results of this study will shed light on societal facets such as adherence to social distancing, utilization of healthcare systems, job security, and mask usage that will educate decisions of policymakers and public health officials in times of crisis and provide insights for predicting real-world events related to pandemics (e.g. an economic recession, case spikes). Additionally, this study provides a framework for conducting analyses on social media's informal writing style, advancing machine learning and data science techniques for unstructured text analysis.

Abstract Name: Hierarchical importance of the physical factors influencing the attributes of Laser-Induced Graphene

The hierarchical importance of physical factors influencing the attributes of Laser-Induced Graphene (LIG) remains underexplored, limiting the optimization of its fabrication process. Understanding how these factors interact and contribute to LIG's properties, such as sheet resistance, electrochemical activity, and surface wettability, is crucial for advancing its applications. In this study, we uniquely integrated machine learning techniques with experimental data to analyze and predict the relative significance of these physical factors. Using experimental data complemented by synthetic data generated through neural networks, we applied predictive algorithms to uncover patterns and hierarchical relationships. The machine learning algorithms, logistic regression and decision tree provided consistent findings, which revealed that sheet resistance and microstructure are the two most important process variables that are determinants of LIG's performance, with surface wettability playing a significant yet secondary role. Additionally, the study identified specific conditions under which electrochemical activity is optimized, enhancing LIG's functionality. This research provides a framework for data-driven optimization of LIG fabrication, paving the way for broader applications in electronics and materials science and can guide practitioners to quantitatively identify the most important physical factors to control graphene formation.

Abstract Name: Evaluating Digital Pathology Softwares: Performance Comparison Between QuPath and HALO in Tau Pathology Assessment

Image analysis software has become more common in the field of pathology; however, many of these tools have been developed and optimized for cancer samples. Non-neoplastic brain tissue presents unique challenges for these tools due to lower cellularity and variability in tissue morphology. In this study, we evaluated and compared two digital pathology software options' abilities to quantify tau pathology in postmortem brain samples from the hippocampus and middle frontal gyrus (MFG). Immunohistochemistry was used to assess AT8 expression in 36 autopsied brains stratified according to CERAD-NP scores and Braak stages. Slides were digitized using Aperio Scan Scope XT (20x) and analyzed with QuPath and HALO IndicaLabs software. Optical density (OptD), percent positivity, and object density (ObjD) were measured with each. ObjD values were manually determined for each slide and used to validate digital measurements via ordinary least squares regression models. Further analysis included Spearman's correlation and ANOVA ($P < 0.05$). Digital measurements correlated with manual ObjDs in both regions except for HALO-derived OptDs ($P > 0.05$). HALO showed strong relationships between digital and manual ObjDs ($\rho \geq 0.70$) in both regions, whereas QuPath showed a strong relationship between these measurements in the hippocampus only. Significant differences were observed between HALO and QuPath ObjDs and OptDs ($P < 0.01$). Significant differences between Braak stages were found for all QuPath measurements except MFG ObjDs ($P > 0.05$). HALO-derived ObjDs and percent positivity values showed significant differences between Braak stages ($P < 0.05$), but OptDs did not ($P > 0.05$). Digital and manual methods of quantification and scoring significantly correlated in both HALO and QuPath, thus supporting their effectiveness at accurately assessing tau pathology. QuPath demonstrated consistent performance and better differentiation between Braak stages, whereas HALO showed stronger correlations with manual ObjDs, implying a more robust method for object detection and classification.

Abstract Name: Implications for Transitions of Care for Women Diagnosed with Metastatic Breast Cancer at the End-of-Life

Background: Patients and their families with metastatic breast cancer (MBC) experience successive disease progressions and ultimately transition from active treatment to supportive care only at the end of life (EOL). As this occurs, families assume an increasingly greater role in decision-making, providing support, and caregiver responsibilities. Methods: This is a secondary analysis of semi-structured interview data, collected between August 1st, 2020-December 31st, 2020. The designated personal representative (DPR) or family

member of women deceased from MBC (N=167) between October 1, 2016, and March 1, 2020, was contacted for participation in a Quality of Death and Dying (QODD) survey and a subsequent telephone interview to discuss their and their loved ones' EOL experiences. For this secondary analysis, three reviewers examined the transcripts and were analyzed for themes surrounding the caregiver experience. Results: Participants were primarily male (n=13; 81.25%), had a spouse or supportive partner (n=13; 81.25%), and were older than 60 years of age (n=10; 62.5%). Themes identified from the semi-structured interviews (n=16) around caregiver experiences, included the importance of joint decision-making, caregiving challenges, and communication with healthcare providers (HCP). Of the cohort, 62.5% (n=10) participants reported an overall positive experience with their HCP, and 68.7% (n=11) had hospice care services. However, 43.7% (n=7) still reported negative experiences during the transition of care between active treatment and comfort-only support, describing the experience as "lacking compassion, unrealistic, a complete failure, and with very little overall support." Conclusion: While there are designated metrics for poor-quality EOL care experiences, this secondary analysis suggests that one measure of high-quality EOL care is the sensitive management of the transition from active treatment to supportive care only. Care transitions are crucial to high-quality EOL care experiences and bereavement for families. More exploration is needed to provide sensitive, higher quality care.

Abstract Name: HANDI: Human Advancement through Next-Gen Design and Innovation

Creating a personalized prosthetic requires a cumbersome process involving manual measurements, mold creation, and time-consuming fitting sessions, often leading to delays and imperfections. The HANDI system (Human Advancement through Next-Gen Design and Innovation) helps make this process faster and more accurate by streamlining the customization process using digital assistance, thus providing better precision, fit, and functionality. The HANDI system approach starts by accurately scaling a pre-designed 3D prosthetic model using precise measurements from different parts of the recipient's body. This automation saves time and effort in the production of the prosthetic. On top of using a digital algorithm to automate the scaling and measurements, the HANDI system uses 3D printing technology to automate physical production as well. Using 3D printing to manufacture the prosthetic nearly guarantees that the prosthetic will have higher levels of precision and comfort for the user than a handmade prosthetic would have. The overall goal of the HANDI prosthetic system is to create access, affordability, and personalization of prosthetics for individuals in need. This, in turn, reduces discomfort and allows the recipient to use their prosthetic more effectively to return to their normal mobility and independence in less time. The HANDI system can also be configured to work with remote healthcare settings, providing possible customization and manufacturing of prostheses without the need for an in-person assessment. Besides the practical advantages, this technology opens the door to broadened accessibility. By reducing the need for skilled manual labor, this system can allow for easier access to prosthetics for the individuals who truly need it.

Abstract Name: Towards the Critique of Algorithmic Subjectivity

This article aims to explore a form of algorithmic subjectivity first developed by Luciana Parisi in her 2019 article: "The Alien Subject of AI." Breaking from Parisi's original formulation, I argue that current understandings of "subjectivity" and "Artificial Intelligence" are in need of revisions, predominantly via a rigorous mathematical understanding of algorithmic and computational processes, and an updated conception of postmodern subjectivity to match. Beginning with an overview of the fundamental mathematical and logical bases for modern computational algorithms, I argue that perennial issues plaguing discussions around computation and AI (such as continuity vs. discreteness, determinism vs. stochasticity, and computation vs. intelligence) should be reframed as problems of scale (within which certain boundary conditions delimit the inherent contingency of the universe). Following this, I leverage a critique of the ontological binaries that define current understandings of computation, algorithms, and machine intelligence by situating them within the larger epistemological context of instrumentalization and automation. Using case studies of machine learning algorithms and social media algorithms, I demonstrate that general claims about "algorithms" and "algorithmic subjectivity" from both laypersons and academicians fly in the face of technical understandings, carrying implications for theoretical work in the field.

Abstract Name: The MyGov Platform Bridging Technology and Democracy for Accurate Data Collection and Youth Participation

The "MyGov" application is a transformative platform designed to modernize voting systems and demographic data collection, addressing challenges such as data inaccuracies and low youth voter turnout. Traditional methods of data collection and electoral engagement often fail to capture the diversity of populations, particularly in nations like Ivory Coast (West of Africa), where young people face significant barriers to civic participation. "MyGov" leverages cutting-edge technologies, including secure facial recognition, data encryption, and real-time analytics, to provide a user-friendly and inclusive interface that facilitates secure voting, accurate demographic data collection, and enhanced citizen-government interaction. This project integrates advanced data modeling techniques with robust security protocols to ensure reliability and fairness. Features like digital voting, integrated tax management, and real-time feedback mechanisms empower users while providing policymakers with actionable insights. The platform also offers a scalable model for countries seeking to modernize their electoral systems and improve public trust in governance. Drawing on my background in statistics and lived experiences during Ivory Coast's 2010–2011 conflict, to drive societal change through data-driven innovation; this project reflects a commitment to using technology and data-driven solutions to promote social equity, strengthen democratic institutions, and enhance civic engagement. By fostering accessibility and innovation, "MyGov" exemplifies the potential of digital tools to transform governance and empower communities worldwide.

Abstract Name: Enhancing Security in Healthcare 5.0 through Fog Computing

Rapidly evolving technology has transformed public healthcare systems from the conventionally disease-oriented healthcare 1.0, to the patient-oriented healthcare 5.0. One focus of the healthcare 5.0 model is to provide the capability of remote diagnoses and treatments through cloud computing, also known as telehealth or smart healthcare. Some examples of these technologies are the IoT (Internet of Things), big data analysis, and artificial intelligence. Telemedicine and virtual care played an important role in the bigger picture of building a smart city with smart healthcare. The COVID-19 pandemic accelerated this transition, showcasing the high functionality of these digital technologies. However, with telehealth growing in the United States by 4,347% annually, significant security and privacy concerns have been revealed. Reported threats included database attacks, privileged-insider attacks, traffic analyses, and DDoS attacks. Since the IoT relies on cloud computing for data processing and storage services, many of its applications suffer from inherited challenges such as unreliable latency and lack of mobility, in addition to the security threats. Fog computing has appeared as an evolutionary solution to these challenges. It can provide optimized latency and cost management, along with enhancing security. In this project, we will study the threat models that have been recently adopted by the US's healthcare 5.0 and discuss its security requirements. We will also review how researchers of the field address security threats by applying various access control schemes. We will then focus on adopting two encryption/decryption schemes, triple-DES (Data Encryption Standard) and AES (Advanced Encryption Standard), in the fog nodes to preserve data confidentiality. Fog computing can reduce security concerns, since the necessity of data transmissions to the cloud is minimized and the security risks are significantly reduced. Allowing the encryption and decryption at the fog nodes will add another layer of security for data integrity and confidentiality.

Abstract Name: Perspectives Today, Casting Visions for Tomorrow: How South Korea's Future Leaders View Division and Reunification

How do the future policymakers and leaders of South Korea view the division of Korea and future reunification? This study investigates the perceptions of elite university students at Seoul National University regarding the division of Korea and the feasibility and desirability of reunification. By focusing on this critical demographic—South Korea's future policymakers and leaders—the research examines how generational shifts, economic challenges, cultural divides, and global influences shape attitudes toward reunification. My findings highlight the erosion of a shared Korean identity among younger South Koreans, compounded by decades of ideological and cultural isolation. Despite broad support for reunification as a long-term goal, participants emphasized the need for gradual and phased approaches, prioritizing economic integration and trust-building initiatives. This research contributes to the literature by addressing the underexplored perspectives of South Korea's elite youth, offering insights into the challenges and

opportunities of reunification in a globalized and generationally shifting context. Policy recommendations include enhancing intergenerational dialogue, fostering cultural exchange programs, and developing transparent economic strategies to engage younger generations and address practical concerns about reunification.

Abstract Name: Effects of Brachial Plexus Birth Injury on Bone Resorption in a Rodent Model

Brachial plexus birth injury (BPBI), one of the most common neuromuscular injuries in children, occurs when excessive stretching of the neck during birth damages the brachial plexus nerve bundle innervating the neck and upper trunk. Most newborns affected by BPBI recover within 4-6 weeks, but up to 30% experience long-term muscle deficiencies and some incur permanent nerve damage. Severity of deficiencies depends on injury location relative to the dorsal root ganglion (DRG), either nerve avulsion proximal to the DRG (preganglionic injury) or ruptures distal to the DRG (postganglionic injury). Our previous work in rat models showed that at 8 weeks post-injury, rats with a preganglionic injury had a decreased bone formation rate in the injured limb compared to the uninjured limb. Trabecular bone microstructure in the humeral head was deteriorated in both postganglionic and preganglionic injury groups but was substantially more so with preganglionic injury. In this study, we are examining the effect of BPBI on bone resorption through osteoclast activity. Sprague Dawley rats 3-6 days old underwent preganglionic, postganglionic, or sham neurectomy or disarticulation (mimicking limb disuse without nerve injury) of one forelimb and were sacrificed at 2, 3, 4, 8 or 16 weeks post-injury. Injured and uninjured humeri were harvested, and the proximal growth plate regions were cryosectioned longitudinally, affixed to slides, and stained with tartrate resistant acid phosphatase (TRAP) to assess osteoclast activity. Slides were then imaged and analyzed using MATLAB for percent TRAP staining per bone area. Analysis is ongoing, but preliminary results indicate that preganglionic and postganglionic groups have lower osteoclast activity in their injured limbs compared to uninjured limbs. These findings will provide further insight into the timing of bone metabolism changes following BPBI, which can inform clinical treatments.

Abstract Name: The effects of light and prey resource availability on *Cymbomonas tetramitiformis* growth.

Cymbomonas tetramitiformis is a unique marine prasinophyte species for the way in which it can perform both phototrophy, using light as a source of energy, and phagotrophy, using predation to obtain energy. This is

known as mixotrophy, and *C. tetramitiformis* is a mixoplankton, being able to switch between trophic modes under resource limitations. We investigated the limits of light and prey availability for *C. tetramitiformis* to study how it switches between trophic modes. To do so, we created treatments of regular light/regular prey, regular light/low prey, low light/regular prey, and low light/low prey and measured cell density over 5 weeks. Based on prior knowledge that most mixoplankton species do not grow well without light, we hypothesized that growth under standard conditions of regular light and regular prey availability would be the greatest. Initially, the regular light conditions showed the greatest growth, but cells counts decreased quickly. Low light treatments took longer to start growing but eventually showed great growth. Under standard conditions *C. tetramitiformis* appeared to utilize their resources quicker than under constrained conditions, which lead to a shorter lag phase and a quicker stationary and death phase. The longer lag phase in low light/low prey could be because the strain needed more time to switch trophic modes and adjust to the conditions. Once it did, it grew to the same extent as regular light and prey. This indicates the ability of *C. tetramitiformis* to switch trophic modes and adjust to limiting conditions.

Abstract Name: Refining the Existing aDBS Ethical Framework to Address Racial Disparities for Black and African American Patients

Adaptive deep brain stimulation (aDBS), also known as closed-loop deep brain stimulation, is a version of DBS that offers improved treatment for movement disorders including essential tremor, dystonia, and parkinson's disease. While aDBS is a promising development, its novelty presents greater ethical risks due to limited research on its mechanisms and clinical applications. Parkinson's disease (PD) is a chronic movement disorder for which aDBS provides avenues for improved care. Despite the favorable potential of aDBS, prior research indicates that African American and Black patients with PD experienced disparities in receiving open-loop DBS treatment. These disparities can translate to aDBS treatment, making considering their presence within ethical approaches imperative. This paper evaluated Baker et al.'s existing ethical framework for aDBS, refining the framework to address disparities for Black and African American patients. To elaborate on these considerations, peer-reviewed literature was evaluated to understand the disparities Black and African American PD patients face when seeking DBS treatment. The ethical challenges faced by Black and African American patients were then identified and addressed within the categories of the ethical framework proposed by Baker et al. Aspects of the existing framework, such as addressing expanded inclusion criteria, were identified for their strengths in acknowledging disparities. However, the framework could be refined to address crucial challenges within informed consent and patient autonomy. These gaps were improved upon by adding more considerations for clinicians and industries to address medical mistrust, implicit and explicit bias, and socioeconomic disparities when providing or considering aDBS treatment. Including more thorough considerations for ethical challenges created by racial disparities can guide improving quality aDBS care. The findings of this paper demonstrate the importance of considering racial disparities within medical policy, innovation, care, and future ethical structures.

Abstract Name: The Relationship Between Undergraduate Research Participation and Educational Outcomes

This study investigates the relationship between participating in funded undergraduate research programs and pre- and post-graduation success among students at Kennesaw State University (KSU). Prior research suggests that engaging in research activities during undergraduate studies contributes to critical thinking skills, hands-on experience, and professional networking, all of which are crucial for career advancement (Seymour et al., 2004). Participation in undergraduate research has been associated with higher rates of employment and acceptance into graduate programs (Seymour et al., 2004). Moreover, involvement in research fosters a sense of professional identity and improves communication skills, further contributing to long-term career success (Jones et al., 2019). This study utilizes retrospective data from KSU's Offices of Undergraduate Research and Institutional Research to analyze pre-graduation success metrics, such as academic progression and retention. In addition, we used LinkedIn profiles to collect data on post-graduation outcomes, including employment status and further education. We analyzed data from 2019 to 2024, with a sample of 980 students who attended KSU and received funding from a KSU Office of Undergraduate Research program. The data includes several different funded programs, such as the First-Year Scholars Program, the Summer Undergraduate Research Program, and the Peer Ambassadors Program, providing a comprehensive view of students' participation in these programs. By assessing the influence of funded undergraduate research, the findings will provide insights to enhance research opportunities and support student success before and after graduation. Additionally, the results will explore whether participation in these research programs contributes to long-term outcomes, such as securing employment, pursuing further education, and overall career development. By examining these relationships, the study aims to provide evidence that can inform the development of initiatives designed to support student success during their academic journey and potentially foster meaningful post-graduation achievements.

Abstract Name: Bridging the Knowledge Gap: Assessing Naloxone Awareness and Access in Utah's Opioid Crisis

Opioid use disorder is a significant cause of morbidity and mortality in the United States (Steenblik et al., 2023). Utah has seen an unprecedented rise in overdose incidents in recent years, with opioids emerging as the primary contributors (U.S. Attorney's Office, District of Utah, 2024). Opioid-related deaths in Utah have far surpassed the number of deaths caused by firearms, falls, and motor-vehicle accidents (Utah Office of the Attorney General, 2024). An effective strategy to prevent opioid-related deaths is to increase access and awareness of naloxone—a medication designed to reverse opioid overdose by competitively binding to opioid receptor sites (SAMHSA, 2024). When given quickly and correctly, efficacy of opioid overdose reversal following naloxone administration can range from 75-100% (Rzasa Lynn & Galinkin, 2017). Considering the ongoing opioid crisis in the state of Utah, the purpose of this study is to evaluate the effectiveness of a naloxone distribution program in the University of Utah Emergency Department (UUED) along with the knowledge, perception, and access patients have regarding naloxone. Patients presenting at the UUED were surveyed using convenience sampling, as well as a 30-day follow-up survey via phone. Among

data collected thus far, 55.7% of surveyed patients (n=1,330) said that they did not know what naloxone was. Furthermore, 72.9% of respondents (n=1,324) did not know where they could currently get naloxone. Although effective overdose reversal drugs exist, data from the UUED suggest that patients overwhelmingly don't know what naloxone is or where to get it. This critical gap exposes the need for improved opioid education and naloxone distribution (OEND) programs across the state, and continued efforts to increase the availability of naloxone through free distribution initiatives. Furthermore, it is recommended that investment be made to improve the social perception of OEND programs and mitigate the harmful effects of associated stigma.

Abstract Name: Changes in Mitochondrial Electron Transport Chain Complexes Expression in Postmortem Human AD Brain

Alzheimer's disease (AD) is the most common cause of dementia, with an estimated 6.9 million Americans aged 65 and older currently living with Alzheimer's dementia. Postmortem studies of AD brains have shown that mitochondrial dysfunction plays an important role in the pathogenesis of AD. The electron transport chain (ETC) within mitochondria, comprising five complexes, plays a crucial role in ATP production through oxidative phosphorylation. Recent findings have observed alterations in the function of these complexes in AD brains, leading to impaired energy metabolism and increased oxidative stress. This study aimed to investigate these claims through Western blot analysis of various complexes, using postmortem human brain Broca area 8 tissue from both Alzheimer's disease (AD) and non-disease (ND) models. Our results showed a significant decrease in the protein expression of complexes I, III, IV, and V in the Alzheimer's disease (AD) brain compared to the non-disease (ND) brain. Furthermore, our analysis of sex-based differences revealed no significant variations in complex protein levels between males and females in Broca area 8. Additionally, we will test this on Broca area 22 tissue using our various samples to see if there is a similar trend between AD and ND brains. A comparative study between these two areas will help us understand how AD is affected region by region and see if there is a similar trend in sex-based differences. These findings can contribute to future research on mitochondrial dysfunction in AD, helping to regulate and understand the underlying mechanisms, and identifying new targets for therapeutic development.

Abstract Name: Channel-Based analysis of Neurological Disorders Using Permutation Entropy and Machine Learning

Neurological disorders are conditions that affect the brain and/or the body's nervous system. Often referred to as "invisible" disorders, they are not detectable by any physical indicator, but can be life-hindering to those afflicted. Conducting research on these disorders is a particularly challenging area, because they typically manifest through behavior, thoughts, and emotion— factors hard to quantify. Electroencephalography (EEG) is one of the ways we can measure brain activity data; a subject wears a brain cap with multiple electric sensors to observe the electrical activity of the brain. In our project, we aim to understand the patterns of various neurological disorders by analyzing EEG data to measure the similarities and differences of channels between disorders and healthy conditions. For the comparative analyses, we'll use TDBrain dataset, containing EEG data for each subject recorded with 26 channels in two conditions: one set with eyes open, and one set with eyes closed. First, two types of filtering (i.e., bandpass and notch filtering) are applied to remove noise. Second, we will compare different EEG time segments to determine the optimal window. Representing the patterns as selecting an appropriate segment window is essential for capturing sudden changes associated with various disorders and improving the overall classification accuracy. Third, features will be extracted using permutation entropy to show effectiveness in distinguishing the patterns associated with different neurological disorders and healthy conditions. Additionally, a region-based analysis will be conducted to identify the most significant brain regions linked to the disorders. We will compare data across the two eye conditions, aiming to identify condition-specific channels and their patterns with various disorders from the healthy states. Finally, we will generate a predictive model utilizing machine learning techniques to distinguish neurological disorders from healthy conditions. This research was sponsored by the National Science Foundation under Grant No. (2219634)

Abstract Name: Language Development: The Social Influences Necessary for Bilingual Language Acquisition in Infants and Adolescents

Language acquisition relies on the biological capacities of children to develop language and the environmental stimuli that allow for such acquisition; while monolingual development has been well-researched by psychologists and linguists over past decades, the effects of environmental stimuli on bilingualism display scant research as to the importance of interpersonal relationships on the acquisition of multiple languages. This research examines the psychological studies exploring the effects of interpersonal relationships of the child to their parents, siblings, and other stimuli, such as communities and technology, to the child's linguistic development. The referenced works focus on the relationships between the child and their interpersonal environment and each relationships' effects on the native-level acquisition of multiple languages, specifically the family's primary language and a secondary language of cultural importance. The environmental component of language composition is crucial to bilingual development, as children often rely on such linguistic relationships to develop native-level abilities in their primary and secondary languages. There was a positive relationship found between a child's bilingual attainment and parental responsiveness to the acquisition of a secondary language, as well as a positive relationship between a child's linguistic ability in the presence of a sibling, under which they are able to better develop their receptive and expressive vocabulary in a second language. The review does not account for differences in a child's upbringing, such as single-parent households, multigenerational households, or external familial and peer relationships, which explain differences in a child's attainment of secondary languages. A focus on more complex interpersonal relationships between the child and their interactions may explain differences in bilingual acquisition.

Abstract Name: Green Power: Paper-Based Bacterial Batteries

Papertronics, or paper electronics, is revolutionizing next-gen healthcare, environmental monitoring, displays, flexible electronics, and energy storage with a low-cost, green, sustainable approach. The key challenge is ensuring an independent, self-sustaining power supply for use in resource-limited environments. The objective of our project was to develop a bacterial-powered battery for flexible paper electronics and enhance the lifespan and power performance. Bacterial batteries, or Microbial Fuel Cells, typically consist of anodic and cathodic chambers separated by a proton exchange membrane (PEM), allowing only H⁺ ions or other cations to pass from anode to cathode. A conductive load connects the two electrodes, completing the external circuit. In the anodic chamber, microorganisms oxidize organic matter and transfer electrons to the anode, completing the respiration process. The battery component fabrication consisted of PEDOT:PSS + DMSO on paper for the anode, PEDOT:PSS + DMSO + Ag₂O on paper for the cathode, and a PEM constructed from wax printed on paper. Thus, an entirely paper-based battery platform is developed, decreasing the production cost and simplifying the fabrication process. Over a 7-week time-span, the paper-based biobattery array increased power generation to ~45 $\mu\text{W}/\text{cm}^2$. Our 3D conductive paper fiber environment improved power performance and lifespan, revolutionizing microbial energy for on-chip paper power supplies.

Abstract Name: Novel Low-cost Device for Real-time Measurement and Health Monitoring of Field-Deployed Solar Panels

Solar power has emerged as a potential renewable and sustainable energy source. Measurement, testing, and evaluation of solar panels are important for industrial quality control, education, and research and development. Commercial instrumentation exists to perform such measurements in a production factory or research labs. However, such instruments are very expensive and bulky. In addition, they are not suitable to deploy in a solar power field. Such limitations pose a barrier to continuous monitoring of solar panels' health after production when they are commissioned outdoor in a solar power plant. In this project, we have developed an innovative solution to address these challenges. We have designed and fabricated a portable low-cost device for remote real-time monitoring of solar panels. Our device costs less than \$100 and it can measure solar panel's electrical parameters and compute its power output within 2% accuracy compared to commercial lab-grade instruments that costs >\$3,000. Our low-cost device integrates an ESP32

microcontroller, a capacitive load, an analog front-end comprising of operational amplifier, an energy harvesting circuit, solid-state switches, temperature sensing circuit, and an analog-to digital converter circuit. The device is capable of measuring a solar panel's voltage, current, and tracing the current-voltage characteristic curves under different ambient conditions. The integrated direct Wi-Fi on the microcontroller allows the device to remotely monitor the panel's health. In addition to the hardware, we have also created an open-source python program that can autonomously analyze the performance of a solar panel by collecting and analyzing I-V curves in real-time to assess a solar panel's power output and its health and alert the maintenance personnel in case of any faults or malfunctioning. In addition, our system enables novel strategies to achieve higher efficiency of a solar plant, thus producing more renewable energy for a sustainable world.

Abstract Name: Temporal Patterns in Boxelder and Basswood Ecophysiology

Plant physiologists know that most traits result from both environmental and genetic factors, but often struggle to quantify the relative importance of each for any given trait. Research by Dr. Jake J. Grossman and his students applies this framework to the water usage of two tree species, boxelder (*Acer negundo*), and American basswood (*Tilia americana*) in temperate continental woodlands of Northfield, Minnesota. Grossman's lab has measured TLP (turgor loss point, an index of drought tolerance) and other metrics that characterize water use physiology over the growing season. He has hypothesized that there is ecologically consequential seasonal change in TLP throughout the calendar year, even when accounting for species of tree, year-specific environmental factors, and location. To explore this hypothesis, we applied hierarchical clustering to a TLP time series and found that observations from trees of the same species cluster together. We then fit a segmented line model to predict TLP and found that it varies across species and time, suggesting that different tree species adapt to various environmental factors throughout the season differently. We found a characteristic seasonal pattern in TLP: it drops in the beginning and end of the growing season, but is constant in the middle. We found that 34.8% of the variance in TLP can be explained by species, time of year, and year. This variance demonstrates the effect of individual differences and species-level adaptations upon trends of drought tolerance over time.

Abstract Name: A Quantitative Analysis of Atlantic Coast Conference (ACC) Football Game Duration

This study aims to identify the variables that influence Atlantic Coast Conference (ACC) football games. This study examined 442 ACC conference and non-conference football games from 2019-2023. Six variables were used: total number of plays, total number of scoring plays, total number of fouls, replay stoppages, replay stoppage time, and commercial format. Data was collected from the ACC and then cleaned and organized in Microsoft Excel. A simple regression model was created in Excel. Additional regression analysis with dummy variables was generated using R. Total number of plays was the most influential variable while total number of scoring plays was the least influential variable on game duration. The regression analysis showed the statistical significance of the six variables and predicted game durations within 10 minutes for 78% of the games studied. Ultimately, the results of this study are useful for both conference and league administrators interested in learning more about the factors that influence college football game duration. The project also highlights the difficulty of predicting game length due to the extreme variability of college football games.

Abstract Name: How Ideology and Cognitive Skills Influence Motivated Reasoning About Electoral Poll Information

The political landscape in the United States has become increasingly polarized in recent years, with political discourse often becoming heated and people relying mainly on information congenial to their ideology. This paper examines the propensity of individuals (college students and faculty in our sample) to engage in motivated reasoning — the tendency to engage in self-serving beliefs — when evaluating the accuracy of electoral polls for the 2024 Presidential Election. Using a between subjects randomized experiment, I assess the levels of motivated reasoning when participants are presented with polling information which either favors their preferred candidate (good news) or the opponent (bad news). I hypothesize that participants are more likely to incorporate good news than bad news in their beliefs (motivated reasoning). I also expect that the degree of motivated reasoning is positively correlated with both cognitive reasoning skills and the strength of political ideology, as supported by previous research. Specifically, to measure cognitive reasoning skills, participants complete a Cognitive Reflection Test (CRT). Strength of political beliefs will be assessed through questions on political affiliation and ideology. Motivated reasoning is measured by the degree of belief updating. Specifically, participants first estimate their preferred candidate's 'true' popularity after viewing an electoral poll showing a tie. Then, they are presented with a second poll — randomly assigned to show either good or bad news — and asked to revise their estimate. Lower levels of belief updating in response to bad news, compared to good news, would indicate a reluctance to accept unfavorable information, thus showing evidence of motivated reasoning. Therefore, my methodology allows for a nuanced analysis of the relationship between motivated reasoning, cognitive reasoning skills, and the strength of political ideology.

Abstract Name: Strategic decoupling and China's global economic transformation

Previous researchers have investigated the impacts of the U.S.-China Trade War (UCTW) through the changes in the global value chains of prominent multinational corporations (MNCs). The UCTW led to the “strategic decoupling” of global supply chains, whereby MNCs shifted foreign direct investment strategies and offshored previously held industrial investments abroad for new trade routes favorable to rising tariffs on either side. Escalations of trade tensions have threatened the supply chains for many MNCs, and due to the export-oriented nature of these firms, tariff hikes from the trade war have forced the shifts of many firms’ supply chains and foreign direct investments (FDIs) (Blanchard et al., 2021). Furthermore, Chinese MNCs have sought new regions for growth, such as Central Latin America and Central and Eastern Europe, to begin “greenfield” investments that were close to main trading hubs before the trade war, e.g. Mexico and Eastern Europe (Ortiz Velásquez & Prudencio Vazquez, 2022; Ramasamy & Young, 2022). Analysis of the changes in FDI flows has been ambiguous regarding the effects on the global value chains (GVCs) of firms whose MNCs invest in sub-Saharan African states. This research will investigate the changes in inward FDI flows by Chinese MNCs into Sub-Saharan African states and further contribute to analyzing the reality of the post-trade war international trade order.

Abstract Name: The Association of Social Support with Response to Leg Cycling Ergometer Exercise in Knee Osteoarthritis Pain in a Hispanic Dominant Community

Osteoarthritis (OA) affects ~600 million people worldwide, most commonly affecting the knee joint. A leg cycling ergometer is a commonly recommended exercise to ameliorate knee OA pain, but responses vary, suggesting that patient characteristics may be associated with the treatment response. Social support has been increasingly recognized as a factor associated with knee pain, yet its association with the effects of exercise on knee pain remains unknown. Thus, we sought to examine the associations of social support to changes in knee pain following the leg cycling ergometer in people with knee OA. We hypothesize that higher levels of social support would be associated with greater changes in knee pain. This secondary analysis of a clinical trial involved participants with knee OA completing a 25-minute leg ergometer exercise. Social support was assessed using PROMIS measures (instrumental and emotional support). Outcomes included changes in knee pain on a numeric rating scale and pain sensitivity at the knee as assessed with pressure pain threshold (PPT). Linear regression models, adjusted for age, sex, and BMI, were used for analysis. Seventeen participants were included (mean age: 54 years, 53% female, mean BMI: 32, 59% Hispanic). Instrumental support was significantly associated with changes in knee pain ($\beta = 0.162, 0.003, 0.322, p = 0.046$). No significant associations were found for emotional support and knee pain changes or for either type of support with knee PPT changes. Contrary to our hypothesis, higher instrumental support was associated with increased knee pain following exercise, though with a small effect estimate, while both instrumental and emotional support were not associated with changes in PPT. Our results suggest the level of social support may not be a predictor for exercise response to knee OA pain, and there may be other factors contributing to the variability in the exercise response.

Abstract Name: Satb1 and Satb2 can homodimerize independently of DNA

Gene regulation is essential for virtually all biological processes. Eukaryotic cells use the compaction of individual chromatin fibers as one method of silencing or activating genes. Tightly compact regions of heterochromatin typically contain inactive genes, while loosely organized regions of euchromatin usually contain active genes. The organization of chromatin into these structures is accomplished by chromatin architectural proteins such as Satb1 and Satb2. Although Satb1 is known to interact with DNA as a homodimer, it is currently unclear whether Satb2 binds in a similar manner. However, the significant homology between Satb1 and Satb2 suggests that both proteins might bind DNA in the same way. Furthermore, it is unknown whether Satb1 homodimerization is dependent on DNA. Here, we demonstrate that Satb1 and Satb2 both form homodimers independently of DNA. This was determined using two fluorescently tagged versions of Satb1 or Satb2. The first contains a mutated Nuclear Localization Sequence (NLS) that confines the protein to the cytoplasm, while the second has a functional NLS. When these proteins are co-expressed in HeLa cells, the wildtype protein is able to relocate the nuclear import-deficient protein into the nucleus, demonstrating DNA-independent dimerization.

Abstract Name: Democratic Erosion In Haiti

Democratic erosion or autocratic consolidation is a process that occurs over long periods with concrete actions taken to alter a regime from democratic to non-democratic. This analysis aimed to demonstrate the precursors to erosion, symptoms of erosion, and resistance to erosion or the aftermath of the decline present in Haiti from 2019 to 2020 under the presidency of Jovenel Moïse. Erosion was measured using the V-Dem democracy index and demonstrated more than a 2% decline in the chosen period. The recency of the selected period demonstrated Haiti's worsening state of affairs. This analysis also delved into Haiti's history and features in its institutions that aided in further autocratic consolidation and reduction in horizontal and vertical accountability. Additionally, severe lack of accountability, widespread violence, and barely functioning executive and legislative branches are also analyzed and explored while efforts to combat oppression and restore democracy are considered. This analysis seeks to validate the severity of events while providing detailed accounts of how they aided in the autocratic consolidation of Haiti. Conventional (economic inequality, media repression, reduction in freedom and fairness, etc.) and unconventional (co-opting democratic rhetoric, taking advantage of dysfunctional opposition parties, manufacturing discontent, etc.) paths to democratic backsliding are dissected. Indicators of backsliding and authoritarian behavior the Haitian state possessed before the Moïse regime are also synthesized throughout this analysis. Keywords: democratic erosion, backsliding, authoritarianism, autocratization

Abstract Name: Potential Function of YDL167C in *Saccharomyces cerevisiae*

YDL167C is a gene with an unknown function within the single celled eukaryotic organism, *Saccharomyces cerevisiae*. Research was conducted to learn more about the unknown function of this gene. This research consisted of bioinformatics searches and wet lab experiments. The four methods used during our research included bioinformatics research, YDL167C deletion, spot assay testing growth under four different stress conditions, and morphological analysis. Bioinformatics allowed the discovery of protein domains, the ability to find genes with similar functions, and the predicted protein localization. The potential location of the Ydl167p was suggested to be in the cytoplasm. The results of bioinformatics research showed that YDL167C may be associated with the binding of DNA and RNA. Deletion of YDL167C in yeast was completed by using a PCR-based strategy. A PCR product was created to replace YDL167C with URA3 and then used to transform yeast. Next, a confirmation PCR reaction was performed to confirm that URA3 was properly inserted into the YDL167C chromosomal location. Spot assays were then performed to compare the growth of ydl167c to the wild-type strain under different stress conditions. The stress conditions chosen were temperature gradient of 30°C, 37°C, and 42°C, 10 mM caffeine, 100mM hydroxyurea, and 300 mM MgCl₂. Our spot assay results suggest that the ydl167c strain has an increased fitness at 42°C compared to the wild-type strain. In the morphological analysis, 100 log-phase cells of wild type and ydl167c strains were measured to determine their budding stage. The morphological analysis results showed that the ydl167c strain displayed an increase in unbudded cells, suggesting that entry into the cell cycle is impacted deletion of YDL167C.

Abstract Name: Variables of Justice: Examining Disparities in Felony Sentencing

Significant disparities exist in incarceration rates, with minority groups being overrepresented in the prison population. This issue is deeply rooted in the historical context of the criminal justice system, where systemic inequalities have persisted over time. The literature on this topic focuses on a criminal's race and where they live when trying to find sentencing patterns. However, identifying the factors that contribute to the disparities in felony sentencing within the criminal justice system, beyond the variable of race, is crucial for understanding and addressing systemic inequalities. This project analyzes data from the Monitoring of Federal Criminal Sentences 2020-2021 from the United States Sentencing Commission to explore whether disparities in sentencing have lessened over time and what factors contribute to these disparities besides race. Within the existing dataset, dependent and independent variables were selected to demonstrate the relationship between sentencing and the factors influencing incarceration sentences. Data recording was completed to facilitate the use of ANOVA. After selecting, the dependent and independent variables, an ANOVA plot was generated in SPSS to show the comparative relationships. The resulting data (means,

statistical significance, and percentages) was input into Excel to create bar graphs. These graphs illustrate the relationship between the independent (age, race, gender, criminal history, education, and citizenship) and dependent (total months in prison) variables and allow for filtering of felony crimes by any variable. The comprehensive approach used in this study, combining ANOVA and graphical representation, provides a clear illustration of the disparities and their contributing factors. The analysis highlights the significant impact of race as well as education level, gender, generational differences, criminal history, and citizenship status on sentencing outcomes. These findings underscore the persistent and multifaceted nature of disparities in incarceration sentences.

Abstract Name: Role of Splicing Factor EXC-7 and UNC-75 in Neuronal Maturation in *C. elegans*

Neurons are formed and integrated into neuronal circuits during embryonic development. After birth, they undergo functional and anatomical changes driven by tightly regulated genetic programs. The underlying mechanisms contributing to neuronal maturation and how these neurons mature post-birth are poorly understood. Alternative splicing (AS) is a post/co-transcriptional mechanism in which splicing factors (SFs) are recruited and act upon premature mRNA strands to produce multiple mRNA isoforms from one gene. The expression of these isoforms can change depending on the stage of development, causing differences in how an individual gene is expressed. This isoform-switching process allows for greater functional diversity within a specific gene. This study aims to test the hypothesis that AS regulation alters neuronal isoform expression, contributing to neuronal maturation. I will use the model *Caenorhabditis elegans* due to its well-characterized cell lineage, rapid development cycle, and ease of genetic amenability. I will focus on the *exc-7* and *unc-75* SFs (mammalian orthologs are ELAVL and CLEF families). Both contribute heavily to neurological processes and maturation, such as aiding in the regulation of neuron differentiation and synaptic transmission. Computational methods allow for the analysis of bulk and single-nuclei RNA-sequencing data generated in the lab and published for public access across developmental stages in *C. elegans*. Utilizing developmental bulk RNA-sequencing data across the entire nervous system (NS) of *C. elegans*, I can evaluate NS-wide SF expression changes across different larval stages. With this, I will be able to identify isoform switching that contributes to expression changes found in the differential expression analysis. Knowing that the NS comprises multiple neuronal cell types, I will be using single-cell methodologies to evaluate SF expression changes in specific cell types. Completing this, I expect to evaluate *exc-7* and *unc-75* SF expression changes across whole NS development and specific neuronal cell-types.

Abstract Name: Let's Go! Exploring Trip Planning Behaviors

For many, traveling on a vacation is a time of relaxation to escape the struggles of the real world, but that is not always the case. Scholars have studied the effects of planning a vacation itself, with a focus on how women and men engage in trip planning behaviors differently. The current study examines individuals' experiences while planning a trip to Walt Disney World (WDW) with an emphasis on understanding the influence of parental status on planning and the timing of planning activities. The data was collected via a survey posted on various WDW social media trip planning sites and consists of a subsample of 213 out of the 262 individuals that completed relevant items about previous trip planning experience. While our study was open to individuals regardless of gender, or trip planning experience, our sample consisted of 85% female-identifying individuals and 15% male-identifying individuals who had planned and completed one trip to WDW. 209 respondents provided information about who they visited the parks with, with respondents equally split between parents traveling with children (n=103) and individuals traveling without children (n=106). Results from the 213 subset found that a majority were planning for at least one other individual (74.88%) and began planning more than six months in advance of their trip (64.79%). Some of the most stressful aspects of trip planning to WDW were attraction and dining reservations whereas the least stressful aspects were transportation to and from WDW. Additionally, another subset of 112 respondents who were actively planning a trip and had previous trip planning experience, reported that an overwhelming majority felt that their previous experience helped with their current trip (99.12%). This research is important because it expands our understanding of trip planning behavior and has implications for studies of travel studies.

Abstract Name: The Cyclops's Terror: The Sublime That Disempowers in Góngora's Polifemo y Galatea

The short epic poem *Fábula de Polifemo y Galatea* by Luis de Góngora (1561–1627), arguably the most consequential early modern poet in Spanish, recounts the myth of the formidable and fearsome cyclops, his unrequited love for beautiful Galatea, her preference for young and handsome Acis, and Polyphemus's murderous rage at discovering the two lovers. While existing scholarship has thoroughly explored themes such as the satirical nature of Polyphemus's courtship and the contrasts between the two male rivals, less attention has been given to the effects of the terror the cyclops evokes and how it suppresses the two lovers. This study adopts an interdisciplinary approach to uncover the effects of terror within the poem. Theories of horror and terror highlight the stark contrast between the hypermasculine, aggressive, and loud cyclops and the soft-spoken, handsome, and relatively effeminate Acis. Furthermore, the concept of the sublime, a term originating with Greek philosopher Longinus (1 A.D.) and later expanded by XVII and XVIII European thinkers, reveals the underlying gender and power dynamics. This analysis demonstrates how the cyclops's violence enforces a form of gendered terror that dominates not only the lovers, but also the reader. As the poem unfolds, the horror experienced by Galatea and Acis mirrors the reader's own captivity to Polyphemus's sublime presence, underscoring the inescapable force of his destructive power. By deepening our understanding of the *Polifemo*, we can uncover how early modern literature engages with themes of gender, power, and the sublime, opening the text to modern interpretations of terror.

Abstract Name: Building Compassion and Connection: A Case Study of Humane Education Through Middle Level Book Club Experiences

Introduction Humane education aims to foster empathy, respect, and responsibility by teaching about animal welfare, environmental stewardship, and social justice. This study examines middle school students' experiences in a humane education-focused book club intended to promote compassion and critical thinking. The goal is to explore how participation influences students' understanding of humane education and their approach to societal issues. **Literature Review** Research suggests that humane education can significantly impact empathy and prosocial behavior (Weil, 2024), with students developing a deeper compassion for others through ethical awareness activities (Bruneau et al., 2023). Book clubs, specifically, have been shown to enhance critical thinking and collaboration skills, providing a supportive space to explore complex themes (Smagorinsky & Johnson, 2021). This study extends this research by examining whether a book club on humane education can deepen students' ethical and solutionary skills. **Methods** This case study was conducted in a middle school book club with three participants over one semester (September–December 2024). Parental consent and child assent were secured, and the SFA student researcher completed CITI training on human ethics. The study utilized pre- and post-surveys to assess students' understanding of humane education, problem-solving enjoyment, and perceptions of group discussions. Both quantitative (Likert scale) and qualitative (open-ended questions) data were collected. **Data** Survey analysis showed increased understanding of humane education; initially, only 40% “strongly agreed” they knew what humane education meant, which rose to 70% in the post-survey. Confidence in making a difference also rose from 50% to 80%. Open-ended responses highlighted students' excitement about learning how small actions contribute to societal benefits, enhancing their sense of social responsibility. **Conclusion** This study highlights the effectiveness of book clubs as humane education platforms, fostering compassion, ethical thinking, and a solutionary mindset. Future research could investigate the long-term impact of humane education on students' attitudes and behaviors.

Abstract Name: Azidation of 1,3-Dienes Using Zhdankin's Reagent

Azides (N₃) represent an important compound in the chemical industry that can be utilized for biorthogonal chemical reactions that are important in fluorescent applications and can be utilized as precursors for many pharmaceutical scaffolds. Typically, azides function as an intermediate that can be converted into other nitrogen-containing compounds upon derivatization. The incorporation of azides onto alkenes has been thoroughly studied, but their addition to 1,3-dienes has seen few deliberate studies. This work reports three divergent protocols for the copper-catalyzed addition of azides to 1,3-dienes in a chemo-, regio-, and site-selective manner using Zhdankin's reagent. Representative product derivatization and mechanistic insights are also demonstrated.

Abstract Name: Chesley Bonestell: Designing the Future

This paper looks at the work of Chesley Bonestell, an astronomical illustrator whose paintings of space fueled public interest, and motivation for space exploration before manned space travel. Born in 1888, Bonestell discovered his love for painting early on, as well as his fascination with astronomical paintings in 1905, after viewing Saturn at Lick Observatory in San Jose, California. Bonestell would transition to work as an architect, working on designs for the Golden Gate Bridge, followed by a career in painting backgrounds for science fiction media. Chesley Bonestell combined architectural and cinematography skills to create his own imaginative depictions of planets. His iconic painting, Saturn as seen from Titan (1944), along with his artistic contribution to The Conquest of Space (1949), inspired countless enthusiasts and scientists to reach for the stars. Working closely with notable figures like rocket scientist Wernher Von Braun, bridged the gap between idealization, and a technical reality. Bonestell's impact on space exploration and society is underscored by his lasting recognition for space enthusiasts, including having a crater on Mars and an asteroid named in his honor. This paper reflects Bonestell's legacy as the "father of space art," whose work remains a continuous glimpse into the pursuit of space exploration.

Abstract Name: Caging The Bird: Analyzing the Proto Neurodivergent Horror in Shirley Jackson's The Bird's Nest

Jackson's propensity for themes of control and isolation makes many of her novels something of a beacon for feminist analysis. Considering the recent resurgence in popularity of *The Haunting of Hill House* and *We Have Always Lived in the Castle*, queer and feminist scholars are quickly claiming Jackson as one of their own. However, critics ignore one crucial lens in their analyses: Critical Disability Studies. While many of Jackson's works echo disabled and neurodivergent politics, these overlooked politics are perhaps best encapsulated by one of Jackson's most overlooked novels. *The Bird's Nest*, published in 1954, is a novel explicitly about a woman named Elizabeth who is the host of a Dissociative Identity Disorder system. More importantly, it is a novel about disability that positions doctors as a source of horror. While current scholarship certainly engages with Jackson's portrayal of Elizabeth from a broadly feminist perspective, the novel's relative obscurity has translated to a gap in scholarship from the novel from a strictly Disabled perspective. By employing the lens of Mad Studies, one of Critical Disability Studies' many offshoots, to the novel, this analysis hopes to show how Jackson's use of sarcasm and narration presents a wildly ahead of its time critique of how the partnership of misogyny and ableism is inherently horrific. Additionally, while this analysis cannot comment on how well *The Bird's Nest* has aged as a piece of representation, a Mad Studies reading of Jackson's novel hopes to highlight how this horror novel engages with neurodivergence almost 40

years before the passing of the ADA. To write horror that centers Disabled experiences, one must analyze the overlooked classics of yesterday.

Abstract Name: Assessing the Impact of Business Cycles on the Equity Premium in the United States

The equity premium puzzle is an unresolved issue in economics concerning the larger than expected difference between the average return on traditional equity versus risk-free debt. Significant research has been conducted on factors contributing to the premium's existence, such as investor risk aversion and measurement of the premium itself, but less work has been done on the impact that business cycle fluctuations may also have on this phenomenon. Utilizing data on GDP estimate measures, recessions in the United States, and national yield curves, we assess the way economic booms and busts may influence the equity premium. Primarily, we first examine relationships between GDP estimate measures, such as personal consumption expenditures; risk aversion measures, such as the price of volatile stocks; and equity premium measures, such as an upper bound on the premium. These relationships are identified through linear regression tests, as well as lead and lag correlations to assess future predictions. Next, we correlate the various equity premium and risk aversion measures with the growth rates of GDP estimate measures, testing the influence of fluctuations in components of the national economy. Next, we further this understanding by categorizing quarters by their recession status and analyzing equity premium levels under these conditions. This is mainly carried out via equal variance tests between recession and non recession groups for the equity premium and risk aversion measures. Finally, we investigate the risk-free debt component of the equity premium through more lead and lag correlations, this time with quarterly US bond returns. Our results lead us to conclude that business cycle fluctuations have a notable relationship with equity premium levels, although that connection may be more striking with smaller individual indicators, such as the dividend price ratio and gross initial public offering, than necessarily the macroeconomy as a whole.

Abstract Name: The Effect of Arachidonic Acid on Colorectal cancer cells

Colorectal cancer is one of the most prevalent cancers in the U.S. today, most typically caused by chronic inflammation of the bowels. The mechanism of inflammation is controlled by cyclooxygenase-2 through the synthesis of prostaglandins from arachidonic acid. Arachidonic acid is an unsaturated, omega-6 eicosanoid fatty acid that is found in many meats and is the precursor for prostaglandins and many other fatty acid derivatives. Arachidonic acid in certain quantities was found to decrease the proliferation of cancer, but contrastingly also found to increase the growth rate of cancer in higher quantities. In the absence of COX-2, arachidonic acid can induce apoptosis in high enough amounts. In amounts higher than ~100 μ M, apoptosis

occurs. In the presence of cyclooxygenase, this amount is not clear. Arachidonic acid is theorized to cause apoptosis of cells by causing excessive oxidative stress or through disrupting membrane fluidity. The goal of this study is to find the threshold of the anti-tumorigenic abilities of arachidonic acid. This was done through establishing baseline growth curves through a positive and negative control. The positive control was growth in normal media with fetal bovine serum (FBS) and the negative was growth of cancer in media with FBS absent. These curves will serve as basis of comparison when adding arachidonic acid to the HT-29 colorectal cancer cells.

Abstract Name: Collegiate Engagement as a Catalyst for Inclusive Leadership and Sexual Health Advancement

This project examines the relationship between collegiate campus involvement and the promotion of sexual health and wellness among students. The central research question investigates how engagement in inclusive leadership and campus organizations influences students' understanding and practices regarding sexual health. Drawing from a foundation of existing studies on health communication and peer-led interventions, this research aims to contribute to the discourse by highlighting the intersection between leadership roles and health advocacy in higher education. The methodology involves a quantitative survey to measure sexual health knowledge, attitudes, and behaviors among students with varying levels of campus involvement. This approach provides a comprehensive understanding of statistical trends and patterns, shedding light on the complexities of collegiate sexual wellness. Preliminary findings suggest that students engaged in inclusive leadership roles demonstrate higher sexual health literacy and are more likely to access campus wellness resources. Expected results will explore how peer influence within organizations fosters a culture of openness and reduces stigma around topics such as consent, sexually transmitted infections, and contraception. These findings will be contextualized within broader discussions on the role of higher education institutions in promoting public health and leadership development. By addressing the intersection of involvement and health, this research seeks to empower colleges to adopt strategies that integrate sexual wellness into leadership development programs. The discussion will emphasize actionable recommendations for creating inclusive, health-promoting environments on campuses, ultimately contributing to a generation of informed and proactive leaders.

Abstract Name: Storytelling as a Window into Social Engagement and Health

Storytelling is a very old practice that fosters connection, understanding, and the transfer of wisdom across generations. Defined as the act of sharing narratives through verbal and non-verbal means. Storytelling serves as a crucial bridge in building social connections. However, in the post-pandemic era, older adults face

increasing isolation and loneliness, with significant implications for their mental and physical health. Loneliness defined as the dissatisfaction with unfulfilled social need, and social isolation, rooted in the absence of meaningful connections, are linked to the higher risks of mental health conditions like anxiety, and depression. This can lead to illness such as Dementia. This research investigates the potential of storytelling to mitigate these challenges by promoting community engagement among older adults, with the specific focus on residents of Watervliet, NY. Particularly in the Watervliet Housing Authorities Quinn Apartments. By exploring how storytelling fosters a sense of belonging, preserves personal histories, and builds intergenerational connections, the study seeks to answer the following questions: How does storytelling impact the well-being of older adults? Can story telling reduce the perception of older adults as the "forgotten generation"? How can community-based storytelling initiatives enhance social engagement and create meaningful connections? The study aims to address gaps in research on the health benefits of storytelling for community-dwelling older adults. By integrating evidence from successful community story telling programs and assessing their applicability, we propose tailored interventions to combat isolation such as senior fairs, monthly meet ups, and community games. Storytelling not only offers a medium for shared experiences but also reinforces the critical role older adults play in Watervliet's community history, and identity. Ultimately, this research seeks to establish storytelling as a tool for enhancing well-being, fostering resilience, and creating inclusive, connected communities.

Abstract Name: A Novel Virtual Reality-Based Platform for Kinetic Visual Field Testing

Visual field testing has long been a standard for diagnosis of degenerative eye diseases. However, traditional methods have been associated with mechanical complication and unfavorable conditions for patients, especially those with physical or cognitive impairments. This paper presents a novel virtual reality (VR)-based solution to address the issues of traditional kinetic visual field testing, which has been plagued by patient discomfort, inflexibility of machine maintenance and maneuverability due to underlying mechanical complications, and operator dependency. By replacing the physical equipment with digital, software-based solutions, the virtual environment brings the potential to eliminate many of these logistical and mechanical challenges. The developed VR application uses Unity as its platform and the Varjo XR-4 Aero as its head-mounted display to replicate the Goldmann visual field test, allowing for the incorporation of advanced features such as gaze tracking to monitor patient compliance. Other benefits include reducing test time through automation, increasing accessibility for patients with mobility impairments, and enabling testing from more comfortable environments such as the patient's home. Additionally, the system's integration of gaze tracking allows for real-time detection of irregularities, which could ensure accurate results and reduce the likelihood of false positives or negatives. Preliminary testing demonstrates feasibility and sensitivity of the system, by comparison of results from a healthy and visually impaired patient. Despite the promising advantages of the virtual model, some limitations remain, including field-of-view constraints and the need for device-specific adaptations for gaze tracking. Nonetheless, the application demonstrates the potential of VR to streamline the testing procedure, enhance patient comfort, and improve the overall efficiency of visual field assessments. Future work will focus on expanding compatibility across different devices, pursuing larger scale testing, and addressing current limitations to enhance the system's effectiveness.

Abstract Name: Controlling a Triple-Jointed Robotic Arm to Detect and Trace 3D Surfaces for Medical Applications

The use of robots in surgical processes and hospitals has become more common throughout the last decade. These robots can perform complex operations with a generally low risk to patients. This study describes the control system for a robotic arm and vision system that detects the curved surface of a wound in 3D and traces the curved surface, applying plasma to accelerate the wound healing process. The machine developed utilizes a triple-jointed arm, driven by stepper motors and a servo. A stationary stereo camera feeds frames and a depth map to a Raspberry Pi 5, where a YOLOv8 segmentation model runs inference to detect the location and shape of the wound. Using the depth map, a 3D curve is approximated. The curve is then converted to machine coordinates. Next, inverse kinematic calculations are performed to determine the target angles of each arm joint such that the end effector is at a specific point on the curve. The target angles are sent to an Arduino Mega 2560 controller, via USB serial. On the Arduino, PID controllers are used to position each of the joints to the target angles. To comply with ISO standards, the machine includes safety features such as an emergency stop button, manual overrides, and status lights. The machine also includes a temperature sensor (an IR sensor), used to maintain a safe temperature at the wound surface and prevent cell damage. Our presentation will cover the instrumentation and control methods applied, using the camera for wound detection, and toolpath generation. In addition, it will cover the methodology, safety features, machine specifications, electrical components, and mechanical design.

Abstract Name: Chemical Characterization of Lenoir and Parental Wines Utilizing Untargeted LC-MS-Based Metabolomics

Amid rapidly changing environmental conditions, grape varieties with drought-tolerance and resistance to pests that produce high-quality wine have become highly sought after by winemakers and enologists. The Lenoir varietal (a.k.a. Black Spanish, Jacquez), one of the oldest American hybrid grapes, displays natural resistance to Pierce's disease and Phylloxera. The rootstock is particularly valuable for winegrowers in the warm winter regions of the southeastern United States, such as California and Texas. There has been no precedent for the chemical characterization of Lenoir and how it may correlate to its potential parental wines according to its metabolite composition. Herein, we aim to elucidate the metabolomic profile of Lenoir and investigate correlations between the varietal, its possible parental wines, and selected control wines. This study utilizes a mass spectrometry-based metabolomic workflow to characterize the relationship between Lenoir and its four hypothesized parentals—Cabernet Sauvignon, Black Muscat, Cabernet Franc, and Norton. The phenolic and metabolomic profiles of ten mono-varietals were obtained utilizing liquid chromatography-mass spectrometry (LC-MS). Chemometric tools such as Principal Component Analysis (PCA) and Partial Least Squares Discriminant Analysis (PLS-DA) were utilized to analyze the multivariate data and identify

groupings while elucidating prominent relationships between the varietals. The metabolomic analysis identified 150 unique flavonoids across the wine samples, with several important flavonoids shared between Lenoir and its potential parental varieties.

Abstract Name: The Symphony of the Cell: Using Data Sonification to Engage Students in Molecular and Cellular Biology

As technology continues to evolve and influence our lives, the demand for careers in science, technology, engineering, and mathematics (STEM) has only grown. However, challenging content and lack of valuable experience often prevents students from finding a sense of belonging in these fields, discouraging many from considering futures in STEM. Thus, alternative learning techniques that both introduce foundational concepts and engage students are essential to addressing this need. A common difficulty for many students is understanding how protein sequence and structure contribute to protein function, and how errors in proteins impact the overall function of a cell. To present these foundational concepts to introductory students, our team has developed a virtual authentic-learning tool that utilizes data sonification in which each amino acid in a primary protein sequence is assigned a musical note and rhythmic value based on its hydropathy. This software allows harmonious music segments to be composed from primary sequences of functional proteins. Moreover, this software may also be used to model disease-associated point mutations by creating dissonance in music segments, allowing the user to audibly identify mutations and understand how errors impact cellular symphony. Our hypothesis is that this data sonification learning module will both increase student understanding of the molecular basis of disease and improve student attitudes toward STEM. Our preliminary results show this activity changes student attitudes following presentations to middle school and high school student groups supporting this hypothesis and future expansion of the models.

Abstract Name: Quantifying Colorant Concentrations in Crystalline Glazes

Zinc silicate-based glazes are used to create large, visually stunning, macrocrystals reaching up to several centimeters in diameter. Since the zinc silicate is colorless, copper, nickel, cobalt, and iron compounds are added at single percent-by-mass levels to produce colored crystals. When more than one colorant is used, isolated regions of macrocrystal formation and coloration can form, despite a uniform glaze application prior to kiln firing. The mechanism of this localization is not well understood. X-Ray Fluorescence (XRF) spectrophotometry is a technique well-suited to analyze the glaze composition, but suffers from the limitation of being a bulk technique. Scaling the XRF signals from the colorant element(s) to zinc is found to be an

effective way of correcting for the highly variable glaze depth, allowing quantitative determination of the colorant concentration.

Abstract Name: Landlocked Developing Countries Trade Policy Analysis

Landlocked developing countries (LDCs) face significant challenges, such as high transport costs and limited market access, due to their limited access to oceans. This study focuses on Mongolia as a case study to explore these challenges and identify strategies that could benefit other LDCs. Using economic data from 1990 to 2023, key indicators such as inflation, import and export volumes, GDP, foreign trade volume, share of world trade, and tariffs were analyzed across 32 LDCs. The gravity model method and case analysis were employed to examine trade dynamics, particularly with economic size and geographic distance. Additionally, the export diversification index was used to assess the variety and distribution of products exported by these countries. The findings aim to inform policy decisions that support sustainable economic growth for landlocked nations, helping them overcome geographical disadvantages.

Abstract Name: Monitoring Space Weather with CosmicWatch Muon Detectors

The Earth is bombarded continuously by charged particles from outer space; these particles—mostly protons—interact with the Earth's atmosphere, creating a shower of particles, including muons that reach the Earth's surface. The rate of cosmic rays impacting the Earth has a significant dependence on solar activity. We have been monitoring the muon rate at Earth's surface using student-built CosmicWatch detectors. Over several months in 2024, we have measured variations in the muon rate corresponding to solar activity, including a number of intense solar storms. We compare our results to those of cosmic ray monitoring stations around the world. Our results show that space weather can be monitored by inexpensive, easily deployable CosmicWatch detectors.

Abstract Name: Crossroads: Labor, Masculinity, and Blackness in the Origins of Blues

This project explores the multifaceted factors that contributed to the emergence of blues and jazz music in the United States. It recognizes that a complex interplay of influences, including labor, anti-Black racism, and gender roles, shaped this music's compositions, culture, and reception. Additionally, this project seeks to shed light on the ongoing struggle to preserve blues and jazz as essential African American and American art forms, particularly in the face of attempts to erase the central role of Black musicians. By examining the intersections of Blackness, gender, geography, and labor, this project hopes to inform the academic community and the broader public about the historical origins and significance of blues and jazz. Ultimately, this project aims to bridge the gap between fans and listeners and the scholarly study of this music, providing a modern perspective on its rural African American roots. This project aims to analyze blues and jazz music using various intersectional lenses and to argue the intrinsic African American identity in the music by examining how it's been shaped by labor, gender, geography, and Blackness. My research questions are as follows: Was blues created in response to laboring conditions in the nineteenth century? At what point in the twentieth century did blues become labor in itself? Did these labor roles positively or negatively impact masculinity, and how was that expressed in blues as the music progressed? What role did blues play in the reclamation of African American identities in the post-emancipation United States? Lastly, how can we preserve the history of blues and jazz music as a quintessential African American art form in the twenty-first century while exploring new understandings of the music's origins?

Abstract Name: Dressing for the Glass Ceiling: Suffragette and Dress Reform Fashion and Perceptions of 2024 Female Presidential Candidates

While many scholars have discussed the influence of the glass ceiling in holding women back from entering politics, little research has been done on the influence of fashion as a barrier. Women's fashion became explicitly politicized in the 1850s with the growth of the dress reform movement. Later, in the early 1900s, women began harnessing fashion as a tool to gain respectability in their fight for suffrage. The goal of this research paper is to examine how fashion has influenced the perception of American women in politics over time and how fashion may be an invisible component of the glass ceiling that has made it more difficult for women to become involved in politics. This study analyzes photos of the American suffragists' fashion during the 1900s and 1910s and images of female presidential candidates in the United States. This analysis of peer-reviewed studies identifies the links between fashion and the opinion of politicians, as well as how counterstereotypic presentation may help women present themselves as leaders rather than women when running for political office. This comprehensive literature review also evaluates media coverage of politicians' fashion through articles in the popular American newspapers The New York Times and The Washington Post. The findings of this study demonstrate a continued tradition of political women employing fashion as a tool to fight negative stereotypes due to their gender. While fashion can be beneficial for female politicians, it has also become a necessary aspect of campaigning that male politicians do not have to contend with to the same degree when entering the political sphere.

Abstract Name: Who Has the Power on Campus?: University Professors and Academic Freedom

The 2024 election has many university educators worried about how academic freedom will be impacted during the Trump presidency. In order to picture the possible future of collegiate academic freedom, it is important to understand how it has shifted into the form it takes today. Academic freedom, as defined by the American Association of University Professors, protects and allows professors “to speak freely when participating in institutional governance, as well as to speak freely as a citizen.” Using archival material from the Abby Marlatt papers, 1945-2007, at the University of Kentucky (UK) Special Collections Research Center, this research will explore the 1962 case in which Dr. Marlatt and Professor Morin were penalized for their political activity. Known as the “handbill incident,” this activity occurred in downtown Lexington outside of school hours with no university affiliation. Their case fell under academic freedom as it related to their ability to speak freely as a citizen; however, they still encountered serious consequences. More recently, UK experienced significant power shifts during the summer of 2024. The University Senate was dissolved, giving power to the president and administrators and effectively relegating the new Faculty Senate to an advisory role. This research will discuss the impact of the dissolution on academic freedom and the protection of professors’ free speech “when participating in institutional governance,” if this “institutional governance” has been revoked. Comparing these two tests of faculty academic freedom that happened 60 years apart will provide a greater understanding of university power dynamics and how they impact the faculty’s academic freedom.

Abstract Name: Wireless Personal Pulse Oximeter with Bluetooth

This project aimed to develop a portable, real-time heart rate and oxygen level (SpO2) monitoring device using the MAX30102 sensor with the BGM220P microcontroller module. The device is designed to be provide critical health metrics that can be displayed on an OLED screen as well as transmitted via Bluetooth communication. The MAX30102 is a sensor for pulse oximetry and heart-rate monitor module. It operates on the principle of emitting red and infrared lights and calculating the vital components using light absorption characteristics of oxygenated and deoxygenated blood cells (Hgb) in the blood. An OLED display was chosen for its portable feature and clear visual output, and the display is driven by the SSD1306 controller, which communicates with the microcontroller over an I2C interface. The BGM220P is a microcontroller module with Bluetooth interface, chosen for its processing power which is at 32 bits. The microcontroller was to manage sensor data acquisition, processing, and display output. The software for the project was developed entirely in C language with Simplicity Studio IDE. The web application at <https://heartratesurf.netlify.app/> was developed with javascript to allow users to monitor their heart rate and blood oxygen level with their smart devices such as phone, tablet, or laptop. The website can be reached by any smart device that has Bluetooth, and the device works by placing the finger on the MAX30102 sensor. The sensor is programmed into SpO2 and Heart rate mode where it emits red light that is visible to the eyes. Upon finger placement the

device immediately starts sampling and display the calculated oxygen level and heart rate. These results are filtered by a buffer in order to remove noise and inconsistencies.

Abstract Name: Synthesis of cDNA Libraries to Observe Interactions with Dengue Virus NS4B Proteins

Dengue virus (DENV) is transmitted from Aedes mosquitos to humans in mostly tropical regions, and there is no effective treatment or vaccine. Upon entering a host cell, DENV viral proteins create a viral replication complex within the endoplasmic reticulum. The viral nonstructural protein 4B (NS4B) is crucial for anchoring and initiating this complex and can be observed through protein-protein interactions. In addition to viral proteins, NS4B has also been determined to interact with cellular proteins. To identify additional cellular binding partners of NS4B, a mammalian-2-hybrid platform was created. NS4B was subcloned into a pVP16 cloning vector and ligation was confirmed by restriction digest. A cDNA library was constructed from total Vero DNA followed by ligation of resulting cDNAs into a pM-Gal4 cloning vector. Preliminary tests indicate that a large size range of cDNAs have been successfully cloned. This work is a preliminary step toward identifying cellular proteins that interact with NS4B and determining potential roles of this viral protein in both viral replication and disturbance of cellular functions.

Abstract Name: Comparing the Transfection Efficiency of Vero Cells Using Calcium Phosphate, Verofect, and Lipofectamine 3000

Transfection is the process of introducing foreign genetic material to eukaryotic cells. This process requires certain chemical reagents or physical processes to deliver nucleic acids and plasmids to the cell. Fluorescent genes such as GFP or RFP are often inserted into plasmids to best visualize the effectiveness of the transfection. A high transfection efficiency is vital when studying the roles of exogenous cellular or viral proteins in cellular pathways. Vero cells are a common cell line used for studying viral infection, however they are notoriously difficult to transfect. This study compares the transfection efficiency of 3 different reagents: Calcium phosphate, Verofect (Oz Biosciences), and Lipofectamine 3000 (ThermoFisher). Variations of transfection protocols and reagents were used to determine the best method of Vero transfection. Cells were transfected using vectors that express fluorescent proteins fused to cellular proteins (GFP-Rab-8, and GFP-Rab-11) or Dengue Virus NS4B protein (RFP-NS4B). Our results indicate that Verofect is the most

effective, as it had the highest estimated transfection efficiency at 90%, followed by Lipofectamine 3000 at 60-70%, and finally calcium phosphate at 10-20%. Comparing the vectors used, RFP fluorescence was more difficult to determine by fluorescent microscopy, which could result in artificially low transfection efficiency by our calculations. Overall, Verofect, a reagent designed specifically for transfection of Vero cells, did outperform both Lipofectamine 3000 and calcium phosphate.

Abstract Name: Population changes of ciliate *Nassula variabilis* exposed to cyanobacterial strains of *Microcoleus* as food source

Nassula spp. is a ciliate grazer that specializes in feeding on cyanobacteria. Various studies have observed the responses *Nassula* has to feeding on toxic and non-toxic cyanobacteria, with results ranging from population growth to increased mortality. *Microcoleus* is a mat forming cyanobacteria that can produce anatoxin-a, which can be harmful to aquatic life and animals. In this experiment, we used laboratory cultures of *Nassula variabilis* isolated from Ellicott City, Maryland, non-toxic and toxic strains of *Microcoleus* from Eel River, California, and the Shenandoah River, Virginia, and toxic strains isolated from a tributary to the Virgin River in the Zion National Park, Utah grown in BG11 culture medium. We transferred 20 ciliates in 2 mL well with BG11 and 1 mL medium with *Microcoleus* filaments. The experiment was done in 24-well plate, in triplicates for each *Microcoleus* strain, and control treatment with non-toxic *Oscillatoria* species. The number, color, relative position and mortality within the well of each ciliate was recorded daily, for period of 30 days. Trends showed rapid decline of all *N. variabilis* cells within the first week, likely due to the stress of new environment. *N. variabilis* exposed to *Oscillatoria* showed declined population health, but soon recovered. Of those remaining, ciliates grazing on *Oscillatoria* increased in population, those grazing on non-toxic *Microcoleus* from the Shenandoah River maintained a steady population for several weeks before decline, and those grazed on the toxic *Microcoleus* strain from the Shenandoah River experienced a small increase in population before declining after several weeks. Ciliates exposed to *Microcoleus* from California died after 3 days, regardless of toxicity, while ciliates exposed to *Microcoleus* from Utah died after 7 days. Further study is needed to understand the influence of anatoxin-a variants on ciliate survival and potential transfer of toxins within the food web.

Abstract Name: Digitizing the Past: The The Schauffler College Archive at Defiance College

The Schauffler College of Religious and Social Work was founded by Henry A. Schauffler (1837-1905) on Jan 23, 1886. Located at present day Fowler Drive in Cleveland, Ohio, the Schauffler College merged with

Clara Schauffler née Hobart's Slavic Bible Readers' Home in 1890, and sought to train young women to serve as missionaries to the Slavic immigrant population of Cleveland. Over the course of the summer of 2024, we were given the opportunity to work with the Schauffler Archive and Defiance College to develop and implement a process for digitizing the thousands of files and artifacts within the Schauffler College Archive. In this time, we uncovered the nearly forgotten stories of a number of Schauffler students, including Mrs. Asayne Sato who attended the college from 1908-1909 before returning to Japan to work in diplomatic relations, Ms. Annette Goltscher who graduated in 1925, spoke eight languages, and became one of the first policewomen in Cleveland, and Ms. Sibusisiwe Violet Makanya, of Umbumbulu, Natal, South Africa, the first Black South African social worker and a powerful proponent of Black girls' education in apartheid South Africa. Using modern technology, we are working to archive the Schauffler College collection with Ohio Memory-and thereby making it readily available to interested parties-while preserving and amplifying the voices of these women for current and future generations. Through digitizing the Schauffler College collection, it will not only be preserved from the inevitable degradation of paper ephemera as well as allowing access for the use of up-and-coming technologies such as AI translations, but also setting an example of the nature of historic preservation of material culture, particularly in the case of immigrant, minority, and otherwise marginalized populations.

Abstract Name: Bridging the Divide: Addressing Healthcare Inequities Between Rural and Urban Communities

The healthcare disparities between rural and urban communities in the United States are a pressing issue, reflecting systemic inequalities rooted in geographic isolation, resource scarcity, and economic insecurity. Residents of rural areas face significant challenges in accessing timely and adequate care, leading to poorer health outcomes and delayed treatments for chronic and acute conditions. This paper delves into the discussion of two contrasting healthcare delivery models-centralized hospital systems and decentralized rural clinics-and evaluates their relative efficiencies in meeting the unique needs of rural communities. Decentralized clinics provide accessible, culturally appropriate care by placing healthcare providers within rural communities. Decentralized clinics do well in providing routine, preventive, and chronic disease management care services. This approach fosters better patient-provider relationships. When supplemented with telehealth innovations, they can also transcend geographical and financial barriers, connecting rural residents with much-needed access to specialized expertise without expensive and timely travel. In turn, centralized systems are vital in providing specialized care that is unavailable at smaller facilities; however, their distance from rural populations makes them inaccessible and negatively affects delayed care and deteriorating health status. The hybrid model capitalizes on the complementary strengths of dispersed community clinics and central full-service hospitals through advanced telehealth networks. It minimizes the logistical barriers and enhances local access to care, making the specialist care, when required, significantly improve rural health outcomes. Given the integration of these two models, an expansive policy intervention encompassing the expansion of Medicaid, investment in broadband infrastructure, and workforce development is essential for its overall success. These are essential to making healthcare delivery sustainable in rural areas, where particular challenges include provider shortages and unreliable digital infrastructure. From this perspective, the hybrid model offers a promising path for reducing health disparities and improving outcomes through a comprehensive healthcare system with equal care for rural populations.

Abstract Name: Stories of an Intergenerational Neighborhood: Living and Learning with Older Adults as Health Science Students at a Personal Care Home

An intergenerational community places emphasis on socialization and cooperation across generations. Intergenerational interaction between older adults (OAs) and youth increases self-esteem, decreases social isolation, and promotes quality of life. This project presents a novel intergenerational community in a personal care home that situates graduate health science students as neighbors to older adult residents, requiring at least four hours of intergenerational interaction a week. The purpose of this study is to assess the impact on quality of life and ageism in this intergenerational living from the student and OA resident perspective. A mixed methods study design was utilized to assess ageism of health science students and illustrate the lived experiences of students and OAs living together. Students and OAs from a single personal care home were recruited. Students were assessed pre/post at least five months of interaction, while OAs were assessed post. Quantitative student outcomes on ageism included pre/post assessment using the Relating to Older People Evaluation (ROPE) and the Geriatric Attitudes Scale (GAS). Upon preliminary analysis, minimal changes were noted in student ageist perceptions quantitatively pre/post interactions. Qualitative reporting included 30-minute semi-structured interviews with student residents pre/post and OAs post. Individual content analysis was followed by consensus coding to validate thematic results. Qualitatively, intergenerational living was valued by students and OAs. The students and OAs identified the experiences as influencing future healthcare knowledge, breaking stigmas, learning from wisdom, and impacting mental health through authentic relationships. Creating intergenerational communities is a concept in its infancy. This arrangement may improve quality of life of both students and OAs. Considering the mental impacts of higher education and isolation in older adult communities, HCPs should advocate and consult on the creation of intergenerational living communities.

Abstract Name: Exploring the Perceptions of Black Pre-Professional Birthing People on Maternal Health in the United States

According to the CDC, Black birthing people in the US are three times more likely to die due to pregnancy related causes than White birthing people. There are multiple factors that contribute to these disparities, including socioeconomic status, systemic racism, and discrepancies in health care provision. Although education should be a protective factor, it has no effect on the disparate health outcomes in Black birthing people. The purpose of this study was to explore perceptions of pre-professional Black birthing people on maternal health and describe areas for improvement. Using a descriptive design, a convenience sample of 28 Black participants completed a demographic questionnaire and answered 4 open-ended survey questions

about views on maternal health, such as “Choose 5 different words/phrases that describe your views on maternal health in the US?”. Responses were then examined using comparative thematic analysis. 3 themes emerged: Quality not reflecting expense, Concern towards birthing associated with high mortality, and Feeling overlooked despite importance. Based on the findings, it is recommended that quality care be made more affordable and accessible regardless of race/ethnicity, providers receive more education about culturally competent care, and patients receive education to advocate for themselves during the perinatal period.

Abstract Name: The Burden of Fetal Alcohol Syndrome in South Africa: Prevalence, Impact, and Implications

Fetal Alcohol Syndrome (FAS) is a preventable condition caused by alcohol exposure during pregnancy, leading to cognitive, physical, and behavioral impairments in newborns. It is one of the leading preventable causes of developmental disabilities worldwide, with profound and lifelong effects on individuals and families. FAS affects less than 1% of the general population globally, but South Africa is disproportionately impacted, with over 6% of the population diagnosed with the disorder. Despite this, the South African government and the Department of Health have made limited efforts to address the issue. This study aimed to explore the causes and consequences of FAS in South Africa using interviews and secondary data. Our findings highlight the pervasive and long-lasting effects of alcohol consumption during pregnancy, particularly cognitive impairments and physical developmental delays in affected children. In regions with high alcohol consumption, we found a direct correlation between higher rates of FAS and a lack of public awareness about the risks of drinking during pregnancy. Interviews with healthcare providers revealed significant barriers to prenatal care, with many expectant mothers in rural and economically disadvantaged areas unable to access timely guidance or screenings. These findings underscore the urgent need for action to address FAS in South Africa. The high prevalence of the disorder calls for substantial investment in awareness campaigns, particularly in rural communities, and improvements in healthcare infrastructure to ensure all pregnant women have access to education and prenatal care. Strengthening these areas is essential to reducing the long-term societal and economic costs of FAS and improving the well-being of affected individuals and families.

Abstract Name: Characterization of Inhalable Vocal Fold ECM in Treating Vocal Fold Injury

Endoscopic surgery, often resulting in irreparable vocal fold (VF) scarring, is a common intervention for laryngologists seeking to treat voice disorders caused by vocal fold (VF) injury. One tissue-engineering

approach to treating VF injury leverages tissue-specific porcine-derived extracellular matrix (ECM) hydrogels, given their low immunogenicity, inherent bioactivity, and morphological versatility. Recently, our laboratory has developed a porcine-derived vocal fold lamina propria ECM hydrogel (VFLP-ECMh) that preserves native proteins and exhibits anti-fibrotic properties through modulating TGF- β 1-mediated fibroblast activation in vitro. However, surgical intervention is required to administer this biomaterial. To mitigate challenges associated with endoscopic surgery, we developed a non-invasive delivery strategy; capitalizing on human respiration to deliver an aqueous VFLP-ECM extract directly to the VFs via nebulization (nebVFLPx). This study investigates the therapeutic potential of nebVFLPx for VF regeneration. We assessed biocompatibility of nebVFLPx by evaluating both its cytotoxicity and its anti-fibrotic activity in vitro. We've demonstrated that nebVFLPx is minimally cytotoxic when cultured with human dermal fibroblasts (HDF) for 24h as shown by Picogreen and MTT assays. RT-qPCR determined nebVFLPx reduced ACTA2 gene expression in HDF differentiated with TGF- β 1 24h prior to treatment. Additionally, to determine the required nebulization dose for future in vivo studies, we quantified the concentration of solubilized VFLP-ECM before and after nebulization using UV-visible spectrometry. Future studies will assess the correlation between nebVFLPx concentration and ACTA2 gene expression in HDF. To obtain deposition in the larynx during delivery in vivo, nebulized droplets should be between 4–7 μ m. We investigated ECM particle size via dynamic light scattering (DLS) and nebulized droplet size distribution using brightfield microscopy. DLS determined VFLP-ECM particles were 1- μ m in diameter after nebulization, droplets were between 5-6 μ m. This comprehensive characterization is crucial for advancing nebVFLPx toward preclinical studies for VF regeneration, offering valuable insights into its physical, chemical, and biological properties.

Abstract Name: Use of duration-of-transit measurements in determining the orbital inclinations and sizes of exoplanets

This project is a test of a new methodology for the measurement of the properties of exoplanet orbits that utilizes the data from the Transiting Exoplanet Survey Satellite (TESS). In this project I investigated variations in the light curve observed from stars over one-month periods and used that information to detect possible planets orbiting the star, as well as their size, orbital radii, and the angle that they pass across the disk of the star. This last property is a new measurement which has not been done before. I then looked for changes in the orbital angle over the course of multiple transits to determine whether this method could be used to detect not only exoplanet orbits, but also changes in the orbit over time. Being able to detect these orbital changes would represent a significant advance in exoplanet detection as they might be indications of additional planets which might not otherwise be directly seen in transit studies.

Abstract Name: Evaluating Text, Code, and Image Generation in Language Models

Large Language Models (LLMs) are learning models that are trained to be able to understand and generate text, code, and images given prompts. The process of creating prompts for these models is known as prompt engineering. This project presents an experimental study, where we take a closer look at how LLMs perform across different tasks, including writing stories, explaining and debugging code, and creating images. We also evaluate different techniques used for prompt engineering and the ability of LLMs to self-evaluate and improve its generated output. We use metrics such as correctness, relevance, creativity, clarity in our evaluations. Our experiments contribute valuable insights into understanding prompt engineering and boundaries in LLM generation. For example, our results show that text-based tasks such as code refactoring and test case generation have the highest scores for correctness and clarity, while explanations showed slightly lower clarity. For image generation, styles like "Painting" and "Photo" scored highest in quality, coherence, and relevance, while "Infographic" prompts had lower ratings and greater variability. These results suggest differences in how models handle logical representation across visual and textual outputs. When comparing different models, we found that, for example, GPT-4 and Claude-Sonnet are consistently strong across metrics, including quality, relevance, and creativity. On the other hand, models like GPT-4 Turbo and O1-Preview demonstrated occasional variability, particularly in relevance and quality. Qualitative feedback from evaluators highlights strengths in logical consistency and contextual understanding in LLMs but identifies challenges in generating highly creative or adaptive responses. Overall, our results showcase both the strengths and areas for improvement in the area of prompt engineering and identify cases where specific models or prompting techniques are better suited than others.

Abstract Name: The Seizure and The Shattering: Unnatural Feminist Narratology in Nonfiction Texts by Lauren Slater and Maggie Nelson

Brian Richardson's definition of "unnatural narrative theory" in "Unnatural Narrative Theory" set a precedent for narratologists and readers of unnatural narratives alike, describing it as the theory "of fictional narratives that defy the conventions of nonfictional narratives and of fiction that closely resembles nonfiction." What is missing from this definition, and the work of many papers on this branch of narratology, is the consideration of nonfiction works that employ the unnatural. This presentation will first explicate two examples of unnatural narratology within the nonfiction genre: *Lying: A Metaphorical Memoir* by Lauren Slater and *The Argonauts* by Maggie Nelson. Both defy genre conventions and the "natural" structure of memoir through nonmimetic and antimimetic elements, including unnatural temporal order, intertextuality, and genre hybridity. Slater and Nelson accomplish the transgression of traditional narratology through two different approaches: where Slater blurs the demarcation between truth and fiction under the guise of a memoir, purposely writing into the form as a way to break it apart from the inside, Nelson employs the unnatural by writing away from the memoir and into a work of "autotheory" which breaks the binaries of gender and genre alike. This presentation will then examine how the latter – gender and genre – are inextricably bound in these

works, therefore qualifying both as unnatural feminist narratologies. What is accomplished in these texts is not only the successful subversion of a genre largely ruled by an allegiance to the “natural” modes of writing and patriarchal order, but also the inception of feminist theory and hybridity within the memoir – an apparatus of unnatural narratology serving as an emblem for the future of feminist creative nonfiction. Ultimately, this presentation will argue that Slater’s and Nelson’s works are important seminal texts for deconstructing genre boundaries in nonfiction because they successfully implement unnatural feminist narratology.

Abstract Name: The Economic Feasibility of Nuclear Small Modular Reactor (SMR) Technology in the United States

In the face of global climate change and increasing energy demands, the debate over nuclear power's role in the energy mix remains highly relevant. As the United States seeks to reduce its carbon footprint while ensuring a sustainable and cost-effective energy supply, nuclear Small Modular Reactor (SMR) technology presents a potential option alongside other sources. SMRs are characterized by inherently safe engineering and lower upfront and long-term costs, offering a possible zero-carbon energy source capable of meeting substantial baseload electricity needs. This thesis will conduct a cost-benefit analysis to assess the overall feasibility of SMR technology in the U.S. energy mix, including both the financial and societal impacts. To do this, I will first evaluate whether SMRs provide a safe, stable, and cost-efficient energy alternative to traditional nuclear technology by comparing their fixed, variable, operating, and maintenance costs and dissecting respective safety and waste production aspects. After this, I will compare the projected Levelized Cost of Energy (LCOE) and return on investment metrics of SMR technology with both solar and wind energy to determine financial viability. Additionally, a major component of the macroeconomic implementation of new technologies is public perception, something particularly important when discussing nuclear power. This thesis will gauge the public perception of SMR technology by conducting a nationally-representative survey of 1,500 participants ran using Prolific, a respected online survey platform widely used in economic studies. These surveys will offer insights into the societal impact of SMRs, helping to quantitatively assess whether public willingness to accept aligns with the potential of Small Modular Reactors. Through this gained understanding of the technical, financial, and societal factors of SMR technology, I will provide a comprehensive assessment of SMR technology's economic feasibility and potential role in the U.S. energy mix.

Abstract Name: Understanding the human burial signatures using ground penetrating radar and magnetic gradiometer: A case study on Agua Mansa Pioneer Cemetery

Surface geophysical surveys using ground penetrating radar (GPR) and magnetic gradiometer will be used to understand the burial signatures at the Agua Mansa Pioneer cemetery. Agua Mansa was a 6.3-acre pioneer cemetery in Colton, California that was actively burying from 1854 to 1963. Currently, the cemetery site consists of the ruins of an old church, a replica church, and many unmarked graves. According to burial records, there are approximately 2,000 human burials known at this site with only a few hundred headstones still standing. The settlement was established in the 1830s by settlers from Abiquiu, New Mexico. Up until 1862, Agua Mansa was a prevalent farming settlement when a flood destroyed most of the settlement which never fully recovered. The cemetery was not affected due to its location on a hilltop, most of its destruction came in the early 1900s when it was vandalized. GPR is a non-invasive geophysical technique that utilizes electromagnetic waves to map the subsurface. The magnetic gradiometry is a second non-invasive geophysical technique that identifies any anomaly with an anomalous magnetic body. Together the two methods will provide more in-depth data to indicate locations of unmarked burials while the signal characteristics will correlate from marked burial signatures. Additionally, through surface survey and historical background research, the types of burials at Agua Mansa will be identified. Expected results of this project include identified locations of unmarked graves characterized by high amplitude reflectivity in 3D surface maps and magnetic low. However, the presence of any metallic object with the burial may also result in magnetic highs.

Abstract Name: This study examines LGBTQ+ self-discovery after 40, exploring psychological, social, and cultural influences, including mental health, life experiences, and societal barriers, aiming to promote inclusive policies and broaden identity understanding.

This study explores the process of LGBTQ+ self-discovery and coming out for individuals aged 40 and beyond, a demographic that challenges ageist assumptions and broadens the understanding of identity formation. With an increasing number of LGBTQ+ individuals embracing their authentic selves later in life, this research aims to address the unique psychological, social, and cultural factors influencing their journeys. Through a mixed-methods approach, this study examines the mental health implications, social support systems, intersectional identities, and the impact of life experiences such as previous marriages, parenthood, and careers. The research also investigates the barriers and opportunities faced by these individuals in the realms of health care, legal issues, and workplace dynamics, as well as the role of media in shaping late-in-life self-discovery. By focusing on the lived experiences of LGBTQ+ individuals over 40, this study seeks to inform more inclusive policies, support systems, and societal attitudes, promoting mental health and well-being across all stages of life. Ultimately, this work contributes to the growing body of literature that validates diverse life paths and timelines for LGBTQ+ identity formation.

Abstract Name: Exploring Mixed Media Pipelines for Animated Short Films

This project is researching the many ways mixed media can be achieved in UW Stout's Senior Animation Capstone course. We aim to figure out how accessible it is to create a mixed media short throughout the course of one year. Looking at past senior thesis films, many students have veered towards using solely 2D animation for their capstone course- even though the program sequence for the animation BFA heavily pushes for use of 3D methods. We hope that experimenting with mixed media will allow for students to utilize every skill they have learned from courses required for the animation degree. We will create an animation that combines 2D animation with 3D environments and characters, using resources from the school and beyond. Mixed media includes different types of animation, texture, and even music. We want to explore collaborations between students and composers to enhance future UW Stout animation student's thesis films with narrative scores. We hope to find that the pipeline is manageable for students to do, allows for pointed portfolio pieces, creates a better workflow for capstone, matches industry standards, and bridges the gap between music production and narrative shorts.

Abstract Name: Mutually-Exclusive Interaction of Connexin 43 with Src and ZO-1 is Regulated through a Single Phosphorylation Event

Connexin 43 (Cx43) is a transmembrane protein that forms gap junctions (GJs) - cellular channel structures necessary for direct cell-cell communication. Cx43 GJ function is regulated through phosphorylation on the serine and tyrosine amino acids along Cx43 C-terminus (CT). Functional, open GJ channels interact with a scaffolding protein, zona occludens 1 (ZO-1). However, the interaction of Cx43 GJs with a non-receptor tyrosine kinase Src closes GJ channels, thus decreasing cell-cell communication. In turn, the binding of Src to Cx43 also helps regulate Src's oncogenic activity. While it is well-established that Cx43 is unable to interact with both Src and ZO-1 simultaneously, the molecular mechanism that regulates these mutually exclusive interactions remains unknown. Our laboratory screened mutants of Cx43 and observed that mimicking serine 373 phosphorylation on Cx43 recruits Src, while ZO-1 is unable to interact with Cx43 when this site is phosphorylated. On the other hand, Src interaction with the phospho-dead (alanine) mutant of Cx43 was decreased. We hypothesized that S373 phosphorylation serves as a regulatory switch that dictates whether Cx43 will interact with Src (when phosphorylated) or with ZO-1 (when not phosphorylated). We conducted pull down assays between purified, GST-tagged CX43CT S373 mutants and Src in healthy cells and cancer cells. In addition, we utilized a truncated mutant of Cx43CT lacking the last four C-terminal amino acids, thus preventing its interaction with ZO-1. Our results demonstrate that the S373E mutant, as well as the truncation mutant, were able to recruit Src more effectively when compared to the S373A and WT Cx43. Importantly, expression of the Cx43 S373E mutant decreased levels of Src-driven cell proliferation in prostate

cancer cells when compared to the expression of the S373A mutant. This work provides evidence that Cx43 phosphorylation dictates Src and ZO-1 recruitment to Cx43CT in both healthy epithelial cells and cancer cells.

Abstract Name: The Effects of Nature Therapy on Stress

Stress is extremely prevalent within our modern-day society. The need to earn an education, maintain a steady income, support family members, and spend time with friends can cause intense pressure. Recently, research teams have been looking for new and effective ways to decrease stress levels. Our project focused on the effects of nature therapy on stress. Nature therapy involves an individual connecting mindfully with nature, a process which has been demonstrated to improve one's physical and mental health. Because stress is not an easy subject to measure, our study involved objective measures (ex: heart rate, blood pressure, heart rate variability, sleep score, stress score, and salivary cortisol and alpha-amylase levels) and subjective measures (ex: surveys). For the first half of the four-week study, individuals continued their daily routines for baseline stress measurements. During the second half, participants completed nature therapy activities to determine if the nature therapy reduced the stress measurements. The goals of our study included assessing the impact of nature therapy on the objective and subjective measurements of stress in this small pilot study (N=10) and determining which stress measurements are best for larger, future nature therapy studies. This study, involving human subjects, was approved by Westminster's Institutional Review Board, and confidentiality was maintained on all participant data. The results of our data show a statistically significance decrease in perceived stress following the two weeks of a nature therapy intervention. There were also several individuals who were found to have significant findings for certain stress-related metrics. These results bring up the question of whether specific people are more susceptible to the benefits of nature therapy. Correlation analysis indicates a number of our stress metrics are positively correlated. This small, pilot study indicates that nature therapy does reduce perceived stress. It also provides the groundwork for larger stress-related studies.

Abstract Name: Nutritional Knowledge, Dietary Habits, and Protein-Iron Intake: A Comparative Study of Omnivorous and Plant-Based Diets in College Athletes

Individuals generally adhere to one of three dietary patterns: vegan, which excludes all animal products, vegetarian, which is primarily plant-based but may include select animal-derived products, and omnivorous which incorporates both plant-based and animal-based sources. As plant-based diets become increasingly popular in the general population, their adoption is likely to rise among collegiate athletes. However,

concerns persist regarding the adequacy of protein intake in plant-based diets and its impact on athletic performance. While research supports that well-balanced plant-based diets can fulfill nutritional requirements, the specific dietary adequacy and nutritional knowledge among collegiate athletes remains insufficiently studied. This study investigates athletes' perceptions of sports nutrition and evaluates the sufficiency of their dietary intake in meeting performance-related nutritional requirements. We further assess the alignment of reported caloric and protein intake with established recommendations. Using an original survey of collegiate athletes (n=59), we found that while 98.3% of athletes are aware of their protein requirements, 50.9% perceive a deficiency in their intake, underscoring a gap between knowledge and practice. Moreover, while 59.3% of athletes often believed their caloric intake to be adequate, preliminary analysis of a 3-day dietary log suggests actual intake may fall short of perceived needs with athletes reporting an average intake of 1,105 calories below recommendations. This study provides critical insights into the dietary practices of collegiate athletes, highlighting the need for improved nutritional guidance tailored to athletes. This research also addresses a significant gap in the literature regarding the interplay between dietary choices and nutrient sufficiency in athletic populations.

Abstract Name: Battle of the Sexes: The Impact of Gender on Household Spending and Saving

What factors influence the spending behavior of Americans? Arguably, one of the most significant and relevant indicators of the U.S. economy is the spending and budgeting patterns of households. The Federal Bureau of Labor Statistics tracks these patterns, along with other key economic indicators, to assess the overall health of the national economy. I hypothesized that gender did not have an impact on saving, spending, and budgeting patterns in American household. I conducted research by creating a questionnaire and collecting 142 completed surveys through Amazon Mechanical Turk. The data was analyzed using IBM's SPSS software. My results showed me that gender was a defining factor among respondents. I found a significant difference in the responses from different genders. While 86.1% of females agreed or strongly agreed that they noticed increased prices, only 61.8% of males replied similarly. This was statistically significant at less than 1%. I also saw 52.7% of females admitted they save between \$3001 to \$5000, as opposed to 17.3% of males who said they save an amount within the same range. This finding was found statistically significant at the <1% level. These findings contradicted my hypothesis. From this I can conclude that more females are likely to confidently claim that there have been price increases in necessary goods and services. Females are also more likely to save more monthly for future goals. I believe that the public could take advantage of this knowledge to recognize the differences between genders in the economic and financial sphere.

Abstract Name: Relationships Between Perceptions of Older Adults and Willingness to Work Among

Undergraduate Healthcare Students

This study aims to identify the perceptions that undergraduate students with a healthcare-focused major and/or minor at James Madison University have towards older adults, as well as identify these students' willingness to work with older adults as their intended patient population. The primary objective of this research is to see what relationships exist within these two variables, followed by looking at the differences across demographic groups and fields of study. The analyses may expand knowledge and advance understanding about ageist perspectives and how it will influence the future of healthcare. Currently, there is a lack of research on the identified variables; literature exists about specific careers in healthcare, such as nursing, but not analyzing several health professions together. Much of the research that has been done on willingness to work with older adults is also exclusive to Asian participants, so there is a need for expanded research in the United States. With the present lack of future healthcare professionals willing to work with this population, there will be gaps in care for older adults, which will create problems within the healthcare system, such as increasing rates of age-related disabilities and deficiencies in quality of long-term care. From December 2024 through January 2025, data will be collected using an instrument derived from two existing surveys: the Fraboni Scale of Ageism and the Willingness to Work with Elderly People Scale. Pearson correlations will be conducted analyzing the independent variables of perceptions of older adults among the sample and sub-samples and dependent variable of willingness to work with older adults aiming to identify and the possible impact perceptions may have on willingness to work with this population. The insight from the study may assist in improving healthcare education and training, strengthening the desire and willingness to work with older populations.

Abstract Name: The Influence of Experimenter Gender on Hormones, Behavior, Physiology, and Voice

Subtle contextual factors can shape behavioral outcomes, making scientific reproducibility difficult. Experimenter gender may be a factor contributing to between-study variance, yet it frequently goes unreported. This lack of reporting could be an important variable to the ongoing reproducibility crisis (Klein et. al., 2018). Research across multiple disciplines shows that experimenter gender can affect participants' pain perception, hormones, and decision-making processes (for review see Chapman et al., 2018), however no single study examines the impact of experimenter gender on hormones and hormonally-dependent behavior and physiology simultaneously. Our study systematically explores how experimenter gender affects participants' estrogen and testosterone levels, risk-taking behavior, grip strength, anxiety, and voice. We examined these effects in both male and female participants. All measures were collected from participants on three consecutive days. On each day, the participants interacted with either a male experimenter, female experimenter, or no experimenter, in a randomized order. Preliminary results suggest that experimenter gender influences risk-taking behavior, with females taking more risks around female experimenters compared to male experimenters, while males took more risks around female experimenters. Our findings also indicated that experimenter gender affects vocal stability, with male participants showing the highest amplitude instability in the presence of a female experimenter and the lowest in the no-experimenter condition. We are currently conducting an additional study to determine whether these vocal changes impact listener perception of the speaker across multiple attributes (e.g. attractiveness, confidence, trustworthiness, etc.). Enzyme-linked immunoassays will be used to determine whether salivary hormones can predict the

behavioral and physiological changes. These findings highlight the importance of reporting the experimenter's gender in research, as it may influence participants' physiology, behavior and vocal acoustics. By analyzing this overlooked variable, our study contributes to a deeper understanding of factors that may impact replicability issues in scientific research.

Abstract Name: Vignette Analysis of Bystander Intervention Strategies: Contexts of Negative Alcohol Consequences

There is a culture on college campuses that promotes excessive drinking and thus can lead to a number of dangerous situations including sexual assault, alcohol overdose, and other related injuries. One method of combating this issue includes university training modules that aim to shape students into what is referred to as an “engaged bystander” to promote safer drinking environments. A plethora of research has been conducted on bystanders' personal barriers and motivations with respect to sexual assault interventions. However, there is a relative paucity of literature examining bystanders to alcohol consequences. Therefore, the current project will 1) develop a measure of alcohol-related bystander perceptions; 2) assess the relationship between drinking location and endorsement of the bystander strategy; and 3) explore the likelihood of intervention depending on the state of (e.g., intoxicated or not) and the gender of the drinker in the story. Participants will be from one university and will complete the survey online. The survey will have eight vignettes counterbalanced between male and female presentations. These vignettes are composed of both open-response and multiple-choice questions that propose a specific situation and ask participants to describe their thoughts and intentions when a friend is experiencing negative consequences due to alcohol consumption. Data collection is ongoing. Potential results from this study have several implications. For example, if students report a lower likelihood of intervening based on location, intoxication state, or gender, different bystander training interventions can be developed. In addition, these differences may provide initial evidence of biases that the participants might have.

Abstract Name: Practice Domestic Architectures: a survey and speculation on subversive spaces

This research aims to investigate a curious architectural type nearly lost to history and susceptible to being forgotten by posterity: the practice cottage. There exists little documentation considering its ubiquity in the

early-mid 20th century. How can this type, originating from the home economics (HE) movement, be documented, celebrated, preserved, and recontextualized using architectural analysis? By challenging preconceived notions of HE as sexist, regressionist, and disabling, this analysis attempts to reposition HE and the practice cottage as sites of both gender and racial subversion. In 1919, the term “practice cottage” was first used in the annual report of the Federal Bureau for Vocational Education (FBVE), funded by the Smith-Hughes Act of 1917. After the passage of this act, dozens of single family homes were constructed on college campuses for HE departments. They were described as “fitted up as an average home... in which the vocational students carry on all of their work.” (see link) Cohorts of young women, led by female faculty, would live and work at the house, a 1:1 laboratory for care work skills. These buildings subverted the typical understanding of a heteronormative, single family home, becoming a space for and by women, without male oversight. Under the guise of preparation for the ultimate, stereotypical female role—homemaker—these buildings supported unconventional relationships, communal living, and higher education for women, a type of quiet liberation. This research proposes a cohesive survey of the practice cottage, utilizing archival architectural documentation along with relevant government reports. The project will produce a congruent drawing collection, 3-d digital models, and written analysis, uncovering latent social and spatial relationships. This research suggests that looking towards a radical past might provide insights on potential futures. In our increasingly complex contemporary context how might the field reconsider “practice” domestic architectures as sites of subversion and liberation?

Abstract Name: Sociodemographic disparities in uninsurance rates for Medicaid expansion versus non-expansion states

OBJECTIVE: To compare uninsurance rates by sociodemographic characteristics in Medicaid expansion states (California, New York) versus non-expansion states (Texas, Florida). **BACKGROUND:** Health insurance is a key determinant for health care access. In 2014, the Affordable Care Act introduced an optional Medicaid expansion for states to extend health insurance eligibility to low-income adults. While some states adopted the expansion, others opted out. **METHODS:** Using publicly available data from the US Census Bureau (data.census.gov), we extracted 2023 uninsurance estimates and percentages by select sociodemographic characteristics (sex, age, race/ethnicity, and citizenship status) for California, New York, Texas, and Florida. These states were selected as proxies for expansion and non-expansion states given their similar demographic populations (e.g., large proportion of Latinos and noncitizens) and differing political climates. **RESULTS:** Texas and Florida had overall higher uninsurance rates (16.4% and 10.7%, respectively) compared to California and New York (6.4% and 4.8%, respectively). For non-expansion states, the groups with the highest uninsurance rates were males (TX: 17.4%, FL: 12.1%), 19-64 year-olds (TX: 21.7%, FL: 15.5%), Latinos (TX: 25.6%, FL: 15.6%) and American Indian/Alaska Natives (TX: 21.8%, FL: 33.8%), and non-citizens (TX: 46.8%, FL: 29.7%). Meanwhile, those same groups had lower uninsurance rates in expansion states: males (CA: 7.5%, NY: 5.8%), 19-64 year-olds (CA: 9.0%, NY: 6.8%), Latinos (CA: 10.4%, NY: 9.7%) and American Indian/Alaska Natives (CA: 11.5%, NY: 14.0%), and non-citizens (CA: 20.5%, NY: 17.4%). **DISCUSSION:** Overall, the selected non-expansion states had worse uninsurance rates compared to expansion states. These results persisted across sociodemographic characteristics. These findings evidence how state policy climates can impact an individual’s access to care and exacerbate disparities for different subgroups.

Abstract Name: Fanfiction as a Reflection of Available Representation: A Critique on Mass Media

With the lack of reputable disability representation in popular superhero media, fans turn to fanfiction to write the representation they long for. This absence of proper representation in media can feel like the erasure of disability, and in compensation, fanfiction paves the way for authentic representation in media. Fanfiction authors do this by reacting to specific choices made by the mass media outlets through their creations. Fan studies scholars have examined fan reactions for decades, categorizing them into two groups: affirmative (agreeing with the source material) and transformative (disagreeing with the source material). Affirmational fans interpret the canon text without challenging its ideologies, expanding upon it in ways that remain consistent with the original narrative. Transformational fans challenge and shift the canon text into something different. Fanfiction is considered a transformative reaction. Informed by disability studies and fan studies, this research aims to study fan reactions around disability to understand what it is they affirm/transform from the source material. When a disabled identity is explored in the canon, do the fanfictions respect it? Or do they choose to alter it? What about an able-bodied identity? What facets of identity are the ones that receive alteration as opposed to approval? By analyzing 2,000 fanfictions within the MCU and DCU, this rhetorical critique will encourage future rhetoricians to think critically about the realities they affirm/transform from media representations. This methodology, as a part of a broader project, will lay the foundation for a more comprehensive rhetorical critique of the representational choices made by mass media outlets. This analysis will reference models of disability, such as the medical, social, and identity model, to deepen our understanding of these representational dynamics. In doing so, this research will contribute to the ongoing conversation regarding the responsibility of artist and audience.

Abstract Name: Enhancing the Efficacy of Adoptive T Cell Therapy for Patients with Diffuse Large B-Cell Lymphoma by Ablating Galectin-3–Ligand Interactions

Diffuse large B-cell lymphoma (DLBCL) is a major form of non-Hodgkin lymphoma that impacts over 10,000 individuals annually. This malignancy often relapses and is refractory to initial standard therapeutic approaches, underscoring the need to develop innovative therapies. Chimeric Antigen Receptor (CAR)-T cell therapy is a promising immunotherapy approach using patient T cells engineered to express CARs targeting cancer cell surface markers that are adoptively-transferred back into patients to elicit anti-tumor T cell activity. While therapeutic responses are promising, there is a need to develop a more effective CAR-T cell

formulation with enhanced anti-tumor efficacy and in vivo persistence. Early data from our laboratory suggest that DLBCL patients exhibit heightened serum levels of galectin (Gal)-3 that could bind Gal-3 ligands on CAR-T cells and dampen functional activity and even induce cell death. We hypothesize that interference of Gal-3 binding to CAR-T cells could protect CAR-T cells from the immunodampening effects of Gal-3 to thereby enhance CAR-T cell therapy against DLBCL and improve patient outcomes. In this project, we will evaluate the effects of a novel orally-active Gal-3 inhibitor, GB1107, designed to block Gal-3 binding to its ligands on cell surfaces. We will conduct flow cytometry-based binding and cell death assays using GB1107, recombinant human Gal-3 (rhGal-3), annexin-V/propidium iodide probes, and in-house prepared CAR-T cells to assess whether GB1107 can block Gal-3 binding to CAR-T cells and protect them from Gal-3-mediated cell death. In addition to examining dose-dependent inhibitory activity against Gal-3 binding to T cells, we will also assess selectivity of GB1107 against blocking Gal-3 by comparing potential blocking activity to other common galectins, Gal-1 and Gal-9. Resultant data will offer new insights into how Gal-3 modulates immune responses in DLBCL and show whether a Gal-3 inhibitor can potentially enhance CAR-T cell function in patients undergoing CAR-T cell therapy.

Abstract Name: Dissecting the role of Rep68 structural motifs on Adeno-Associated virus replication.

Adeno-associated virus (AAV), specifically serotype 2, is a human parvovirus in the Parvoviridae family, known for its low immunogenicity and ability to infect a wide variety of cell types. This makes AAV a valuable tool in gene therapy, where the AAV genome can be modified to replace viral genes with therapeutic genes of interest. Thus it has promise in gene therapy and treating genetic disorders such as muscular dystrophy, hemophilia, and certain forms of blindness. It also has implications in cancer research and for studying gene function. AAVs consist of a single-stranded DNA genome that is non-enveloped and dependent on helper viruses, such as adenoviruses or herpesviruses. The protein Rep68 is focused on because its critical DNA binding and helicase-ATPase domain activities are important for AAV replication. Specifically, this study used the AAV Helper-Free System to produce AAV2 particles without requiring the use of a helper virus, simplifying the process and prioritizing the production of essential plasmids for AAV replication. Using plasmids pRC2 (expressing Rep and Cap genes), pHelper (expressing adenoviral helper functions), and pAAV which codes for Green Fluorescent Protein (GFP), we aim to test the effects of the Rep68 mutants F364A, C405H, H456A, and H582A on replication efficiency and the mechanisms by which Rep68 facilitates viral DNA replication. Microscopy images of Pro 293-T cells after plating and 24 hours before transfection showed ideal cell culture confluency with no contamination. However, the western blot and fluorescence microscopy results did not show sufficient GFP expression thus we were unable to test the mutants yet. In future research, PEI can be used in place of the phosphate calcium protocol for transfection to be able to test the mutants. Ultimately by learning more about how Rep68 facilitates viral DNA replication, AAVs can become better vectors for gene delivery.

Abstract Name: How College Students Perceive Domestic Violence in The United States: An Interview Study

As domestic violence has increased in the US since the 2020 Covid Pandemic, its impact has devastated many American lives. Perception of this violence plays a key role in its continuation as society's beliefs on this topic can greatly influence how it is addressed culturally and legally. This interview study examined how college students in the United States, one of the most vulnerable populations to intimate partner violence, perceive domestic violence. 18 college students from a large public university located in Virginia were recruited using formal and informal networks of college students through the process of snowball sampling. Semi-structured qualitative interviews that entailed open-ended and conversation-based questions were securely administered through Zoom. The questions approached topics such as base-line definitions, legality, victims, personal connections, and mental schemas. Qualitative data analysis through the means of analytical memos and closed coding were then conducted on the transcripts. Preliminary findings show that emerging themes include cycles of abuse, societal and legal shortcomings of justice, and the patterns of stereotypes. The perception of abuse being circular signified that violence can be viewed as inherently perpetual and even generational. Participants believed the justice system does not bring justice to survivors and they faulted the ease of believing abusers and victim blaming. However, they acknowledged the nuances of proving someone as guilty. Participants were able to identify demographics that they thought to have more abusers vs survivors. This displayed clear prejudice which opened the door to question how this can affect outcomes for both survivors and abusers.

Abstract Name: Understanding the Experiences of Caregivers of Pediatric Patients with Neuromuscular Disorders Using Noninvasive Ventilation

The overall objective of this research is to understand the experience of caregivers of pediatric patients who use noninvasive ventilation (NIV) for respiratory support as a result of a neuromuscular disorder (NMD). A brief questionnaire will initially be administered to gather demographic information. A descriptive qualitative approach will be used. Data will be gathered using semi-structured interviews. Audio and/or video recordings of each interview will be transcribed using Zoom and destroyed after confirming accuracy of transcription. Deductive thematic analysis will be performed with the transcribed interviews to gain a better understanding of the experiences of caregivers of pediatric patients with NMDs who use NIV.

Abstract Name: Dynamic Blade Design: Bridging the Gap Between Walking and Running

Amputation of the lower limb impacts mobility and quality of life for over 1 million people worldwide annually, and post-operative recovery is prolonged and imperfect. Research shows that existing prosthetics only mimic natural biomechanics 30% of the time, and in cases of failure, 60% of the time are due to stresses of walking, running, etc. We originally designed a blade that mimicked the walking and running blades currently on the market by sharpening the bends of a running blade and flattening the bottom. But soon realized that this design was only the first step of closing these gaps, we decided to transition to a bio mimic approach where we effectively took lessons from kangaroos, dogs, and humans to inform a more resilient and functional prosthetic blade that could better approach the functionality of the missing limb. Kangaroo legs have a similar structure to the original blade design, but their muscles add more support and make their legs more resistant to the ground force reactions produced when they jump. The dog's hind leg anatomy is like the kangaroo's but on a smaller scale which gives us better proportions for the blade while maintaining the power output. For the human feet, the design process was broken into three sections: the heel, the arch, and toes. The bone structure found in the human foot gives it the strength to withstand the impact of heel strike and toe push, and the muscles add the elasticity needed for the foot to flex upon impact and return to its initial shape. The heel required a sturdier material while the arch and upper foot would be made with a more flexible material, and then the toes would be made with a material with a higher elastic value so that they could provide additional spring during dismount.

Abstract Name: The Relationship between Sleep and Food Choice in a College-Age Population

Introduction: College students are at greater risk for sleep deprivation and poor-quality nutrition compared to other populations. Interventions that target sleep hygiene may improve overall health, decreasing the chronic disease risk and its detrimental impact on quality of life and healthcare spending. Sleep deprivation is linked to increased food motivation, decreased self-control around food, and increased consumption of calorie-dense, nutritionally depleted foods (Rihm et al., 2019; Benjamins et al., 2020). Purpose: This study examines how sleep hygiene affects food choices in a college-aged population. Methods: Participants were interviewed about sleep patterns and food choices using the Sleep Quality Survey (SQS) and the National Institute of Health's Fruit/Vegetable Quick Food Scan. Data on food intake were also collected. Open-ended questions were used to gather qualitative data on sleep and its impact on food choice. Descriptive statistics and Pearson's correlational analyses were conducted to examine the relationship between sleep patterns and food choices. Results: Twelve female subjects and one male subject, with a mean age of 25.9 years (SD = 4.6), completed the study. The average hours of sleep per night was 7.2 hours (SD = 1.0), which meets the American Sleep Association's recommendation of 7 hours. Moderate inverse correlations between sleep duration and sugar intake and between sleep quality and BMI were identified ($r = -0.46$, $r = -0.42$).

respectively); however, these were not significant ($p > 0.05$, both). No other statistically significant relationships were found between sleep and BMI, mean energy intake, added sugar intake, fiber intake, or sodium intake for this population. Conclusion: In this study, sleep patterns were not significantly associated with food choices. Further investigation with a larger sample size, focusing on participants with inadequate sleep, will help to clarify the relationship between poor sleep and food choices.

Abstract Name: Breaking Barriers: Women's Representation and Challenges in STEM Careers

The underrepresentation of women in STEM careers persists as a significant challenge despite decades of progress in gender equality. This research explores the multifaceted barriers faced by women in STEM, including cultural biases, systemic obstacles, and the lack of role models, while highlighting actionable strategies for fostering a more inclusive environment. Drawing from a combination of qualitative interviews and quantitative data analysis, this study investigates how workplace dynamics, educational pipelines, and mentorship programs influence women's participation and retention in STEM fields. The findings reveal persistent stereotypes that discourage young women from pursuing STEM careers, unequal access to opportunities for professional development, and the challenges of navigating male-dominated environments. Additionally, the research underscores the importance of early interventions, such as hands-on STEM experiences for girls, and institutional reforms aimed at dismantling discriminatory practices. A critical analysis of successful case studies demonstrates how targeted initiatives, including diversity-focused recruitment and retention strategies, can effectively bridge the gender gap in STEM. This study also proposes a framework for creating supportive ecosystems that empower women in STEM through mentorship, sponsorship, and community-building efforts. By addressing structural inequities and amplifying the voices of women in STEM, this research aims to contribute to the broader goal of achieving gender equity in innovation-driven industries. Ultimately, this work seeks to spark dialogue among educators, policymakers, and industry leaders about the urgent need to break barriers and create opportunities for women in STEM, fostering a future where diverse perspectives drive scientific discovery and technological advancement.

Abstract Name: Nano-Hydroxyapatite vs. Fluoride: The Fight for Remineralization

Nano-hydroxyapatite is becoming an increasingly popular ingredient in fluoride-free oral hygiene products. The intent of this research is to settle the debate: Which product yields more effective results in the overall fight for remineralization? Our research uses quantitative studies found in scholarly, peer-reviewed articles. A trendy subject for those interested in a more holistic lifestyle, nano-hydroxyapatite is a biocompatible, biomimetic agent. It is a nanoscopic synthetic derivative from hydroxyapatite, which is a naturally occurring mineral found in bones and teeth. Since nano-hydroxyapatite is still relatively new to the dental market, the

overall efficacy is currently under discussion. Fluoride is the current gold standard for remineralization that has been researched and supported by dental professionals for decades. When comparing the two, nano-hydroxyapatite has not yet been seen as an equal. The articles we reviewed used in vitro, single-blind, and double-blind methods to accumulate effective research. Each study used a controlled amount of demineralized enamel as the subject, and separately applied nano-hydroxyapatite and fluoride products directly onto the enamel. These studies then compared the extent of remineralization after a prolonged time, ranging from immediate results to 6 months. Three studies demonstrated that fluoride had a significantly greater outcome in its effectiveness than nano-hydroxyapatite. In contrast, the results of three different studies that compared similar products showed that nano-hydroxyapatite was the superior out of the two. A final study was reviewed showing that there was no significant contrast in comparison of the two seemingly equal products, reinforcing the tie. With this insightful information, we have concluded that nano-hydroxyapatite and fluoride are equally as effective in the process of remineralization. With a promising future, nano-hydroxyapatite proves itself as a strong contender within the scope of dentistry.

Abstract Name: Cultural Center for Fostering Inclusivity and Diversity: Focus on Learning About Latin American and Hispanic Culture

The project explores the creation of a cultural learning center designed to preserve and celebrate Hispanic and Latin American heritage while fostering cross-cultural understanding. The primary research question centers on how such a facility can empower individuals to embrace their cultural identity, facilitate the intergenerational transmission of traditions, and create a sense of belonging within diverse communities. The center's purpose is to address the challenges faced by Hispanic and Latin American populations in maintaining their cultural heritage amidst the pressures of assimilation and cross-cultural interactions. The growing disconnect between Hispanic and Latin American communities and their linguistic and cultural roots highlights the importance of this research. Studies indicate that third-generation Hispanic individuals in the United States often lose fluency in Spanish and face judgment from their community for it. Simultaneously, there is a widespread desire among Hispanics for future generations to retain their language and cultural heritage. This project aims to provide a unique contribution by addressing this gap through design solutions that emphasize inclusivity, accessibility, and cultural engagement. The research includes literature reviews of existing cultural centers, case studies of successful inclusive design projects, surveys and interviews with Hispanic and Latin American individuals, and analysis of demographic and cultural trends. The center also features an auditorium, café, children's center, library, workshops, classrooms, meeting areas, and a gift shop, creating an inclusive space for cultural learning, community-building, and celebrating Hispanic and Latin American heritage. The project is expected to result in a design that fosters cultural pride, intergenerational dialogue, and cross-cultural understanding. The center's impact will extend beyond its physical structure, enriching family life and community cohesion. By addressing language preservation, cultural education, and social inclusivity, this project will offer a framework for building environments that celebrate diversity and unity in a globalized world.

Abstract Name: Reddit Netnography Exploring (Ex)Cannabis Users' Hedonic and Eudaimonic Well-Being Outcomes and Understanding the Role of Online Forums for Informal Health Communication

Cannabis use can have profound impacts on health and well-being outcomes. These outcomes can be analyzed from the hedonic-eudaimonic well-being theory. Hedonic well-being refers to momentary pleasures, discomforts, and sensations, while eudaimonic well-being refers to fulfillment, actualization of goals, and developing meaningful relationships with oneself and others. Due to the widespread legalization and liberalization of cannabis in the U.S., it is important to explore how (ex)cannabis users perceive and experience these well-being factors. Furthermore, it is timely to learn how cannabis health outcomes are communicated among (ex)cannabis users. Studies have found that social media platforms can offer meaningful spaces for health communication and successfully encourage health improvement. Thus, this research is two-fold: (1) seeking to explore how (ex)cannabis use impacts hedonic and eudaimonic well-being and (2) to understand the online platform, Reddit, as an informal health communication channel. The data were collected from four cannabis-focused Reddit communities. The study follows netnographic methodology using constructivist grounded theory for data analysis (i.e., adhering to the initial, focused, and theoretical coding). In total, 2532 posts were collected from the various online communities. The current preliminary data analysis includes 435 coded posts. The preliminary findings indicate that cannabis use can have both positive and negative effects on hedonic and eudaimonic well-being. For instance, the data suggests cannabis can contribute positively toward enhancing social connections while negatively impacting one's purpose in life, which represent eudaimonic well-being meanings. Regarding hedonic well-being, cannabis' positive impacts are related to pleasure, while negative outcomes are related to emotional outcomes. Additionally, the data shows that Reddit offers a supportive channel for discussion of sensitive topics related to one's overall health. Previous studies have also found Reddit to be an effective platform for discussing cannabis experiences. These findings can inform cannabis education and shed light on digital health communication.

Abstract Name: Pain and Palliative Care Among Hospitalized People Living with Dementia Who Are Hospitalized

Dementia is an umbrella term for a group of neurodegenerative diseases that may affect many aspects of bodily function and interfere with numerous daily activities. Along with disease progression, people living

with dementia experience progressive declines in cognitive, functional, and communicative capacities. This increases the risks of PlwD experiencing inadequate health-related management while unable to advocate for their own needs or preferences in care. One of the most important and recognizable beings, people living with dementia (PlwD) are likely to experience unrecognized or under-managed pain due to the presence of dementia. Palliative care is a philosophy of care that aims to provide structured, continuous care with consideration of a person's overall well-being. PlwD, especially those in more advanced stages, have trouble communicating their pain or discomfort, and palliative care is useful because it focuses on managing those symptoms using comfort-based pharmacological and nonpharmacological strategies. Pain is particularly a problem in treating PlwD because it can lead to increased agitation and behavioral disturbances, decreased participation in rehabilitation, an impaired immune response, overuse of psychotropic medications, and overall worsening cognitive health. We aim to examine the changes in pain-related symptoms of PlwD in the hospital setting before and after palliative care subspecialty consultations. We will conduct a secondary analysis using a subset of the sample from an ongoing retrospective cohort analysis, which employs electronic health records from the hospitals within the University of Pittsburgh Medical Center network. We will utilize descriptive analysis to characterize our included sample, and the Wilcoxon Signed Rank test to investigate the potential changes in pain. We hypothesize that with the implementation of palliative care service, PlwD will reduce pain severity with fewer adverse events. Overall, our analysis anticipates providing a preliminary understanding of the relationship between pain and palliative care in hospitalized PlwD.

Abstract Name: Preventing Sexual Assault on College Campuses: A Review of the Literature Review

In our Literature Review, we researched preventative measures for sexual assault on college campuses. This topic is of great importance as sexual assault remains steadily prevalent. For example, 26.46 of undergraduate women experience nonconsensual sexual contact by physical force or inability to consent (Association of American Universities Climate Survey, 2019). We learned that there are a multitude of ways for universities and students to work together to prevent sexual assault on college campuses. The most well-supported approaches included increasing bystander training and intervention (Ahren et al., 2011; Wantland, 2008), active campus commitment, and correcting misconceptions surrounding sexual assault and men's understanding of consent (Zapp et al., 2021). Within our review, bystander intervention can be described as interjecting in degrading conversations to correct misconceptions, refusal to participate in risky behaviors, and speaking up for victims. Campus intervention was looked at primarily as environmental factors such as emergency call buttons, well-lit areas with minimal dark spots, and the distance between buildings, as well as security surrounding campus buildings. The idea of correcting misconceptions and men's understanding of consent was analyzed less compared to the first two strategies in our review. This topic consisted of ensuring men, particularly Fraternity members could have a greater understanding of the topic of consent as well as what sexual assault consists of. It is our opinion that a great deal more emphasis should be placed on teaching undergraduate students, especially men, what is and is not consent. This could be promoted through orientation seminars to the university or mandatory 1-credit courses in the first semester, including review and attention to sexual scripts, how pornography often does not depict consent, and what exactly consent is and isn't.

Abstract Name: Evaluating Data Privacy, Security, and Trust in the Adoption of Wearable Sensing Devices for Construction Safety and Health Management

The adoption and implementation of wearable sensing devices (WSDs) in the construction industry has been slower than that of other industries such as healthcare, likely due to privacy, security, and trust concerns of industry professionals. Understanding the factors associated with these concerns will enable stakeholders to gain better insights into their relationships and how they influence the future of WSDs in the construction industry. This study aims to examine the impact of data privacy, security, and trust on the adoption and implementation of WSDs for safety and health management in construction. First, the constructs and factors associated with privacy, security, and trust are identified, defined, and characterized. Second, applicable theories and models for adoption and implementation with respect to privacy security, and trust in WSDs will be reviewed. This would be followed by the development of a conceptual framework that will be used to evaluate key stakeholders' perceptions of the impact of data privacy, security, and trust in the adoption of WSDs. A survey of key stakeholders will be conducted to evaluate their perception of the potential impact of these factors on the adoption and implementation of WSDs in the construction industry. The findings of this study are expected to help foster the effective adoption and implementation of WSDs among construction stakeholders for the prediction and prevention of injuries, illnesses, and fatalities in the construction industry.

Abstract Name: Classification of High-Energy Particle Precipitation Events Using Computer Vision

Earth's radiation belts host high-energy particles in a delicate balance which can be disrupted by certain events, such as Electromagnetic Ion Cyclotron (EMIC) waves, resulting in particles falling towards the Earth's atmosphere. This Energetic Particle Precipitation (EPP) can deplete atmospheric ozone, interrupt telecommunications, and destroy sensitive electronic components. For our efforts, we have chosen to direct our focus towards EMIC waves as they have the greatest impact on the aforementioned effects of EPP due to their tendency to precipitate the highest energy electrons and to provide a strong foundation for the future application of our methods to include multiple sources of EPP. Data collected by the twin ELFIN satellites aims to provide researchers with a deeper understanding of this region of space and the varying sources of EPP. We aim to further this field of research by applying the YOLO Computer Vision framework to the ELFIN dataset in order to identify EMIC-induced EPP events. This identification is made possible by the unique data signature of EMIC-induced EPP: an elevated rate of electron precipitation at relativistic ($\gtrsim 500$ keV) energy levels which tapers down as energy levels decrease. To train a YOLOv8 model, we constructed a labeled training set by isolating EMIC wave events, plotting them against a graph of standardized dimensions displaying the J_{prec}/J_{trap} ratio (the number of electrons which fall into the atmosphere over the number of electrons which are trapped in orbit), and introducing seeded randomness to improve model performance. We present our results of the trained YOLO models and their application towards determining the distribution of EMIC detections in the magnetosphere from ELFIN data. These results are compared with currently published research on EMIC-induced EPP. With our models and findings, future researchers will develop a better understanding of how to predict EPP-causing events and protect against them.

Abstract Name: Mathematical Modeling of COVID-19 With a Focus on Asymptomatic Transmission

In 2020, the global COVID-19 pandemic erupted. Without knowledge to combat the disease, hospitals around the globe were overrun. Scientists and mathematicians, using past information on extremely infectious viruses, began investigating the effectiveness of social distancing, facial coverings, and eventually, vaccinations. Mathematical models can be used to explore the quantitative effectiveness of vaccinations, facial coverings, and create predictive models to aid the creation of policies in order to prevent future surges in cases. This project will utilize the ordinary differential equation SIR model to explore susceptible (S), infectious (I), recovered (R) populations to explore impact of asymptomatic individuals. The products of this model can be used as a reference for preventative measures for future epidemics that follow a similar pattern to COVID-19.

Abstract Name: The American Battle Monuments Commission: Death, Commemoration, and the Nation-State

This presentation explores the role of the American Battle Monuments Commission (ABMC) in constructing a post-WWI commemorative language of honor, sacrifice, and duty. It takes up questions such as “What audience were ABMC spaces created for?”, “How did architects, such as Paul Philippe Cret and Thomas Harlan Ellett, interpret and make evident the United States's claim to political, social, and cultural authority through their works?”, and “How were stylistic choices linked to America's self-perception in the postwar era?”. It pursues answers to these questions through the lens of architecture and asserts that the ABMC's spaces were intentionally designed to project a dominant image to the country's wartime allies. This presentation builds on the theoretical proposals of Hutchinson in *Nationalism and War* and Von Stackelberg and Macaulay-Lewis in *Housing the New Romans: Architectural Reception and Classical Style in the Modern World* to assert that the ABMC produced works of ethnosymbolism that were intentionally designed in architectural styles reminiscent of antiquity. It uses two sites of memory and mourning- the Chateau-Thierry Monument and St. Mihiel American Cemetery- as case studies to analyze and draw conclusions about the ABMC. Critical to this project is moving beyond a simple examination of architecture as space devoid of meaning and understanding it as the intersection of a rich social, political, and cultural debate surrounding death and the nation-state. It concludes by suggesting that these spaces were intentionally designed to signify nationalistic prestige and commitment to America's allies, were constructed for a European audience, and were the manifestation of an innovative, and unique style.

Abstract Name: Parent Factors and their Effects on Emerging Adult Internalizing Behaviors

This study examined how parental anxiety and depression influences emerging adult (EA) anxiety and depression, and whether this influence is carried through deleterious parenting behaviors such as overparenting, distress intolerance, and hostility. Research has indicated that parental mental health issues can disrupt emotional regulation, leading to distress intolerance and as a result, parenting behaviors such as hostility and overparenting (a parenting style that restricts a child's autonomy and is developmentally inappropriate). These parenting behaviors have been linked to increased depression and anxiety within emerging adults. The current study included 290 EAs and their closest parents; each completed surveys that measured mental health, parenting styles, and self-perceptions. Self-reported anxiety and depression were measured using the Depression Anxiety Stress Scales. Distress intolerance was measured using the Coping with Children's Negative Emotions Scale. The Multidimensional Overprotective Parenting Scale was used to measure overparenting, and the Warmth and Hostility Scale measured hostility. Key findings suggest that parental depression was associated with EA depression both directly and indirectly (through distress intolerance and hostility). Parental depression was also related to overparenting; however, overparenting did not predict EA depression. For anxiety, no direct link between parental and EA anxiety was found. Parental anxiety was associated with distress intolerance, overparenting, and hostility. However, the only significant mediation found for EA anxiety was the path among parental anxiety, overparenting, and EA anxiety. These results indicate that parental mental health is key in predicting EA mental health, especially when considering the role of parenting behaviors. Namely, parental mental health may spillover and adversely impact parental decisions, leading to behaviors such as overparenting, distress intolerance, and hostility. Future interventions aimed at reducing parental distress intolerance and hostility, as well as educating parents about the impact of overparenting, may help reduce harmful parenting behaviors and in turn, EA depression and anxiety.

Abstract Name: Modeling Resistivity in Nanoscale Copper Interconnects

In this work, physical models of resistivity-size scaling and temperature effects in nanoscale copper interconnects are explored. Interconnects are a vital component of microprocessors, connecting elements within them. As microprocessors scale down in size, interconnects must also shrink. With decreasing size, the resistivity of interconnects becomes prohibitive to latency. As a result, analyzing an interconnect's resistivity at advanced technology nodes is important. Electron scatterings from phonons, grain boundaries and sidewalls are used in a model of resistivity versus interconnect size. Grain boundary scatterings are modeled using a reflectivity parameter R ranging from ideal case $R=0$ of no electron reflection at a grain boundary to

the worst case, $R=1$ where all electrons are reflected. Sidewall scattering contributions include sidewall roughness approximated to a sinusoidal form and use a different specular parameter p , which is dependent on the liner material used. Tantalum, modeled as non-conducting, and graphene, which is conducting, are considered as liner materials. To model temperature effects on resistivity, the Bloch-Grüneisen formula is used to model electron-phonon scattering. Our work shows that for a smooth interconnect of cross-sectional area 800 nm^2 and aspect ratio 2, as R increases from 0.25 to 0.75, resistance per unit length increases from $5.07\text{E-}2$ to $2.77\text{E-}1 \text{ Ohm/nm}$. As p increases from 0.25 to 0.75, resistance per unit length decreases from $3.21\text{E-}2 \text{ Ohm/nm}$ to $1.07\text{E-}2 \text{ Ohm/nm}$ for the same size. At the same dimensions, when surface roughness of 2 nm is added it accounts for 1.10% of the total resistivity. Roughness accounts for 15% of total resistivity when it is at 35% of total linewidth. We also discuss the role of topological metals in replacing copper as interconnects. Our work sheds light on the physics behind resistivity-size scaling in interconnects and can be used for interconnect design, optimization, and benchmarking at advanced technology nodes.

Abstract Name: Selection analysis of TBR1 gene in primates

The TBR1 gene encodes a transcription factor essential for the development of the brain, influencing cortical layer formation, cognitive development, and social behaviors. Although many primate species share the same TBR1 gene sequence, they exhibit distinct cognitive and behavioral patterns, suggesting that variations in TBR1 expression, rather than nucleotide sequence differences, may contribute to these disparities. This study aims to investigate whether changes in TBR1 gene expression in primates are linked to evolutionary fitness. In this first phase of our research, we analyze the TBR1 gene sequence across several primate species to identify signatures of positive or purifying selection. To assess this, we employ the PAML (Phylogenetic Analysis by Maximum Likelihood) software, which allows for the detection of selective pressures on the gene. Our findings will contribute to understanding how evolutionary changes in TBR1 expression may influence brain development and behavior in primates

Abstract Name: A Novel Approach to Brain Vessel Segmentation Using MRI for Alzheimer's Disease Research

Alzheimer's disease is increasingly recognized as having a vascular component, with studies suggesting that impaired blood flow and vessel abnormalities contribute to cognitive decline. Consequently, methods to study the morphology of brain vessels are warranted. Current techniques allow for viewing 3D MRI brain scans to examine a patient's vessels, but automated methods to segment these vessels and obtain quantifiable metrics lack reliability and accuracy. We present a novel image analysis algorithm designed to accurately segment brain vessels from 3D MRI images, enabling more detailed analysis. Our algorithm begins by preprocessing the image into 'variance wells' (vWells), a type of 'superpixel' derived from the variance in the image's intensity. vWells are small, irregular, and relatively homogeneous clusters of adjacent pixels, which can be connected to segment objects in an image while preserving sharp boundaries. The computed vWells are arranged into a graph structure where vWells serve as nodes, and edges connect adjacent vWells. The algorithm takes two manually placed points along a vessel, then uses the graph structure to connect and complete the corresponding section of a vessel by leveraging the statistical relationships between adjacent vWells. Detailed visualization tools allow users to superimpose the segmentation as a semitransparent surface over the original MRI data, facilitating visual confirmation of segmentation accuracy. By combining these automated techniques with human supervision based on detailed visualization, our approach provides a robust and reliable method for brain vessel segmentation. Preliminary application of our method to segment the Circle of Willis arteries, a vital network for maintaining cerebral blood flow, in 27 time-of-flight MRI scans demonstrates its ability to consistently provide precise, quantifiable metrics (such as diameter, length, and curvature of vessel structures) across diverse 3D MRI datasets. This capability supports large-scale studies of vascular abnormalities linked to cognitive decline and advances Alzheimer's disease research.

Abstract Name: Self-Advocacy Experiences of Individuals with Cancer Living in Rural and Low Socioeconomic Areas

Background/purpose: Patient-centered care depends on patients' ability to communicate values, needs, and priorities with their healthcare team ("self-advocacy"). Self-advocacy research has not addressed experiences of rural and/or low socio-economic status (SES) patient populations, limiting the ability to tailor interventions for these individuals. This study aims to describe self-advocacy experiences among underserved patients with cancer. **Methods:** We recruited adults with a history of cancer through an online research registry and an ongoing cancer clinical trial whose home addresses were considered (a) rural and/or (b) low SES determined by Rural-Urban Continuum Codes (RUCC) ≥ 4 and Area Deprivation Index ≥ 60 , respectively. Participants completed a one-on-one semi-structured phone interview regarding their cancer-related self-advocacy experiences. Qualitative data was organized and analyzed according to the RADaR qualitative approach to summarize participant-reported behaviors, barriers, and facilitators of self-advocacy. **Results:** Participants (N=30) reported a mean age of 62 years; 76.7% were female, and 70% had an advanced cancer diagnosis within the past 24 months. 23% live in a rural area and 100% live in an underserved area. Five major themes emerged from participants' self-advocacy experiences: the healthcare team, treatment process, barriers to care, connectedness, and advocacy. Various sub-themes were identified within each topic. Connectedness and barriers to care directly related to living areas were mentioned in half of the interviews analyzed. Participants either had implicit trust in their healthcare team or reported receiving inadequate, impersonal care. Many participants reported that their self-advocacy was either unproductive or not initiated. **Conclusions/Implications:** The results demonstrate that rural and low SES patients with cancer face barriers to accessing person-centered care. Future work should explore how to directly address these barriers. Our team is currently using these results to guide the development of a peer navigator intervention for high-need underserved cancer patients.

Abstract Name: Dynamic Changes of Ca²⁺ Cycling During Neonatal Mouse Heart Regeneration

Myocardial infarction (MI) is a leading cause of heart failure, with high mortality rates due to the adult human heart's limited regenerative capacity, resulting in scar formation rather than myocardial regeneration. In contrast, some neonatal mammals, including mice, can regenerate damaged myocardium by reactivating cardiomyocyte proliferation. Intracellular Ca²⁺, a key second messenger in numerous signaling pathways, has only recently been implicated in cardiac regeneration. It was also found that the cardiac-specific protein LRRC10, that is crucial for cardiac regeneration, regulates transients (CaT) and CaT recovery was compromised in *lrrc10*^{-/-} zebrafish hearts, leading to impaired regeneration. However, the regulation of CaT required for cardiac regeneration remains poorly understood. The preliminary data for this study aims to elucidate the role of intracellular Ca²⁺ cycling in mammalian cardiac regeneration and its regulation. We hypothesize that the CaT properties change dynamically during neonatal heart regeneration in an LRRC10-dependent manner, and cholinergic and beta-adrenergic stimulation exhibit blunted regulation of CaT during neonatal mouse heart regeneration. To demonstrate the feasibility of our experimental approach, we conducted a pilot study using high-resolution optical mapping (3,333 frames/s, 60 microns per pixel) to measure CaT in neonatal mouse hearts. Control hearts (postnatal day 8, n=4) were compared to post-MI hearts (postnatal day 8, n=6) following surgical induction of MI on postnatal day 1. The hearts were Langendorff-perfused at 37°C and loaded with the Ca²⁺-sensitive fluorescent dye Rhod-2AM. Pacing was performed at a physiological rate of 10 Hz. We observed altered CaTs in post-MI hearts compared to age-matched controls, specifically a widespread reduction in CaT upstroke velocity and a trend towards shortened CaT duration. We anticipate that in wild-type (WT) hearts, these CaT alterations should be restored by P28 as the myocardium recovers, but not in *lrrc10*^{-/-} hearts.

Abstract Name: Deep Sea Adaptation to Hydrostatic Pressure

The planet is covered in extreme environments that are constantly changing. The organisms that live in these environments must adapt to the unique problems these environments impose. This research focuses on discovering how organisms adapt to living at the bottom of the ocean. One of the main problems this incurs is problems that arise from high hydrostatic pressure. High hydrostatic pressure is predicted to denature

proteins, increase the viscosity of fluids, and disrupt membrane dynamics. We aim to identify genes and pathways that are changed in response to changing pressures deep in the ocean. Other research groups have looked at the effects of pressure on individual organisms such as *Apostichopus japonicus* (sea cucumber) and *Bathycyma lactea* (sea limpet). In their research, they performed deep-seq experiments that looked at the transcriptional response of pressure. Our goal is to take these datasets and identify universal adaptations to increased hydrostatic pressure. To accomplish this, we are annotating these genomes in order to find homologous genes between these species. Then we plan on identifying genes that have a similar change in expression in response to changes in pressure. The genes identified from this analysis will be tested in a model organism to see if they confer resistance to pressure. Our research will help people adapt to working at extreme depths.

Abstract Name: Applying Novel Methods for Assessing the Blood Brain Barrier after Traumatic Brain Injury

Traumatic brain injury (TBI) affects over 10 million people annually and is induced by a mechanical force to the head. The subsequent injury is focal, diffuse, or a combination of both. Following a focal TBI, astrocytes become reactive and form a border that is thought to prevent blood leakage from broken vessels reaching the healthy surrounding brain. However, it remains unknown whether the blood brain barrier (BBB) is repaired on vessels damaged in the injury. In contrast, blood vessel breakage is rare in diffuse mild TBI (mTBI), but BBB impairment is abundant. Our lab previously demonstrated that, in the case of diffuse mTBI, astrocytes fail to assemble a protective border or to repair the BBB, leading to continual leakage of blood-borne factors into surrounding tissue even months after the injury. BBB disruption is linked to numerous neurodegenerative disorders; thus, it is of interest to have tools to assess BBB damage in the context of TBI to determine potential therapeutic targets. In the present study, we test the applicability of tools from other fields in a novel context: BBB and TBI. We show that mice expressing a green fluorescent protein (GFP) tag on the tight junction protein zona occludens 1 (ZO-1) can be employed to assess BBB changes after injury. We further demonstrate that, while protein cross-linking with paraformaldehyde (PFA) fixation frequently renders BBB protein antigens unrecognizable by antibodies, a 3% glyoxal fixation protocol allows for effective visualization and quantification of BBB and vasculature proteins after TBI using immunohistochemistry. Finally, we show that peripheral injection of the small, fluorescently-tagged molecule cadaverine can be used to reveal BBB damage several weeks after focal stabwound injury, which has not been previously reported.

Abstract Name: End-of-Life Care and Bereavement: Impact on Siblings of Patients with Chronic Illnesses

Introduction: Cancer and advanced heart disease are the two leading causes of disease-related deaths among US children (1,2,3). With the time and emotional demands of caring for a critically ill child, the needs of siblings can be overlooked; the impact of end-of-life treatment on siblings is understudied (4,5). Thus, we conducted a secondary analysis of bereaved parent interviews to explore the impact of death on bereaved siblings. **Methods:** We performed a secondary analysis of semi-structured interviews of bereaved parents about their perspectives on high-quality EOL care. Interviews were conducted with bereaved parents in Alabama whose child (0-21 years at the time of death) died of cancer or advanced heart disease ≥ 6 mo before the interview. Although not directly asked about, quotes related to siblings were identified and inductively and iteratively grouped into themes by a coding team. **Results:** Sixty parents, representing fifty-one children, were interviewed. Forty-seven were mothers (78%), twenty-four (51%) were Black, and twenty-two (49%) were White. Twenty-seven (53%) children died of AHD and twenty-four (47%) of cancer. Children died at a mean age of 7.9y and a median of 3.4y before the interview. Many parents (36; 60%) discussed themes regarding the impact of end-of-life treatment on siblings. Parents identified changes in siblings during end-of-life care and bereavement, including difficulty expressing feelings, personality changes, and risky behaviors. Parents also discussed the importance of bereavement support for siblings, which they did not always have access to. To mitigate these effects, parents tried to make life as normal as possible for siblings. They looked for tangible support including childcare and monetary support from the community and medical team and guidance explaining end-of-life processes to siblings. **Conclusions:** While not specifically asked, many parents discussed the psychosocial health of bereaved siblings. This emphasizes the importance of addressing sibling well-being at end-of-life and in bereavement.

Abstract Name: Producing and analyzing synthetic signals: sending and receiving cell populations in the *Drosophila* wing imaginal disc

Notch receptors, found across multicellular organisms, play critical roles in development and are implicated in diseases, notably cancer, due to system mutations. Operating via mechanosensitive activation, adjacent cell-derived ligand Delta binds to Notch, undergoing endocytosis and inducing mechanical stress on the ligand-receptor complex. This stress prompts structural changes in Notch's extracellular Negative Regulatory Region (NRR), leading to cleavage by ADAM protease and subsequent γ -secretase cleavage, releasing an intracellular domain that acts as a transcription factor, modulating Notch target genes. Recent advances have facilitated the development of synthetic Notch (synNotch), which can convey tailored signals from neighboring cells and holds promise for therapeutic interventions. SynNotch utilizes distinct ligand-receptor binding domains and incorporates foreign transcription factors to induce specific responses, such as producing GFP or eliciting therapeutic behaviors. However, understanding synNotch's functionality within tissue contexts still needs to be improved, requiring consideration of factors like tissue growth, cell arrangement, and response strength for effective therapeutic application. To investigate Notch receptor signaling, techniques involve generating cell populations with exclusive traits through recombinase-mediated ligand and receptor gene expression switching. Subsequent fluorescent immunohistochemistry of dissected wing imaginal discs allows visualization of ligand cells and signaling patterns under a fluorescent microscope. These experiments aim to characterize mechanosensitive receptors in *Drosophila*, design novel receptor combinations, and assess their impacts on fly wing and nervous system development, offering insights into mechanosensation and potential therapeutic avenues in developmental biology and neuroscience.

Abstract Name: Mitigating Caffeine Toxicity in Planaria: Identifying Protective Agents in Evodia Extract

In Seattle, caffeine equivalent to the amount in 30,000 8-oz. cups of coffee is pumped out into waterways daily! The purpose of this project is to identify compounds in the fruit of the honey tree (*Evodia rutaecarpa*) that is native to Eastern China that block caffeine's detrimental effects on regenerating planaria. Caffeine has been called an "emerging chemical of concern" in local waterways because of its increasing concentration in drinking water supplies while causing conditions such as oxidative stress, reproductive issues, and even fatality in aquatic life (Vieira et. al., 2021). The available treatments for caffeine-polluted water all have drawbacks: high energy consumption, excessive chemical usage, high cost, and toxic by-products, to name a few; thereby making large scale implementation futile and this necessitates preventative measures (Raj et al., 2021). A compound in *Evodia* that has been shown, in part, to reduce caffeine-induced sleep disturbances in mice is evodiamine (Ko et al., 2018). The purpose of this study is to identify other compounds in *Evodia* that also reduce the negative action of caffeine. *Girardia dorotocephala* (planaria), a species of flatworms, was used as the model species because of its high regenerative capacity and the known detrimental impacts of caffeine on its growth. Preliminary data shows that planaria that were subjected to a treatment containing an extract of *Evodia* and caffeine showed lower levels of abnormal growth and death than those that were subjected to caffeine alone. The *Evodia rutaecarpa* extract will be fractionated and the resulting fractions will be tested for their ability to inhibit the deleterious effects of caffeine. The expected result of this study is that 1-2 fractions will have the desired activity and allow us to isolate the compound(s) that inhibit(s) caffeine degradation in regenerating planaria.

Abstract Name: Investigating the expression and regulatory differences of transposable elements between inbred laboratory mice.

Transposable elements (TEs) are repetitive DNA sequences capable of replicating and repositioning within the host genome. These elements make up over 40% of human and mouse genomes, with long interspersed nuclear elements (L1s) alone accounting for more than 20%. L1s have evolutionary significance, as their cis-regulatory motifs can be exapted for host benefit. Understanding TE expression and regulation across individuals within a population is imperative to inform future studies on mechanisms of variation and

evolution. This study evaluated TElocal, a tool designed to quantify TE locus expression in mouse genomes. We found that monomeric repeat variation (MRV) of L1MdTf promoters may alter expression of L1 elements, leading us to hypothesize that TE insertions will have variable expression between mouse strains, and that MRV may cause this variability. Using previously generated mESC RNAseq data from 10 inbred mouse strains, we obtained gene and transposon locus read counts from TElocal (v1.1.1). Outputs were normalized using DESeq2 R package [v1.44.0]. Normalized read counts were correlated with MRV data, and the identified intergenic L1 loci expression levels were compared between each strain. We observed differential expression of L1 loci between strains and found that promoter length influenced variable TE expression. To validate TElocal's performance, we compared the expression of intronic L1 loci with their associated genes. For instance, within the highly expressed gene Phf14, the intronic L1 showed significantly lower expression across all strains, with minimal correlation between gene and L1 expression variability. These findings demonstrate that MRV can alter TE expression and that genic TE insertions have a different regulatory landscape than intergenic insertions. TElocal proved effective for investigating allelic heterogeneity and regulatory effects of TEs. Future studies will use this tool to explore cis-regulatory elements binding TEs and assess TE influence on gene expression across tissues and evolutionary timelines.

Abstract Name: How Governance Practices and Strategic Decision-Making Influence Financial Performance in Family-Owned Businesses in North Georgia, USA

This research examines how governance practices and strategic decision-making influence the financial performance of family-owned businesses in North Georgia, USA, addressing a gap in existing literature by clarifying links between governance structures, strategic choices, and measurable outcomes. These enterprises face unique challenges due to intergenerational ties, overlapping roles, and distinctive frameworks. Focusing on leadership roles, decision-making procedures, and succession planning, it measures their combined effects on Return on Assets (ROA), revenue growth, and profit margins. Adopting a mixed-methods design, this study combines structured surveys and in-depth interviews with business owners and executives, conducted in cooperation with the local Chamber of Commerce. This approach ensures findings remain grounded in real business conditions, offering insights valuable to local and similar contexts. Additionally, the secondary data broadens the analysis, revealing how industry-specific and macroeconomic factors shape results. Guided by stewardship theory, which highlights leaders' intrinsic motivation to serve their enterprises' long-term interests, this investigation shows how thoughtful governance and informed strategic decisions can address complexities in family business structures. Although centered on North Georgia, this study's frameworks can guide governance improvements and strategic refinements nationally and internationally. By integrating quantitative and qualitative methods, this research enriches scholarly dialogue on family business management and bridges the gap between academic research and practice. In demonstrating how prudent governance and informed strategies bolster financial performance across varied environments, this study underscores its significance for diverse economic landscapes and offers adaptable, evidence-based guidance well beyond the region examined.

Abstract Name: Exploring Carnitine-Dependent Mechanisms of Valerobetaine in Breast Cancer Migration Inhibition

Breast cancer results in roughly 297,500 cases each year in the United States with over 43,000 deaths. These deaths result from the ability of cancer to break the cell life cycle and uncontrollably proliferate and metastasize throughout the body. Notably, more than 75% of breast cancer related deaths are due to metastases. The hallmark of reprogramming cellular metabolism enables cancer cells to augment fat metabolism in addition to glycolysis, driving increased tumor aggressiveness and heightened metastatic rates. Currently, there are no FDA-approved drugs that specifically target metastases or inhibition of migrating cancer cells. Therefore, potentially inhibiting fat metabolism could cause a reduction in metastases and migration of cancer cells; however, current inhibitors of fat metabolism are extremely toxic and have not been translated to the clinic. Previously, we discovered Valerobetaine (VB), a microbe-derived, non-toxic molecule capable of inhibiting fat metabolism, as a potential therapeutic. Initial experiments focused on demonstrating that VB could reduce the migration of MCF-7 breast cancer cells under fatty acid supplementation using scratch assays. These studies confirmed that VB mitigates the pro-migratory effects of increased fat metabolism. Subsequent research explored VB's mechanism of action, hypothesizing that it functions through carnitine-dependent pathways. Through treatment groups including carnitine supplementation and utilizing scratch assays, we observed that VB's inhibitory effect on migration was reversed, implicating the carnitine shuttle in its mechanism. These findings suggest VB as a promising co-therapeutic for reducing metastatic behavior in breast cancer, supporting its potential translation into clinical use.

Abstract Name: The Lasting Consequences of Climate Change on Crop Cultivation in Eastern Thailand

This research sought to determine the lasting consequences of climate change on tropical crop cultivation in Eastern Thailand, mainly the Chanthaburi province. This region grows many crops, but durian, a cash crop, has significant market demand domestically and internationally. During June-July 2024, the research team conducted structured interviews with fifty-two farmers in Eastern Thailand. Furthermore, they conducted ten semi-structured interviews with key stakeholders in government offices related to agriculture, experts from crop-specific trade associations, and researchers focused on agricultural economics. Through these methods, they found that climate change fundamentally altered agricultural practices in Eastern Thailand. Findings reveal that climate change has fundamentally altered agricultural practices in the region, with water-related challenges—such as drought, flooding, and rain variability—emerging as the most significant drivers of impact. Farmers consistently cited water shortages, access limitations, and management difficulties as major concerns. Additional climate factors, such as temperature fluctuations, heat, wind, and seasonality further threaten crops. These weather patterns have led to increased crop stress, diminished yields, and lowered produce quality, particularly for water-intensive crops like durian. Shifting seasonality and shortened growth cycles further disrupt agricultural operations, leading to unpredictable harvest times and increased input costs. Despite limited government support, farmers have demonstrated resilience by adopting adaptive strategies such as intercropping, improving water management infrastructure, and diversifying crop types. However, these measures often require significant financial investment, limiting access for smaller farms and exacerbating economic inequalities. Farmers also expressed concerns about the sustainability of certain

adaptation practices, which may inadvertently contribute to long-term environmental degradation. Yet, despite these crises and difficulties adapting in the long run, market demand for durian continues to drive decision-making.

Abstract Name: Exploring Disparities in Metastatic Breast Cancer Treatment Timeliness

Healthcare inequity is a global challenge, with individuals in low- and middle-income households disproportionately affected by conditions such as metastatic breast cancer, which require timely detection and treatment. This study aims to develop predictive models that promote health equity by using diverse, representative data to identify and address health disparities in cancer care. Specifically, we examine how factors such as socioeconomic status, geographic location, race, gender, and access to healthcare resources influence treatment accessibility and diagnostic timelines. We analyzed a dataset containing 13,173 metastatic breast cancer patient records, including demographics, diagnoses, treatment options, and insurance data. Through exploratory data analysis, ANOVA, and correlation analysis, we investigated how these factors relate to the waiting period to treatment. Our findings revealed that payer type and race significantly influenced the time to treatment, suggesting potential disparities in access to or quality of care. Correlation analysis indicated weak or negligible relationships between metastatic diagnosis periods and individual factors such as age, household median income, and BMI. Addressing these disparities could help improve the equity and quality of cancer care, ultimately reducing differences in treatment timelines and patient outcomes.

Abstract Name: The Impact of Von Hippel-Lindau (VHL) Gene Knockout in Osteocytes on Bone Marrow Microenvironments and B Lymphocyte Development

Little is known about the effects of environmental factors, particularly oxygen levels, on B cell development and immune function; specifically focusing on the role of the Von Hippel-Lindau (VHL) gene. B lymphocyte development is influenced by microenvironments during periods of altered homeostasis, but the exact impact of hypoxic conditions and VHL deficiency in early osteoblasts on bone marrow is not well understood. We hypothesized that an inducible VHL gene knockout reporter in early stage osteoblasts would alter bone marrow function and subsequently affect B cell development. Using techniques such as tissue digestion, hemocytometer cell counting, and flow cytometry (FACS), we examined green fluorescence protein (GFP) expression in VHL homogenous knockout mice (Tagln-ERT2-Cre;Ai213;Vhlfl/fl) treated with tamoxifen. GFP detection in single-cell suspensions from duodenal tissue resulted in 0.14% detection compared to non-induced controls. Further work will focus on confirming the VHL knockout via DNA extraction from heterogeneous Vhlfl/+ mice and more thoroughly analyzing any impacts on bone marrow deficiency and B

cell development. Analyzing these changes results longitudinally may be helpful in determining how microenvironmental changes may result in delayed progression of B cell development.

Abstract Name: Priced out of Life: Alabama's Insulin Crisis

Alabama's high insulin costs are bankrupting people and dragging down the state's economy. The rising cost of insulin is such an essential topic to many people because in Alabama, almost everyone knows and loves someone who is affected by diabetes, whether it be type one or type two. Diabetes affects children, teens, and adults, and people with type 1 diabetes depend on insulin every day. The unequal distribution of diabetes is caused by several factors, including age, race, socioeconomic level, genetic susceptibility, lifestyle, and underlying medical disorders. This problem is more prevalent in rural areas and low-income communities across Alabama. It is essential to comprehend how diabetes impacts different populations to create effective preventative and treatment plans. We also must consider the accessibility to these treatment plans and see if insulin at its varying prices is affordable for families and individuals afflicted with this disease. Our research shows that the high insulin cost is primarily due to market and government failures. The market failure in the insulin industry can be attributed to the lack of competition. The government's failure is due to Alabama's

unwillingness to expand Medicaid despite the fact that many low-income individuals lack insurance that may reduce the cost of insulin. Through a case study of Alabama's insulin crisis, I expect to find evidence to demonstrate how high cost of insulin affects vulnerable populations by showing the existing insurance and coverage gaps and how these require governmental action at the state level.

Abstract Name: Investigating the Role of Interfascicular Matrix During Ligament Failure

Ligaments and tendons have spatially heterogeneous mechanical properties that are poorly understood. At the mm-length scale, ligaments and tendons are composed of fascicles, which are collagen-dense stiff and aligned fibers, and a compliant interfascicular matrix (IFM) that connects the fascicles. Despite the differences in these components, previous studies have treated ligaments and tendons as homogeneous materials. Making this assumption is useful when testing materials because it allows for the identification of material properties and simplifies the mathematics needed to calculate strain data. This method relies on the hypothesis that the pre-failure portion of the stress/strain relationship in ligaments is entirely dependent on the behavior of fascicles. As a result, past research has primarily focused on fascicle-direction loading. However, more recent research has sparked debate about where failure in ligaments begins, as fatigue failure could be a result of microtears in the IFM, fascicles, or both. Given that the IFM is a material that is not well understood, and therefore an individual model for the IFM is needed before we can fully understand how ligaments and tendons behave. This study aims to isolate and begin characterizing the mostly unknown mechanical properties of the IFM. To do this, we will perform ligament tensile tests in a novel orientation. Previous studies have sliced in between fascicles in order to easily get thin sections of tissue. However, we have developed a unique tool that allows us to consistently create thin sections while slicing through the stiff fascicles. Additionally, we developed an original staining protocol that aids in fascicle/IFM identification without altering the mechanical properties of the material. Combining our data with existing data will help create a more robust model for IFM behavior, and gaining this knowledge will help create models that can accurately predict failure in ligaments and tendons.

Abstract Name: Assessing the Impacts of Beaver Dam Analogues on Stream Morphology

Beaver Dam Analogues (BDAs) are temporary, semi-permeable structures built by humans to replicate the environmental impacts of natural beaver dams on streams. Made out of wooden posts and willow branches, BDAs are a low-tech, low-cost solution that can be implemented in streams as a restoration method, specifically in streams that experience more erosion from fast water flowing through narrow parts of the channel. BDAs are intended to reduce erosion and increase deposition in the channel. It is hypothesized that

BDAs cause the stream width to increase. However, the specific impacts of BDAs on stream geomorphology are still unknown. Here we show how stream width varies in proximity to BDAs compared to how stream width fluctuates under non-BDA conditions for a restoration site along Red Canyon Creek near Lander, Wyoming, USA. We specifically examined stream widths directly at the BDA and 0.5 meters upstream of the channel for BDAs 12 through 29 using daily data for the years 2017, 2019, 2021, 2022, and 2023. We compared how the stream width for each BDA changed from 2017 to 2023. From our collected data, we found that from 2021 to 2023 100% of the stream widths measured at BDAs became wider and 94% of the stream widths measured 0.5 meters upstream of the BDA became wider. Wider stream widths likely occur as BDAs alter flow patterns, directing the stream into the side of the channel. Our results show that the installation of BDAs in streams has potential to cause the stream width to increase and to overall aid in stream restoration. Altogether, our results provide useful information regarding the impacts of beaver dam analogues as an affordable solution when considering how to improve the ecological health of streams.

Abstract Name: Discovering Drug-Like Compounds by Targeting Protein Interactions Using a Yeast-3-Hybrid System

Traditional drug therapies often target a limited number of conserved sites, such as ATP-binding regions. However, the use of these sites often leads to off-target toxicity in both malignant and normal cells, limiting therapeutic specificity. Current research on non-ATP inhibitors can identify more effective drug targets that promote selective apoptosis, specifically in cancer cells. This study is using yeast (*Saccharomyces cerevisiae*) as a model system to investigate protein interactions and design specific peptides with the intention to disrupt interactions specific to cancer cells. The objective of this project is to detect interactions between retinoblastoma (RB1) and human Cyclin A (CCNA2) in Yeast-2-Hybrid (Y2H) and Yeast-3-Hybrid (Y3H) systems. CCNA2 and RB1 were cloned into two different expression vectors, pGBK and pGAD. Once the CCNA2-RB1 interaction is detected using the activation of reporter genes in a Y2H system, a third plasmid that encodes for the amino acid sequence HAKRRLIF will be introduced. This peptide sequence was previously demonstrated to disrupt the CCNA2-RB1 interaction in vitro, so the expectation is that it will disrupt the protein-protein interaction in the Y3H system as well. Following this proof of principle, an oligo/peptide library will be generated to develop a high-throughput screen for disruption of any combination of protein interactions. Promising candidates will be converted into peptide-mimetic compounds. Then, the inhibitory drug-like compounds will be optimized into pharmaceutically relevant compounds using REPLACE (Replacement with Partial Ligand Alternatives through Computational Enrichment) technology. Using the Y3H system, drug-like compounds can be developed with the ability to disrupt protein interactions specific to cancer cells.

Abstract Name: Assessing the Impact of State-Contingent Debt Instrument Issuances on Industrial Development in Emerging Markets

Nations are increasingly relying on capital markets to stabilize their economies, posing significant challenges and opportunities that could lead to either a debt crisis or financial prosperity. Innovative sovereign debt restructurings have been more common because of this growing financialization, leading to the increased use of state-contingent debt instruments (SCDIs). SCDIs are floating rate bonds that are typically linked or indexed to variables or events such as a country's GDP to improve a debtor country's capacity to service their debt. The impact of SCDIs on spurring industrial growth is not clear. The proliferation of industrial projects such as public transportation highlights the importance of recognizing the role of how national debt can affect infrastructure. Using aggregated SCDI issuance data from 25 countries from South America, Africa, and Europe over 1989 to 2020, this paper tests the effect of these issuances on infrastructure development. I examine both public and private sector projects using a method of an instrumental variable regression. I also explore the effectiveness of SCDIs on domestic growth in crisis versus non-crisis situations through case studies of Greece, Portugal, and Ukraine. I hypothesize that SCDI issuances have proven to be effective in sovereign debt management; thus, I expect there to be a positive effect on infrastructure development and the effect to be larger on public sector projects than in the private sector.

Abstract Name: Understanding Weapons of Bacterial Warfare

Phage-tail-like bacteriocins, also known as tailocins, are virus-like toxins used by bacteria to compete with other bacteria for resources. Tailocins have highly specific killing abilities; they can kill genetically closely related bacteria, but not the producing strain or more distant bacterial relatives, and because of this specificity they are promising alternatives to antibiotics. In 2019, the CDC estimated more than 2.8 million antibiotic-resistant infections occur in the U.S. annually, with more than 35,000 deaths. As antibiotic resistance is becoming more prevalent, alternative therapies are becoming increasingly necessary. To ultimately develop tailocins for clinical treatment, more research is needed to understand the underlying mechanisms of tailocin specificity. The Karasov Lab studies tailocins produced by wild populations of the pathogenic bacterium *Pseudomonas syringae*, an abundant pathogen that infects the model plant, *Arabidopsis thaliana*. We found that tailocins are highly conserved in wild populations of *P. syringae* and frequently used in bacterial competition amongst pathogenic strains. We identified 70 genes in the *P. syringae* genome which were involved in a bacterial sensitivity to a tailocin. 6 were involved in the biosynthesis of the O-Antigen Polysaccharide (O-PS): an important part of the lipopolysaccharide (LPS) found on gram-negative bacterial membranes which contain long sugar chains. Tailocins bind target cells with high specificity by using their tail fibers to interact with target cell O-PS akin to a lock and key interaction. My current research aims to broadly characterize the LPS of strains of wild *P. syringae* to identify relationships between LPS composition and sensitivity to tailocin. Additionally, I aim to identify specific sugar monosaccharides that make up the O-PS which the tail fibers bind to. This research will greatly contribute to the understanding of tailocin-LPS interactions to better understand how tailocins identify and kill their targets, and how bacteria evolve resistance to tailocins.

Abstract Name: Sustainable Green Hydrogen Stations for Hydrogen Vehicles in Kentucky

Our previous research was working on sustainable photovoltaic (PV) uses and a hybrid between hydrogen generation and PV energy. With the decline in natural resources and limited recycling options for electric vehicle batteries, we have expanded our research to utilize green hydrogen for hydrogen vehicle stations using excess PV energy. Hydrogen is a reliable source of energy for the future of vehicles, as it is clean, reliable, and can be generated through hydrolysis with minimal risks. Hydrogen production through hydrolysis, using Polymer Electrolyte Membrane (PEM) electrolyzer, results in electricity, water vapor, and heat as byproducts. The ways that hydrogen can be produced vary on a large spectrum. Hydrolysis splits water into hydrogen and oxygen, in which we can store the hydrogen in hydrogen fuel cells. Any type of energy source such as geothermal, biomass, solar, and wind can produce hydrogen for vehicles or other applications. This is due to the hydrogen being split by electricity during hydrolysis. In this study, we focus on the feasibility of on-grid PV-based hydrogen charging stations, leveraging existing PV data and excess electricity from current load profiles for hydrogen conversion across Kentucky. Considering energy sources, some are more hazardous and expensive. Hydrogen poses minimal risk and produces only a small amount of heat. Although it is combustible, just like gasoline, hydrogen can be stored safely. Using our modeling and simulations, we projected hydrogen production and utilization for light and heavy-duty hydrogen vehicles. Introducing hydrogen stations offers a practical alternative to gas stations, addressing energy sustainability while mitigating recycling challenges.

Abstract Name: Morgan Le Fay: Chivalry's Hidden Threat

Once portrayed as a wise healer, the mythological character Morgan Le Fay changed in literature after her disagreements with King Arthur, quickly becoming a deceiving temptress. She fits this evil characterization in Sir Gawain and the Green Knight, creating a game to trick Arthur's knight, Gawain, and reveal the flaws of knighthood in general. Her significance as a character is highlighted in this story, as she is the one responsible for the entirety of Gawain's adventures. However, she is not revealed as the puppet master until the end of the story, in which she is briefly introduced by the Green Knight, receiving all of the blame for the suffering of Arthur's knightly court. Many scholars have argued that this delayed revelation strategically overshadows Morgan's power and control over the narrative, attempting to obscure the fact that a female figure is responsible for defaming knighthood. I add to this argument that this obscurity is necessary to hide the reality of the weakness of knighthood and patriarchal dominance, both relying on women to be able to perform their

duties. Morgan playing the role of the puppet master of this threat to knighthood and chivalry symbolizes the real threat to King Arthur's court, knighthood, chivalry, and male power: women. Through hidden control and manipulation of Gawain's decisions, Morgan leaves a lasting effect on not only Gawain, but knighthood and chivalry together, symbolized through the green girdle, the beheading game, and the reversal of typical gender roles of herself and Lady Bertilak. Hidden, dominant, feminine, and successful, Morgan is concealed from the plot of the story to warn of what can really happen if women are granted control.

Abstract Name: Lower Your Expectations: A Quantitative Analysis of Individual-Level Factors Influencing Black and Latino IPV Survivors' Experiences of Institutional Betrayal by the Criminal Legal System

This study investigates the impact of individual-level factors on institutional betrayal (IB) among Black and Hispanic victims of intimate partner violence (IPV) who interacted with the criminal legal system (CLS). A total of 199 participants who are 18 years or older, identify as a woman, transgender, or nonbinary, have experienced IPV, and identify as Black and/or Hispanic completed a Qualtrics survey assessing their experiences with IB. The Institutional Betrayal Questionnaire (IBQ-2), adapted for the criminal legal context, was used to assess participants' experiences. ANOVA analyses were conducted to examine the relationships between IB scores and various individual characteristics: age, presence and number of children, education, employment status, and sexuality. Results revealed significant differences were observed in IB scores by age, with younger participants (18-29) reporting higher levels of betrayal compared to older participants (40+). The presence of children was associated with lower IB scores, and individuals with more children reported lower levels of institutional betrayal than those with fewer children. Higher education levels were linked to greater perceptions of IB, and full-time employed individuals reported higher IB scores compared to part-time or unemployed participants. Finally, LGBTQ+ individuals experienced higher levels of institutional betrayal compared to heterosexual participants. These findings underscore the critical role of expectations in shaping perceptions of IB in the CLS. The study highlights the importance of understanding how individual expectations of victim/survivors affect experiences of IB and suggests that institutions must address these factors to offer more equitable and supportive responses.

Abstract Name: Artificial Intelligence Use in Classrooms

The world of deep-learning artificial intelligence is still new and underexplored in a wide range of fields. One such area is that of education. Artificial intelligence use in classrooms is underutilized, and many educators still have mixed feelings about how A.I. might be integrated. Looking into the limited available research, as well as engaging with current and future educators, one finds the many different ways that artificial

intelligence can be used to assist educators with grading and creating assignments, as well as students in a wide range of classes, including those in special education (Rice, 2022). Based on prior research conducted regarding artificial intelligence use in classrooms, survey questions were developed and distributed to the participants (N = 188) (i.e., 76 teachers at different education levels, elementary to university, as well as 112 current undergraduate teacher education students). These responses were analyzed using SPSS 29 to investigate differences among grade levels, fields of education, and those with and without classroom teaching experience. Amongst the responses, participants generally agreed that artificial intelligence could be used to grade close-ended questions, though greatly opposed letting A.I. grade open-ended questions. There were significant differences in the responses based on the participants' levels. Responses also indicated that educators believe older students would be more likely to use A.I. to cheat. Many current educators also believe A.I. will become commonplace in schools, though many undergraduate students said the opposite. The responses to the survey indicate that many people are still unsure about A.I. or do not feel confident or knowledgeable about it. While education is a human-focused field, deep-learning artificial intelligence has the potential to be of great benefit to both students and educators provided more research is conducted.

Abstract Name: Tsc1 Gene Annotation in Newly Sequenced *Drosophila*

Diabetes Mellitus (Type I and II) represents a growing health crisis, with over 10.5% of the U.S. population diagnosed and 34.5% of adults prediabetic, as reported in the 2020 National Diabetes Statistics Report. Both conditions increase the risk for a range of comorbidities, including cardiovascular diseases, blindness, and neurodegeneration. Insulin resistance, a hallmark of Type II diabetes, is influenced by genetic factors, obesity, and diet. Studies in model organisms like *Drosophila melanogaster* have revealed conserved genetic pathways related to insulin signaling that may provide insights into the molecular mechanisms underlying insulin resistance. For example, *D. melanogaster* genes like Tuberous sclerosis complex 1 (Tsc1), and insulin-like peptides, play critical roles in insulin signaling, with mutations in these genes affecting oxidative stress, growth, and lifespan. This study is part of the Genomics Education Partnership's (GEP) Pathways Project, which focuses on annotating genes within conserved metabolic and signaling pathways, particularly the insulin signaling pathway, across various *Drosophila* species. The primary aim of this project is to annotate the genes Tsc1 in nine newly sequenced *Drosophila* species, to explore the evolutionary conservation of these genes and their regulatory regions. Using bioinformatics tools such as the UCSC Genome Browser, FlyBase, Gene Record Finder, and NCBI BLAST, we identified gene orthologs, examined their genomic neighborhoods, and constructed gene models based on the genomic data. By comparing the gene structures and their evolutionary conservation across species with decreasing similarity to *D. melanogaster*, we aim to deepen our understanding of insulin signaling and its regulation. Ultimately, this research will contribute to the broader goal of elucidating how gene regulatory regions evolve in the context of conserved pathways and their implications for human health.

Abstract Name: Mentoring Beyond Our Ken: Uncovering Interdisciplinary Research Potential

While a growing body of literature speaks to the benefits, best practices, and methodologies of undergraduate research, relatively little guidance exists for faculty mentoring research outside their disciplines. We tend to supervise projects that advance our own research areas or, at a minimum, pertain to those subjects we teach, and most students gravitate toward mentors who are experts in their proposed field of research. Given a natural inclination to build upon our core expertise, what cause is there to deviate from a well-established formula for mentor-mentee relationships? This researcher proposes three reasons, based on firsthand experience, to consider deviating from the standard path: meeting student need, facilitating interdisciplinary collaboration, and uncovering exciting new opportunities for mentor and student growth. My ongoing role in advising research beyond my discipline began with two students seeking a mentor who could help them investigate incentives and barriers to cybersecurity education. These undergraduate researchers recognized the potential for a professor outside cybersecurity to lend fresh perspective on their topic and needed someone willing to engage with sometimes unfamiliar terminology, concepts, and issues. The ensuing partnership has illuminated how much good communication, strong research methodology, and equal amounts of humility and curiosity can transcend topical divides. Crossing subject matter borders is not without its challenges. When faculty from disparate fields team up to co-mentor interdisciplinary projects, they benefit from a safety net of both resources and knowledge, supporting each other in times of need. Navigating this process alone whilst guiding research outside your area of expertise can be uniquely taxing, yet also provides opportunities for mentor resourcefulness and academic enrichment. Additionally, students may feel more empowered to contribute in areas that draw primarily from their major focus. This research aims to further an exploration of the limitations, benefits, and different approaches to interdisciplinary mentoring partnerships.

Abstract Name: Exploring circadian variations in autonomic input preceding ventricular tachycardia and ventricular fibrillation: a pathway to predictive models for sudden cardiac death

This study investigates circadian variations in heart rate variability (HRV) and nonlinear dynamics (NLD) leading up to VT/VF cardiac arrests among in-hospital patients, with a focus on comparing these patterns with a standard control group, ultimately aiming to develop predictive models for sudden cardiac death (SCD). Sudden cardiac death (SCD) remains a significant public health concern, affecting between 300,000 and 400,000 Americans every year. Ventricular tachycardia (VT) and ventricular fibrillation (VF) are leading causes of SCD, often occurring unpredictably. There is a time-of-day variation in SCD with an early morning predominance that corresponds to early morning increase in sympathetic nervous activity. Analyzing HRV and NLD can reveal autonomic changes that precede these life-threatening arrhythmias. We examined telemetry ECG data from patients who experienced VT/VF cardiac arrests at UAB Hospital, excluding those in ICUs or with conditions such as metastatic cancer. Using Kubios HRV Scientific analysis software, we assessed HRV indices (e.g., LF/HF ratio, RMSSD, TINN, AC) and NLD parameters (e.g., DFA α 1, DFA α 2, sample entropy). Our study underscores the importance of considering temporal patterns in arrhythmogenesis and supports the potential for HRV analysis in predicting sudden cardiac death. By comparing these patterns with a control, insights into the specific mechanisms underlying ventricular arrhythmias can be elucidated.

This will also allow us to develop predictive analytics to help identify patients who are at risk for sudden death using HRV analysis of their ECG along with clinical factors (e.g. presence of CAD and/or CHF).

Abstract Name: Impact of Live Harp Music on College Students' Heart Rates During STEM Exams: Role of Anxiety and Learning Style

This study explored the effect of live harp music (LHM) on the heart rates of college students during a series of STEM exams. The initial research questions aimed to determine if LHM would decrease students' heart rates during an exam, and if students' anxiety and/or learning style mattered. Music has been associated with its ability to reduce anxiety, but research related to how live harp music interacts with individual traits like anxiety levels and learning styles is lacking. Insights into how music interventions may improve testing performance may be valuable. Within a repeated-measures experiment, college students in a STEM course completed one exam in a quiet environment and the next exam, 3-weeks later, in the same environment but with music from a therapeutic harpist. Mean heart rates, state anxiety scores, and learning style preferences were recorded and analyzed. ANOVA analyses resulted in a linear model with an adjusted R² of 79.97% in which learning style, state anxiety and live harp music interacted to account for the majority of the variance found in students' exam heart rates. Results suggest that the effect of harp music during an exam depends on students' state anxiety and learning style preference. Increased heart rates were observed in students with higher state anxiety and preference for visual learning during the exam with live harp music. Students with non-visual learning preferences and lower state anxiety were less affected by live harp music or protected from exam-related physiological arousal.

Abstract Name: The New Way to Train: Social Anxiety Related to Exercise, Online Fitness Programs, and the Motivators and Barriers to Exercise in College Students

Feelings of hesitancy and anxiety when attending a gym are common among those who exercise less frequently and can significantly impact one's motivation to engage in physical activity. On average, university students report being sedentary for 7.29 hours per day. To meet the CDC recommendation of 150 minutes of moderate weekly physical activity, students must have consistent, frequent exercise habits. The goal of the current study was to explore how anxiety is tied to gym attendance. Participants included 333 individuals who were, on average, 19.5 years old (SD=1.55, Range=18-34). Most participants (263) were female, and over half had attended a gym within the last week. Participants completed an online questionnaire that assessed gym and exercise habits, motivators and barriers to exercise, and anxiety levels, including social anxiety related to exercise. Preliminary t-test results suggested that frequency of gym attendance was tied to both perceived barriers and motivators related to their gym attendance. Namely, people who attended the gym less than once a week cited more barriers that prevented them from going than those who attended more than once per week. Conversely, those who exercised more than once a week identified several motivators to exercise compared to those who did not exercise as frequently. In addition, those who exercised less frequently reported higher levels of social anxiety related to exercise than the more frequent exercisers. Finally, correlational analyses revealed that those with higher levels of general anxiety perceived more barriers to exercise than those with lower levels of anxiety. Similarly, those with higher levels of anxiety had fewer motivators. Our results suggest that anxiety may be related to reluctance to attend the gym. Addressing the major barriers anxiety may present could play a role in encouraging more consistent gym participation and promoting physical activity.

Abstract Name: Experiencing Multiculturalism in a Cultural New World Order

In a world of ever-increasing connectivity, our society's stratification through the use of identity rhetorics and monocultural dominance has established an unwelcome precedent for multicultural people. While many scholars focus on this endless diversification of identities by which to seclude ourselves within multiculturalism, this paper will examine the challenges of existing as simply a multicultural person. The paper poses questions as to what defines multicultural people and the positives and negatives of their multicultural existence. This study is based on sociological research of multiculturalism, personal perspective, and critical analysis of modern artists that fall within the multicultural category. I will argue that multiculturalism is vastly misunderstood on academic, social, and artistic levels, while still reflecting the positive ideal of what modern society should be striving for in the general populace.

Abstract Name: Communicating Scientific Research to the General Public: Eutrophication in the Red Cedar Watershed, Wisconsin

The Red Cedar Watershed, located in Western Wisconsin suffers from eutrophication; an over enrichment of phosphorus and nitrogen. While eutrophication and the green coloring it brings to Dunn County's lakes, Menominee and Tainter, has been a great community concern in recent years, there is no clear discourse on the causes and effects of eutrophication in the Red Cedar Watershed. Since 2014, UW-Stout's Linking Applied Knowledge in Environmental Sustainability, or LAKES program has been conducting research to find what is causing lakes Menominee and Tainter to turn green. In 2024, with the help of mentors Dr. Tina Lee and Arthur Kneeland of the University of Wisconsin-Stout, I researched how we can communicate the LAKES findings from 2014-2023. This process consisted of familiarizing myself with the topic by reviewing all eighty-six past LAKES research projects, conducting a literature review on scientific communication, and by interviewing local experts in scientific communication and media fields. Next, short and long term plans were created on how to communicate the LAKES findings to the general public. By the end of the summer of 2024, a general use infographic was created containing the causes, effects, and possible solutions to the eutrophication in the Red Cedar Watershed. This infographic was posted to local news webpages, posted in the Menomonie Public Library, and spread with help from the Dunn County Democrat and Republican offices. As for long term plans, different mediums of spreading LAKES research have begun to be designed, such as drink coasters containing a QR-code to LAKES research and K-12 lesson plans regarding eutrophication in the Red Cedar Watershed. Data has also been collected in 2019 and 2024 regarding where Dunn County residents get their news, this can be used in future years to get LAKES research on news outlets which most locals use.

Abstract Name: The Effectiveness of Microbreaks in On-Duty Patrol Officers

This study evaluated the effectiveness of micro-breaks in reducing musculoskeletal pain and stress levels among police department employees, a population often exposed to prolonged sitting while on duty. **METHODS:** Micro-breaks, defined as short, scheduled stretching sessions with mindful breathing, were implemented once an hour during shifts over a 16-week period. Participants completed a weekly survey reporting full and partial micro-break completions as well as stress and pain levels using a 10-point scale (0 = no stress/pain; 10 = max stress/pain). The full micro-break stretching protocol targeted the upper and lower back, neck, legs and feet, shoulders, and hips. **RESULTS:** Week 1 stress levels positively correlated with decreased upper back pain ($r = 0.73$, $p = 0.003$), neck pain ($r = 0.52$, $p = 0.055$), and lower back pain ($r = 0.61$, $p = 0.111$). Strong negative correlations were observed between stress levels and both partial ($r = -0.70$, $p = 0.016$) and full ($r = -0.64$, $p = 0.035$) completions of the micro-breaks protocol. Mixed-effects models revealed no statistically significant effect of time on stress levels ($\beta_1 = -0.037$, $p = 0.373$) or lower back pain ($\beta_1 = -0.066$, $p = 0.260$). Individual analysis revealed a moderate reduction in neck pain ($r = -0.55$, $p = 0.125$) and a statistically significant reduction in upper back pain ($r = -0.93$, $p < 0.001$) over time for Subject 1. Statistically significant reductions in stress ($r = -0.72$, $p = 0.043$) and low back pain ($r = -0.81$, $p = 0.017$) over time were observed for Subject 2. **CONCLUSION:** These findings suggest that while group-level effects of micro-breaks did not significantly reduce stress or pain levels over a 16-week period, individual-level improvements in pain and stress indicate the potential for individualized micro-break strategies to mitigate occupational health risks among police officers.

Abstract Name: Povidone Iodine: The Hidden Strength in Dental Care

10% Povidone Iodine (PVP-I) is a potent antimicrobial agent that identifies specific pathogens of dental caries and periodontal disease, disrupting pathogenesis. This study aims to determine if implementing a PVP-I protocol in the oral cavity is a primary preventative agent against bacteria contributing to dental caries and periodontal disease. The credibility of this research is supported by peer-reviewed studies, journals, articles, and reports through quantitative data. The accumulation of bacteria initiates both periodontal disease and dental caries. With over five hundred species of bacteria in our mouth, PVP-I is a broad antiseptic that fights against the most dangerous pathogens. Dental caries prevails as the most preventable chronic disease affecting people of all ages. When PVP-I was used to halt the progression of decay by terminating *Streptococcus mutans*, patients exhibited a 95% disease-free oral environment for 12 months. Likewise, periodontal disease affects one in every three adults over thirty. Subgingival irrigation of PVP-I adjunctive to periodontal therapy decreased pathogen counts by 95% in 44% of pockets with ≥ 6 mm pocket depths. With the rise of antibiotic-resistant bacteria, the need for effective alternatives is critical. PVP-I offers a compelling solution, as it remains effective without developing resistance in dental settings. This analysis will broaden the knowledge of the uses of PVP-I as an adjunct to periodontal therapy and as an addition to fluoride varnish to prevent and remineralize dental caries. Prevention is the primary focus of dental hygiene. Dental professionals should consider utilizing PVP-I in their practice due to its effectiveness, safety, and alignment with the core value of maintaining and improving oral health.

Abstract Name: Quantitative Comparisons of Three Colocated Air Samplers with Simultaneous PM2.5 [Particulate Matter] Measurements

The quality of the air that we breathe has tremendous impacts on our health; bad air quality can lead to short-term eye, nose, and throat irritation, and long-term chronic respiratory conditions. It is important to monitor air quality and understand what metrics indicate potential hazards, in attempts to better measure the healthiness of communities and indirectly its' individuals. Not all air sensors are calibrated to measure metrics the same, and this study will compare values across air sensors via the PM2.5 air quality standard. In this study we focus on measuring particulate matter – which can come from dust kicked up on roads from cars, vehicle exhaust, wildfires, industrial site emissions, and more – using PurpleAir sensors located across Northwest Indiana. PurpleAir does not release proprietary information regarding the formulation of parameters included in the Air Quality Index that is posted on their publicly-available website. Due to potential discrepancies between standardized air sensors and PurpleAir instruments, we are evaluating the accuracy of our measurements against industry standard air sensors. In order to more confidently determine PurpleAir measurements' validity for air quality metrics, we compared them to commercial-grade sensors

such as the TSI DustTrak, Thermo Fisher pDR-1500, & DRUMAir cascade impactor using qualitative graphical and quantitative statistical tools. These sensors are of the caliber used by government agencies such as the EPA, and these research efforts provide a novel and necessary service to communities that depend on these sensors as their only local full time air quality measurement. We expect relative trends in particulate matter concentration to be well reproduced amongst the sensors and absolute comparisons to require scaling factors. As part of our community projects, we also study archived air quality measurements in our attempts to inform future community health and policy decisions.

Abstract Name: The Missing Void: Womenswear, Lack of Pockets and its Effect on Daily Life

More than half of the United States population is frequently left out of having useful pockets, which are an essential, yet often overlooked feature in clothing. Historically, womenswear has been molded to match the beauty standards of the day, sometimes allowing for pockets, while at other times, the feature has been left out completely. This study brings into the conversation a nuanced anthropological perspective on gender differences in modern clothes in the United States, specifically through the difference in pockets. The current research study created space for discussion and investigation into the fashion industry and cultural norms set around gender and clothing. The researcher recruited a hundred and sixty-two participants from a medium-sized regional midwestern university for a mixed-methods survey. The survey included Likert scales, multiple choice, and open-ended questions to explore the attitudes and experiences of people who wear women's clothing regarding pockets and how the accessibility of pockets affected their daily lives. Open-ended questions were analyzed qualitatively using manual coding for thematic meanings specifically through a gender lens, while quantitative questions were investigated using chi-squared tests and analysis. Preliminary themes from the qualitative analysis found that participants believe that the lack of pockets in womenswear stems from aesthetic expectations in fashion as well as due to the primarily female use of purses. Other themes discovered included the impacts of capitalism, sexism, sexualization of female bodies, blaming of the fashion industry, forced reliance on others, men's expectations, historical values influencing modern clothing, and the devaluing of essentials carried by people who dress in womenswear. Lack of pockets in womenswear is an often-overlooked phenomenon that relates to gender inequality and other cultural factors.

Abstract Name: Emergent Bilingual Preschoolers' Math Proficiencies and Development

Emergent bilingual children are typically born and raised in family settings where the primary language of communication is other than the one used as the medium of instruction in their school settings. While these children may carry unique assets in working memory, they typically demonstrate significantly lower achievement levels when compared to their monolingual peers. Research is needed to identify practices that

would embrace the learning characteristics of emergent bilinguals and further nurture their growth. In this mixed-methods study, we tracked the Math development of emergent bilinguals across one year and supplemented this data with classroom observations to arrive at characteristics of supportive environments for emergent bilingual students. The Math abilities of seven emergent bilingual preschoolers of mixed age and gender from a campus lab school were measured at four-time points. On average, these preschoolers scored lower than their monolingual peers at all four times but demonstrated significant growth from time one to time 4, with an average growth of 37 points, thereby attesting to the supportive classroom environment. Between times 3 and 4 of the study, qualitative case study observations were conducted of the bilingual children along with an ethnographic photo study with a classroom teacher. Analysis of the qualitative data yielded valuable information on effective teaching practices for emergent bilinguals. While primary instruction was in English, teachers emphasized key discourse and content words in their interactions with the children. This appeared to provide the children with a vocabulary for connecting their acquired knowledge. Additionally, teachers engaged in culturally sensitive pedagogy, welcoming the children's bilingual funds of knowledge and practices. In this context, they encouraged translanguaging and gender-neutral discourse, further widening the scope of interactions for all children. Further research is necessary to unravel the nuances of classroom practices that support emergent bilingual students from specific language backgrounds.

Abstract Name: Using Transit Photometry to Search for Systems With Multiple Exoplanets

Transit photometry is a well established method of searching for exoplanets in which photometers measure the luminous flux of stars, looking for periodic dips in the flux. If there are regular dips in the flux, each occurring with a regular duration, it is possible that there is an exoplanet orbiting the star. However, this method can only be applied when an exoplanet orbits along Earth's line of sight of the star. Even a few degrees of inclination in a planet's orbit will prevent it from blocking its star's light from our point of view. It is unlikely that all planets in a system will be on the necessary orbital plane to observe a dip in flux. This makes it difficult to find multiple planets in a system using the transit method. Our research focuses on using the changes in the orbital characteristics of transit-applicable exoplanets to search for systems with multiple planets. Using data from NASA's Transiting Exoplanet Survey Satellite (TESS), we examined several years worth of observations of a known exoplanet. The planet orbits HD 219666, a main sequence star roughly 300 lightyears from Earth. In this data, we have detected an increase in the inclination and decrease in transit time of the planet. We suspect the changes to be caused by the gravitational effects of another planet in the system. We aim to apply this method to other systems with known exoplanets in an attempt to observe similar changes

Ella Booe-Scott

TX - Lubbock Christian University

Authors:

Abstract Name: Child Sex Trafficking, Occupational Therapy, and the Biopsychosocial Model of Health

It is estimated that nearly 300,000 children in the U.S. alone are trafficked for sex each year. Globally, it is estimated to be closer to 1.7 million. There are many organizations seeking to rescue children from these horrific environments, resulting in a need for specialized aftercare programs. The purpose of this paper is to investigate the role of occupational therapists in the recovery process of children coming out of sex trafficking settings, using the biopsychosocial model of health. Because there is such a broad set of implications and needs for these children, this holistic model is valuable to identifying the biological, psychological, and social needs of children, and how each of these can be addressed by occupational therapists as they interact with survivors. There has historically been a gap in the field of occupational therapy for how to handle these delicate situations, so through a review of literature identifying the needs of survivors, this study proposes means to identify and improve upon these shortcomings using an interdisciplinary cohesion of psychology, rehabilitative therapies, and social work. In bridging these gaps, there is a hope to improve the recovery experience for survivors, prevent retraumatizing patients, and assist occupational therapists in their fieldwork surrounding an often hidden or ignored social issue, making it more easily approachable.

Abstract Name: Enhanced Bioactivity of Titanium Implants via Silicide-Bioglass Coating

In recent years, the field of biomedical engineering has seen significant advancements in the development of biomaterials for implantable devices and tissue engineering applications. Titanium (Ti) and its alloys have gained widespread popularity due to their excellent mechanical properties, but they have low bioactivity (fusion with bone tissue). In this study, we propose a novel approach to enhance the bioactivity of Ti implants and integration of titanium within the human body by coating the titanium surface with bioactive glass, mediated by a titanium silicide layer. The experimental methodology involves depositing a silicide coating on titanium substrates using a combination of reactions with eutectic salts, a reducing agent, and heat. Then, bioactive glass is grown onto the metals using a general sol-gel method. Analysis is accomplished using scanning electron microscopy (SEM) and X-ray diffraction (XRD) to assess the morphology, phase composition, and surface properties. We show that the interfacial silicide coating on titanium significantly enhances adhesion of bioactive glass, thus improving the biocompatibility of titanium, whereas bioactive glass has little affinity and cannot be grown onto bare titanium. The results of this study have the potential to contribute to the development of improved biomaterials for orthopedic and dental applications, where a strong and stable bond between the implant and surrounding tissue is crucial for long-term reliability.

Abstract Name: Dynamics of Microorganisms in Compost

Composting is nature's way of recycling - reducing waste, enhancing soil health, combating climate change, and offering economic benefits. Central to this process are microorganisms, yet limited research exists on which species dominate throughout compost curing and how environmental conditions influence their presence. Partnering with NC State's compost facility, we established a representative compost pile (17' L x 17' W x 7' H) equipped with 24 HOBO loggers to continuously record temperature. Over a seven-week period, weekly samples were collected using 50 mL test tubes and preserved with QIAGEN Bacterial DNA/RNA Protect for subsequent DNA and RNA sequencing. This analysis aimed to identify the microbial communities present and examine their succession in relation to composting conditions. Specifically, we focused on the interplay between temperature, humidity, and depth from the surface on microbial composition and activity. The findings of this study contribute to a deeper understanding of the microbial dynamics that drive composting efficiency and offer insights for optimizing composting practices.

Abstract Name: Role of TET1 in the early stages of atherosclerotic plaque development

Context: Among the vital organs in our body, the heart is a key organ where acute conditions may lead to severe adversities. Their underlying causes often cannot be diagnosed until hospitalization of the patient. A typical example of this phenomenon is atherosclerosis, as its progression in blood vessels is asymptomatic, only detected by ultrasound or CT scan. High cholesterol (mostly oxidized LDL/oxLDL) levels within blood vessel walls are a known causative factor: macrophages (immune cells) intake oxLDL and transform into large, obtrusive foam-cells that build up within blood vessels and form atherosclerotic plaques. In most cases, by the time the patient first presents with symptoms, the disease has already advanced and surgery is required to save the patient. Rationale: In patients with atherosclerosis, multiple plaques are often seen in different stages of growth, ranging from initial to advanced. Surgery is inevitable to remove advanced-stage plaques. In current treatment regimens, medications are prescribed to lower blood cholesterol. However, there are no treatment plans in place to stop growth of already-existing plaques that are in the initial stages. Purpose: Epigenetic proteins were reported to initiate molecular mechanisms in several disease conditions. However, their role in the development of atherosclerotic plaques, and the cellular proteins they regulate during foam-cell formation, are yet to be deciphered. Research question: Does intercepting early-acting disease mechanisms prevent initiation and/or progression of atherosclerosis? Methods: Through cell culture, the role of a unique epigenetic protein, TET1, was investigated. In my study, monocyte-derived macrophages were first treated with the TET1 inhibitor Bobcat339. Then, they were treated with oxLDL, and the effect of TET1 inhibition on foam-cell formation in presence of oxLDL was studied. Results and conclusions: Inhibition of

TET1 protein prevents plaque development by preventing foam-cell formation, and also by indirectly initiating autophagy-induced cell death in existing foam-cells.

Abstract Name: Design And Synthesis of a Library Of Fluorescein-Based Fluorogenic Carbonates For Human Carboxylesterase Structure-Activity Relationship (SAR) Studies

Human carboxylesterases (CESs) play a major role in the metabolism of many drugs, however, existing tools to study CES1, one of the two forms of CESs, are plagued by various limitations. To address these issues, we have previously developed a fluorescein-based fluorogenic carbonate chemical tool (FCP-1) and demonstrated that FCP-1 can report on CES1 activity in live cells. The aim of the current study is to improve specificity for CES1 by determining a structure-activity relationship (SAR) of fluorogenic carbonates. To achieve this, a library of fluorescein-based fluorogenic carbonates are being synthesized in one step from fluorescein and corresponding chloroformates. The compounds were subsequently characterized using ¹H and ¹³C NMR spectroscopy to confirm the structures before evaluating if they are suitable for use in live cells. This work aims to deepen the understanding of the substrate scope of CES1 to improved tools that study CES1-mediated drug metabolism and better design of drugs that are metabolized by CES1.

Abstract Name: Myokine Expression in Subscapularis, Supraspinatus, and Biceps Muscles following Brachial Plexus Birth Injury

Brachial plexus birth injury (BPBI) is caused by extreme stretching in the neck during childbirth, damaging the brachial plexus nerve network spanning the neck and shoulder. Presenting in roughly 1 out of 1,000 human births, BPBI often leads to inhibited muscle function, bone deformation, and paraplegia. While the extent of injury varies with severity and type (nerve avulsion or rupture), affected muscles often experience muscle atrophy and reduced functionality. Transforming growth factor beta 1 (TGF-B1) and fibroblast growth factor 2 (FGF-2) are necessary for cell repair and protein synthesis. Previous studies show that TGF-B1 regulates muscle repair, while FGF-2 contributes to cell proliferation in injured skeletal muscle. However, the impact of these myokines on muscle growth and repair following BPBI is unknown. This study aims to determine myokine expression during neuromuscular growth following preganglionic (mimicking nerve

avulsion) and postganglionic (mimicking nerve rupture) BPBI. To replicate BPBI, Sprague Dawley rats underwent preganglionic or postganglionic neurectomy, forelimb disarticulation (mimicking disuse), or sham surgery at 3-6 days postnatally. Rats were euthanized at 2, 3, 4, 8, or 16 weeks post-injury. Subscapularis, supraspinatus, and biceps brachii muscles from injured and uninjured limbs were each harvested, digested, and centrifuged to produce a tissue lysate. The lysate solution was analyzed for FGF-2 and TGF-B1 levels by enzyme-linked immunosorbent assay (ELISA). Preliminary results indicate that at 4 weeks, both injured and uninjured biceps muscles have greater FGF-2 expression than the corresponding subscapularis and supraspinatus muscles in both disarticulation and sham groups ($p < 0.01$). Ongoing analyses are focused on 2, 3, 8, and 16 week timepoints. Once adequate data are collected, groups will be compared using two-way ANOVA with Tukey's corrections for multiple comparisons. These findings will provide insight into potential mechanisms underlying muscle detriments following BPBI, which can be used to test new treatment strategies.

Abstract Name: The Cost of Being Female: A Survey on the Pink Tax

The "pink tax" refers to the price disparity between products and services marketed to females, often for items that are nearly identical to those marketed to males. My research explores public perceptions of this economic phenomenon, specifically testing if male and female responses differ. I hypothesized that females would view the pink tax as unfair, while males would find it fair. I also hypothesized that more females would support laws against the pink tax. To test my hypothesis, I created a 16-question survey and distributed it through Amazon MTURK, where I was able to collect 180 responses which were then analyzed using IBM's SPSS. Contrary to my hypothesis, I found that a significant portion of females (47.8%) viewed the pink tax as somewhat fair, with only 9.8% finding it somewhat unfair. Furthermore, 86% of males supported legislative action to make the pink tax illegal, compared to 73.93% of females. A notable 26.1% of females disagreed, compared to just 8.1% of males. These results suggest that many females do not see the pink tax as unjust but still support policy changes to address it. Interestingly, a higher percentage of males favor legislative action, revealing a discrepancy between public perception and actual support for legislative reform. The findings are significant at the 2% and $< 0.001\%$ levels, respectively, challenging commonly held assumptions about gender-based views on the "pink tax," therefore advancing research about gender-focused economic studies.

Abstract Name: Morphometric analysis of the human jaw through time

Understanding the evolution of mandibular morphology provides key insights into the interplay between diet, technology, and human adaptation. Ancient human mandibles were typically larger and more robust,

reflecting the mechanical demands of tougher diets. In contrast, more recent mandibles are smaller and less robust due to dietary shifts and technological advancements, which have reduced masticatory demands. Very few studies, however, have quantified the differences between ancient and present-day mandibles, which may be particularly gracile due to ultra-processed foods in the contemporary diet. In this study, we compare mandibular morphology of contemporary Floridian populations and agricultural populations from Sudan 350 BCE-350 CE to explore how changes in diet and lifestyle influence jaw shape. We hypothesize these two groups will have significantly different mandibular shape, with the ancient agricultural population exhibiting greater overall robustness and larger muscle attachment sites than the modern Floridian population. To test this hypothesis, mandibles will be 3D scanned and compared using geometric morphometrics quantitative methods. Comparative analysis will be focused on indicators of shape, thickness, and masticatory muscle attachment sites. We expect to find support for our hypothesis, showing that softer, processed diets in modern contexts require less chewing effort, resulting in less mechanical demands on the jaw, and ultimately shaping morphology over time. This study will highlight the role of dietary and technological shifts in shaping mandibular evolution and the functional pressures that contributed to the modern human jaw's smaller, less robust morphology. Understanding these evolutionary changes has broader implications for studying craniofacial adaptation

Abstract Name: AI-Based Phishing Countermeasures

Phishing attacks are among the most prevalent forms of cybercrime, exploiting human vulnerabilities to deceive individuals and organizations. This research seeks to explore the human element in phishing attacks to develop more effective prevention strategies. Phishing's success is deeply rooted in psychological and behavioral factors, which influence an individual's susceptibility to these attacks. Our study aims to identify these key psychological traits and behaviors that heighten vulnerability, such as cognitive biases, trust in online communications, and lack of cybersecurity awareness. In addition to this exploration of human factors, we will conduct a comprehensive literature review of the latest Machine Learning (ML) techniques used to detect and prevent phishing attacks, examining their strengths, limitations, and real-world applicability. To deepen the understanding of human vulnerabilities in phishing, we will also gather data through surveys, interviews, and Open-Source Intelligence (OSINT), ensuring a diverse and multidimensional perspective on the issue. By analyzing this data, we aim to bridge gaps in current knowledge and provide new insights into how human behavior can be better addressed in phishing prevention strategies. Furthermore, the study will explore potential areas for improvement in existing mitigation methods, considering both technological and behavioral approaches. The findings will contribute to the body of knowledge by offering practical, data-driven recommendations for designing more targeted and effective countermeasures to protect individuals and organizations from phishing attacks. Ultimately, this research aims to provide a foundation for future developments in both human-centered and Machine Learning-based phishing defense strategies.

Abstract Name: Subversive women: Trauma, violence and nation building in Ernesto Sábato's trilogy

This presentation proposes a (re)examination of Ernesto Sábato's trilogy *El túnel*, *Sobre héroes y tumbas*, and *Abaddón el exterminador* from both gender-based and juridical perspectives. Through a re-reading of the trilogy, I introduce the concepts of suicidio-femicida as a lens to explore how the female protagonists experience distinct forms of sexual and ideological violence due to their transgressions of Argentine societal gender norms. This analysis not only brings to light historically overlooked forms of gender violence but also employs a juridical framework to (re)evaluate past and present contexts, denouncing the patriarchal structures that perpetuate oppression, injustice, and impunity. Building on the theoretical frameworks of gender theorists like Judith Butler and Rita Segato, and drawing from psychoanalytic theory and trauma studies as articulated by Giorgio Agamben and Cathy Caruth, I will investigate how the female body and identity were central to the construction of national identities and nation-building processes across Latin America in the post-independence period. I argue that these novels, through their portrayal of female characters, reflect the broader cultural and political dynamics of nation-making and the deeply embedded gender hierarchies that persist within them. While existing scholarship on Sábato's trilogy offers valuable contributions, it overlooks the gendered dimensions of violence and the psychoanalytic underpinnings of these texts. My contribution lies in applying an interdisciplinary approach that integrates gender theory, trauma studies, and juridical analysis to explore the intersections of trauma, gender-based violence, and national identity formation in Sábato's work. Considering the current political context in Argentina under President Javier Milei, my research aims to examine how national political discourses legitimize gender-based violence, reinforcing harmful ideologies that threaten to reverse advancements in women's rights. Through this, I aim to deepen our understanding of how gender violence operates in the collective imagination and historical memory of the region.

Abstract Name: Exploring Gender Differences in Perceptions of AI's Impact on Social Media

Artificial Intelligence (AI) is increasingly shaping social media through content personalization and moderation, raising questions about its influence on public opinion and trust in digital news. Gender plays a key role in shaping perceptions of AI's impact, with men and women potentially viewing its applications differently. This study explored gender-based perspectives on AI's role in social media, focusing on its effects on information credibility and privacy. Data from 155 participants, collected via Amazon Mechanical Turk, were analyzed using IBM's SPSS. The first hypothesis proposed that women would be more skeptical than men about AI's use in news, citing greater concerns over misinformation. The second suggested that women would view AI as less problematic when applied to creative content. The results confirmed these hypotheses and were statistically significant at the 1 percent level. Women were more likely than men (56.3% vs. 43.4%) to see AI as 'somewhat beneficial' for creative content applications. However, they also expressed greater caution about AI-generated news, with 37.5% of women strongly agreeing that AI contributes to more believable fake news, compared to 18.4% of men. These results indicate that women perceive AI as more beneficial for creative purposes but harbor greater concerns about its role in spreading misinformation. Understanding these gender-based differences can guide the development of AI tools that better address diverse concerns, enhancing both trustworthiness and user satisfaction on social media platforms.

Abstract Name: Optoelectronic Characterization of III-V Laser Diodes

Light emitting sources commonly made from III-V materials are used in photonic integrated circuits (PICs). The application for PICs that we are interested in is for light detecting and ranging (LiDAR) that can be used for autonomous vehicles. I took optoelectronic measurements of GaAs (gallium arsenide) and InP (indium phosphide) laser diodes and compared them to a packaged laser diode. I recorded their characteristics to determine which lasers could be incorporated in PICs for LiDAR applications. Optoelectronic characterization consists of current-voltage (IV), light-current-voltage (LIV), and intensity vs wavelength characterization and provides important information about the laser's properties, including operating point, threshold current, turn on voltage, and efficiency.

Abstract Name: Congenital transmission of Chagas disease: The role of newborn therapy on the disease's dynamics

Chagas disease is caused by the protozoan blood-borne pathogen *Trypanosoma cruzi*. The World Health Organization (WHO) classifies Chagas disease as one of 21 neglected tropical diseases worldwide, with an estimated 6–7 million people currently infected. The disease is primarily transmitted through Triatomine bugs. It can also be spread congenitally, orally (food-borne), or through blood transfusions and organ transplants. Congenital transmission plays a significant role in new infections in both endemic and non-endemic regions. In endemic areas, 22.5% of new cases result from mother-to-child transmission, while in non-endemic countries, it is the primary source of new infections. In this talk, I will present the impact of congenital transmission on Chagas disease dynamics using a mathematical model. The main question guiding this research is: how does treating a proportion of infants born to infected individuals impact the progression and spread of Chagas disease? To address this, ordinary differential equations were used to model disease transmission through vector-to-human, human-to-vector, and congenital routes. The control reproduction number (R_0) was calculated from these equations, and MATLAB simulations were used to visualize the model's behavior under various conditions. The results illustrate the importance of treating a high proportion of newborns to reduce the number of infected cases. However, the findings show that while the therapy given to newborns is necessary, it is not sufficient to curb the transmission of Chagas disease. Strategies to reduce vector transmission must also be in place. If vector transmission can be controlled, then treating at least 55% of the newborns could be enough to eliminate the disease. This study highlights that a comprehensive approach, including both vector and congenital transmission control strategies, is essential for eradicating the

disease. Ultimately, this provides useful information for shaping policy and developing better strategies to control the spread of Chagas disease globally.

Abstract Name: The Romanticization of Human-Vampire Relationships: How Twilight and The Vampire Diaries May Prime Young Women to Accept Dating Violence and Abuse

The first literary vampire can be traced back to 18th century Germany, with Johann Wolfgang von Goethe's poem "Die Braut von Korinth," but the stereotypical features of a vampire are traditionally accredited to Bram Stoker's Dracula. Modern vampires, such as Edward Cullen and Stefan Salvatore of the Twilight and The Vampire Diaries series respectively, have managed to win the hearts of teenage girls all across America with their sex appeal and charismatic nature. According to Bandura's Social Cognitive Theory, individuals learn new behaviors by modeling and imitating the actions of those around them. This comprehensive literature review investigates the connection between the human-vampire relationships in Twilight and The Vampire Diaries and teenage girls' acceptance of dating violence and abusive behaviors from intimate partners. This study aims to examine how both Twilight and The Vampire Diaries create popular modern vampire narratives that may promote harmful messages to female youth regarding future romantic relationships. This analysis of peer-reviewed studies finds that harmful gender stereotypes and literary tropes are used on both female and male characters, the vampires exhibit manipulative and predatory behaviors, and the idea of true love overpowers the abusive behaviors of Edward and Stefan in the eyes of young girls, possibly creating a link between sex and violence. The findings of this study display a positive correlation between exposure to media violence and acceptance of dating violence among teenagers, as well as a positive correlation between exposure to sexually-oriented television and both the acceptance of the sexual double standard and earlier sexual timing expectations in relationships. New vampire media is still being produced, so it is important to understand what messages are being portrayed to teenage girls and how exactly these messages are altering their values regarding love in heterosexual relationships.

Abstract Name: Montessori-Based Dementia Care: A Path to Meaningful Engagement

Few programs provide dementia friendly environments and activities for adults with Alzheimer's disease and related dementias (ADRD) (Buettner, Lundegren, Lago, Farrell, & Smith, 1996). Montessori-based activities focus on ability and facilitate positive engagement and affect (Jarrott, Gozali, & Gigliotti, 2008). This research project aimed to enhance clinical skills of undergraduate students by focusing on

creating and implementing Montessori-based activities for adults with ADRD. Research participants were four college students who majored in Communication Sciences and Disorders. The students created two Montessori-based activities aiming to capitalize on their abilities including the five senses and engaging in meaningful conversation topics with the participants. The flower activity provides opportunities for students to appropriately set up and guide adults with ADRD to arrange vases, choose flowers based on color, texture, scent, and personal preferences with visual and auditory support. The toolbox activity offers opportunities for students to guide adults with ADRD to sort common household items and the tools (hammer, screwdriver, tape measure, etc.) and to discuss the function and sensory qualities of each with visual and auditory support. Each activity was implemented for 30 minutes two times a week for an 8-week duration in a local memory care facility. A student was paired with 1-2 adults with ADRD, set up and implemented the activities, and used one of the two versions of a script (downward/simplified and upward/more challenging) to facilitate meaningful conversations based on the abilities of the adult with ADRD. Engagement and communicative behaviors of the students and adults with ADRD were documented using a 5-point rating scale and descriptively. Qualitative and quantitative data will be analyzed. The expected outcome is for college students to develop clinical and interpersonal skills to support adults with ADRD and curate a dementia friendly environment.

Abstract Name: Investigating the link between APOE4 and severe COVID-19 infection with human cortical organoids

As of September 2024, SARS-CoV-2, the virus responsible for the COVID-19 pandemic, has infected over 750 million people worldwide. Up to 30% of COVID-19 patients have also reported neurological symptoms, such as brain fog, anosmia, and delirium, that can last weeks after infection. Previous research suggests that APOE4, the leading genetic risk factor for late-onset Alzheimer's Disease (AD), induces more severe SARS-CoV-2 infection in patients and more severe neurotropism in human stem cell models. Additionally, prior studies using 2-D and 3-D stem cell models of the human brain indicate that COVID-19 infects neurons and glia and that APOE4 increases infection of both cell types. However, whether APOE4 directly or indirectly alters cell-type susceptibility to SARS-CoV-2 infection is unclear. To address this question in a human-relevant model system, we generated human cortical organoids (CO) enriched in excitatory neurons from induced pluripotent stem cells (iPSCs) from patients with either the APOE3/3 or APOE4/4 genotype. At late developmental time points, COs were infected with SARS-CoV-2 for 1 hour and harvested at 7 days post-infection for RT-qPCR and immunohistochemistry. Preliminary results show that APOE4 does not affect overall SARS-CoV-2 infection in COs but does increase glial populations post-infection, suggestive of heightened astrocyte reactivity. COs from both APOE genotypes had increased neuron maturation following infection with SARS-CoV-2. This data suggests that APOE4 may alter astrocyte reactivity, potentially inducing neuroinflammation, to increase vulnerability to SARS-CoV-2 without increasing SARS-CoV-2 neurotropism in the cortex. These findings provide insight into the mechanisms through which APOE4 increases COVID-19 severity and highlight the importance of understanding how genetic risk factors influence viral infection in different patient populations.

Abstract Name: Cyanobacterial Mat Communities Associated with Caribbean Coral Reefs

Coral reefs are sensitive indicator ecosystems that support a wealth of biodiversity in marine environments, and their decline is a global concern. Benthic cyanobacterial mats (BCMs) are increasingly present in coral reef ecosystems and may contribute to coral death and disease. However, the composition of BCMs and their competitive relationship with corals remains in question. We conducted field sampling of BCMs from the coral reefs of Roatan, Honduras, in order to determine their species composition (e.g. cyanobacteria and other microorganisms including microalgae). With the help of the Roatan Institute for Marine Sciences (RIMS), ten samples were collected in May 2024 from three dive sites within Roatan Marine Park. Each benthic mat sample was taken at a depth of 6-18 m from sand and macrophyte substrates. Mats ranged from dark red-purple, to brown, to light yellow-green in color, and from typical crustose benthic mats, to small spherical growths, to feathery coverings of macrophytes. The samples were preserved with TEM fixative (4% concentration) and DNA/RNA shield (4%) for microscopic and genomic analysis, respectively. Common cyanobacterial genera microscopically identified in our samples were *Lyngbya*, *Oscillatoria*, *Phormidium*, *Pseudanabaena*, and *Spirulina*. Future molecular analysis will provide species and/or strain-level taxonomic resolution, as well as toxin gene presence. Our study did not measure toxin production; however, further research should be conducted to determine cyanobacterial contributions to water column toxin levels. Cyanobacterial mats should continue to be characterized and monitored. In order to progress with coral transplantation and recovery efforts, more data needs to be collected regarding the full ecological impacts of microalgae and cyanobacteria on reef ecosystems.

Abstract Name: How Does Racial Bias Impact the Perceptions of Black Women Regarding Maternal Care?

Between 1999–2002 and 2018–2021, the maternal mortality rate in the United States increased by 144% from 9.65 to 23.6 deaths per 100,000 live births. Although women of all races are affected by maternal mortality yearly, it is especially prevalent in black women. In the United States, black women are three times more likely to die from pregnancy-related causes than non-black women. Despite advancements in medical technology and obstetric care, Black women continue to experience adverse maternal health outcomes at alarmingly high rates. Research suggests that perceptions of racial bias and discrimination during maternity care contribute to this disparity. These experiences can lead to mistrust in healthcare providers, delayed or inadequate care, and heightened stress levels, all of which can negatively impact maternal health. Despite advancements in medical technology and obstetric care, Black women continue to experience adverse maternal health outcomes at alarmingly high rates. Research suggests that perceptions of racial bias and

discrimination during maternity care contribute to this disparity. These experiences can lead to mistrust in healthcare providers, delayed or inadequate care, and heightened stress levels, all of which can negatively impact maternal health. The purpose of this thesis project is to explore Black women's perceptions and experiences of racial bias during maternity care.

Abstract Name: Policy Implications for Relocating Socially Vulnerable People Out of Public Housing

Relocating people from public housing is a critical issue for policy analysis. Policy initiatives such as Moving to Opportunities, HOPE VI, and Choice Neighborhood have presented significant challenges that have negatively impacted residents who are poor, people of color and who are socially vulnerable. This process also disrupts established communities, threatens access to essential services, and raises fundamental questions about social equity. As cities redevelop, we must carefully consider the impact of moving these communities to ensure that progress in a way that promotes social justice. The election of Barack Obama as the first African American president marked significant progress toward America's ideals of equality and liberty. His presidency symbolized a step forward from the nation's history of racial injustice, with impactful policies like the Affordable Care Act and DACA promoting inclusion and equity. However, challenges such as political backlash, xenophobia, and voter suppression persist, threatening these advancements. This can be seen in the recent housing policies aimed at relocating poor and Black families out of public housing. The rise of discriminatory policies emphasizes the need to protect civil rights. This research will explore the potential impact relocation policies have on socially vulnerable communities. Using data from the Choice Neighborhood relocation project, this study will explore the impact this policy has on residents in an urban community in Virginia. Preliminary data suggest that the Choice Neighborhood policies have negative impacts on residents' access to resources, but significant improvements in living conditions. Implications for policy analysis and practice will be discussed.

Abstract Name: Calculus, Geometry, Numerical Analysis, and Beyond: New Developments in Harmonic Numbers and Circumcenters

The work introduced here presents new developments on old concepts in geometry and calculus, such as the concepts of circumcenter and harmonic numbers. These developments are presented analytically and the work displayed here also shows how to prove them numerically. The analytical proofs involve known results and concepts, including but not limited to the Riemann Zeta function, famously related to the Riemann Hypothesis. The Riemann Zeta function is a summation that has uses in the field of number theory and statistics. The Riemann Hypothesis, which provides a framework for predicting prime numbers, is often used

in physics, statistics, and other fields dealing with random numbers. The work introduced here presents solutions to two open problems published in the College Mathematics Journal during 2024. One problem, proposed by Ovidiu Furdui and Alina Sîntămărian, involves evaluating the summation of a product of harmonic numbers. In this problem, we can see a clear connection to higher powers of the Riemann Zeta function. The solution involves manipulating series, applying the definition of the Riemann Zeta function, and research conducted by the author of the problem. The other problem, proposed by Tran Quang Hung, states that the circumcenters of a particular collection of circumcenters fall into the same circumference under certain circumstances. The solution to this problem presented here involves creating an equation to find the cartesian coordinates of the circumcenter, the reduction of trigonometric identities, and analytic reasoning. The analytical solutions to both problems were developed in parallel to numerical procedures that hinted at the correct solution.

Abstract Name: Mathematical Model of Fibrin Networks Under Tension

Stroke is a leading cause of death and disability worldwide, so understanding how blood clots degrade is critical for improved treatment efficacy and safety. Blood clots are polymer networks composed of fibrin fibers under tension, though existing models of blood clots do not account for this tension. We created a mesoscale mathematical model of fibrin fibers under tension, beginning with simple spring and mass networks. We initially tried to leverage software with pre-existing mass/spring capabilities, but ultimately decided that constructing our own customized Python model was necessary. Using AI and open source code, we built a numerical model that can be extensively adjusted to account for various biomechanical conditions. Our model includes small networks of masses and springs under tension that rearrange each time a fiber (spring) is degraded. In this poster, we present our model and preliminary results. In the future, we will incorporate laboratory data to refine the simulations and obtain physiologically realistic results. Ultimately, this research may provide greater precision in stroke treatment for individual patients and reduce adverse or even fatal side effects.

Abstract Name: The Use of a *Granisotoma rainieri* Antifreeze Protein to Cryopreserve *Drosophila melanogaster* Eggs

Many cell types can survive being frozen for long-term cryogenic storage; unfortunately, *Drosophila* eggs cannot. When fruit fly eggs are frozen, the ice crystals that form as a result pierce the cell membrane of the eggs, leaving the egg unable to hatch due to the damage. Other species avoid freezing damage by synthesizing antifreeze proteins which *Drosophila* do not make. In this experiment, we will be transforming

fruit fly eggs with the gene which codes for GrAFP, an antifreeze protein found in *Granisotoma rainieri*, snow fleas, in an attempt to breed fruit flies which can express the GrAFP protein. If this experiment is successful, it would allow researchers around the world to maintain stocks of genetic interest without the need to maintain live animals. As there are thousands of *Drosophila* laboratories all around the world, the ability to cryopreserve fruit fly eggs would save money and many thousands of hours which could be better spent carrying out experiments. We will subclone the gene for GrAFP into a plasmid which will allow us to incorporate the gene into the *Drosophila* genome. The plasmid will then be sent off to another lab to be microinjected in *Drosophila* eggs. We will receive the larvae back and breed the transgenic flies. The transgenic flies will be tested to see if their eggs are freeze-tolerant and to test whether the GrAFP protein is being expressed in the eggs.

Abstract Name: The Effect of Rise Time and Timbre on the Perception of Plucking and Bowing

This research aims to investigate the acoustic components of instrument timbre that convey to listeners whether a string is being plucked or bowed. Past research has focused on whether plucks and bows are perceived categorically, with mixed results (Cutting, 1982; Rosen & Howell, 1983; Kewley-Port & Pisoni., 1984; Smurzyński, 1985). However, much less work has been done on what other factors can be manipulated to create hybrids and how people actually perceive them (Peynircioğlu et al, 2016). This project intends to extend auditory categorical perception research by looking at multiple stimulus dimensions. I will create hybrid stimuli that transition from a bow to a pluck by blending temporal and spectral aspects of the sounds, with the goal of creating a plausible morph. Participants will provide judgments of the sounds on the degree of blending and quality of morph via a Qualtrics survey. Expected results will reflect modulations of these ratings depending on the level of the parameters mentioned above. We hypothesize that morph ratings will be highest when the pluck and bow ratings fall within a mid-range, as opposed to them being at either extreme or the pluck having dominance over the bow, and vice versa. The results will provide insight into human auditory perception and inform methods for creating realistic morphs, which can be applied in music technology as well as in AI sound creation.

Abstract Name: Measuring the Distance of an Indoor Shotput Throw Using Computer Vision

On the Westminster College track and field team, we throw implements indoors for practice during the winter season but cannot measure the distance of the indoor throws due to limitations in the indoor set up. Because of this, the task was undertaken to create a program using Python to extract data from a video of a throw, input the data into a projective motion model, and extract the distance the throw would have gone. We

processed the video frame by frame, identifying the location of the implement using its color. Since the implement is a fast-moving object, we used a frame comparison technique to verify that the identified objects were the implement. Once the object was successfully identified, we then used the frame rate and throwers height to estimate the distance assuming the throw travels along a parabolic path.

Abstract Name: Chemical Reaction Pathways for the Degradation of PFOA via Pin to Water Cold Atmospheric Pressure Plasma

In recent years, chemicals known as PFAS (per- and poly-fluoroalkyl substances) have risen to the forefront of the public eye due to health organizations issuing a health warning, citing likely carcinogenic effects starting at extremely low levels of exposure. Moreover, PFAS is a major problem for both the environment and humans because it cannot degrade naturally due to the resilient fluorocarbon bonds that cannot be broken down by standard chemical water treatment processes. This study was conducted to determine the degradation of PFOA in water and elucidate the chemical reaction pathways via pin-to-water discharge CAP (Cold Atmospheric Pressure Plasma). CAP is a promising technology due to its ability to generate both oxidative and reductive species, unlike standard chemical processes, making CAP technology equipped to handle the PFAS contamination crisis. In this study, 20uM solutions of PFOA in water were treated under plasma with or without a surfactant (to bring PFOA to the site of degradation). Treatment times ranged from 0-120 minutes. Solutions were quantified using a Liquid Chromatography Mass Spectrometer to determine how much degradation was achieved. Results indicate that CAP degraded PFOA by 80% in 120 minutes. Using a surfactant, PFOA was degraded by 90% in 30 minutes. To understand the reaction pathway of the plasma, scavengers were used to target the reducing species (isopropanol for the H radical and sodium nitrate for the hydrated electron) since they are the most common in plasma. Results indicate that the hydrated electron is responsible for 64% of PFOA degradation, while the hydrogen radical is responsible for 51% of PFOA degradation, with marginal error due to detection limitations. The advances made with the degradation of PFOA utilizing CAP technology, and the understanding of chemical pathways CAP produces, show promise in eradicating toxic forever chemicals while highlighting the lesser-known world of plasma technology.

Abstract Name: Designing the New Frenchman: The Creation of a National Costume of France

The French Revolution attempted to entirely refashion society, including its clothes. Artists like Jacques-Louis David designed a distinct new style for the French Republic, yet despite the names attached, the style did not survive. Some of these designs have endured as fashion plates, including eight by David. They range from costumes for the civilian to the legislator, as well as a couple for military use. Toga-like mantles, close cut hose, and tri-color sashes were a break from the cutaway coats of the time. By comparing these illustrations to the other prominent Revolutionary fashion- the sans-culotte- it is possible to see where these designs failed to meet the practicalities of the day. However, they also display the ideological weaknesses of the Revolution, such as not considering the working man, like the sans-culotte, to be worthy of imitation. These designs have received relatively little research focus, excepting Aileen Ribeiro's chapter on them in *Fashion in the French Revolution*. Nevertheless, they are a useful case study of the Revolution in the time before the Terror. The efforts to create a new national costume for France in 1794 demonstrate the inherent conflicts in creating the new system, as well as the aesthetic and philosophical inspirations that drove the Revolutionaries.

Abstract Name: Behind the Curtain: The Influence of Tourism and Production Costs on Broadway Success

Broadway serves as a cultural and economic cornerstone of New York City, yet the financial success of its productions is shaped by an intricate interplay of external and internal factors. This study investigates the relationship between Broadway's economic performance, NYC tourism numbers, and production costs, focusing on the central research question: To what extent is Broadway's success dependent on increasing tourism and decreasing production costs? By analyzing this key relationship, the study builds on limited existing research, offering new insights into the economic drivers of one of the world's most iconic entertainment industries. Using quantitative methods, data from four decades (1980–2023) were analyzed across three hypotheses. The first explored the correlation between annual NYC visitor numbers and Broadway grosses (N = 44 years of data). The second tested the relationship between Broadway grosses and material production costs (as indexed by the key costs - i.e., lumber and cotton price; N = 521 months of data). The third examined the combined effects of tourism and production costs on Broadway's financial outcomes through multiple regression analysis (N = 44 years). While findings strongly supported the impact of tourism on grosses (e.g., $R^2 = .95$, $p < .001$), production costs alone showed no significant correlation. However, when considered alongside tourism (via multiple regression), cotton prices emerged as a significant predictor $\Delta R^2 = .006$, $p = .023$, emphasizing the multifaceted nature of Broadway's financial success. These results emphasize Broadway's reliance on tourism while highlighting the nuanced role of cost management, particularly the significance of cotton prices over lumber, in balancing creative excellence with financial sustainability. The study also encourages future research to examine broader success metrics, emphasizing adaptability and resilience amid external disruptions like global crises and economic shifts. Overall, this research enhances understanding of Broadway's economic dynamics while providing a framework for addressing challenges in a changing cultural and financial environment.

Abstract Name: The Effect of Spirituality and Religion on the Cessation of Drug use and Crime Among Reentering Offenders

The role of religiosity in post-release substance use and criminal activity has produced mixed findings in the prisoner reentry literature. While some studies highlight its protective effects, few have explored the distinct impacts of religiosity and spirituality on post-release behavior. This study addresses that gap by analyzing a contemporary sample of 352 formerly incarcerated individuals. Results indicate that spirituality significantly influences the cessation of substance use, though its effect on reducing post-release criminal activity is moderate. In contrast, religious involvement, while offering some protection, has a weaker impact on both outcomes. These findings offer valuable insights into how religiosity and spirituality shape the reentry process, with implications for policy and practice.

Abstract Name: The AI-Cancer Annotation and Recognition Evolution (AI-CARE): Transforming Pathology

The exponential advancement of Large Language Models (LLMs) such as OpenAI's GPT-4o has unlocked transformative potential across diverse sectors, with healthcare emerging as a critical area of application. The global healthcare system faces a persistent shortage of medical professionals, coupled with increasing demands for accurate and timely diagnoses. Annually, millions of cancer cases are diagnosed worldwide, with early detection significantly enhancing patient outcomes. However, the diagnostic process often involves time-consuming image analysis, which can be prone to human error. To address these challenges, this research explores integrating multi-modal GPT sophisticated image recognition capabilities into the healthcare framework. We propose developing a Python-based diagnostic tool leveraging GPT's image processing strengths to accurately identify and classify cancerous cells in medical images, focusing on breast cancer biopsies. The tool aims to provide reliable preliminary screenings that can assist pathologists in making informed decisions by training the model to recognize phenotypic traits associated with malignant cells. The system is designed to accept user prompts for labeling and distinguishing between healthy and cancerous cell groups, thereby streamlining the diagnostic workflow. Preliminary results demonstrate that the GPT integrated model achieves high accuracy in pattern recognition tasks, showing promise in reducing diagnostic errors and expediting the screening process. However, challenges such as response consistency and the necessity for extensive training data remain. Ongoing refinements aim to enhance the model's precision and reliability, making it a viable adjunct tool in clinical settings. This research marks a crucial stride in harnessing AI-driven technologies to bolster medical diagnostics. By enhancing the precision and efficiency of cancer cell identification, the proposed system has the potential to ease the burden on healthcare providers, expedite patient recovery, and ultimately enhance clinical outcomes. The successful implementation of this model could reshape pathology practices, offering scalable solutions to meet the burgeoning demands of global healthcare.

Abstract Name: A Study in the Standardization of Automotive Vinyl Wrap Examination

Automotive vinyl wraps have increased in popularity with their numerous benefits over alternative methods like repainting. The increase in vinyl-wrapped vehicles presents new challenges for forensic investigations in cases such as general accidents or hit-and-runs. While there are standardized methods for automotive paint analysis, no such methods exist for automotive vinyl wraps. There is currently no defined way to examine evidence involving vinyl effectively and consistently, making such evidence difficult to process and potentially unusable. This project aims to understand the physical and chemical properties of vinyl wraps and their discrimination abilities to evaluate the possibilities of vinyl wrap comparisons for future examinations. Vinyl from multiple manufacturers, of different colors and finishes, was observed optically using microscopy and chemically using an ATR-FTIR (Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy). Initial variations in patterns and behaviors were documented to assess distinguishability. With RStudio, spectral data was analyzed using pairwise comparisons and PCA analysis for each tested sample to determine whether differences in specific variables affect the discernibility of samples. From the preliminary data analysis, a general decrease in correlation was observed between colors, finishes, different roll positions, and manufacturers. With current findings from this project, we aim to offer general methods for examination that may also provide discriminating thresholds for evidence leading to inclusion or exclusion.

Abstract Name: Enhancing Bee Colony Health Monitoring through Non-Invasive Acoustic Analysis with LSTM Neural Networks

The health of bee colonies is vital for ecosystem sustainability and agricultural productivity due to bees' critical role in pollination. Traditional monitoring methods are often invasive and labor-intensive, lacking the ability to detect early signs of colony distress. This research proposes the utilization of advanced LSTM neural network models to analyze acoustic bioindicators as a non-invasive approach for monitoring bee colony health. We employ a meticulously curated dataset comprising monthly audio recordings from various bee colonies across different countries, enriched with metadata such as colony number and country of origin. The dataset also includes comprehensive biological data on pathogens, hormones, metabolic indicators, and parasites, featuring specific markers like ABPV, BQCV, DWV, IABPV, KBV, LSV1-4, P.larvae, SBV, V.apis, and V.ceranae. Leveraging the temporal sequence modeling capabilities of LSTMs, the proposed model is designed to capture intricate patterns within the audio data that correlate with changes in colony health. The LSTM neural network's proficiency in handling sequential data makes it particularly suited for analyzing the dynamic acoustic signals produced by bee colonies, which may contain subtle indicators of stress or disease not detectable through conventional analysis. The anticipated outcome is a predictive model capable of identifying early signs of unhealthy conditions within bee colonies. This early detection system would enable beekeepers to implement preventive measures promptly, potentially averting colony collapse and supporting

sustainable apicultural practices. By providing a real-time, non-invasive monitoring tool, this approach could significantly enhance bee health management, with positive implications for agricultural output and ecological balance. This research aims to bridge the gap between advanced machine learning techniques and practical apicultural applications, demonstrating the potential of combining acoustic analysis with LSTM neural networks to monitor and preserve bee colony health effectively.

Abstract Name: Biosensors for Space-flight Neuro-Ocular Syndrome

This project aims to develop miniaturized devices using nanotechnology and advanced materials like graphene and carbon nanotubes to continuously monitor physiological pressures, particularly intraocular pressure (IOP). Elevated IOP is a key marker in the diagnosis and treatment of Spaceflight Associated Neuro-ocular Syndrome, which is recognized as a health risk for NASA astronauts. Our approach involves designing a contact lens tonometer embedded with graphene-carbon nanotube nanocomposite films, which offer heightened sensitivity and real-time, non-invasive monitoring of IOP. Methods include the synthesis and fabrication of nanocomposite films, characterization of their mechanical and electrical properties, and integration into flexible contact lenses. Simulated ocular environments are going to be used to test the biosensors sensitivity and accuracy under dynamic pressure conditions. Preliminary results indicate that the carbon nanotube films provide reliable and highly sensitive IOP measurements, outperforming traditional tonometry methods. These findings suggest that the contact lens tonometer could offer a more effective way to monitor IOP, improving patient care for elevated IOP which can be seen in SANS or glaucoma. This research not only advances healthcare technology but also provides undergraduate students with valuable interdisciplinary research experience in biomedical engineering and materials science. The project contributes to future innovations in non-invasive medical devices, aiming to improve diagnostic accuracy and patient outcomes.

Abstract Name: Judge Ed Johnstone and the Fight for Prison Reform: A Case Study in Justice, Humanity, and Dignity

In 1976, eight inmates from the Kentucky State Penitentiary filed suits alleging unconstitutional conditions and treatment. These cases were later consolidated into a class action with inmates from the Kentucky State Reformatory. Presided over by Judge Ed Johnstone of the U.S. District Court for the Western District of Kentucky, the case addressed issues such as vocational education, protective custody, and living conditions. Renowned for his dedication to justice and dignity, Judge Johnstone exemplified fairness and hard work. This analysis draws from the Ed Johnstone papers, 1970s-1980s, at the University of Kentucky Special Collections Research Center. These primary sources, including letters, court documents, and personal notes, offer insight

into his judicial philosophy and efforts to improve prison conditions. Secondary sources, such as legal commentaries and analyses of the era's prison reform movements, contextualize his work within broader systemic challenges. This study employs qualitative methods to establish a timeline of significant events and analyze the judge's direct interventions, including prison inspections and communication with inmates. His respectful treatment of inmates and hands-on approach significantly contributed to improving prison conditions in Kentucky, setting a precedent for fairness and dignity. Amid ongoing concerns about systemic inequities and inmate treatment, this research underscores the relevance of his methods today, offering valuable lessons for courts striving to implement fairer practices.

Abstract Name: Proliferation and Consequences of Lethal Autonomous Weapons Systems Integrating Artificial Intelligence

This report explores the integration of artificial intelligence (AI) into Lethal Autonomous Weapons Systems (LAWS), with a focus on the ethical, regulatory, and technological challenges that arise from this convergence. As leading nations like the United States, China, Russia, and Israel advance their capabilities in autonomous systems, the use of AI in loitering munitions, sentry systems, drones, logistical systems, and more raise profound questions about accountability, security, and compliance with international humanitarian laws. Public awareness and perception on the matter is suboptimal, with an outspoken minority standing opposed to their usage and the major militaristic power's decision to abstain from diplomatic efforts of regulation. Some of the sources referenced include a report from MIT science policy review, the government of China's website, the book "Four Battlegrounds" by Paul Scharre, and more (all citations included in poster). The methodology consisted of aggregating data on AI usage from these sources, and putting it in historical context of ethical warfare. While intending to leave the audience with several questions to deeply consider, the conviction is asserted that unchecked AI integration will present disastrous consequences unseen in any advancement previously seen in warfare, including the atomic bomb.

Abstract Name: Curling Connections: Exploring the Impact of Team Cohesion on Performance

Team cohesion is most often described as the strength and existence of interpersonal connections within a team, and remains an essential element for team work and ultimately for team success. Several studies have looked at the effect of team cohesion on success in various sports, such as basketball, volleyball, Nordic skiing, and soccer both at collegiate and professional levels. However, no prior research has been done to explore the relationship between team cohesion and performance within curling teams. Curling is a team sport with four players on a team; each player has a different role within the team, but all roles are important

in influencing the success of the team through constant, clear communication. Miscommunication and misinterpretations can quickly cause issues within the team atmosphere and the game itself. The aim of this study is to examine the relationship between team atmosphere and cohesion on performance within curling teams. In this correlational study, which has been approved by the College of St. Scholastica's Institutional Review Board (IRB), data was collected through a secure online survey administered via Qualtrics. In addition to minimal demographic information, content of the questions addressed curling experience, personal experience within curling teams, and team performance. Preliminary results show that self-reported cohesive curling teams are associated with higher performance and that teams with positive environments have higher cohesion than teams with negative environments. This research will impact the curling community and greater sports community by generating and expanding knowledge on the role team cohesion plays in affecting performance.

Abstract Name: The Immunomodulatory Effect of Plasma-Treated Biomaterials

Cardiovascular disease is the leading cause of death in the United States, with over 700,000 deaths reported in 2022 alone. Autologous vein replacements, a common procedure performed after heart attacks, can only be used a limited number of times to repair damaged blood vessels, highlighting the need for alternative replacement methods. One potential solution is the use of biomaterials to create cell scaffolds, which can form artificial veins. However, to overcome the challenge of achieving a biocompatible surface, a surface modification technique called plasma-enhanced chemical vapor deposition (PECVD) can be used to add amine groups to the biomaterial, creating an amine plasma polymer. The primary aim of this project is to evaluate the immune response of neutrophils when exposed to plasma-treated biomaterials. Biomaterials induce a foreign body reaction that activates the immune system, with neutrophils being the first immunological cells to contact the material. While much research has focused on macrophages, there is limited understanding of how surface modifications of biomaterials trigger the pro-inflammatory response in neutrophils, known as NETosis. In this study, we analyzed cytokine content, the percentage of apoptotic cells, and the presence of NETosis in neutrophils exposed to biomaterials with varying quantities of amine groups. Our findings suggest that higher levels of amine groups on the biomaterial surface increase the likelihood of a pro-inflammatory neutrophilic response. This was supported by increased IL-8 protein release (a marker of the pro-inflammatory pathway in neutrophils) measured by ELISA, elevated apoptosis levels observed through flow cytometry, and a trend of increased citrullinated cells (a marker of NETosis), also detected by flow cytometry.

Abstract Name: The Impact of Childhood Abuse on Female Gang Membership

This review is written to collect, engage with, and analyze the current literature by examining gendered disparities in terms of influences on gang membership and violence within the gang. This review seeks to determine how predictor experiences like violence during childhood influence violent behavioral outcomes such as gang membership among adolescent females. This paper seeks to holistically examine the prevalence of female gang membership, reasons for joining a gang with an emphasis on the effects of ACE (adverse childhood experience exposure), disparities in crimes committed and roles within the gang, and differences in perceptions of the gang. This paper evaluates the presumptions and accepted notions surrounding female gang membership both historically and in a more modern context. This review challenges the existing literature to bring to light the experiences of female gang members and bridge the gap between the understanding of domestic violence and trauma and its influential nature on behavior for females in the context of criminality.

Abstract Name: AI-Powered System for Improving 911 Emergency Response

Classical emergency response systems, such as 911, fail to process a large number of emergency calls in populated areas. Such systems are prone to human errors. Human operators work for very long hours handling exhausting calls, which puts them under huge mental pressure. In this research, we propose a full system that uses Artificial Intelligence to support human operators in responding to 911 calls. The first stage of the system is to use Sentiment Analysis on the caller's voice to determine their Age Group and the Urgency Level of the call. The second stage is to convert the voice into text using the Whisper Model. The third stage uses our Named Entity Recognition model to derive the Caller's Name and the Emergency Address. The third stage uses the Classifier Model to determine the Emergency Type: Medical, Mental Health, Crime, Fire, Animal Control, National Security Threats, or Natural Catastrophes. The fourth stage invokes the trained Modular Large Language Models to handle each type of the seven emergencies. The LLMs are trained on official manuals from official public safety organizations. If the caller's name is mentioned, the system will access their health records database and tailor the recommendation based on their medical conditions. The final stage is to produce questions to ask the caller, resources to deploy by the operator, procedures to follow until help arrives, and help the operator with their conversation with the caller. First, we show how the modular approach improved the efficiency of our overall system. Second, we show how to use context awareness of the environment and the individual to give more personalized responses. While this research is focused on AI use in Public Safety, our contributions could be viewed as a reference for developing other AI-powered systems.

Abstract Name: Development of a Rapid Assay for Detection of the Isocitrate Dehydrogenase 2 (IDH2) R172K Point Mutation using Recombinase Polymerase Amplification (RPA)

Mutations within the Isocitrate Dehydrogenase 2 (IDH2) gene are associated with the diagnosis of low-grade gliomas. The prevalence of IDH2 mutations in glioma is approximately 2.2%, however, these point mutations found within the catalytic site of IDH2 confer survival benefits compared to their wild-type (WT) IDH2 counterparts. Mutations found at IDH2 R172 are prognostic indicators for life with progression free survival and overall survival increasing roughly four-fold. Rapid detection of these mutations and maximal resection of the tumor allows patients to receive these benefits. Utilizing synthetic DNA and the isothermal nucleic acid amplification technique, Recombinase Polymerase Amplification (RPA), rapid discrimination between WT and mutant sequence was achieved. Six RPA primer sets were screened for amplification of the IDH2 R172 gene region. Upon successful amplification of the IDH2 R172 region, the selected primer set was optimized utilizing a Locked Nucleic Acid (LNA) to successfully discriminate between R172 Wildtype (WT) and R172K mutant sequences. The optimized assay is able to discriminate between the IDH2 WT and IDH2 R172K point mutation within 5 minutes at 44 degrees Celsius. This rapid detection allows for potential use of this technique during the surgical window. Current endpoint analysis uses agarose gel electrophoresis for confirmation that the IDH2 R172K point mutation is being amplified. However, this is a time-consuming analysis for a rapid nucleic acid amplification technique. Future iterations of this RPA include the use of a real-time fluorescence-based reporter system allowing for specific identification of mutational status. Another option for detection would be using a cleavase assay to detect the specific sequence. Once a reporter system is established, the RPA for detection of the IDH2 R172K SNP will be tested in more complex biological matrices and discrimination will be tested against other IDH2 R172 mutants such as R172M, R172W, and R172G.

Abstract Name: Do Nursing Students Perceive That They Are Educationally Prepared to Care for Minority and Ethnically Diverse Populations upon Graduation?

Every individual has the right to receive safe and efficient care in the healthcare setting. As healthcare grows and demographics evolve rapidly, it is crucial that frontline workers, particularly nurses, are adequately prepared to address the unique needs of minority and ethnically diverse populations. Over recent years, the importance of culturally competent nursing care has gained significant attention in the literature. However, a significant gap exists in understanding how effective current nursing school curricula is in preparing students for this critical aspect of patient care. This study intends to address the central research question: "Do Nursing Students Perceive That They Are Educationally Prepared to Care for Minority and Ethnically Diverse Populations upon Graduation?" The purpose of the research is to assess how current nursing students perceive their readiness to provide culturally competent care and evaluate their views on how well the nursing school curriculum has prepared them for this responsibility. This study will use a quantitative research methodology using an online survey distributed to currently enrolled nursing students across different cohorts at Georgia Southern School of Nursing. The expected findings will suggest that due to insufficient prioritization of cultural competency education in nursing school curricula, the students will lack confidence in preparation to care for ethnic and minority patient populations. The results from this research aim to contribute to existing

research on cultural competence in nursing education and propose potential improvements in current nursing school curricula.

Abstract Name: The Effects of DEAD-Box Protein Overexpression on *S. cerevisiae* 23S RNA Narnavirus Viral Load

The utility of DEAD-box proteins (DBPs) in remodeling RNA secondary structures and ribonucleoprotein complexes across prokaryotic and eukaryotic kingdoms has long been known to the scientific community. In recent years, DBPs have been investigated regarding their role in viral infections, particularly if they impose a pro-viral or anti-viral influence. The 23S +ssRNA Narnavirus is a ubiquitous virus within *Saccharomyces cerevisiae* which exists in a low copy number, is considered non-detrimental, and presents with no obvious phenotypic effects. In an opportunity to investigate the viral roles of DBPs, *S. cerevisiae* which possessed the 23S virus was grown in nitrogen deficient media to artificially increase the viral RNA copy number. Likewise, viral positive *S. cerevisiae* groups were transformed with expression vectors to upregulate one of two proteins, DBP1 or DBP2. Overexpression of these DBPs allowed for the assessment of their effects, if any, on the overall viral load and strand quantity under variable nitrogen conditions using RT-qPCR. In the following study, we attempt to assess the quantitative effects of two overexpressed *S. cerevisiae* DBPs on the viral load of a 23S RNA Narnavirus. The minimal virulence of the 23S virus offers an advantageous model to investigate DBPs as a potential anti-viral agent.

Abstract Name: Cost-Benefit Analysis of the Lafayette College Composting Program

This thesis evaluates the costs and benefits of the Lafayette College composting initiative. The urgency of environmental sustainability has prompted many campuses to explore composting programs as a solution for waste management, particularly for food waste, which constitutes nearly a quarter of landfill content. The study employs a comprehensive cost-benefit analysis to assess both financial and environmental impacts of the program. Key costs include capital and labor needed for production, measured using invoices from the Lafayette College Office of Sustainability. The rebound effect, where increased awareness may lead to higher food disposal rates, is also considered a cost. My study will follow prior literature to estimate the magnitude of this effect on Lafayette's campus. Benefits of composting include reductions in carbon and methane emissions, savings from decreased waste hauling, potential revenue from selling compost, and community benefits from the program, which is a non-market value. These benefits will be assessed using compost volume data from the Office of Sustainability, EPA values for greenhouse gas emissions, market prices for

compost, and a community survey that uses contingent valuation to gauge willingness to pay for the program. This research addresses a gap in the literature by providing a holistic view of composting's impact, incorporating both economic and environmental aspects, including market and non-market values. It discusses short-term and long-term net benefits and offers strategies for managing high startup costs, such as optimizing resource use. Additionally, it cautions against relying solely on composting, advocating for a comprehensive sustainability approach. By demonstrating that composting programs can be financially sustainable and beneficial over time as a strategy for waste reduction and environmental stewardship, this study serves as a model for similar institutions seeking to enhance their sustainability efforts through compost, fostering a culture of sustainability in higher education.

Abstract Name: Pittsburgh's Untapped Resources: Enhancing Support for the Rising Number of Unaccompanied Children

This mixed-methods research study had two primary questions. We examined policies and practices related to the care of unaccompanied children (UC) — persons under 18 years of age without legal immigration status and a parent or guardian crossing the southern border of the U.S. with them — to learn the effects of those policies and procedures on their well-being. We further sought to understand the role played by our local region — Pittsburgh — in UC care. For context, we examined several factors including the historical context of policies impacting UC, the “push and pull factors” for UC and their families, the roles played by local, state, and federal governments as well as non-profit organizations, and the trajectory for UC from the time of their border crossing to a legal proceeding determining their long-term status. We conducted our research with the empirically based assumptions that (1) UC require protection from both malicious actors and further traumatization and (2) UC should be reunited with family members or other safe adults as quickly as possible. Our methods included an analysis of secondary data and semi-structured interviews with experts involved in policy or direct practice with UC, particularly in Pittsburgh. We noted significant recent improvements in UC-related policies and procedures which will likely contribute to increased UC well-being and protection. We recommend further development by creating child-friendly immigration courts and employing trauma-trained professionals at the border. We also noted a growing number of UC and a corresponding increased need for temporary residential care and services, especially in non-border states. And while Pittsburgh has one temporary residential facility currently serving UC, we concluded that Pittsburgh is underutilized and has both the capacity and willingness to serve many more persons within this vulnerable population.

Abstract Name: The Financial Fallout of Divorce

Divorce income trajectories for men and women. This paper investigates the economic consequences of divorce, with particular attention to how income changes and recovers between the genders. Most often, women experience tremendous economic declines in terms of earnings, increasing risks related to poverty and declining opportunity costs for wealth formation. These findings reported here are often determined by system-level factors, such as the persistent gender wage gap, the financial burdens incurred by child custody responsibilities, and the uncompensated work associated with caregiving responsibilities. Meanwhile, men generally experience far more uniform economic outcomes with many reporting improved economic fortunes after divorce. This paper investigates these determinants of inequities by analyzing the impacts of alimony, child support enforcement, and remarriage on economic outcomes. Alimony and child support policies seldom go far enough in the relief of women's financial burdens, while remarriage often confers greater economic benefits on men due to their established sources of income and societal norms that favor them. It further investigates long-term economic consequences of divorce for different income groups and reveals that individuals from low- and middle-income groups are more affected by divorce compared to their counterparts in the higher-income groups. This article synthesizes findings from the existing economic literature and conducts a rigorous analysis of policy interventions with a view to shedding light on the strengths and weaknesses of extant systems in place to reduce income inequality. It highlights the now pressing need for equitable policies that support both genders—through strengthened child support enforcement, progressive alimony reform, and other measures aimed at dealing with the gendered dimensions of unpaid care work.

Abstract Name: Development of low-cost antibody binding assay using *Staphylococcus aureus*

Antibody binding assays are a vital component in healthcare research and play a crucial role in understanding biological processes, diagnosing diseases, developing therapies, and much more. While there are multiple assays on the market testing for antibody binding, they are all very expensive which limits their use in research, especially at primarily undergraduate institutions. The interactions between antibody and *Staphylococcus aureus* were investigated to determine if a novel and inexpensive antibody binding assay could be developed. To do this, we incubated a fluorescent nonspecific antibody with *S. aureus* for 5 hours. At the same time bacteria alone and antibody alone were incubated in the same conditions for the same amount of time to serve as negative and positive controls, respectively. Each tube was then split in two, with one being centrifuged to form a pellet comprising of bacteria or antibody or both, and the other one left alone. Fluorescence was measured for the liquid in each tube. We hypothesized that any fluorescent antibody that was bound to bacteria would end up in the pellet, while antibody that is unbound would stay in the liquid component. Therefore, by measuring only the liquid component, we hypothesized the fluorescence would decrease in the bacteria with antibody tube that was centrifuged when compared to the bacteria with antibody tube that was not. We also hypothesized that the bacteria alone and antibody alone tubes would have no change in fluorescence. Trends in the fluorescence readings showed that there was not a decrease in the antibody alone tube, not a decrease in the bacteria alone tube, but there was a decrease in the centrifuged tube with both bacteria and antibody. Indicating that this method could potentially be used in the development of a new antibody binding assay.

Abstract Name: Mechanical Properties of Ultra High Performance Concrete reinforced with Basalt Minibars

A major challenge for civil engineers working on more sustainable infrastructure is the reliance on steel for concrete reinforcement. The high cost of production and susceptibility to corrosion associated with steel rebar promotes research into potential alternatives. Basalt fiber presents a viable solution that is naturally occurring, releases less CO₂, and lighter weight. Basalt fiber mini bars could be used in concrete mixes to provide more reliable reinforcement. However, there is a need for comprehensive process-structure-property relationship for basalt reinforced concrete mixes. Furthermore, the mechanical behavior of the concrete is influenced by critical factors including fiber orientation, fiber volume fraction, and porosity within the resulting part. This research evaluates the mechanical properties resulting from randomly dispersed basalt mini bars in an ultra high performance concrete mix. American Society for Testing and Materials standards were used to test flexural beams, compression cubes, and tensile samples after 28 days of curing. Select samples were examined qualitatively using high-resolution micro X-ray computed Tomography to evaluate the distribution of the mini bars within the mixes spatially. It was found that basalt mini bars improved the compressive, tensile, and flexural strengths compared to tests of samples without reinforcement. Increasing the percent volume of mini bars further improved sample performance, showing promise for basalt minibars as a reinforcement for concrete mixes.

Abstract Name: Gratitude, Fear of Failure, and Mindfulness as Predictors of Neuroticism

This study sought to identify predictors of neuroticism in undergraduate students. Previous literature revealed connections between neuroticism, mindfulness, gratitude, and fear of failure. Specifically, negative correlations between neuroticism and the following facets of mindfulness were found: non-judging, acting with awareness, non-reacting, and describing. Additionally, gratitude has been shown to correlate negatively with neuroticism. The relationship between fear of failure and neuroticism was also investigated based on literature indicating high levels of worry relating to both neuroticism and fear of failure. Thus, the following hypothesis was proposed. Mindfulness test scores (describing, observing, acting with awareness, non-judging, and non-reacting), gratitude scores, and fear of failure scores would predict neuroticism scores. To test this hypothesis, the Five Facet Mindfulness Questionnaire– Short Form (FFMQ–SF), Gratitude Questionnaire 6 (GQ–6), Performance Failure Appraisal Inventory– Short Form (PFAI–S), and the neuroticism subscale of the Revised Eysenck Personality Questionnaire– Abbreviated Form (EPQR–A) were administered to one hundred twenty-six (N = 126) undergraduate students from statistics, positive psychology, marriage and intimate relationships, Christian tradition, and general psychology classes. Upon IRB approval, instrument packets and consent forms were distributed with professor permission. Participation was voluntary and confidential. The data were analyzed by a multiple regression analysis using SPSS software. A significant regression model was found: $F = 12.458$, $p < .001$, $R = .652$ and $R^2 = .425$. From this model, the following were found to be significant predictors of neuroticism: fear of failure ($\beta = .308$, $p < .001$); describing ($\beta = -.283$, $p < .001$); non-reacting ($\beta = .239$, $p = .002$); acting with awareness ($\beta = -.195$, $p = .019$); and

observing ($\beta = .181$, $p = .016$). Limitations included the homogeneity of the sample; future researchers were advised to include more sample diversity.

Abstract Name: Role of vitamin A in the activation of dendritic cells innate immunity against the virus:

They aim to study the role of retinoic acid signaling in dendritic cells in their innate immunity activation against viral infections. Vitamins are essential to our diet as they play a crucial role in various biological processes and building immunity. Vitamin A is a fat-soluble vitamin found in foods from animal sources and some vegetables containing beta-carotene. It gets metabolized inside the body to produce retinoic acid which regulates different cellular functions. Retinoic acid modulates the function of many types of immune cells, and its specific role in dendritic cell activation has not been fully characterized. This research will help illuminate retinoic acid's effect on dendritic cell functions and its role in innate immune activation against different viruses. The team is currently utilizing flow cytometry, Western blotting, and real-time PCR techniques to study dendritic cell activation in response to viral exposure and document its effects on T lymphocyte activation. The anticipated results of this study will be conclusive of retinoic acid signaling in dendritic cells playing an essential role in immune activation.

Abstract Name: Sleep and Stress in Higher Education: Investigating the Interplay and Academic Performance

Sleep health is a crucial aspect of total well-being; nevertheless, it is increasingly undermined among college students due to multiple circumstances, with stress being a primary culprit. This literature review examines the intricate relationship between sleep patterns, stress, and academic life among young adults in higher education environments. College students frequently encounter substantial academic, social, and personal pressures, resulting in impaired sleep and diminished sleep quality, which can further intensify stress and adversely affect cognitive function, emotional regulation, and academic achievement. The review analyzes recent studies on the impact of chronic stress on sleep cycles and the reciprocal influence of sleep deprivation on stress levels. Furthermore, it examines the influence of lifestyle factors, like screen time, caffeine intake, and irregular schedules, in sustaining this cycle. The review evaluates interventions and tactics demonstrated to enhance sleep quality and alleviate stress among college populations, including mindfulness, cognitive behavioral therapy for insomnia (CBT-I), and improved time management techniques. This review synthesizes existing research on the interrelated concerns of sleep health and stress management, emphasizing their significance in college wellness programs and providing recommendations for future study to enhance students' sleep and mental health.

Abstract Name: Effect of a Baffle Shroud on a Submerged Heat Exchanger in a Thermal Storage Tank with a Charging Loop

The effect of a cylindrical baffle on the heat transfer to a submerged copper coil heat exchanger in an experimental solar thermal storage tank with a charging loop is explored. Previous studies have been conducted to optimize the geometry of the tank, with the charging loop being explored in this study for the first time. The heat exchanger is located within the annular region created by the baffle and the wall of our storage tank. The charging loop functions by pulling cold water from the bottom of the tank, reheating it, and returning this heated water on top of the tank. Three initial tank temperature cases are investigated: a stratified tank with the top 60% of the tank at 60°C and the bottom 40% at 40°C; an isothermally charged 60°C tank; and an isothermally charged 40°C tank. The effect of the baffle on heat transfer is investigated by comparing experiments with and without the baffle for all three cases. For the stratified tank, the baffle has been shown to increase the heat transfer over the first 30 minutes by 7%. For the 60°C isothermal tank, the baffle has been shown to increase the heat transfer over the first 30 minutes by 18%. For the 40°C isothermal tank, the baffle has been shown to increase the heat transfer over the first 30 minutes by 10%. The primary factors for increasing heat transfer are velocity of storage fluid over the heat exchanger and tank stratification. Tank stratification was increased with the baffle for the isothermal cases, but decreased with the baffle in the stratified case. Velocity of the storage fluid always increased with the baffle. The improved heat transfer when the baffle is in place is attributed to increased velocity for the stratified case, and both velocity and stratification for isothermal cases.

Abstract Name: Quantifying Barn Owl Plumage Coloration and Its Relationship with Diet

Sexual ornaments are traits that increase the sexual fitness of a species by attracting mates. Melanin-based sexual ornamentation appears widespread in birds. However, the mechanistic basis of these ornaments remains unclear, along with their link to diet and environmental conditions. Here, we examine the impact of diet on melanin deposition in Barn Owls (*Tyto alba*), a species known to advertise individual quality via melanated plumage. Specifically, we test the hypothesis that diet impacts melanin deposition indirectly via body condition using a unique owl population from Kauai, Hawaii with highly varied diet (ranging from

rodents and insects to seabirds). Stable carbon and nitrogen isotope data from feathers were used to quantify diet, then compared with body condition indices and melanin deposition in Primary 5 for 19 Barn Owls. To estimate melanin deposition, we manually measured the width of transverse bars (melanated bars on the feather) on Primary 5, then measured transverse bar size as a percent of total feather surface area using ImageJ. We found that transverse bar width alone was significantly correlated to diet, such that owls consuming higher quantities of rodents (prey conferring higher body condition) had wider transverse bars. Our results provide partial support for the hypothesis that diet and body condition can control melanin deposition.

Abstract Name: Representation, Resilience, and Challenges: The Journey of Black Female Engineering Students at an HBCU

By providing an equitable environment and fostering a strong sense of community, Historically Black Colleges and Universities (HBCUs) can create an environment that enables underrepresented students to thrive. The study aims to reveal HBCUs' unique role in affirming racial identity and representation while addressing systemic inequities in engineering spaces. Using Crenshaw's Intersectionality Theory and narrative analysis, the authors report findings from a 40-minute focus group of four Black female undergraduate students majoring in engineering at an HBCU. The focus group session was conducted via Zoom, recorded, transcribed verbatim, and analyzed manually. Key themes related to identity, representation, community, and inequities emerged through thematic analysis. Analysis of key themes suggests that participants highlight the importance of representation in engineering, describing how seeing successful Black females in similar roles fosters empowerment and validates their capabilities. Despite these positive aspects, participants also described challenges, such as overcoming stereotypes, earning respect in male-dominated spaces, and navigating microaggressions. Institutional gaps were identified, particularly the need for more funding and targeted programs for Black female engineers, such as initiatives to support professional development and peer networking. However, participants noted areas for growth, particularly in expanding resources for engineering programs and fostering inclusivity within academic and professional spaces. The significance of community was another recurring theme, with participants emphasizing how peer and faculty support at an HBCU contributes to resilience and academic motivation. These results contribute to a larger urban context by offering valuable insights into the lived experiences of Black female engineering students at HBCUs and the importance of tailored support and advocacy to promote equity and inclusion for Black female students in engineering spaces.

Abstract Name: Understanding Barriers To Bariatric Surgery

This study explores factors influencing patient dropout rates from the bariatric surgery program at The University of Chicago to improve access and outcomes. Bariatric surgery is the most effective long-term treatment for morbid obesity, a condition affecting over 20 million U.S. adults and linked to severe health risks. Despite its benefits, high attrition rates, particularly among socioeconomically disadvantaged patients, remain a significant barrier. The research examines how socioeconomic challenges, limited healthcare access, psychosocial factors, and communication gaps contribute to attrition, based on preliminary data from a questionnaire at The University of Chicago. Using a mixed-methods approach, it combines quantitative analysis of patient demographics with qualitative insights from interviews to understand these barriers comprehensively. Initial findings highlight the role of systemic inequities, such as low income and healthcare inaccessibility, in driving dropout. Future efforts will focus on developing targeted strategies to reduce attrition, ensuring equitable access to bariatric surgery and its life-saving benefits.

Abstract Name: War in the Age of AI: Strategic Decision Making

This study examines the transformative impact of AI on strategic decision-making in modern warfare. Scholarly and Research Context: While existing literature often focuses on the technical capabilities of AI in military applications (e.g., autonomous weapons, target recognition), this project examines the crucial intersection of human and machine intelligence in the high-stakes environment of strategic decision-making. By analyzing how AI interacts with traditional military doctrines and human cognitive biases, this research seeks to identify potential vulnerabilities and unforeseen consequences of incorporating AI into military command structures. This project draws upon and contributes to scholarship in military strategy, human-computer interaction, and AI ethics to provide a comprehensive analysis of AI's influence on the future of warfare. Central Research Question: How does the integration of AI impact strategic decision-making in modern warfare, specifically regarding: The evolving roles of human commanders and AI systems. The influence of AI on the speed and accuracy of strategic decisions. The ethical implications of using AI in warfare. The potential consequences of AI integration for strategic outcomes. Methodology: This research employs a three-pronged approach: Literature Review: Examining existing research on AI, military strategy, and decision-making. Expert Interviews: Gathering insights from military strategists, AI developers, and defense analysts. Comparative Analysis: Analyzing different military doctrines and approaches to integrating AI into strategic decision-making across various nations. Conclusions and Expected Results: This research aims to provide a nuanced understanding of the complex interplay between human judgment and AI-driven

insights in military contexts. It is expected to identify best practices and potential pitfalls in leveraging AI for strategic advantage, highlight ethical implications (accountability, bias, unintended escalation), and offer insights into how AI might shape the future of warfare. The findings will contribute to ongoing scholarly and policy debates surrounding the responsible development and use of AI in the military domain.

Abstract Name: THE STAINING OF BOVINE EMBRYOS TO DETERMINE CELL NUMBER AS A POTENTIAL PREDICTOR OF IN VIVO VIABILITY, AND SINGLE EMBRYO PCR ANALYSIS.

The efficiency of embryo transfer in cattle is dependent on the pregnancy rate of recipient females that receive transferred embryos. A significant proportion of embryos are freezing in liquid nitrogen then later thawed for transfer. This study aimed to stain thawed bovine embryos immediately after thawing to determine the number of cells present. Bovine morula and blastocyst stage embryos were stained with Hoechst and Propidium Iodide (PI). PI is a fluorescent dye that binds to DNA and penetrates only dead cells. This property makes it useful for identifying non-viable cells. In contrast, Hoechst attaches to the DNA in both living and dead cells, giving an estimate of the number and distribution of cells. Embryos were stained by incubating them in PI solution at 38.5°C. To get rid of extra dye, they were then thoroughly washed in PBS/PVP. The embryos were then incubated at room temperature and stained with Hoechst. After that, stained embryos were put on a glycerol-coated slide and observed with blue and red filters under an epifluorescent microscope. The second objective of the work was to use PCR to determine if single embryos could be analyzed to determine sex. A thorough method for examining bovine embryos is provided by the combination of staining and PCR techniques, which combine molecular and visual data to improve comprehension of embryonic progress and viability. For objective 1, the results of our study were 56.5 of cells per embryo ($n = x$ embryos). For objective 2, PCR analysis of single embryos was able to determine a Y-specific gene.

Abstract Name: Enhancing Bankruptcy Prediction: A Comparative Study of Imputation Techniques in Financial Data

Bankruptcy, the legal status of an entity unable to repay its debts, carries significant consequences for economies, businesses, and individuals. Predicting bankruptcy is crucial as it helps stakeholders make informed financial decisions and mitigate risks. In this study, we utilize a dataset on Taiwanese bankruptcy cases to explore methods for improving prediction accuracy through effective preprocessing—a crucial step in data preparation that ensures cleaner and more reliable inputs for analysis. The preprocessing techniques used include mean, median, and k-nearest neighbors (KNN) imputation to address missing values. While

mean and median imputation replace missing data with simple statistical measures, KNN imputation leverages patterns in the dataset by filling gaps based on the most similar instances. Each approach offers unique benefits: mean and median are computationally efficient, while KNN captures complex relationships, making it a robust option. However, KNN imputation did not always outperform other methods, particularly when missing data was clustered or when outliers and non-linear relationships between variables were present. In these cases, simpler methods like mean or median imputation sometimes provided better results. Observations from correlation analysis revealed that KNN imputation preserved variable relationships better than the other methods, particularly for financial ratios with high interdependence. However, in cases of extreme skewness, the correlation patterns deviated, making mean or median imputation more reliable. Visual representations were employed to illustrate the performance differences. Results reveal that KNN imputation outperformed the other techniques overall by retaining underlying data structure and reducing biases. This study highlights the importance of preprocessing in building accurate predictive models. By demonstrating that KNN imputation leads to better outcomes, this research emphasizes the value of sophisticated techniques in financial risk analysis and lays a foundation for improving bankruptcy prediction.

Abstract Name: Integrating a Local Large Language Model for Research and Education at the University of Central Oklahoma

Large Language Models like ChatGPT have made a devastating impact on our day-to-day lives. Their ability to generate code from a variety of programming languages and being able to solve complex problems has made new discoveries from different disciplines. It is imperative to conduct LLM research and explore the application of these models to maximize their full potential for research and education. Our vision is to make a local LLM ecosystem to conduct research and educational endeavors within our college. Some of the key elements we want to add are a Retrieval-Augmented Generation (RAG) system, a user-friendly chatbot website, and different LLMs. The first thing to do is to create an Application Programming Interface, or API, that grabs the sender's message from the website and uses that message to build a prompt and send back a response to display to the user. We intend to use the Torch library from Python to utilize a Graphics Processor Unit, or GPU, to run our back-end service for the website to connect to. The next thing to do is to build a user-friendly chatbot website that allows a user to send messages to our API. We intend to use Vite to help increase efficiency for our website. Some other things we are including are a history bar for users to create a new chat, allowing the user to open a different chat, giving them an option to delete their chat, and being able to export the conversation into a Javascript Object Notation (JSON) format.

Abstract Name: Comparative Analysis of Renewable Energy Adoption in France and Sweden

This research investigates the disparity in renewable energy adoption between France and Sweden, despite both countries operating under EU-wide programs such as the Renewable Energy Directive (RED) and the European Green Deal. Between 2017 and 2022, Sweden's renewable energy share increased from 53.4% to 66%, while France's share grew from 15.8% to 20.3%. Sweden's success is attributed to consistent policies, high carbon taxes, and community-driven projects, which have fostered investor confidence and public acceptance. In contrast, France's reliance on nuclear power, complex permitting processes, and fragmented policies have slowed renewable energy development. This study employs a mixed-methods approach, integrating quantitative data—such as energy adoption rates, emissions reductions, and financing mechanisms—with qualitative analysis of policy frameworks, regulatory processes, and cultural factors. Sweden's cohesive strategies reduced greenhouse gas emissions from 1.0 to 0.6 tonnes per capita and transport emissions from 148.2 to 66.6 g/km, while France saw declines from 6.8 to 5.7 tonnes and 133.8 to 103.1 g/km, respectively. The findings underscore the importance of stable, long-term policies, streamlined regulations, and community engagement in achieving renewable energy targets. Sweden's model provides a replicable framework for France and other EU countries seeking to accelerate renewable energy transitions. Recommendations include simplifying France's permitting processes, increasing carbon taxes, and adopting community-driven renewable projects. This research highlights the critical role of national policy execution in meeting EU climate goals and offers valuable lessons for countries navigating renewable energy transitions.

Abstract Name: Effects of the Timeout Production Schedule on Behavior Maintained by Concurrent Schedules of Reinforcement

Timeout is a signaled, response-dependent, and time-limited period in which the prevailing schedule of reinforcement is suspended. Results from applied and basic research suggest that punishment effects of timeout depend, in part, on the punishment production schedule. The present study extends this work by evaluating effects of the timeout production schedule on rats' response rates in a two-lever concurrent arrangement. In each condition, concurrent variable interval schedules operated on two response levers. During Baseline conditions, no timeouts were delivered. During Timeout conditions, 30-s timeouts were produced according to one of the following schedules: FR1, VR2, VR5, or VR10. Results indicate that the punishing effects of timeout are an inverse function of the ratio programmed on the timeout production schedule. Results and their theoretical implications will be discussed in the context of contemporary and historical research on punishment.

Abstract Name: Understanding the Martian Atmosphere and Seasons Using and Analyzing Martian Cloud Data

Mars has a very thin atmosphere compared to Earth's atmosphere, but Mars has seasons and clouds like Earth. Several of the Mars Orbiters have collected data that allows scientists to combine and understand more about the clouds. Water-ice clouds and carbon-dioxide ice clouds are the types of clouds found on Mars. There is a correlation between what types of clouds are seen in specific locations based on the season that Mars is in. Mars data from the NASA Citizen Science Project in MY29 was split into 3 sets called the Clear Season (Ls= 0 to 140 degrees), another season in between (Ls= 150 to 230 degrees), and the Dusty Season (Ls= 180 degrees to 328 degrees). Each set has its own cloud characteristics. It is found that in the clear season, clouds are most often in the equatorial region. In the mid-range between the clear and dusty season, daytime clouds are found normally in the mid-latitudes and night-time clouds are seen in the equatorial region. In the dusty season, clouds are frequently found in the northern hemisphere and at night are primarily in the southern mid-latitudes to northern mid-latitudes. We are analyzing the data to visually understand the similarities between seasons. New information can give insight into the composition of the clouds as well as understanding thermal tides and gravity waves for temperature drops.

Abstract Name: Through Their Eyes: The Struggle for Identity Among Black Girls and Women in The Bluest Eye

Toni Morrison's exploration of Black identity delves deeply into the intersections of race, gender, and societal expectations, particularly focusing on the experiences of Black women and girls. Her novel *The Bluest Eye* examines how systemic oppression and internalized white beauty standards distort self-perception and self-worth, especially for young Black girls like Pecola Breedlove. By addressing themes of trauma, resilience, and community dynamics, Morrison critiques societal structures of racism and patriarchy while celebrating the strength and agency of Black women. Her narratives combine personal and historical dimensions, offering a profound critique of societal norms and their generational impact. This paper examines *The Bluest Eye* through a Black feminist critical lens, exploring how Morrison's work critiques oppressive systems and highlights pathways for resistance and self-empowerment. This study explores how beauty standards, especially Pecola's obsession with blue eyes, affect identity, showing how trauma shapes her self-perception through the Breedlove family's struggles. It also examines the different kinds of support in the community, particularly through the child protagonists. The analysis highlights Morrison's contribution to Black feminist criticism, emphasizing her call for cultural change, better representation of Black girls and women, and the importance of self-love in resisting systemic oppression, as seen in *The Bluest Eye*.

Abstract Name: Food Forensics: Tetraplex PCR Analysis for Meat Type Authentication

Food fraud, including mislabeling and adulteration of meat products, poses significant risks to consumer health, religious and ethical compliance, and market trust. This study investigates the authenticity of processed mixed meat products sold in Maryland, addressing these critical concerns. A total of 56 products, including turkey, chicken, beef, and pork-based items, were analyzed using advanced molecular techniques. DNA was extracted using the Cetyltrimethylammonium bromide (CTAB) method, with Nanodrop spectrophotometry employed to ensure high DNA purity and concentration. Multiplex PCR was then used to simultaneously amplify the isolated DNA samples with species-specific genetic marker, Cytochrome c oxidase subunit I (COI) gene. Agarose gel electrophoresis confirmed the presence of DNA fragments corresponding to the labeled meat types. The results revealed accurate labeling in most products, but a subset showed adulteration, with undeclared meat constituents identified. Notably, two soy-based vegan samples were validated as meat-free, confirming their authenticity. This research highlights the effectiveness of DNA-based methods like multiplex PCR in detecting food fraud or errors unintentionally introduced or contaminations encountered during the sample processing, packaging and delivery, and this molecular technique ensures consumer trust, and promotes transparency in food labeling. Future work will expand the scope of testing to include a broader range of food products.

Abstract Name: The Mentality of Women: The accuracy of mental illness treatment in Dreaming in Cuban

Cristina Garcia's novel *Dreaming in Cuban* follows the life of Celia del Pino, telling her ill-fated tale of mental decline. Celia is a strong but obsessed woman, leading to her gradual insanity, subsequently Jorge, Celia's husband, admits her to a "hospital," which in truth is an insane asylum. During Celia's time within the mental institution, she endured conditions such as "The food [being] inedible" (Garcia 51). She also witnesses violence against her friend Felicia, who was "burned in her bed" (Garcia 51). Celia endured many similar incidents. Following Celia's release her obsession with Fidel Castro (referred to as El Líder) manifested. My essay continues the conversation Garcia began in *Dreaming in Cuban* about women and the treatment they endured within mental facilities. Little research has drawn attention to the "madhouse" in Havana known as Mazorra, an environment similar in conditions to Celia's asylum. Mazorra was one of the first and only Cuban public mental institutions that was opened on a former slave plantation. Mazorra was said to be "plagued by violence, shortages, disease, and the absence of verifiable mental treatment" (Lambe 95-96). The asylum was reported many times for frequent abuse but did not close until Fidel Castro's rule in 1959, which he vowed to rebuild the hospital and make healthcare a priority. However, in 1980, Castro gave Cubans permission to flee Cuba to South Florida in the Mariel boatlift. This group of Cubans consisted mostly of mental patients, who were undesirable to Castro. My essay uses these historical examples to describe the effect that Castro's rule had on Cubans who were mentally ill showing that, even after Celia's

treatment, her mental decline reveals how obsession with Castro's corrupt Cuba reflects the decline of mental health conditions on the island during the time of El Líder's reign.

Abstract Name: Territorial Ambitions: A Comparative Study of Soft and Hard Irredentism in Russia

What explains state choices to pursue policies of Irredentism through violence instead of peaceful means? Irredentism, a strategy aimed at annexing territories based on historical, nationalist, or geopolitical claims, has been studied extensively by scholars of international relations due to its destabilizing effects, however, less is known about why states choose to utilize annexation policies through violence (hard) or peaceful (soft) means. This research employs a neopositivist small-n methodology comparative exploratory case study, based on Alexander George's and Andrew Bennett's Case Studies and Theory Development in the Social Sciences, to examine the factors influencing states to choose violent over peaceful irredentist policies. Focusing specifically on exploratory case studies of Russia's actions in Crimea (Ukraine), Abkhazia and South Ossetia (Georgia), Narva and Setomaa (Estonia), and Transnistria (Moldova), the study identifies key independent variables including economic disparities, military strength, regime types, cost of conflict, and international involvement. The findings ultimately support that lower economic differences, higher costs of conflict, democratic governance, and greater international oversight tend to reduce the likelihood of violent irredentism, challenging different existing social theories on state conflict and territorial integrity. Conversely, autocratic regimes and weak international responses correlate with more aggressive annexation strategies as seen in Crimea, Ukraine, and Abkhazia and South Ossetia, Georgia. While military power does not consistently predict violence, other factors such as economic considerations and political structures play a significant role in contributing to the understanding of irredentist behavior and offering insights for policymakers on how to prevent territorial conflicts through stability. Ultimately, the empirical data compiled in this study is an important contribution to developing conflict-related theory. The explanations offered are pivotal to the understanding of aggressor state policies and the prevention of frozen conflicts in the Russian sphere and beyond.

Abstract Name: Epidermal Growth Factor Receptor Phage-Mediated Cancer Control

The focus of this research project is to identify potential bacteriophage inhibitors of the overactive Epidermal Growth Factor Receptor (EGFR) present in cancers. Receptor Tyrosine Kinases (RTKs) are transmembrane proteins that play a crucial role in transmitting extracellular signals to the interior of the cell, thereby regulating fundamental physiological functions. Epidermal Growth Factor Receptors (EGFR) represent a prominent subgroup of RTKs, primarily responsible for mediating the effects of epidermal growth factor

(EGF) and related ligands involved in numerous cancers. EGFR overexpression or mutations are frequently observed in cancers such as lung, colorectal, and glioblastoma, making them attractive therapeutic targets. EGFR-targeted therapies, including monoclonal antibodies and small molecule inhibitors, have been approved for clinical use in cancer treatment. A potential inhibitor of EGFR RTKs is bacteriophages. Bacteriophages, or phages, are viruses that possess a highly specific affinity for bacterial receptors, which allows them to infect and replicate within bacterial cells. This specificity in host recognition forms the basis of our research strategy, as we seek to adapt this property to target mammalian cells, specifically EGFR RTKs. To create a living model of overactive EGFR in mammalian cells, transfection of the EGFR plasmid, tagged with green fluorescence protein and G418 resistance, will be performed to create a stable cell line. The cell line will remain in G418-treated media and be tested with EGFR inhibitors and fluorescently tagged antibodies to confirm EGFR RTK presence. Lastly, the cell line will be panned with multiple bacteriophage libraries, and the results will be titrated to identify phages that are able to bind consistently to EGFR. Once successfully identified, the phages will be sequenced and tested for their effectiveness in blocking EGFR RTK transmission in the hope that they can induce apoptosis of the target.

Abstract Name: Detecting Volatile Organic Compounds in Urban Air

Ivy City and Brentwood neighborhoods in Washington, DC have auto body shops, factories and major roadways surrounding the area contributing to volatile organic compound (VOCs) air pollution. Families living in these areas are at risk of breathing in toxic VOCs. Toluene, xylene, and benzene are VOCs that come from vehicle gas emissions and can cause adverse health effects including cancer. Our goal was to identify and quantify the presence of VOCs in air collected from these two neighborhoods to generate quantitative data that the community can use to advocate for improvements in air quality. We collected outside VOCs onto sorbent tubes for 24 hours at residential homes. Then the sorbent material (Tenax) was transferred into glass vials for analysis by headspace gas chromatography-mass spectrometry (GCMS). Our results show that xylene and toluene are two major VOCs present in these areas. Comparison against standards prepared from a VOC mix yielded concentrations of toluene (0.08-0.85 ppb) and xylene (0.05-0.76 ppb) that we found were similar to those that the Environmental Protection Agency found in their Ivy City study. By collecting more data at different areas around Ivy City and Brentwood we will aim to monitor these compounds, raise awareness and inform the community of these volatile compounds.

Abstract Name: Development of the topographical pair correlation function for classification of aortic shape and pathology

Quantitative descriptors allow high-dimensional medical images to be converted into low-dimensional features capable of differentiating organ shapes that correlate with disease progression for diagnostic purposes. An important example is aortic dissection and aneurysm, which are imaged using high-resolution CT scans and for which morphometry has long been used to predict disease state and surgical outcomes. We present a novel and interdisciplinary approach to quantitatively describe aortic morphology for the better classification of the progression of dissection. The pair correlation function, commonplace in statistical mechanics, is adapted into the topographical pair correlation function (TPCF), which is calculated from the point estimates for curvature constrained to the surface of a meshed image and used as a metric to describe aortic shape. Comparison with single-point statistics suggests that the TPCF provides powerful features for classifying the state of aortas from CT images and more broadly in assessing morphological features of a diversity of organs.

Abstract Name: Phase-Contrast Imaging Using X-ray Grating Interferometry with Application to Computed Tomography

Fiber-reinforced composites are highly attractive to several industries including defense, aerospace, and automotive, due to their high weight, high strength and stiffness, and resistance to corrosion. High-resolution X-ray computed tomography and imaging are powerful non-destructive evaluation techniques to characterize the internal microstructure of composite materials. Furthermore, X-ray imaging affords the ability to characterize spatially key microstructure features of interest including porosity, cracks, and fiber orientation that can significantly influence the material composite part's performance. However, conventional X-ray imaging techniques, based on detecting differences in the material densities, are not effective for materials such as carbon fiber reinforced composites where the matrix and fiber materials have similar densities, resulting in limited capability to sufficiently differentiate the fiber and matrix phases within the material. Phase-contrast X-ray imaging interferometry is an emerging technique to overcome this limitation based on the refractive properties of materials, boasting orders of magnitude more sensitivity to material variations, enhancing the contrast for low or similar-density materials. In this study, a custom high-resolution X-ray grating interferometry imaging system utilizing three interference gratings based on the Talbot self-imaging effect is developed to demonstrate phase-contrast imaging techniques for a fiber-reinforced composite part.

Abstract Name: Variations of Humor styles and their influence in well-being on forensic science students who are exposed to violent images

This research, using Martin's (2003) humor styles, explores humor diversity among students and Forensic professionals who are frequently exposed to graphic violence in their curriculum or job. It examines humor's impact on well-being, its psychological significance, and its role in stress navigation and social success. According to Martin (2003), a sense of humor can be seen as a cognitive ability, habitual behavior, and an emotion-related trait like a coping strategy or defense mechanism. In the area of violent and graphic images, research indicates that watching violent movie content increases anxiety in late adolescents (Madan et al., 2013). Exposure to violent media can erode mental well-being over time, affecting an individual's emotional state, interpersonal relationships, and overall life quality. Violent Content consumption and a higher rate of aggressive behavior were highly correlated (Mößle et. al., 2014). Using the Humor Styles Questionnaire (HSQ) and The Scales of Psychological Well-Being (SPWB) the purpose of this project is to explore: How students who have been exposed to violent images as part of their curriculum use humor and its impact on their well-being. Additionally, interviews will be conducted with professionals in the field to explore their coping strategies and how humor contributes to their well-being. As a current Forensic Science student who is also studying psychology, I find that maintaining a robust mental health is crucial for forensic scientists. The nature of their work involves delving into the darker aspects of human behavior, and its exposure can lead to heightened stress levels and emotional strain.

Abstract Name: An Examination of the Roberts Court: Bias in the use of Scientific Evidence

Scientific evidence is often a determinant factor in how the Supreme Court decides a case. Yet little research has been done examining its use. This project investigates how Justices of the Supreme Court of the United States have historically used or misused scientific evidence in landmark cases. Focusing on the Supreme Court under Chief Justices Roberts as the case study, it attempts to answer the question: "Is the Roberts Court's approach toward using scientific evidence consistent within itself over time and among Justices?" Additionally, this project seeks to determine how the presence of scientific or social scientific evidence or lack thereof has been used by Justices on the Supreme Court to support or influence decisions. Research methods in this project include analysis of landmark SCOTUS caselaw, as well as inquiries into specific scientific methods and evidence as needed to substantiate claims concerning cases reviewed. Research on scientific topics relies on peer reviewed articles, studies, and findings published by reputable scientific organizations. The hypotheses are that the Supreme Court of the United States does not consistently use scientific and/or social scientific evidence, if available, and these inconsistencies broadly fall along political and demonstrated ideological leanings of the Court. Ultimately, the purpose of this research is to determine how scientific or social scientific evidence plays a role in Supreme Court decisions, and whether there is a trend among Justices of purposefully misunderstanding or misusing scientific data to manipulate decisions.

Abstract Name: The Implications Natural, Fluorescent, and LED Lights Have for Academic Productivity in a College Classroom

The purpose of my proposal is to determine the physiological effects natural light, LED light, and fluorescent light have on the academic productivity of college students in an academic classroom. Previous studies have compared the effects of colored LED light, finding different advantages color can have for classroom activities while others have observed the impact natural and artificial light have on emotional wellbeing of students in educational settings that prove the benefits of natural light. However, there is a lack of studies comparing the effects of all three kinds of light (natural, fluorescent, and LED) as well as determining their effect on academic productivity. Therefore, the research design will be a between subjects' experimental design with a sample of 30 college-aged subjects who will be randomly assigned to one of three testing conditions: natural light (A), fluorescent light (B), and LED light (C). All students will complete a timed number test used in a study by Chaveznava-Treviño and colleagues to measure academic productivity. The test will be a single piece of paper with a column on the right-hand side for subjects to write the total of the numbers (0-9) they saw. The mean productivity scores from this test and standard deviations will be found and compared in a T-chart. The results will show the impact light has on academic productivity and its following implications for the development of optimal light systems in educational buildings.

Abstract Name: Mini Satellites Efficient and Beneficial System

Information from space exploration and observation are always in demand but one of the issues that occur when wanting information is having reliable, powerful space applications to help deliver information back. Mini satellites are the best way for gathering space information as they are always growing, looking for ways to improve, cost efficient compared to other space applications, and can be sent in bulk for more space coverage and backups in case of errors or damages. Researchers and scientists are always trying to find ways to explore to obtain new information about space in the most efficient way possible. Mini satellites are the most efficient way space application possible for obtaining information as their lifespan on average is around a year, their energy system helps provide power for itself during times of eclipse, and being sent in quantities will cause less maintenance. Looking for efficiency in mini satellites is one of the huge factors that should be taken into account during constructing. Supercapitors and fuel cells will help with providing an excellent amount of power along with many benefits when used in space applications. This paper will go over briefly over mini satellites, introducing fuel cells and supercapacitors with what they can provide in space applications through thorough research from former and recent articles, academic papers, and case studies. A system is proposed regarding a mini satellite that will be powerful and efficient based on fuel cells and supercapacitors in gathering space information.

Abstract Name: A Statewide Study of Wildfire Impacts on Air Quality

In the last few decades, wildfires in Texas have increased in intensity and frequency. 1 in 6 Americans live in areas with significant wildfire risk in 2022. Between 2018 - 2022, 43,351 wildfires burned 1,789,914 acres across the state of Texas and during this 5-year period, 84% of all wildfires ignited within 2 miles of a community. The largest wildfire in Texas history occurred this year on February 26 in Hutchinson County, burning over 1 million acres of land. The wildfire smoke affected surrounding areas like El Paso, listing an air quality index (AQI) of about 126. This AQI indicates an unhealthy air quality for sensitive groups of people, especially elderly and kids. We use various geoprocessing tools and ArcGIS Pro to map the major wildfires in Texas during the last 10 years (2013-2023). Wildfires that burned at least 10,000 acres are considered major fire events. We investigate various attributes of wildfires such as acres burned, duration of fires, vegetation type burned, cause of fire, etc. and plot these data to illustrate the spatial distribution. Particulate matter (PM), an air pollutant, is emitted from wildfires, which can lead to cardiovascular and respiratory diseases. Using wildfire data from the National Interagency Fire Center and air quality data from the U.S. Environmental Protection Agency, we will find the impacts of wildfire events on PM concentrations in Texas. The outcome of this project will help us identify the contribution of wildfire-driven PM in Texas.

Abstract Name: Synthesis and Characterization of Mixed Carboxylate Ligand Rhodium Complexes

Two rhodium compounds with similar structures have been investigated for their toxicity to cancer cells. Previous studies indicated they may not follow the same mechanism of toxicity because one is more toxic than the other in both HeLa (cervical cancer) and MDA-MB-231 (breast cancer) cells. Those two compounds contain a metal-metal bonded dirhodium core that is surrounded by four carboxylate ligands to form either dirhodium tetraacetate ($\text{Rh}_2(\text{OAc})_4$) or dirhodium tetrabutyrates ($\text{Rh}_2(\text{OBu})_4$). We proposed synthesizing new dirhodium compounds with a mixture of acetate and butyrate ligands to provide new complexes to investigate the apparent differences in toxicity mechanisms. This research project focused on synthesizing four new compounds: $\text{Rh}_2(\text{OAc})_3(\text{OBu})$, *cis*- $\text{Rh}_2(\text{OAc})_2(\text{OBu})_2$, *trans*- $\text{Rh}_2(\text{OAc})_2(\text{OBu})_2$, and $\text{Rh}_2(\text{OAc})(\text{OBu})_3$. Each compound was synthesized, purified by high-performance liquid chromatography, and characterized by mass spectrometry along with proton and carbon nuclear magnetic resonance spectroscopies. These four compounds have now been tested in cancer cell studies, and it was determined that their toxicities are greater than $\text{Rh}_2(\text{OAc})_4$, but still less than the toxicity of $\text{Rh}_2(\text{OBu})_4$. Future studies can focus on the determination of the mechanism of toxicity for these compounds.

Abstract Name: Using Optogenetics to Test the Limits of Multitasking in Drosophila

Multitasking, such as walking and talking, is common for humans and other animals, yet we are limited in how many behaviors we can perform simultaneously. The neural circuit mechanisms that limit multitasking are not well understood. Uncovering these mechanisms will help us understand how brains seamlessly combine some, but not all, behaviors. In turn, this will improve our understanding of some movement disorders wherein certain symptoms are exacerbated while multitasking. I am investigating the neural circuitry behind the ability to multitask in a genetic model system, the fruit fly *Drosophila*. *Drosophila* are ideal for these experiments because their relatively simple brains can control a large suite of stereotyped behaviors that can be experimentally driven via optogenetic stimulation of key neurons. During the first stages of my project, I developed a platform to record and manipulate complex behaviors, and started by testing the interaction between locomotion and courtship singing via wing vibrations by activating neurons that drive wing extension. I am now testing the ideal activation protocol to test how multitasking context shapes wing extension. I will then conduct closed-loop experiments to investigate wing extension during single and multitasking contexts. If performing multiple simultaneous behaviors creates interference between neural circuits, I expect to find a lower probability of wing extension in the multitasking context. The results of my project will help uncover how neural circuit interactions shape an animal's ability to multitask.

Abstract Name: ArgoBot: Chatbot for Academic Engagement and Streamlined Information Delivery Utilizing Large Language Models

With the advancement and availability of generative AI tools, such as ChatGPT, education requires great understanding of regulations and protocols, as well as a basic understanding of technology in regard to accessing resources or receiving information, particularly as these pillars of education apply to the modern college student. This project examines the effectiveness of implementing ArgoBot, a chatbot agent built utilizing a large language model (LLM) to inform college students of their university's guidelines through harnessing the university's Student Handbook as the database for the LLM. Through this implementation, ArgoBot can answer a variety of questions regarding the UWF handbook for all students to utilize as a valuable resource. Langchain is used as the language model integration framework to facilitate document analysis, summarization, and building the chatbot application. Google Gemini is used as the base Large Language model and the API token generation and tracking platform, which is then fine-tuned utilizing the UWF handbook as the database from which query answers are refined. Finally, the Python-based software Streamlit is used to deliver the interactive data app that will be hosted on the open-source platform HuggingFace, featuring an engaging and user-oriented interface. Studies have shown that the results of implementing integrated chatbots for educational purposes have proven effective in delivering accurate information to input queries, increasing productivity for both students and faculty. These results suggest that a

similar approach implemented by ArgoBot will generate positive results and transform the learning environment to encourage more productive learning and academic engagement. This project will also work to expand the database to include the university's unique Public Knowledge Base as a resource for more specific questions that may arise in the future.

Abstract Name: Poll Houses of America: Architecture for the Act of Voting

Voting is an essential part of the democratic process and as such is a crucial part of any adult American's life. A polling place refers to a building in which voting occurs, a polling station is a room in which voting happens, and a voting booth is a semi-private stall where the voter marks their ballot. In the United States, voters usually cast their votes in public or municipal buildings, instead of in polling places built specifically for this purpose. From an architectural point of view, this condition begs the question, are there any purpose-designed and built polling places in the U.S., and if so what do they look like? This is important because in the field of architecture great significance is given and taken when creating buildings with symbolic purpose and public use. To answer this question, I began by searching through and contacting state and local historical societies and databases across the country. This included registries like the National Register of Historic Places and the Historical Marker Database. Several sources confirmed the previous existence purpose-built polling places in Wisconsin, Maryland, and Ohio, but none of these structures are still in use. All of these were small, single-room buildings built without an architect's participation. In the case of Ohio, many of the structures were portable for easy deployment in cities on election day. In Wisconsin and Maryland, the structures were permanently located in rural areas. It appears that this organization of small and single-room polling places was discontinued after World War II likely due to population growth, and the later enactment of the Americans with Disabilities Act. This still leaves the question of why is voting is not significantly represented in our architecture or why have architects not proposed any innovations in the architecture used by Americans for voting.

Abstract Name: Exploring Demographic Factors and Mental Health Personal Stigma Among Undergraduate Nursing Students

Nursing students face significant mental health challenges due to demanding coursework and clinical requirements. However, the relationship between demographic factors and mental health personal stigma (MHPS) is unknown. This study explored the relationship between age, gender identity, and racial/ethnic identity and MHPS among undergraduate nursing students (UNS). This study was guided by Tajfel's Social

Identity Theory, which examines how group identities shape perceptions. This cross-sectional study used a secondary data analysis from the 2022-2023 Healthy Minds Study, focusing on a subset of UNS (N=2,286) from over 100 United States colleges and universities. Age was treated as a continuous variable, while gender and racial/ethnic identity were dichotomized as female vs. non-female and White vs. non-White, respectively. MHPS was operationalized using Likert scales across three statements: 1) accepting someone who has received mental health treatment as a close friend; 2) perceiving mental health treatment as a failure; and 3) thinking less of someone who has received mental health treatment. Data were analyzed for descriptive and correlational statistics using SPSS Version 29. Age and stigma were examined with Kendall's tau, while gender and racial/ethnic identity differences were assessed with Mann-Whitney U. Older participants exhibited greater stigma regarding thinking less of someone who has received mental health treatment ($\tau=-.082$; $p<.001$). Non-female participants exhibited greater stigma regarding close friend acceptance ($U=1.998$; $p=.046$). Non-White participants exhibited greater stigma across all statements: close friend acceptance ($U=5.286$; $p<.001$), perceiving mental health treatment as a failure ($U=-6.029$; $p<.001$), and thinking less of someone who has received mental health treatment ($U=2.754$; $p=.006$). Findings indicate demographics may shape MHPS among UNS. Limitations include social desirability or recall bias and the inability to determine causality or track changes. Nursing programs can use these findings to incorporate targeted interventions for older, non-female, and non-White students to combat MHPS.

Abstract Name: Masked Capitalism in State-sponsored Settler Colonialism of Philippine Labor Bureau Settlement Programs under American Rule

In the first half of the 20th century, state-sponsored settler colonialism in the Philippines under American rule deployed colonists, often poorer Philippine urbanites, to displace and assimilate indigenous people of the interior. Drawing on Labor Bureau reports, this paper traces how the colonial government sought to “effectively and systematically” use homesteader migration to the interior to advance both explicit and unstated governmental goals. Explicit goals centered on the economic exploitation of indigenous land and resources, coupled with the erasure of indigenous land tenure systems, while the state’s propagandistic rhetoric framed these efforts as improving Filipino well-being. However, while the aims of replacing and assimilating indigenous people and denying their land rights for economic gain were overt, the stated goals of improving the non-indigenous Filipinos’ conditions were in tension with underlying capitalist aims. Settler colonists were selectively supported based on their capital sufficiency, ensuring their capacity to produce commodities within the colonial economy. Exceptions were made for capital-poor migrants deployed to interior regions where labor was required to sustain large-scale capitalist enterprises. Conversely, Filipinos from areas where industrial labor was in demand were excluded from homesteading opportunities. These strategies reveal the extent to which colonial settlement policies were shaped by capitalist interests, exposing the structural tensions between the overt goals of settler uplift and the covert priorities of economic exploitation. The geographies of governmental policies reveal hidden capitalist influences on indigenous displacement under empire.

Abstract Name: Analysis of 18th-20th Century Ghost Show Letterpress Posters

With this work, I researched, designed, and printed letterpress posters inspired by late 18th through 20th-century advertising for spook shows—live magic shows that played with the idea of the paranormal. This research consists of analyzing the visual language of the genre and looking for similarities and differences in typography and illustrative elements used for these show prints. A large part of this project was inspired by author Mark Walker's book, *Ghostmasters*, a collection of research written to preserve the history of this rare piece of American theatrical heritage. These ghost shows were a large part of popular culture that has since been forgotten. My aim with the project was to analyze the posters designed and printed by Triangle Poster and Printing Company, a show card print shop based in Pittsburgh, Pennsylvania. Triangle Poster has served the entertainment industry since 1905 printing original posters, billboards, and other forms of outdoor advertising. They've created work for festivals, races, circuses and revues, and more fringe events like freak and ghost shows. In the 19th Century, the public became fascinated with spiritualism and the paranormal. Audiences flocked to local theaters to witness the claims of mediums and mystics, promoted via broadsides and posters in cities and towns. The tradition of these shows carried on well into the 20th Century, and Triangle played a part in its promotion of "ghost shows" by designing some of the most well-known posters of the genre. Inspired by Triangle and the ghost show aesthetic, I designed a poster and produced my custom print blocks with a CNC router, and printed them with a Vandercook proofing press. Combining analog and digital processes, I handwrote the typographical elements, manipulated old photography, and combined them using Adobe editing software. The design was routed onto a woodblock using CNC, then printed on letterpress.

Abstract Name: Intersectional Limitations of the SDG Program: SDG 2 in Berlin, Germany

The United Nations' Sustainable Development Goals (SDGs) are 17 objectives designed to improve the economic, political, social, and environmental viability of nations across the globe. While these measures are widely used as a reliable measure of a country's well-being, this paper argues that the SDGs, and particularly SDG 2 "Zero Hunger," are designed in a way which ignores intersectionality, limiting the validity of SDG measures. Using the city of Berlin, Germany, as an example, this paper explores aspects of the concepts of food and hunger which are not considered in the United Nations' official criteria. These aspects include the appropriation of and capitalization on ethnic foods, the exclusionary politics and practices of community gardens and kitchens designed to promote food access, and the weight- and health-based discrimination in the wording itself of SDG 2 which leads to continued misinformation about fatness in Germany and abroad. This demonstrates not only continued social injustices in Germany, but also the limitations of using SDGs as a sole marker of a country's prosperity and long-term sustainability.

Abstract Name: RNAseq Analysis in Bulldog Fetal Hydrops

Fetal hydrops is a condition where excessive amounts of fluid build up in multiple places in the fetus. It often leads to serious birth complications and is usually fatal. It is relatively common, with 1 in every 1700 births being afflicted by fetal hydrops. Although the etiology and contributing factors are unknown, it has been noted that it follows an autosomal recessive pattern of expression. Bulldogs are a good model organism for this condition, due to genetic lineage logging by clubs and sample availability. Necropsies were performed on stillborn puppies diagnosed with fetal anasarca. Multiple organs were harvested and stored for expression or sequence analysis (RNA/DNA). The kidney samples were sent for RNA sequencing. Data received required further processing against healthy controls whereas the company report only compared expression changes between diseased pups. Due to the lack of appropriate controls and the complexity inherent in big data and RNAseq analysis, it was deemed necessary to try to reproduce the results from raw data, with more representative healthy control. As the initial experiments in RNAseq, the first steps required the establishment of a proper pipeline from published bioinformatic protocols. Several pipelines were tested until outputs were comparable to the company analysis. An initial review of the differential expression shows an abnormal amount of ribosomal genes that were downregulated.

Abstract Name: The Perceived Success of Rehabilitation and Reintegration Programs from the Perspective of Felony Offenders in Northern Colorado

Criminal justice reform programs in the United States of America have grown and developed as studies have found that older methods of criminal punishment are ineffective in terms of reducing the likelihood of an inmate being reincarcerated after release, referred to as "recidivism." With the growth of these reforms, ground-breaking systems have been integrated into prisons in the form of rehabilitation and reintegration programs which serve to reduce recidivism. However, with the development of numerous new unique and powerful programs, determining which rehabilitation and reintegration programs are most effective in reducing recidivism in felony offenders in the U.S. is critical. Past research suggests that different programs serve to reduce recidivism in a variety of ways. While an arts-based program shows significant success with those who have a knack for being creative, work-based programming has shown to be more successful for those in need of funds to save for post-release or restitution. This current research study seeks to address this question with a mixed methods survey that is being disseminated to halfway house clients in a medium-sized, mid-western city. The research participants are rating various rehabilitation and reintegration programs that they have experienced. Participants are also providing short answers to open-ended questions on the survey regarding what they view as the biggest barriers to reintegration and recommendations for programs. This research study emphasizes the importance of individual approaches in reintegration and rehabilitation programs for felony offenders, and the results can be used to inform possible future adjustments to offered programs within this community.

Abstract Name: Investigating the role of DAF-18/PTEN in regulating the age-dependent activity of the DAF-16/FOXO transcription factor to preserve healthspan

The Insulin/IGF signaling (IIS) pathway determines longevity and lifespan in diverse species, including humans, by regulating gene expression through its control of the activity of FOXO transcription factors. In *C. elegans* roundworms, the activity of the FOXO transcription factor DAF-16 progressively increases during aging, leading to the upregulation of evolutionarily conserved genes that protect animals from environmental stressors. In fact, DAF-16-mediated innate immunity is the principal means of defense from microbial pathogens in older animals. One determinant of the age-dependent function of DAF-16 is the dual-specificity phosphatase DAF-18, an ortholog of the human tumor suppressor PTEN. We sought to find where DAF-18 is expressed in adult animals and to determine whether its lipid or protein phosphatase activity is more important for its function later in life. In adult animals we found that DAF-18 is primarily expressed in the nervous system where it is required for the increased expression of DAF-16 transcriptional targets in distal tissues including the intestine, indicating a cell non-autonomous function. To pinpoint the neurons in which DAF-18 is expressed, the progeny of males expressing DAF-18::GFP mated to a series of hermaphrodites expressing an RFP-tagged protein in subsets of known neurons were examined to look for a merger of the green and red fluorescent signals. Through this approach, we narrowed down the possible neurons in which DAF-18 may be expressed to five chemosensory neurons that produce neuroendocrine signals. Functional characterization of *daf-18(yh1)* mutants that lack lipid phosphatase activity but retain protein phosphatase activity suggests that DAF-18 dephosphorylates lipids and not proteins to modulate the age-dependent activity of DAF-16, suggesting that it may counteract and inhibitory signal transmitted through the IIS pathway. Our studies reveal a role for DAF-18 in preserving organismal health and have implications for the age-dependent function of PTEN in humans.

Abstract Name: Baker's Constitution View and Degrees of Moral Value

In her book *Persons and Bodies*, Lynne Rudder Baker outlines her Constitution View, a form of person essentialism. I will argue that although I find the Constitution View to be a compelling account of what we as humans most essentially are, there is a problematic ethical implication that arises from her theory. The problem in question is that non-persons maintain radically inferior moral status in comparison with persons. To tackle this problem, I will first introduce person essentialism and explain Baker's Constitution View, including what capacity Baker believes to be the essence of a person. Then, I will introduce the idea of moral status as a matter of degree and discuss an accepted method of assigning an individual moral status that is contingent on present interests. Next, I will reject both this emphasis on the capacity for interests as well as Baker's assertion that non-persons will always have radically inferior moral value. I argue that although I believe moral value is a matter of degree, it should be based on the potentiality for future interests/first-person points of view, not on current capacity. I then apply my modification of Baker's Constitution View to individuals considered non-persons under her definition, including fetuses, infants, and adults who lack first-person perspectives (such as those in PVS or experiencing late-stage dementia).

Abstract Name: Empowering Graduates: The Impact of Undergraduate Research in Developing Career Readiness Competencies

The value of higher education is a pivotal topic as students and families assess the return on investment of a college degree. Programs like the Virginia Talent and Opportunity Partnership aim to enhance career readiness through providing students resources that align with language employers use, as well as how to demonstrate and develop skill proficiencies. Undergraduate research experiences (UREs) are recognized for boosting workforce readiness and confidence, yet their long-term impacts, especially for non-STEM students, are underexplored. This study used a mixed-methods approach to evaluate the impact of UREs on students' professional and intellectual growth. Reflections from 186 fourth-year students with at least one year of URE participation were analyzed using the National Association of Colleges and Employers (NACE) career readiness competencies as a framework. A codebook was developed to link competency behaviors with research skills, and thematic content analysis identified trends in competency development. High inter-rater reliability, measured by Krippendorff's Alpha (≥ 0.7), validated the coding process. Results indicated that students frequently showed confidence and gratitude for their UREs, with career and self-development, along with communication, being the most developed competencies. The frequency of each competency mentioned did not significantly vary by first-generation status, gender, race, ethnicity, or socioeconomic background. Both STEM and non-STEM students exhibited comparable growth trends, affirming the value of UREs in preparing students for diverse career paths. Building on these findings, we are partnering with our career center to pilot the Career Readiness Report, a self-assessment tool, with first-year researchers. The tool evaluates NACE competencies through 360-degree feedback including peers, coworkers, faculty, and supervisors, providing a framework to track growth and align student development with workforce needs. This study underscores the lasting value of undergraduate research experiences in preparing students to succeed in a dynamic and diverse workforce.

Abstract Name: Supporting Children's Grief and Loss

Grief is a universal experience that displays itself in a plethora of ways, each unique to the individual. For young children, navigating grief is a challenge, as their brains are still developing and their understanding of death and dying is limited. They are also in the early stages of learning how to manage their emotions and may have difficulty expressing emotions as a result (Children's Bereavement Center, n.d.). Grief is something everyone experiences at one some point, and it is important that the prominent figures in a child's life are equipped with the proper tools to guide their children through their loss. One of the main ways to support

children's grief is by being straightforward with young children when discussing death and dying (Danielson & Colman, 2023). This may seem counterintuitive when trying to be sensitive to their needs, but young children have magical thinking. This means that children think that their thoughts or actions can influence the outcome, and they need concrete information to have an accurate understanding of reality. For example, a child may think that their sibling died as a punishment for their bad behavior, so if they behave really well, it will bring their sibling back to life. Therefore, clarity helps them to better process the situation. Alongside concrete information, there are many ways to encourage healthy grieving and coping strategies amongst young kids. This presentation aims to inform parents, caregivers, and other practitioners on how to help young children grieve in a way that is healthy and beneficial. It helps parents learn how to support their children's grief and how to be open about their own grieving process. The entire family benefits from this openness around grief and loss as it promotes healthy healing.

Abstract Name: You Are More Resistant Than You Think

Antibiotics are often a necessary part of a person's medical care. Many of these antibiotics are used to treat gastrointestinal infections, ciprofloxacin being one of them. Oral antibiotics can cause shifts in the microbiota and cause inflammatory effects creating more suitable conditions for pathogens. Although beneficial antibiotics can cause dysbiosis and further damage to the epithelial. Lactobacillus is a beneficial bacterium that lives in the gut. Previous studies have shown that some strains of this bacteria are inherently resistant. However how clinically relevant antibiotic doses, such as ciprofloxacin, alter Lactobacilli abundance and IL-10 production in intestinal T cells has yet to be studied. This research aims to study how clinically relevant doses of antibiotics alter the presence of lactobacillus. Using a technique called population analysis profile (PAP) the resistance of Lactobacilli species to ciprofloxacin will be examined. By conducting population analysis profiles, we were able to visualize how lactobacillus responded to different antibiotics to predict the outcome of its effect on IL-10 production.

Abstract Name: Protoporphyrin IX as a Candidate for Polariton Research

We are interested in conducting polariton candidacy research on protoporphyrin ix and other similar porphyrins. Polaritons are hybrids between molecules and light that are made by bombarding a sample of molecules with light in a mirror cavity that traps the light in the sample for a significant period of time, possibly changing the reactivity of the molecule and making chemical reactions possible that might otherwise

not be. Protoporphyrin ix is an aromatic molecule that can be readily isolated from brown eggshells and has a structure nearly identical to heme and very similar to that of chlorophyll. For this reason, we think that protoporphyrin ix polaritons may have significant and impactful applications in the alternative energy production area as well as in the medical area. In this presentation, we show the results of electronic structure calculations that demonstrate protoporphyrin ix's candidacy for polariton research as well as showing the steps required for isolating it as a natural product from brown eggshells.

Abstract Name: Can Halophiles Be Present In Ice Nucleating Particles in the Atmosphere?

This project centers on the possibility of salt-thriving halophiles to serve as ice-nucleating particles (INPs) in the atmosphere. This task presents a challenge due to the diversity of the bacteria and archaea domain and the limited data available in bioaerosols to become cloud ice formations. Microorganisms such as bacteria, fungi, and pollen contain biologically derived materials that can act as INPs, initiating the freezing of water droplets in clouds even at relatively warm temperatures. Ideally, I would predict that different strains of haloarchaea will react differently based on their optimal salt concentrations: those from a less saline environment may be better microorganisms for INPs since they are able to interface with more water molecules in the moderately saline brine. This project consists of testing three different isolated strains of haloarchaea for optimal salinity and temperature profiles. These data would be coupled with measurements of their ability to induce freezing. Understanding the behavior of halophiles under specific environmental conditions is crucial to expanding our understanding of biological impacts on clouds, especially over saline lakes such as Great Salt Lake. What's more, forming INPs may have positive impacts on the water crisis of the west.

Abstract Name: Natural Things - An Original Modern Jazz Composition

This project explores the development of my personal style as a jazz artist, focusing on idiomatic music writing for a quintet featuring tenor saxophone, piano, guitar, bass, drums, and voice. The work aims to express my understanding of jazz vocabulary, rhythm, melody, harmony, texture, and its rich cultural history, spanning from swing to modern jazz. It also examines improvisation as a form of intercultural communication and highlights the spirit of collaboration central to jazz. Through the composition of Natural Things, I aim to fuse traditional jazz elements with my evolving artistic voice. The research context of this project lies in the intersection of historical jazz forms—bebop, post-bop, modal, and modern jazz—and my personal creative exploration. This work builds on my deepening engagement with jazz as a language of improvisation, focusing on how each instrument in the ensemble communicates with the others. It contributes to the broader discourse of contemporary jazz by blending established idioms with modern sensibilities, while fostering collaboration in performance and composition. The methodology for this project involved writing idiomatic parts for each instrument, while also allowing space for improvisation within a cohesive structure. I

led rehearsals and managed the recording process, collaborating with a team of 12 professionals, including musicians, engineers, and designers. The album was released through Distrokid on all streaming platforms and in a limited vinyl edition, with original artwork. The expected outcome is to gain a deeper understanding of jazz as both a creative process and a cultural dialogue. The experience of composing, performing, and recording Natural Things has strengthened my grasp on jazz tradition while pushing my personal boundaries. This project represents my growth as a jazz artist, integrating history, culture, and collaboration into a unified musical expression. A recording is available via this link <https://music.apple.com/us/album/natural-things/1767742839>

Abstract Name: The Relationship Between Mindfulness, Repetitive Negative Thinking, and Worry

This study aimed to find the predictors of repetitive negative thinking and worry. Previous literature acknowledged connections between mindfulness and repetitive negative thinking and mindfulness and worry. For example, there was a negative correlation between mindfulness and repetitive negative thinking, as well as mindfulness and worry, and a positive correlation between repetitive negative thinking and worry. It was hypothesized that the five facets of mindfulness (observing, describing, acting with awareness, non-judging, and non-reactivity) would predict repetitive negative thinking scores as well as worry scores. To test this hypothesis, the Five Facet Mindfulness Questionnaire Short Form (FFMQ-SF), the Penn State Worry Questionnaire (PSWQ), and the Perseverative Thinking Questionnaire (PTQ) were administered. One hundred fourteen (N = 114) undergraduate students of all classifications participated in this study from different classrooms, such as General Psychology, Social Problems, Introduction to Criminal Justice, and Introduction to Biblical Faith. Results showed that mindfulness significantly predicted lower repetitive negative thinking scores, in addition to worry scores. Specifically, non-judging and acting with awareness were key predictors of repetitive negative thinking, while non-reactivity, acting with awareness, non-judging, and observing predicted worry. The study highlights the value of mindfulness practices in managing repetitive negative thoughts and worry. Limitations included similarity of the sample, and future research is advised to incorporate more diverse populations to further investigate these relationships.

Authors:

Abstract Name: Know Your Every Move

Through personal experience, I have been deeply inspired by themes of lust and relationships and women empowerment and sexualization. Through my choreography, I focused on how women embody both sensuality and strength. Additionally, I aimed to explore the concept of male lust and its impact. When I first listened to Michael Jackson's Dirty Diana, the song sparked a vision of storytelling through dance. The intensity and narrative of the song provided the perfect framework to express these themes. This creative

process allowed me to interpret my ideas through movement, with the music serving as a guide. The piece became an exploration of emotions and dynamics, enabling me to translate abstract ideas into choreography. It also deepened my understanding of partnering and the interaction between dancers, highlighting the importance of connection and chemistry. Throughout this piece there is partnering in multiple ways to showcase the themes I wanted to explore. This project feels like a cornerstone in my portfolio, serving as a foundation for future works. It has not only refined my skills in crafting narratives through dance but also ignited my interest in addressing contemporary and social issues through movement. The experience has inspired me to delve deeper into themes that challenge societal norms, encouraging dialogue and introspection. Moving forward, I hope to continue creating pieces that provoke thought and resonate with audiences on a personal and societal level. This journey has taught me the power of dance as a medium for storytelling and advocacy, reinforcing my commitment to exploring meaningful themes in my art.

Abstract Name: NGC 2168 Age Cluster

This research investigates the precision and accuracy of age determination in open star clusters using the astrostatistical software package BASE-9. The project is divided into two parts. First, the collective properties of the selected cluster, NGC 2168, are analyzed to derive its age by other researchers in our team. Second, we derive the ages of individual stars within this cluster, again using BASE-9. We will evaluate the reliability and validity of the age determinations by comparing the results for individual stars with those of the cluster. This research aims to contribute to the understanding of precision in age determination for both star clusters and individual stars. This research will also advance the knowledge of stellar evolution and star cluster properties.

Abstract Name: Algorithm Bias in AI-Driven Technology: A Retrospective Analysis of Healthcare Equity Trends in Academic Radiology Journals

To develop a more equitable healthcare environment, algorithm bias must be overcome to reduce the prevalence of unsuitable treatments given to systematically disadvantaged groups. Algorithm biases are computational errors based on generalized datasets, due to incomplete AI data, design, and deployment. This issue should be confronted because AI bias is highly relevant to diverse patient groups and ascribing specific treatments. Publication trends can act as an indirect indicator for how relevant and reported algorithm bias is in each medical specialty. This investigation evaluates publication trends in algorithm bias within scholarly radiology journals and aims to mitigate algorithm bias by directing attention to the issue. Data was gathered from PubMed databases and a search string was then implemented to isolate terminology corresponding to

algorithm bias in radiology journals published from 2000 to 2023. Article information including title, publication, year, manuscript length, and number of citations were exported and analyzed. The trend in publications per year was assessed using linear regression. Results show that there were 3,276 algorithm bias related publications during the study period. Algorithm bias publications showed a generally linear increase ($r^2 = 0.943$) with notable increases (50+ more from the previous year) in 2013 and 2022. It was found that Medical Physics published the greatest abundance of algorithm bias related studies among radiology journals during the study period with 177 publications. The only other journal with over 100 or more publications was Magnetic Resonance in Medicine (100). Overall, the frequency of algorithm bias publications has increased rapidly since 2000, suggesting the increasing importance of eliminating algorithm bias while managing AI technology.

Abstract Name: Exploring Factors Behind the Significant Decline in Accounting Graduates in Recent Years and Strategies for Promoting Accounting Careers

The American Institute of Certified Public Accountants (AICPA)—a non-profit professional organization representing certified public accountants (CPAs) in the United States—has reported in its recent 2023 Trend Reports that the number of bachelor's and master's degree graduates in accounting has dropped significantly since 2021. In this research, the interest lies in learning more about why the number of U.S. graduates with bachelor's and master's degrees in accounting majors is declining and identifying the influential factors behind the significant drop in recent years. The primary focus involves examining historical trends and statistical data related to the enrollment and graduation rates of accounting majors across U.S. educational institutions. Quantitative analysis was conducted to uncover patterns in graduation rates and explore contributing factors, including shifts in student preferences, economic conditions, and technological advancements such as automation and artificial intelligence. The study also highlights broader influences, such as the 150-hour CPA certification requirement, negative perceptions of the profession, and societal changes, including indirect factors such as declining birth rates and evolving career guidance. This study is crucial for informing educational institutions, industry stakeholders, and policymakers to ensure the sustained growth of the accounting profession in the U.S. Through a comprehensive exploration, this study aims to contribute meaningful insights to accounting education and the profession, with the ultimate goal of encouraging a revived and sustained interest in pursuing accounting careers in the United States.

Abstract Name: Circadian rhythm disruption by unpredictable disturbance and its effects on physical activity and lifespan

Circadian rhythms are vital for helping humans adapt to changes in their environment and regulate internal

physiology. With the emergence of technology, night-shift work, and jet lag, human sleep cycles are increasingly disturbed. Several studies have investigated the short-term outcomes of sleep disturbance and demonstrated the consequences of sleep disruption in terms of behaviors and diseases. However, research assessing the effects of varied amounts of unpredictable circadian disturbance, individual response, and long-term impacts is lacking. Here, we investigate how varied lengths of unpredictable, forced movement impact baseline activity and lifespan of *Drosophila melanogaster*. We used four strains from the *Drosophila* Genetics Reference Panel (DGRP) to compare animals with diverse activity patterns and both sexes. The unpredictable disturbance treatment consisted of four randomized 30-minute daily rotations on the TreadWheel. The TreadWheel is a device that rotates fly vials, causing the flies to climb the sides of their enclosure continuously. We measured daily animal activity and tracked mortality for disturbed and control groups. We found that 5-day and 20-day unpredictable disturbance treatments can influence the activity level of the animals. Activity levels varied depending on treatment, genotype, and sex. Across all genotypes and sexes, we found few effects on lifespan. Males from one genotype showed a significant increase in survival in response to both disturbance treatments. Our results indicate that unpredictable disturbance can have negative, positive, or no impact on daily activity. Furthermore, activity and lifespan are highly dependent on genotype and sex. These results make clear the complexity of predicting individual response to disturbance and pinpointing how much disruption is considered harmful.

Abstract Name: Honoring Sacrifice: The Repatriation of Fallen Soldiers of World War II

From May 1946 to December 1951, the United States government, with the help of civilian workers, undertook the Return of the Dead Program, a mass repatriation effort for fallen World War II soldiers. Through this program, the United States recovered more than 171,000 bodies -- all returned to the United States for burial. At the same time, another 110,000 bodies were buried in foreign American cemeteries. Although the program did return a significant number of fallen soldiers buried in temporary graves, it did not address the fallen missing in action. My research uncovers the efforts of civilian and governmental agencies to repatriate WWII veterans who were MIA in the European theater from the 1960s onward. Few historians have addressed the topic of the repatriation of these American soldiers. My research, therefore, utilized records from the Department of Veteran Affairs to reconstruct how civilian groups inspired federal action, culminating in the creation of the Defense POW/MIA Accounting Agency in 2015. Despite the DPAA's successful return of nearly 1,000 Americans missing from World War II, the continued recovery and return of soldiers missing in action would not be successful without the efforts of American and European civilian-led groups, like Archeologo Dell'Aria. The United States and non-governmental groups must continue their combined efforts to repatriate the dead.

Abstract Name: Experimental Study of Photocatalysis for Degradation of Common Agricultural Pesticides

The global expansion of agriculture has led to increased contamination of water systems, posing significant risks to both the environment and human health. Photocatalysis is an eco-friendly and energy-efficient process that utilizes light to activate titanium dioxide (TiO₂), producing reactive species that break down harmful and toxic chemicals into non-toxic byproducts. This research investigates the effectiveness of TiO₂ under varying conditions, including pH levels, exposure durations, and catalyst concentrations. Experiments were conducted using pesticides with various active ingredients, treated in a photoreactor system. Degradation efficiency was assessed by comparing pesticide concentrations before and after treatment. Results showed that TiO₂ effectively reduces pesticide concentrations, with optimal degradation achieved under specific conditions, particularly at certain pH levels and exposure durations. These findings highlight the importance of optimizing environmental factors for effective photocatalysis. Additionally, the study examined the reusability of TiO₂ to determine its potential for repeated use. This research demonstrates the potential of TiO₂ photocatalysis as a sustainable and innovative solution to water pollution caused by agricultural fertilizers.

Abstract Name: Asymmetry Kitchen; A Design Solution for Left-Handed Users

Kitchen designs are typically optimized for right-handed users, often resulting in poor ergonomics and discomfort for left-handed individuals. The Asymmetry Kitchen project aims to address these challenges by creating a product tailored specifically to the needs of left-handed users. The objective is to develop a multi-functional, practical design that enhances the kitchen experience for left-handed cooks. The design process involved thorough research and evaluation, leading to valuable insights and practical solutions for improved usability. This strategic approach integrated multiple ideas to identify needs and develop a functional solution. Left-handers are three times more likely to have major accidents in the kitchen therefore increasing accidents and injuries that can be prevented with a functional solution. 10.6% of the population in the world are left-handers as of March 2020. The final product is an intuitive, accessible kitchen cart that offers comfort and efficiency, featuring a caster system for easy mobility. Customizable, durable, and easy-to-clean materials were carefully selected to ensure durability in a kitchen environment and adaptability to existing kitchen aesthetics. Key design elements include left-hinged doors, left-oriented handles, and a cutting board that swivels to accommodate left-handed use. By considering the unique needs of left-handed cooks, this design helps eliminate awkward workarounds and empowers users to move freely and comfortably for successful meal preparation. The cart's thoughtful design, from its smooth-rolling casters to its practical layout, provides a seamless integration into various kitchen spaces. Overall, this product offers an inclusive and practical solution that enhances usability, comfort, and joy in the kitchen for left-handed users.

Abstract Name: A Home Designed for the Visually Impaired: A Response to Diabetic Retinopathy

People with visual impairments have unique needs that differ from those of others. The challenges they face, such as distinguishing objects or navigating spaces, can be intensified by specific health conditions, such as diabetic retinopathy. Therefore, designing a home with contrasting tones, textured walls, and subtle changes in flooring can aid visual recognition, enabling individuals to more easily navigate and manage their living spaces. When designing for someone with a diabetic retinopathy visual impairment, it's crucial to take their specific needs and accommodations into account to support their daily tasks and overall well-being. After multiple case studies and research from previous visual impairments designs such as Rue Magazine and Architectural Digest, it concluded multiple design aspects emerging together for users with diabetic retinopathy. Prioritizing the layout of the home is also essential, ensuring clear pathways and reducing navigational challenges. Unfortunately, people with disabilities are often not given the full consideration they deserve in many design processes. While many homes may meet basic regulatory compliance, they can still fall short of offering comfort, independence, and a true sense of belonging for individuals with disabilities. By incorporating diabetic retinopathy-friendly color schemes, unobstructed walkways, and an accessible bathroom, environments can be created that allow people with visual impairments to navigate their homes with greater ease and safety. As these individuals move through spaces thoughtfully designed to meet their needs, they gain confidence in their ability to interact with their environment, ultimately enhancing their quality of life and fostering a sense of independence. Implementing moveable furniture, easy-to-clean materials, and accessible features, allows the end user to have confidence in navigating their space independently. Overall, this design is carefully tailored to the needs of an individual with visual impairments and intends to empower the end user.

Abstract Name: Factorizations in the lattice of the subspaces of a vector space over a finite field

Geometric lattices play a fundamental role in various fields such as combinatorics, algebra, and cryptography due to their rich structural properties and numerous applications. In this research, we consider a geometric lattice L whose atoms have been partitioned into two sets: A and B . We aim to address the following question: assuming that two subsets of atoms in A are equivalent if the join of their elements is equal, how many elements at the j -th level of L can be obtained by taking the join of atoms in A ? To answer this, we propose a recursive formula for this number, denoted as l_j . We approach this problem by studying the dynamics of the equivalence classes in the power set of A when an element is removed. We contextualize and extend this formula to the specific case of the lattice of subspaces of a vector space over a finite field. This allows us to find the number l_{sj} , which only considers the join of exactly s atoms in A . Finally, the lattices of this form have significant implications in cryptography, where the impact of our contribution is rigorously analyzed.

Abstract Name: “No soy un robot”: implicaciones éticas y estéticas de la traducción literaria asistida por computadores

Literary translation is a field that presents itself as a spectrum of possibilities to carry meaning from one language to another or within the same language. In this sense, the translator carries out the task of interpreting the cultural and textual elements of a source text, so they can be brought into a different language and culture. The abundance of meaning that emanates from a text implies an abundance of possible outcomes for a translation. This process can be equated to that of scientific outreach, for it implies the transformation of specialized knowledge into terms more easily understood by the public outside of academia. The more a topic is discussed and theorized, the more knowledge becomes available to share. Furthermore, with the recent development of artificial intelligence technology, the role of Large Language Models (LLM) in the practice of the humanities is increasingly questioned. Literary translation, being a craft that requires constant interpretation of the source material and depends a great amount on aesthetics for its existence, serves as a perfect case study for the capacities of AI in the field of translation. This project seeks to develop instances of interaction between translators and LLMs, as well as to create outreach products such as workshops, zines and infographics to bring humanistic and translation theories to cultural spaces outside of academia to promote the social appropriation of knowledge.

Abstract Name: A Cost-Effective Biaxial Mechanical Testing System for Vascular Specimens

In vivo, blood vessels undergo continuous cyclic deformations and loading patterns as blood pressure fluctuates with every heartbeat. Mechanical characterization of blood vessels is thus pivotal for understanding how the vasculature (mal)adapts to various pathologies. Commercial mechanical testing devices pose significant cost barriers, warranting the development of affordable alternatives. Toward this end, we have designed a device to characterize the circumferential and longitudinal (thus biaxial) mechanical properties of small blood vessels using cost-effective and open-source hardware and software for approximately 10% of the cost of commercial systems. Circumferential distension is measured continuously via live tracking of the vessel's inner and outer diameters using a microscope camera, while intraluminal pressure is controlled automatically using a syringe pump. Each end of the specimen is attached to a parallel beam load cell to enable continuous measurement of longitudinal force, while longitudinal stretch is prescribed with automated translation stages. During testing, the vessel is submerged in a bath maintained at 37°C using a heating pad and thermistor. This setup replicates physiological conditions, ensuring accurate representation of mechanical behavior. All electronic components, including pressure transducers, load cells, and stepper motors, interface with custom open-source software through a microcontroller board. Our experimental setup allows live visualization and real-time analysis of inner/outer diameters, pressure, and longitudinal force/stretch as the software compiles data from the pressure transducers, load cells, and microscope camera. Validation studies using hydrogel conduits of known mechanical properties and murine arteries are ongoing. This device overcomes limitations of current open-source pressure myography systems, which do not measure longitudinal force or automatically control circumferential/longitudinal loads, while avoiding the prohibitive cost of current biaxial systems. More broadly, the measurement of such detailed mechanical properties facilitates future studies to enhance our understanding of vascular function, structure, and adaptation to diseases and therapies.

Abstract Name: Differential Modulation of Gene Expression in the Green Crab *Carcinus maenas* in Response to Hypoosmotic Stress vs Elevated Temperature

The green crab, *Carcinus maenas*, lives in estuaries where salinity and temperature vary widely. Although exposure of crabs to either hypoosmotic stress or elevated temperature resulted in increased levels of the hormone methyl farnesoate (MF) in the blood, the time-courses for the responses to these two stressors were different. When crabs were transferred to seawater with elevated temperature, levels of MF in the blood increased after just 2 hours and attained maximum levels (3-fold above basal levels) within 10 hours of transfer. In contrast, when crabs were transferred from full-strength to dilute seawater, levels of MF in the blood did not increase until after 6 hours and did not attain maximum levels (10-fold above basal levels) until 48 hours after transfer. Even when crabs remained at elevated temperature, levels of MF decreased to basal levels within 24 hours. In contrast, following transfer to dilute seawater, levels of MF in the blood remained elevated at maximal levels for as long as the crabs remained in the dilute seawater. The purpose of the current study was to examine possible mechanisms for regulation of MF levels. Specifically, we measured expression of farnesoic acid O-methyltransferase (FAOMeT), the enzyme that catalyzes the final step of the MF biosynthetic pathway. While determining the gene sequence of the enzyme, two isoforms of FAOMeT were discovered. Each is coded by a different gene. The sequence of the short isoform of FAOMeT is identical to that of the long isoform, except that it lacks a 15-base pair segment of nucleotides. When crabs were transferred to hypoosmotic seawater, the short isoform of FAOMeT was upregulated (5-fold above basal levels at 10 ppt salinity). In contrast, when crabs were transferred to seawater with elevated temperature (from 14°C to 28°C), the long isoform of FAOMeT was upregulated (2.5-fold above basal levels).

Abstract Name: Exploring Enzymatic Degradation of New Plastic Materials for Digestible Pet Toys

Plastic materials used in pet toys often pose health risks when ingested due to being non-digestible. This research study investigates new plastic materials as alternatives to conventional plastic toy-fillings, such as polyester fibers. The newly invented materials have the potential to be digestible materials that create safer options for pets and reduce environmental pollution. To assess degradation in canine digestion, the samplers were put under five conditions to mimic the canine gastrointestinal environment. Preliminary findings suggest that they have enzymatic degradation. Approximately, ten percent degradation is observed after 14 days. Future studies will focus on other factors, such as pH levels, to understand if the materials are digested faster in different conditions.

Abstract Name: From BirdNet to BugNet: Leveraging AI to enhance Cicada Detection through expanded Training Libraries

Insect biomonitoring plays a critical role in assessing habitat quality, informing conservation efforts, and in early detection of invasive species. Passive acoustic monitoring has the potential to revolutionize insect monitoring, but acoustic insect recognition is presently a challenge. Current deep learning and Tensor Flow models accurately identify thousands of bird species, but insect calls have been traditionally viewed as noise. As a continuation of previous research, we will advance the ability of the convoluted neural network BirdNet to identify periodical cicadas. BirdNet is an open-source deep learning program that ingests wave files, converts them to spectrograms, and then compares those images to a training data set. Last semester, we developed a custom cicada classifier for BirdNet using binary classification. After gathering extensive new data, we aim to improve the classifier's accuracy and precision. We will also modify the classifier to allow BirdNet to recognize specific cicada species using multinomial classification. Since our acoustic data mainly contains *Magicicada cassini* and *Magicicada septendecim*, we will create a training library for each species, plus a non-cicada library. After training, we will test the classifier using a separate validation library for both species and non-cicadas. In future work, we aim to perfect the cicada classifier for citizen use and allow public access. In addition to helping bridge the gap between scientists and citizens through citizen science, this project also supports insect biomonitoring for conservation, agricultural management, or invasive species identification.

Abstract Name: AquaGator: Autonomous Underwater Robot

We present AquaGator, an automated underwater robotic sensor system designed for water quality monitoring. AquaGator is a portable system consisting of multiple sensors on a mobile robotic platform for autonomous data collection and analysis across varying depths of water. Motivated by the environmental challenges of toxic algae blooms in the Northwestern Pennsylvania region, our system addresses the limitations of the traditional methods that are often labor-intensive. AquaGator provides a cost-effective and accessible solution to streamline water quality data collection and facilitate efficient data analysis. The robotic platform can autonomously navigate to desired depths, measure water quality parameters over a set period, and provide live data graphs through a user-friendly dashboard. The system's dual functionality includes a manual control mode and an onboard underwater camera, providing visual insights into aquatic environments. The software developed for this project also facilitates the generation of in-depth analytics, providing actionable insights into the health of aquatic environments. This project is undertaken in collaboration with the local Conservation District, which plans to deploy AquaGators for routine water quality monitoring and educational initiatives. The successful implementation of depth automation is expected to significantly streamline the conservation district's water quality monitoring processes, providing a sustainable tool for the ongoing health assessment of local aquatic ecosystems. By providing a sustainable and practical tool for aquatic ecosystem assessment, AquaGator contributes to advancing environmental monitoring technologies and supporting informed conservation practices.

Abstract Name: Am.I.: A Robotic Replacement Unrealized

The rise of artificial intelligence in the arts has sparked significant controversy, with many fearing it as a threat to the human experience and creativity in making and appreciating art. Generative artificial intelligence is at the crux of the conversation because it can train off of existing art, literature, and other media to provide near instant gratification through the creation of "new" content. Critics often argue the media created by artificial intelligence is mediocre or inherently lacking some quality only a human can produce. Posthumanism challenges these ideas of human supremacy and advocates for the dissolution of anthropocentrism and the boundaries of what society currently defines as the human experience. Am.I. is a robotic work of art that utilizes large language model artificial intelligence and robotics to create an immersive visual and auditory experience to challenge fears exacerbated by anthropocentrism and demonstrate how artificial intelligence acts as an extension of the human experience and creativity and not as

a replacement. Programmed in Python and housed in a 3D-printed skull with moving eyes and a jaw, Am.I. engages in Socratic dialogue with another artificial intelligence, exploring themes of human existence using a large language model. This project exemplifies the potential for artificial intelligence to provide a window into the human psyche as seen through the lens of technology and build upon our existing creative experiences while not replacing them.

Abstract Name: Passing on a Legacy: Understanding the Role of Identity Formation and Social Relationships in Succession Planning on Intergenerational Family Farms in Rural Georgia

While the vast majority of farms in the United States are family-owned and operated, the number of farms and the number of family farms continue to decline nationwide. Succession, or the process of educating a younger family member in preparation to inherit the farm, is a key factor in the continuance of intergenerational family farms. This project studies the succession process on family farms in rural Georgia which have remained owned and operated by the same family for at least two generations. Using qualitative data collected from fifteen semi-structured interviews with intergenerational family farmers in the state of Georgia, this study explores the social and economic factors that affected current family farmers' process of taking on responsibility on their family farms and how these same social and economic factors affect their approach to planning to pass the farm on to the next generation. The study finds that social factors, specifically personal identity formation and familial relationships, affect succession in ways which can either reinforce or contradict the overall negative effect that economic conditions, specifically rising costs of machinery and materials and volatility in crop prices, have on intergenerational family farm succession and succession planning. Finally, the study concludes by recommending broader, more extensive research into factors affecting succession planning on farms in different regions of the United States.

Abstract Name: Impact of Neural Stimulation of Ventral Attention Network (VAN) on Vigilance and Fatigue: Utilizing Electroencephalography (EEG) and Transcranial Alternating Current Stimulation (tACS)

Seminal research suggests a connection between the temporoparietal (TPJ) and inferior frontal gyrus (IFG). Testing of this region known as the Ventral Attention Network (VAN) has identified a theta band oscillation between (4-8 Hz) of connectivity during spatial attention tasks. Vigilance and spatial attention tasks induce high levels of mental workload, increase cognitive fatigue, and have an impact on mood. A prior randomized controlled study also suggests that VAN stimulation provided faster reaction times during an auditory spatial attention task compared to controls ($p < .01$). Previously, self-reported fatigue during auditory spatial attention tasks has been vague, with minimal documented connection between mood, fatigue, and cognitive workload. The present study focuses on targeting the VAN with direct stimulation using a transcranial

alternating current stimulation (tACS) technique. To stimulate the VAN, we are utilizing an oscillation frequency of 5 Hz. This frequency was identified using current density modeling in a prior study, showing an ideal VAN oscillation frequency amplitudes which decreased during time-on-task ($p < .01$). We will be utilizing randomization to administer either the 5Hz frequency or sham stimulation during an auditory psychomotor vigilance task (aPVT). This task will be performed by the subject for approximately 30 minutes. During this task, participants will be asked to identify beeping tones while simultaneously listening to white noise. Additional assessments examining mental workload, fatigue, and mood will be utilized to further compare experimental stimulation versus controls. We expect results to show a decrease in self-reported cognitive fatigue in our experimental stimulation group compared to sham stimulation. Results that are aligned with our hypothesis have wide-ranging implications and applications, including potentially using tACS to mitigate fatigue-related impairments which are common across a variety of neurological, autoimmune, and medical disorders.

Abstract Name: A Sick Country: Novelistic Representations of Venezuela's Disease Crisis Under Chavismo and Its Current Relevance

Since 1998, Venezuela has experienced the slow decay of democracy and the strengthening of its current authoritarian regime, leading to one of the largest humanitarian crises of our time, with 7.7 million Venezuelans having fled the country. In a nation where political, economic, and social structures have been dismantled by the Chavismo regime, the once-renowned public health system has deteriorated to the point where everyday citizens can no longer rely on the public or private sectors for even the most basic healthcare needs. This project focuses on the country's current health crisis, specifically the resurgence of preventable diseases and the critical lack of vaccination. Through the analysis of qualitative data from reports, articles, interviews, and contemporary novels, I aim to shed light on how Venezuelans are affected by these specific health challenges. Additionally, I highlight the resilience and coping mechanisms of Venezuelans, contributing to the global discourse on disease outbreaks and the failure of vaccination efforts in politically unstable regions.

Abstract Name: It's All Endurance

I've always been a runner. My mother was a runner, my younger sister is a runner, it was sort of expected of me to do the same. At first, I was absolutely horrible. I could barely run a mile without stopping, however as time went on I improved. I made lifelong friendships with my teammates who pushed me to do my best. This piece shows that gradual improvement. From struggling in the back, to running, to racing; the complete story of my highschool running career. However, my highschool running career is over, and as I look back, I can

say that it wasn't completely what I wanted timewise, but the experience of having my teammates was more than I could have ever asked for. Now, I'm on a new team, with completely new people and I'm the only freshman girl on the distance side of the club team, so I have to restart. That is why I am looking forward to the second panel, away from all of my experiences that brought me to where I am today. I'm looking forward to the future, both figuratively and literally within this painting. I'm looking forward to becoming part of the team and making friends. I'm looking forward to racing and improving my times. And tomorrow I will, but I'll have to work for it. What's coming next is not a short sprint, it's all endurance.

Abstract Name: What can magnetic biomarkers tell us about the Eocene-Oligocene Transition in the North Atlantic?

A significant episode of climatic change in the last 66 million years was the Eocene-Oligocene Transition (EOT), a global cooling that began approximately 33.3 million years ago. While the climate records for EOT have been investigated in detail in the Southern and Pacific oceans, there remain major geographic and ecological areas of impact that lack information. These gaps include the impacts of this change on thermohaline circulation in the North Atlantic, which serves a major control for global temperature regulation. My project aims to improve this knowledge gap by measuring high-resolution records of environmental change across the EOT by studying fossil remains of magnetotactic bacteria (MTB). MTB are a rich archive of environmental change which allows us to use their fossil record as a pathway to understand the impact of global cooling on deep sea communities. By using core samples retrieved from Site U1411, collected offshore of Newfoundland during International Ocean Discovery Program Expedition 342, we will document the concentration and preservation quality of these fossils across the Eocene-Oligocene Boundary. We will accomplish this by performing two measurements: First Order Reversal Curves (FORCs) and analytical electron microscopy. FORCs can be used to assess the relative contributions of magnetic particles within a bulk sample. We use these data to select samples of interest, prepare magnetic extracts, and examine them using a Scanning Transmission Electron Microscope. These observations provide physical images and chemical information of the fossils we are studying and allow us to understand their level of preservation and confirm our previous findings. By understanding the fossil remains of some of the smallest organisms in the ecosystem and how they are preserved over time, we can learn more about the deep-sea oxygen, nutrient availability, and redox conditions on the sea floor during the transition from a greenhouse to icehouse world.

Abstract Name: Unpaid Internships: Exploring the Hardships of Social Work Students

There is little empirical evidence regarding the consequences of unpaid internships, specifically among social work students. Despite unpaid internships bringing professional experience, this practice perpetuates socio-economic disparities and continues a cycle of exploitation. Under the Council of Social Work Education, bachelor's students must complete a minimum of 400 hours of unpaid internships and master's students must complete a minimum of 900 hours in a two year program. This study aims to identify and explore specific challenges faced by social work students in their senior year and Masters at George Mason University. Researchers distributed an exploratory survey to social work students through email. The survey included open-ended and closed-ended questions regarding the impact of unpaid internships on their mental health, financial circumstances, and living stability. Responses were systematically organized in Microsoft Excel for data collection and analysis. Researchers conducted a peer review process to examine each other's work to confirm the fidelity of data collection procedure and to ensure accuracy and reliability. Findings of this study demonstrate that social work students are at risk for mental health problems, emotional distress, and financial instability due to the demands of unpaid internships. This study highlights the intensified challenges encountered by social work students at the Bachelor's and Master's level. While this serves as an initial step in identifying the impact of unpaid practicums on students, future research with a representative sample is necessary to fully capture the challenges and experiences of social work students.

Abstract Name: Analyzing potential mechanisms of SUDEP correlated with Hypoxic conditions in Dravet Syndrome

Dravet Syndrome, a type of epilepsy caused by a mutation in the SCN1a gene, leads to an extensive range of symptoms, including seizures and premature mortality, with the leading cause of death being Sudden unexpected death in epilepsy (SUDEP). Other than its high premature mortality rate, this type of epilepsy has a high rate of pharmacoresistance, making it difficult to find a treatment for every patient. One of the observed side effects of Dravet Syndrome is generalized hypoxemia. Studies have shown that hypoxia following seizure activity may result from changes in brainstem neurotransmission in cardiorespiratory centers (amygdala), including changes in neurotransmitter function and oxidative stress. To better understand hypoxemia in relation to Dravet Syndrome, the amygdala and brainstem were analyzed through the use of a Pimonidazole assay to understand its role in respiratory insufficiency. The Pimonidazole assay allows for the assessment of hypoxia in different tissues and cell types. Developing a model simulating hypoxic exposure and an immunohistochemistry protocol with the pimonidazole assay will allow the identification of damage caused by hypoxic stress in the brain stem and amygdala. The data observed from this experiment will provide more data to help us determine SUDEP and the underlying mechanisms of the SCN1a gene. Using the pimonidazole assay, we hypothesize we will be able to identify a biomarker that will better help us identify Dravet syndrome in patients and better understand how it affects current patients with this condition.

Abstract Name: Exploring Cellulose Nanofibrils for the Replacement of Agar in Media for the Cultivation of Wood Decay Fungi

Improved methods for fungal growth and maintenance are needed to generate more effective protection strategies that reduce degradation of wood products. Many current studies regarding fungal growth utilize agar, which is becoming an overused resource with negative environmental implications. The goal of this research is to evaluate gelling agents in conjunction with cellulose nanofibrils (CNF) as alternatives for agar in fungal growth media and its effects on fungal growth and decay rate. Our preliminary studies use Pectin, Xanthan Gum, or Gellan Gum dissolved in 1% CNF and 1.5% Malt Extract Broth to determine the conditions that result in solidification. Wood decay fungi is then cultivated on the alternative media/s, as well as the agar control. The radial growth rate of the alternative media and the control over time is recorded and their average is taken to record fungi growth. The results of these allow us to identify an alternative gelling agent that is more sustainable compared to traditional agar as the natural source of agar, algae, is being overly exploited. Gelling agents are used in a multitude of other scientific disciplines, causing this project to have far-reaching implications leading to better methods for fungal growth and maintenance.

Abstract Name: Lipidomic and Proteomic Characterization of Calcifying Extracellular Vesicles

Vascular calcification, characterized by the deposition of mineral plaques in arterial walls, poses a considerable threat to cardiovascular health, potentially leading to complications such as myocardial infarction. Under conditions of stress, diabetes, hypertension, and hypercholesterolemia, vascular smooth muscle cells (VSMCs) in the medial layer of arteries can adopt a phenotype similar to osteoblasts (HOBs), which are responsible for bone formation and mineralization. These VSMCs can then produce hydroxyapatite, a key mineral involved in both bone and vascular calcification, which HOBs produce naturally. It has been shown that both VSMCs and HOBs secrete extracellular vesicles (EVs) that carry lipids and proteins to initiate the mineralization process. Despite these similarities, recent data suggest that VSMCs generate calcifying EVs through a mechanism distinct from that of HOBs. To further investigate this, our group is conducting lipidomic and proteomic characterization of extracellular vesicles (EVs) from both vascular smooth muscle cells (VSMCs) and human osteoblasts (HOBs) treated with osteogenic media, which creates an ideal environment for calcification. The collected EVs, isolated through ultracentrifugation, will be analyzed using mass spectrometry for their protein and lipid content. This analysis aims to provide a better understanding of the specific lipids and proteins within these EVs that contribute to calcification, advancing our knowledge of the underlying mechanisms of pro-calcified extracellular vesicles formed from each cell type.

Abstract Name: Impact of Sit Spots on College Students' Mood

There is a current mental health crisis on college campuses, with greater incidences of anxiety, depression, and other adverse effects among 18-22-year-olds. Many campus interventions have focused on a sense of belonging, but a lesser explored area is how instructional practices, specifically those relating to mindfulness, can support student well-being. Existing literature studying contemplative or mindfulness pedagogies (e.g., sit spots) has shown positive physical and mental health outcomes. Few rigorous studies have examined the effects of mindfulness practices over time or how an individual's disposition to mindfulness impacts engagement in these pedagogies. Building on this work, this research aims to evaluate the impact of a brief, repeated mindfulness practice (8 x 20-minute sit spots within 1 month) on student mindfulness disposition and positive and negative affects. The pre and post study will be conducted in three classes: ENS 1100, WHE 2850, and BIO 3642 over Fall 2024, Winter 2025, and Spring 2025. Student participants will complete the sit-spot intervention as a homework assignment at a location on or near campus. Two measures will be used to assess the research objective. The first is the Positive and Negative Affect Short-Form (PANAS-SF), a 10-item scale measured on a 5-point Likert scale that assesses positive and negative emotional experiences within the last week. The ten-item scale includes positive affective states such as active, determined, and attentive and negative affective states such as afraid, nervous, and hostile. The PANAS is a cross-culturally validated tool tested widely on college students. The second is the Mindfulness Process Questionnaire (MPQ), a scale that measures the process of repeated engagement in mindfulness activities, focusing on how the individual has intentionally practiced the mindfulness skill. Results will inform future teaching practices for faculty members invested in enhancing student mental wellness in their classes.

Abstract Name: Limiting Attorney Fees Limits Access to Justice

Access to justice is a fundamental principle embedded in the rule of law. It places an emphasis on the idea that all individuals must have equitable access to the justice system, in tandem with the requirement for people to be treated equally within the bounds of the justice system. The United States embodies this principle in the governing documents of the country. There is a constitutional assurance that all people have the right to trial by jury, equal protection, due process, and the right to petition the government for redress of grievances, which includes access to courts. Despite these guarantees, procedural and systemic barriers persist. Alabama not only faces the issue of rural residents experiencing limited access to legal representation and justice, but there are statutory limitations that prohibit using recovered funds to pay for any kinds of legal fees. We hypothesized that this limitation further complicates and prohibits access to justice for Alabama residents who are seeking to be exonerated from wrongful conviction by the state. Upon utilizing qualitative methods of research, including surveying Access to Justice Commissions across the United States and finding that none of the respondents found anything comparable in their respective state statutes, we additionally performed a comparative content analysis of existing research on the topic. The Alabama statute is

representative of a systemic failure to provide justice to those who have already suffered the profound injustice of wrongful incarceration. Our findings underscore the necessity of reevaluating access to justice frameworks, all in the pursuit of understanding and applying due process and equal protection.

Abstract Name: Monstrous Consequences: Bong Joon-ho's use of the Giant Monster Genre in *The Host* and *Okja* to Influence Audience Perceptions on Ecological Degradation and Urbanization

This paper examines two 21st-century South Korean giant monster films by Bong Joon-ho - *The Host* (2006) and *Okja* (2016) - to analyze how the plot elements and narrative characteristics of the giant monster genre are used to critique South Korea's socio-political landscape and environmental challenges. By portraying the eco-monsters as direct consequences of human actions - industrial pollution in the case of *Gwoemul* and corporate exploitation for *Okja* - both films link the greed-driven decisions of those in power to the ecological degradation that follows. Because *The Host* and *Okja* tell the stories of marginalized communities and their disproportionate exposure to environmental harm, both films expose the role of economic inequality in shaping societal responses to ecological crises. Bong Joon-ho also utilizes sensorial elements in these films - such as the human-animal interactions in *Okja* and the sounds and appearance of *Gwoemul* in *The Host* - to heighten the emotional and physical impact of the ecological issues presented. Through their exploration of ecological crises, power structures, and immersive storytelling techniques within the giant monster genre, *The Host* and *Okja* offer a compelling critique of modernity and survival. By blending South Korean cultural contexts with global concerns about environmental degradation, these films challenge the Eurocentric narratives that dominate much of international cinema and open the door for a broader range of diverse perspectives on ecological issues.

Abstract Name: Characterization of Virulence Factor Expression in *V. cholerae* "Hyperswarming" Mutants

Vibrio cholerae is an aquatic, highly motile Gram-negative bacterium that serves as the etiological agent of the human disease, cholera. The disease is characterized by profuse watery diarrhea that can result in severe dehydration and death if left untreated. *V. cholerae* possesses an array of robust virulence factors that promote movement, colonization, and pathogenicity. The bacterium has a powerful, single polar flagellum which facilitates movement within the human host to reach its preferred niche in the small intestine. Following colonization of host epithelial tissue, *V. cholerae* expresses several essential virulence factors, the most notable of which are cholera toxin (CT) and the toxin-coregulated pilus (TCP). CT is an ADP-ribosylating enterotoxin that acts as the primary pathogenic agent and is responsible for the massive loss of fluid from intestinal host cells. TCP is a Type IV pilus that facilitates microcolony formation and CTX Φ toxigenic

conversion. These two elements are under the control of a key transcriptional activator, ToxT. Previous studies have observed an inverse relationship between motility and ToxT-dependent virulence factors. This study demonstrated this phenomenon in hypermotile *V. cholerae* spontaneous mutants, known as “hyperswarmers” (HS). Some of these mutants possess single point mutations in ToxT, which are predicted to result in a loss of function. Thorough analyses of ToxT activity have shown significant reduction in CT and TCP expression within the HS/ToxT mutants. These strains exhibited significantly reduced CT/TCP expression in β -galactosidase transcriptional assays. TCP expression was also found to be completely defective in a CTX Φ transduction assay. Future work will focus on further characterization of virulence factor expression, as well as interrogating other ToxT-dependent genes that may be responsible for the hyperswarming phenotype. This analysis may help elucidate the observed inverse link between *V. cholerae* motility and ToxT-dependent virulence factors.

Abstract Name: Changes in Chemical Properties of Surface Waters in Dunn County

The chemical properties of surface water are some of the indicators used to assess the health of lakes and rivers. Monitoring changes in chemical properties allows for action to be taken to resolve any developing or on-going problems in the body of water. This study monitored the pH, conductivity, levels of Na, K, Ca, Mg, and P in surface water locations in Lake Menomin, Lake Tainter, and the Red Cedar River in Dunn County, WI. Water samples were collected from June to September. Vernier sensors were used to measure the pH and conductivity, and an Atomic Absorption Spectrometer was used to determine the concentrations of Na, K, Ca, Mg, and P. Water samples collected from both sites in Lake Menomin, showed a decrease in pH from 8.76 ± 0.04 to 6.79 ± 0.01 ; the pH of samples collected from the same sites in September went back to the same level in June. In conductivity, the only significant change observed was an increase from 224 ± 0 mS/cm to 1545 ± 1 mS/cm in samples collected in one site; this can be attributed to increases in the Na and K concentrations. The P levels in the same samples decrease from 5010 ± 1036 ppm to 3000 ± 202 ppm. Water samples from Lake Tainter showed similar declining trend in pH from June to August in both locations. The only other change in the chemical properties that is significant is decrease in the K concentration from 14.70 ± 0.20 ppm to 4.98 ± 0.08 ppm. Except for the Ca concentration, no significant changes in the other chemical properties were observed in water samples from the Red Cedar River. The Ca concentration collected from the River Road Boat Landing increased from 18.88 ± 1.15 ppm to 27.84 ± 0.67 ppm.

Abstract Name: Multispecies Algae Cultivation for Biofuel Production

Fossil fuels contribute to climate change and are non-renewable. Biodiesel has been proposed as a sustainable, renewable alternative to fossil fuels. First-generation biodiesel is produced from oilseed crops. The process of producing this form of biodiesel has shortcomings such as land use, energy consumption, and other negative externalities. A promising solution to this is biofuel produced from algae. Algae has higher yields of combustible oil than seed crops, it rapidly consumes CO₂, it grows rapidly, and it has a smaller production footprint than other feedstocks. Currently, research in this area involves growing algae strains in monocultures, which must be protected from contamination and grown in carefully regulated environmental conditions. Multi-species cultures might provide a low-maintenance alternative to monocultures if they are resistant to invasion or adaptable to fluctuating environmental conditions. In this project, we test the hypothesis that multi-species algae cultures can produce oil at a rate that is comparable to that produced in monoculture. Oils from several unique multi-species algae cultures were extracted via enzyme assisted extraction methods and converted into biodiesel via a base-catalyzed trans-esterification reaction. We report extracted oil yields, composition of extracted oils as determined by GC-MS, and the characteristics of the converted biodiesel as determined by ASTM fuel standards testing.

Abstract Name: The Potential and Functionality of 3D-Printed Organs for Transplant Recipients

Bioprinting technology for creating 3D-printed organs has been a concept since the late 20th century, but it is only recently being further developed and revolutionized as a solution to the organ shortage crisis. This technology holds the potential to assist thousands of people in need of transplants by being more cost-effective, reducing the likelihood of transplant rejection, and increasing accessibility. By using the recipient's own tissue samples, bioprinting can create customizable organs using techniques such as inkjet bioink. Information for this research was gathered from peer-reviewed articles accessed through platforms like Google Scholar, JSTOR, and Mendeley. Additional data, such as statistics unavailable in peer-reviewed sources, was obtained from reliable online resources. Results from clinical trials discussed in peer-reviewed articles demonstrated the promise of 3D-printed organs. These trials showcased success in creating anatomically accurate and functional structures that maintained functionality over specific periods. The purpose of this research was to evaluate the feasibility of creating 3D-printed organs and their potential to serve as an alternative to traditional organ transplants.

Abstract Name: From Bottling Plant to Buried Trash: Archaeology of Atlanta's Soft Drink Industry

Atlanta, Georgia has been a major hub for soft drink production since the rise of the industry at the turn of the 20th century. The world's most popular soft drink, Coca-Cola, originated in Atlanta, and was first bottled in 1899, which attracted its lesser-known competitors and knockoffs from the surrounding Southeast and beyond. In this presentation, I discuss my work in analyzing the soft drink industry of 20th-century Atlanta based on the bottles, fragments, cans, and bottle caps found in the MARTA Archaeological Collection, an array of 100,000 artifacts excavated by Georgia State University alongside the construction of Atlanta's commuter rail in the 1970s. The study is within the realm of historical archaeology, which the Society for Historical Archaeology defines as "the study of the material remains of past societies that also left behind some other form of historical evidence" and "attempt[s] to discover the fabric of common everyday life in the past." Academic research on soft drink history and archaeology is scarce, but it is a relatable topic to the public. Throughout my ongoing research, I have compiled a catalog of all 350+ relevant artifacts from 54 brands spanning from 1900 to the 1970s, and by utilizing associated historical research, I can use the data to find possible socioeconomic preferences, patterns, and trends among Atlanta's consumers and industry alike. The scope of the collection presents substantial data for tracking brands throughout the time and space of 20th-century Atlanta to uncover an untold history of the Southeastern soft drink industry and its role in the city's history.

Abstract Name: A toy model for 2-dimensional spin-fluctuation-induced unconventional superconductivity

Superconductivity had been one of the most enigmatic phenomena in condensed matter physics, puzzling the best theorists for 45 years, since the original discovery by Kamerlingh-Onnes in 1911 till the final solution by Bardeen, Cooper and Schrieffer (BCS) in 1957. The original BCS proposal assumed the highest-symmetry form for the superconducting order parameter Δ , namely, a constant, and a uniform pairing interaction due to attractive mediation of ionic vibration. While it was rather soon realized that generalizations onto k -dependent order parameters and anisotropic pairing interaction was straightforward, only thirty years later, upon the discovery of high-temperature superconductivity in cuprates, high-order angular dependence of Δ and repulsive interaction, mediated by spin fluctuations or Coulomb repulsion brought such "unconventional" into the spotlight. In 2008 yet another such system was discovered, and eventually the idea of repulsion-mediated unconventional superconductivity was generally accepted. Apart from the two specific systems mentioned above, a large number of various specific implementations of this idea have been proposed, and it is becoming increasingly clear that it is worth studying mathematically how unconventional superconductivity emerges, and with what properties, for a simple, but sufficiently general theoretical model. In our project, we study systematically unconventional superconductivity in an isotropic two-dimensional model system of electrons, subjected to repulsive interactions of a simple, but physically motivated form: a delta function peaked at a particular momentum (from 0 to twice the Fermi momentum), or Gaussian of varying widths.

Abstract Name: Assessing the role of Pico in the spatiotemporal regulation of actin cable assembly in *Drosophila* oogenesis

Dynamics and organization of actin filaments contribute to cell motility, development, and many other cellular processes in a variety of organisms. Some actin structures are composed of bundles of actin filaments called cables. In *Drosophila melanogaster*, actin cable arrays with asymmetric growth dynamics in ovarian nurse cells carefully displace their nuclei to allow their cytoplasmic contents to move from the nurse cells into the developing oocyte. Without these spatially and temporally controlled actin cable arrays, the nucleus will block the flow of nutrients from cell to cell and prevent proper oocyte formation and reproductive success. It is already known that cortically localized Enabled (Ena) and Diaphanous (Dia) proteins work together to polymerize the actin filaments that are bundled into these actin cable networks. Further, the regional cortical enrichment of Ena produces the characteristic asymmetry, with faster-growing cables developing only where Ena localizes with Dia, but not where Dia is present alone. We seek to understand the molecular mechanisms responsible for the regional cortical enrichment of Ena. Lamellipodin (Lpn) contributes to the cortical localization of Ena in some contexts in mammalian cells, but its functions are poorly understood. We are testing the hypothesis that Pico, the *Drosophila* ortholog of Lpn, plays a role in the regional cortical enrichment of Ena in nurse cells. To accomplish this, we are examining actin cable assembly and Ena localization using immunofluorescence and live imaging in Pico mutant nurse cells. We predict that loss of Pico will result in mislocalization of Ena and short, symmetric cable networks that ultimately fail to displace the nucleus. These experiments will increase our understanding of fundamental mechanisms orchestrating the assembly and function of the actin cytoskeleton.

Abstract Name: Alzheimer's Disease Neuropathology Present in TgF344 Rat and Ketone Diester Effects on TgF344 Behavioral Impairments

Alzheimer's disease (AD) is a progressive neurodegenerative disease affecting millions worldwide. AD causes cognitive defects, such as memory loss, and is characterized by specific pathology such as amyloid-beta plaques, phosphorylated tau (phospho-tau), neuroinflammation associated with gliosis, and neurodegeneration. However, the role of neuropathology in the basolateral amygdala (BLA) in AD has not been well studied. In this study, we aim to elucidate the pathology trajectories which diverge between normative aging and AD in the BLA, as well as alleviate pathology and associated fear extinction impairment symptomology with a ketone diester dietary supplement. Using immunohistochemical approaches, we measured amyloid, phospho-tau, microglial and astrocytic activation (using Iba1 and GFAP, respectively) to determine pathology progression in BLA nuclei ranging from young, 3 months old, to aged, 24 months old, wildtype rats and transgenic Fisher-344 AD (TgAD) rats. Immunostaining highlighted pathologies of interest, including amyloid beta plaques, phospho-tau, gliosis, and neuronal nuclei count. Results suggest early amyloid and phospho-tau pathology is observable in the BLA. Additionally, we report greater activated microglia and astrocytes within the BLA of young TgAD rats. In TgAD rats, aging is associated with greater amyloid and tau accumulation. In the older WT rats, increased activated microglia and astrocytes irrespective of genotype is also seen. Young TgAD rats on a ketone diester supplementation showed decreased fear extinction impairment relative to controls as well. These results highlight the effectiveness of the TgAD rat model at simulating AD pathology in humans and show the BLA as an epicenter of early AD pathological and behavioral changes.

Abstract Name: Analysis of Differences in Rural and Urban Moth Diversity

Our research was dedicated to comparing the diversity of moths in urban and rural areas. Last year, in a similar project, we observed a decrease in the percent macrolepidoptera, driven by collapse of certain families in urban habitats. We repeated observations at two of those locations, one urban and one rural, and added two additional locations to see how robust these observations were across years and sites. Night observations were conducted and with the deployment of a light trap we were able to photograph the moths as they landed. We observed a similar decrease in macrolepidoptera in urban habitats, but the responses of individual families was distinct from year one.

Abstract Name: Inequalities in Healthcare: A Comparison of Anthropological and Biomedical Approaches to Race, Class, and Gender of Ovarian Cancer Patients

Medical anthropologists aim to understand how health, healthcare, and illness manifest given sociocultural and political contexts. Comparatively, biomedicine utilizes research-based biology and physiology to develop medicine and healthcare. Despite studying the same topic of healthcare, the two fields approach it differently such that medical anthropologists consider biomedicine to be limited in breadth. These varied approaches raise the following questions, in order of increasing importance: In which ways might disparities based on race, class, and gender of patients with ovarian cancer manifest in clinical trials and medical treatment? What can political and anthropological concepts elucidate about these inequalities? How do medical anthropology and biomedicine differ in their respective approaches to recognizing and analyzing health disparities? This thesis compares biomedicine and medical anthropology through an analysis of published scientific articles of both medical anthropology and biomedicine regarding ovarian cancer, its diagnosis, and treatment. Their respective integrations of race, class, and gender with reference to ovarian cancer are to be established, if they exist. Then, the effects of these integrations on ovarian cancer treatment and patients are analyzed through the lenses of intersectionality, medicalization, and political economy. I suggest that biomedicine frequently fails to incorporate sociocultural intersectional approaches in the diagnosis and treatment of ovarian cancer. That is not to say that no biomedical scientists analyze ovarian cancer with respect to race, class, or gender, but they limit the number of sociocultural variables in their studies. I claim that if the racial, socioeconomic, and gender differences remain unaddressed by biomedical practitioners, the morbidity and mortality of ovarian cancer patients will persist.

Abstract Name: the gender binary (I am bad at Math)

There has always been a masculinized relationship with technology. Coming from a background where I am bad at mathematics, I have always had a troubled relationship with technology. Concepts such as computer science and engineering are completely foreign to me. Binary language is taken towards an autobiographical approach, as a Nonbinary individual my existence within the gender binary is glitched. Within painting, I can create digitally abstracted spaces where I reference old internet user interfaces such as Windows 95—taking the calculator from that software and painting 80085 about my chest dysphoria. In this world there are 3 depictions of myself, two profiles and one in the middle, using repetition about glitched spaces. I paint an expression of despair and hopelessness due to gendered oppression. Using mediums such as spray paint on Masonite board I can create colorful abstractions of my queer identity. These bright saturated colors are expressions of myself, colors such as hot pink bring me intense joy. Then covering these up with mediums such as oil and acrylic to hide myself within the digital world. In addition, I use pixelated linework to convey the glitch of self in the binary world. On top, I added repurposed and used motherboards and technology to reference the engineering aspects of mathematics. Lastly, I pixelate the text boy girl to refer to the gendered spaces and assist the viewer in understanding the metaphor of the digital gender binary. As one exists within the gender binary as a glitch there is extreme discomfort and complexities based on my lived experience.

Abstract Name: Stratification of Martial Arts-Related Brain and Spine Injuries Presenting to the Emergency Room throughout the U.S.

IntroductionNeurological injuries may occur as a result of consistent blows during contact sports. To advance the safety of the sport, further understanding mechanism of injury is paramount. In this study, the prevalence and characteristics of martial arts-related cranial and spinal injuries were examined. **Methods**The National Electronic Injury Surveillance System (NEISS) was surveyed for martial arts injuries from 2014-2023. All case narratives were reviewed and fighting style, primary injury, mechanism of injury, and case notes were extracted. Hospital disposition, patient age, and gender were also extracted. Patients were grouped into age cohorts in ten-year increments. Weighted survey analysis was used to calculate national estimates and confidence intervals. The association between age and specific diagnosis was analyzed using logistic regression. All statistical analyses were performed in R. P value ≤ 0.05 was considered significant. **Results** A ten-year period of 1,104 martial arts narratives yielded 36,635 spinal and cranial injuries. The average participant age of injury was 24.5 years. Jiu-jitsu (26.9%) and karate (26.8%) were most frequently associated with injury. Lumbar (19.8%) and cervical (18.3%) strains were the most frequent injuries, with throwing or flipping an opponent to the ground (17.1%) identified as the prevalent mechanism of injury. Concussions (18.4%) were also prevalent with jiu-jitsu (26.8%) and karate (26.7%) being the most common modalities. Patients with concussions tended to be younger than those with other injuries, with the largest cohorts being 10-19 years (30.6%) and 20-29 years (23.4%). **Conclusions**Injuries sustained during martial arts are of increasing concern, particularly among younger populations. This study aims to raise awareness of the inherent risks associated with techniques like throwing or flipping opponents in combat sports, which can lead to serious injuries. Increasing awareness, can empower both physicians and participants to promote safer practices in contact sports such as martial arts.

Abstract Name: Metabolic profiles and intrinsic antibiotic resistance of bacterial species isolated from Indiana Caverns

Investigations of cave ecosystems are limited due to the oligotrophic nature of caves and challenges associated with accessing sample sites. To increase our understanding of cave bacterial parameters, we examined metabolic properties and antibiotic resistance of cave bacteria. We hypothesized that antibiotic resistance is not limited to human-dominated environments but can be found in isolated ecosystems. Sediment and water samples were collected from the Deep Darkness section of the Indiana Caverns,

Corydon, IN. Using colony PCR and DNA sequencing three bacterial species were isolated: *Serratia surfactantfaciens*, *Pseudomonas soli*, and *Bacillus paramycoides*. We assessed their ability to metabolize a range of carbon substrates using 96-well BIOLOG Ecoplates. Heatmap analysis showed high carbon substrate utilization of polymers (Tween 40, Tween 80) and carbohydrates (D-Mannitol, N-Acetyl-D-Glucosamine) across all species. Others such as D-Cellobiose and α -D-Lactose were less utilized. *B. paramycoides* portrayed the highest levels of metabolic activity overall, disproportionately utilizing Pyruvic Acid Methyl Ester. Antibiotic susceptibility testing (AST) showed *B. paramycoides* was resistant to 57% of the antibiotics, including erythromycin, vancomycin, and clindamycin. *S. surfactantfaciens* was susceptible to 38% of the antibiotics such as amikacin, levofloxacin, and meropenem, with 62% resistance to antibiotics including nitrofurantoin and gentamicin. *P. soli* was resistant to 54% of the antibiotics such as nitrofurantoin, ampicillin, and aztreonam. AST revealed delayed growth responses beyond the standard 24-hour timeframe for some antibiotics, highlighting limitations of traditional testing protocols in capturing adaptive resistance mechanisms. This study implies that remote environments such as subterranean ecosystems harbor bacteria that have mechanisms which enable resistance to common antibiotics. Our findings emphasize the concern about antibiotic resistance, which may have great implications for natural ecosystems and public health. Further research should focus on identifying the resistant genes and patterns, and refine testing methods to better assess bacterial adaptation and resistance in clinical and environmental contexts.

Abstract Name: Barn Swallows Size and Elevation: Testing Bergmann's Rule

Bergmann's rule suggests that endothermic animals in cooler, higher latitudinal regions tend to be larger than those in warmer, lower latitudes. Most studies in support for this rule focus on sedentary animals, while migratory and smaller animals tend to vary more in support or opposition to the rule. Barn swallows (*Hirundo rustica*) are a generalist species of migratory aerial insectivore that have breeding sites across the globe over various latitudinal and elevational ranges. The different temperatures at a barn swallows breeding site may have an impact on their body mass as well. Understanding how Barn Swallows' body size changes across elevation can provide insight into how this migrating bird may or may not follow Bergmann's Rule. Global data taken from 2009-2024 across the northern hemisphere was used to analyze three subspecies of barn swallows: (*H. r. erythrogaster*, *H. r. gutturalis*, and *H. r. rustica*), to determine if elevation and or latitude of their breeding sites would have an impact on their mass. Interestingly we found *H. r. erythrogaster* supported the rule, while *H. r. gutturalis* showed no significant impact in mass across elevation or latitude, and *H. r. rustica* displayed a negative impact for mass across elevation and a positive in relation to latitude.

Abstract Name: Analyzing Relatedness of Fin whale populations in the Pacific using genetic markers.

This project consist of analyzing the relatedness of a fin whale population in the Pacific, more specifically, Gulf of California (GOC). This specific population has been isolated derived by a founder effect from the Eastern North Pacific (ENP) population of fin whales. Studies have shown that this fin whale population has low levels of genetic diversity, which can lead to series of consequences such as reduced fitness or possibly extinction. The more diverse, the better a population maintains its fitness. The goal is to identify the degree of relatedness of 156 individuals in GOC (107) and ENP (49) populations, using 14 microsatellite loci with two genetic analysis softwares (COLONY & CERVUS). Allele Frequencies were used to identify relatedness in which indicated that GOC presented more than ENP. This is because of their Heterozygosity and PIC scores being low, and Non-exclusion probabilities being higher. Other tests such as Identity Analysis and Full-Sibling and Half Sibling analysis which provided information about individuals who share at least 50-25% of their loci. The results for GOC population showed presence of a degree of relatedness, having high presence of individuals at least sharing $\frac{1}{4}$ of their microsatellites rather than $\frac{1}{2}$.

Abstract Name: Exploring the Transformative Effects of incarceration on Maternal Identity

Currently, 58% of women in prison are mothers, many of whom struggle to maintain their maternal identity in a restrictive environment (Bertram, 2023). Motherhood involves various practices that reinforce maternal identity, such as daily caregiving, emotional support, and involvement in children's education and routines. However, previous literature suggests that incarceration limits these opportunities, disrupting the mother-child bond and challenging the mothers' sense of maternal identity. This quantitative study explores the experiences of incarcerated mothers, focusing on how their maternal identities are affected and reformed during incarceration. Through a survey using a modified version of the Myself as Mother Differential Semantic Scale conducted with women across multiple penal institutions, this research aims to fill a gap in the literature that predominantly centers on the impact of maternal incarceration on children rather than on the mothers themselves. By giving voice to these women and examining their self-reported data, this research seeks to contribute to a deeper understanding of the complexities of maternal identity in the context of incarceration and to inform better practices and policies that support incarcerated mothers. The preliminary findings in this study found that incarcerated mothers vary in cognitive operations based on race/ethnicity, particularly Black mothers scoring higher in social support and well-being than other racial and ethnic demographics. Additional findings also indicate that neither offense type or age at separation significantly impact the cognitive aspects of maternal identity. These preliminary findings from an ongoing study could help raise awareness and inform programs that support incarcerated mothers particularly those in need of specific aid to strengthen cognitive aspects of maternal identity .

Abstract Name: Claiming Her Own Voice(s):Wheatley-Peters and Al-Mansour's Battle(s) to Owning Self-Authorship

In light of the precarity of women's rights following the 2024 U.S. Presidential election, the significance of recognizing the narratives and contributions of female leadership and female creativity in male-dominated fields has never taken a higher priority than the present. This project seeks to amplify the social activist voices of two Women of Color creators, Black American poet Phillis Wheatley-Peters and Saudi Arabian filmmaker Haifaa Al-Mansour, respectively and conjointly drawing parallels between these two creators' mutual struggles of owning the female voice. The purpose of this research proposal is to critically examine how and to what extent female authors, specifically female authors of color, are allowed to retain literary and creative ownership over their own process of storytelling and how their own creations are validated or invalidated by the institutional and societal structures in which their respective work is preserved and examined. Despite her celebrated literary contributions in Early American Literature, Wheatley-Peters' own authorship is questioned before a "council" of white enslavers; Al-Mansour's logistical and social struggles of filmmaking in a country that limits both cinematic expression and female agency will be the second part in the comparative study of this project. By drawing upon the scholarship published in the Association of African American Studies and CIS Student Research Journal, this project will examine the poetry and letters of Wheatley-Peters and the cinematic productions of Al-Mansour. Both Wheatley-Peters and Al-Mansour's authorship, work and impact of legacy will be analyzed within the framework of feminist lens combined with intersectionality of race and ethnic liberation in post-colonialism political structures. Wheatley-Peters' work will open up analysis of the intersections between race and Black Womanhood in America. Al-Mansour will represent the intersectionality of feminism in Saudi Arabia and the post-colonialist structure, while acknowledging Western interference within the lens of post-colonialism in the Middle East.

Abstract Name: How Cooking Methods Affect Polychlorinated Biphenyl (PCB) Concentrations in A Lake Erie Game Fish

Polychlorinated biphenyls (PCBs) are persistent organic pollutants that are frequently detected in aquatic environments. These compounds accumulate in the fatty tissues of fish, including walleye (*Sander vitreus*), a popular choice among recreational anglers. Consuming PCB contaminated fish poses significant health risks, including developmental delays, neurological issues, immune system suppression, and potential carcinogenic effects. Although fish consumption advisories provide recommendations for safe intake, they often neglect to address the influence of cooking methods—such as baking, frying, and smoking—on PCB concentrations. This study explores how these cooking methods impact PCB levels in walleye fillets collected from Lake Erie. Fillets from 60 walleye were paired, with one fillet remaining raw while the other underwent one of the three cooking methods before PCB extraction and analysis. The PCB concentrations in raw and cooked fillets

were then compared to evaluate the effect of each method on PCB retention. The cooking methods evaluated in this study did not significantly impact the total PCB concentrations in fish fillets compared to raw samples. However, statistically significant increases were observed in the concentrations of specific PCB congeners. This increase is likely due to moisture loss during cooking, which concentrates the PCBs in the remaining tissue. These findings provide critical insights into the influence of cooking methods on PCB exposure, highlighting important considerations for food safety, public health policies, and dietary guidelines to minimize PCB-related health risks.

Abstract Name: Belonging in the Senegal River Valley: A West African Perspective on Kinship and Integration

Following the 1989 Senegal-Mauritania conflict, 50,000 black Mauritians were forcibly expelled into the neighboring state of Senegal. These Mauritians belong to multiple different ethnic groups that are also present in Senegal, though to varying degrees of social salience. This paper seeks to assess how different ethnic groups have experienced integration into Senegal, and analyze what factors – such as language, family, and finances – have influenced their ability to belong within the Senegalese community. In the thirty years since the conflict, these migrants and refugees have had several influences on their integration process, including kinship ties, ethnic ties, history of discrimination, and government and administrative influence. Starting with a detailed history of the conflict and a background into kinship and ethnic research in the region, I perform thematic analysis on qualitative interviews that I conducted with Mauritanian migrants and refugees who currently reside in Senegal to understand the individual and contextual drivers of integration and belonging. This study has broad implications for the future of refugee policy in West Africa, and scholars and policymakers can incorporate lessons about how refugees of different backgrounds were able to feel at home in a neighboring nation.

Abstract Name: Political Opinions Over Women's Health Care and its Effect on Female Voters

The United States 2024 presidential election triggered discussions regarding the future of women's healthcare. News articles deemed this to be a top issue in this election, stating that healthcare is a mobilizing factor for voters, and how the future elected president will have an impact on women's healthcare (Levitt, 2023). One study examined the heightened concerns amongst young women, particularly on aspects regarding to overall healthcare, contraception, prices, availability, and safe abortions (Judge et al., 2017). In this project, I researched how women at UW-Stout view government involvement regarding women's healthcare, and how potential future impacts influenced who they planned to vote for, either Democrat representative Harris or Republican representative Trump. My goal was to better understand the views of

women at UW-Stout regarding their elected candidates, and what issues and factors were most significant to them when deciding who they would vote for. To accomplish this, an original survey was distributed to 1,000 female UW-Stout students, staff, and faculty. Questions included political demographics, opinions on the presidential candidates and government involvement, and emotional responses to politics. Results indicate that the majority of respondents voted for Harris, and that access to women's healthcare was an important issue to them, but not the most important. In addition, most felt neutral about the future of women's healthcare. Harris voters were very aware of her opinions on women's healthcare, while Trump voters were less aware of his opinions, and also unwilling to change their party affiliation. These findings document what a population at UW-Stout found most important when selecting their candidate. Contrary to predictions from the press, access to healthcare and keeping bodily autonomy were not decisive. Despite feeling that the government, specifically the president, should be protecting women's healthcare, women did not vote only on this issue.

Abstract Name: Faith Under the Führer: Protestant Churches in Nazi Germany

This research seeks to examine Protestant churches in Nazi Germany and their varied reactions to Hitler's Third Reich. The research was conducted using a variety of primary sources, including Dietrich Bonhoeffer and Martin Niemöller's writings and sermons. Scholarly secondary sources such as books and periodicals from experts in this field of study were also utilized. The research traces the Nazi rise to power, an overview of the *Kirchenkampf* (Church Struggle), and the Confessing Church's resistance with emphasis on figures like Bonhoeffer and Niemöller. Hitler campaigned on a platform purporting to support religious freedom. However, his subjugation of Christian churches to the state and persecution of dissenting Protestant pastors revealed that the Christian church was merely another pawn in his quest for political power. The *Kirchenkampf* exemplifies the reactions of Protestant German churches to Hitler's rule. The German Christian Movement (GCM) endorsed Hitler's radical racial theories against the Jews and abandoned Christian doctrines in favor of a neo-pagan religion based on pseudoscience. The Confessing Church, in contrast, confronted the unbiblical rhetoric used by both the Nazis and the GCM, with pastors like Niemöller and Bonhoeffer opposing Hitler's regime. Niemöller initially supported the Nazis but realized that Christianity and Nazism were incompatible, leading him to voice opposition that resulted in his imprisonment. Niemöller survived his incarceration and spoke publicly afterward about the complacency of both the Christian church and ordinary Germans in allowing the Holocaust. Bonhoeffer engaged with the ecumenical Christian movement abroad, arranged for the escape of Jews from Germany, and participated in an assassination plot against Hitler that resulted in his execution. These men remain admirable figures of the Confessing Church's struggle against Nazism. However, the Church also faced difficulties such as disunity and a hesitancy to criticize the German state that inhibited its efficacy in challenging Hitler's regime.

Abstract Name: Testing turn alternation in a species of Porcellio and Trachelipus: A pilot study

It's well documented that terrestrial isopods of the genera Porcellio and Armadillidium exhibit spontaneous turn alternation (TA), a navigational strategy aimed at maintaining a straight path while exploring new terrains, finding food, or escaping predators. Of the many extant species of Porcellio, research on TA has mainly focused on *P. scaber* and *P. laevis*, which leaves TA behavior of the other Porcellio species undocumented. With my planned honors thesis set to investigate spontaneous turn alternation between captive-bred and wild-caught Porcellio spinicornis, a pilot study was warranted to confirm if *P. spinicornis* exhibits TA at a rate significantly above chance. During the collection of *P. spinicornis*, a large number of Trachelipus rathkii were inadvertently captured and, considering TA has not been documented in any member of the Trachelipus genus, these animals were included in the pilot study as well. In order to test TA in *P. spinicornis* and *T. rathkii*, each subject was run through a commonly employed multiple T-maze. Analyses revealed that both *P. spinicornis* and *T. rathkii* perform TA at rates significantly above chance. Furthermore, when comparing sex within each species, it was found that *P. spinicornis* males, but not females, and *T. rathkii* females, but not males, significantly exhibited TA. The current study is the first to document TA in *P. spinicornis* and any member of the Trachelipus genus. Furthermore, the data suggests that TA may follow a pattern of sex-specific selection that could differ among species of terrestrial isopods. Ultimately, this pilot study confirmed that *P. spinicornis* are reliable models for TA research while expanding our understanding of TA across the many genera and species of the terrestrial isopod.

Abstract Name: The Silenced Holocaust: How U.S Interference Has Affected Guatemalan Lives in Today's Society

While past research has been conducted on the effects of the United States' interference with Guatemala over the past century, and how that has affected the state of the country politically, there has been a lack of discussion regarding how this has affected Guatemalan people culturally. Guatemala is a country that often is outcasted by a large percentage of Latin America socially, and continues to be silenced in the politically, especially in the United States, due to false misconceptions that have been created and continue to be widespread based on the effects of the bioterrorism the country experienced at the hands of the U.S., as well as it's silent Holocaust and how that affected its people. This research is inspired by my experiences growing up as a Guatemalan American woman in the U.S., learning from my parents' cultural experiences growing up in Guatemala and migrating to the United States. Living in Los Angeles, where there is a significant percentage of the Guatemalans residing in the country, I've witnessed various first hand narratives. Through collecting data from digital sources such as online research journals and databases, I've also collected first-hand testimonies from the Guatemalan community about how these misconceptions have followed them throughout their lives and ultimately had a negative effect on them in various aspects. I have also collected examples of our government's repeated exclusion of the country, and how this has affected the Guatemalan people living in the United states, who make up a significant portion of our country's population as migration of Guatemalan immigrants continues to rise. Ultimately, I hope this research can inspire a call to action to bring more awareness, both culturally, and legislatively, to the issues Guatemalan people have faced at the hands of our country, and encourage the start of reparation.

Abstract Name: Bridging the Divide Between Civic Knowledge and Civic Engagement: Navigating Pedagogical Tensions in Civics Education for Elementary Students

The terrain of civics education is vast and divided. While the literature points to the necessity of both the knowing and the doing of citizenship, much of the teaching and learning of civics in our current context fails to account for the complexities of this tension. Our study attempts to bridge the divide between transmissive (knowledge) and transformational (engagement) civics education approaches and is guided by the following research question: How do students, and teachers, come to think about citizenship after participating in an 8-week curriculum experience that privileges both civic knowledge and civic engagement? To do this, we fused elements of an action civics curriculum (The iEngage Civics Institute) with the components of a traditional civics curriculum (Hillsdale College's 1776 Curriculum). Our inquiry followed the methodological structure and assumptions associated with a qualitative multiple case study. We were interested in an in-depth understanding of how the study's participants (three inservice teachers, three preservice teachers, and 50+ students located across three different school sites and primary grade levels) came to think about citizenship after experiencing a curriculum bridging the divide between transmission and transformation. We relied on the three sources of evidence associated with case study design (documents or artifacts, semi-structured interviews, and observations) to construct a rich description of each case. While transmissive and transformational approaches appear oppositional, we highlight the necessary tension and complementary nature of these approaches. We discuss how a civics curriculum that embeds both knowledge and engagement cultivates students who are well-versed in understanding civic structures and the foundational principles undergirding these structures, while simultaneously encouraging youth to view themselves as necessary and influential civic participants who can affect change in their schools and communities.

Abstract Name: External Validation of a Caffeine Population Pharmacokinetic Model in Neonates with Congenital Heart Disease using Pragmatic Trial Design

Caffeine is a promising drug that has reduced rates of acute kidney injury (AKI) in preterm neonates and may prevent postoperative AKI in neonates with congenital heart disease (CHD). To understand the effects of caffeine on AKI in this population, caffeine disposition must first be characterized. We previously developed the first population pharmacokinetic (PopPK) model of caffeine in neonates with CHD undergoing cardiac surgery using an opportunistic, clinically-integrated trial platform. Bypass time significantly affected caffeine disposition. Here, we performed an external model validation in a new cohort of neonates with CHD. External validation is the gold standard in determining model generalizability but is often overlooked due to clinical trial burden. We enrolled neonates with CHD receiving caffeine and collected PK samples. Clinical and demographic data were extracted from the health record. Predictive accuracy of the model was evaluated graphically (prediction corrected visual predictive checks; pc-VPC) and quantitatively (root mean square errors, prediction errors, mean prediction errors, and mean absolute prediction errors). The fraction of model predicted values within 20% and 30% of observed values were calculated for both population and individual predictions. Dosing simulations were conducted to target exposures matching those in preterm neonates receiving caffeine for apnea of prematurity. Fourteen infants were enrolled in the validation cohort. Quantitative metrics of model performance were acceptable, suggesting that our model described the validation cohort well. The pc-VPC showed agreement between model-predicted and observed concentrations. Mean (SD) simulated caffeine concentration was 6.2 (5.2) mg/L, which is lower than the reference range of 15-25 mg/L. We successfully validated our PopPK model to improve caffeine dosing in neonates with CHD—a population that may require higher dosing to match reference exposures. Further, we demonstrated the feasibility of an efficient, opportunistic, clinically integrated trial platform that can be expanded to other drugs in other populations.

Abstract Name: Thermophilic Biodegradation of Plastic and Lignocellulosic Wastes

Plastic and lignocellulosic biomass waste pose significant environmental challenges that require sustainable solutions, as much of this waste is disposed of in landfills instead of being recycled into value added products such as textiles and biofuel. Current methods for breaking down plastics and lignocellulosic biomass are often inefficient, hazardous, and energy-intensive, emphasizing the need for alternative approaches. Thermophilic biodegradation offers a promising bio-based solution to reduce environmental impact by recycling materials instead of discarding them, saving resources. This project focused on utilizing, isolating, and identifying thermophilic microorganisms from Yellowstone National Park (YNP) to address these challenges through biodegradation and downstream waste-to-product conversion. Thermophiles were isolated from hot springs in the Heart Lake Geyser Basin in southeastern YNP. The collected samples were enriched using either plastic or lignocellulosic biomass as the sole carbon and energy source for growth. The tested plastics included polypropylene, polystyrene, nylon-6, and low-density polyethylene. Some plastics were in their solid film form, while others underwent an oxidation treatment—heat, oxygen, and pressure to create a soluble wax. The tested lignocellulose biomass included Remazol Brilliant Blue R (a lignin analog) and dried corn stover. Promising strains demonstrating growth and degradation capabilities were monitored via optical density measurements to formulate growth curves, and direct microscopy to visualize culture growth. The promising strains were isolated on solid media, before transferring colonies back to a scaled-up liquid culture. After sufficient biomass accumulation, these strains were sequenced for taxonomic identification. By harnessing the unique metabolic properties of thermophiles, this project aims to develop sustainable pathways for

recycling plastics and converting lignocellulosic waste into renewable energy or products. This dual-purpose approach addresses global waste challenges with potentially significant environmental and economic benefits.

Abstract Name: Populist Division: Argentina and Brazil's Roles on the Global Stage

As populism is on the rise worldwide, it is easy to question why that is and what the implications will be. From small countries to the world hegemon, populist leaders are taking the stage and transforming their nation's domestic policies and in turn the world stage. In this study, the Most Similar Systems design will be used to analyze populist politics in Argentina and Brazil and how these have led to different outcomes. President Javier Milei and President Luiz Inácio Lula da Silva have entirely opposed political views, and their domestic policies have differed greatly despite both being populists. Considering this, it is hypothesized that their foreign politics, specifically their interactions with the United Nations, have also been impacted by their populist nature while being contrary to each other in political stances. The research will focus on the conditions that led to these governments being elected, and the impact these countries' internal politics have on international organizations. Specific emphasis will be placed on why the outcomes of populist politics are different for Argentina and Brazil domestically and in the United Nations, even though they hold similar positions as regional powers and world players.

Abstract Name: Tissue Specific Compensatory Regulation of Gene Expression Associated with Copy Number Variants in *Danio rerio*

Copy number variants (CNVs) refer to the loss or gain of copies of a DNA region within the genome. While some CNVs enrich the diversity of an organism and play a role in species evolution, CNVs may also be linked to certain diseases such as neurological disorders, early onset obesity, and cancer. CNVs can affect gene expression sometimes leading to disease by direct overlap of the gene or by indirect effects (outside the gene location). *Danio rerio* (zebrafish) is an excellent model organism for human development as well as disease. Zebrafish share 70% of genetic similarities with humans with 84% of disease associated genes. Additionally, zebrafish genomes contain a large amount of variation with 14.6% of the zebrafish reference genome being variable. This study seeks to compare CNVs, miRNA expression levels, and gene expression levels within the kidney and liver of zebrafish. Array comparative genomic hybridization was used to determine CNV regions in 30 adult Tübingen zebrafish while expression arrays were used to measure gene expression as well as micro RNA (miRNA) expression in kidney and liver in these same 30 fish. Single cell RNA (scRNA) sequencing separating genes into their respective kidney and liver-specific cell types will be used to overlay the collected data, so that each gene will be assorted to specific cell types. Expressive

quantitative trait loci (eQTL) analysis (linear regression model in R) will then be used to explore how CNVs may affect gene expression and the regulatory role played by miRNAs.

Abstract Name: Discovering HSD17 β 4 Inhibitors By Performing Virtual Screening Utilizing Machine Learning & AI Techniques

17 β -Hydroxysteroid Dehydrogenase (HSD17 β) regulates the formation of androgens and all estrogens. 15 HSD17 β isoenzymes have been discovered, which vary in function and tissue distribution. HSD17 β 4 promotes the production of estrone through the oxidation of estradiol and fatty acids. When metabolized, estrone becomes either non-carcinogenic 2-hydroxyestrone or carcinogenic 4-hydroxyesterone. The HSD17 β 4 gene has been shown to be upregulated nearly 5-fold in prostate cancer tissues, with no change in HSD17 β 1, 2, or 3. Additionally, prostate cancer tissues display increased levels of HSD17 β 4 mRNA as well as increased enzymatic activity, making HSD17 β 4 a potential target for prostate cancer. The aim of this study was to discover new HSD17 β 4 inhibitors using QSAR machine learning models. Three NCATS compound libraries (MLSMR, NPC, MIPE) had previously been tested in an HSD17 β 4 inhibition assay, and were aggregated into one large dataset, yielding a curated modeling set of 75,554 compounds, with 286 compounds showing proficient inhibitory activity (AC₅₀ < 10 μ M). This dataset was used to build 22 different QSAR models using various model architectures and feature sets. The best three models (Tree-based (RF and XGBoost) and deep learning-based (DLCA)), as selected by PPV and AUC values based on a 5-fold cross validation procedure, were used for a virtual screening campaign performed on two larger compound libraries. 64 compounds from each library were selected by the three models independently without overlapping. Thus, 348 compounds were nominated and tested in corresponding in vitro assay. This resulted in a 38% hit rate, a 3-fold increase compared to original qHTS hit rate (14%). When looking for more specific activity levels: 14% of the compounds had an AC₅₀ < 30 μ M, and 2% of the compounds had an AC₅₀ < 10 μ M. These 9 compounds with an AC₅₀ < 10 μ M serve as promising starting points for further medicinal chemistry optimization.

Abstract Name: Phenotypic Analysis of Threshed Barley Seeds Using PlantCV

Plant science has developed numerous approaches to breed plants with optimal genotypes and phenotypes for

agriculture, yet achieving a balance is often challenging. In barley, for instance, an ideal seed would require minimal threshing to remove chaff. However, if the chaff detaches too easily, seeds can break, reducing yield. Traditionally, "thresh-ability" in domesticated barley is assessed manually in the field, a method that is both error-prone and limited to binary classification. To address this, the Gehan Lab developed a quantitative approach for assessing thresh-ability. PlantCV was employed to analyze images of threshed barley collected by Dr. Yunqing Yu, enabling a more precise evaluation of thresh-ability across genotypes. Using PlantCV, barley thresh-ability could be characterized with continuous, numerical values instead of the binary "hard thresh" and "easy thresh" categories assessed by manual testing. Results confirm that PlantCV provides a successful, quantifiable measure of barley thresh-ability.

Abstract Name: Space utilization increases user interaction and satisfaction within academic settings

Effective space utilization and user interaction rely heavily on Human-centered design (HCD) principles and a psychological understanding of interior design. Key elements of HCD consist of understanding the project's context, identifying the underlying problems through stakeholder and shareholder engagement, and applying solution-oriented thinking to create meaningful modifications. This study emphasizes the importance of these elements in redesigning an academic building. The Gardner Steel Conference Center (GSCC), located on the University of Pittsburgh's campus, is underutilized, with its current layouts failing to support students' needs and preferences. Multiple surveying methods revealed that students sought designated individual studying areas, tables for conceptual group project work, and space for social interaction before and after lectures. These insights led the team to adopt a solution-driven approach aiming to redesign the space to achieve enhanced student utilization and satisfaction. The proposed redesign introduced several key modifications: additional individual study areas, designated Zoom conference spaces, collaborative group study areas, and an appointed social zone. The addition of Zoom conference spaces, a nonexistent feature in current campus locations, gives students a designated space to communicate with teams, project clients, and take job interviews online. The proposed changes increase seating capacity with usable tables by 83%, meeting the needs of stakeholders while also aligning with student preferences. Follow-up surveys with the student population showed positive feedback regarding the proposed changes, indicating vastly improved space utilization and user satisfaction. This study demonstrates how a Human-centered design approach, supported by thorough stakeholder engagement and solution-oriented thinking, can effectively transform academic spaces to better support the needs of students and enhance overall campus life.

Abstract Name: Optimizing Course Registration and Academic Planning at Miami Dade College Using a Data-Driven System

This project focuses on developing a comprehensive course registration system to enhance academic planning and optimize scheduling at Miami Dade College, Padron campus. The system will allow students to securely log in, select their preferred courses and schedules for upcoming semesters, and provide data that academic departments can use to make data-driven decisions about course offerings and scheduling. By collecting students' course preferences and preferred time slots, this system will store the data in a SQL database, where it can then be analyzed to identify patterns and trends. These insights will inform decisions regarding which classes to offer, efficient faculty allocation, and time slots that align with student demand. The project's core architecture relies on a MySQL relational database supporting entities such as students, courses, majors, and course prerequisites. Python is used to handle application logic, data management, and security protocols, including password hashing and secure data storage. The physical setup incorporates a Raspberry Pi to run the system in a compact, standalone configuration, with an integrated touchscreen interface for ease of use. This approach provides a scalable and secure solution, enabling students to manage their academic plans with real-time guidance while also empowering administrators to allocate resources effectively and address evolving student needs. By aligning student demand with course scheduling, this system seeks to improve resource management and promote student satisfaction, offering a powerful tool for academic planning and institutional decision-making.

Abstract Name: Characterizing the Promoter Elements Driving UVRAG Expression

Transcription converts DNA into RNA upon its activation at a gene's initiating promoter site through the binding of an RNA polymerase II enzyme and assisting basal transcription factor proteins. During activation, regulatory transcription factor proteins are recruited and bound at the promoter to positively or negatively modulate the rate of transcription beginning with the transcription start site indicated as +1. As a tumor-suppressor, UVRAG interacts with Beclin-1 protein to regulate autophagosome vesicles degrading the oncological epidermal growth factor receptor. By characterizing the UVRAG promoter, positive promoter elements required to maximally express UVRAG will be established to increase the functional understanding of transcriptional regulation and maintain autophagosome formation. UVRAG's putative promoter was identified, PCR amplified, and subsequently subcloned into a promoterless pGL3 Basic vector to gauge promoter activity by analyzing the expression of the fluorescent luciferase gene carried on the vector. The

synthesized recombinant plasmid was transiently transfected into human embryonic kidney cells where a dual luciferase assay revealed a 57-fold luciferase expressional increase when compared to pGL3 Basic indicative of a fully active promoter. Consensus transcription factor binding sites were then located and mapped using bioinformatics to identify positive regulators. Through site-directed mutagenesis of the promoter, deletion constructs were created around existing transcription factor binding sites at -1148bp, -935bp, -725bp, -478bp, -177bp, and -89bp relative to the preliminary transcription start site in order to evaluate discerned transcription factors based upon luciferase levels of ensuing transfections and assays. Determination of these positive promoter elements may allow positive transcriptional regulation to be used as a prophylactic tool upon further gene regulation studies.

Abstract Name: The Key to the Success of Barbie (2023): Combining Viral Marketing and Engagement Opportunities

Barbie (2023) by Greta Gerwig was a landmark film both in terms of marketing and audience reception on a global stage and brought in over 1.445 billion dollars at the box office. The general public's analysis focuses on the unique marketability factors in the film's success, such as the cultural significance of Barbie or the popular stars involved in the production, but ignores the underlying foundation to which the film was publicized. This foundation is replicable across campaigns, unlike the aforementioned factors which are highly unique to the film and irreducible. This study aims to address the most successful and universally applicable marketing method utilized by Barbie (2023), which is identified to be strategically released promotional material paired with opportunities for engagement. This study analyzes past viral film campaigns and the typical Hollywood campaign timeline to put the success of Barbie (2023) in a broader promotional context and examine the origins of the two-pronged engagement strategy, as well as the impacts of the contemporary movie-going culture. The research indicates that this campaign's leading the audience on a journey through the timed release of small pieces of information is the most successful and widely applicable strategy used by the Barbie (2023) team. By recognizing and analyzing this framework to which each specific promotional material was applied, other films can similarly amass a deeply involved audience and build engaging campaigns.

Abstract Name: The Role of the CD6/CD318 Axis in Anti-Tumor Immunity

Checkpoint inhibitor blockade has revolutionized cancer immunotherapy. However, its clinical use is limited by the appearance of severe autoimmune side effects and resistance of cancer cells to lymphocyte killing. CD6, expressed by T cells and NK cells, plays a central role in the generation of autoimmunity. In both

CD6-/- mice and CD6-humanized mice treated with UMCD6, an anti-human CD6 monoclonal antibody, striking reductions in clinical signs of autoimmunity, pathogenic Th1/Th17 responses, and inflammatory cell infiltration into the target organs are observed. CD6 has two well-known ligands: CD166, also known as Activated Leukocyte Cell Adhesion molecule (ALCAM), and CD318 (CDCP1). Both CD6 ligands are highly expressed in cancer. We first tested the effects of interrupting the interaction between CD6 and CD318 with UMCD6 on the ability of lymphocytes to kill the cancer cells. Co-culture experiments of cancer cells and lymphocytes showed substantial enhancement of cancer cell death in the presence of UMCD6, which was more pronounced than that generated with pembrolizumab (anti-PD-1). Next, we demonstrated that the augmentation of lymphocyte cytotoxicity by UMCD6 was due to direct activation of NK cells and CD8+ T cells, which included profound changes in gene and protein expression of several activating and inhibitory receptors. Using advanced molecular techniques such single-cell RNA-sequencing and various in vivo cancer models, we are currently dissecting the mechanisms by which internalization of CD6 with UMCD6 enhances cytotoxic lymphocytes to kill cancer cells. Our most recent findings reveal that disrupting that interaction enhances lymphocyte-mediated tumor cell killing of breast and prostate tumors while minimizing immune-related adverse events, addressing key limitations of current immunotherapies. This work will advance the understanding of immune-tumor interactions and identify the CD6/CD318 axis as a promising, safer target for precision oncology, with the potential to improve outcomes for patients with cancer.

Abstract Name: Ansys Flow Modeling of a Small Scale Dual-Rotor Helicopter with Multiple NACA Airfoils

Performance measurements are crucial for helicopter design and are typically derived from generated thrust. However, experimental thrust measurements can be influenced by various factors, potentially leading to inaccuracies in assessing a system's capabilities. Our previous experimental results show the impact of various NACA airfoils on the performance of a dual-rotor helicopter (SREJNGL-31.5"×3.5"×9.4") including the thrust at various operating conditions (~2000 rpm). The thrust measurements incorporated a load cell connected to a microprocessor to obtain thrust values. To validate our experimental results, our current work includes theoretical modeling of the rotating blades using Ansys finite element analysis. For this purpose, various NACA airfoils with differing maximum camber (0-4%) and maximum thickness (18-24%) were employed. The NACA airfoils coordinates were obtained from <http://airfoiltools.com/>. We hypothesize that ANSYS modeling will predict higher thrust values than the experimental results. The study employs a refined mesh approach, utilizing 57.97 mm elements and analyzing 175 mm airfoils operating at a maximum rotational speed of 2000 RPM. The computational methodology leverages high-fidelity ANSYS meshing to create a detailed numerical model of the helicopter's rotor dynamics. This model systematically calculates critical aerodynamic parameters, such as thrust generation and Reynolds number characteristics, across different NACA airfoil geometries. Preliminary results indicate variations in thrust and normal air velocity for five NACA airfoils (NACA #2412/6409/0024/0015/2415). The predicted thrust values ranged from 56 N-to-122 N, while vertical air velocity varied from 41 m/s-to-61 m/s. The study specifically focuses on modeling the complex fluid dynamics around the rotor blades, capturing intricate aerodynamic interactions and turbulent flow patterns. Theoretical flow visualization was conducted using advanced computational techniques. These results will be compared to experimental data obtained via laser sheet and high-speed camera visualization. Full results will be presented at the conference.

Abstract Name: Determination of 2,3-Butanedione and 2,3-Pentanedione in E-cigarettes Using HS-GC

E-cigarettes are often marketed as safer alternatives to cigarettes. It is a common misconception that e-cigarette vapor is harmless and consists only of flavored water. A study previously published by Harvard suggests that over 90% of e-cigarettes contain 2,3-butanedione, also known as diacetyl, a food flavoring known for its intense buttery flavor. It is often substituted with 2,3-pentanedione. Both flavorings have been linked to severe respiratory disease and damage. In 2019, both were proposed as additions to the U.S. Food and Drug Administration's "Harmful and Potentially Harmful Constituents List", but they currently remain "generally recognized as safe" by the FDA. The goal of this study was to develop an effective method to analyze the 2,3-butanedione and 2,3-pentanedione levels in e-cigarette juice using headspace gas chromatography (HS-GC). HS-GC was used because of its effectiveness in detecting volatile organic compounds. This method allows for analysis of 2,3-butanedione and 2,3-pentanedione in the vapor phase, which minimizes sample preparation. Of the eight e-cigarette samples tested in this study, 75% contained detectable levels of diacetyl and 100% contained detectable levels of pentanedione. Given the increase in vaping in the United States, especially in younger populations, this data shows a need for further research and regulation of e-cigarettes.

Abstract Name: From Harm Reduction to Forced Treatment: Neoliberal Governmental Discourse and the Decline of Alberta's Supervised Consumption Sites

Supervised consumption sites represent national and international action to address the growing opioid overdose mortality crisis through harm reduction. However, implementing spaces for supervised substance use remains controversial. In 2019, the Alberta United Conservative Government released with Alberta Health, 'Impact: A Socio-Economic Review of Supervised Consumption Sites in Alberta'. Following publication, the review became an important referent document used by governments to prevent supervised consumption sites from operating; as Alberta's overdose deaths increased, the provincial government froze site funding, shutting down North America's busiest sites while the Third Circuit Court of Appeals blocked plans to implement Philadelphia's site, 'SafeHouse'. This study informs communications literature by examining how the review frames the opioid crisis and addiction to legitimize the closing of supervised consumption sites, shifting previous academia's focus from supervised consumption site implementation as a health service to their closure as a socio-economic problem. This cross-sectional case study asks, what discourse is produced in Alberta Health's 'Socio-Economic Review of Supervised Consumption Sites in Alberta'? The methodology is informed by Van Dijk's Critical Discourse Analysis and Foucault's concepts of power and knowledge to examine how socio-economic claims are normalized as health knowledge to legitimize addiction treatment policy. Two themes—site inefficiency and societal risk—reveal a neoliberal discourse on health services. Findings indicate that neoliberalism silences the voices of site users and social issues to emphasize the negative community impact of supervised consumption sites. Consequently, Alberta Health's review produces a neoliberal governmental discourse that repositions the fundamental problem underlying drug addiction away from the silenced, systemic, socio-economic marginality site users face to the

salient, socio-economic challenges that harm reduction sites impart on the community. This discourse erodes health and social services like harm reduction to legitimize the Alberta Government's newest addiction treatment proposal, the forced treatment model, increasing disciplinary measures against society's most vulnerable.

Abstract Name: Bum Painter or “so-called” Architect?: Oscar Bluemner’s Transition to Painting

This paper explores Oscar Bluemner’s transformative journey from architecture to painting, a transition shaped by legal conflict, cultural critique, and a personal reevaluation of his professional identity. Educated in architectural theory and design at Berlin’s prestigious Königlische Technische Hochschule, where he was awarded the Royal Medal for a painting of an architectural subject, Bluemner’s early accomplishments positioned him for a successful career in Germany. However, after immigrating to the United States in 1892, he faced challenging circumstances and illness before eventually forming a partnership with New York architect Michael J. Garvin. Together, they undertook the design of the Bronx Borough Courthouse, an ambitious project in the Baroque Revival style. The courthouse project, however, marked a turning point. When Garvin claimed exclusive credit for the design, Bluemner sued for breach of contract in a prolonged case that finally settled in 1912. Though financially beneficial, the legal dispute deepened Bluemner’s disillusionment with the architecture industry, which he saw as increasingly driven by consumer values at the expense of artistry. His frustration with American materialism, expressed in a later essay condemning “the great stomach-question” that prioritizes profit over art, reflects a growing ideological divide that influenced his decision to leave architecture altogether. With the funds from his legal settlement, Bluemner embarked on a tour of Europe, where he immersed himself in contemporary art, studying diverse movements and experimenting with new techniques. Returning to New York, he devoted himself to painting, drawing on his architectural training to inform his compositions. This paper situates Bluemner’s transition within broader cultural contexts, illustrating how his professional and ideological conflicts catalyzed his transformation into an influential American Modernist painter.

Abstract Name: AI vs Human Creativity: Investigating the Effectiveness of AI-Generated Advertisements

With rapid advancements in artificial intelligence (AI), many companies have begun incorporating generative AI into their advertising strategies, producing unique and engaging commercials that transcend the limits of traditional advertising. Given the immense success of these campaigns, this research aims to investigate if AI-generated ads can outperform their human-made counterparts in increasing consumer demand, and if so, the

factors contributing to their greater success. To answer these questions, we first conducted two case analyses on Nike's "Never Done Evolving" ft. Serena Williams campaign and Coca-Cola's "Y3000" campaign. Next, we devised a theoretical framework of three potential success factors for AI-generated ads (complexity, creativity, and familiarity). Finally, a week-long field study was conducted on 240 Carnegie Mellon University students across different years and majors to study the effectiveness of AI-generated ads in increasing club membership of campus organizations, with club membership serving as a proxy for consumer demand. In this study, participants were randomly partitioned into four groups, with each group surveyed on how likely they were to join a club after viewing one of four posters (three AI-generated posters based on each factor of success and one human-made poster). Through this study, we discovered that although AI-generated posters are generally more effective than human-made posters in capturing people's attention, their human-made counterparts are still more effective in increasing club membership. While AI-generated posters attract a larger audience, there is greater variation in the interest level of the audience. Future research can further explore the impact of AI advertisements on various aspects of marketing, such as click-thru rates and sales on different marketing platforms such as e-commerce.

Abstract Name: Targeted Protein Deactivation Using Chromophore Assisted Light Inactivation

Light is an important tool in chemical biology and is often applied to investigate protein function in a complex biological system due to its high level of spatiotemporal control. Methods of optical protein activation exist, however, the deactivation of proteins using light is less common. Chromophore-assisted light inactivation (CALI) is a method of optical protein modulation that relies on a photosensitizer that generates reactive oxygen species when irradiated with a specific wavelength of light. This can result in the oxidation of the protein of interest and eventual removal of activity. Here, I describe a method of optical deactivation of the beta-lactamase enzyme, OXA-48 through the covalent delivery of three different photosensitizers using amine-reactive N-hydroxysuccinimide or isothiocyanate-activated small molecules. Through this work, I have demonstrated efficient labeling of the protein of interest and optical deactivation upon light irradiation of photosensitizer-labeled proteins.

Abstract Name: *Adelpha erymanthis fortunata*: Unraveling the Species and Subspecies Connection

Among nymphalid butterflies, the genus *Adelpha* is one of the most species rich genera, with over 300 named species and subspecies. This diversity is associated with adult color patterns that vary geographically and

exhibit mimetic convergence to signal unprofitability to predators. The mimetic similarity among *Adelpha* species has long been recognized for making species identification and taxonomic organization a challenge. Nearly a century ago, it was recognized that immature stage morphology and host plants often differ between *Adelpha* species, providing a potential solution to these challenges. Recent molecular evidence for several geographically widespread *Adelpha* species indicated high levels of intraspecies variation suggesting the presence of cryptic species, and the potential for other differences. This is evident in *Adelpha erymanthis*, which comprises four subspecies across Central America and northwest South America: *erymanthis*, *esperanza*, *adstricta*, and *fortunata*. Research in Costa Rica found that the immature stages and host plants of *A. e. adstricta* differ significantly from those of *A. e. erymanthis*, leading some researchers to propose treating them as separate species. Observations in western Ecuador further corroborate this distinction, with *A. e. fortunata* sharing similarities in immature stages and host plant use with *A. e. adstricta* and not *A. e. erymanthis*. Analysis of the mitochondrial gene cytochrome oxidase subunit I (CoI) provides additional evidence that *A. e. fortunata* and *A. e. adstricta* are monophyletic and distinct from *A. e. erymanthis*. Together, these findings indicate that *A. e. adstricta* and *A. e. fortunata* represent subspecies of the same species *A. adstricta*, separate from *A. e. erymanthis* and *A. e. esperanza*. This research highlights the utility of integrating molecular, morphological, and ecological approaches in insect taxonomy, even in butterflies, one of the most well-known insect groups.

Abstract Name: Tualang honey has a protective effect against cutaneous immune responses and skin cancer

Ultraviolet (UV) B radiation leads to DNA damage by generating cyclobutane pyrimidine dimers (CPDs). UVB-induced CPDs can also result in immune suppression, which is a major risk factor for non-melanoma skin cancer (NMSC). UVB-induced CPDs are repaired by nucleotide repair mechanisms (NER) mediated by xeroderma pigmentosum complementation group A (XPA). We have previously demonstrated that treatment with tualang honey (TH) led to a decrease in DNA damage and inflammatory markers following UVB in a keratinocyte cell line. The purpose of this study was to investigate the use of TH as a chemopreventive agent against development of skin cancer. SKH-1 hairless mice fed with TH (0.1% v/v) for two weeks prior to a single dose of UVB (180 mJ/cm²) led to a significant increase in XPA in skin and DNA repair cytokines IL-12 and IL-23 in draining lymph nodes. Furthermore, when subjected to the photocarcinogenesis protocol, mice fed with TH developed significantly fewer tumors in comparison to mice fed on drinking water. Our data demonstrate that TH has a protective effect against UVB-induced DNA damage, immune suppression, and skin cancer. Future studies will further investigate the potential of TH as a preventive treatment for NMSC.

Abstract Name: Unpacking Bias, Accountability, and Ethical Practices in AI

This study is based on understanding how text-to-image generative AI platforms perpetuate biases such as racism and sexism and decoding how this bias is programmed within large language models and datasets. In this study, the results of generative AI are analyzed through the lens of affect and affect theory, as they are applied to investigate the machine learning and computer theory behind generative AI algorithms. The purpose of the study is to explain why generative AI is biased and whether this bias is generated due to current trends or to deficits and biases within the database that it draws information from. By understanding how generative AI is coded, we seek to understand whether and how generative AI is able to predict trends, even outpacing human prediction. These conversations are all correlated to the ethical implications of generative AI, and whether as we move forward with the expansion of text-to-image AI platforms, there should be mechanisms of accountability imposed for ensuring that these platforms operate in ethical and responsible ways. This research also examines whether use of AI can also further perpetuate stigmas against race and gender by either further encouraging it by its use or rather that AI is being fed such stigmas by analyzing the current trends of the social and political climate of the world. The goal of this study, however, is to understand the origins and mechanisms of bias within generative AI, particularly with regard to tropes of sexism and racism, and to create a proposal for best practices which would help encourage and implement guidelines to create more ethical and conscientious use and application of generative AI platforms.

Abstract Name: Evaluating the Robustness of Discriminative and Generative Text Classifiers Across Various Noise Conditions

Text classification systems are fundamental to applications such as sentiment analysis, spam detection, and topic modeling. Deep learning models, particularly discriminative and generative classifiers, have become prevalent in addressing these tasks. Discriminative models classify text by directly modeling the conditional probability of class labels given input text in order to learn the decision boundaries. In contrast, generative models approach classification by modeling the joint probability between text and class labels, utilizing Bayes' Rule to infer classifications from class-conditional probabilities and priors. Previous studies have focused on comparing the peak performances between the discriminative and generative models, showing both linear and non-linear discriminative models reaching lower asymptotic errors compared to their generative counterparts. However, real-world text data frequently contains noise, arising from human input errors, web artifacts, or other disruptions. Robustness to noise is crucial for maintaining model performance during inference. This study investigates the robustness of text classifiers, comparing LSTM-based discriminative and generative text classifiers across varying noise levels and types. The evaluation provides insights into the resilience of these models under noisy conditions, highlighting their performance trade-offs and informing the development of noise-resistant classification systems. The expected findings aim to identify strengths and weaknesses of these two types of models which can provide a detailed understanding of the classification performance of the models under real world settings.

Abstract Name: Nostalgia and Time Perception

Nostalgic reflection is linked to a number of psychological benefits, including enhanced mood, greater sense of meaning in life, and bolstered social belongingness—but its effects on everyday cognition are less clear. Given that nostalgia is a complex emotion linking the past to the present, this project explores its effects on time perception across two scales: subjective lifespan and perceived duration of tasks in the present. In a between-groups study, 112 participants completed an Event Reflection Task (Sedikides & Wildschut, 2018), during which they wrote about either a nostalgic memory or an ordinary autobiographical memory for five minutes. Then, participants completed three scales measuring subjective lifespan. One scale captured the perceived distance of the memory they wrote about (i.e., how far away the memory feels relative to when it actually occurred), and two scales captured perceived lifespan (i.e., how old one feels they have been alive relative to their chronological age). Participants then estimated the duration of three in-lab tasks, including time spent writing about their memory during the Event Reflection Task, the length of a neutral film clip (low cognitive load task), and time spent completing a pattern recognition test (high cognitive load task).

Preliminary analyses suggest that nostalgic memories feel further away in time than ordinary memories, that nostalgic reflection (compared to ordinary autobiographical reflection) expands the perceived length of one's life, and that nostalgic reflection increases the perceived duration of low cognitive load tasks, but not high cognitive load tasks. These findings contribute to emerging conversations surrounding the use of nostalgia as a therapeutic tool. Specifically, its effects on subjective flow of time may be relevant to mindfulness and stress reduction techniques. Furthermore, the benefits of nostalgic reflection may be relevant to those living with disorders known to alter time perception, such as ADHD and schizophrenia.

Abstract Name: Aging in Displace: How do Aging Immigrants in Chicago Chinatown (Re)Construct Narratives on Successful Aging under Transnational Migration?

Asian-born immigrants are among the fastest-growing aging populations in the U.S. Despite this growth, older immigrants remain an under-researched population in the field of aging. This research explores how first-generation immigrants in Chicago construct narratives of successful aging within the context of their transnational life experiences. The study examines three central questions: (1) How does migration influence elders' perceptions of their life course and expectations of successful aging? (2) What cultural logics and categories do they employ to navigate the challenges of aging in the U.S.? (3) How does the timing of migration shape their life narratives? By addressing these questions, the study aims to expand scholarship on successful aging and aging in place. Community-dwelling older adults aged 62 and above (n = 100) were

recruited, and their conceptualizations of successful aging were evaluated using the Successful Aging Inventory. This is followed by semi-structured interviews with 20 elders, exploring life events, migration challenges, and current experiences. Regression analysis is applied to analyze the survey data. A grounded theory approach combined with an intersectional life-course analytical lens is used to analyze the qualitative data, emphasizing the interplay of identity, structural forces, and agency. Results reveal older immigrants adapt to transnational settings by reconstructing cultural norms of aging, and structure the narratives of wellbeing in current life in relation to the past challenges. The findings challenge the essentialist assumptions about older adults as passive and static agents that hold onto the ethnic traditions. This study shed light on the strategies that aging immigrants used to anchor themselves emotionally and symbolically in a transnational context, which will not only provide a broader conceptualization of successful aging by putting the subjectivity of immigrant elders at the forefront of the analysis but also expand the scholarship to be inclusive of the large ethnic-Chinese immigrant population.

Abstract Name: The Effect Of The 2011 Great East Japan Earthquake, Tsunami, and Nuclear Power Plant Disaster on Pregnant Woman

This research discusses the impacts of the 2011 Great East Japan earthquake, tsunami, and the Fukushima nuclear power plant explosion on pregnant women's health. Multiple aspects of these women's health are discussed including psychological impacts, effects on the mother and baby after birth, as well as a smaller examination on domestic violence on pregnant women after the series of natural disasters. The research process occurred through an extensive literature review of over 15 journals and science articles that were published after 2011. Major findings of this literature review include increased susceptibility to harmful pregnancies, increased psychological stress, and increased levels of domestic violence for pregnant women. These factors may play a factor in influencing the low birth rate in Japan. Understanding how the intersectionality of health influences the intersectionality of natural disaster (risk, resilience, and recovery) can serve as a strong basis for societal improvement in future disaster preparedness for at-risk populations. In some cases, this investigation may be a solution to a seemingly unrelated, pre-existing, long-term issue a nation has been facing as well. Future considerations for research include how varying levels of stress affect pregnancy and the long term effects of stress during pregnancy on the development of a child .

Abstract Name: Integer Sequences of Five Stranded Spiral Knot Determinants

Spiral knots are a generalization of the well-understood torus knots, characterized by one moving strand and labeled by strand number, base word, and repetition. By fixing the strand number and base word, we obtain integer sequences of spiral knot determinants. This study explored such sequences for spiral knots with five

strands, following on the work done by Kim-Steers-Taalman in Sequences of Spiral Knot Determinants. We utilized two methods of finding the determinants of spiral knots: the crossing-matrix method and the chessboard coloring method. Both processes yielded identical resulting sequences which were unique from preexisting sequences recorded in the Online Encyclopedia of Integer Sequences (OEIS). In the future, we plan on proving a conjecture made about the resulting sequences, as well as determining if any of the integer sequences yielded from this study are a product of others found in the OEIS.

Abstract Name: Beyond the Brochure: Admissions Videos as a Catalyst for Campus Belonging

The research project Beyond the Brochure: Admissions Videos as a Catalyst for Campus Belonging explores how diversity ideologies —whether universities adopt a multicultural or colorblind approach to racial diversity—might potentially impact students' belonging (Slaten et. al., 2017; Karaman & Cirak, 2017; Walton & Cohen., 2017) and psychological safety (Morton et al., 2024). The study involves two types of narratives presented in videos: one featuring a colorblind narrative, which downplays racial and ethnic differences by emphasizing commonalities and promoting the idea that "we are all the same," (and the other featuring a multicultural narrative, which celebrates and values diversity by highlighting the unique contributions of different cultural groups. This study will include undergraduate students from a University in S.E region of the United States and CloudResearch participants. Participants will be asked to imagine they are in the college application process and are watching a fictional admissions video about an institution they are eager to attend. Half of participants will be asked to watch a video that used a colorblind ideology, others were asked to watch a video that uses a multicultural approach. Afterwards they answered questions about their psychological safety and sense of belonging. Anticipated results based on the hypothesis assume that videos emphasizing multicultural ideologies will foster stronger feelings of belonging and psychological safety, particularly among underrepresented groups. I hope to highlight the critical role of the ideologies that inform institutional messaging that shape perceptions of equity and inclusivity before students even step foot onto college campuses, specifically through admissions promotional videos, and that this research contributes to the ongoing development of frameworks for implementing DEI programs and initiatives within colleges and universities that effectively address the needs of marginalized students. This research has been approved by the IRB of The University of Richmond and will be conducted beginning January of 2025.

Abstract Name: Nostalgia Across Cultures

Nostalgia is a bittersweet emotion marked by a sentimental reflection on one's past accompanied by a sense

of longing for the irrevocable. Critically, nostalgic reflection is linked to several psychological benefits, including enhanced mood, bolstered sense of belonging, and greater sense of meaning in life—particularly in the face of psychological distress (Sedikides & Wildschut, 2018). However, given that much of this research has been conducted on Western populations, this study investigates whether the benefits of nostalgia persist cross-culturally, and whether these effects are moderated by cultural orientation (i.e., an individualist vs. collectivist mindset). In an online study, 179 participants from nine countries completed the Culture Orientation Scale (Triandis & Gelfand, 1998) and an Event Reflection Task (Sedikides & Wildschut, 2018), during which they wrote a short essay about a nostalgic memory. Both before and after this exercise, participants completed a mood scale, the General Belongingness Scale (Malone et al., 2012), and the Meaning in Life Questionnaire (Steger et al., 2006). Collapsed across all nine countries, nostalgic reflection resulted in a modest mood boost, a slightly bolstered sense of belonging in both the acceptance and rejection dimensions of the scale, and a greater presence of meaning in life paired with a diminished search for meaning. While these benefits appear to persist across cultures regardless of cultural orientation, individuals scoring higher in collectivism demonstrated a relatively greater increase in acceptance scores. While this study is ongoing, these early findings offer a note of hope for the use of nostalgia as a therapeutic tool in our increasingly globalized world. Given that deprivation of belonging can lead to severe anxiety (Baumeister & Tice, 1990), and presence of meaning predicts life satisfaction (Steger et al., 2006), the protective benefits of nostalgia could potentially enhance psychological well-being for diverse populations.

Abstract Name: The Saudi Economic Awakening: How is Vision 2030 Transforming Women's Economic Role?

This study examines the impact of Saudi Arabia's Saudi Vision 2030 policies on female labor force participation rates (FLFPR) and its economic contribution in Saudi Arabia (SA). While previous scholarly research has documented the historical constraints of traditions and religion on women's economic participation in SA, limited empirical and quantitative analysis exists on the effectiveness of recent reforms in increasing women's workforce participation. Using publicly available quarterly and annual SA census data, the research employs a quantitative analysis comparing pre-reform (2013-2017) and post-reform (2019-2023) periods, with 2018 designated as the reform implementation year. Methodology utilized after data collection includes both statistical processes (paired t-test, Mann-Whitney U test), as well as econometric time series & regression analyses to assess the significance of the relationships between FLFPR and SA's GDP. Findings reveal a statistically significant increase in FLFPR post-reform, as well as a significant relationship between the FLFPR and SA's GDP. Although the substantial growth is partially credited to Vision 2030 policies, the analysis discusses several shortcomings that remain as a hinderance to the women population in contributing to the national GDP. This research contributes to understanding how targeted policy reforms can transform women's economic participation in traditionally conservative societies, while highlighting areas requiring continued development to achieve Saudi Vision 2030's desired economic outcomes from women. Keywords: Saudi Arabia, Saudi Vision 2030, female labor force participation, economy, GDP, women, reform

Abstract Name: Making a mineral: the evolution of P58 biomineralization proteins in echinoderms and related animals

Background: Biomineralization is the process by which organisms produce minerals to harden tissues, an essential process for the formation of skeletal tissue. P58a and P58b are two closely-related transmembrane proteins required for the proper formation of the calcified endoskeleton of sea urchin embryos. The aim of this project is to reconstruct these proteins' evolutionary history. Methods: We identified P58a and P58b related proteins using BLAST to align the complete *S. purpuratus* proteome against hemichordate, chordate, and other echinoderm proteomes. Based on this analysis, a phylogenetic tree was generated using P58-related sequences from 3 echinoids, 2 holothuroids, 3 asteroids, and 3 vertebrates. This phylogeny was restricted to the Fc-binding protein-like domain, a highly conserved motif in P58 proteins likely important for function. Results: Our results (Figure 1) indicate the presence of echinoid-specific duplications. Single orthologs of three P58 family proteins, P58a, P58b, and P58-like, are found in all echinoid (sea urchin) species, strongly supporting the view that a duplication of these genes occurred prior to the evolutionary diversification of echinoids. In asteroids, the P58 protein is most closely related to P58a. No asteroid ortholog is more closely related to p58b than p58a, indicating no duplication. Hemichordates and chordates have only one P58-like protein similar to P58a/P58b, suggesting no duplication. P58 proteins appear to be specific to Ambulacraria as closely related proteins are absent in vertebrates, echinoderm relatives. This is because they form an outgroup that doesn't overlap with the P58 clades and have domains not present in the closely related P58 groups. Conclusions: Our phylogenetic analysis shows that the P58 family has undergone several lineage-specific duplications within ambulacrarians, with echinoids (sea urchins) exhibiting the greatest number of duplications. The expansion of this gene family in echinoderms may have allowed P58 proteins to adopt new functions associated with calcite-based endoskeleton formation.

Abstract Name: PARE at IU Indianapolis

PARE is the prevalence of antibiotic research in the environment and it is the basis of this research project. Antibiotic resistance is prevalent when trying to treat diseases, but it is also present in the soil and other aspects of the environment. The presence of resistant bacteria is an issue because it can build from lower trophic levels and harm humans and animals. Most of the antibiotic resistance comes from human or animal waste or the runoff water from agricultural land. To combat antibiotic resistance in the environment, the prominent geographic regions of resistance must first be located. Several institutions across thirty of the United States and Puerto Rico, including Tufts School of Medicine, are investigating antibiotic resistance in the environment through the PARE project¹. The IU Indianapolis chapter of PARE has the following goals: determine the prevalence of antibiotic-resistant bacteria across Central Indiana and to examine the biological factors that antibiotic resistance is affected by. To achieve these goals, soil samples from different locations across Central Indiana were plated in a serial dilution on plates with varying concentrations of Tetracycline to test the antibiotic resistance. The biological factors that antibiotic resistance is affected by were tested by

growing the plates at varying temperatures and pH concentrations. Keywords: Antibiotic resistance, PARE project, soil sampling, Temperature, pH

Abstract Name: Maternal Health and Climate Change through the Lens of Infrastructural Violence

The increase in climate disasters from rising temperatures and sea levels disproportionately affects pregnant women globally. Climate change has triggered infrastructural collapse in regions facing severe natural disasters. Structural violence, exacerbated by climate change, consists of/includes infrastructural violence that directly impacts global maternal health. The inadvertent oppressive nature of some infrastructure within cities may create barriers to maternal and neonatal care in crisis situations. This research will examine the negative impacts of infrastructural violence and will link how infrastructural violence can affect maternal health during/after climate related disasters. Approaching maternal health and climate change through the lens of infrastructural violence can help better address structural and social disparities. Maternal health research exposes health disparities among multiple vulnerable populations and their contributing factors. This project uses the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) to structure a rapid scoping review. Since infrastructural violence is a relatively new concept and is contained within the much larger umbrella of structural violence, words that could discuss infrastructural violence were added to the search terms. Inclusion criteria were studies published from 2011 through 2024, in English, that addressed climate, maternal health, and included terms that imply infrastructural violence. Exclusion criteria included grey literature and articles that do not mention infrastructure. Articles were searched through three core databases: PubMed, PsycINFO, and CINAHL. A rapid-scoping review along with a completed PRISMA diagram, will be created and published on literature that focuses on the concepts of infrastructural violence, climate change, and maternal health.

Abstract Name: Building a comprehensive comparative osteological collection of Gulf of Mexico fishes for scientific studies

McWane Science Center (MSC), Birmingham, AL is building a comprehensive comparative osteology collection of marine fishes from the Gulf of Mexico. In the Gulf of Mexico, over 500 unique species of marine fishes have been recorded. Nearly all existing collections of Gulf of Mexico fishes are comprised of preserved specimens in jars. Therefore, there is no comprehensive publicly accessible skeletal collection of these fishes anywhere in the world. To date, MSC has obtained over 300 species of fishes that would have otherwise been discarded. In a collaboration with the Dauphin Island Sea Lab, Alabama Aquarium, and

Alabama Deep Sea Fishing Rodeo, specimens will continue to be saved for this project and will continue to increase the taxonomic scope of the collection. The specimens are prepared following a specific protocol that includes manual defleshing and chemicals. For larger specimens, flesh is removed with standard dissection tools. For smaller specimens, the flesh is dissolved in a bath of water and potassium hydroxide. Extracted skeletons are placed in 10% hydrogen peroxide bath which serves as a final cleaning and degreasing agent. Processed specimens are permanently cataloged into MSC's scientific collections. Our goal of building this osteological collection is to support various scientific studies, including paleontological, archaeological, and fisheries biology. Photographs of diagnostic elements, like dentaries, neurocrania, and otoliths, will eventually be uploaded into MSC's online Alabama Biodiversity Database to be accessible by a global audience.

Abstract Name: The Impact of Transfer from 2-Year to 4-Year Campuses

This poster presentation will highlight the results of an ongoing study that looks at the institutional structure of a large, Hispanic-serving research institution that also supports four, two-year "branch" campuses. By examining both institutional data and student narratives collected via semi-structured interviews this study seeks to understand the experiences of students transferring from these two-year branch campuses to the main university branch. The particular focus looks at how the transfer process affects three metrics of student wellbeing: happiness, confidence, and sense of belonging. Further, this study aims to triangulate narrative data with outcomes such as graduation and drop-out rates of transfer students, and the tendency of some university students to return to their branch campuses. It does so by considering campus, regional, and racial/ethnic cultural ecologies (cultural rhetorics) alongside quantitative data on these outcomes via institutional records where trends will be identified. The poster will present some of this data and excerpt interviews with transfer students and "bounce back" students. The goal of the project and poster will be to present an assessment of the changes in students' social and emotional well-being during and after the transfer process. The research questions guiding the study are as follows: 1. In what ways does the transfer process influence student confidence, happiness, and sense of belonging? 2. From a student perspective, are there significant differences in the way branch campuses foster a strong sense of community? 3. How do students from branch campuses experience preparation and encouragement to transfer? The purpose and goal of this research is to make visible, the stories of transfer students by better understanding their challenges and successes so that the institution might better address their needs.

Abstract Name: Health Monitoring via RFID-based Respiratory Tracking System

Monitoring breathing rates using commercial off-the-shelf (COTS) RFID systems present a scalable and efficient solution for real-time respiratory tracking. In this system, an antenna emits radio signals reflected back by RFID tags, which are lightweight and easy to attach. For breath monitoring, periodic body movements caused by inhaling and exhaling, such as chest expansions and contractions, can be extracted. The unique tag IDs enable monitoring of multiple patients simultaneously, making RFID technology a promising candidate for multi-patient breath monitoring. Our goal is to develop a prototype system using COTS RFID technology to accurately monitor breathing rates, even in rooms with multiple patients. This allows for consideration of various scenarios, such as the material of clothing, placement on bare skin, signal noise in the room, and unwanted vibrations. To ensure effectiveness, the prototype must handle these scenarios while remaining practical, user-friendly, and efficient. It should provide real-time data that is easy to interpret and can be integrated into larger patient management systems for seamless sharing of vital signs. Currently, we have developed code in Java to extract signals from the antenna and in Python to process the data. Using methods such as phase calibration, normalization, and filtering, we identify relevant data while discarding noise. Environmental factors have posed challenges, as signals sometimes fail to accurately reflect breathing patterns post-processing. To address this, we are testing the system in different environments to identify conditions that produce cleaner signals. The ultimate aim is a robust system capable of adapting to diverse environments and accurately monitoring breathing patterns, paving the way for broader clinical applications. By overcoming these challenges, RFID-based breath monitoring could become a valuable tool in patient care, offering a scalable, efficient solution for real-time monitoring in various settings.

Abstract Name: Mercury and Selenium in Round Goby from the Pennsylvanian Waters of Lake Erie and its Tributaries

The round goby (*Neogobius melanostomus*), an invasive species in the Great Lakes, accumulates harmful contaminants such as methyl mercury, due to its diet of zebra mussels (*Dreissena polymorpha*) and interaction with sediment. Methyl mercury's properties facilitate bioaccumulation in goby tissues, enabling trophic transfer to higher levels in the food web, potentially affecting significant fish species. Selenium, however, can reduce the bioavailability of mercury in the diet. A higher selenium-to-mercury ratio in tissues can mitigate mercury transfer. While mercury accumulation in round gobies has been documented in Lake Erie's western basin, little is known about levels in the central basin. This study assessed mercury concentrations and selenium-to-mercury ratios in round gobies from Pennsylvania's Lake Erie waters and tributaries. Round gobies were collected, euthanized, homogenized, and acid-digested for analysis. Mercury and selenium concentrations were measured using an inductively coupled plasma mass spectrometer (ICP-MS).

Preliminary findings showed gobies from Presque Isle Bay had the highest mercury levels (up to 17.3 ng/g), while those from other areas exhibited lower levels. Analysis revealed a decline in selenium-to-mercury ratios as gobies increased in size, resulting in higher mercury bioavailability. This raises concerns for native game fish that prey on gobies, potentially leading to mercury accumulation and human health risks through fish consumption. These findings highlight the importance of understanding contaminant dynamics and trophic

transfer in invasive species to protect aquatic ecosystems. Further research and management strategies are needed to address ecological and public health concerns linked to mercury bioaccumulation.

Abstract Name: Bad Blood, Good Guts? Inhibition of Apolipoprotein C3 Induces Increased Lymph Triglyceride Output and Intestinal Lipid Absorption

Heart disease is the leading cause of death in the world. A major predictor of heart attacks and cardiovascular disease (CVD) is accumulation of plasma triglycerides due to overproduction of apolipoprotein C3 (apoC3), an important regulator of triglyceride metabolism. As such, medication inhibiting apoC3 (e.g. Olezarsen®) is currently in clinical trials to reduce risk of CVD. Recent research determined that apoC3 inhibition by a liver-targeting anti-sense oligonucleotide (ASO) led to an unexpected increase in intestinal triglyceride output, suggesting that while loss of apoC3 in the liver may reduce liver-derived triglycerides, a compensatory effect occurs in the gut. We investigated this hypothesis using an apoC3 knockout (KO) murine model where we could directly test triglyceride secretion into the intestinal lymphatics. Our studies used 8–12-week-old male apoC3KO mice compared to age-matched C57BL/6J mice (n=9). Both groups were given an intraduodenal infusion of 3H-triolein in a lipid emulsion (SMOFLipid®) and mesenteric lymph flow was collected for 6-h post-infusion. Total lipids were then extracted from the gastrointestinal tissue. Using thin-layer chromatography (TLC) and enzyme-linked immunosorbent assay (ELISA), we determined the relative uptake and distribution of 3H-labeled lipid throughout the small intestine and lymph. Preliminary results analyzed using Student's t-test with $\alpha=0.05$ show a statistically significant increase in lymph triglyceride output in apoC3KO mice, confirming previous findings. Further, we found an increase in the appearance of 3H-triolein in the small intestine of apoC3KO mice (compared to C57BL/6J), indicating that in the absence of apoC3, dietary triglyceride is absorbed more quickly from the luminal to lymphatic space, or that enterocytes in apoC3KO mice package dietary triglycerides more efficiently than their wild-type counterparts. These outcomes suggest that treating hypertriglyceridemia with apoC3 ASO may increase intestinal lipid absorption, which could have significant clinical ramifications.

Abstract Name: Bridging the Gap in Parathyroid Research: Comparing Classic and Normocalcemic Hyperparathyroidism Using the TriNetX Database

Objective: Previous studies from single-institution cohorts have shown that patients with normocalcemic primary hyperparathyroidism (ncPHPT) are just as symptomatic as patients with classic PHPT. There is currently no large-scale database analysis of ncPHPT, so with the TriNetX database, a large international database, trends on ncPHPT can be studied over a large cohort of patients. The aim of this project is to characterize the diagnostic and treatment paradigm for ncPHPT in the TriNetX database. **Methods:** We conducted a retrospective cohort study of patients with ncPHPT using the TriNetX Research Network, which includes patients from 52 health care organizations from 2007-2023. ncPHPT was defined as having $PTH \geq 66 \text{ pg/mL}$ and calcium between $8.4\text{-}10.4 \text{ mg/dL}$. We excluded patients with secondary, tertiary, and classic hyperparathyroidism and other hypercalcemia inducing factors. **Results:** We found 5,092 patients with ncPHPT; 78.2% were female, average age was 69 ± 13 years, and 78.9% were white. The average serum calcium was $9.7 \pm 0.5 \text{ mg/dL}$, while the average serum PTH level was $97 \pm 77.5 \text{ pg/mL}$. Of these, 2,036 (40%) underwent a parathyroidectomy. Pre-surgery, calcium averaged $9.9 \pm 0.1 \text{ mg/dL}$ and PTH averaged $96 \pm 152 \text{ pg/mL}$. Post-surgery, calcium averaged $9.3 \pm 0.6 \text{ mg/dL}$, while PTH averaged $52 \pm 33 \text{ pg/mL}$. **Conclusion:** In this large multi-institutional cohort, the minority of patients with ncPHPT underwent a parathyroidectomy. Education about the benefits of surgery for these patients to these providers is needed.

Abstract Name: Effects of Modulating Bone Remodeling on Hematopoietic Stem Cell Expansion

The strong, positive correlation between aging and accumulation of somatic mutations has been well-documented in research. While most of these mutations remain inconsequential, if a cell does not repair this error before proliferation, it can become cancerous. Hematopoietic stem cells (HSCs) are a type of cell with the ability to duplicate and differentiate into all types of blood cells, including lymphocytes, monocytes, and erythrocytes. In rare circumstances, a mutation can arise in an HSC that creates a growth advantage, leading to the selective proliferation and overrepresentation of blood cells derived from these mutant “clones”. This process is known as clonal hematopoiesis, and mutations in genes involved in epigenetic regulation (TET2, DNMT3A, IDH2) are the major drivers of clonal hematopoiesis in humans. The medical term for the mutant expansion is clonal hematopoiesis of indeterminate potential (CHIP) where a mutated clone accounts for at least 4% of derived blood cells. Individuals with CHIP are at increased risk of developing hematologic malignancies, atherosclerosis, and myelodysplastic syndrome (MDS). HSCs mainly reside in the bone marrow, a dynamic heterogeneous environment characterized by cavities undergoing resorption and/or deposition activities. Cavities exhibiting both are known as M-type cavities, and these microdomains have been shown to support the proliferation of mutants specifically. Clinical data from TriNetX database on osteoporosis patients reveal that bisphosphonates, a class of drugs with anti-resorptive effect, reduce the risk for MDS. Using in vivo intravital imaging and peripheral blood analysis, we investigated the potential suppressive effect of zoledronic acid, the most commonly prescribed bisphosphonate, on inhibiting clonal expansion. While engraftment data from the peripheral blood analysis showed seemingly no suppressive effect, in vivo imaging depicted a clear decline in mutant clones, leading us to believe that secondary

hematopoietic organs like the liver and spleen may play a previously unaccounted role in clonal hematopoiesis.

Abstract Name: Collaborative Design: Effective Theming of Personalized Prosthetics

Vuillermin et. al. estimate congenital limb differences are present in approximately 5 in 10,000 children, with many rejecting prosthetic devices. Among pediatric users, a lack of aesthetic appeal is a significant factor contributing to rejection. To address this, Limbitless Solutions cultivates collaboration between users and designers to understand individual visions for personalized prosthetics, reducing the likelihood of rejection. This research explores the principles of effective theming, emphasizing artistic representation and user collaboration to create tangible outcomes from unique concepts. This proposal outlines an iterative design process for creating uniquely themed cosmetic sleeves, progressing through four stages: theme analysis, concept art creation, experimental paint development, and actualization. Instrumental to the application of this methodology is the active participation of users and a focus on translating preferences into tangible artistic outcomes. Select pieces are displayed in the Franklin Institute's Body Odyssey exhibit. This creative research was applied to the development of four uniquely themed cosmetics to showcase the iterative experience. The first integrates UV reactive paint to emulate the fluorescent patterns under black light in an arcade, using the design elements of variety, shape, and contrast to create visual dynamics. In the next, a light-sensitive color shifting pigment and stencils are used to mimic comic stylization. Harmony is created through an analogous color scheme and the use of pattern furthers variety on the cosmetic. The third draws inspiration from lava lamps using a glow-in-the-dark paint additive, organic shapes, and fluorescent colors to achieve visual contrast. Rounded shapes promote affinity throughout the cosmetic, while a tetradic color scheme creates contrast and movement. The final design employs weathering techniques modeled off character armor design, using texture and balance to further the narrative. By integrating user preferences into this design process, this research demonstrates how effective theming of personalized prosthetics can reduce rejection rates.

Abstract Name: Global Mosquito Observations Dashboard (GMOD): Advancing Mosquito Surveillance Through Citizen Science and Artificial Intelligence

Mosquitoes are recognized as the “world’s deadliest animal” according to the U.S. Centers for Disease Control and Prevention, posing as the leading global health threat, causing more fatalities than any other animal. Addressing this prevalent issue requires enhancing public awareness and strengthening mosquito control measures worldwide. Traditional mosquito surveillance and control methods, such as hand landing catch and natural repellents, are often time-consuming, costly, and lack scalability. In contrast, the widespread availability of mobile devices equipped with high-resolution cameras presents a unique method to approach mosquito monitoring. To leverage this potential, the Global Mosquito Observations Dashboard (GMOD) was developed as a free, public platform to improve the detection and monitoring of invasive and vector mosquitoes. GMOD is an interactive web-based application that collects and displays real-time mosquito observations and habitat data generated globally by citizen scientists. By integrating data from four data streams, the platform enables comprehensive visualization of mosquito population trends and geographic distributions worldwide. Furthermore, GMOD acts as an educational resource that highly promotes global data sharing and collaboration in mosquito management. With continuous data collection, GMOD has provided valuable and actionable insight into the distribution, abundance, and prevalence of mosquito species globally. This research aims to leverage the free platform to actively engage citizen scientists in community-based surveillance efforts, thereby expanding the global monitoring of mosquitoes. As GMOD continues to evolve, the integration of artificial intelligence for species identification holds significant promise to enhance public health initiatives in reducing mosquito-borne diseases, particularly in regions where traditional surveillance methods face challenges.

Abstract Name: ECLIPSE: Enhanced Containerized Lab Infrastructure for Platform-Independent Student Engagement Using Virtualization

The ECLIPSE Project addresses disparities in student access to computing resources in computer science courses. This applied research project explores the application of virtualized infrastructure and containerization to provide platform-independent, remote access to lab environments, creating equitable learning opportunities for students with heterogeneous hardware and software configurations. Current educational resources often depend heavily on students having specific hardware or software, creating an inequitable learning environment. Utilizing hypervisors, VLANs, and automated provisioning, the infrastructure delivers Virtual Machines (VMs) or containers tailored to specific course requirements in computer science. This approach provides a scalable solution that removes traditional educational platform barriers, allowing students to access the same consistent environment from any device. By automating the provisioning and management of virtualized resources, ECLIPSE enhances the speed of deployment, simplifies maintenance, and minimizes the need for specialized local hardware. Ultimately, this project aims to create a sustainable and inclusive infrastructure for computer science education that can quickly expand to other disciplines.

Abstract Name: Mentoring Interdisciplinary Undergraduate Research: Benefits and Challenges

A plethora of literature highlights the benefits of Undergraduate Research (UR), including the development of critical thinking, problem-solving, and communication skills. These skills are essential for preparing students for competitive employment. Employers increasingly seek recent graduates who can communicate effectively with people from diverse backgrounds and perspectives. Furthermore, problem-solving in the workplace has progressively shifted toward a team-based approach, often involving experts from various disciplines who bring different perspectives and expertise to the table. Furthermore, collaborating with colleagues from diverse fields fosters the development of integrated solutions. As the real world relies on a multidisciplinary workforce, this presentation addresses how faculty mentors from two disciplines bring their students to collaborate on an interdisciplinary project that benefits the community. The project began as an intervention aimed at improving children's social-emotional well-being within the community. The UR project covered a range of psychological topics, including parenting and gender roles, with a primary focus on helping children develop emotional intelligence and social skills while documenting their progress. Due to the impact of the pandemic, the project transitioned to virtual lessons, which highlighted the need for additional tools. This led to collaboration with a faculty in the field of Computer Science (CS). An undergraduate student in CS developed an emotional app designed for children and their families, while psychology students tested the effectiveness of this educational tool. The process required students from both disciplines to collaborate in the app's development and testing phases. This experience allowed them to appreciate the benefits of teamwork and work collectively on an interdisciplinary project. Since the project has multiple phases, it necessitates ongoing efforts over time. As such, there are challenges for faculty mentors to ensure that junior researchers can continue the project's momentum. More benefits and challenges will be shared and discussed at the upcoming conference.

Abstract Name: It Takes a Village: Strategic Planning and Administrative Support for UR Success

Higher education faces challenges in providing students with the broad knowledge and skills necessary to succeed in a fast-changing world. To effectively apply classroom learning to solve real-world problems, higher education needs to reimagine how to deliver high-impact learning. As Georgia's designated Public Liberal Arts University, Georgia College & State University (GCSU) prioritizes mentored undergraduate research and creative endeavors as part of its signature high-impact learning experiences called GC Journey. Early access to undergraduate research through collaboration with faculty mentors, has yielded long-term benefits. This approach guides students to actively explore their areas of interest while building research capabilities and developing critical thinking skills essential for employment and advanced studies. This presentation shares a model of how Undergraduate Research is integrated into a series of signature experiences valued by our university with administrative support. It requires students to graduate with five transformative learning experiences and high-impact practices. All students must participate in a first-year seminar and engage with GC Milestones, a career services program that spans all four years of their education. Students then choose three additional transformative experiences from the following options: undergraduate research, leadership, community-based engagement, internship, and study abroad. The goals of the session are: To discuss how to integrate UR and high-impact learning through administrative support. To

demonstrate how to embed undergraduate research in curricula and collaborate with faculty across disciplines. This presentation is tailored to faculty, staff, and administrators seeking ideas and/or solutions to create high-impact learning from mentored projects. The audience will be invited to share their strategic planning and experiences to facilitate a continuing dialogue about creating high-impact learning in undergraduate education.

Abstract Name: An AI-Driven Approach to Optimizing Academic Scheduling

Academic scheduling in higher education, particularly within highly interconnected departments such as mathematics and science, presents a complex optimization challenge with significant implications for student success and institutional efficiency. This research frames the scheduling process as an optimization problem, utilizing historical data and artificial intelligence (AI) to develop a mathematical model aimed at increasing enrollment, accelerating graduation timelines, and improving student satisfaction. The study leverages institutional data, including class enrollment trends, classroom availability, course co-enrollment patterns, and demand fluctuations, to construct predictive equations. AI techniques are applied to uncover patterns and constraints, facilitating the development of a robust optimization model. Using Python-based solvers, the model generates mathematically efficient schedules designed to support academic schedulers in making data-driven decisions. This approach highlights the potential to streamline academic operations while aligning institutional objectives with the needs of students.

Abstract Name: Intranasal Oxytocin and L-Dopa Alter Social Motivation in Mice as Measured by the Weighted Door and Ladder Task

Social motivation is a driver of social interaction and is reduced in multiple clinical disorders including ASD, depression, and schizophrenia. We recently developed and validated two measures of social motivation for mice: the ladder task and the weighted door task. These tasks require mice to exert increasing effort to access a social partner. The willingness to exert effort to access a social partner by performing increasingly difficult trials demonstrates their motivation for social interaction. We currently aim to demonstrate that social

motivation can be manipulated by altering oxytocinergic and dopaminergic activity. Male and female, adult C57BL/6J mice were administered oxytocin, L-dopa, or saline intranasally and then tested on the ladder task and weighted door task. In the weighted door task, oxytocin increased the frequency of approaching the weighted door in early trials with less weight. In later trials with higher weight, oxytocin groups approached the door with the least frequency. L-dopa administration was associated with maintaining a high frequency of door approach over the higher weights. Time spent pushing the door was higher in later trials when mice were administered L-dopa. In the ladder task, oxytocin administration produced the shortest latency to climb the ladder when at the earliest trials in which the ladder is horizontal. Oxytocin administration produced the highest latency in later trials with increased steepness. L-dopa administration resulted in sustained lower latency across the trials. Taken together, the intranasal administration of oxytocin is associated with increased social interaction when low effort is required and decreased social interaction when high effort is required suggesting a decrease in social motivation. However, L-dopa is associated with sustained motivation as required effort increases suggesting an increase in social motivation. Understanding the neurochemical basis of social motivation will further the development of pharmacological treatments for decreased social motivation in clinical disorder.

Abstract Name: How Tau and Etoposide Shape Microglia Activation in Alzheimer's Disease

Microglial activation plays a crucial role in neuronal death during Alzheimer's disease (AD). In healthy brains, homeostatic microglia maintain physiological immune responses and neuronal health. In AD, microglia respond to the accumulation of amyloid-beta (A β) and tau pathology by increasing their phagocytic activity and cytokine production. The initial neuroprotective microglial response becomes dysregulated and neurotoxic significantly. While the mechanisms behind this damage are known, the key factors that influence the microglial response in AD remain unclear. We aim to investigate how tau, A β , and other damaging stimuli affect the microglial response and subsequent neurotoxicity. We treated a mouse immortalized microglial (IMG) cell line with different tau isoforms ON3R and ON4R tau to mimic early increases in tau levels. IMG cells were also treated with etoposide to simulate the damage resulting from the failure in DNA repair mechanisms. In addition, we used a combination of lipopolysaccharide and interferon-gamma, pro-inflammatory, and interleukin-4, anti-inflammatory, microglial activation controls. All treatments were performed at 37°C for 24 hours. We then utilized flow cytometry to assess changes in the expression of markers associated with pro-inflammatory activation (CD11c, CD45). We also evaluated morphological changes through surface area quantification. Our results indicate that tau-driven activation leads to decreased CD45 and CD11c expression. Conversely, etoposide activation increased the CD45 expression. These findings were corroborated through surface area quantification, which showed increases in the area of cells treated with etoposide, a change not observed in tau-treated cells. Our findings suggest that the microglial activation phenotype promoted by tau does not exhibit changes typically associated with pro-inflammatory activation; instead, it appears to align more closely with an anti-inflammatory profile. Conversely, the microglial response to etoposide resembles the pro-inflammatory profile. This indicates that different AD-associated stimuli activate microglia in distinct ways, potentially resulting in differences in neurotoxicity.

Abstract Name: Targeting Hepatic E4BP4 to Treat Metabolic Associated Liver Disease

Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease in the US. 20% of these patients develop steatohepatitis and eventually progress to cirrhosis (scarring of liver), liver failure, or liver cancer. At the moment, there are no effective therapeutics. Our lab has discovered a critical role of hepatic E4BP4 in promoting the disease progression of MASLD. E4BP4 is a transcription factor that is originally implicated in circadian rhythm regulation. We found that decreased E4BP4 levels can lead to reduced liver injury, inflammation, and lipid accumulation in mice with fatty liver disease. What this suggests is that blocking E4BP4 may be a potential target to treat liver disease and slow down fibrosis progression. To uncover underlying molecular mechanisms, we want to generate a conditional knockout mouse model to express an E4BP4 mutant specifically in the liver using CRISPR gene-editing technology. We will design gRNA primers to delete E4BP4 using CRISPR technology. We will then insert the gRNA into our CRISPR Cas9 expressing plasmid and then insert the plasmid into an AAV vector which will let us knockout E4BP4 in-vivo. With our results we hope to show and validate the successful CRISPR mediated in-vivo knockout of hepatic E4BP4. In the future we hope to use this CRISPR system to knock out E4BP4 in mice and study the role of this protein in MASLD progression. A very long term goal would be one day putting this to clinical use in real patients, although the path remains a very long one.

Abstract Name: PenPal Cards: A modern way to share your research

In the fast-paced world of academia, effective networking and sharing research findings are essential for advancing knowledge and fostering collaboration. However, traditional methods—like exchanging paper business cards or distributing lengthy resumes—often fall short in meeting researchers' modern, digital needs. These outdated approaches make it challenging to share work, connect with peers, and build meaningful, long-term professional relationships. To address these challenges, we conducted a comprehensive study to develop PenPal Cards, a customizable digital tool tailored for academic professionals. Our research methodology involved interviews and surveys with over 200 researchers, academic professionals, and conference organizers. This extensive data collection allowed us to identify key pain points in academic networking and design a solution that meets these needs. PenPal Cards enable researchers to seamlessly share their portfolios—including publications, affiliations, and contact details—via a simple tap or scan. The tool also generates concise, shareable summaries of research and integrates with widely used platforms such as ORCID, Google Scholar, and ResearchGate. An analytics feature tracks engagement, providing insights into profile views and facilitating meaningful follow-ups with potential collaborators. Through iterative testing and deployment in academic environments, PenPal Cards have demonstrated significant impact. Early adopters reported greater engagement at conferences, improved follow-ups with collaborators, and enhanced visibility for their work. By creating a more accessible and impactful way to network, PenPal Cards are poised to transform how researchers connect and collaborate, ultimately fostering innovation and knowledge-sharing across disciplines.

Abstract Name: Analysis of Pain Scales for Multifactorial Assessment

Experiencing acute pain during childhood is common, but assessing the pain of pediatric patients can be difficult for healthcare professionals, and mis-assessment can lead to improper care and increased discomfort for the patient. Pediatric dentists use pain assessment scales to provide their patients with effective pain management and to track the effectiveness of this management over time. However, commonly used assessment scales, such as the Wong-Baker FACES pain scale, only assess pain intensity, a single component of an inherently multidimensional pain experience. Because the pain experience is individualized and subjective—affected by factors like intensity, discomfort/agitation, development, and culture—a multifactorial approach would create a better representation. This project aims to provide dental professionals with information on validated unidimensional assessment scales for different dimensions of pain. By compiling and analyzing existing literature, this project identifies and categorizes validated assessment scales based on the pain component measured and the relevant age group. Additional information such as reliability, validity, benefits, and drawbacks are summarized in a table. This study found that while a majority of assessment scales measure pain intensity, lesser known and used scales measuring other pain dimensions can be used in combination for more accurate assessment and appropriate treatment implementation. Dental pain varies depending on the cause, so which scales are used can be left up to the dental professional based on the situation and which aspect of pain needs to be assessed. Proper use of these scales aids the dentist in a more robust understanding of the patient's pain experience, setting up better communication and effective pain management.

Abstract Name: Patterns of Gene Flow Among Invasive Earthworm Populations

Earthworms are invasive to Minnesota, decreasing the species diversity of native forests. Little is known about how these worms spread and maintain their hold in Minnesota forests. Invasive species, like earthworms, usually start out as small populations with low genetic diversity, yet they are able to adapt and spread quickly. This is considered to be a genetic paradox since genetic variation in populations is necessary for adaptive evolution to occur. One way that populations can gain genetic variation is through gene flow—an evolutionary process that occurs when individuals from one population migrate and reproduce with individuals from another population. Gene flow among earthworm populations may occur through natural dispersal (individuals traveling on their own) or through human-assisted dispersal (through soil or bait). Natural dispersal by earthworms is limited by how far individuals can travel, and by barriers in their way typically causing a positive correlation to exist between geographic distance and genetic distance. In contrast, human-assisted dispersal/gene flow is not limited by the same constraints as natural gene flow, allowing

earthworm populations to become more genetically diverse and potentially breaking the correlation between geographic and genetic distance. This study investigated the relationship between geographical and genetic distance in earthworm species *Aporrectodea rosea* in Itasca State park. Using two allozyme genetic markers we genetically analyzed earthworms collected at known distances apart from 16m to 5km. We expected to see a clear positive trend that would align with natural gene flow. We found that there was a statistically significant positive trend between geographic distance and genetic distance. However, there remained a lot of variation within that trend that may suggest the impact of human activity. Understanding how earthworms and other invasives maintain their hold on the environments they inhabit is needed as we find methods to mitigate their spread.

Abstract Name: Analyzing the Influence of Personal and Professional Factors on Central Ohio Public High School Teachers' Attitudes and Practices Towards Students with Visible Limb Differences

Inclusive education is a critical component in teaching, particularly in creating environments where students with disabilities can thrive. This research investigates Central Ohio public high school teachers' attitudes and practices toward students with visible limb differences, focusing on personal and professional factors influencing these attitudes. While inclusive education has expanded significantly, particularly for students with physical disabilities, gaps remain in understanding teachers' specific experiences and preparedness to accommodate students with visible limb differences. This study addresses the gap by examining the attitudes, experiences, and educational backgrounds of secondary school teachers, particularly how these factors shape their confidence and ability to foster inclusive classrooms. Using a mixed-methods approach, data were collected through questionnaires distributed to 45 teachers and semi-structured interviews with 9 participants. The study identified correlations between teachers' years of teaching experience and their confidence in accommodating students with limb differences. Additionally, qualitative analysis revealed seven major themes from teacher interviews, including the role of personal experiences, approaches to modifications, and collaboration with special education professionals. The findings suggest that while teachers generally support inclusive education, their practical implementation strategies and confidence levels are significantly impacted by their previous interactions with individuals with disabilities and the professional development they have received. The implications of this research are twofold. First, it emphasizes the importance of targeted professional development and continuous education on accommodating students with physical disabilities. Second, it highlights the need for more research on specific disabilities, such as visible limb differences, as opposed to broader categories like physical disabilities in general. By exploring these specific experiences and perceptions, this study provides insights into improving teacher preparedness and enhancing inclusive education practices. The results will contribute to ongoing discussions about ways to support students with disabilities, ensuring that all students, regardless of their physical differences, have equitable access to education.

Abstract Name: The Investigation in *C. elegans* of Genes That Affect CMT Type 1 Disease

Charcot-Marie-Tooth (CMT) type 1 is a genetic disease that results from the damage of the myelin sheath, a protective cover of the nerves. This damage does not allow the nerve signals to be properly transmitted to the brain, leading to problems associated with movements and sensations. CMT type 1 is known to be caused by mutations in the human genes of PMP22, LITAF, and EGR2. *Caenorhabditis elegans* (*C. elegans*) are microscopic nematodes. The genes that cause CMT type 1 in humans are found to be similar to the *C. elegans* genes of *vab-9*, *F36G3.3*, and *EGRH1*. Mutation in these genes that cause CMT type 1 disease in humans can be observed in the *C. elegans*. The goal of this project is to perform experiments on *C. elegans* to find which specific genes contribute to CMT type 1 disease. To study how each gene affects CMT type 1 disease, the characteristics (swimming, crawling, number of body bends) of each mutant *C. elegans* with individual mutation of *vab-9*, *F36G3.3*, or *EGRH1* were observed. To study the effect of mutated genes on the worm's anatomy, each mutant *C. elegans* was mated with wild-type worms that had fluorescently colored nerve or muscle cells. Each offspring was observed under a fluorescent microscope. Comparing the fluorescently colored nerves and muscles of mutated and wild-type *C. elegans* will allow us to further determine how these genes contribute to the CMT type 1 disease.

Abstract Name: An In vivo *C. elegans* Model for Assessing Virulence of Food-borne Salmonella Pathogens

Salmonella bacteria are a major cause of foodborne illness in the United States, responsible for approximately 1.35 million infections and 26,000 hospitalizations annually. While the mechanism of some Salmonella strains' infections are well-characterized in humans, emerging variants require a deeper understanding of the molecular infection processes. *Caenorhabditis elegans* (*C. elegans*) presents a promising platform for this research, due to its established use as a model organism and the similarity of its intestinal cells to those of humans. By feeding *C. elegans* with strains of Salmonella isolated from previous outbreaks in the United States, this project aims to investigate the infection mechanisms of emerging pathogenic strains by modeling the differential kill rate. Results have indicated that *C. elegans* is well suited to modeling the nuanced differences between pathogenic strains, even genomically equivalent serovars isolated from different outbreaks. This is evidenced by the significantly different survival time experienced by worms feeding on each strain of bacteria. As an invertebrate, *C. elegans* provides a method of modeling foodborne pathogens, with the possibility of expansion into the modeling of other pathogens with implications in human health.

Abstract Name: Quantifying and Analyzing Microplastics in Northern Wisconsin Beach Sand Samples using National Oceanic and Atmospheric Administration Method

The unfortunate characteristic of microplastics is that they are everywhere, ranging from the human body to beaches. Their resistance to environmental decomposition and potential to absorb pollutants poses them a hazard for all organisms and environments. Therefore, studies were conducted to develop methods to recover and quantify microplastics from different sourced samples, including beach sand. In this experiment, a developed method produced by the National Oceanic and Atmospheric Administration (NOAA) was utilized and adapted to test for their efficiency in extracting microplastics, size of 0.3-5mm, from beach sand samples collected from beaches of Wisconsin's peninsula. Pink polyethylene microspheres, a microplastic typically used for cosmetic, industrial, or medical applications, were used as our example to test for the recovery rate accuracy of microplastics in beach sand. Based on NOAA's method, our samples first undergo density separation, which separates floating microplastics in a NaCl and lithium metatungstate solution from settled solids, such as sand and rocks. The floating solids pass through wet peroxide oxidation (WPO), which eliminates any organic material that may be present or attached to microplastics. It undergoes a second density separation to collect any floating solids, which is later identified under a dissecting microscope. A common trend in our results was the lack of pink microspheres appearing in the second density separation, which meant the method yielded little to no recovery rate. In addition, organic materials were still present, which was not wanted due to their potential to latch onto microplastics, making identification difficult. There were some signs of pink microspheres with the settled solids instead of the floating solids, meaning WPO could cause microplastics to attach to the settled solids. Overall, adjustments to the NOAA method must be made to investigate where microspheres may have gone and if this impacts other microplastics found in beach sand samples.

Abstract Name: Political orientation and Global Crises: How political orientation Affects Awareness of Children in Conflict

This study explores how political orientation influences the awareness and perceptions of humanitarian crises affecting children in conflict zones around the world. Specifically, it examines the correlation between individuals' political views, ranging from liberal to conservative, and their recognition of how wars and civil unrest affect vulnerable populations, particularly children. The research situates individuals within the political spectrum, focusing on key issues in contemporary U.S. politics such as abortion, immigration, international relations, and climate change to assess whether and how these ideological stances shape empathy and concern for global humanitarian crises. Through survey methods, participants are asked to indicate their relative positioning on these issues, and their awareness of attitudes toward the plight of children in conflict zones is evaluated. The questionnaire will include questions to assess participants' awareness and engagement with the Russo-Ukrainian War and Israel-Hamas War as well as the exposure to news reports about children affected by war. This study aims to contribute to the broader understanding of how domestic political divisions may extend to global issues and potentially influence public support for international humanitarian efforts. The findings may provide valuable insights for academic institutions, researchers international agencies, and non-governmental organizations working to bridge political divisions

and promote greater awareness constructive discussion, and social engagement with respect to global child welfare issues.

Abstract Name: Metacognium: A Novel Neuroscience-Informed Psychoeducation Program for Substance Abuse

Substance abuse is prevalent among college students, with nearly half meeting the criteria for alcohol or cannabis use disorder within their first three years. During this critical age of adolescence, neurobiological alterations make young adults more prone to pursue impulsive, maladaptive coping behaviors such as substance abuse, which in turn detrimentally impact neurodevelopment. To prevent these implications and the emergence of substance use disorders (SUDs), there is a need for a comprehensive prevention and intervention program informed by neuroscience tailored to adolescent populations that translates our understanding of the neurobehavioral basis of addiction. Metacognium is a novel neurocognitive program designed to enhance metacognitive awareness, cognitive resilience, and stress-coping skills, thereby preventing substance misuse. Delivered via mobile and web platforms, it combines psychoeducation with game-based training targeting cognitive functions like impulse control, emotion regulation, stress management, and problem-solving. This program offers students evidence-based psychoeducation on key neurocognitive functions implicated in substance use and cognitive components of resilience and instructs participants on how to implement metacognitive and compensatory strategies within the context of real-life scenarios that involve substance use. A preliminary study was conducted on students at VCU, which involved delivering this application and assessing its clinical potential by conducting pre- and post-intervention assessments. Among participants (n=68), 55.9% reported alcohol use, 47.1% cannabis use, and 16.2% tobacco use prior to the intervention. After engaging with Metacognium's sessions, participants demonstrated a statistically significant increase in metacognitive awareness and delay discounting alongside a significant decrease in alcohol intention intoxication, anxiety, and depression levels. Future enhancements include integrating additional Research Domain Criteria-based modules, cross-cultural adaptations, and daily exercises to reinforce neuroscience-based practices in everyday life. Metacognium demonstrates promise as an accessible, evidence-based approach to mitigating substance misuse among adolescents.

Abstract Name: Exploring Sustainability Education in Babson's First-Year Entrepreneurship Course

Sustainability is often not emphasized enough in business courses for students to learn how to solve business problems with an ecological mindset. As such, entrepreneurial courses need the appropriate frameworks and teaching methodologies to enable students to understand what being sustainable means and how to embed it

in their decision-making. By studying examples of how professors teach sustainability in Babson College's Foundations of Management and Entrepreneurship (FME) course, this project hopes to synthesize and suggest ways for professors to better engage students in learning about social and environmental sustainability and applying those concepts. This study considers how sustainability can be successfully embedded into a disciplined-based course, rather than a short-term course or program. It considers both professors' and students' perspective. The results are based on the quantitative and qualitative analysis of interviews and surveys with 14 professors and 11 sections of students during the Fall 2024 semester of the first-year entrepreneurial course (where teams of students develop and propose business ideas and the three most-voted-on ideas in each section are launched as real businesses in the Spring semester). More than 200 student survey responses were collected in the beginning and end of the semester. In addition to these, an analysis of the business ideas developed by all 18 sections of students during the first semester was conducted to understand how students incorporated ideas of social and environmental sustainability. FME Professors who 1) emphasize sustainability throughout the semester, 2) provide strong value propositions of why students should care about sustainability and 3) effectively implement diverse methods of teaching sustainability, will result in students caring more about it and implementing such ideas into their ventures. Their teaching methods should be applied for other FME courses to more effectively engage students in learning about social and environmental sustainability.

Abstract Name: Exploring the Associations between In-Person Peer Rejection and Online-Only Friendships for Sexual and Gender Minority Youth

When transitioning to adolescence, youth shift from viewing family as a primary source of support to relying more heavily on their friends for support. This is especially true for sexual and gender minority (SGM) youth, who face higher levels of in-person social threat, such as increased peer rejection, discrimination and victimization. These youth may not be able to safely turn to those around them for social support and may find other ways to gain friendship support. Online-only friends (OOFs) can provide additional social support for adolescents who may face higher levels of in-person peer rejection. SGM youth, who may experience higher levels of peer rejection, may be more likely to seek friends online and may engage in more intimate disclosure with these online communities. The current study aims to explore the associations between SGM youth's experiences with OOFs and the levels of in-person peer rejection they experience. Because of the mix of positive and negative online experiences SGM teens can have with OOFs, it's important to keep exploring whether this vulnerable group has more OOFs and considers them supportive. We hypothesize that levels of in-person peer rejection will have an indirect effect on the link between SGM status and OOFs, such that SGM youth will have higher in-person peer rejection which in turn will predict likelihood of having OOFs. We also hypothesize that among those with OOFs, SGM youth will have higher levels of intimate disclosure with OOFs than their non-SGM peers. This study will add to the growing literature about OOFs, and specifically SGM OOF experiences on social media, which opens the door for future research on the role of supportive OOFs have for SGM teens

Abstract Name: Microsoft Copilot Accurately Extrapolates SRS-22r Pain and Management Satisfaction

Outcomes based on Clinical History

Introduction: Patient-reported outcome measures (PROMs) play a crucial role in spine surgery research. However, maintaining a robust database presents logistical challenges, including the need for data vendors and research coordinators, often resulting in missed assessments. Artificial intelligence (AI) chatbots, like Microsoft Copilot, may offer a free solution by predicting patient outcomes based on clinical history. This study evaluates Microsoft Copilot's ability to predict a patient's preoperative quality of life using provider-documented patient history. **Methods:** Copilot was given de-identified preoperative notes from patients with spinal deformity (n=29) who underwent surgical correction and was prompted to predict five SRS-22r subscores. Paired t-test analysis was utilized to then compare these AI-generated subscores against the patients' actual SRS-22r sub-scores to assess for variance. **Results:** Of the five subcategories, the analysis failed to detect a significant difference between the patient-reported pain score (2.39 +/- 0.63) and Copilot-generated pain score (2.21 +/- 0.56; p = 0.39). Paired t-test was also unable to detect a significant difference between the patient-reported management satisfaction score (2.9 +/- 1.0) and Copilot-generated management satisfaction score (2.90 +/- 0.67; p = 0.9845). The remaining SRS-22 subcategories (mental health, function, and self-image) showed a significant difference between patient-reported and Copilot-generated scores (p < 0.05) suggesting that Copilot is unable to predict these with equal variance. **Conclusion:** No significant differences were found between patient-reported and Copilot-generated SRS-22r pain and management satisfaction subscores, indicating that chatbots may offer a viable and feasible retrospective method of PROM collection. This approach could be especially beneficial for low-resource institutions looking to develop a research enterprise.

Abstract Name: India in the Middle: India's Behavior across Formal and Informal Organizations

India's rising influence as a middle power has the potential to contribute to the transformation of international organizations and the dynamics of the international system. India's foreign policy centered on non-alignment has allowed it to advance its position through building relationships with diverse sets of countries. However, how these varied relationships, positions, and engagement objectives differ across organizational settings (e.g. formal versus informal) remains unclear. This research project uses India as a model to understand how emerging state participation and behavior differ across formal and informal organizations. Using BRICS and the United Nations General Assembly (UNGA) as prototype informal and formal organizations, respectively, this study uses hypothesis testing and document content analysis to evaluate India's health and environmental policy from 2021-2023. The hypotheses test India's behavior through its engagement with leadership, institutional reform, research and technology, international relationships, and colonial history. The research study finds that in BRICS, India uses health and environmental policy to strengthen its leadership as a representative for the Global South and motivate international institutional reform. However, in UNGA, India prioritizes its own agenda and role in the international system, relying on technological and research advancements and a specific interest in reforming the United Nations Security Council. This study finds that India is using different methods to grow its power across, and in both, informal and formal international organizations as evidenced by its engagement with leadership, reform of traditional institutions, and technology.

Abstract Name: Redefining Accessibility in Museum Spaces: Methodologies and Practices for a More Inclusive Future

Our presentation assesses Creativity in the Time of COVID-19: Art as Medicine, an exhibition drawing on a database of art collected between 2020 and 2022 in response to the Covid-19 pandemic. We examine the showcase done by the Digital Humanities and Literary Cognition Lab (DHLC) at Michigan State University in the Fall of 2024 to determine how successful we were in creating a uniquely inclusive space and further using it as a case study for accessibility in museum spaces at large. Our exhibit was structured around an accessible design philosophy that goes beyond ADA compliance to connect diverse audiences to our archive. The DHLC actively sought to platform artists from BIPOC, LGBTQIA+, disability, and international communities to reflect the diverse nature of responses to COVID-19. We also selected art pieces representing a range of sensory modalities to accommodate varied access needs and preferences. Alongside these selections we provided audio descriptions for visual impairment, tactile artworks for multisensory engagement, audio captioning for aural impairment, and a respite space to promote the mental wellbeing of our visitors. We also ensured the gallery prioritized adequate space for mobility aids. To evaluate the success of the exhibit at depicting diverse pandemic experiences through highly accessible art, the DHLC gathered visitor feedback through an online survey accessed via QR code and written responses from artists, keynote speakers, and accessibility experts. We analyze this feedback and synthesize it into an effective action plan for coordinating future exhibitions. Our methods, including the iterative improvements based on feedback responses, can be applied to various learning and exhibition spaces. The results of this exhibit demonstrate how accessibility benefits all visitors, enriching museums by redefining how art can be experienced and appreciated in a more inclusive future.

Abstract Name: Spatially Resolved Mechanical Properties of Glass Fiber Reinforced Thermoplastic Composites for Automotive Applications

Fiber-reinforced composites (FRCs) are attractive to the automotive industry due to their high specific strength, low weight, resistance to corrosion, impact, and wear. FRCs reinforced with glass fiber yield superior mechanical and physical properties including excellent tensile strength, stiffness, and low density. However, a comprehensive process-structure-property for FRCs on multilength scales is not well understood. Manufacturing processing considerations such as fiber length, orientation, and defects such as voids can largely influence the resulting mechanical behavior of the part. Tensile properties evaluation involves subjecting a FRC material to an uniaxial force in tension until failure, providing key data such as tensile modulus, strength, and strain. Digital image correlation (DIC) is an increasingly used non-contact full-field

strain measurement technique tracking surface displacement through high-resolution imagery, affording the ability to measure local strain variations along the gage section of the tensile part and identifying local stress concentrations as the part is subjected to tensile loading. These local variations result from changes in fiber volume fraction and alignment and matrix-rich regions along with possible occurrence of porosity. In this work, glass fiber-reinforced polypropylene composites are evaluated for tensile properties using DIC to measure tensile deformation behavior as a function of strain evolution. Also, high-resolution X-ray computed tomography is used to visualize and obtain qualitative information on the fiber bundle and resin composition within the composite material. These initial results composites show promise for further development of the structure-property relation of FRCs.

Abstract Name: College Students Opinions on Workers unions, Minnesota and Wisconsin

Unionization efforts in the workplace have made the news in recent years, with the very public writer and actor strike in 2023 and ongoing efforts to unionize service industry jobs. Gen Z has been at the forefront of efforts to unionize service industry jobs for organizations such as Starbucks and Amazon. An article by the Center for American Progress found that Gen Z is more supportive of unions than any other generation, with a mean approval rating of 64.4% (Glass, 2023). This paper analyzes survey data collected from University Wisconsin-Stout undergraduate students to see what level of support unions exist at the college level and what specific factors may cause this increase in support. The research found significant support for unions at the college level, with 90% of students feeling somewhat positive, positive, or neutral towards unions and 60% viewing unions as Positive or somewhat positive, aligning closely with the results from previous literature. Factors such as gender, knowledge, previous work with a union, and state of origin were found to be statistically significant predictors of view of workers' unions at the .05 level.

Abstract Name: The Loneliness Epidemic and Political Alignment, Exploring How Politics Influence the Social Connections of College Students

In the United States, the positions of the Democrats and Republicans have become more divisive, increasing polarization and partisanship among the American public. Alongside this trend, we have also seen an increase in Americans reporting experiencing loneliness. Could the growing partisan divide contribute to a person's sense of being alone? Through analysis of an original survey, results indicate a correlation between Ideology, political party, and feelings of loneliness. Those identifying as Republican or having a conservative ideology had lower levels of loneliness compared to Democrats or those with more liberal ideology. Part of this loneliness may be from Democrats' feeling uncomfortable or unsafe around those with more right-leaning ideology, leading to a greater willingness to cut people off or avoid others based on political affiliations. Democrats were more likely than those from any other political party to report they had cut someone off due

to politics. However, in interviews, people described avoiding friends as mutual rather than one person cutting the other off. This may indicate that conservatives may be cutting people off at similar rates but citing different reasons than “political affiliation.” This research suggests that, in a polarized political climate, relationships can suffer and contribute to loneliness. Finding ways to bridge partisan divides might have broader positive impacts in terms of individual well-being.

Abstract Name: Making Meaning Out of Learning: a Rhetorical Analysis on Medical Pedagogy and Its Contributions to Physician Bias

Rhetoric studies the construction of meaning through language, and exists in every realm of discourse. This concept extends to pedagogy, in that the rhetoric of educational material shapes how students apply this knowledge later on. While this relationship is not inherently harmful, one must consider how rhetoric can be applied when constructs such as sexism and racism permeate into systems of learning, particular in medicine. Research demonstrates that across different demographics, there tends to be discrepancies in treatment and care based on preconceived notions that medical providers hold, some starting from pedagogy. My research, therefore, attempts to identify exactly how educational language can contribute to physician bias. To determine this relationship, I will conduct a rhetorical analysis of medical textbooks and observe how they attend to two particular topics: pain, and cardiovascular disease (CVD). I will parse through two separate texts and consider how information is presented, and then compare my findings to current research that suggests different outcomes for women and people of color. At the time of this proposal, I have found particular cases of biological differences not being considered when discussing cardiac exams, which I have linked to poorer accuracy for cardiac exams on female patients. I have also found gaps in consideration for social determinants as a factor in medicine, and hope to extend this further as I proceed with my research. By observing these two topics and how rhetoric tactics are used to discuss them, I hope to track how language shapes medical discourse, and in turn, possible avenues of bias. This project aims to not only apply a rhetorical perspective on current medical pedagogy, but also encourage the considerations of the humanities when developing medicine, particularly so that no marginalized population gets left behind.

Abstract Name: Association Between Area Deprivation Index and Subarachnoid Hemorrhage Risk Factors

Subarachnoid hemorrhage (SAH) is a life-threatening hemorrhagic stroke caused by bleeding in the brain's arachnoid space. While global incidence has decreased due to reductions in SAH risk factors, they have not been reduced in all areas, and socioeconomically disadvantaged populations still experience higher SAH incidence. This study examined relationships between measures of socioeconomic status (SES) and SAH risk factors in a single stroke center. We hypothesized that lower SES would be associated with higher rates of hypertension (HTN), diabetes (DM), tobacco, alcohol, and drug use, and a higher body mass index (BMI). Demographics and past medical history, including HTN, DM, tobacco, alcohol, and drug use, and BMI, were obtained from the patient, family, or record. Tobacco was recorded as no/never and yes/quit. BMI was categorized using WHO standards as low, normal, overweight, and obese. The area deprivation index (ADI), obtained from the University of Wisconsin School of Medicine Neighborhood Atlas and patient zip codes, was used as a measure of SES, with higher scores indicating increased deprivation. This retrospective analysis of 215 SAH patients (mean age 54 years, 76% female, 84% white) used logistic and linear regression models to examine ADI measures (state decile, national percentile) and rates of risk factors controlling for race, gender, and age. Significant relationships between ADI and tobacco use were identified: a one-unit increase in ADI state decile raised the odds of tobacco use by 1.2345 times ($p < 0.001$), and a one-unit increase in ADI national percentile increased the odds by 1.0258 times ($p < 0.001$). No associations were found between ADI and HTN, alcohol and drug use, BMI, or DM. This analysis suggests that individuals from more deprived areas have higher rates of tobacco use, emphasizing needs for targeted patient education to reduce SAH risk and diseases associated with similar risk factors.

Abstract Name: Cell Sources of Donor-derived Extracellular Vesicles that Elicit Transplant Rejection

Transplantation involves grafting donor organs, tissues, or cells into a recipient, but rejection can occur when the recipient's T and B lymphocytes in secondary lymphoid tissues (i.e. lymph nodes and spleen) recognize the transplant's foreign proteins (allo-antigens) and initiate an immune response against them. Recent studies have shown that donor allo-antigens are released cell-free from transplants (allografts) via secretion of small extracellular vesicles (i.e. exosomes) that traffic to secondary lymphoid tissues where they initiate the anti-donor immune response. The goal of my project is to investigate in mice the lineage(s) of the cells in allografts that release the vesicles that promote transplant rejection. This will lead to an understanding of the mechanism of communication between allografts and the recipient's immune cells through graft-derived exosomes, so that future donor-specific therapies can be developed to prevent rejection. I will use a mouse model of skin transplantation to test whether graft-derived parenchymal cells (e.g. keratinocytes), endothelium, or antigen-presenting leukocytes (e.g. dendritic cells) are the source(s) of donor-derived exosomes that carry allo-antigens to the graft-draining lymph nodes. Exosomes released by these specific cells in skin allografts will be tagged with red fluorescent protein (RFP) linked to the exosome-specific protein CD63, in a transgenic mouse model generated in my mentor's laboratory. RFP expression will be targeted to exosomes released only by a specific cell type in each mouse line. I will perform skin transplants on BALB/c mice with these cell-type specific RFP-CD63 C57Bl/6 donor mice. Two days after surgery, detection and quantification of uptake of graft-derived RFP⁺ exosomes by the recipient immune cells in the graft-draining (brachial) lymph nodes will be done by immune-fluorescence confocal microscopy on tissue sections. The presence of RFP⁺ exosomes in the graft-draining lymph nodes after transplantation will allow us to pinpoint the cell types of the skin allografts that release the exosomes.

Abstract Name: Art Criticism Activity: Look Out, Look In, Look Forward

As future art educators, an important part of our job is to critique art and engage students in the process of critiquing. We have designed a new format to use as a tool and guide when considering a work of art. This model uses simple terms to reflect on the aesthetics, meaning, and potential future of a work. Because we are observing visual art, we will focus on the sense we use the most: sight. To think more deeply about a work of art, we invite students to “Look Out, Look In, and Look Forward.” First, the student looks at the exterior of the piece, then reflects on their inner thoughts and feelings, and finally expands into alternative ideas.

Abstract Name: Investigating Interactions Between Bacteria Infecting Patients With Cystic Fibrosis

Cystic Fibrosis (CF) is an autosomal recessive genetic disorder characterized by mucus buildup in the lungs, leading to chronic bacterial infections that drive high morbidity and mortality rates. *Staphylococcus aureus* (SA) and *Pseudomonas aeruginosa* (PA) are the primary pathogens in CF lung infections, with SA more common in younger patients and PA predominating as patients age. Co-infection with both bacteria is associated with a rapid decline in health, yet the mechanisms of this interaction are not well understood. This study aims to investigate interactions between clinical isolates of SA and two PA strains—PAO1, a wild-type strain that typically kills SA, and PDO300, a strain known for its ability to coexist with SA. A control SA strain, JE2, is used to validate PA behavior. SA clinical isolates are cultured alone and in combination with each PA strain, with survival assessed through cell counts after 24 hours. SA survival is measured as fold change, with a 100-fold decrease in survival considered indicative of significant killing. There are three distinct responses among the clinical SA isolates: isolates killed only by PAO1, isolates eliminated by both PA strains and isolates that survive coculture with both strains. So far, out of 14 SA isolates tested, five have been found to be killed by PAO1 only, five were killed by both, and four to coexist with both PA strains. Additionally, this research aims to deepen the understanding of how SA and PA coexist and contribute to mucus buildup and chronic infection within the CF lung environment, ultimately guiding the development of more effective treatments to prevent lung function decline in CF patients.

Abstract Name: The Effect of Ultrasound-Targeted Microbubble Cavitation on Microglial Activation and Amyloid-Beta Clearance in an In Vitro Alzheimer's Disease Model of the Blood-Brain Barrier

Alzheimer's Disease (AD) is a devastating neurodegenerative disease that affects millions of Americans. Among other pathological hallmarks, AD is characterized by a buildup of amyloid-beta ($A\beta$) aggregates in the brain. Unfortunately, there is currently no cure for AD and treatment options are limited. One of these limitations is the blood-brain barrier (BBB), which decreases the therapeutic efficacy of potential treatments by inhibiting their brain permeability. Ultrasound-targeted microbubble cavitation (UTMC) causes transient BBB hyperpermeability and has shown great promise for improving drug efficacy in humans. Microglia are the resident immune cells of the brain, they play an important role in AD because they are responsible for clearing $A\beta$ from the brain via phagocytosis. However, $A\beta$ is known to cause microglial pro-inflammatory activation which can promote neurotoxicity and cause further cognitive decline. UTMC has been shown to affect microglia, but the relationship between $A\beta$, microglia, and UTMC is poorly understood. This project studies the effect of UTMC on $A\beta$ uptake by microglia and clearance across the BBB, and its impact on microglial inflammation. I developed an in vitro co-culture transwell model of the BBB to study the interaction with microglia proximal to the endothelial monolayer that comprises the BBB. I aim to determine whether UTMC increases microglial uptake of $A\beta$ via immunofluorescence imaging. I also aim to elucidate the inflammatory response of microglia to UTMC through quantitative polymerase chain reaction and have shown that UTMC promotes inflammation. I hypothesize that UTMC induces microglial inflammation as well as increased uptake and clearance of $A\beta$. Due to the pivotal role of microglia in AD and the emergence of UTMC as a promising therapeutic for the treatment of AD, studying the effect of UTMC on microglia in this context is important to predicting both its safety and potential therapeutic benefits.

Abstract Name: Moth wing flexural stiffness is tuned to flight behavior

Insect wings are flexible appendages deforming under applied force, critical for aerodynamics, stability, and sensation. Wing deformation patterns are dictated by wing flexural stiffness, which quantifies the bending

magnitude of an object due to an applied force. Across insects, wing flexural stiffness increases with wing size; however, interspecific variation in locomotor behavior may independently impact flexural stiffness. For example, fishes swim utilizing flexible fins, and fin stiffness is strongly influenced by species-specific locomotor behavior. Like fishes, insect locomotor behaviors are highly variable. This study examines the relationship between flight behavior and wing stiffness using species from two moth sister-families known for differences in flight behavior, hawkmoths and wild silkmoths. Hawkmoths, flying with long, slender wings at high frequencies, are hypothesized to use stiffer wings than silkmoths, which use short, square wings at slow frequencies. To test the hypothesis, stiffness along the span (length) and chord (width) of each forewing and hindwing of 14 hawkmoths and 34 silkmoths was measured in vitro using a force transducer. Consistent with existing literature, forewing and hindwing flexural stiffness increase with wing size. For a given wing, spanwise stiffness is greater than chordwise stiffness and forewings are stiffer than hindwings. Significantly, when comparing the sister-families, hawkmoths utilize stiffer wings than silkmoths, supporting the hypothesis that interspecific differences between flight behavior and wing flexural stiffness are correlated. In both families, a direct relationship exists between wing shape (aspect ratio, AR) and stiffness, and silkmoth wings are stiffer than hawkmoths at a given AR. These results demonstrate that wing size and shape have different relationships with stiffness, suggesting unique and complex wing deformation patterns between silkmoths and hawkmoths. Thus, wing stiffness and deformation are features contributing to the divergent flight behavior between these two moth families.

Abstract Name: Nanopore sequencing as a tool supporting taxonomic research in historically neglected marine micromollusks

Natural product-derived compounds offer exceptional chemical diversity compared to those artificially synthesized. Marine micromollusks, defined as mollusks less than 1 cm in shell size, represent an untapped source of these compounds. Despite their ecological significance, micromollusks remain understudied—particularly in Southeast Asia, a region characterized by high marine biodiversity. Given the bioprospecting potential and the lack of systematic research on Southeast Asian micromollusks, there is a pressing need to implement Operational Taxonomic Units (OTUs) and catalog the biodiversity of these organisms. In the Philippines, local fishermen often collect micromollusks using a traditional method known as lumun-lumun, which involves creating artificial microhabitats for mollusk larvae settlement by placing nets in different water depths. Our study leveraged nanopore DNA sequencing technology to identify micromollusk specimens collected using the lumun-lumun technique in the Philippines over the past decade. From 68 lumun-lumun specimens, we successfully obtained mitochondrial DNA sequences (~658 base pairs) from 23. Those sequences were matched with the NCBI BLAST (Basic Local Alignment Search Tool) to three mollusk families and 8 OTUs: Triphoridae (n=1), Cerithiidae (n=4), and Columbellidae (n=3). This research highlights the efficacy of our in-house nanopore sequencing pipeline to overcome taxonomic ambiguities in historically understudied marine micromollusks. The barcoding approach supplements traditional morphological classifications, providing an integrative framework to enhance biodiversity cataloging. Furthermore, our findings support the exploration of bioactive compounds in these organisms, offering critical insights into potential pharmacological applications. Our work bridges traditional knowledge and modern molecular techniques, setting the stage for future discoveries in natural product pharmacology while promoting the conservation of marine biodiversity.

Abstract Name: Modeling JWST Observations of Protoplanetary Disk Outflows with RADMC-3D

Young stars are surrounded by protoplanetary disks that must shed angular momentum via outflows to sustain the process of star formation. The dynamics governing protoplanetary disk outflows are not very well understood, although theory indicates they may be magnetically driven. The high resolution of the James Webb Space Telescope (JWST) has allowed to observe these disk outflows and infer their morphologies and origins. We have created a program to model H₂ emission from protoplanetary disk outflows using the radiative transfer software RADMC-3D. This program allows users to input parameters for the star and disk, generate models based on magnetohydrodynamic outflow theories, and compute synthetic images and fluxes of H₂ emission. We used our program to model JWST observations of the HH30 protoplanetary disk outflow, deriving key parameters such as the mass-loss rate. Here, we present our model of the HH30 H₂ outflow and its morphology, highlighting the broader implications of modeling molecular emission in high-resolution outflow observations. As more data from JWST becomes available, these modeling methods will provide deeper insights into the physics of protoplanetary disk winds.

Abstract Name: Silenced and Sidelined: Examining the Intersectional Impact of Ableism and Racism on Maternal Health

While access to maternal health services and technologies have increased for some over recent years, historically marginalized and oppressed populations in the United States are still facing barriers to quality care. Women of color and disabled individuals have faced reproductive oppression, such as forced sterilization and inadequate healthcare, often rooted in traditional views of who is considered a "fit" mother. The reproductive justice framework provides an in-depth perspective on the roots of health inequity as it relates to reproductive health and highlights advocacy, social justice, and human rights. There is currently a lack of research on the outcomes and experiences of disabled birthing persons. This study will utilize the PRAMS data to analyze the adverse maternal health outcomes of disabled birthing persons, especially those who are located at the intersection of ableism and racism. Using STATA, the analysis will calculate the prevalence of adverse maternal health outcomes, examine differences by ability status and racial identity, and explore their intersection. Preliminary findings support disparities in maternal health outcomes by race and ability status. We hypothesize that the rates of adverse maternal health outcomes will be higher among non-white birthing persons across the varying levels of ability status for gestational diabetes, premature rupture of membranes, and hypertension, with racism having a stronger impact. This project will highlight the impacts of racism and ableism, contribute knowledge on maternal health disparities, and contextualize findings using

a reproductive justice framework. Findings of this study seek to inform evidence-based practices in the field of maternal health and improve health outcomes for birthing persons with various racial identities and abilities.

Abstract Name: Impulsivity regulation through COMT Val158Met gene expression in relation to substance abuse, mental health, and risk for adverse life events

This study examines the relationship between impulsivity and mental wellbeing. Previous studies show that high impulsivity can have drastic social/economic consequences (Schutte et al., 2023). Because poor impulse control may increase substance abuse and negatively affect finances/social activities, impulsivity may increase stress, anxiety, and depression (Du et al., 2023). Thus, impulsivity likely increases drug use and traumatic adverse life experiences which increases stress, anxiety, and depression. Dopamine is a key neurotransmitter involved in impulse control and other neural functions (Bondrescu et al., 2024). Dopamine reuptake rates may be regulated by the COMT Val158Met rs4680 gene (Bondrescu et al., 2024). Given the genotype may affect a person's dopamine reuptake and impulsivity, the COMT genotype is predicted to have a relationship with impulsive decisions and propensity for engaging in high-risk behaviors. Faster dopamine reuptake may leave the brain with lower dopamine levels which may lead participants to artificially raise dopamine levels through substance use or other negative sensation-seeking behaviors. Participants took surveys to assess previous adverse life experiences (Life Events Checklist; LEC), substance use (Alcohol, Smoking, and Substance Involvement Screening Test; ASSIST), depression, anxiety, and stress (Depression, Anxiety, and Stress Scale; DASS-21). A delay discounting task (millisecond.com) measured impulsive decision making. Participants provided a saliva sample for DNA extraction, allowing analysis of COMT Val158Met genotype expression. Our preliminary analyses ($N = 88$) show a positive relationship between frequency of negative life events (LEC) and substance use, ($r(83) = .35, p = .001$). Additionally, a greater number of adverse life events (LEC) suggests higher stress ($r(87) = .26, p < .05$) and anxiety levels ($r(86) = .26, p < .05$). Data collection and analysis is ongoing. We hypothesize that impulsivity is regulated by COMT gene expressions, and that increased impulsivity would affect participants' substance abuse, mental health, and risk for adverse life events.

Abstract Name: Building a Community of Mentors and Scholars

The Franklin College Department of History cultivates undergraduate research using a holistic approach where each faculty member serves as a mentor for each major across various stages of development. The curricular design provides intentional sophomore, junior, and senior coursework that enables students to hone their independent research, writing, and presentation skills, while they also build their own supportive community of scholars. Beginning with their sophomore public history course, students participate in a community-facing group project that fosters professionalism, confidence, and awareness of archival research. Often supported through grant projects, these public history projects expose students to resources that support research, as well as a broad understanding of scholarly work. In a re-imagined junior-level course, students grapple with historiographic understandings of the past, as they develop their own research questions. Every department faculty member provides constructive feedback on the initial prospectus and its presentation as these students transition to their senior research seminar. Their efforts to produce original scholarship require independent research, peer collaboration, and faculty mentorship. Recognizing the diverse range of strengths and abilities, the history program provides one-on-one faculty mentorship, while encouraging students to rely on each other for support, guidance, and feedback. Cultivating a culture of mentorship and celebration around undergraduate research has become an intentional focus of the history department. Highlighting opportunities to build relationships among students within cohorts has led to increasing efforts to create activities that bridge cohorts, so that, for instance, seniors provide guidance for juniors and sophomores and juniors celebrate seniors. This culture has increased the level of student work, resulting in national conference presentations and statewide awards. This larger student community has attracted students invested in scholarship, research, and campus leadership, which reinforces the department's efforts to foster a community of mentors and scholars.

Abstract Name: Negative Stereotypes of Greek Life and their Effect on Fraternity and Sorority Members

This project's objective is to understand how negative media coverage of Greek life affects those who take part in it. News media commonly talk about Greek life in a negative light, but people continue to be strongly affiliated with these communities. Studies of media coverage have shown that it has a negative impact on mental health (National Library of Medicine), whereas many studies of Greek life have shown a positive trend on mental health of its participants (Newport Institute). My study, however, examines the intersection of such findings: how media portrayals of Greek life affect those in it. I want to look at the common stereotypes of this community to try to understand where they come from and their effects. Montana State University's divided student population (Greek and non-Greek) offers a good opportunity for the study of the translation of such stereotypes from news media to student attitudes. My study engages the Greek life community through an initial survey and then, where applicable, follow up interviews. Additionally, I have interviewed university faculty who work with the fraternities and sororities to broaden perspective on this topic. Although this research is still in progress, survey results are demonstrating that members of the fraternity-sorority life community feel negative effects from what they hear around campus and on social media that most often leads to members not wanting to wear their Greek letters out and refraining from telling others of their association. My presentation will review further findings and discuss what would be required to reshape the discourse.

Abstract Name: Entomophagy in Education: Exploring the Role of Insects as Sustainable Food Sources

Entomophagy, the practice of consuming insects, offers a sustainable alternative to traditional protein sources like cattle and chickens, which are more resource and land intensive practices. Insects have been a part of the human diet for centuries, providing a rich source of protein and micronutrients. In the Entomophagy Lab (Miami Dade College), biology students explore this practice through hands-on activities with mealworms (*Tenebrio molitor*). Students construct mealworm containers to support their life cycle, from egg to larvae to adult and back to egg, while harvesting a portion of the larvae for consumption. Throughout the lab, students learn about the biology, ecology, and sustainability of mealworms, integrating these topics with real-world applications of entomophagy. During the cooking phase, students develop personalized recipes using mealworms and other ingredients, presenting their creations to food critics, including peers, staff, and faculty. This experiential learning lab merges sustainability, nutrition, entomology, and ecology, offering students a unique, interdisciplinary approach to biology. A detailed lab handout, rubric, and a video featuring highlights from the lab will be shared with conference attendees.

Abstract Name: The Complexities of Identity in the Works of Phillis Wheatley-Peters and Honoreé Fanonne Jeffers

This poster explores the complexities of identity in the works of Phillis Wheatley Peters and Honoreé Fanonne Jeffers, emphasizing how personal heritage, race, and historical context shape self-perception and the struggle for recognition. Through an analysis of Wheatley-Peters's poems "To the Right Honorable William, Earl of Dartmouth" and "On Being Brought from Africa to America," as well as Jeffers's poetic exploration in *The Age of Phillis*, the paper examines how both poets navigate the tension between African heritage and colonial American society. Wheatley-Peters's work highlights the negotiation of identity through her literary craft, where she simultaneously asserts her voice and challenges the societal constructs imposed on her as an enslaved woman. Jeffers, in turn, delves into Wheatley-Peters's life, reflecting on themes of family, lineage, and heritage, suggesting that self-identity is shaped by both personal resilience and the cultural legacies passed down through generations. Jeffers, in her examination of Wheatley-Peter's life and work, furthers this exploration by highlighting the intricacies between personal and collective identity, especially through the lens of connections to her family and homeland. Together, these poets shed light on the never-ending impact of heritage on self-discovery, emphasizing that identity is not merely a reflection of where one comes from, but a complex, evolving narrative shaped by personal resilience and cultural history. This poster will demonstrate how both poets illuminate the ongoing struggle for identity and belonging, particularly for Black Americans whose individual narratives were erased through the transatlantic slave trade. By engaging with their works, this poster contributes to a deeper understanding of how history, family, and personal agency intertwine to form complex and evolving identities.

Abstract Name: Using ChatGPT to Improve Readability of Spasmodic Dysphonia Patient Education Websites

Online patient education materials often exceed the recommended 6th to 8th grade reading level, limiting accessibility and creating a challenge for the average consumer with low health literacy. At the same time, AI large language models (LLMs) are being increasingly used as a tool across the healthcare field and as an everyday search tool. This study examines how utilizing AI LLMs, specifically ChatGPT, can improve the readability of online patient education materials about spasmodic dysphonia, a neurological voice disorder which causes involuntary spasms in the muscles of the larynx. Fourteen patient education websites addressing the questions “What is spasmodic dysphonia?”, “What causes spasmodic dysphonia?”, and “How is spasmodic dysphonia treated?” were selected to provide baseline content for comparison with AI-generated output. ChatGPT was then prompted to generate responses to the same three questions using each of the websites as its primary source of information. The readability data of the original and ChatGPT-generated content are currently being analyzed using four readability formulae through the Oleander Readability software and Microsoft Word for Mac. Initial findings suggest that the use of AI LLMs like ChatGPT have the potential to generate patient education materials which more closely meet recommended readability levels, allowing for more accessible patient education materials and promoting the use of plain language in the healthcare field.

Abstract Name: Pain, Pleasure, and Performance: Transforming Gender and Sex Through Body Modification

“Modern primitives” are a group of individuals that came to prominence in the modern body modification subculture in the late 1980s. “Body modification” as used in my research refers to alteration of the body that falls outside of the cultural norm; this includes, but is not limited to, piercing, tattooing, scarification, and various types of surgical modification when done within an underground subcultural setting. Modern primitives’ role in the progression of body modification as a subculture and industry is contested. My study examines the history of this movement within modern body modification, using a research methodology that includes a literature review of *In the Flesh: The Cultural Politics of Body Modification* by Victoria Pitts, *Body Art: Body Modification as an Artistic Practice* by Matthew Lodder, as well as publications from various body modification websites, books, and zines, such as the *Body Modification Ezine*. I also utilize documentaries and texts from prominent modern primitive figures, including Roland Loomis (also known as Fakir Musafar) and Jim Ward. I analyze the ways that the modern primitive movement has influenced Queer culture, SM/fetish culture, and the broader development of the modern body modification community and industry. I also evaluate criticisms of modern primitives, including the claim that they are culturally appropriative. I create a synthesis that recognizes the role of modern primitives in the development of modern body modification, while identifying other ideologies that focus on queer affirmation and ways to feel

embodiment/validity through body modification. I aim to contribute a nuanced perspective to the existing literature on modern body modification, and challenge societal perceptions of body modification. I explore the way that gender is conceptualized, altered, and transformed through body modification, on both a personal and societal level.

Abstract Name: Quantification of Organic PM_{2.5} from Biomass Burning

Particulate matter (PM) has been identified to be one of the main contributors to air pollution. The PM vary in size with typical particle diameters ranging from <0.1 to 10 µm where particles with 2.5 µm in diameter were the focus of this study. Varying amounts of human exposure to PM_{2.5} has shown to increase the risk of cardiovascular, respiratory, neurological, and reproductive disorders and disease. The main contributors for PM_{2.5} emissions have been identified to be agricultural, prescribed, and wildfires (biomass), crops and livestock, and fuel combustion. The chemical composition and concentrations of organic PM_{2.5} from biomass burning was determined via gas chromatography mass spectrometry (GC-MS). Biomass was sampled locally which included leaves and twigs from various deciduous tree species during the span of January 2025, through March 2025. Levoglucosan (LG) and various carboxylic acid species including saturated straight chains, unsaturated chains, and oxo and hydroxy acids were the focus of the study.

Abstract Name: Synthesis of Lithium Orthosilicate Composites for High-Temperature CO₂ Capture

Precombustion CO₂ capture, used in integrated gasification combined cycle (IGCC), sorption-enhanced steam-methane reforming (SE-SMR), and sorption-enhanced water-gas shift (SE-WGS), offers efficient hydrogen production by simplifying traditional processes. SE-SMR combines reforming and water-gas shift into a single step, reducing both capital and operational costs. Operating at 550-650°C, SE-SMR produces nearly pure CO₂, ideal for sequestration or industrial use. The development of this single-step technology is key to transitioning from grey to blue hydrogen, accelerating decarbonization in the transportation industry. While most sorbent development has focused on CaO-based materials, lithium orthosilicate (LOS) shows unique potential for SE-SMR applications. LOS has a high theoretical CO₂ uptake (>35% by mass) and favorable thermodynamics in the target temperature range. Unlike CaO-based sorbents, which require energy-intensive temperature swing adsorption, LOS operates in a pressure swing mode, simplifying reactor design

and enabling less capital-intensive hydrogen production systems. Our group has developed a nanostructured LOS composite material that shows rapid uptake kinetics and cyclic stability up to 80 cycles. These composites were synthesized using wet chemistry methods, followed by extensive characterization through thermogravimetric analysis (TGA), X-ray diffraction (XRD), N₂ adsorption, Fourier transform infrared spectroscopy (FTIR), and electron microscopy. The ultimate goal is to integrate the LOS material into a laboratory-scale swing reactor system, where a combined catalyst-sorbent system generates hydrogen in one reactor while regenerating the sorbent in a sister reactor for continuous operation. Future work will focus on refining synthesis methods and optimizing reactor conditions. Additionally, further characterization will assess the impact of varying conditions on the material's composition, behavior, and ideal reaction settings for scalable, cost-effective hydrogen production and CO₂ capture.

Abstract Name: Freshwater Turtle Abundance & Biodiversity in the D.C.-Baltimore Corridor: Impacts of Habitat Protection and Temperature

Freshwater turtles are important components of wetland and pond ecosystems throughout the world. Unfortunately, >60% of all turtles are endangered or recently extinct, and a variety of threats – from wetland habitat loss to an onslaught of invasive species – face remaining populations. To help understand local drivers of turtle community composition and population health, we characterized the diversity of freshwater turtles found in wetlands and ponds adjacent to Bowie State University campus and in the nearby Patuxent Research Refuge in Bowie and Laurel, MD. We also measured the abundance of a locally common species, the eastern painted turtle (*Chrysemys picta picta*). By contrasting our two major study sites, a wildlife refuge and a campus edge, we aimed to investigate the general impact of habitat modification and protection on local turtle communities. We also investigated the impact of daily temperature on painted turtle catch rate to understand how the temporal distribution of trapping effort impacted our dataset. Based on 42 days of trapping distributed among three years, we found that daily high and daily low temperatures were unrelated to the abundance of trapped painted turtles (catch per unit effort, CPUE, measured as number of turtles/number of traps per day). In addition, we found that the mean Simpson's Diversity Index was significantly higher at the Patuxent Research Refuge, but the mean CPUE of eastern painted turtles was significantly higher around Bowie State campus. Our data show that extensive habitat protection benefits rarer turtle species – those most likely to require conservation action. However, our data also suggest that eastern painted turtles could benefit from reduced competition in more human-modified sites.

Abstract Name: Frontier Femininity: Gender and Power in Oklahoma's Territorial Era

Prior to statehood, the Indian territory, which would later become the 46th state of Oklahoma, was a hotbed of radical and progressive political movements. In the era before the 19th Amendment, women played an instrumental role in the social and cultural development of the state. On an institutional level, they helped shape the future of the state through militant advocacy, and their words were later put into the Oklahoma State Constitution. These influential women of all backgrounds also helped shape and redefine the narrow gender roles prescribed to them by the traditional, patriarchal social order. I plan to clearly demonstrate on a systemic and local level the nuanced position these women occupied. Because of all the shared struggle between them, their actions and beliefs were anything but uniform. I will juxtapose two of the arguably most influential women of the time, both Kate Bernard and Alice Robertson, to highlight this fact. Bernard was a revolutionary firebrand who passionately spoke on the social injustices inherent to the territory, while Robertson was a staunch traditionalist and anti-suffragist. They also occupied both sides of the political aisle but shared a common goal, whether intentionally or unintentionally, in radically changing the gendered status quo. Aside from these two influential activists, I will also dedicate a portion of my presentation to other individuals. Many other women share in Barnard's and Robertson's influence, from indigenous voices, the many black women who either migrated or were forcefully brought over, and many prominent socialist writers. My medium for this research will be an oral presentation. This topic is important because it has largely been left to history, and more people need to know about the contributions made to society by traditionally marginalized people.

Abstract Name: Characteristics of the Structure and Selected Biological Activities of Polysaccharides Isolated from Hemp

Hemp (*Cannabis sativa* L.), an industrially significant crop, holds vast potential for various applications due to its rich composition of bioactive compounds, including polysaccharides. This research aims to characterize the structural properties and explore the biological activities of polysaccharides isolated from hemp. By investigating these compounds, we seek to uncover their potential applications in industries such as pharmaceuticals and biotechnology, with a focus on their antioxidant, anti-inflammatory, and immunomodulatory properties. The study will employ techniques such as gas chromatography, mass spectrometry, and NMR spectroscopy to analyze the molecular composition and linkage patterns of hemp-derived polysaccharides. Through these methods, we aim to bridge existing knowledge gaps and optimize extraction processes for the efficient utilization of these bioactive molecules. Ultimately, this research will contribute to the growing understanding of hemp polysaccharides and their potential in enhancing both scientific and industrial applications.

Abstract Name: Hands with EMG for Low-cost Prosthetics: Elastic and Rigid

Myoelectric devices are the industry standard technology for prosthetic devices. However, the average cost for a myoelectric prosthesis ranges from \$20,000 to \$60,000, depending on the degree of upper limb amputation and the hand features. Most prosthetic hands on the market today are made of hard, specialized materials that quickly drive up the price of production and thus are not equitable to all in need. A team of engineers at the University of Melbourne developed a prosthetic that featured a flexible 3D-printed body called the X-Limb, with a total cost of \$200. Although compliant, it had decreased rigidity and a shorter lifespan of use. The purpose of this abstract is to describe the development of an affordable, quality, and sustainable prosthetic hand that can be of help to low-income families through 3D printing and commercially available electronics. The myoelectric team is comprised of 15 multidisciplinary undergraduate engineering students and is further broken down into a design team – focused on the morphology and mechanics of the prosthetic hand, and the programming and electronics team – focused on the internal circuitry of the upper extremity prosthetic device and an EMG sensor that captures electronic signals from the muscle. Determining the ideal balance between hard and soft robotics to address their respective challenges is one of our core objectives. At the time of writing, the design team tested various models developed by the members to explore different levels of filament elasticity and finalized the finger and thumb designs. The electronics team is researching EMG sensors and control strategies to closely mimic hand and wrist movements. Ultimately, our design will be validated by an upper-limb amputee using our prosthetic device in activities of daily life (ADLs), such as gripping different door handles and fine motor skills, like eating or dressing oneself.

Abstract Name: Costimulatory domains in chimeric antigen receptor T cells alter cytokine responses and contribute to a more toxic CAR T cell therapy in acute lymphocytic leukemia

The survival rate for adults with acute lymphocytic leukemia (ALL) is 74%. Current treatments have debilitating side effects so safer and more effective treatment options are needed. Novel cancer immunotherapies use chimeric antigen receptor (CAR) expressing T cells. CARs target tumor-associated antigens and enhance T cell responses. CAR T cell therapy is a new treatment for ALL however toxicities include cytokine release syndrome (CRS) caused by an overactive immune response. One way to reduce CRS is to alter the costimulatory domain in the CAR T cell. Therefore, we developed CAR T cells containing different costimulatory domains to test the role of costimulation in CRS induction. We used a chimeric-PD1 (chPD1) receptor with the Programmed Death 1 receptor as the tumor-targeting domain. The purpose of this

study was to compare if inclusion of different costimulatory domains, CD28, 4-1BB, and Dap10, in the chPD1 receptor altered tumor cell cytotoxicity and cytokine secretion in response to ALL cells. Additionally, whether T cell secretion of inflammatory cytokines was required for tumor cell cytotoxicity and release of CRS-inducing cytokines was evaluated. Using LDH cytotoxicity assays, it was determined that chPD1 T cells had significant tumor cell killing compared to control T cells. ELISAs and LEGENDplex assays were used to assess chPD1 T cell cytokine secretion. Compared to 4-1BB and Dap10, inclusion of CD28 in the chPD1 receptor increased secretion of CRS-related cytokines. Blocking antibodies were used to test the requirement of T-cell cytokine secretion in CRS induction. Blockade of IFN γ , GM-CSF, and IL-10 alone or in combination did not decrease tumor cell death. However, blockade of these cytokines did alter release of CRS-related cytokines from leukocytes. Therefore, CAR T cell costimulatory domains alter CRS induction and CAR T cells containing 41BB and Dap10 may be safer options for ALL treatment.

Abstract Name: Investigating Collective Functions of Diverse RsmE-regulated Extracellular Secretions in *Pseudomonas fluorescens*

Microbial cells frequently interact and aggregate to form densely populated biofilms. Localized clusters of cells develop spatial structures that optimize selfish (genotype-specific) access to space and resources, but also those that promote cooperative interactions among different genotypes. In densely populated laboratory colonies of *Pseudomonas fluorescens*, diverse mutations in the *rsmE* gene, encoding a translational repressor, are exclusively selected through the formation of a unique spatial structure that alleviates the problem of overcrowding. When *rsmE* is non-functional, multiple secretions are de-repressed that consequently form the dominant spatial structure. An extracellular polysaccharide (EPS) creates a region of low cell density by pushing away the neighboring wildtype (WT) cells, while a biosurfactant establishes a defined genotypic boundary for this region by locally sequestering the EPS. However, when both the EPS and biosurfactant genes are knocked out in a *rsmE* mutant, the resulting triple mutant (MS*) retains the ability to form much smaller and high-density patches. These observations suggest the involvement of additional RsmE-regulated secretions that provide a fitness advantage, albeit at a reduced level. Here, we aim to identify these additional secretion genes through random transposon mutagenesis of the MS* genome. The mutants were screened for the absence or reduction of patch formation within the WT population, and they were further screened to ensure an equal growth rate as the WT in monoculture. We report our findings of the disrupted genes through whole genome sequencing and interpret their collective functions with the EPS and biosurfactant through confocal microscopy. Disentangling individual and collective functions of diverse secretions within a dense population remains a significant challenge in the field. However, understanding these processes is crucial, as the secretions are expected to be functionally conserved across many clinically significant microbial species.

Abstract Name: Investigating Neural Network Design Through the Analysis of Weight Distribution Patterns

Motivation: Neural networks (NNs) are continuously being integrated into increasingly more critical aspects of society, however our understanding of the underlying organizational patterns within NNs is limited. Biological NNs are highly organized in physical space with proximal regions activating together at higher rates than non-proximal regions. In this work, we develop a set of tools to elucidate the design and organization of weights in NNs. While software tools for the creation and development of NNs are robust, there exists a shortage of tools aimed at analyzing and visualizing the distribution of weight values across large numbers of these NNs. Understanding the distributions of NN weights can provide researchers with practical insights like how to most efficiently initialize weights in order to reduce network training time. It may also help draw a more explicit link between organizational patterns in artificial and biological NNs. Methods: Here, we present a suite of tools to generate, visualize, and compare the statistical distribution of weights across large numbers of small NNs. Key features include a pipeline to generate networks given some architecture and functions to visualize and analyze the statistical distribution of weights in networks generated by the pipeline. Weight values are partitioned into discrete bins and aggregated across networks. We then fit probability distributions to these aggregated data and compare them via KL-divergence. This allows for the identification of unique and conserved distributions of weight values in the set of networks. To date, we have trained and analyzed the distributions of weight values across >50k networks utilizing this suite of tools. Going forward, we aim to develop Bayesian tools to analyze conditional probabilities between distributions. Availability: The tools are available free and open-source at: github.com/sharifware/Large-Scale-Design-and-Analysis-of-Neural-Networks/

Abstract Name: Effects of caffeine on risk-taking behaviors in decision-making tasks

Attention-deficit/hyperactivity disorder (ADHD) is a disorder characterized by hyperactivity and impulsivity. Caffeine is used more frequently amongst those with ADHD. Research on caffeine's effects on risk-taking is conflicted. Some research suggests caffeine may have adverse effects on cognitive abilities, but other research suggests caffeine may be useful in the treatment of impulsivity symptoms associated with ADHD. Some research on caffeine indicates there could be benefits on the clinical implications of caffeine, but research is severely limited and needs to be further explored. The present study will examine the effects of caffeine on risk-taking in those with high and low ADHD symptomology. Participants will be asked to come into the laboratory for two sessions; participants will randomly be assigned to receive a caffeinated beverage during one session and a placebo beverage during another session. The first session will measure risk-taking, impulsivity, ADHD symptomology, and mood, while the second session will only measure risk-taking and mood. The present study seeks to determine whether ADHD serves as a moderator between caffeine and risk-taking behaviors in decision-making tasks. It is hypothesized that ADHD is a moderator of the relationship between caffeine and risky decision-making, and caffeine consumption will result in decreased risk-taking scores on a decision-making task for those high in ADHD symptomology and increased risk-taking scores on a decision-making task for those low in ADHD symptomology.

Abstract Name: Portrayal of Hatshepsut and Lady Six Sky: Transcending Gender in Ancient Egyptian and Mayan Civilizations

This research examines ancient Mayan and Egyptian art depicting queens of their respective civilizations including a stone relief sculpture of Lady Six Sky (702 A.D.) from the Mayan culture and a large granite kneeling statue of Hatshepsut (1479-1458 B.C.) from Egypt. Both women are depicted in a masculine manner. This study's significant questions are as follows: What social, political, and religious structures existed in each civilization, how are they different, if at all and why? What significance did each woman hold in her respective society? Did sexism play a role in how these women were portrayed in relation to their respective civilizations? Through my research, I will demonstrate that various similarities existed regarding not only their societal structures, but also the social position of women. This study, based on a formal and historical examination of these two works of art, demonstrates that women were powerful social figures and leaders within the cultural and political context of their respective civilizations, regardless of existing in a patriarchal society. While there is some disagreement among scholars regarding the masculine depiction of these female rulers in roles typically held by men, it is important to evaluate these works and explore their similarities regarding representation.

Abstract Name: Indigenous Protest Art in the United States and Australia: Edgar Heap of Birds and Richard Bell

Protest art by Indigenous peoples in the United States and Australia has exposed contemporary colonialism in various ways. However, there is limited scholarly research on the topic. This study examines the similarities and differences in contemporary Indigenous protest art by Cheyenne Arapaho artist Edgar Heap of Birds (Hok E Aye Vi) in the United States, and Aboriginal artist Richard Bell in Australia. This examination demonstrates that both artists produce work that highlights stolen land and appropriation of Cheyenne Arapaho and Aboriginal cultures by exposing transgressions in the United States and Australia and therefore controlling indigenous histories. To begin, the similarities and differences regarding colonization of their native lands will be provided. Second, the examination of how the artists demonstrate the past and continued colonization of their Indigenous peoples and land through their art. Third, the difference in the subject matter of these artworks will be addressed, followed by a discussion of obstacles the artists faced when exhibiting their protest art. This research is based on information discovered in historical and scholarly documents, formal examination of artworks, and interviews with the artists. This study is important because of persisting

colonization tendencies in both countries that need to continue to be exposed and challenged in many ways, including protest art.

Abstract Name: The Computational Study of Peptide and Small Molecule GLP-1 Receptor Agonists

The Computational Study of Peptide and Small Molecule GLP-1 Receptor Agonists Katelin C. Coleman¹, Tiffani M. Holmes² ¹Department of Animal Sciences, College of Agriculture, Family Sciences and Technology Faculty & Staff, Fort Valley State University ²Department of Natural and Computational Sciences, College of Arts and Sciences, Fort Valley State University The objective of this study is to investigate the interactions (i.e. London dispersion forces, hydrogen bonding, and pi stacking) of GLP-1 receptor agonist compounds with the GLP-1 receptor (GLP-1R) using molecular modeling techniques, further leading to better understanding of these compounds and developments of more proficient drugs. GLP-1, or glucagon-like peptide 1, is a hormone that naturally releases within the gastrointestinal tract, specifically the pancreas, in response to the intake of glucose, regulating blood glucose levels. As the body consumes glucose, GLP-1 directly binds to the GLP-1R at the surface of pancreatic beta cells, triggering the release of insulin and inhibiting glucagon secretion. Health conditions like obesity and diabetes are linked to a reduction of GLP-1 within the body, further leading to insulin resistance and metabolic complications. The developments of GLP-1 receptor agonists drugs like Wegovy, Saxenda, and Ozempic are utilized to combat these conditions. Two highly produced types of GLP-1 receptor agonists drugs include small molecule GLP-1 agonists and peptidyl GLP-1 agonists. The small molecule GLP-1 receptor agonists dargulipron, berberine, and orforglipron and the peptidyl GLP-1 receptor agonists liraglutide, tirzepatide, and exenatide are reviewed in this study. The docking of dargulipron and berberine result in a bonding affinity of -10.3 kcal via conventional hydrogen bonding and pi-type intermolecular forces, indicating the presence of strong interactions. The analysis of the remaining molecules is in progress. The interactions of these compounds will depict the degree of bonding that they have to the receptor, helping to understand which drugs are potentially most efficient.

Abstract Name: Everybody Needs a Hero: Body Politics, X-Men, and Transgender Futures

From the post-World War II era onwards, superhuman bodies have become a site of conflict, described as a contested, unstable ground wherein multiple parties attempt to control the same space - which in this case, implies the body of an individual, positioning the self as inherently political in nature. In turn, this has led to the continued relevance of the superhero genre into the 21st century. As new laws targeting the transgender community continuously emerge, audiences can draw parallels between the embodied political conflict of

mutants in fiction and the real-world marginalization and disempowerment of trans individuals, with focus given to the unique intersections of race, gender identity, and sexual orientation. This in turn provides the space for the examination of governmental control over an individual's body, including the allowance and denial of access to gender affirming healthcare, reproductive care, education, and overall societal perceptions of gender and its expected norms. I intend to propose a new direction for the superhero genre to explore in the future that more directly addresses the conflict between the state and the marginalized self. Emerging from the previous restrictions and guidelines put into place by the Comics Code Authority, I propose that the inclusion of these embodied themes of autonomy and conflict in mutant-centric superhero media allows for connections to be drawn between transgender and mutant identities. Utilizing Ramzi Fawaz's concept of fluxability, as well as a queer-feminist theoretical framework, I argue that these characters and themes directly connect to the present-day experiences of the transgender community. I will be analyzing how these aspects serve as both a mirror to the reality of embodied advocacy, as well as a means to more closely examine the role – or lack thereof - that the government has on the body of an individual.

Abstract Name: The Double Life of Franz Schubert: Der Doppelgänger and Homosexual Identity in 19th Century Vienna

The poet Heinrich Heine and the composer Franz Schubert faced persecution in their social and cultural contexts due to certain aspects of their identities. Heine's upbringing as a Jewish man living in the 19th Century led to conflicting feelings about his own faith and, eventually, he converted to Protestantism in order to find more commercial success as an author. Nevertheless, his heritage as a Jewish man still followed him and caused his work to be not taken seriously by others. Due to the discrimination he faced, Heine felt deeply connected with the term *doppelgänger* which refers to a person or an apparition that has the exact same appearance of another person that they are not directly related to. Heine went on to write a poem titled *Der Doppelgänger* and, later on, Schubert would use this poem to provide lyrics for his song cycle titled *Schwanengesang*. Though Schubert wrote compositions including Hebrew and texts from the Jewish tradition, there is speculation that he did not compose *Der Doppelgänger* with Heine's original intentions in mind. Schubert manifested his own life in two different avenues by being a successful composer and a homosexual, which was taboo in Vienna in the 19th century. Schubert utilizes unique musical elements to illustrate Heine's themes, such as the consistent use of the note F# and a double articulation. The ideas of a notable queer theorist named Gayle Rubin combined with the analysis conducted by musicologists David Bretherton and David Løberg Code allow thematic and musical connections to blossom in *Der Doppelgänger*. This paper will utilize a musical, literary, and New Historicist framework to analyze the events in Schubert and Heine's life, as well as conditions of life in Germany and Vienna during their lifetimes, to evaluate what meanings each artist intended in their individual settings of *Der Doppelgänger*.

Abstract Name: Investigation of Time Impact of Power Flow Solver Algorithms on Transmission Outage Scheduling

The increasing complexity of power grid systems, driven by renewable energy integration, growing electrification, and climate change-induced uncertainties demands a time-efficient approach to optimize transmission outage scheduling. The recent devastation caused by Hurricane Helene in western North Carolina, which led to prolonged power outages, underscores the critical need for resilient tools to enhance grid reliability. This research aims to develop an optimization tool using MATPOWER, an open-source package for solving steady-state power system simulation and optimization problems, to streamline optimized outage scheduling while maintaining grid reliability that meets N-1 contingency criteria. Outage scheduling is an extremely time-intensive power flow simulation process that involves constraints such as transmission branch and generation outages scheduled throughout the year. Studies on the usage of power flow solver algorithms and their simulation time impact on outage scheduling remain limited in the literature. The research goal is to provide a tool that is a flexible, user-friendly platform that adapts to real-time conditions, reducing simulation time and operational costs, and improving grid resiliency. The tool allows for the dynamic integration of constraints, including resource availability, outage duration, and operational limits, which will enable the tool to generate precise and efficient schedules for an IEEE 118-Bus System case; a test case representing a portion of the Southeastern Electric Reliability Council (SERC) region. Preliminary analysis in a workstation with a 32-core Xeon CPU indicates that integrating power flow algorithms like Newton-Raphson and Gauss-Seidel enhances scheduling efficiency. Extensive simulation results identify the Newton-Raphson Sparse Hybrid solver as the fastest, improving power flow processing time by an order of magnitude compared to the standard Newton-Raphson solver. These time-efficient solvers coupled with multi-core processing capabilities will address growing challenges in outage scheduling and support efforts to maintain reliable and efficient power systems in the face of increasing demands and climate-induced uncertainties.

Abstract Name: Navigating the Complexities of Colombia's Armed Conflict: From Historical Legacies to Contemporary Challenges and Prospects for Peace.

The Colombian armed conflict has caused a significant impact on the lives of millions of Colombians and has deeply affected several generations, but to understand the conflict, there must be a historical context and an analysis of the causes, the phases, the impact on the civilians and the resolution attempts and prospects of the Colombian armed conflict. This paper argues that the Colombian armed conflict has deeply entrenched itself in Colombian society, resulting in human rights abuses, displacement, economic instability, and collective psychological trauma inflicted on ordinary people. Although there have been attempts at resolution, peace negotiations, and demobilization of the guerrillas, significant challenges remain in addressing the root causes of the conflict to achieve a sustainable and stable peace in Colombia. This project emphasizes the voices of civilians who have experienced the conflict firsthand through a series of interviews conducted by the author called Survivors of Life. These oral histories include the stories of Diego Zamorra, who immigrated to the U.S. due to safety concerns, and Herlinda Martinez de Origua, who remained in Colombia. At the same time,

her daughter and granddaughters chose to leave in search of a brighter future. These personal accounts offer a window into the civilian experience—voices too often overshadowed by the political and military aspects of the conflict. By sharing these narratives, this paper seeks to illuminate the complex, shared trauma among Colombians and challenges the quick judgments often made about immigrants without understanding the full scope of their experiences. Through these oral histories, this paper aims to illuminate the human cost of the Colombian armed conflict, raising awareness of its deep and lasting impact on ordinary lives while contributing to the ongoing conversation about conflict resolution and peace-building.

Abstract Name: Investigating the interplay between TLR4 signaling and AHR activity in small intestinal epithelial cells: implications for necrotizing enterocolitis

Necrotizing enterocolitis (NEC) is a gastrointestinal inflammatory disease that primarily affects premature infants. In NEC, bacterial factors are thought to elicit an excessive response by the immature immune system. In the gastrointestinal tract, this robust inflammatory response leads to excessive apoptosis of the epithelial cells comprising the barrier between the lumen of the gastrointestinal tract and the underlying tissue allowing for bacterial invasion of the underlying tissue, leading to ischemia, necrosis, and potentially sepsis and death. Activation of the aryl hydrocarbon receptor (AhR), an immune system modulator, has been shown to be preventative against the pathogenesis of NEC in a murine model. However, no research has been conducted on the potential benefits of AhR activation following pathogenesis. As such, we focused on the effects of AhR activation following pathogenesis within a model system: rat small-intestinal epithelial cells treated with lipopolysaccharide (LPS), a bacterial endotoxin implicated in NEC. qRT-PCR revealed a decrease in AhR expression following LPS treatment. In this model, AhR activity, assessed by expression of the AhR target gene Cyp1a1 following treatment with the ligand indole-3-carbinol (I3C), was comparable to no LPS control. MTT assays indicated that treatment of the cells within our model with I3C rescued cytotoxicity. Surprisingly, scratch assays revealed a decrease in wound healing ability in the LPS + I3C treatment group, while no differences were observed with either treatment alone. These results may reflect the ability of I3C to rescue relatively mild insults (LPS) but not more significant injury (LPS+Scratch). Our continued research has sought to determine the potential for another AhR ligand, indole propionic acid (IPA), to rescue LPS-induced cytotoxicity. Currently, our findings do not suggest that IPA is capable of ameliorating LPS-induced metabolic deficits. Overall, our research indicates that I3C treatment, and potentially AhR activation, rescues LPS-induced cytotoxicity but not wound-healing ability.

Abstract Name: The Future of Monovalent Cation Energy Storage: Liquid Metal and Red P

The demand for energy storage in applications such as electric vehicles, consumer electronics and grid storage is ever increasing. Lithium-ion batteries (LIBs) are currently the state-of-art in electrochemical energy storage. The annual EV Li-ion battery demand for sustainable development is projected to grow to up to .7 TWh per year by 2030, a 7x increase compared to the current demand projection. In order to meet this energy demand, we propose to use EGaIn, a liquid metal, as a “self-healing” agent for red phosphorous in anodes to achieve longer cycle lives and higher capacities. Red phosphorous (RP) has been the subject of extensive research due to its relatively low cost compared to other commonly used anode materials in LIB’s, stability in air, low toxicity, and extremely high theoretical capacity for Li⁺ ions at 2596 mAh g⁻¹. Graphite, a currently commercially used anode material, has roughly a 7x lower capacity of 372 mAh g⁻¹ compared to RP for Li⁺ ions. RP’s main drawback is that it has a volume expansion of up to 300% during charging. This can cause delamination of the RP from the anode, resulting in capacity fade due to the RP becoming electrically disconnected from the anode. To mitigate this delamination, we propose to use EGaIn to maintain electrical contact with delaminated red P particles. EGaIn has been used as a “self-healing” agent for silicon, another high-capacity anode material in LIB’s, that also suffers from high volume expansion. In our work, we fabricate a composite film electrode comprising EGaIn and RP nanoparticles in a carbon polymer matrix. We perform material characterization of the electrode before and after electrochemical characterization of the electrode. This strategy of using EGaIn in combination with RP may help develop effective approaches for the integration of other high volume expansion active materials in anodes.

Abstract Name: Environmental Restoration Target Estimation Around Dale B. Engquist Nature Preserve

This project analyzed soil parameters from multiple locations owned by the Shirley Heinze Land Trust in Porter County, Indiana, some of which are being ecologically restored or have been restored in the past. The samples were collected from prairie, forested wetland, riverine wetland/floodplain ecological areas, and current agricultural areas that are to be restored to each of those same environmental types. To measure the effectiveness of the rehabilitation mentioned above, this project compared bulk density, soil chemistry, organic matter, aggregate stability, and particle size analysis from the agricultural area to those from restored and natural settings. This allowed the estimation of targets and a baseline to assess the effectiveness of future rehabilitation projects. The results show SOC content varied by environment type, with highest values found in forest soils. Furthermore, bulk density was found to be highest in prairie and previously cultivated soils. These results helped us to learn more about restoration projects on plots of land that have been used for agriculture for an extended period of time and can help other environmental projects find effective ways of rehabilitating formerly cultivated land.

Abstract Name: Comparison of Virtual Currency Methods in a Virtual Reality Exergame

This study investigates the use of the Infinadeck omni-directional treadmill, a "360-degree moving floor" that enables users to naturally walk in virtual reality (VR) environments by continuously returning their position to the center of the treadmill. This research aims to determine user preference between two methods in a VR game for earning virtual currency: walking points versus kill points. Additionally, participants' heart rates will be recorded to assess the potential of the application as an exergame, a game that users play for both fun and exercise. As a relatively new technology, use of omnidirectional treadmills in VR applications has not been thoroughly explored, with even less research regarding their potential to combine physical activity and gaming. This study seeks to contribute new insights into the features of VR walking games that encourage prolonged and vigorous engagement to meet the criteria for effective exercise. Participants will be tasked with completing a 30-minute playtest session in which they complete both walking objectives and enemy kill objectives. After each playtest session, subjects will complete a brief questionnaire to provide feedback on their preferred virtual currency-earning method and offer suggestions for improving the game. The anticipated outcomes include increased heart rates during gameplay and positive reception to the game's features, highlighting the omnidirectional treadmill's potential for combining entertainment and fitness. This research aims to bridge the gap between immersive VR technology and exercise, offering practical insights into how game mechanics can enhance user motivation and physical activity within virtual environments.

Abstract Name: Remedios Varo: Peregrinaciones

At the time of her death, the artist Remedios Varo (1908-1963) left behind over 500 works of art, the majority of which were created in her adopted country of Mexico. Known for her meticulously crafted fantastical paintings, Varo underwent exile and displacement due to first the Spanish Civil War, and later World War II, which led her to relocate to Mexico, where she would create prolifically for the remainder of her life. This paper will examine the effect of those experiences on the artist and the work she produced, attesting to Varo's ability to translate complex emotions regarding the human condition and uniquely communicate her personal history. Using biographical, formalist, and contextual analyses informed by the concepts of exile and of the Other in modern art, I aim to investigate the theme of pilgrimage- both physical and metaphysical- in the artwork of Varo's mature artistic period. Surveys of medieval art and alchemical culture, contemporary research on pilgrimage, and scholarship on Otherness in the canon of European art will be cited as frames of context for approaching Varo's artwork. Although the theme of pilgrimage in Varo's work is noted in existing scholarship, my research seeks to more thoroughly articulate the relationship between Varo's work and her own experiences, synthesizing significant through lines in Varo's life and work to create a comprehensive view of the artist. By focusing on the continuity of movement, I explore how Varo's migrations informed her artistic development and the narratives present in her paintings; first looking at images suggestive of liminality, then conceptual journeys, and finally, literal movement.

Abstract Name: The Vindolanda Tablets: Understanding Romanization on the Northern Frontier

The Roman frontier has been the subject of much research and debate among those historians concerned with understanding Roman authority and acculturation in the far reaches of the Empire. The interactions between Romans and recently conquered indigenous peoples with concern to cultural diffusion represent a topic which has previously suffered from a lack of evidence. The Vindolanda tablets, discovered in 1973 within a few miles of Hadrian's Wall, help paint an immensely detailed picture of the Roman frontier and the interactions which took place there. The discovery of this newfound corpus of evidence shows that the process of Romanization which took place on the Roman frontier was a highly complex matter. It is clear that Romanization takes place as a consequence of interaction between Roman or Romanized peoples with non-Romans, with specific emphasis placed on economic interaction within the context of supplying the Vindolanda fort. The tablets detail these economic interactions which either imply or explicitly state interactions between the Roman state and the indigenous peoples of Britain. Therefore, the Roman military, as a byproduct of its economic interactions with the local non-Roman civilian populace, was an agent of Romanization, especially in a recently pacified area like Vindolanda. Ultimately, the Vindolanda tablets illustrate that the Romanization process which took place on the Roman frontier was an intricate matter that involved economic interaction between the Roman garrison and the nearby indigenous population of Britons. These interactions represented a catalyst for Romanization to take place through both direct contact and a restructuring of the local economy to focus around the supply of the garrison.

Abstract Name: Examining the Impact of the Blood-Brain Barrier and the Gut-Brain-Axis on Brain in Zebrafish

Through the bidirectional communication along the gut-brain axis (GBA), microbial metabolites interact with the central nervous system (CNS), influencing neuronal development and cellular health. A key factor in CNS health is the blood-brain barrier (BBB), a semipermeable structure that surrounds brain microvasculature. The BBB regulates the movement of molecules and ions between the blood and the brain, helping to maintain a stable brain environment. Novel studies in mice have shown increased blood-brain barrier (BBB) permeability in response to knockdowns in the microbiome, supporting the BBB as a communication mechanism in the GBA. In this study, zebrafish were treated with an antibiotic cocktail (ABX) for 6 days to knock down gut microbial colonization. RT-PCR was used to quantify the relative bacterial abundance post ABX treatment and to analyze expression of BBB-related genes in brain tissue. *Mfsd2a*, a transcytosis regulator, was assessed. It is hypothesized that the expression of these genes will decrease in response to microbial knockdown, which correlates to increased barrier permeability. Bacterial abundance increased by a 1.4-fold change in ABX fish ($n = 10-12$), while *mfsd2a* expression had a 1.5-fold increase ($n = 10-12$, $p = 0.05$). Though these results are unexpected, we suspect that the ABX treatment administered allowed for the colonization of bacterial species that promoted BBB integrity. Future studies will identify changes in specific

bacterial species and analyze a broader range of genes implicated in BBB integrity to understand further how these two systems interact.

Abstract Name: Using DNA Metabarcoding of Diatom Communities in the Buffalo Creek Watershed for Water Quality and Forensic Application

Diatoms are unicellular algae that are found in freshwater and are directly impacted by water quality. This research was to compare diatom community assemblies for 2 tributaries of Buffalo Creek from 2022 and 2024 using eDNA metabarcoding. Diatom community assemblies can vary based on year, season, and other environmental factors. Environmental factors that can change the community makeup of a location include pH, conductivity, and nutrient levels. Community profiles, aka biotic profiles, are records of the diatom community taxa and what environmental conditions make up the current habitat. These profiles can be used to determine water quality through indicator species as well as used in environmental forensic evidence linking diatoms to a specific tributary or watershed with trace evidence. These diatom community profiles were determined with eDNA metabarcoding using the *rbcL* gene and were validated with morphological taxonomic determinations. In order to determine if either extraction technique would give a biased result, DNA was extracted from both a filtered supernatant and the pellet (sediment) of each sample. Comparing the community profiles of the two tributaries in the Buffalo Creek watershed reveals differences and similarities in the community makeup between the two sites. This could be due to the two tributaries being from the same drainage system and having the same water chemistry. However, there is also variability in diatom communities across two years and potential bias toward certain diatoms in a community when using only the sample supernatant versus the pellet. These community profiles can guide future applications in creating full biotic profiles that can be used to study diatom transference in forensic science casework.

Abstract Name: Kinship and Character: Assessing Dark Personality Traits in Relation to Sibling Presence and Absence

The Dark Triad theory, which includes three socially aversive personality traits—Machiavellianism, psychopathy, and narcissism—helps explain negative interpersonal behaviors that impact workplace productivity and well-being. Traits characteristic of the Dark Triad theory can inform how individuals interact

with others and their behavior in team settings, potentially influenced by family dynamics in childhood such as parent-child and sibling relationships. While existing research has primarily focused on correlations between these traits and parental relationships, the direct relationship between Machiavellianism and psychopathy and growing up with siblings has not been thoroughly explored. This study aims to examine the relationship between Machiavellianism, psychopathy, and work ethic with the presence or absence of siblings. The research will be conducted through a Qualtrics survey that includes the 16-item Machiavellian Personality Scale, the 20-item Psychopathy Checklist-Revised, the 50-item International Personality Item Pool questionnaire, and a short form of the Multidimensional Work Ethic Profile, along with demographic information. The survey will be anonymous, it will be administered electronically via email and social media (Instagram), and responses will be stored in password-protected folders and servers. Results will be reported in an aggregated and de-identified format to ensure confidentiality. This study aims to contribute to the limited research on Machiavellianism and psychopathy in relation to sibling relationships. From this study we expect to find individuals without siblings will exhibit higher levels of Machiavellian and psychopathy traits compared to those with siblings. Findings could provide insights into developing these traits and inform workplace strategies, such as employee training, leadership development, improving interpersonal dynamics, enhancing collaboration, and promoting ethical behavior. Keywords: Machiavellianism, Psychopathy, Siblings, I-O Psychology, Workplace Behavior

Abstract Name: RND Efflux Pumps as Survival Mechanisms in *Pseudomonas* Species

Abandoned mine drainage, a widespread issue in Pennsylvania, creates harsh conditions that influence bacterial evolution and behavior. Specifically, the development of enhanced resistance traits and adaptive mechanisms in *Pseudomonas* species has been observed in these contaminated environments. Looking at specific mechanisms of toxin excretion in gram negative bacteria, such as *Pseudomonas*, RND (Resistance-nodulation-division) efflux pumps are one of the major contributors. RND efflux pumps are multi-protein complexes that transport a variety of substances, such as toxins, out of the cell. In *Pseudomonas* species there are 4 major RND efflux pumps, which are MexAB-OprM, MexCD-OprJ, MexEF-OprN, MexXY-OprM. Among these 4 pumps, MexAB-OprM pump is the primary efflux pump in *Pseudomonas* species. The MexAB-OprM efflux pump consists of three parts, MexA, the periplasm linker protein, Mex B, the cytoplasmic transporter pump, and OprM, the outer membrane channel protein. By silencing the different components of the MexAB-OprM RND efflux pump, the overall function of the pump in contaminated environments can be assessed. This experiment targeted the periplasmic linker protein, MexA. Using environmental strain, BL10, and lab strains *Pseudomonas aeruginosa*, *P. fluorescens*, and *P. mendocina*, the organism's ability to grow in the presence of antibiotics, metals, and toxic organic molecules was tested. In order to assess if any other RND efflux pumps compensated for the difference, changes in gene expression were tracked using RT-qPCR for all 4 major RND efflux pumps in *Pseudomonas*. Resistance mechanisms that arise in bacterial species living in contaminated environments pose significant ecological and public health concerns, and this project aims to examine the importance of RND efflux pumps in *Pseudomonas*.

Abstract Name: Effects of Winter Events on Central California Beach Sediment

Sediment on any beach is constantly moving. Sediment volume varies due to longshore drift, tides, wind, wave action, and runoff. This is most obviously seen when comparing the low beach sand elevations of winter to high beach sand elevations of summer. Higher wave energy and storm strength in winter remove sand from the beach while calmer summers allow for transport of sand back onto the beach. Beach profiles have been taken twice a year since 2018 to measure these seasonal changes in sediment volume on two beaches on the Central Coast of California. The profiles have captured an area where creeks run to the beach and may or may not reach the ocean depending on the season. In this study, measurement intervals have been increased to observe the more immediate changes due to rainfall events, periods of high wave activity, and spring tides. Understanding how individual events effect erosion rates and sediment removal gives a clearer picture of what is happening to the beaches between the seasonal measurements. With ongoing analysis throughout the winter 2024-2025 season, larger discontinuous changes caused by winter events are predicted versus steady, gradual change throughout the time observed.

Abstract Name: Factors that Impact Burnout in Music Majors

The effect of burnout on music majors has become more prevalent and studied within the past decade. Researchers have found that burnout and imposter syndrome have highly impacted undergraduate music majors (Nápoles, et. Al., 2024). Some research shows that burnout is more prevalent among music education majors, compared to performance and other types of majors. (Vandenberghe & Huberman, 1999). Mak et. Al. (2019). Investigating the common denominators for burnout and the unique characteristics of music students, we can hopefully shed light on why students are feeling overwhelmed, overworked, and fatigued. The purpose of this study is to investigate the factors that impact burnout in music education majors and examine and explore ways that it can be prevented in undergraduate music programs. A survey was created using Qualtrics software that was distributed to undergraduate music majors. Questions addressed course load, ensemble participation, outside employment, degree concentration, and demographic information. Open-ended questions asked students to comment on their feelings of burnout, contributors to burnout, and personal experiences. The results of this study will inform undergraduate music education majors and the educators who work with them and can assist in creating a plan of action to positively impact the mental health of students. By analyzing data from various programs, majors, and degree concentration areas, we can use the information to make burnout less common and more manageable in undergraduate music majors. With more knowledge on this topic, we can develop strategies and initiatives to better support retention in music education programs. This work will help students create strategies for dealing with burnout and imposter syndrome.

Abstract Name: Generating an in-vitro Model of MPS-IIIA “Sanfilippo Syndrome” via CRISPR/CAS9 and Exploring Potential Therapeutics in a PUI Setting

Autosomal recessive inheritance of a defective SGSH gene coding for the enzyme sulfamidase is responsible for mucopolysaccharidosis (MPS) type IIIA, characterized by the effects of heparan sulfate accumulation in lysosomes. The syndrome presents with coarse facial features, central nervous system dysfunction, behavioral difficulties, intellectual disability, sleep disturbance, hyperactivity, loss of communication skills, and loss of mobility. Failure to develop cost effective research methods and long-term treatment options leaves the average age expectancy at just 10-20 years of age. Gene editing techniques including ZFNs, TALENs, and CRISPR/Cas9 have been explored as both models and potential therapeutic interventions for mucopolysaccharidosis types I, II and III. However, an in-vitro model of MPS IIIA, the most severe type of MPS, has yet to be developed. Therefore, we present a model test an in-vitro human cell line model of MPS IIA using a K562 lymphoblast cell line, CRISPR/Cas9 gene editing, and a heparan sulfate enzyme-linked

immunosorbent assay (ELISA). We hypothesized that disruption of SGSH would reduce or eliminate function of the sulfamidase enzyme, resulting in toxic heparan sulfate accumulation in the cell that could be quantified by an ELISA. Furthermore, we hypothesized Fluoxetine, an experimental drug treatment, would reduce heparan sulfate levels in the cell based on previous evidence in an MPS-IIIa murine model. Our work demonstrated the K562 lymphoblast cell line is a cost-effective and viable cell type for quantifying heparan sulfate levels. Preliminary drug treatments also suggest Fluoxetine may be capable of reducing cellular heparan sulfate levels in-vitro. Altogether, this work points to the potential of creating a sustainable cell model of MPS-IIIa, with the possibility of recapitulating specific patient mutations via the CRISPR/Cas9 editing system in the future.

Abstract Name: Wilderness or Theme Parks? Addressing National Park Overcrowding Through Entrance Fees

The National Park Service (NPS) is undergoing a strategic shift as it faces increased pressure to limit overcrowding in various national parks. Increased visitation has resulted in park resources becoming strained, leading to trail deterioration, reduced safety, maintenance backlogs, etc. To address this issue, the NPS has begun experimenting with different methods of dealing with overcrowding. A proposed solution is to increase park entrance fees with the intended effect of reducing demand, i.e., overcrowding. There has been significant debate regarding whether such a strategy would work, as well as if the potential pricing-out effect goes against the NPS mission of providing access for all citizens. Utilizing data from 30 US National Parks over the period 1993-2023, an economic analysis of national park visitation trends was conducted in this study to answer the question, "How do park entrance fees and various socioeconomic factors affect national park visitation rates?" with the purpose of evaluating the viability of an increased entrance fee strategy. Examined factors include entrance fees per vehicle, fuel prices per gallon, and median household income. Utilizing statistical software and various econometric/statistical techniques, we constructed a regression model that demonstrates the relationship between the socioeconomic factors and changes in national park visitor rates. The model found that entrance fee increases that occurred in the research period had no effect on visitation on average (a small, statistically significant negative effect occurred in less visited parks), meaning that while increased entrance fees could potentially be used to address budgetary issues, alternative methods such as timed-entries and permitting systems should be explored to address overcrowding. This project will help policymakers make informed decisions on park management strategies, including pricing, as park overcrowding becomes increasingly prevalent.

Abstract Name: Clinical Alarm Fatigue in the Acute Care Setting

Nurses are overexposed to a variety of alarms in the clinical setting. IV pumps and telemetry equipment all produce auditory and visual alarms. These alarms are crucial for patient safety; however, many are deemed false or “non-actionable” leading to a phenomenon called alarm fatigue, or when nurses are desensitized to the alarms. This dangerous problem can put patient safety at risk. It is shown that nurses who received education on alarm fatigue and supplemental information on their telemetry equipment lowered reported rates of alarm fatigue all together. If nursing students are given education on the topic and how to combat the issue, patient safety could improve. Using a pre-test/post-test to measure learning, students in their final semester of the nursing program will be provided with education about the danger of alarm fatigue and how to combat the issue. With acuity levels in the hospital increasing, there is a need for equipment that will alert the nurse when a problem arises. Unfortunately, this can also lead to alarm fatigue for the nurse and could put other patients at risk. It is hoped that being proactive and addressing the issue will improve patient safety outcomes.

Abstract Name: Poverty in Japan and the United States

This paper discusses the problem of poverty in two of the most economically developed countries –Japan and the United States. Even in this wealth, it is clear that poverty is systemic and that the process continues to favor one group over another. In the United States, poverty is racially and sexually segregated, and in Japan, educational inequality and child poverty are aggravated by cultural prejudices and insufficient social protection. Social costs of poverty are evident in both countries – suicides bear signs pointing to economic factors as well as social pressure. The paper also analyses cultural representations of poverty based on Andres Serrano and Tetsuya Ishida. Serrano's pictures depict the social reality of people experiencing homelessness in the US, while Ishida's surrealist paintings portray the different aspects of Japanese society's aloofness. By examining these problems and how they are depicted in culture, this research advances the understanding of how poverty can be eradicated only through significant system changes and social efforts.

Abstract Name: The Concept of Loss and Trauma in Children’s Books in Japan and the United States

The subject of this paper concerns the concept of loss and trauma in children's books in Japan and America. The study contended that there are significant differences in the way trauma and loss are represented and handled in books for children, largely because of societal and cultural differences in the approaches each country takes toward these emotions. First, the socio-emotional differences between the United States and Japan is discussed. Understanding these differences is important, for they provide the narratives and

emotional tone in children's books about how each society influences readers to process and cope with adversity. Second, the investigation of each country and details of specific styles and themes of illustration within children's books are presented. The sections will demonstrate how cultural norms of visual and narrative storytelling construct and frame themes of loss, separation, and survival. Particular attention will be given to illustration in children's books to enlighten when images support or subvert text to carry deeper emotional resonance. The comparative conclusion will highlight the cross-cultural dynamics of representing loss and trauma for children in the implications of emotional development. Understanding these differences helps to ascertain new insights into how children's literature reflects broader values and societal attitudes. This research is supported by academic sources and primary material, including artwork in children's literature and writings from the period.

Abstract Name: Unsupervised Detection of Cyber Threats Using K-means Clustering on the UWF-ZeekDataFall22 Dataset

In the rapidly evolving landscape of network security, the detection of advanced persistent threats (APTs) and zero-day attacks has become increasingly critical. Traditional intrusion detection systems (IDS), which rely on signature-based methods, struggle to recognize new or emerging threats, as they depend on predefined attack patterns. To address these limitations, this research applies unsupervised machine learning techniques, specifically K-means clustering, to enhance the detection capabilities of IDS. The study utilizes the UWF-ZeekDataFall22 dataset, a comprehensive collection of Zeek network traffic logs labeled with the MITRE ATT&CK framework, which categorizes various tactics and techniques used in real-world cyber-attacks. The primary goal of this research is to accurately distinguish between normal and malicious network traffic without the use of labeled training data. By experimenting with different cluster labeling strategies, the study finds that labeling clusters containing more than 50% attack data yields the highest precision and recall for identifying cyber threats. This unsupervised approach not only significantly improves IDS but also enables the detection of previously unknown and evolving attack patterns. Furthermore, the results demonstrate the adaptability of clustering techniques to identify and respond to cyber threats in real-time scenarios, where new, unknown attack behaviors may arise. The findings of this research underscore the potential for using unsupervised learning methods like K-means clustering to provide robust, automated monitoring of network security. With its capability to detect both known and novel attack patterns, K-means clustering offers a valuable and scalable tool for improving the efficiency and effectiveness of IDS in today's increasingly complex and dynamic cybersecurity environments.

Abstract Name: Creative Composition and the Correlation to the 21st Century American Contemporary-Dance Field

As the American contemporary dance field transitions into its next “era” due to evolving technological integrations, the patrons across the dance community desire new approaches to engage with original choreographic compositions. Within this adaptation, there is a call to investigate how dance artists can apply the tools within their artistic “toolbelt” to adapt to the unique needs, and future trends which define and shape the contemporary dance field. The following study investigates how creative compositional tools correlate to the unique mediums of the field, specifically within the post-covid-19 era, where dance artist practice their choreographic engagement within the physical and metaphysical world. This research contributes to the body of knowledge through the investigation of choreographic structures applicable in the 21st century. In addition to the study of compositional tools, this research aims to address trends in consumer behavior by investigating impactful ways to present one's artwork within a technologically autonomous environment. The research methodology is structured to use a qualitative descriptive model that employs auto-ethnography as the primary method of data collection. Over the course of 8 weeks, eight to ten participants will engage in seminar-style studio practice courses, where participants will be exposed to different compositional tools, then asked to reflect upon the perceived effectiveness for composing original work within technologically integrated mediums. This methodology is built upon Skains 2018 methodology for practice-based research in the fine arts, which culminates to a final creative artefact. My research and composition of this new dance has allowed me to continue to deepen my knowledge of composition tools codified within the era of post-modern dance, and how to wield them into the new and unique mediums of the 21st century.

Abstract Name: Enhancing Security with Combined RSA and AES Encryption Layers

This study presents a novel multilayer cryptographic security scheme that integrates RSA (Rivest-Shamir-Adleman) and AES (Advanced Encryption Standard) encryption techniques into a unified security system. RSA, a public-key encryption method, relies on the computational difficulty of factoring large integers, while AES, a symmetric-key encryption scheme, excels in securing large datasets with speed and efficiency. By combining these methods, the proposed hybrid system leverages the strengths of both algorithms: RSA for securely exchanging symmetric keys or handling smaller data sets, and AES for efficiently encrypting large volumes of data. Layering RSA encryption with AES enhances security by diversifying cryptographic primitives, making attacks significantly more challenging by requiring adversaries to compromise both public-key and symmetric-key algorithms. The study evaluates the security, computational performance, and practicality of this approach by testing it against well-known threats, including Man-in-the-Middle (MitM) and Side-Channel attacks. Findings demonstrate that the layered combination of RSA and AES creates a robust and resilient security model, offering practical solutions for modern cryptographic challenges.

Abstract Name: Does exposure to a male or female sibling in the womb affect reproduction in sheep? A preliminary study of the impact of sex of littermate on fetal loss in ewes

In litter bearing species, such as rodents and pigs, exposure to a male littermate in-utero may negatively affect the reproductive potential of female co-littermates as adults. In sheep, little is known about the effect of sex of littermate on the pregnancy rate and a ewe's ability to carry offspring to term. Based on previous studies, ewes born with a male co-twin (FM) or two males as triplets (FMM) had greater embryonic loss from ovulation to lambing, but the analysis did not include fertilization failure or fetal loss. Fetal mortality is often underestimated in domestic livestock and contributes to economic loss in the sheep industry. This study aims to determine if in-utero exposure to a female or male co-twin or triplet affects pregnancy rate and fetal loss in the adult ewe. Pregnancy diagnosis using ultrasonography was conducted on approximately days 35 to 50 of gestation in 1,189 ewes (927 as twins and 262 as triplets) at the U.S. Sheep Experiment Station from 2015-2017 and 2023 ranging from 1 to 6 years in age. Breeds included Polypay, Suffolk, Targhee and Rambouillet. Pregnancy and lambing rate, average number of fetuses and lambs born per ewe will be determined. Fetal counts at ultrasonography will be compared to corresponding lambing records to determine the percentage of total (complete pregnancy loss) and partial (reduction of litter size only) loss occurring in ewes born with a male or female littermate (co-twin or triplet). Statistical analysis will be determined by ANOVA using the PROC MIXED and procedure of SAS. We hope that examining this effect on pregnancy rate and fetal loss will provide greater insight into how interactions with male offspring in-utero may potentially affect reproduction in the adult ewe.

Abstract Name: Understanding Juvenile and Adolescent Gorillas: Revisiting Gorilla gorilla gorilla (Western Lowland Gorilla): Supporting Conservation Efforts

Primatology has many applications relating to species conservation, population growth efforts, and understanding evolution. Non-human Primates in captivity deserve the best care available; understanding social development at a young age is critical in providing this. Western Lowland Gorillas were observed from the fall of 2022 through the summer of 2023 at Franklin Park Zoo. This group included 5 related individuals and one unrelated silverback male. The two youngest individuals, Aziza, age 7, and Pablo, age 3, were the focus of this research. Timed 1-minute intervals were used for focal observations approximately 3 times a week. Out of 22 behaviors, Pablo's highest active behavior was social play, at 7.52%. Eighty-six percent of this behavior was with his sister Aziza, with 24% spread among the other gorillas. Aziza was beginning to engage in more adult behaviors over the observation period, with increased time spent self-grooming. Overall, these two individuals showed typical age-appropriate behaviors for young gorillas, in a socially well adapted group. This shows the importance of maintaining a family-like group for gorillas to provide opportunities for species-specific social development in captivity.

Abstract Name: Social Media and Reputation Management

The rapid pace of social media has completely changed how companies respond to crises, making readiness and swift action critical to preserving reputation and trust. This thesis proves the importance of crisis management and image repair tactics through content analysis and by dialing into a real-world case study of a small business in Kenosha, WI: Rustic Road Brewing Company. Through an analysis of how small businesses might handle crises such as customer complaints, internal conflicts, and social media backlash, this study reveals practical ways to minimize crises despite fewer resources. It underlines the necessity of clear communication, proactive planning, and transparency to prevent minor problems from escalating. Ultimately, this study offers practical advice on how businesses can successfully handle crises while preserving their brand and encouraging customer loyalty.

Abstract Name: The Powers Program: A Summer Research Experience Designed for Early Undergraduate Students

Alverno College is a women's college and the first Hispanic serving institution in Wisconsin, with programs aimed at expanding access to STEM education to women from historically underrepresented groups. Our Powers research program is unique in its emphasis on providing students with research experiences as early as their first summer (early researchers), while also offering opportunities customized for advanced students (advanced researchers). Our early researcher track aims to increase STEM identity, build skill and confidence in laboratory settings, and create competitive student researchers ready for subsequent off-campus research and internship experiences. We have designed our program around known best practices for first generation and underrepresented students, including an emphasis on community-based research. Student researchers conduct meaningful water analysis projects, sampling water from local waterways and sharing their results with community partners. During our six-week program, early student researchers attend weekly laboratory meetings and professional development sessions aimed at exploring STEM opportunities and providing academic advising assistance. Select advanced student researchers serve as peer mentors for the early

researchers, assisting faculty in supporting field and laboratory skill development. All student researchers are required to present their work at an on-campus research symposium, and we have developed a cohort model of travel that has been highly successful in supporting student research fellows to attend and present their work at regional and national professional conferences. Since 2018, we have supported 89 total student research fellows (63 unique student fellows) and participants have a 95% persistence rate in the college, with program evaluation suggesting gains in our student researchers in measures of persistence, self-efficacy in STEM, and personal identity as scientists.

Abstract Name: Barriers to Collegiate Education: Nursing School for Single Parents

AbstractThis study looks at the challenges that are faced by single-parent nursing students and what they encounter at UCO. Nursing School comes with challenges such as program costs, varying clinical schedules, software fees, liability insurance, and heavy cognitive load. Stress and anxiety are heightened during Nursing school. Parent students already experience stress and anxiety due to juggling and trying to balance everything and attend school. The review of the literature provides information on significant stressors such as financial constraints, lack of support systems, time constraints, parenting guilt, and lower graduation rates than peers without children. The literature reveals a gap in knowledge and research among this population of students, specifically single-parent nursing students. Many research articles are about parent students and the barriers faced by obtaining post-secondary education. The study proposes interventions to improve their educational experience. Using the Social Determinants of Health framework shows the correlation between SDOH and single-parent and parent students. This project proposes an on-campus childcare facility by showing a need through qualitative and quantitative research. The study discussed ethical considerations and outlined the research design for the proposal. The project aims to improve the educational environment for single-parent nursing students, enhancing their academic success and well-being.

Abstract Name: Enhancing Rheumatoid Arthritis Care: The Promise of Natural Supplements

AbstractBackground: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by persistent joint inflammation, causing debilitating pain, stiffness, and progressive disability. While conventional treatments like disease-modifying antirheumatic drugs (DMARDs) and biologics have significantly improved outcomes, many individuals still experience inadequate symptom control or adverse side effects. This highlights the need to explore complementary therapies that may enhance RA management and improve quality of life. Purpose: This proposal aims to explore the efficacy of natural supplements as adjuncts to conventional RA treatment. The focus will be on four commonly used supplements—omega-3 fatty acids, curcumin (derived from turmeric), ginger, and vitamin D—which have gained attention for their potential

anti-inflammatory and immunomodulatory properties that may contribute to symptom relief and improved disease outcomes. Method: A synthesis and critical evaluation of the current evidence-based practices and policies regarding the use of these natural supplements in RA management will be conducted. This evaluation aims to provide evidence-based recommendations for healthcare providers and patients considering the integration of these supplements into a comprehensive RA treatment plan. Conclusion: The existing literature supports the use of omega-3 fatty acids and curcumin as promising adjunctive therapies for RA, with ginger and vitamin D also showing potential in alleviating symptoms. These findings suggest that natural supplements may offer valuable complementary options for RA patients, enhancing treatment efficacy and improving quality of life. Keywords: rheumatoid arthritis, natural supplements, omega-3 fatty acids, curcumin, ginger, vitamin D

Abstract Name: Byte Sized Attention: Exploring the Link Between Social Media Consumption and AI Usage in Academic Settings

Research Question: Is there a relationship between the duration of time spent engaging with the short-form social media content and the likelihood of employing Artificial Intelligence to aid in or complete class assignments? Artificial intelligence (AI) has been on the rise amongst students as a quick and simple way to complete assignments. The use of AI in the classroom has skyrocketed as new technology is developed and distributed at an unprecedented rate. At the same time, short-form content, such as videos on popular social media apps, are published and consumed by students at an even faster rate. Teaching professionals are claiming that it is becoming increasingly difficult to hold the attention of students, as well as encouraging students to produce original work. This has created a lack of student engagement with content material and overall attachment to classes and courses. Literature primarily focuses on the poor use of AI in the classroom, though research rarely focuses on why this may be. To address this gap, a mixed-method study using an explanatory sequential design will be used to analyze the relationship between the duration of time spent engaging with the short-form social media content and the likelihood of employing AI to aid in or complete class assignments. The study will be conducted at a state university in central Pennsylvania. A college wide survey will be administered focused on duration of screen time on social media apps and the frequency at which students use AI to complete assignments throughout a week. Focus groups will be conducted with randomly selected students to further understand the relationship between social media and AI use amongst peers. The anticipated conclusion is that the longer a student engages with short form content it will positively affect the likelihood of utilizing AI to complete/aid in class assignments.

Abstract Name: Evidence of Low Energy Nuclear Reactions in Palladium Nanoparticles Exposed to Deuterium

The existence of “cold fusion”—potential nuclear reactions in a condensed matter, room-temperature environment—has been controversial since the 1990s when possible evidence of low energy nuclear reactions (LENR) emerged. Previous LENR experiments focused on heat generation in electrolytic cells, but heat-based experiments failed to demonstrate direct nuclear origin because they didn’t marry a nuclear active environment (NAE) with in situ, high-resolution radiation detectors. This study aims to discover evidence of LENR via measuring radiation by-products with solid-state detectors coupled to isotopic changes in the palladium nanoscale composite, as measured via energy dispersive spectroscopy (EDS). The study is experimental with the aim of developing a model of LENR. Palladium nanoparticles are solution-grown via a potassium tetrachloropalladate solution that is mixed with trisodium citrate dihydrate and tannic acid, centrifuged, and grafted upon an aramid nanofiber porous hydrogel. The dried composite is exposed to deuterium gas while adjacent silicon detectors survey the charged particle and photonic environment. The experiment is predicated on previous observations that the NAE resides in nanoscale potential wells which motivates the utilization of nanoparticles interconnected into a percolating network. The results indicate that after some period of deuterium loading, photons consistent with gamma-rays were produced as well as internal conversion electrons. Specifically, depending on the particular preparation conditions, gamma-rays and internal conversion electrons with energy of 477, 94, and 37 keV were spectroscopically detected. In some cases, these prompt reactions were accompanied by isotopic changes as measured via EDS. The appearance of gamma-rays suggests that nuclear reactions are occurring within the nano-composite. Next steps focus on reproducing the various measurements and localizing the NAE via transmission electron microscopic studies. Through discovering evidence of LENR, this research will allow for a greater understanding of nuclear reactions and the development of higher efficiency energy generation.

Abstract Name: Food Insecurity and Gender Based Violence on a Global Scale: A Scoping Review

In this study, we present the findings of our literature review investigating the association between food insecurity and gender-based violence on a global scale. It is well-documented that food insecurity, or the inability to access and benefit from affordable, adequate, reliable, safe, and healthy food, has many adverse repercussions for social wellbeing, nutrition, and overall health. However, the connections between food insecurity and gender-based violence (GBV) are just beginning to be documented. GBV is defined as any act of violence that results in, or is likely to result in physical, sexual or psychological harm or suffering, predominantly toward women. This includes sexual, physical, mental, and economic harm, as well as threats of violence, coercion, and manipulation. In this study, we conducted a literature review using databases including Research Gate, Google Scholar, and PubMed, as well as NGO websites, using the search terms (“gender-based violence” OR “intimate partner violence” OR “domestic violence”) AND (“food insecurity” OR “nutrition”). The inclusion criteria for scoping the reviewed studies were a) published in English, b) focused on studies that focus or mention the association between food insecurity and GBV, and c) published within the past 10 years (2014 to 2024). In total, 13 studies met our inclusion criteria. Reviewing these studies revealed that being food insecure is associated with higher rates of experiencing GBV. In this poster,

the authors present the main mechanisms connecting these phenomena and identify potential pathways to developing interventions that tackle these linked phenomena.

Abstract Name: From Ruin to Radiance: Harnessing the Power of Art for Social Change

From Ruin to Radiance is a triptych that addresses ruinous flooding issues in marginalized communities within Norfolk, VA. These works capture natural efforts to enhance our environment through a timeless renewal of an urban environment. We invite you to engage with this exploration of flood-threatened shelters that can be uplifted to ensure a more sustainable and equitable present. As a mixed media artist, I explore the relationship between humanity and the environment, particularly in the context of climate change. For this project it was my vision to show the vitality created in environments through green infrastructure. My works depict the beauty and radiance that can arise from destruction through our ability to adapt and know that we all can coexist and benefit from natural habitats. My inspiration for these works comes from Nina Jordan's art, which explores themes of safety and security in the places we call home. I am also influenced by Xavier Cortada, who uses his art projects to raise awareness about climate change, rising sea levels, and threats to biodiversity. My research included: Peer-reviewed articles. Attending conferences to learn more about the subject. Collaborating with my community to explore ways to reduce global warming effects. Encouraging viewers to install rain barrels can reduce stormwater runoff pollution and enhance groundwater filtration, ultimately helping to conserve our water bodies.

Abstract Name: Discovering the Effect of Red Blood Cell Lysis Buffer on the ESKAPE Pathogens

Healthcare associated infections caused by antimicrobial-resistant ESKAPE pathogens are currently a leading cause of mortality and morbidity worldwide. ESKAPE stands for *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and *Enterobacter* spp. Photoacoustic flow cytometry (PAFC) transforms light waves into sound waves and is used to detect optical tags which attach to analytes such as cells. The tagged analyte is flowed through a 3D printed flow chamber and interacts with a pulsed laser light at 532nm, via optical fiber. It produces ultrasonic sound waves that are amplified by a transducer and stored in an oscilloscope. We use bacteriophage as an optical tag for bacteria by removing the capsid containing the bacteriophage DNA and replacing it with a larger, dyed microsphere which increases the optical absorption of the bacterium. Red Blood Cell Lysis Buffer (RBCLB) is used to lyse red blood cells from whole blood samples. Combining this knowledge, we aim to develop a novel method to rapidly identify the ESKAPE pathogens in whole blood samples, using PAFC analysis, to improve the diagnosis timeline for healthcare associated infections. Extracting bacteria from whole blood adds a new

level of complexity and requires a lysis step prior to PAFC analysis. It was hypothesized that growing each of the ESKAPE pathogens in PBS versus RBCLB would indicate if the lysis buffer posed a threat to the survival of bacteria during the lysis process. The following procedure was executed for each type of bacteria: culturing, diluting, plating, data collection, and statistical analysis via Mann-Whitney U test. We found that RBCLB had a strong effect on the gram-negative strains and some effect on the gram-positive strains. Future research includes collecting more data, infusing whole blood samples with bacteria, lysing the sample, and detecting the bacteria using photoacoustic methods.

Abstract Name: Experimental Ethics: Twentieth-Century British Chemical and Biological Warfare Trials

Twentieth-century British science may be characterized by significant wartime influence, empirical frameworks, and civilian scientists paving the path for twenty-first century bioethical standards in experimentation. These factors, in conjunction with popular debates surrounding the use of chemical and biological weapons, manifested in a larger discussion, lead in many cases by scientists, of the ethics of experimenting on humans and animals, particularly in such chemical and biological weapons trials. These experiments built upon the Listerian age of experimental medicine and pushed the ill-established bounds of bioethical experimentation such that a new, radical form of patriotic exceptionalism in scientific experimentation was born out of the chemical age, and coterminously, civilian scientists carved a convoluted path to each of the tenets of bioethics as part of a broader reaction to wartime science. This dichotomy significantly impacted the trajectory of western physiological trials, medical practice, and medical education well into the twenty-first century, resulting directly in widespread recognition of autonomy, non-maleficence, beneficence and justice. Via analysis of records of researchers and trial participants, existing literature, archival materials, and legal documents, this project examines the extent to which the establishment at Porton Down and its colonial counterparts established a new framework for bioethics, how civilian scientists functioned and communicated within a military framework, and whether bioethical malfeasance—in terms of non-consensual experimentation, animal testing, and lethal experiments as a means to an end—can be justified by the law, popular opinion, or otherwise, through an intellectual and material historical framework. This study further establishes the intersectional nature of material history, intellectual history, and historiography necessary for a comprehensive contextualization of twentieth-century approaches to physiological experimentation in the British chemical and biological weapons development programs.

Abstract Name: A Discrete Pizzetti Formula and Applications to Digital Image Reconstruction

Pizzetti's "mean-value formula" expresses the average of a function over a ball or sphere as a power series involving its iterated Laplacians. We show a discrete formula that approximates mean values of functions of two real variables based on Pizzetti's formula. Similar to the five-point stencil for the Laplacian, we approximate iterated Laplacians by taking the value of the function on equally spaced points on a circle. Through Taylor expansion, we get the derivatives necessary to obtain the iterated Laplacians in Pizzetti's formula for two dimensions. As the number of points in the discrete approximation goes to infinity, the coefficients obtained by this method approach the coefficients in Pizzetti's formula. We also explore when the coefficients obtained are equal to those of Pizzetti's formula. Our discrete Pizzetti formula has applications in digital image reconstruction, or inpainting, the process of recovering lost or damaged information in images, which in many cases, involves taking the average of a function in some set near a specific point.

Abstract Name: Gradual Reduction of Self-Injurious Behavior: An Investigation into Clinicians' Perspectives Through the Theory of Planned Behavior

Self-harm is increasing at alarming rates. The DSM-5-TR defines non-suicidal self-injury (NSSI) as deliberate bodily harm without the conscious intention of causing death. Although several evidence-based NSSI treatments exist, these significant increases suggest a need for additional approaches. Most NSSI interventions require immediate cessation of the behavior leading clients to feel unsupported and frustrated with their autonomy, often resulting in the discontinuation of services. Recent literature suggests that harm-reduction techniques used for substance use disorders may be effective for NSSI. When abrupt cessation is not practical, harm-reduction aims to reduce the dangerous consequences of the behavior. This approach enhances client autonomy, leading to improved therapeutic relationships and treatment outcomes. This study will examine mental health practitioners' attitudes toward harm-reduction and gradual reduction approaches to treat NSSI. This involves the gradual decrease in frequency, intensity, and/or life-threatening nature of self-harming behavior by breaking it into smaller, more manageable goals. The Theory of Planned Behavior (TPB) will serve as the theoretical framework to measure how practitioners' attitudes, subjective norms, and perceived behavioral control influence their willingness to adopt gradual reduction approaches for NSSI. A mixed-methods survey approach will be used, with approximately 50 participants recruited from mental health facilities and doctoral-level training clinics in Tampa, Florida. Data will be collected anonymously through Qualtrics surveys. We anticipate that practitioners with more years of experience will have more positive attitudes towards a gradual reduction approach to NSSI in inpatient and outpatient settings. Additionally, we hypothesize that there will be a difference in overall TPB constructs among all practitioners depending on setting, with those in inpatient settings indicating more support for these interventions. This research aims to expand the current understanding of NSSI treatment by exploring the feasibility and acceptability of gradual reduction, which can result in complete abstinence, improving chronic self-injury recovery successes.

Abstract Name: Method for Assessing Obstacle Height in Mountain Bike Trails Using a Distance Sensor Array

Advanced development techniques for mountain bike systems are becoming increasingly prevalent as both recreational and professional athlete interest in mountain biking has grown. Some advanced development techniques can utilize trail profile data for specific trails in order to create new specialized components or fine tune parameters of existing components. However, information regarding the measurement and modeling of such surface profiles is severely limited. One possible method to measure trail profiles is to use a set of distance sensor arrays. The present work is an investigation of a configuration which consists of two arrays of three sensors each, one set mounted on the front wheel hub and another set on the rear hub of a standard mountain bike. By utilizing measured values from the arrays, a geometry-based algorithm and case structure have been developed to determine obstacle heights for several scenarios. The scenarios which were investigated in the current work include a single obstacle at each wheel and obstacles of different heights at both wheels simultaneously. The developed algorithm was able to successfully determine obstacle heights for each of the aforementioned scenarios. One limitation of the present work arises with the transition to experimental application. For modelling purposes, the distance sensor field of view (FoV) was treated as single line, while the actual FoV of most distance sensors is typically conical in shape, which could lead to errors in the current algorithm and inaccurate data. Future stages of this work will investigate mathematical modelling with these conical measurement scopes and experimental validation.

Abstract Name: Doll Liberation: Barbie's Evolution in the Second Wave of Feminism

The release of the Barbie movie in the summer of 2023 reignited debates about feminism and representation surrounding the iconic doll. This paper investigates the conjunction of feminism and intersectionality through the lens of Barbie, tracing her evolution throughout the Second Wave of Feminism. By contextualizing Barbie's history within the broader framework of feminist movements, this research argues that the franchise was more forward-thinking in addressing intersectional issues than critics and historians typically acknowledge. Through a unique historiographical approach to analyzing primary sources, media, and biographical materials, this paper traces Barbie's journey as she evolves into a more inclusive franchise, influenced by powerful feminists and civil rights activists. By highlighting the complex relationships between gender, intersectionality, and women's rights, this paper concludes that Barbie serves as a powerful emblem of womanhood, inspiring women to not only pursue diverse careers but also actively engage in feminist movements.

Abstract Name: Expediting Diapause in *Osmia lignaria* Through Temperature Manipulation

Temperature has been thought to play a key role in diapausal emergence for insects and tested in several species; however, its relative importance compared to other factors is still widely disputed. We analyzed the effects of expediting diapause in the hymenopteran species *Osmia lignaria*, a popular pollinator used in commercial and amateur agriculture or gardening. Our previous study (the first of its kind) found that mimicking seasonal temperatures in a shortened period resulted in early emergence from diapause. We specifically looked at the effects of expedited diapause on longevity, emergence synchronization, and emergence rates using three different treatment groups: a control, following standard overwintering processes, a natural treatment group undergoing expedited seasonal temperatures with daily fluctuations, and a treatment group undergoing stable expedited seasonal temperatures. Each group contained around 40 bees. The controls were kept at 1.1°C throughout November-April, then taken out to begin the emergence process. For the stable treatment group, we decreased the temperature by 12°C every five days to 1.1°C and left them for a month, increased the temperature to 3.9 °C, and left them for another month. Following this, we increased the temperature every 3 days by 12°C until we reached 21°C. The day/night fluctuating group followed the same schedule listed above; however, for each day, a high and low temperature was predetermined using a random number generator. Analysis is ongoing. If our results show it is possible to get *O. lignaria* out four to five months early with minimal impacts on efficiency, longevity, and synchronization, this could change the solitary bee and agricultural industry completely. *O. lignaria* could pollinate and improve the crop quality of crops previously inaccessible to them, allow for staggered generations, and more control on when and what *O. lignaria* emerges and pollinates.

Abstract Name: Non-Target Effects of S-Methoprene on Solitary Hymenopterans

One of the most problematic threats facing pollinators today is the extensive usage of pesticides. The non-target effects of pesticides have come under intense scrutiny in the last two decades, yet S-Methoprene has remained understudied. S-Methoprene is a larvicide found in over 500 different products and is a competitive inhibitor of the Juvenile Growth Hormone (JGH), a key factor in several developmental processes. Due to its mirrored hormonal structure, S-Methoprene can be absorbed through the larval skin and sit on JGH active sites preventing successful development in most insects. S-Methoprene's low specificity and placement in water sources used by many insect species could lead to many non-target effects in pollinators. I tested the non-target effects of this larvicide by collecting hymenopteran larvae from the Mullen's Pollinator Meadow from May-July 2024, and dosing treated larvae with two drops of 0.00245 g/L concentrated S-methoprene from Amdro brand mosquito dunks. Following this, I tracked their development daily, noting instar changes, cocoon formation, pre-pupal transitions, and living status. I then used chi-squared contingency tests and two-sample t-tests to analyze differences in mortality, time survived, and developmental advancement rates between the treatment and control larvae. Overall, I collected 98 larvae from *Isodontia Mexicana* (35) and *Ancistrocerus adiabatus* (63) with 47 control larvae and 51 treated larvae. My results showed treated larvae were 3.5 times more likely to die, had a significantly lower mean time alive, and are 3 times less likely to

advance to the next instar following treatment than control larvae. These results show that S-Methoprene could have serious non-target effects for hymenopterans and pollinators in general. More studies need to be done to understand the true ecological impact that this chemical has, as well as other effects it may have on pollinators.

Abstract Name: Debugging Virtual Corporate Reality: a Gamified Market Simulation of Salop's Circular City Model

Virtual Corporate Reality (VCR) is an interactive model of market simulation, based on Salop's circular city model, a variant of Hotelling's linear city model. The model consists of a circular market structure, where product differentiation is captured by spatial positioning around the circle. In this web exercise, students are assigned to teams of "firms" with an initial endowment of cash and a single differentiated good equidistantly located from other teams. These student firms then set prices, announce new products, and relocate old products with the objective of generating profit to achieve a higher grade in a class context. Our analysis focuses on class gameplay data from 11 industries, each containing three student firms. The challenge in this project was to identify the source of the Perl code's incorrect demand calculations. We ran experiments on the VCR system under various conditions to isolate the effects of factors including product placement, industry number and composition, and pricing strategy. We conducted analysis of diverse presentations of the bug by comparing displayed demand calculations with results from the formula for demand and expected estimations from the system. We identified product collocation, identical pricing, and the relative number of products in neighboring industries as the features that created the incorrect demand calculations. These findings allowed us to correct code that improperly indexed arrays in the neighboring industry, interfering with indexing in the industry where the bug occurs. This research contributes to the improvement of educational tools used in industrial organization and game theory market simulations.

Abstract Name: The Secret Garden: How Classic Children's Literature Tends Virtue

This research highlights the importance of reading classic children's literature by establishing the genre's transformative influence on an individual's development, a unique impact that has a lifelong effect on its reader. By exploring the scholarship of education philosophers such as William Kilpatrick and Vigen Guroian, as well as the essays of classic children's storytellers such as J.R.R. Tolkien and C. S. Lewis, this research examines the role of classic children's literature within the development of a child's healthy imagination, moral code, personal identity, and sense of cultural literacy. The findings of this research conclude that it is classic children's literature's ability to cultivate a child's moral imagination, a term

popularized by political philosopher Russell Kirk, that bestows its lifelong, transformative impact on its reader. The process in which one develops their scope of imagination, morality, and identity through exposure to classic children's literature will be metaphorically illustrated through the events of Frances Hodgson Burnett's classic tale, *The Secret Garden*. Mary Lennox's experiences tending the secret garden will be explored on the levels of the soil, seeds, flowers, and the garden itself to symbolize a child's imagination, moral formation, personal identity, and cultural literacy.

Abstract Name: Navigating Parental Involvement: How Demographics and COVID-19 Have Reshaped Educational Engagement

Research consistently links parental involvement to improved academic outcomes, yet defining and measuring it remains complex due to its multifaceted nature. Using data from the National Household Education Survey's (NHES) Parent and Family Involvement in Education (PFI) surveys conducted in 2019, 2023, this paper examines how parental involvement in education has evolved before and after the COVID-19 pandemic, focusing on disparities across race, income, educational attainment, and household structure. Descriptive and bi-variate analyses will establish baseline associations between demographic factors and parental involvement indicators. Regression analyses will isolate confounding factors, and comparison t-tests will identify significant shifts in patterns of involvement between 2019 and 2023. The expected findings aim to give insight into how the pandemic influenced parental engagement, with a focus on whether it exacerbated educational disparities or fostered new attitudes and practices, particularly among minority groups. By contextualizing these changes, this research seeks to inform strategies and practices that foster educational equity as schools and families navigate the post-pandemic era.

Abstract Name: Vitamin C Content Lost in Cooking Yellow Bell Peppers

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available products and food items using titration techniques. Ascorbic acid is a water soluble nutrient found in some fruits and vegetables and has many benefits including immune system support. It can also help stave off cardiovascular disease and cancer and helps with the absorption of other nutrients such as iron. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the

highest concentration of vitamin C, a crucial antioxidant that plays a vital role in human health. The experimental approach involves titrating the samples, employing 2,6-dichloroindophenol (DCIP) as the titrant, chosen for its ability to exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. The purpose of this project is to show that consuming raw yellow bell peppers will provide the highest Vitamin C content and also to show that by cooking yellow bell peppers, a significant amount of Vitamin C is lost not only in the cooking process, but in the water strained from the peppers after cooking.

Abstract Name: Sound Tracking and Localization in Blind Athletics

Blind and Visually Impaired (BVI) tennis is played with foam balls containing a mechanical rattle that makes a sound only while changing its momentum. The present study examined the effects of head placement and age on sound localization and tracking in blindfolded participants. The findings can benefit blind athletics as we can learn how to both optimize players' sound localization ability, leading to more efficient coaching techniques that can increase success and enjoyment of the sport, as well as retention of new players. In this study, sighted and blind participants aged 18-60 were blindfolded as BVI tennis balls were tossed at them by a researcher standing 20 feet in front of them. The balls were thrown at five different target points at -15° , -7° , 0° , 7° , 15° from where the researcher was standing. In 3 blocks of trials, participants had both ears, left ear, or right ear towards the researcher tossing the balls. The ball bounced three times before reaching the target point. Participants stood in the "ready" position with a standard tennis racket, assuming a high squat so that the head of the racket touched the ground, and shuffled laterally to make contact with the BVI tennis ball. Another researcher sat behind the participant giving hand signals to communicate which target the first researcher should be tossing to, and logging the participants' performance. Participants were significantly more successful at contacting the ball when both ears faced the ball rather than just one. There was not enough data collected to confirm the effect age has on the general population's sound localization and tracking abilities. As blind tennis grows worldwide, coaches of sighted athletes who typically have players turn to hit a ball, will know to coach blind athletes to keep both ears pointed toward the ball.

Abstract Name: Dissecting Heterocosmic Fictions Through William Blake's Laocoön (c. 1826-7)

To understand and interpret William Burke's Laocoön, I intend to analyze the Romantic's way of narration and creativity, the expression of 'things as they might be and ought to be'. M.H Abrams provides a crucial concept of the Romantic movement – the "Heterocosmic" model of Romantic fiction – which emphasizes the imagination when interpreting the natural world. Contemporary thinkers from the Sturm und Drang movement would react to the post-Kantian theories of beauty, and give not only beauty its autonomy, but also the work of art. By using the imagery of the Vatican's Laocoön Group, Blake's etching offers insight on the heterocosmic reality that exists within each and every piece of art. Blake's etching evokes three layers of visual storytelling – The mythic account of Laocoön, Blake's reinterpretation of Apollo as the 'Angel of the Divine Presence', and the visual rhetoric of the engraving itself, appearing as a manifesto of Blake's theology. Embellished with allegorical proverbs, Blake attempts to syncretize the Greek and Hebrew divine within Laocoön through a chaotic visual approach, protest against the Greek classic, and work of the imaginative and contemplative viewer. In this paper, I will consider philosophy behind Romanticism, the heterocosmic fictions of literature, contemporary Romantic artwork, and the role Gnosticism played in Blake's radicalism against the Enlightenment and Neoclassicism in Laocoön.

Abstract Name: Is There a Difference in Bird Diversity Among Prairie and Lake Habitats in Central Minnesota?

Biodiversity plays an essential role in ecosystem stability. Habitat changes from human activities also threaten this role. Our study examined how habitat type and urbanization affect the number of birds and bird diversity across two campuses in central Minnesota. The first campus is rural Saint John's University (SJU), and the second is suburban College of Saint Benedict (CSB). We predicted that there would be more bird species in habitats with water as compared to habitats without water bodies. We also predicted that bird species numbers would be greater on SJU, which has a large natural area, which CSB lacks. Observations were conducted weekly in prairie (non-water adjacent) and water-adjacent areas, at four locations over two months. Data was analyzed with chi-square goodness of fit. We did not find a significant difference in bird numbers between habitat types ($\chi^2=1.080$, $df=1$, $p=0.299$). We did find a significant difference in type of bird group found in the habitats (songbirds, corvids and waterfowl). Based on the data results, songbirds and corvids preferred prairie habitats, while waterfowl preferred water-adjacent areas (songbirds: $\chi^2=6.231$, $df=1$, $p=0.012$) (corvids: $\chi^2=341.822$, $df=1$, $p<0.0001$) (waterfowl: $\chi^2=455.008$, $df=1$, $p<0.0001$). Additionally, due to data limitations, we could not draw a clear conclusion about the differences in bird diversity between the two campuses. Our findings highlight the importance of conserving habitats to support bird populations and maintain ecosystem balance. Further research is needed to better understand biodiversity patterns in both urban and rural environments.

Abstract Name: Identification of the Antifungal Mechanism of EIPE-1 against *Cryptococcus neoformans*

Cryptococcus neoformans is a fungal pathogen found in soil and bird droppings that causes severe infections in immunocompromised and immunocompetent individuals. Cryptococcal meningitis, a serious manifestation, affects approximately 152,000 HIV/AIDS patients annually, resulting in 112,000 deaths worldwide. Current antifungal treatments are limited by toxicity and increasing resistance, underscoring the need for novel therapeutic options. Our lab identified a eumelanin-inspired compound, EIPE-1, with significant antifungal activity against *C. neoformans*. EIPE-1 treatment results in abnormal fungal cell morphology and alters the regulation of genes responsible for cell wall synthesis, membrane assembly, and cell stress responses. Based on these findings, we hypothesize that mutations in these pathways confer resistance to EIPE-1. To test this, we screened mutants from the *C. neoformans* mutant library, focusing on transcription factors, kinases, and phosphatases. Mutants were co-cultured with an m-cherry fluorescent cryptococcal strain and treated with the minimum inhibitory concentration (MIC) of EIPE-1 or left untreated as controls. Flow cytometry analysis after 24 hours showed that most mutants were more susceptible to EIPE-1 than wild-type strains, suggesting EIPE-1's efficacy in targeting key pathways. Future experiments will validate these findings by exposing mutant strains to increasing EIPE-1 concentrations to confirm resistance patterns. Additionally, Western blot analyses will examine protein phosphorylation in relevant pathways, providing insight into the mechanism of action of EIPE-1. These studies aim to pinpoint how EIPE-1 interacts with critical fungal signaling pathways, offering a foundation for its potential development as a novel antifungal therapy. By addressing the rising resistance to current treatments, EIPE-1 may represent a significant advancement in combating life-threatening fungal infections such as cryptococcal meningitis.

Abstract Name: Traditional Faith, Contemporary Doubts: Is Christianity Adapting to Generation Z?

This study analyzes how members of Generation Z interact with the Christian church and considers whether these interactions are different from how members of Generation X engage with religion. The focus is on the generations' differences in socialization to see if they account for divergences in their faith identities. The researchers paid special attention to social media to see if its use impacts participants' faith practices or lack thereof. Drawing on several focus groups and individual interviews with eight members of Generation X and ten members of Generation Z, the team sought to identify environmental factors that may have contributed to participants' generational differences vis-a-vis faith. The researchers used thematic coding with Dedoose software to analyze participants' experiences with religion and the Christian church and to better understand intergenerational trends in faith formation. The researchers' findings indicate that Generation Z is open to human difference, community is important and may impact people's faith life, and the Christian church is slowly evolving to reflect the needs of the current era.

Abstract Name: Mixed Reality's Utility for Segmenting Large Displays in Medical Settings

Background: Presenting information via holographic windows during endovascular surgery may decrease cognitive load by mitigating the split-attention effect, and allow intraoperative adjustment, overcoming limitations of conventional large monitors, thereby potentially revolutionizing surgical interfaces and improving patient outcomes. Endovascular surgeries, including cerebral angiographies, and stroke rescue therapies are common medical procedures during which a catheter is inserted into an artery and passed through a patient's vasculature. During these procedures, the surgeon is required to consume many different information streams at once including preoperative scans, and intraoperative X-ray feeds. Currently, many angiography systems provide this information on a single large monitor. This solution comes with significant drawbacks from a usability standpoint. During the procedure, surgeons must maintain a sterile surgical field, which prevents their physical interaction with the monitor. Methods: We are currently working on a study to determine the difference in behaviors when referencing information on a large monitor compared to mixed reality. After developing an understanding of how virtual monitors are utilized during fine motor tasks, we hope to explore new approaches for hands-free interaction. Concurrently, we are investigating its benefits for surgical ergonomics. Additionally, we plan to run a study regarding occlusion resolution strategies. Results: In a study designed to investigate the benefits of mixed reality systems in information-mediated tasks, we found no significant difference in performance. However, in interviews, almost every participant noted the task-dependent nature of information display replacements. Conclusion: Augmented reality presents opportunities for users to interact with information without limitations of the physical world, and the requirements of endovascular procedures create an important use case for these techniques. By developing a better understanding of user behavior when presented with holographic monitors in the operating room, we can begin to work toward designing better surgical interfaces in mixed reality to decrease task load, and save lives.

Abstract Name: Agent-Based Modeling of Fibrin Fiber Network Formation

Blood clots are held together by a network of fibrin fibers. It is widely accepted that fibrin networks form through lateral aggregation (forming parallel, chain-like networks of fibrin) and branching. However, new imaging is showing a potentially different formation mechanism, one that involves existing fibrin fibers forming a “criss-cross” structure when one fiber comes into contact with another. Our agent-based model aims to render accurate fibrin interactions to better understand how fibrin networks form. We model individual fibers that rotate and move randomly each timestep. The fibers are represented by a single line with a radius around the midpoint to indicate the interaction region. To start, 60 fibers are randomly oriented and placed inside the “world.” As time progresses and fibers move, any portion of the fiber may enter the radius of another. When this occurs, they stick together and stop in place. We adjust different variables to coincide with different physiological conditions to see which produce results most like experimental output. Early results of our random-motion model suggest that biologically accurate interactions are only possible if the fibers have first reached a critical length. Future models may measure interaction angles, allow for fibers of different lengths, and include details of fiber polymerization.

Abstract Name: Mapping Aquifer Layers and Determining Hydraulic Properties of Glacial Aquifers to Assess Surface-Groundwater Connectivity in the Shingobee River Watershed, Minnesota

Groundwater in Minnesota is an important topic for a variety of water resource uses. The abundance of these water resources allows for large quantities to be used for the purposes of agriculture, industry, human consumption, and generation of power. Understanding the relationship of groundwater and surface water in Minnesota is also important for water resource management. Excessive use of pumping causes stress on aquifers around the state. Mapping the aquifer layers and determining their properties and the degree of confinement is valuable for management. This study was conducted at the Shingobee experimental site, which was originally run by the USGS before being transferred to the University of Minnesota and Bemidji State University in 2022, to study the 28 square kilometer watershed in physical, chemical, and biological aspects. The primary objective was to identify the layers that store and transmit groundwater, and map their spatial distribution. The secondary objective was to analyze pumping test data to determine hydraulic properties such as hydraulic conductivity, transmissivity, and storage coefficient, and to understand the flow regime and connectivity within the layers. The data was collected from observation wells along with information from the Minnesota County Well Index. Cross-sections based on well logs were created for layer mapping. Pumping tests data was analyzed qualitatively to understand flow regimes and quantitatively to determine hydraulic properties. Three aquifer layers were identified and mapped. Pumping test data indicates that these layers are hydraulically connected.

Abstract Name: Bridging the Gap: Developing an LGBTQIA+ Resource Toolbox to Enhance Nursing Education and Culturally Competent Healthcare

Background: Despite AACN efforts to promote diversity, equity, and inclusion, significant gaps persist in nursing education concerning LGBTQIA+ healthcare. Research indicates 80% of nurses receive little/no formal education on LGBTQIA+ health. LGBTQIA+ individuals face inequitable health outcomes due to provider biases and lack of clinical training. A scoping review of nursing LGBTQIA+ health education emphasizes the need for comprehensive resources to improve provider education and reduce disparities. Purpose: An LGBTQIA+ Resource Toolbox was created to educate nursing students, nurses, and healthcare providers on delivering informed, culturally competent care to address gaps in nursing curricula. Methods: An LGBTQIA+ Resource Toolbox was developed to provide current information on LGBTQIA+ care for educators, students, and healthcare providers. The toolbox contains resources specific to LGBTQIA+ health. First-time and return-users are invited to complete a survey assessing their knowledge and current practices toward LGBTQIA+ care. Data is collected on demographics, knowledge, and healthcare practices. Returning users are asked about practice changes after using resources. Results: Most users (126) are female, white, and heterosexual; 4 identified as non-binary. Most users are 20-29 and 50-59 years old. The toolbox reached nurses and providers in 29/50 states with 40.8% practicing in the Northeast. Self-reported practices of inclusive care by first-time users included: 17.11% ask pronoun/name, 9.21% ask about sexual orientation/identity/expression; 18.42% intake/medical forms include pronouns/name, 11.4% use inclusive posters/resources on LGBTQIA+ health; sexual orientation and gender identity is included in employment's nondiscrimination policies (14.04%) and single-stall restrooms (10.09%) are reported by users. Return-users reported improved knowledge and attitudes after using the toolbox. Conclusion: Based on survey results, there is strong engagement among users of the LGBTQIA+ Resource Toolbox. Results of the survey demonstrate interest in implementing changes in clinical practice to better support LGBTQIA+ patients.

Abstract Name: "The Hanging Place: America's First Civil War in Monmouth County, New Jersey"

Many contemporary historians see the American Revolutionary War as localized civil wars fought within different military frontiers, each being waged along different lines but containing similar events. Monmouth County, New Jersey is one of these frontiers that saw heavy fighting due to reasons such as property rights and vengeful militia units. The county's story has been analyzed as a civil war before, but not compared with other fighting areas or how the area and fighting changed over time. This project aims to determine the factors and causes of a civil war within revolutionary Monmouth County and how they relate to the larger scope of the war and tell a unique and separate story within the county. Monmouth County had significant involvement in a military frontier and in the American Revolution as a whole. This project aims to build on previous theories by other historians to prove that Monmouth County experienced significant fighting and change during the war and can fall under the theory of being a civil war. The violence seen within its borders is significant to the story of the Revolutionary War but also holds a unique space within its story. I have analyzed multiple primary sources, including letters from Monmouth's citizens, legislation to ban loyalists from the county, and writings by George Washington and Thomas Paine to help write my paper. Other scholarly works have contributed to my argument, including local historians Michael Alderberg, Mark Lender, and Gary Stone. Monmouth County directly represents a trend in fighting that other military frontiers experienced during the American Revolutionary War. Other frontiers saw significant fighting, but the actions seen within Monmouth County can help explain why the conflict was important and why the county's story directly relates to the causes of the American Revolutionary War.

Abstract Name: Evaluating Statewide Fentanyl Policies: A Comparative Analysis of Texas and Colorado

Incorporating four primary interviews with high-level policymakers, this research evaluates statewide solutions in Texas and Colorado to the fentanyl epidemic, a pressing public health crisis, to identify appropriate responses to this critical policy challenge. Reflecting their particular institutions and politics as well as contrasting drug laws and fatality rates, the two states have adopted distinctive approaches, rendering them useful cases for comparative analysis. The existing research recognizes the effectiveness of specific remediations, specifically medication availability, telemedicine consultation, penalty enhancements, and harm reduction, as well as highlighting pre- and post-COVID-19 challenges. However, little in-depth case study analysis has been conducted to unpack the contextualized effectiveness of key solutions across states. To this end, four semi-structured interviews were conducted with Michael Davidson, Communications Professional at the Colorado Consortium for Prescription Drug Abuse Prevention, Mike McDaniel, Director of Houston High-Intensity Drug Trafficking Area, Wendell Campbell, Drug Intelligence Officer at HHIDTA, and Texas House of Representatives Member Gene Wu, sponsor of fentanyl-related bills. The results suggest that a universal solution to the fentanyl epidemic is highly improbable. Essentially, policymakers must embrace multifaceted approaches with varying degrees of focus on healthcare, education, harm reduction, and law enforcement. These strategies include expanding access to medication-assisted treatment, implementing school-based prevention programs, establishing harm reduction facilities, and enhancing law enforcement operations to dismantle fentanyl trafficking networks. The research is clear that enabling drug users to seek aid and treatment through the healthcare system is more effective than prioritizing penalty enhancements. While this research offers a window into different statewide approaches, further research is needed to evaluate the long-term impacts of Texas' recently enacted fentanyl laws and Colorado's existing policies.

Abstract Name: Interdisciplinary Mentorship: Strategies for Designing and Powering Cameras for Wildlife Research

The Wildlife Research Project exemplifies the power of mentor-student collaboration in addressing environmental challenges, particularly those impacting endangered species. Led by a team of faculty at Miami Dade College, this initiative spans multiple disciplines—engineering, renewable energy, physics, and biology—leveraging Raspberry Pi-based video cameras to monitor wildlife in their natural habitats. The project involves coding Raspberry Pi devices, designing engineering solutions, performing power calculations for solar energy systems, and observing ecological interactions, all of which require substantial mentorship to guide students through advanced concepts. Undergraduate students, often at the beginning of

their academic journeys, rely on instructor guidance to master these interdisciplinary tasks. Through the project, students develop technical and scientific expertise, gaining hands-on experience in both camera design and video analysis. Their efforts provide valuable insights for scientists and park managers, enhancing our understanding of species behavior, ecological dynamics, and urban wildlife interactions—especially within Miami's unique environment. Mentorship plays a pivotal role in this initiative, fostering curiosity and equipping students with the tools to navigate cutting-edge research. By collaborating with mentors, students not only learn but also transition into leadership roles, mentoring peers and engaging with field experts. This cyclical model of collaboration cultivates innovation, drives meaningful research, and prepares students for careers as researchers, educators, and leaders.

Abstract Name: Investigating Mechanisms of Antioxidant Treatment on Drug Resistant Breast Cancer

Understanding mechanisms underlying cellular drug resistance is essential for addressing the rise of drug-resistant breast cancer (BC). The Warburg effect facilitates aggressive cancer cell proliferation by promoting metabolic shifts that favor glycolysis. While antioxidants demonstrate potential as cancer treatment, their effects on BC is complex. A transition to aerobic respiration (OXPHOS) in BC induces oxidative stress and leads to accumulation of reactive oxygen species (ROS), as these cells lack the compensatory mechanisms to adapt to such changes. Shikonin (SHK) is an antioxidant that induces mitochondrial dysfunction and apoptosis in cancer cells, potentially linked to this metabolic shift. This study will elucidate that SHK modulates the metabolic function of drug resistant BC by facilitating a transition from Warburg to OXPHOS. To evaluate these effects, we employed an experimental protocol involving MCF7 (non-drug-resistant), MDA-MB-231 (drug-resistant), and MCF10A (non-cancerous epithelial) breast cells. We assessed cell viability, metastatic potential, oxidative stress, oxygen consumption, and gene expression. Results demonstrate that SHK significantly induces cell death in MCF7 and MDA-MB-231 cells at concentrations of 16, 20, and 24 μ M over 24 hours, compared to untreated and DMSO-treated controls ($p < 0.01$). Furthermore, cancer cells exhibited significant differences in oxygen consumption in relation to SHK concentrations and cell type ($p < 0.01$). However, ROS production in MCF7 cells did not show significant variation over time ($p < 0.55$), as MCF7 cells grow via OXPHOS. These findings support our hypothesis, with ongoing analysis.

Abstract Name: A Genocide in North America: Investigating Modern Indigenous Reconciliation Efforts

My project examined and compared the operations and effects of the Residential School System in Canada

and the American Indian Boarding School System in the United States. It responded to the question of how North American governments participated in the maltreatment of Indigenous populations and have differed in their approaches to Indigenous recognition and reconciliation efforts historically and currently while assessing Indigenous self-determination and the long-lasting effects of intergenerational trauma. One of my motivations for researching this history was the sheer lack of scholarly work on these assimilative institutions, notably on the American end. Scholars who have worked to examine the Residential and Boarding Schools concur that the settler-colonialist practices used align with Indigenous claims of abuse, trafficking, kidnapping, and extermination despite governmental denialism. The purpose of my project was to shine a light on Indigenous-led movements and discoveries about the atrocities committed in these institutions and to educate the masses on this vastly under-covered and dark portion of North American history. My project utilized a historical research methodology by identifying the question, evaluating relevant primary and secondary sources, interpreting findings to better understand the past, and applying the information to the present. The conclusion of my project validated the findings of biological remains on former sites, which align with the historically ignored claims of Indigenous populations. By using a plethora of credible articles and official government statements, I was able to close the gap between said declarations and their factual existence. My project also affirmed the stark difference in governmental action and representation between Canada and the United States regarding their role in the parallel systems, the U.S. being decades behind and millions of dollars short. The overall consensus of my project urged North American governments to take legitimate action toward reconciling the horrors of their past actions.

Abstract Name: Analysis of Visayan/Bisayan/Cebuano Philippine Traditional Vocal Repertoire

The traditional vocal repertoire of Central Visayas in the Philippines is a rich tapestry that encompasses diverse linguistic traditions and subdialects, including Visayan, Bisayan, and Cebuano. This oral heritage provides a unique opportunity for comparative analysis. This research focuses on a portion of the repertoire collected by Priscilla Magdamo; materials collected under the auspices of Silliman and Indiana University. Magdamo transcribed traditional folk songs of the Philippines into six volumes, four of which are used in this study. The overall purpose of this research is to present a preliminary baseline of the repertoire. In addition, preliminary pedagogical merits of the songs will be identified for potential use in Aural Skills curriculum as examples used in classrooms are primarily taken from the Western classical tradition, limiting students' experience with different types of music. Drawing from the music pedagogy of Zoltan Kodály's pitch maps and post-tonal quantitative methodologies, scholars can discern normative patterns and outlier variations in pitch collections as well as scalar patterns across different song repertoires. By employing techniques such as tonic-centered successive-interval arrays and composite pitch collection mappings, researchers can delve deeper into the structural nuances and tonalities inherent in the Central Visayan vocal traditions. Analysis showed that there are patterns within the song collections used, such as almost every song containing pitch classes two and five. This means that most songs contain a supertonic and subdominant, implying that there may also be some form of predominant function within them. Having form that can be viewed through this lens also implies that the songs contain material that aligns with concepts taught in Aural Skills classes. As such, it is expected that the repertoire contains other normative patterns, and that students will be able to understand and find use in the addition of Philippine folk songs to their curriculum.

Abstract Name: Wingstop: From Dream to Reality

Wingstop, the nationally acclaimed wing-focused restaurant chain, has had a long, rich history of success. However, before becoming famous, it remained a simple dream and ambition of its founders, Bernadette Fiaschetti and Antonio Swad. This research essay reflects Wingstop's chronological history, from its first opening in Garland, Texas in 1994, to its franchising in 1997, and to its recognition as the 'official wings of the Dallas Cowboys' in 2009, to its nationwide impact today. As one of the first restaurants in America to concentrate on wings, Wingstop has been a leader in developing this market. For my research, I utilized several magazine and newspaper articles to get the beginnings of the concept itself, such as the Fort-Worth Star-Telegram. In addition, the paper also utilizes other primary sources such as interviews of the founders and other employees and franchisees. I used other documents to complete the story, in particular the loyal support of customers throughout its expansion.

Abstract Name: Does Nectar Availability Drive the Abundance and Movement of a Rare Butterfly Species?

Nectar is a vital resource for the survival and proliferation of many species, including a variety of bats, flies, bees, and butterflies. Variations in the abundance, distribution, and diversity of nectar resources can limit the populations of these species. For the Crystal skipper butterfly (*Atrytonopsis quinteri*), life in their native, range-limited coastal dune habitat consists of a low diversity of floral species compared to other habitats (e.g., forest, prairie) and their access to these nectar resources may be affected by urbanization. Our goal is to understand how the distribution of nectar sources correlates with the distribution of the Crystal skipper. To study this, we analyzed floral abundance and Crystal skipper mark-recapture data from 6 transects across 3 sites (i.e., urban, protected land, and dredge spoil land) to determine whether nectar availability correlates with butterfly abundance and recapture probability across these study sites. From this data, I expect that the more diverse and abundant nectar sources within a habitat will indicate a higher concentration of Crystal skippers within that area. In addition, for the urban areas, I expect them to contain fewer Crystal skippers because of a lower abundance and diversity of nectar sources. In identifying the correlation between the Crystal skipper and the nectar sources needed for its survival, we can develop a better understanding of the impact of the diversity and distribution of nectar sources as well as the necessary steps to conserve and protect the Crystal skipper species. In turn, the Crystal skipper can act as a model species as we can use the information from this research to assist in the creation and development of conservation plans for other range-limited species'.

Abstract Name: Genetic correlation between Dental Disorders and Alzheimer's Disease: A Polygenic Risk Score and Mendelian Randomization Study

Background: Despite prevalence and rising rates of Alzheimer's disease (AD), the inherited associations with comorbidities, such as oral health are poorly understood. This study aims to identify possible the genetic and causal relationships between several dental conditions and AD. Methods: Genome-wide association study (GWAS) of sixteen dental conditions to create polygenic risk scores (PRSs) in independent AD discovery with adjustments for the top principal components (PC1, PC2). Nominally associated conditions were reevaluated in a replication analysis to confirm directionally of correlation. Further analysis of correlation evaluated with additional covariates (sex, age, and APOE ε4 count). PRS associations with AD in the discovery and replication samples were then meta-analyzed. Potential causal relationships between AD and dental conditions was evaluated by a bidirectional two-sample Mendelian randomization (MR) analysis, focusing on the significant dental conditions from PRS analysis. Results: The PRS meta-analysis identified two risks associated dental disease PRSs (Dentures, DMFS/Dentures combined), and two that were protective (Nteeth, excluding or including HCHS/SOL) ($p < 0.0125$). In the MR analysis, periodontitis combined with loose teeth inferred a positive causal relationship with AD as the outcome (Wald Ratio p-val: 0.036). In the reverse MR analysis, there were no notable relationships. Conclusions: Our results suggest a genetic connection between dental disease conditions (Nteeth, dentures, and DMFS/dentures) and AD. Periodontitis combined with loose teeth showed a causal relationship unidirectionally with AD. This highlights the consequence of oral health in the prevention of AD from a genetic perspective. Further studies on the clinical observations are warranted to better understand applications.

Abstract Name: Focus on POWER: Mixed Methods Insights for the Preservation of Physical Function in Soft Tissue Sarcoma patients.

Introduction: Soft tissue sarcomas (STS) are rare, malignant tumors found in the trunk and extremities of the

body. They are treated with surgery, chemotherapy, and/or radiation. Despite treatment advances, patients experience side effects like functional decline, fatigue, and reduced quality of life. Prehabilitation (preoperative exercise and diet interventions) improves postoperative outcomes in other cancers, but remains understudied in STS. This study assessed STS patients' needs and preferences for a lifestyle prehabilitation program. Methods: STS patients completed an online questionnaire including demographics, cancer and treatment characteristics, and current physical/dietary activity. Participants also completed a semi-structured interview addressing their treatment experiences, symptoms, lifestyle behaviors, feedback on prehabilitation, and nutritional programming. Data from the interviews were analyzed by 5 research team members using an inductive approach through thematic text analysis. Results: Participants (N = 20) were 50% female, ages 22 to 77 years. Patients who received chemotherapy before surgery (83%) felt fatigue and loss of appetite. Patients who received radiation (63%) felt fatigue and loss of physical function. Five themes emerged from the interviews for patients' needs and preferences: (1) Prehabilitation lifestyle resources allow ownership over recovery; (2) Consistent reinforcement and feedback; (3) Tracking external factors that influence lifestyle habits; (4) Social support from other STS survivors; and (5) Remote access to support and resources. Discussion: Participants emphasized the need for prehabilitation resources like physical activity and nutrition recommendations before surgery, as early access would empower them to take ownership of their recovery. They expressed interest in regular reinforcement and using behavioral tools. Participants suggested future lifestyle interventions should consider factors like mental health, symptoms, side effects, and family stressors when designing programs. Lastly, support from other STS survivors was seen as valuable for accountability and encouragement. Overall, participants viewed a prehabilitation program positively to improve postoperative outcomes and quality of life.

Abstract Name: Estimate of Biomass and Carbon Storage in Cane Creek Mountains Natural Area

Photosynthesis removes carbon dioxide (CO₂) from the air and in woody plants, the carbon is stored for long periods of time. Forests with long-lived and large trees should store significant amounts of CO₂. The purpose of this study was to document the composition and structure of the forest and to estimate biomass and carbon storage in Cane Creek Mountains Natural Area (CCMNA), a local park with a Piedmont monadnock forest type. Data were collected from 46 non-permanent plots in which prism cruising was used to select trees for inclusion in the study. Diameter at breast height (DBH), as well as the species for each tree was recorded. Our results indicate that the size and species of trees in CCMNA are consistent with that of old-growth forests. Oak species are dominant, with 50% of trees being chestnut oak (*Quercus montana*), and 12.6% being white oak (*Quercus alba*). Furthermore, we found that the forest stores between 193.2-214.7 Mg/C/ha (45-50% of biomass), which is significantly higher than that stored in younger Piedmont forests. We examined the relationships between carbon storage and the following values: number of trees (N), species richness (S), Shannon's diversity (H'), % oak, and tree size (DBH). The only significant correlation with carbon storage was tree size. Our results indicate that local parks such as CCMNA are significant carbon sinks so long as they are managed to maintain healthy forests.

Abstract Name: Indeterminate Politics: U.S. Interventionism within Nicaragua

This research accumulates various historical viewpoints, ranging from 1986 to 2023, and constructs a greater holistic work detailing justifications and complexities surrounding U.S. foreign policy towards Central America during the 1980s. It highlights the initiatives and goals of the Reagan administration which dictated U.S. interaction with the nation of Nicaragua and seeks to clarify ongoing historiographical debate surrounding the justification for these projects. This study utilizes documents, testimonies, and speeches from the United States Congress and former President Ronald Reagan to contextualize official statements relating to the role of the United States within Nicaragua. It then places them in comparison with later interpretations of 1980s U.S. foreign policy from authors such as Jeff Bass, Robert Kagen, Roy Gutman, Thomas Carthers, William Schmidli, and several others. In addition to this, notable publications from The Heritage Foundation, The Permanent People's Tribunal, and The Washington Post are used to observe larger media interpretations of U.S. intervention during the time period. Individual publications of political authors such as Andrew Kimmens, William Leogrande, Peter Kornbluh, and Christopher Dickey are also included for the role of observing political opinion of foreign policy initiatives within the time period.

Abstract Name: Investigating the impact of Noise on Hyperspectral Unmixing

A hyperspectral image is a photo created by collecting information from the electromagnetic spectrum and has three axes: x , y , λ . " λ " represents a wavelength value allowing images to be created at different wavelengths and then combined into 3-dimensional data. By analyzing the reflectance values over different wavelengths, distinct spectral signatures called endmembers can be extracted. These endmembers can be used to identify different material in a scene allowing hyperspectral imaging to be used in object detection and classification. However, if a pixel contains multiple endmembers, there is a need to unmix those endmembers to find out the amount of each material in that pixel. Hyperspectral unmixing is the process of determining the weight or amount of a material that is in each pixel of the data. Linear Unmixing is done by recovering a linear combination of the endmembers in an image along with their weights for each pixel. These can then be used to create abundance maps, images that use a color scale to indicate the weight of a material in a pixel, creating a map for each endmember. Hyperspectral processing techniques are used in many fields, with one of note being anomaly detection. This study had the goal of analyzing one of many computational pipelines used in enhancing anomaly detection. The analysis was focused on the pipeline's ability to handle noise in cases of unmixing. It was found that part of the pipeline, edge enhancement, had an undesirable effect on noisy images, while other parts helped mitigate the noise. Another part of the study was to attempt to provide a solution if the pipeline could not handle noise well. Attempted solutions, such as sharpening, saw improvements to unmixing accuracy for some endmembers at the expense of the accuracy of others, indicating a need for a general solution.

Abstract Name: Is Executive Function Similarly Related to Behavioral Outcomes in Typically Developing and Neurodiverse Children?

Executive functions (EF) are a set of neurocognitive processes that help us engage control over our actions, manage the information in our brains, and prioritize ideas that are aligned with our personal objectives. Evidence has shown that EF is essential to child development, especially in its concurrent and longitudinal relation to both academic achievement and school readiness. Research suggests that children diagnosed with neurodevelopmental conditions show greater impairment in EF compared to their neurotypical peers. While the overall relationship between EF development and behavioral outcomes is well established, it is not yet known whether this relationship is moderated by neurodiversity status. The project will investigate the relation between EF in young children and behavioral outcomes by conducting a mixed-effects meta-analysis. It will explore whether the relation between child EF and behavioral outcomes varies depending on whether children are typically developing or have clinical, learning, or behavioral diagnosis. Through this meta-analysis, we hypothesize: There will be stronger, more consistent EF-behavioral outcome relations in neurodiverse vs neurotypical samples. Inclusion criteria involve children between the mean age of 3.0-5.99 years when assessed for EF, primary studies, and studies that used performance-based tasks to measure EF. We conduct a thorough literature search on four databases, complete abstract and full-text screening, and analyze multiple effect sizes from multiple studies. This project addresses the knowledge gap that no meta-analysis has included and compared neurodiverse and neurotypical populations, which could lead to important insights about the nature of EF skills. It is important to know this in order to enhance our understanding of the best ways to foster EF skills in all children.

Abstract Name: Oncolytic virotherapy and chemotherapeutic approaches against malignant fibrosarcoma

Fibrosarcoma is a type of rare and poorly studied cancer associated with a ~40% survival rate at five years after diagnosis. Oncolytic virotherapy, which relies on the use of viruses to kill cancer cells, is being explored as a therapeutic agent against common cancers that show resistance to chemotherapy. One oncolytic virus, Reovirus, has been shown in clinical trials to effectively kill various types of cancer cells while having minimal side effects in patients. However, the oncolytic potential of Reovirus against rare cancers remains largely understudied. Here, we explored the oncolytic potential of genetically-different Reovirus strains in human HT-1080 fibrosarcoma cells. Our research shows that HT-1080 cells are permissive to Reovirus infection and that the infection rate is strain-specific. We quantified the ability of the different viral strains to kill fibrosarcoma cells and assessed their therapeutic effects of combining Reovirus with chemotherapeutics. Our data demonstrates that infection of HT-1080 cells with selected Reovirus strains followed by treatment with chemotherapy results in a significant decrease in cell viability compared to individual treatments. Altogether, we identified two viral strains with strong oncolytic potential in fibrosarcoma cells and demonstrated their enhanced effectiveness when used in combination with common chemotherapeutic agents.

Abstract Name: Examining a Potential Therapeutic approach for Parkinson's Disease Using Overexpression of ATP6VoA1

Parkinson's disease (PD) is the most common neurodegenerative movement disorder and is characterized by the loss of dopaminergic neurons in the substantia nigra pars compacta and aggregation of the α -synuclein protein. Emerging evidence suggests that lysosomal function plays a vital role in removal of α -synuclein aggregates through autophagy. Interestingly, we determined that ATP6V0A1, a subunit of the v-ATPase transmembrane pump that is integral in maintaining lysosomal pH homeostasis and autophagy clearance, is a risk factor for PD. However, we do not know the relationship between ATP6V0A1 function and the development of synuclein pathology. It is possible that, by enhancing autophagy and the clearance of protein aggregates, ATP6V0A1 could slow disease progression and could serve as a potential therapeutic target for treating Parkinson's disease. Here, we show data implicating ATP6V0A1 in PD etiology and validate a number of tools to overexpress ATP6V0A1 in mouse models of synucleinopathy. Future work will determine whether overexpression is capable of reducing synuclein load and preventing cell loss in the pre-formed fibril model of synucleinopathy. Together this study aims to determine whether ATP6V0A1 overexpression is capable of promoting synuclein clearance, potentially mediated by increased activity of the ATP6 proton pump and lysosomal acidification; if so, therapeutic approaches could involve the use of vATPase activators for neuroprotection in PD.

Abstract Name: China-Pakistan Relations: Assessing the All-weather Friendship in a Changing Political Climate

The People's Republic of China (PRC) is an emerging power within the international system and has risen in status in recent decades following significant economic and foreign policy changes. Consequently, the PRC has engaged in what has become an increasingly multipolar world, challenging the United States (U.S.) in areas including economic, technological and militaristic superiority. Since Xi Jinping's ascension to become the paramount leader in 2013, China has deployed a more ambitious foreign policy. The PRC has utilized militarism in regions of strategic importance, while concurrently promoting major investment programs abroad. One of the critical junctures of the PRC's foreign policy apparatus is Pakistan, a longstanding ally of the country that offers significant strategic benefits both in South Asia, as well as the larger global system. It is the intention of this research project to critically examine the China-Pakistan alliance in order to understand the primary motivations that sustain this special relationship. Specifically, this work will scrutinize the

evolution of the Gwadar Port project, from its recognition of geostrategic importance in 1958, to its inclusion in the China-Pakistan Economic Corridor beginning in 2013. As one of the flagship projects of the PRC's Belt and Road Initiative, Gwadar Port is a particularly compelling narrative of bilateral relations and regional geopolitics. Considering both historical trends and contemporary developments, this work will yield an analysis of Chinese foreign policy under the leadership of Xi Jinping, as well as how investment and cooperation between China and its premier South Asian partner will impact the global order amidst a developing Sino-American rivalry.

Abstract Name: Trends of Diagnosis Disclosure Among Individuals with Plasma Cell Disorders

Multiple myeloma, along with precancerous conditions such as monoclonal gammopathy of undetermined significance (MGUS) and smoldering myeloma, represent the most common plasma cell disorders (PCDs) around the world. Coping with such disorders is often a challenging prospect for patients, and the disclosure or withholding of information pertaining to the patient's diagnosis or prognosis may have a significant impact on the patient's perception of their care. We hypothesize that patient perceptions of diagnosis disclosure will be largely positive due to the various psychosocial benefits conferred by the sharing of information with friends and family. In order to investigate these diagnosis disclosure patterns among individuals with PCDs and determine areas for interventions that utilize social support strategies to help patients navigate their diagnosis, we invited participants with PCDs through the HealthTree Cure Hub to complete a 34-question online survey regarding their disclosure trends (n= 510). Participants generally reported sharing their diagnosis with at least one person (98%), with the most common responses being a spouse, domestic partner or significant other (60%) and friend(s) (10%). Most participants that chose to disclose their diagnosis experienced a positive impact in their coping (79%) and became closer with others (55%), whereas patients who chose not to disclose their diagnosis generally reported feeling more isolated in their relationships (56%). Despite some reports of certain negative experiences associated with sharing a PCD diagnosis, the majority of participants expressed no regrets over sharing their diagnosis (87%). Based on these findings, patients generally perceive sharing their diagnosis among their primary social networks to be beneficial to their coping. Oncologists may be advised to promote the utilization of social support to navigate a PCD diagnosis.

Abstract Name: FRESH-Enabled 3D Bioprinting of Emulsion Materials for Tissue Engineering Applications

One of the primary goals of tissue engineering is the development of functional scaffolds that replicate the structural and physiological behavior of native tissues/extracellular matrix (ECM). Recent literature has highlighted that two critical features of ECM are multiphasic structures and porosity, both facilitating valuable functions such as cell migration and infiltration. The challenge is that traditional scaffold fabrication methods struggle to create multiphasic microscale porous architecture. One class of materials that inherently possesses these characteristics are emulsions. However, most current emulsion manufacturing techniques are limited and do not possess the macroscale complexity required for advanced tissue engineering applications, highlighting the need for a platform that can generate more complex shapes. This research addresses these limitations by combining emulsion material fabrication with the Freeform Reversible Embedding of Suspended Hydrogels (FRESH) 3D bioprinting system. The goal of this work lies in developing a system capable of 3D bioprinting complex macroscale geometries with microscale porosity and multiphasic architecture, enabling precise control over scaffold design at both the macro- and microscale. The methodology involves three stages: optimizing a baseline FRESH bath to generate optimized microarchitecture, enhancing the macroscale printability, and evaluating the cytocompatibility of the printed constructs through cell viability assays. Preliminary results have successfully generated the macroscale printability of our emulsion material. Additionally, microscale morphology from scanning electron microscopy (SEM) demonstrates promising potential for optimizing multiphasic microarchitecture. Further refinements are underway to achieve the desired structural and functional properties, laying the foundation for scalable, physiologically relevant scaffolds.

Abstract Name: Dissecting the Impact of SARS-CoV-2 Variants on Olfactory Signaling Pathways and Inflammation in Mice

The Omicron variants of SARS-CoV-2 have posed significant challenges to public health due to their acute and chronic disease burden. Anosmia is a hallmark of SARS-CoV-2 infection, yet the molecular processes

linking inflammation to olfactory dysfunction remain poorly understood, particularly across different viral strains. To address this, we developed a sublethal but pathogenic mouse-adapted SARS-CoV-2 Omicron BA.1 virus (BA.1 MA), comparable to the original mouse-adapted SARS-CoV-2 strain (MA10). This study integrates spatial transcriptomics and histological analysis to provide a detailed and localized perspective of the nasal epithelium's response to infection, enhancing our ability to model and predict human olfactory pathology. Using the GeoMx Digital Spatial Profiling platform, we analyze nasal tissues at 2, 4, and 7 days post-infection with SARS-CoV-2 variants MA10, BA1, and BA5. Gene expression analyses revealed strain-dependent changes in inflammatory mediators (e.g., Il6, Ccl2, Ccl5) and olfactory signaling genes (e.g., Olfr, Gnal, Adcy3). Spatial resolution of transcriptional changes showed infection-induced inflammation correlating with disruptions in olfactory pathways, providing critical insight into localized tissue damage. Our findings highlight upregulated interferon-stimulated genes and IL-1 inflammatory pathways in SARS-CoV-2 infected olfactory epithelial and submucosal regions. IL-1 pathway activation was more pronounced in MA10-infected mice, correlating with greater submucosal damage compared to BA1. MA. Additionally, Ugt1a1 and Ugt2a2, genes implicated in post-infection anosmia in humans, were significantly downregulated in both MA10- and BA.1 MA-infected mice, supporting the relevance of these models to human olfactory pathology. These data underscore the importance of early interventions targeting inflammation to mitigate anosmia. Our study identifies strain-specific transcriptional pathways disrupted in the olfactory epithelium during SARS-CoV-2 infection, advancing our understanding of the molecular basis of anosmia and inflammation across different viral strains.

Abstract Name: Role of Parkinson's Disease-Linked PINK1 in Histone Modifications

Parkinson's disease (PD) is a neurodegenerative disorder characterized by a loss of dopaminergic neurons needed for normal movement. Deletion mutations in the PINK1 gene cause an inherited form of PD with early onset of symptoms, usually under age 45. Recent findings suggest that the mutations in PINK1 decrease removal of dysfunctional mitochondria, but we are exploring alternative functions of PINK1. The purpose of this project is to determine if the protein PINK1 can regulate gene transcription. PINK1 is known to phosphorylate ubiquitin at serine 65 (pS65-Ub), and the Goldberg lab has recently identified the nuclear protein histone H2A to be conjugated to pS65-Ub in wild-type (WT) astrocytes, while being absent in PINK1 knockout (KO) astrocytes. This project aims to determine if PINK1 regulates gene transcription by increasing pS65-Ub conjugation to histone H2A. We hypothesized that the phosphorylated form of ubiquitin conjugated to histone H2A is more stable compared to the non-phosphorylated form. Histone H2A ubiquitination promotes methylation of histone H3, which represses transcription of inflammatory cytokines including interleukin-6 (IL-6), found at higher levels in humans with PINK1 mutations. We used chromatin immunoprecipitation (ChIP) with rabbit anti-pS65-Ub antibody to investigate if we could detect pS65-Ub conjugated to histone H2A in mouse brain chromatin. Quantitative PCR and DNA fragment size analysis showed significant signal using our positive control antibody against histone H3 in both WT and KO samples. We tested various methods of immunoprecipitation using different amounts of nucleosomes with and without purifying the nucleosomes with hydroxyapatite.

Abstract Name: Frontier Fathers in Crisis: Bob Dylan's "Ballad of Hollis Brown" and the Legacy of Familial Struggle in Rural America

This paper examines Bob Dylan's "Ballad of Hollis Brown" within the context of late 19th- and early 20th-century rural America. In a period marked by economic and social transformations—industrialization, job migration—there was a disruption of traditional frontier life, particularly the divide between rural and urban families which led to widespread poverty and shifting family roles. As fathers struggled to maintain their identities and provide for their families, many women and children assumed nontraditional roles, leading to unfamiliar, sometimes-frustrating family dynamics. Patriarchs often felt emasculated and lost, contributing to an increase in violence, which Dylan captures in his haunting portrayal of Hollis Brown, a father who, overwhelmed by his inability to provide, resorts to a tragic murder-suicide. Incorporating historians Linda Gordon's and Steven Ruggles' analyses of the history of family and Elliott West's look at children on the frontier, among others, this paper connects Dylan's song to historical trends, focusing on the challenges of familial anxiety faced by pioneers on the frontier. As the frontier expanded, families often experienced separation and loss, which, combined with economic hardship, led to psychological distress and social breakdown. This pattern of paternal frustration and loss of identity is reflected in Dylan's narrative, where Hollis Brown's act of violence can be seen not just as madness but as an anguished response to overwhelming external pressures. The song serves as a window into the emotional and social realities of rural America, offering a deeper understanding of the personal toll of economic and familial disruption. Dylan's song, through its powerful narrative and evolving performances, remains a significant reflection of the complexities of domestic life and the struggles of those left behind by an industrializing nation.

Abstract Name: Frank Capra, the Great Depression, and the Fallacy of the American Dream

This paper analyzes the depiction of the American Dream in the films of immigrant filmmaker Frank Capra, particularly "Mr. Smith Goes to Washington" (1939) and "It's a Wonderful Life" (1946). Capra depicts a nation in crisis in contrast to the idealized vision of the "American Dream" by contrasting it with the harsh realities faced by ordinary citizens, as seen through his protagonists, Jefferson Smith and George Bailey. Building upon the work of historian Charles R. Hearn, who initially foregrounded the ways that the Great Depression stifled this promise of prosperity, this paper shows how Capra's not-so-sunny vision of American life reflected 20th-century realities. Further, I elaborate upon historian Peter Feuerherd's assertion that Capra subverted the idealized narrative of this dream, among others, by demonstrating precisely how this was so by examining the economic struggles of the protagonist Bailey, a small bank manager. Central to the presented argument is that Capra uses the outsider perspective to highlight the contradictions within American politics and society. Through this lens of the Great Depression and its aftermath, I consider how both films offer a commentary of the political and economic systems that promised prosperity in the early 20th century but often failed to deliver. In "Mr. Smith," Capra critiques the corruption of political institutions and breakdown of democratic ideals, portraying the struggle of the everyman. This theme resonates with modern distrust in government. Similarly, in "It's a Wonderful Life," Capra presents a more personal reflection on the American Dream, exploring the economic struggles of the collapse of the traditional family business in the face of

corporate greed. These films paint nuanced scenarios of American capitalism and politics while providing messages of perseverance and community.

Abstract Name: Analyzing Vaccination Equity: Factors Influencing Uptake for Reemerging and Ongoing Infectious Diseases (COVID-19, Influenza, Pertussis, Measles) Using Data Science and Machine Learning

The MAVEN (Multidisciplinary Analysis of Vaccination Games for Equity) project addresses the global health threat of vaccine inequity in the fight against emerging infectious diseases. Vaccination is essential for controlling and preventing infectious diseases, especially routinely recommended vaccinations for ongoing diseases of high transmissibility. In the study presented here, we utilize publicly available datasets from the U.S. Department of Health and Human Services (HHS), Centers for Disease Control and Prevention (CDC), the United States Census Bureau, and the Mayo Clinic. Our research found a significant association between population heterogeneity and vaccination behavior for historically marginalized communities within California counties during the COVID-19 pandemic. To explore changes in future vaccination uptake trends, we apply predictive modeling using machine learning techniques such as Long-Short Term Memory (LSTM) neural networks to conduct time-series forecasting, using objective optimization techniques such as multi-objective evolutionary ensemble learning to enhance predictive performance. Analogous to the COVID-19 pandemic, we provide insight into how structural, social, and individual factors impact vaccination uptake rates for other reemerging diseases. Our approach focuses on regional factors correlated to the uptake of various pediatric vaccines, using statistical parametric analyses through Python software to then identify the relationship between regional variation and type of vaccine for Diphtheria, Pertussis, and Tetanus (DTaP) and Measles, Mumps, and Rubella (MMR). Understanding these disparities in childhood vaccines recommended during early developmental stages can help guide targeted strategies to improve vaccination coverage and reduce barriers to vaccination access. Extending our analysis, we explore individual factors correlated to influenza vaccination uptakes in the United States. Preliminary findings revealed a strong association between economic, social, and housing factors for vaccination uptakes. Understanding these various factors can help uncover patterns contributing to disease resurgence and provide insight into how to strengthen public health intervention for future infectious threats.

Abstract Name: Validating a Method to Confirm Sex in *Xenopus laevis* Tadpoles

Larval amphibians are important models for understanding vertebrate development. However, it is difficult to discriminate males from females because gonads are not easily distinguished until after metamorphosis. Similar to humans, *X. laevis* tadpoles have chromosomal sex determination. *X. laevis* uses ZZ/ZW-type sex determination, with ZZ chromosomes for males and ZW for females. While human males contain the unique Y chromosome, female *X. laevis* contain the unique W chromosome. In this study, we aimed to validate a method to determine the sex of *X. laevis* tadpoles. I achieved this goal using DNA extracted from the guts of 14 *X. laevis* tadpoles and two *X. laevis* metamorphs. A W-linked (*dm-w*) and Z-linked (*dmrt-1*) gene were amplified using PCR and visualized on a 2% agarose gel. We expected that genetic males would have one band at the expected product length for the Z-linked gene and the females would have bands at both the expected product lengths for the Z-linked and W-linked genes. To further validate the method, I plan to examine adults where I can compare gonadal sex with genetic sex. Future studies can utilize this validated method to reveal possible sex differences in tadpole gene expression, hormone levels, or behavior.

Abstract Name: Food Insecurity in Children's Media: Lived Experiences' Impact on Upper Elementary Students' Perceptions of Similarity to Characters in Picture Books, Liking of Story, and Perceptions of Food Insecure Children

One in five children identifies as food insecure in the USA, and the issue continues to grow. Stigmas about food-insecure individuals remain rampant and misinformed through news and media framing. Yet, depictions of characters facing food insecurity and leading storylines surrounding this topic are limited within children's media—both books and television shows—giving children fewer outlets to learn and understand food insecurity. However, there is prominent research on the benefits of social-emotional learning in children's media content—including authentic, non-stigmatized representations of race, gender, and culture—and its use to lessen stereotype beliefs. Studies show children who perceive themselves as similar or have similar experiences to diverse kid characters can improve their confidence and achievement. While likely applicable, little to no research exists on food-insecure characters and children's lived experience of food [in]security and its impact on perceptions of others and the self. It is important to explore this gap to increase positive representations of food insecurity in children's media. In this study, over 500 upper elementary students (third and fifth graders) in a Pennsylvania school district are anticipated to participate in a classroom-based study involving a read-aloud of picture books. Parental pre-screening questionnaires identify the food security status of involved participants. Classes are randomly assigned to engage with two food insecure-centered books or two control books and answer pre-exposure questions about experiences with food insecurity, and adjective associations with food insecure kids. After exposure, questions are asked about story liking, perceived similarity with character, and the pre-test question about adjective association is repeated. Data will be analyzed using ANOVA tests and coding open-ended responses to assess the relationships between how book conditions and lived experiences of food insecurity impact kids' perceived similarity to characters and their positive attributes towards food-insecure children before and after book exposure.

Abstract Name: Divinity and the Dead: Pantheism in Northeastern Protestant Elegy

Historically, New England elegists have found comfort in Protestantism. It is this very Protestantism, however, that assigns ontological priority to an afterlife, heaven, and in doing so occludes diverse experiences of grief. Nonetheless, within this same elegiac tradition, we find an evolution toward pantheism, which embraces ontological parity, and, in turn, embraces rather than stifles grief. By deconstructing established religious hierarchies, we question whether a singular God, as espoused in traditional Christian theology, can be the only cause of signified meaning in the world. This collaborative research project begins with Anne Bradstreet's Puritan poetics and traces the development of an implicit pantheism in Lydia Sigourney's early 19th-century works. We compare these foundational Protestant poems to elegies by Walt Whitman and Edna St. Vincent Millay, relative exemplars of the pantheistic mode of grief and disruptors of protestant hierarchies. Through an analysis of Whitman and Millay, we argue for a grief which allows for the dead to be celebrated not only as a departed other, but as God. As a framework for our argument, prompted by a reading of John Hunt's 1884 *Pantheism and Christianity*, we analyze the Hellenistic theology of Philo Judaeus through the lens of Jacques Derrida's theory of the trace, positing that Philo's non-ontological God is correspondent to Derrida's ultimate other, an entity existing outside of ontology, yet one the written word reveals and conceals. By engaging with Philo and Derrida as a means to interpret the undeniable presence of religious multiplicity in the American elegiac tradition, this project uncovers a hidden history of longstanding intersection between two seemingly oppositional doctrines, honoring diverse experiences of grief. Our project also evokes further discussion of the nature of grief and the cultural necessity for acknowledging the religious diffusion inherent to poetic expressions of death.

Abstract Name: A Numerical and Differential Analysis of Smoking Habits in Young Adults Following an SEIS Model of Disease Spread

Nicotine dependence is one of the most widespread and costly health disorders in the United States to date. The vaping-to-smoking pipeline is a growing point of contention in youth health regarding nicotine consumption with both evidence supporting and refuting its existence. To help increase understanding of this potential trend, we propose an adaptation of a commonly used differential-equations based compartmental model of disease spread that captures the unique interactions between non-users, e-cigarette users, and combustible cigarette users. We determine the basic reproduction number and analyze the stability of equilibria in the no-smoking case, vaping-only case, and endemic case. We propose possible numerical trajectories of the youth smoking endemic given current usage rates and trends.

Abstract Name: Mind the Gap: Exploring Proposed Mediating Factors Between Sleep Quality and Dissociation

Minor dissociation (feeling a disconnect between one's mind and body/environment) is a near universal experience. Dissociation as a pathology is associated with poorer outcomes for a myriad of mental health disorders. Key to providing better treatment for these disorder subtypes is understanding the causes of dissociation. We use multiple linear regression to analyze the relationship between dissociation and sleep disturbances as mediated by executive dysfunction/cognitive failures, alexithymia (the inability to understand emotions), and post-traumatic stress (PTS) symptoms (excessive nervousness, daytime flashbacks, etc.). Dissociation is significantly positively correlated with poorer sleep, as well as PTS symptoms, alexithymia, and executive dysfunction/cognitive failures. PTS symptoms and cognitive failures seem to significantly mediate the relationship between sleep and dissociation ($R^2 = .67$, $F(4,71)=38.76$, $p < .001$), while alexithymia does not reach significance, suggesting that future research and interventions for dissociative subtypes of mental health disorders should focus on cognitive skills.

Abstract Name: Examining racial and sex differences in novel measures of subjective response to alcohol

Subjective response to alcohol (SR) refers to individual differences in neurophysiological effects during alcohol consumption. Previous research highlights SR as a potential etiological risk factor for alcohol use disorder (AUD) and related problems; therefore, developing a deeper insight into this facet of alcohol use can diminish harms associated with this condition. Research shows significant variance in SR across demographic groups, with evidence from survey measures suggesting males experience lower levels of response to alcohol compared to females and Black individuals need fewer drinks to feel "drunk" compared to White individuals. However, SR survey measures do not capture how intensely people experience alcohol effects within their items. Thus, the current study aims to examine the extent to which racial (i.e., individuals identifying as Black vs. White) and sex (i.e., assigned male vs. female at birth) differences affect SR as defined by both intensity of alcohol effects and number of drinks required to experience effects. Participants ($N=246$) were heavily drinking adults (18-50 years) who endorsed impaired control over drinking and completed a 30-minute online survey. Participants reported the number of drinks to experience alcohol effects using the Alcohol Sensitivity Questionnaire (O'Neill et al., 2002), as well as how intensely they experienced relevant effects. Factor analyses revealed that two factors underlay items assessing alcohol effect intensity (i.e., stimulating vs. sedating effects) and the number of drinks (i.e., lighter vs. heavier effects of alcohol). Linear regression revealed that Black individuals reported higher intensity of stimulating alcohol effects ($\beta=0.14$,

$p=0.03$) and needing more drinks to feel lighter alcohol effects ($\beta=0.21$, $p<0.001$) relative to White individuals. Moreover, males reported needing more drinks to feel heavier alcohol effects ($\beta=0.19$, $p<0.001$) relative to females. These findings highlight the assessment of alcohol effect intensity as important in illuminating important demographic differences in SR.

Abstract Name: Chile Within Mesoamerican Culture

Prior to the Spanish invasion of the Americas, the fruit of the chile or chili plant was used in a variety of ways. These included use within food preparation, and in consumed medicinal remedies. Studying the significance of chile or other foods within the Mesoamerican culture creates opportunities for researchers to better understand the role in which different types of foods impact the Nahua people. This study aims to closely analyze how chile was discussed and used within the Mesoamerican culture, specifically among the Nahua people. Based on analysis of multiple sections within the Florentine Codex, this research aims to understand how the chile was used as an additive within cultural dishes, a component within remedies, and other influential ways; also addressing why they were used. Implementing an approach of literary analysis through compare and contrast of two different translations. The primary source material used within the research is the Florentine Codex, a 12-volume, Indigenous-authored text that is available in the original Nahuatl, with a Spanish translation (and an English translation of both the Nahuatl and Spanish). Analysis within the Codex suggests that chiles had broad culinary, medicinal, and other social significance. The study of the impact of chile shows a narrow look within the culture and practices of the Nahua people, informing how much is still unknown about the Mesoamerican people.

Abstract Name: Heterozygous knockdown of cofilin 1 in rod photoreceptors exacerbates effects of degeneration in a mouse model of retinitis pigmentosa.

Cofilin 1 (CFL1) is an effector of actin cytoskeletal dynamics and contributes to toxic protein aggregation and disease exacerbation across multiple neurodegenerative diseases. In animal models of neurodegenerative disease such as Parkinson's and Alzheimer's, decreasing the endogenous amount of CFL1 is neuroprotective. Our lab has recently discovered CFL1 is expressed in the neural retina and is critical for photoreceptor viability, but the effect of CFL1 in retinal degenerations remains unexplored. Retinitis pigmentosa (RP) is a retinal degenerative disease that can be caused by mutations in the gene for rhodopsin (RHO), including the

P23H mutation. RP results from a loss of rod photoreceptors, leading to vision loss. We investigated the potential neuroprotective effect of rod-specific heterozygous loss of CFL1 (rCfl+/-) in a heterozygous RHO P23H mouse model of RP (rCfl+/-;P23H/+) using electroretinography to measure retinal function in vivo and immunohistochemistry to evaluate rod viability and retinal inflammatory responses ex vivo. We found that these mice displayed diminished retinal function alongside greater rod photoreceptor degeneration, together with increased glial reactivity compared to RHOP23H mice at 6 weeks of age. These results indicate that the heterozygous loss of Cfl1 exacerbates the degenerative effect of the RHO P23H/+ mutation, leading to a more rapid loss of rod photoreceptors, in contrast to other neurodegenerations found in the brain.

Abstract Name: Comparing Gut Bacterial Strains' Responses to Nitric Oxide Stress

Nitric oxide (NO) is a host-produced molecule that disrupts bacterial respiration and acts as a potent antibacterial agent in the mammalian gut, especially in inflammation. *Escherichia coli* is a common human gut bacterium with significant strain variability, including some strains with beneficial functions and others that have been linked to inflammatory bowel disease (IBD). Preliminary data suggest that *E. coli* strains with the nitroreductase (NR) gene family 3VPSM are more abundant in the microbiome of individuals with IBD. This finding suggests a potential link between these NR genes, *E. coli*'s tolerance of nitric oxide, and its influence on autoimmune conditions. However, it remains unclear whether *E. coli* strains differ in their tolerance of NO stress and whether these differences could be mediated by the NR gene family. This research is investigating whether *E. coli* strains vary in their response to NO and whether the NR gene family 3VPSM may contribute to this variation. Using genomic data, I have selected eight *E. coli* strains for this study, including four with the NR gene family and four without. We are culturing these strains in anaerobic conditions with varying exposure to NO, produced from the NO donor DEA NONOate. In a preliminary experiment, an *E. coli* strain with the NR gene family had only an 8% growth inhibition in a 100uM concentration of NO. On the other hand, the type strain, which lacks this gene, was inhibited by 48%. We are further optimizing growth conditions to test differences in growth rates, nitrogen-related compounds using the Griess assay, and gene expression using qRT-PCR). By elucidating the roles of strain variation and nitroreductase genes in NO resistance, this research will enhance our understanding of *E. coli*'s survival strategies and its dual role in health and disease.

Abstract Name: Development and Stability of Mesalamine-Capped Silver Nanoparticles for Targeted

Silver nanoparticles (AgNPs) are innovative materials with broad applications in antiseptics and drug delivery systems. Inflammatory Bowel Disease (IBD) refers to chronic disorders characterized by inflammation of the intestinal lining, primarily including Ulcerative Colitis (UC) and Crohn's Disease (CD). These conditions require localized treatments to manage flare-ups and induce remission. Mesalamine, a 5-aminosalicylic acid (5-ASA) derivative, is a commonly used therapeutic agent for IBD. This study focuses on the synthesis and stability of mesalamine-capped silver nanoparticles (MSA-AgNPs) as a potential drug delivery system for IBD therapy. The nanoparticles were synthesized via chemical reduction using silver nitrate (AgNO_3) as the precursor and sodium borohydride (NaBH_4) as the reducing agent. Unlike the commonly used stabilizer, mercaptosuccinic acid (MSA), mesalamine was employed as a capping agent in this research. Three synthesis methods were evaluated: rough addition of NaBH_4 , steady drop-by-drop addition, and controlled burette dispensing. UV-Vis spectroscopy confirmed the formation of AgNPs with characteristic absorption peaks between 350-400 nm. To assess long-term stability, nanoparticles were tested in two solvents: water and phosphate-buffered saline (PBS). PBS demonstrated superior stability, minimizing aggregation and enhancing suitability for drug delivery applications. Environmental factors, such as pH, were systematically varied to optimize nanoparticle stability and delivery efficiency. For these tests, 10 mL of nanoparticle solution was mixed with 8 mL of buffer adjusted to different pH levels. The results indicate that mesalamine-capped silver nanoparticles, synthesized under controlled conditions, offer promise as a stable and efficient drug delivery system for targeted IBD treatment. This study highlights the potential of MSA-AgNPs to improve therapeutic outcomes for patients with UC and CD.

Abstract Name: Brain Injury Increases Progranulin Expression in Microglia and Astrocytes

Loss-of-function mutations in the gene encoding progranulin (GRN) are a major genetic cause of frontotemporal dementia (FTD). Progranulin is a secreted protein found abundantly in the central nervous system. It has multiple functions in the body, including enhancing lysosomal activity, anti-inflammatory effects, and neurotrophic effects. Progranulin-deficient mice ($\text{Grn}^{-/-}$) have hyper inflammatory responses of both microglia and astrocytes to inflammatory stimuli and injury compared to responses in wild-type mice. Previous literature has shown that levels of progranulin in microglia increase over time after injury, but progranulin in astrocytes has not been well studied. The aim of this study was to document the change in progranulin after injury, focusing on astrocytic levels of progranulin. We subjected mice to unilateral cortical stab wound injury to examine changes in microglial and astrocytic progranulin expression at 1, 4, 7, 10, and 14 days after injury. The uninjured hemisphere was used as a control. Immunofluorescent staining for progranulin and markers of microglia, astrocytes, and neurons were used to assess the change in progranulin levels over time. Astrocytes and microglia exhibited elevated progranulin immunoreactivity beginning at 4 days post injury, which then decreased in astrocytes through the final time point of 14 days, while microglia showed only a downwards trend through the final time point. Neurons showed slightly elevated progranulin immunoreactivity by day 10. These findings suggest that progranulin plays an important role in injury recovery. Future directions will measure Grn RNA to confirm progranulin expression in each cell type, and will determine if progranulin's lysosomal functions are sufficient to reduce reactivity in activated microglia and astrocytes.

Abstract Name: Violence as a Predictor of Migration

Migration patterns are influenced by an intricate mix of push and pull factors that may encourage populations to leave their homes and move elsewhere. This paper investigates how various forms of violence, and fear of violence, influence migration decisions in Mexican states. By analyzing data from 2015–2020, this study evaluates trends in immigration, emigration, and net migration by focusing on indicators such as violent crime, organized crime, firearm crime, and fear of violence, while controlling for poverty levels. Findings reveal that fear of violence significantly deters immigration into states, acting as a strong anti-pull factor. Overall, fear of violence had a negative correlation with net migration, suggesting it is more influential in deterring new arrivals than motivating departures. Violent crime showed a surprising positive relationship with immigration and net migration, which indicated other pull factors, such as economic opportunity, outweigh the potential danger of the violent crime rates. The other indicators of violence did not show a significant impact on the migration rates, except for a negative relationship between net migration and weapon crime on its own. These findings highlight the importance of addressing both perceived and actual violence to mitigate migration pressures and predict patterns, calling attention to the nuanced role fear of violence plays in shaping regional migration dynamics.

Abstract Name: Role of BATF3 in Human Central Memory CD8 T Cells

Basic Leucine Zipper ATF-Like Transcription Factor 3 (BATF3) belongs to the family of AP-1 transcription factors. In the murine model, BATF3 played an intrinsic role in the formation of memory CD8 T cells and induction of robust recall responses. Additionally, in a study on chronic myeloid leukemia (CML) cells, BATF3 regulated apoptosis and survival related genes in the cells through key components: Caspase 3, BAX and BCL-2. Although BATF3 was initially discovered in human T cells, there is limited research on the mechanism of BATF3 regulation of T cell function in healthy human donor cells. We have found that BATF3 is upregulated in activated T cells. Further analysis of differentiated T cells revealed that BATF3 was predominantly upregulated in central memory (CM)-CD8 T cells, suggesting a functional role of BATF3 in CM T cells. We have developed a system to induce central memory T cells from naive T cells that, on analysis, upregulated BATF3. Building on this, we aim to knockdown BATF3 in CD8 T cells to determine its role in regulating proliferation and survival of CM CD8 T cells. We will also use inhibitors of the key pathways involved in the activation, proliferation, and function of T cells with the goal of determining the key

molecules involved in the upregulation of BATF3 in CM CD8 T cells. It is expected that the results from these experiments may narrow down the role of BATF3 in human CM-CD8 T cells.

Abstract Name: Artful Algorithms: Annotating Ancient Maya Vases for a new AI Detection Model

This project utilizes an interdisciplinary approach to developing an artificial intelligence (AI) model capable of recognizing and segmenting hieroglyphic blocks from scanned images of Maya vessels. The objective is to train the AI model to identify and isolate regions of interest within these images, specifically focusing on individual text blocks, integral components of Maya writing. To improve the accuracy and precision of the model, the project employs a combination of manual annotation and rigorous examination. WVU undergraduate researchers in Technical Art History manually annotate the images by marking the boundaries of each hieroglyphic block. This produces a high-quality dataset serving as a “gold-standard,” which allows the model to learn the distinct characteristics of each hieroglyphic block, enhancing its segmentation capabilities. The performance of the model is rigorously evaluated using an Intersectional Reunion metric, which compares the results of the model’s segmentation against the manually annotated data, ensuring the model’s output is accurate and consistent with human expertise, helping identify areas for improvement. The model is refined based on these evaluations, with the goal of maximizing its ability to segment blocks accurately while minimizing errors. This project employs experts in Maya art history and linguistic anthropology with computer scientists in a collaborative, holistic approach to the complex task of Maya hieroglyph recognition and segmentation. This will advance the field of epigraphy and improve the tools available for the analysis of ancient texts. The project anticipates future study in not only identification of entire hieroglyphic blocks but eventually, translation.

Abstract Name: Impact of Solvent Choice on PM6 Solution Conformation for Organic Photovoltaics Devices

The increasing demand for renewable energy sources has accelerated advancements in organic photovoltaics (OPVs), which have the potential to provide a low-cost, flexible, and environmentally sustainable alternative to traditional silicon solar cells. However, OPVs currently exhibit a lower power conversion efficiency (PCE) of 19%, compared to the 26% efficiency of silicon cells. This inefficiency limits their broader adoption in the solar energy market. The morphology of the conjugated polymer films within OPVs largely determines the PCE, as it directly influences both light absorption and charge transport. One key factor in shaping this morphology is the aggregation of polymer chains during fabrication. The choice of solvent used in the

deposition process plays a crucial role in controlling polymer aggregation, as well as the crystallinity and overall film structure. These solvent-driven changes in morphology ultimately impact the PCE of the OPVs. The objective of this research is to explore how different solvents affect the morphology of PM6-based OPVs. To achieve this, PM6 solutions were prepared with varying solvents at different concentrations, followed by spin-coating onto glass substrates to form thin films. Ultraviolet-visible (UV-Vis) spectroscopy was used to measure the absorption spectra of both the solutions and the films, revealing information on polymer aggregation, crystallinity, and the degree of order within the films. Changes in the absorption peak position, width, and intensity are analyzed to reveal the impact of solvent choice on the polymer structure. Data from these measurements help correlate solvent-induced changes in polymer aggregation with improvements in OPV performance. By investigating the relationship between solvent selection and OPV morphology, this research provides valuable insights that contribute to the development of more efficient and cost-effective OPVs.

Abstract Name: Between Policy and Peril: How Italy's Reception System Fails Women

Within the past decade, the refugee crisis in Europe has led to an influx of refugees in Italy, many of them being women who experience SGBV in reception facilities. The project investigates how Italian migration policies from the past 10 years affect Italian reception facilities perpetuating sexual and gender-based violence (SGBV) for women refugees. Previous researchers examined how the lack of adequate reception facilities puts refugees' human rights at risk. Moreover, scholars used qualitative methods, in the form of interviews, adding various frameworks for effective analysis. For primary data, I will employ a direct semi-structured interview methodology to gather in-depth qualitative data from female refugees currently residing in or have previously experienced Italian refugee reception facilities. Furthermore, a thematic analysis of the interviews will evaluate trends between migration policies and the perpetuation of SGBV in Italian reception facilities for women refugees. The results will likely show the correlation between Italian migration policies and the perpetuation of SGBV in Italian reception facilities. Bringing to light the previously stated correlations will push for policy reform to improve the reception facilities conditions, thus ensuring future refugees do not have to endure the same human rights violations, allowing for a safer environment for a better chance of starting a new life.

Abstract Name: Developing a method for detection of volatile organics in dog urine

Studies have shown dogs use urine to mark 'property lines' and assert dominance. Part of this communication is thought to take place through volatile organic compounds in urine. These compounds have not been

extensively studied in dogs and this work aims to develop a reliable method using liquid-liquid extraction to extract volatile organic compounds and then separate the mixture with gas chromatography. Previous work with the urine of dogs and of other animals have found a variety of organic compounds but particularly carboxylic acids, ketones and sulfides of approximately 5-12 carbons. This work utilized aqueous solutions with small amounts of these compounds to develop the method. Previous work had used solid phase microextraction but had problems with reproducible results. This work utilized diethyl ether extraction of typical volatile organics from aqueous solution. A small amount of the extract is injected to a gas chromatography instrument for separation. Detection was with flame ionization where the sample is exposed to a hydrogen flame, and loses electrons, ionizing the organic compounds. Charges from the sample are attracted to an electrode, producing a current which is read. The height and area below the curve is proportional to the presence of the analyte in the sample. Ultimately, we aim to draw connections between the presence and quantity of volatile organic compounds in a sample with the social behaviors of domestic dogs. By studying sample analytes which are similar in character, and can assist in developing a well rehearsed method that will benefit future exploration on this topic.

Abstract Name: Effect of Food Preparation on Vitamin C Concentration in Fruit

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available products and food items using titration techniques. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the highest concentration of vitamin C, a crucial antioxidant that plays a vital role in human health. The experimental approach involves titrating the samples, employing 2,6-dichloroindophenol (DCIP) as the titrant, chosen for its ability to exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. The goal of this team's project to find out how different food preparation affects Vitamin C concentrations in fruits. We will be testing this on three different fruits; pineapple, orange and lemons. The preparation techniques include boiling, freezing and dehydration. Samples of juice from the fresh fruits were tested in both the as obtained and processed condition. The analysis technique consisted of titration using a 2,6-dichloroindophenol sodium salt solution.

Abstract Name: Rethinking Onboarding for High Turnover Development Groups

Software onboarding is a process where new developers familiarize themselves with an existing code base. Researchers have reported the difficulty that new employees have with onboarding (Rollag et al, 2005) and the high learning curve that adjusting to a new project can face (Williams, 2003). In student-led research, the process and problems related to onboarding are exacerbated. This is due to the constant turnover rate of student developers, the lack of experience some students have maintaining legacy software, and the desire by students to focus on features instead of documentation. This creates a situation where new developers often struggle with productivity during the onboarding process. In this case study, we seek to explore the difficulties we faced while onboarding a research project and the potential solutions. When onboarding onto our research project, a full-stack telemetry application, we found it difficult to onboard with the current documentation. The documentation was scarce and had not been updated for a month, which led to us abandoning the current codebase. Karimzadeh & Hoffman also reported a similar finding, where poorly documented projects lead to software abandonment (2018). We propose an assessment-centric approach to the onboarding process. Building on Onwuatigwu and Islam's findings that inviting an external contributor improves documentation, we took their approach one step further. Not only did we include external participants, we also included a final evaluation step to assess the effectiveness of the documentation. After completing the improved onboarding materials, new developers are asked to re-implement an already existing feature, further assisting us to validate whether the documentation adequately prepared them for real contributions and assess their readiness to join the project. We believe this assessment-centric approach can reduce the cognitive overload and productivity gap for new developers. Future studies will evaluate the long-term impact of this approach's effectiveness.

Authors:

Abstract Name: Arrowhead Pathways - Transitional Housing for Former Foster Care Youth

The design of "Arrowhead Pathways" focuses on creating a facility for young adults transitioning from foster care to independence. Central to this is the integration of trauma-informed design principles to address the psychological challenges commonly faced by those aging out of foster care. The design process was informed by research, including interviews with a Oklahoma foster care professional, case studies, and a review of literature and articles, which highlighted the specific needs and challenges of this population. This research guided strategies to enhance social sustainability, safety, mental and physical health, and overall comfort for residents. To support positive outcomes, the facility incorporates inclusive design elements for accessibility and prioritizes the aesthetic appeal of the space. The layout includes flexible living areas, private spaces for reflection, and communal areas for socialization, fostering a sense of community and belonging. Social interaction was a major focus, with spaces like shared dining areas, lounges, and activity areas to encourage engagement and reduce isolation. By creating opportunities for connection, the design supports the mental and emotional well-being of residents, enhancing their ability to thrive in a semi-independent environment. The design also prioritizes staff well-being, addressing the challenges of employee retention in social work-related roles, where burnout and stress are common. Staff areas designed for respite and relaxation provide a supportive work environment, helping to mitigate stress and improve retention. This, in turn, enhances the quality of care provided to residents. Ultimately, "Arrowhead Pathways" combines intentional social spaces for residents, staff-focused areas for employee well-being, and trauma-informed

principles. The result is a balanced environment that promotes both the success of residents transitioning to independence and the long-term sustainability of the staff supporting them.

Abstract Name: Language and Culture Struggles of the Latinx Community in the U.S.A.

In the United States, roughly six in ten Latinx people ages 18 to 29 (62%) and 30 to 49 (57%) face at least one sort of discrimination (Pew Research Center, 2021). Many Latinx individuals in this scenario say they have experienced discrimination from Latinx and non-Latinx people. Their customs and beliefs differ from the traditional American beliefs, making the Latinx community face serious challenges. One of them is language, which creates these barriers in healthcare, education, and other essential services. In recent years, the situation of the Latinx community in the United States has taken a toll; however, recent changes in the community have remained unspoken in the academic side of the world. Recent news articles have highlighted the significance of speaking up and its outcomes, which will be discussed in the presentation. This presentation shares preliminary findings that Latinx people in the United States experience negative mental health decline along with negative impacts on identity. Despite the limited resources that the Latinx community is given, the findings of this study provide different methods of how the Latinx community can unite and speak up, allowing their voices to be heard to make a difference.

Abstract Name: The Phenomena of Tribology: Varnish Removal from Metal Surfaces in Mechanical Components.

Varnish formation in lubricating oil is a significant challenge in industries such as power generation and transportation, where reliability and efficiency are critical. Varnish forms when oil degrades due to exposure to water, dust, and elevated temperatures, accelerating oxidation and deteriorating its properties. These deposits adhere to metal surfaces, obstructing oil flow and causing functionality issues in mechanical systems. Addressing this issue is crucial for maintaining optimal performance and extending the lifespan of mechanical components. Our research explores innovative methods for varnish removal by evaluating chemical cleaners under controlled conditions. Using a custom-designed testing ring, I expose artificially degraded varnish to varying flow rates, temperatures, and chemicals to test their effectiveness. This approach allows us to simulate real-world operational environments and measure varnish removal through visual and mass analysis. The visual analysis is conducted using MATLAB to process the collected visual data and compare its findings with the mass analysis, which quantifies varnish mass removed by the chemical cleaner. This lets us assess the performance of chemical cleaners and our testing apparatus. Additionally, we evaluate

the impact of chemical cleaners on elastomeric seals to ensure compatibility and reliability in long-term applications. This study offers an innovative contribution to the field of tribology by addressing varnish-related challenges with a systematic and quantifiable approach to varnish removal. Varnish removal findings advance the reliability of mechanical systems across essential industries by reducing maintenance costs and downtime while promoting efficient operation. Advancing varnish removal techniques contributes to the development of practical solutions to a persistent tribological problem by maintaining components at optimal performance for longer periods.

Abstract Name: Decoding Post-Chemotherapeutic Cognitive Impairment with a C. Elegans Model

Approximately 1.1 million people a year receive chemotherapeutic treatments after being presented with a cancer diagnosis and as much as half of these patients experience cognitive impairment after treatment. Symptoms can include lower processing speeds, short term memory inhibition, a short attention span, and much more. This is often referred to as Post-Chemotherapeutic Cognitive Impairment (PCCI) and there is a notable lack of investigation on the cause behind it. This research utilizes *Caenorhabditis Elegans* as a model to determine the potential cause of PCCI due to their human-like neurons. To do this, three C. Elegans mutants were exposed to chemotherapies Methotrexate and Mechlorethamine as well as a water control. Of the three variations of C. Elegans that will be used, GLP-1 C. Elegans can form tumors, Clec-47 C. Elegans don't have an immune system, and N2 C. Elegans are the wild-type to be used as a control. Once each of these mutants were introduced to the experimental treatments, we performed a nose touch assay to measure each of their learning ability. Differences in nose touch response and learning ability could indicate that PCCI could potentially be due to the chemotherapy, the immune system response, or the cancer itself. This method can be used as a compass to show where to direct future research on PCCI to further investigate its underlying cause. This is in an effort to redirect cancer research to not only include treatment of physical ailments but also the overall wellbeing of affected patients.

Abstract Name: The Impact of VHL Deletion on Bone Marrow Microenvironments: Insights into B-Cell Development and Hematological Changes

his research aims to identify how bone marrow niches influence immune cell and blood cell development. We are investigating the role of the Von Hippel-Lindau (VHL) gene, a hypoxia response gene, in the regulation of B-cell development and erythropoiesis in the bone marrow. Longitudinal analysis of tamoxifen-inducible VHL gene knockout reporter (iVhlcKO, Tagln-ERT2-Cre;Ai213;Vhlfl/fl) mice was performed. Complete

blood count (CBC) data was analyzed to identify if there were alterations in red blood cell (RBC) counts and hemoglobin (Hb) concentration, providing preliminary insights into the potential hematological effects of VHL deficiency. Future studies will investigate its effects on bone marrow microenvironments and B-cell development, addressing critical gaps in the understanding of hematopoietic regulation under hypoxic stress. One challenge in our study is the validation of the VHL knockout in the iVhlcKO mice. We developed an assay to confirm Vhl deletion in Tagln⁺ cells. We first tested our assay in single-cell suspensions of enzymatically-digested duodenum tissue (which are known to express high levels of Tagln). Cells were analyzed for the GFP reporter using flow cytometry (FACS). Initial testing of the assay showed GFP detection was low, at 0.014%. Optimization of the timing of the enzyme digestion improved GFP detection to 0.14%. Additional testing is in progress. This research has broader implications for understanding the effects of irradiation, myeloablative conditions, and bone-targeting therapies on hematopoiesis, and could inform strategies to enhance B-cell development and maintenance throughout the lifespan.

Abstract Name: Optimization and Validation of an mRNA Multiplex Panel for Identification of Human Biological Fluids

Body fluid identification is an important tool in the field of forensic science as it can provide context in a criminal investigation. Historically, biological fluid identification has been performed using a series of serological tests that result in destructive consumption of precious evidence. Recently, many laboratories have started investigating the utility of mRNA profiling for identification of biological fluids on evidentiary materials. This approach is advantageous because both mRNA profiling and DNA analysis can be performed on a single extract allowing the analyst to retain more of the stain for repeated analyses. Additionally, mRNA based-methods are suitable for mixed stains and are highly sensitive. The purpose of this project is to optimize a multiplex panel for identification of biological fluid specific mRNA transcripts. The process includes co-extraction of RNA and DNA, reverse transcription of the RNA into complementary DNA strands (cDNA), subsequent cDNA amplification and finally multiplex amplification of cDNA using targeted primers specifically designed for mRNA markers that have been associated with forensically relevant biological fluids including peripheral blood, menstrual blood, seminal fluid, vaginal secretions, and saliva. This project draws ideas and procedures from previous studies performed using mRNA for biological fluid identification. Initially studies have focused on perfecting the workflow and assessing performance of primers in singleplex reactions for peripheral blood and seminal fluid samples. We have shown that cDNA can be successfully synthesized after extraction of DNA and RNA from dried biological fluids on swabs using the PrepFiler® and PrepFiler® BTA Forensic DNA Extraction Kits and NEBNext® Single Cell/Low Input cDNA Synthesis & Amplification Kit. Future experiments will include assessing success of PCR amplification using marker-specific primers on single-source fluids. Ultimately, a multiplex panel will be developed that enables forensic analysts to test for several biological fluids using a single, streamlined workflow for each evidentiary stain.

Abstract Name: Integrating Large Language Models into Educational Gamification Programming Application

This study explores the integration of Large Language Models (LLMs), specifically the ChatGPT API, into a gamified educational application designed to teach Python programming for Spanish speaking users. With Python being one of the most in-demand skills in today's job market, this project aims to enhance programming education by automatically generating questions of varying difficulty levels through ChatGPT. The app adapts to users' individual learning needs and offers personalized content based on their progress. By employing interactive and individualized content, the app aims to foster deeper learning and mastery of Python. Moreover, a key component of the application is its use of gamification to increase user engagement and motivation. However, recognizing that game element preferences vary widely among individuals, the project integrates Recommendation Systems to personalize the gamified aspects of the app. This customization maximizes motivation by aligning game features with each user's unique preferences. While the development and integration processes are still underway, this study highlights the potential impact of combining LLMs, Machine Learning, and personalized gamification to revolutionize programming education. More specifically, the work focused on formulating a prompt that generated Python coding questions of varying difficulty. Additionally, the team implemented a pipeline that generates question sets, validates their JSON format, extracts one and translates it for use. Future work will focus on testing the prototype, incorporating other programming languages, and exploring more complex programming concepts. The project envisions creating a highly adaptive learning tool that enhances engagement, motivation, and learning outcomes for users across diverse skill levels.

Abstract Name: Method development and LC-MS troubleshooting for discovering bioactive compounds in herbal plants

Unlocking the therapeutic potential of herbal plants requires precise and reliable analytical techniques to identify and quantify bioactive compounds. This research focuses on developing and troubleshooting methods for separating and detecting bioactive compounds using Liquid Chromatography-Mass Spectrometry (LC-MS) combined with the Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) extraction method. This approach separates chemical compounds based on polarity, facilitating their identification with LC-MS. Nine different phenolic acids were selected for the study, and 0.1M solutions were prepared. All samples were filtered and analyzed using a C18 LC column with a mobile phase consisting of methanol and 0.1% formic acid. The QuEChERS method was applied to both boiled tea samples and tea leaves. During LC-MS analysis, several challenges were encountered, including tubing clogs, salt deposition within the photodiode array (PDA) chamber, leaks due to excessive backpressure, and loss of optimal pressure in the MS vacuum. These issues were addressed by upgrading to larger bore tubing, optimizing flow rates, thoroughly cleaning the PDA chamber, and ensuring gasket integrity. Implementing these solutions resulted in enhanced separation efficiency and more precise identification of phenolic compounds. The systematic approach to troubleshooting and method optimization minimized instrument downtime and improved the reproducibility

of analytical results. This study offers a solution for herbal plant analysis, aiding in the discovery and utilization of bioactive compounds for potential therapeutic applications using the QuEChERS separation method. The QuEChERS method demonstrated excellent reliability in analyte separation prior to LC-MS analysis. The developed methods and troubleshooting strategies ensure reliable and efficient LC-MS analysis, establishing a framework for future research in this field.

Abstract Name: Gender Differences in Trust Levels Toward Law Enforcement Among High School Students

This research project investigates potential differences in trust levels toward law enforcement between male and female high school students. Understanding how gender influences perceptions of law enforcement during crucial developmental stages of a person's life can provide insights into future community relations and policing strategies and may help identify any potential political or treatment-based gaps regarding gender. Existing research has examined trust and confidence in law enforcement across different demographics and contexts but not much so around gender specific areas in regards to the differences in attitudes towards law enforcement or policies between men and women, or around teenagers and highschoolers. The studies that do exist have been focused heavily on undergraduates and have little focus on specific gender perceptions. Utilizing a mixed-methods approach, this study collected quantitative data through surveys and qualitative insights via focus groups. Results indicated that while overall views on law enforcement varied between genders, significant differences emerged in perceptions of law enforcement's societal role and their effectiveness within school settings. Specifically, male and female students held similar surface-level opinions; however, deeper analysis revealed contrasting ethical and logical reasoning behind their views. Their contrasting perspectives included women revolving their conversations around social justice and community based concerns, while men prioritized authority and societal order. Although the focus was on gender-based differences in trust, the findings offer valuable perspectives on the broader opinions of future generations and highlight potential gaps in overall current law enforcement practices and performance.

Abstract Name: Magneto Mechanical Actuation to Treat Brain Cancer

Glioblastoma, a highly aggressive and lethal brain cancer, remains resistant to conventional therapies due to its invasive growth and complex tumor environment. In 2023, there was an estimated number of ~2 million new cases of brain cancer in the world with over 25,000 new cases of malignant brain tumors in the United States alone. Current treatment options, such as ionizing radiation therapy, are associated with high costs—~\$82k per course—and detrimental side effects, including cognitive impairments, which limit their

therapeutic efficacy. This study draws on a unique, completely non-invasive therapeutic modality that relies on magneto-mechanical actuation to enhance the potency of chemotherapy medications, such as paclitaxel and doxorubicin, for targeting glioblastoma cells. This modality is based on the remote actuation of magnetic nanoparticles by non-heating alternating magnetic fields. One critical component is to maximize the conversion of magnetic energy into mechanical agitation of intracellular nanoparticles. Our initial studies are centered on optimizing drug parameters, including exposure times (0-72 hours) and concentrations (0-100 μM), using two colorimetric assays CCK-8 and PrestoBlue to assess cell death. Preliminary data indicate that at desired drug exposure, an increase cytotoxic response against human glioblastoma cells (U87) can be induced. U87 cells will be subsequently exposed to magnetic nanoparticles, which will be stimulated by alternating magnetic fields. This will allow us to study the synergistic effect of chemotherapy and magneto-mechanical actuation. Future studies will attempt to determine the molecular mechanism through which magneto-mechanical actuation induced apoptotic pathways. This modality has the potential to advance the field of cancer nanotechnology and magnetic therapy.

Abstract Name: Perceptions of Misogynistic Culture in Digital Environments: Key Influencing Factors

Misogyny online has become an alarming and pervasive issue in the current age of digital communication. The normalization of social media consumption has led to impressionable audiences becoming more casually exposed to misogyny. Additionally, the prevalence of misogynistic content online has caused hatred, prejudice, and discrimination against women both online and offline, emerging as a pressing societal concern. This study applied TikTok videos to investigate discrepancies in the perception of misogyny in online spaces as a function of gender, and other personal and sociocultural dynamics. Specifically, this research has investigated the impact of the following human dynamics on one's perception of misogyny: a) religious affiliation, b) level of devotion to an organized religion, c) political affiliation, d) level of agreement with major political figures (i.e., Kamala Harris vs. Donald Trump), and e) the cultural background of one's parents/caregivers. A total of 124 participants reported demographic information and rated 20 TikTok videos on a 5-point Likert Scale based on the perceived misogyny and perceived humor of the content. To date, our results have revealed that people who are assigned male at birth have lower perceptions of misogyny ($p < 0.001$) and higher perceptions of humor ($p < 0.001$). People who participate regularly in an organized religion have lower perceptions of misogyny ($p = 0.031$), and those who are more devout to an organized religion have lower perceptions of misogyny ($p < 0.001$) and higher perceptions of humor ($p = 0.014$). More conservative individuals have lower perceptions of misogyny ($p < 0.001$) and higher perceptions of humor ($p < 0.001$). Participants who more closely agreed with Donald Trump had lower perceptions of misogyny ($p < 0.001$) and higher perceptions of humor ($p < 0.001$). These findings highlight the complex interplay between personal beliefs and attitudes toward gender-based discrimination online and suggest a need for interventions targeting the sociocultural contributors to misogyny online.

Abstract Name: Journalism and Desegregation: The Indianapolis Recorder's Coverage of House Bill No. 242

In 1949, the 86th General Assembly of Indiana passed House Bill No. 242, which prohibited schools that segregated students based on race, color, or creed. This research argues that the Indianapolis Recorder, a Black-owned newspaper, built public awareness for House Bill No. 242 in central Indiana. This scholarship examines newspaper publications from the Indianapolis Recorder in 1949, specifically focusing on the day of the bill's adoption on March 10th and its implementation on September 3rd. The Indianapolis Recorder, spoke to and for the African-American community as their publications contained detailed reporting of the bill, including expert analysis from lawyers and civil rights activists. The Indianapolis Recorder also revealed the NAACP efforts to support the bill as well as highlight the politicians who voted for and against the bill. The Indianapolis Recorder's instrumental efforts through their publications throughout 1949 empowered the African-American community of Indianapolis to understand changes in their community. This research builds on existing scholarship of racial history in the state of Indiana and the history of the media in the United States. It fills a gap in the historical narrative by recounting the African American voice in the media, providing greater diversity of perspective on the process of desegregation.

Abstract Name: The effects of spotted lanternfly host plant diet on palatability among spider predator species

The spotted lanternfly (*Lycorma delicatula*) is an invasive planthopper introduced into the US from Asia. Its native host plant, the Tree-of-Heaven (*Ailanthus altissima*), is also an invasive Asian species. The insect's diet is broadening to include commercially important orchard and horticultural plant species. In their native range, lanternflies are putatively chemically protected while feeding on Tree-of-Heaven, but it remains unknown if they are chemically protected while feeding on other non-native host plants. North American spiders may be important predators of lanternflies, but the range of species that feed on them and the inter- and intraspecific range of palatability based on the host plant of the lanternfly remains unknown. We tested lanternfly palatability among lycosid, pisaurid and oxyopid spiders and compared consumption of those actively feeding on the Tree-of-Heaven versus a native species, Staghorn Sumac (*Rhus typhina*). We field-collected spiders, fed them crickets and standardized hunger level prior to offering each spider one of three prey types: a lanternfly nymph collected from a Tree-of-Heaven, a Staghorn Sumac, or a cricket (control). During a 30-min trial, we measured spider attack and predation latencies of prey. We also recorded prey consumption within 24 hours of spider exposure. We hypothesized that Tree-of-Heaven nymphs would be less palatable compared to Sumac nymphs and that these differences would result in variation in palatability across spider species. Preliminary results indicate that palatability varies significantly by host plant and spider species. Tree-of-Heaven nymphs are significantly less palatable than Staghorn Sumac nymphs. We found a trend toward higher predation among larger spider species with smaller spider species feeding on smaller instars. Our results suggest that as lanternfly diet broadens, they could become more palatable to spider predators. This may dampen lanternfly range expansion and allow more opportunities to use spiders as biocontrol agents against this invasive pest species.

Abstract Name: Receptor-Mediated Endocytosis as a Pathway for Cellular Uptake of Nanoplastics

The global rise in single-use plastic products and waste has raised concerns about microplastic and nanoplastic pollution in the environment. Microplastics are particles less than 5 mm in diameter, while nanoplastics are even smaller. Both pose potential risks to human health. Emerging research suggests that nanoplastics accumulate in carotid artery plaques, which may increase the risk of cardiovascular events, such as heart attacks and strokes. However, the pathways by which nanoplastics enter the human bloodstream remain poorly understood. In our study, we investigated how nanoplastics enter mammalian cells and circulate in the body using both ex vivo cellular models and in vivo mouse models. Our results indicate that nanoplastics can enter the bloodstream of mice through oral ingestion. At the cellular level, gut epithelial cell lines efficiently internalize nanoplastics via receptor-mediated endocytosis. Using mass spectrometry, we identified potential receptors that interact with nanoplastics. Moving forward, our research will focus on characterizing these receptors and understanding the pathways that nanoplastics use to enter human gut epithelial cells.

Abstract Name: The 3 I's, Insight, Inquire, Imagination

The "see, think, and wonder" approach, offers a tool for developing critical thinking skills in art education. This poster examines the impact of these routines in fostering students' observational skills, interpretative abilities, and analytical thinking. Through a mixed-methods study combining observational data, structured art activities, and reflective practices, we investigated how students engage with visual media and develop critical thinking capabilities across multiple learning contexts. The research emphasizes the importance of slowing down the observation process to encourage deeper engagement with visual materials, ranging from traditional artwork to political cartoons and multimedia content. Our poster incorporated diverse strategies, particularly emphasizing an art critique game where students evaluated and discussed peer artwork. This collaborative approach and structured peer teaching opportunities created a learning environment that encouraged students to articulate their perspectives and creative choices. Key findings demonstrate that when students observe, and question artwork through guided routines, they show an improved ability to make insightful observations, provide thoughtful peer critique, and engage in deeper analytical thinking. The

research reveals that art education inherently cultivates critical thinking by engaging students in activities requiring analysis, interpretation, and reflective judgment. Particularly significant was the development of "strong thinking" - students' capacity to critically assess their processes, adapt to creative challenges, and persist through difficulties. The study's results indicate that structured visual thinking routines not only enhance art appreciation skills but also develop transferable critical thinking abilities applicable across academic disciplines. This transformation was evidenced by students' increased capacity for self-criticism, deliberate revision, and resilience in facing creative challenges. These findings have significant implications for art education and the broader development of critical thinking skills in educational settings. Our research suggests that implementing see-think-wonder routines creates a foundation for deeper learning experiences.

Abstract Name: Free Speech or Safe Spaces: Students Reluctant to Speak on Controversial Topics Prefer Open Learning Environments

Universities are traditionally viewed as a place where students can learn and practice expression of diverse ideas and perspectives. When talking about campus expression, there are different types of spaces that encourage the sharing of ideas, such as open learning environments, or positive learning environments. Open learning environments are defined as a space in which you can share your ideas without any restriction, while positive learning environments are spaces in which there are restrictions put in place to prevent offensive viewpoints against groups of people. To better understand student expression at the University of Minnesota Rochester, the Campus Expression Heterodox Academy survey was conducted to explore campus expression and students' reluctance levels when discussing topics in the classroom. This research focused on the relationship between students' reluctance to talk about race and politics, and their preference over an open or a positive learning environment. The results showed that University of Minnesota Rochester students who are reluctant to talk about race and politics prefer an open learning environment to a positive environment. This suggests that students who are hesitant to talk about certain topics value free expression. Future research will be focused on understanding the reasoning behind this preference, with the support of qualitative interviews, and further survey analysis.

Abstract Name: Mapping the use of GAI in a higher educational context

The body of scholarly literature on Generative Artificial Intelligence (GAI) is rapidly expanding, exploring various potential applications for these technologies. However, few studies have examined the extent of students' use of GAI and how often they use it. Even fewer have focused on small colleges. This study, conducted between August and November of 2024 at Lyon College, a small liberal arts institution in Arkansas, systematically investigated the utilization of GAI by students within the university context. The primary objectives of this study were to identify the prevalence, extent, and nature of GAI usage among students. For data collection, we developed an anonymous survey composed of seven questions on the use of AI in student's academic lives. This survey included a mix of closed-ended and Likert-scale questions, administered in classes across various departments to maximize response rates and achieve a diverse and representative sample (n = 171). The findings revealed the proportion of students using GAI tools in their academic work, how frequently they use these tools, the specific purposes for which they are used, and which GAI tools are most favored by students. Additionally, the study highlighted differences in GAI usage between native and non-native English speakers, supported by a significant sample of international students (n = 52).

Finally, we compared GAI usage across different fields of study, uncovering notable variations between academic disciplines. This research provides insights into student's use of GAI tools in academia. As AI continues to grow in popularity, it is crucial to understand the spread of these technologies in higher education, both to develop new and effective ways of incorporating AI to benefit students and to promote mindful and responsible use of tools.

Abstract Name: "Describing persons' post-stroke and caregivers' perceptions of music therapy and dyadic treatment during rehabilitation"

Music therapy is an effective treatment for post-stroke individuals, providing client-oriented care with an emphasis on the interactions between neurologic, personal, and cultural factors which influence daily function (Ben-Yishay & Diller, 2011; Magee, 2010). Music therapy can improve individuals' emotional, physical, and communication outcomes (Magee, 2010), as well as motivation toward rehabilitation and participation in activity (Hitchen et al., 2010). The involvement of a caregiver has been identified as an important factor in recovery post-stroke (Kitter & Sharman, 2015; Norup et al., 2013), but the engagement of caregivers as part of music therapy treatment is limited. To optimize dyadic treatment within music therapy, it is critical to first understand dyads' perceptions about music therapy and the use of dyadic intervention. Their first-hand perceptions about these treatments may help to identify potential needs and inform health professionals in providing care (Ekstam et al., 2015). This project aims to explore individuals post-stroke and their caregivers' perceptions of music therapy and potential use of dyadic treatment. Using a phenomenological qualitative research methodology, the research team will recruit dyads: persons post-stroke and their caregivers. Participants will engage in a semi-structured interview to discuss their perceptions of music therapy and dyadic treatment. The interview will be conducted either via phone or in person. The data analysis will occur during the data collection process using MAXQDA software and consensual coding. Through this project, we expect to gain a deeper understanding of stroke survivors' and caregivers' understandings and attitudes toward music therapy and the feasibility of dyadic treatment. The findings for the study will be used to guide future music therapy programs and the use of dyadic treatment.

Abstract Name: Owl pellets as bio-indicators for heavy metals

Contra Costa County is home to many diverse ecosystems in which owls play a vital role as predators. Owls help manage rodent and insect populations, preventing crop damage and the spread of diseases, and maintain high biodiversity in their habitats. The purpose of this study is to use owls, specifically their pellets, as indicators of heavy metals in the environment. Owl pellets serve as an excellent bioindicator of toxic metal

contaminants due to owls' wide hunting ranges and diverse diets. Owl pellets were collected from two distinct ecoregions and analyzed for toxic metals using ICP-MS (Inductively Coupled Plasma Mass Spectrometry). We found that both Black Diamond Mines and Big Break Regional Shoreline samples had only trace amounts of copper, iron and zinc, and there was so significant difference between the two sites. The other metals were not detected during ICP-MS analysis. my teammates are Jose Chaves, Yilin Chen, Mariana Maravilla, Gizelle Tirado

Abstract Name: Developmental and Morphological Effects of Lead Acetate Exposure in Embryonic Zebrafish

Lead toxicity and exposure is presented as a major threat to organisms, which may cause morphological changes. This investigation uses the zebrafish (*Danio rerio*) AB strain as the model organism to assess the impact of lead acetate (PbAc) exposure on the development of zebrafish embryos. Previous studies have noted that there are prevalent changes to the gut microbiome and body malformations, including other physical changes. We hypothesize that lead will specifically affect the intestinal structure of zebrafish and increase physical defects in spinal curvatures. Using indirect immunofluorescence, we examined morphology of the digestive tract with the use of an epithelial marker, E-cadherin. Histology was also implemented in the experiment and presented clear differences in the intestinal tract of the gut and intestinal villi for lead treated embryos compared to the control group. Microscope imaging of zebrafish also presents visible spinal malformations, kinks, reduction in eye size and facial-cranial structures that can be used for further analysis. These findings suggest that lead exposure during critical developmental stages induces phenotypic malformations, warranting further investigation into its effects on eye size, body size, and craniofacial development. Our goal is to explore whether the intestinal morphology changes correlate to a change in the microbiome when in the presence of lead. Future experiments will identify vulnerable windows for developmental exposure, morphological consequences, and structural effects on brain development.

Abstract Name: Green Synthesis of Antibacterial Silver Nanoparticle Dispersed Hydrogels via Cold Atmospheric Pressure Plasma

Hydrogels are three-dimensional polymer network structures that can imbibe large amounts of water, resembling the function of biological tissues. Currently, most hydrogels are synthesized using hazardous initiators such as peroxides or cross-linking agents that are unpleasant for the environment. The purpose of this research is to synthesize antibacterial silver nanoparticle dispersed hydrogels of poly(acrylamide-co-acrylic-acid) (PAAm-co-AAc) in a sustainable way by using cold atmospheric pressure plasma (CAP plasma). By utilizing CAP plasma, chemical species including the hydrated electrons, hydrogen radicals, and hydroxide radicals are generated which lead to chemical reaction pathways such as polymerization. In this study, free radical polymerization of an acrylic acid and acrylamide monomer solution was performed by a CAP plasma. PAAm-co-AAc hydrogels were formed with a high percentage conversion, and a polymerization time of less than nine minutes when 40 milliliters of a 20% monomer solution was mixed and subject to CAP plasma. Silver nanoparticle dispersed hydrogels were synthesized when 2.5mM of silver nitrate or 1.25mM of silver sulfate were added to the monomer solutions. A catalytic effect with both silver sulfate and silver nitrate was observed. Several characterization tests were then conducted on the hydrogels. Crystalline silver nanoparticles (spherical and rectangular) were confirmed via TEM-EDS in hydrogels that contained silver nitrate or sulfate. Nuclear magnetic resonance spectroscopy confirmed the formation of a copolymer and the ratio of acrylamide-to-acrylic acid in our hydrogel samples. Water swelling, gel fraction, and antibacterial tests were conducted to further characterize the synthesized hydrogels. From our chemicals mentioned above, a metal and polymer hydrogel has applications in wound healing/dressing, tissue adhesion, catalysts, conductive material on skin, etc. By harnessing plasma technology to create hydrogels, we are advancing the field of science while exploring sustainable solutions to reduce environmental impact.

Abstract Name: MAP2 Expression in Astrocytes in Vitro and in Vivo

Microtubule-associated protein 2 (MAP2) plays a role in microtubule assembly in neuronal processes. Although MAP2 expression was reported in injured astrocytes more than thirty years ago (PMID: 1692628), this protein is widely used today as a neuron-specific marker in studies of the central nervous system. Here we report in vitro MAP2 expression in rat primary astrocyte cultures, using immunostaining with two independent antibodies. We also confirmed prior reports of in vivo MAP2 expression in GFAP+ astrocytes surrounding the needle track following stereotaxic infusions of the mouse brain. In primary astrocyte cultures evaluated by immunocytochemistry and immunoblotting, astrocytes expressed a low-molecular mass isoform of MAP2 (~75 kDa) but not the neuron marker NeuN. Control primary cultures containing neurons displayed two isoforms of MAP2 (~75 and >250 kDa) as well as abundant NeuN expression. Treating astrocyte cultures with the oxidative toxicants paraquat and hydrogen peroxide or increasing the passages of the astrocytes did not raise MAP2 expression levels by immunoblotting. Increasing the cell plating densities in primary astrocyte cultures or applying the proteasome inhibitor MG132 also did not affect MAP2 or GFAP expression in primary astrocyte cultures by immunocytochemistry. Thus, additional MAP2 expression may

not be observed in cultured GFAP+ astrocytes, as they have already undergone intense gliosis. These findings have significant implications for the common use of MAP2 as a marker of neurons.

Abstract Name: The history of the Crusades and the significance it holds on both medieval and modern societies

The Crusades were a time of political, economic, cultural, and religious impact, and were the origin of the various complex relationships between the Europeans and the Muslims. From the 11th to 13th centuries, it was initiated by European Christians to reclaim the Holy land from Muslim control. The period of the Crusades also has a profound impact on Christian and Islamic medieval and modern societies. There are a great number of articles that mention the long-lasting affects the actions of the Europeans have on Muslim people, or people in the Islamic community, today. One important question to consider during this time period is, "Were Muslims converted to Christianity through the Crusades?" When researching, many historical writers in particular have mixed opinions about the topic of assimilating cultures, traditions, and religions. While there are some works that emphasize assimilation of the Muslims, most discuss other factors and motives from the Europeans that were more significant to them than forceful religious conversion. When delving deeper and coming to the realization that the majority of authors believe that the Europeans did not have any ulterior motives religiously, more questions and concerns can be raised about why the interactions between the Europeans and the Muslims were often so hostile and pugnacious. Since the European Christians, or the "Crusaders," violated Muslim territory to reclaim a religious site, there were other elements that came into play that could have sparked tension and conflict between the two groups of people. Key themes like Muslim resistance, the role of women, certain military strategies conducted by the Europeans, and intervention of the nobility, political, and religious leaders are all common in most works when discussing European-Muslim relations during the Crusades. Even though there are some misconceptions when interpreting this event, there are also many different perspectives of it.

Abstract Name: Various Factors of Hospital Performance Assessment

In today's society, assessment of hospital performance is significant in terms of evaluating healthcare system

management. Understanding the factors that influence hospital performance is crucial for improving variables such as patient outcomes and operational efficiency. This project conducts a systematic review of existing literature to explore various factors that impact hospital performance such as financial management, market attributes, quality and safety, and advanced technologies. Furthermore, this project will also analyze comparable and potentially interrelated variables in hospital datasets through the review of data dictionaries and codebooks. By reviewing previous studies and analyzing data from the American Hospital Association (AHA), we aim to quantitatively operationalize the diverse hospital attributes within the context of the Counte-Howard Healthcare Performance Conceptual Framework as well as examine the relationships between them. This review not only aims to further clarify how different hospital performance factors interact but also identify gaps in the current understanding of this topic. By determining the relationships between the framework, the goal of this project is to develop an expanded framework which assesses hospital performance more objectively and comprehensively. This hospital performance assessment (HPA) framework will allow for improved decision-making for important stakeholders, such as healthcare management officials and policymakers, ultimately leading to enhanced strategies for improving hospital operations and patient care.

Abstract Name: Effects of acute hypoxic exposure in the olfactory system of adult zebrafish

Hypoxia, the lack of sufficient oxygen in tissues to sustain bodily functions, has a deleterious effect on brain health. Zebrafish offer an excellent model to study hypoxia due to extensive neuroplasticity and injury-induced cell proliferation in their central nervous system (CNS), particularly their olfactory system. In this study, we establish a paradigm of acute hypoxic exposure in zebrafish to uncover the effects on the olfactory system's structure and function. To induce hypoxia, zebrafish were placed in a tank with hypoxic levels of 0.6-0.8 mg/mL dissolved O₂ (DO) for 15 minutes and then recovered for 1-day post hypoxia (1 dph). We hypothesized that hypoxia is associated with a loss of smell due to abnormalities in the olfactory epithelium (OE). To study this, we assessed olfactory-mediated responses to cadaverine, an odorant that elicits alarm responses in zebrafish, characterized by freezing, sinking, and decreased exploration of the tank. To assess olfactory epithelium integrity we stained for active mitochondrial dehydrogenase activity to study mitochondrial function and performed immunohistochemistry assays to assess structural degeneration and neuroinflammation in the olfactory system. We measured olfactory sensory neuron (OSN) activity by labeling with c-Fos, a marker of neural activity. In addition, we utilized Alcian Blue stainings of the olfactory epithelium to visualize the mucus layer and the structure of mucus-producing Bowman Glands. We observed reduced responses to cadaverine in the hypoxic group, indicative of olfactory loss. We also found mitochondrial activity reduction, increased astrocyte activation, and apoptosis markers in the olfactory bulb. Interestingly, we found changes in the mucus layer in the OE as well as epithelial swelling along with changes in OSN activation. Collectively, our results characterize olfactory loss associated with degeneration of the olfactory system caused by hypoxia. This work provides insights into hypoxia's impact on olfaction, specifically olfactory morphology and function.

Abstract Name: Reducing Stigma through Mindfulness: An Intervention for HIV-Positive Patients and Healthcare Employees

Project Purpose: Our intervention aimed to reduce the stigma associated with HIV/AIDS among patients by fostering a supportive and understanding environment. Additionally, our intervention promoted gender-affirming care for employees at North Country HealthCare, ensuring that all staff and patients feel respected in their identities. Overall, the initiative aimed to create a more inclusive and compassionate healthcare setting for both patients and staff. **Background:** Stigma can affect both patients and healthcare employees and remains a barrier to accessing adequate health care. This particularly affects patients who are living with HIV since patients who perceive high levels of HIV-related stigma are 2.4 times more likely to delay enrollment in care. Addressing this issue and focusing on gender-affirming care can help improve health outcomes and create a safe environment. **Methods:** Two interventions were used for this project. The first targeted North Country HealthCare employees through a health education lesson focusing on preventing stigma and supporting gender-affirming care. The lesson included role-play scenarios to help employees understand and address stigma and gender-affirming care in the workplace. The second intervention supported Ryan White patients through the creation of a website focusing on mindfulness techniques and stigma-reduction tools. Additionally, we assembled and distributed mindfulness goodie bags containing items such as journals and massagers to promote mindfulness practices and support patient wellbeing. **Conclusions:** During the educational presentation to North Country Healthcare employees, a pre and post-test was conducted. Knowledge about how to reduce stigma among North Country HealthCare employees increased by 13%. Additionally, the comfort of working with HIV patients increased by 13%. Commonly written feedback from our participants included gratitude and an improved understanding of gender-affirming care and stigma. Looking ahead, the Ryan White Part B program will be equipped with digital platforms and interactive activities to better support patients living with HIV.

Discipline: Dance

Authors:

Abstract Name: "Fragments of Us"

The story behind my dance has such a sentimental meaning to the growth and lessons I have learned in my life, and I wanted to create something so vital, that it showcased the importance of knowledge in community. I created this dance with a co-ed cast of 11 dancers who all portray their own experiences under the umbrella of my theme. The purpose of this dance is to invoke the acknowledgement of knowing that you are not alone. Specifically, in the experience of conflicting emotions of love and hate one faces when they lose someone who essentially became a part of you. It is also a lesson of how someone, no matter how long they have been in your life can have a long lasting effect on you. The aspects explored in this piece are the moments of expressing one's anger musically and the remembrance of a once tender love, but now whimsical fleeting memory that is only a daydream you are being pulled out of. This dance demonstrates its uniqueness of letting others know that it is not wrong to experience a vast range of emotions when dealing with a loss of someone you loved, no matter the reason for their now non-existence in your life. While this is a well-known topic, what makes this dance so different is it truly brings to life the embarrassing actions of sniffing a loved

ones shirt, trying to hold on to the memory of them in the form of clothing their loved one once wore. This is showcased in the community of all of them wearing the same outfits with a prop shirt being drawn back to a cream white shirt that represents how we all are grappling with the loss and sentimental tie to a variety of relationships.

Abstract Name: Recalibrating the Self: Affirmation, Rumination, and the Complex Nature of Psychological Integrity

Self-affirmation, a widely studied psychological intervention, aims to bolster self-integrity and promote adaptive cognitive and emotional outcomes. However, its efficacy remains context-dependent and influenced by individual and situational factors. This study investigates how self-affirmation interacts with different types of rumination—positive, negative, and neutral—to affect construal levels, affirmativeness, and dampening of positive emotions. A sample of 275 U.S. adults participated in a mixed factorial design study, where they completed pre-task assessment, rumination induction and affirmation intervention tasks, followed by a series of post-task assessments. Results revealed no significant main effect of self-affirmation on construal levels, although trends suggested potential interactions with rumination. Affirmation increased construal levels under negative and neutral rumination but appeared to reduce abstraction under positive rumination for participants with lower baseline construal levels. Affirmation significantly enhanced engagement with affirming content, as evidenced by higher Affirmation Index scores across conditions. Exploratory analyses showed that affirmation interacted with rumination to influence dampening, with affirmation tempering heightened positive states in positive rumination and reducing overly negative states in negative rumination. Racial differences further moderated these effects, particularly in the dampening subscale, highlighting the importance of cultural and identity-related factors in self-affirmation processes. These findings highlight the context-sensitive nature of self-affirmation, suggesting its effects depend on baseline cognitive states and the reflective context and exploring affirmation's role as a regulatory mechanism that stabilizes cognitive and emotional states.

Abstract Name: The Cognitive Abilities of College Students and their Relationship to a Personal Sense of Uniqueness

PosterTITLEThe Cognitive Abilities of College Students and their Relationship to a Personal Sense of UniquenessData collection is in progress. This study examines the relationship between cognitive abilities and personal uniqueness in college students. While prior research highlights the importance of uniqueness in individual identity, its connection to specific cognitive abilities remains underexplored. Young adults

represent a population where developing a sense of uniqueness is particularly complex due to significant cognitive and social development. Here, we hypothesize that processing speed, academic achievement, working memory, and social cognition will each predict a greater sense of personal uniqueness. Participants will complete assessments measuring their processing speed, working memory capacity, academic achievement, and social cognitive abilities. Self-reported measures of personal uniqueness will be collected to evaluate the relation between cognitive abilities contribute and personal uniqueness. To address Research Question 1: Does processing speed predict a greater sense of personal uniqueness in adolescents? we will conduct regression analyses with processing speed as the predictor. To address Research Question 2: Does academic achievement predict earlier uniqueness development? we will use academic performance as the predictor. Similar analyses will explore the effects of working memory (Research Question 3) and social cognition (Research Question 4) on personal uniqueness. Age and gender will serve as covariates in all analyses. This study is significant because understanding how cognitive abilities contribute to uniqueness can help individuals recognize and embrace their individual differences. These insights may enhance self-efficacy, foster healthier relationships, and improve mental health outcomes, ultimately creating opportunities for personal and social development.

Abstract Name: The Sleep Quality of College Students and its Relationship to Academic Anxiety and Performance

This study examines the relationships between sleep quality, academic stress, and academic performance in college students. We aim to build on existing research by exploring how these factors interact and influence student outcomes. Sleep quality refers to the degree of restfulness and uninterrupted sleep, academic stress involves feelings of worry or nervousness about educational responsibilities, and academic performance is measured by grade point average (GPA) and students' satisfaction with their grades. Participants will complete self-report measures assessing sleep quality, academic stress, and satisfaction with academic performance. GPA will be collected as an objective indicator of academic performance. To address Research Question 1: Is poor sleep quality associated with greater academic stress? we will conduct regression analyses with sleep quality as the predictor and academic stress as the outcome. Here, we hypothesize that poor sleep quality will be associated with higher levels of academic stress. To address Research Question 2: Does poor sleep quality predict reduced academic performance? We predict that poor sleep quality will correlate with decreased academic performance. We will run a similar analysis, using academic performance as the outcome. Age and gender will be included as covariates in both analyses. Both poor sleep quality and elevated academic stress are also expected to contribute to reduced self-efficacy, difficulties in maintaining relationships, and increased risk for poor mental health outcomes. This study is significant because understanding how sleep quality and academic stress affect performance can help students identify strategies to enhance their academic success while reducing stress and anxiety, ultimately fostering improved mental health and well-being.

Abstract Name: Positive versus Critical Self-Talk and their Relationship with Creativity

Oral Presentation
TITLE Positive Self-Talk versus Brooding and their Relationship with Creativity
Data collection is in progress. Many studies have established a relationship between depressive symptoms and creative thought. However, the relationship is not robust and can be found in both directions. Here, researchers wish to further investigate why this occurs. It is likely because studies have examined multiple symptoms of depression, some being related to creativity and others unrelated. We hypothesize that different types of self-talk will be correlated with creativity. Specifically, we predict a positive relationship between positive self-talk and creative thinking, and a negative relation between brooding and creative thinking. Participants from a college sample will be instructed to respond to self-report measures of self-talk and brooding. Additionally, the ability of the participants to produce creative thinking will be measured using an alternative use task. To assess research question 1: Does positive self-talk predict creativity, we will run a regression analysis where positive self-talk is the predictor and creativity is the outcome. Covariates include gender and age. To assess research question 2: Does brooding predict creativity, we will run a regression analysis where brooding is the predictor and creativity is the outcome. Covariates include gender and age. This study can help us better understand the connection between creativity and depression potentially providing an individual with an outlet to better understand one's emotions. This could lead to increased ability to problem solve and make decisions.

Abstract Name: Kintsugi 3D Builder: User Experience Design & Implementation

Photogrammetry is the process of using 2D photographs to generate a 3D model of a real object. Developed by researchers at UW-Stout, Kintsugi 3D is a new software suite that allows users to import and process data from photogrammetry software to generate a more accurate digital representation of a 3D object. Using information derived from source photographs, Kintsugi 3D captures texture, color, material, and shininess more accurately than standard photogrammetry software. The suite's processing tool, Kintsugi 3D Builder, relies upon intuitive UI design and implementation to service both new and existing users. Notable UI contributions include direct import from photogrammetry software, a detailed progress bar, and a modal to select an image from a list of cameras.

Abstract Name: How Jealousy Relates to Relationship Quality and Personality

This study examines how different types of jealousy—emotional, cognitive, and behavioral—relate to relationship quality and personality traits. Building on Attridge’s (2013) findings that emotional jealousy is “good,” cognitive jealousy is “bad,” and behavioral jealousy has minimal associations, the current study expands these relationships by incorporating additional relationship components (investments, alternatives, commitment) and personality factors (attachment styles, self-esteem, Big Five traits, and implicit relationship beliefs). Participants included 140 adults (102 females, males = 25) in romantic relationships. They completed measures assessing jealousy types, relationship quality, and personality. Results showed emotional jealousy positively correlated with satisfaction, commitment, and investments ($r = .31$, $p < .001$), and negatively with quality of alternatives ($r = -.24$, $p = .001$), aligning with prior findings. However, unlike Attridge, cognitive jealousy also positively correlated with satisfaction, commitment, and investments ($r = .15$, $p < .05$). Behavioral jealousy correlated positively with quality of alternatives ($r = .26$, $p < .001$). Personality analyses revealed no significant links between emotional jealousy and personality traits. Cognitive jealousy correlated positively with growth and destiny beliefs, and neuroticism ($r = .15$, $p < .05$). Behavioral jealousy showed mixed correlations: positively with destiny beliefs, neuroticism, and anxious attachment ($r = .20$, $p < .01$), but negatively with agreeableness, conscientiousness, and self-esteem ($r = -.21$, $p < .01$). These findings suggest emotional jealousy aligns with higher relationship quality, reinforcing its “good” label. Cognitive jealousy previously deemed “bad,” also showed positive associations with relationship quality. In contrast, behavioral jealousy, linked to lower self-esteem and alternative quality, supports its “bad” categorization. This research deepens our understanding of jealousy’s complex relationship with relationship dynamics and personality traits.

Abstract Name: Anion Influence on the Hydrogen Evolution Reaction

As we progress toward a renewable energy infrastructure, we must address the intermittent nature of these energy sources by storing energy for use during non peak production hours. One way we can combat this is by leveraging the electrochemical hydrogen evolution reaction to produce energy dense hydrogen molecules that can be used to support the electrical grid. Hydrogen evolution reaction is difficult, however, because it requires expensive catalysts, produces low yields, and has sluggish kinetics. To improve hydrogen evolution we must engineer the interface which is composed of the electrode and electrolyte. Historically, much of the research has been dedicated to enhancing the electrode, however, the electrolyte is now understood to have an equally important impact. Current models on electrolyte effects rely on the assumptions of dilute electrolyte theory where only hydrated cations can influence electrochemical reactions. However, recent research shows the anion can also have an impact on reactivity in certain electrolyte concentrations. We hypothesize then that at higher concentrations of electrolyte the anion will play an important role in how the reaction proceeds and we test this with Cl, F, BF₄, ClO₄, and TFSI anions. By performing cyclic voltammetry we were able to conclude that BF₄ performed the best while ClO₄ performed the worst in terms of current density and these factors were likely due to mass transfer limitations as performing linear sweep voltammetry showed that

CIO4 is most limited by it. Moreover, Raman Spectroscopy points toward a unique mechanism that CIO4 follows which also may explain its poor performance. These findings advance understanding of anion effects in HER, offering new strategies to optimize hydrogen production for renewable energy systems.

Abstract Name: Just Kicking It: Football and Nationalism in Spain during Francisco Franco's Regime

This research project investigates football's role during Francisco Franco's pursuit of a unified Spanish nationalism. While Spain consists of seventeen autonomous communities, Francisco Franco's political goal was to create a Spain with no cultural or linguistic divisions, and football was a tool to achieve this goal. Previous scholars have questioned how politicians use football events for political support. Moreover, the existing research posited a theory called football nationalism to explain football's ability to unify a nation toward a collective goal. This research project will define Franco's Spanish nationalism and use news media sources from Spain's National Library. Analyzing the news media will reveal football's role in Franco's Spanish state. Likely, the research results will indicate Franco endorsed football teams with ties to the Spanish crown while repressing other cultures during his pursuit of a collective Spanish nationalism. Examining football's role during Franco's regime will disclose how leaders around the world are using football and nationalism as a tool to achieve political goals.

Abstract Name: Effects of sound exposure on the growth and intracellular macromolecular synthesis of *E. coli*.

Abstract This study investigates the effects of sound wave exposure on the growth, morphology, and metabolic activity of *Escherichia coli* (*E. coli*). Sound waves, often overlooked as a physical stimulus, have shown potential in influencing biological systems through mechanical and vibrational energy. The research aims to explore whether specific frequencies and amplitudes of sound waves impact *E. coli* growth rates, biofilm formation, and gene expression related to stress responses. Initial experiments involve culturing *E. coli* under controlled conditions while subjecting samples to sound waves of varying frequencies (e.g., 100 Hz to 20 kHz) and intensities. Measurements include growth kinetics (optical density monitoring), metabolic activity (respirometry and ATP quantification), and structural changes (scanning electron microscopy). The study also aims to incorporate transcriptomic analysis to identify changes in gene expression profiles associated with stress, metabolism, and motility. Preliminary results could provide insights into non-invasive methods to influence microbial behavior and may have applications in microbial biotechnology, infection control, and environmental microbiology.

Abstract Name: Can Democracy Survive? A Philosophical Investigation into Tocqueville and Mill's Theories of Cultural Cohesion Considering Rapid Change Due to Immigration

Democratic regimes are often based on shared history and cultural cohesion, while immigration brings diversity in values and practices. Can democracy adapt to this complexity without compromising its principles? Through a comparative thematic analysis of Alexis de Tocqueville and John Stuart Mill's works, this study examines the interplay between cultural integration and democratic resilience. Tocqueville emphasizes the importance of civic associations and a shared democratic ethos, warning that fragmented norms could weaken societal unity. Mill advocates for liberty and individuality, while also acknowledging that cohesion and mutual respect are essential in effective governance. Their philosophies taken together offer a lens to analyze how democracies may find a way to integrate different populations. This research seeks a linkage between 19th-century philosophical frameworks and modern debates on immigration with ethical and structural tensions found within democratic systems. By linking historical thought to contemporary challenges, this study will provide actionable insights for policymakers grappling with global migration's impact on democratic values. Ultimately, it demonstrates that resilience and adaptability are essential for democracies facing the complexities of immigration.

Abstract Name: The Effect of the Great East Japan Earthquake and Tsunami on the Care of Noncommunicable Diseases

Noncommunicable diseases (NCDs) put a significant burden on communities, especially on communities with a substantial elderly population, due to the constant demand for care and medication. This burden is increased during natural disasters such as the Great East Japan Earthquake and Tsunami (GEJET), which disrupted healthcare systems, interrupted medication supplies, and placed additional physical and emotional stress on individuals. These challenges are often severe for elderly populations that are managing chronic diseases, as symptoms typically worsen with elevated stress and reduced healthcare access. This study focuses on understanding the disruptions faced in care for chronic disease patients through a series of literature reviews. Key findings show that typical symptoms of chronic diseases were exacerbated during disasters due to care interruptions and increased psychological stress. Patients typically experience delays in receiving medication, while healthcare providers face challenges in delivering care due to the damaged infrastructure and limited resources. This study also examines the need for comprehensive improvements within the healthcare system for patients with chronic diseases during future disasters. Specific recommendations include improving current infrastructure, increasing disaster preparedness education, maintaining stockpiles of necessary medications, and developing support teams that can provide medical and

psychological support. Addressing these gaps, can ensure that future healthcare systems are more resilient and responsive to natural disasters like the GEJET, which would also reduce the effects seen on patient populations with NCDs.

Abstract Name: Synthesis of Antimicrobial Peptide Analogs for DNA Conjugation

Antimicrobial resistance (AMR) is a global health crisis projected to cause over 10 million deaths annually by 2050. Many current antibiotics which target bacterial proteins are increasingly ineffective due to resistance mechanisms arising from genetic mutations and horizontal gene transfer. This study investigates the use of peptide-DNA conjugates as a novel strategy to combat AMR, leveraging the modularity and versatility of nucleic acids to assemble into nanostructures with the broad-spectrum activity of antimicrobial peptides (AMPs). LL-37 is a well-characterized human AMP that acts by disrupting bacterial membranes, reducing the chance of developing resistance. In this study, we use LL-37 as a proof of concept to assemble into peptide-DNA conjugates. LL-37 is synthesized using Fmoc-based Solid Phase Peptide Synthesis (SPPS) with a propargyl glycine residue at the C-terminus for click-chemistry conjugation with DNA. Liquid Chromatography-Mass Spectrometry (LC-MS) data shows we were able to obtain our desired product. Current efforts focus on improving peptide purity, providing a basis for exploring diverse AMPs to enhance therapeutic options with peptide-DNA conjugates.

Abstract Name: Inducible Lentiviral Re-Expression of PKD1/PKD2 Genes Restores PC1/PC2 in Human Kidney Organoid-Derived Cystic Cells

Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disease caused by mutations in the PKD1 and PKD2 genes, resulting in disrupted polycystin-1 (PC1) and polycystin-2 (PC2) protein function. This leads to cyst formation, followed by inflammation and fibrosis. We hypothesize that re-expressing wild-type PKD1 and PKD2 in mutant cells can reverse cystic structures back to normal tubular cells. Reversal of cyst formation through re-expression of wild-type PKD1/PKD2 genes has been successful in a mouse model. We wanted to assess if this result could be successfully achieved in human kidney organoid-derived cystic cells. To test this, we construct a lentivirus utilizing plasmid vectors to insert PKD1 and PKD2 genes through transfection. This lentivirus transduces human embryonic kidney (HEK) cells by encoding for PKD1/PKD2. Successful transduction is expected to result in the re-expression of PC1/PC2 proteins in HEK cells, observed by the proliferation and intensity of the mCherry reporter signal under microscopy. In conclusion, we aim to discern whether PC1/PC2 function can be restored through re-expression of wild-type PKD1/PKD2 in human

cells. This research will aid in furthering our understanding of ADPKD. Future work will attempt to replicate these results in cystic human embryonic kidney organoids, which will be more applicable as a proof-of-concept to future in vivo research. The re-expression of PC1/PC2 in human cells provides foundational knowledge for applying these results to cystic human embryonic kidney organoids.

Abstract Name: Personalized Portfolio Construction: Leveraging Modern Portfolio Theory for Investor-Specific Portfolios

Many investors have varying degrees of risk appetite, causing the optimal portfolio to vary based on personal preferences. This research seeks to address the question: How can an automated framework optimize equity portfolios for individuals with varying risk appetites using company financial data? I aim to develop a framework that can take either a pre-existing portfolio or an empty portfolio and recommend equities based on company financial information and user preferences, optimizing for high long-term returns. Data will be collected from the US Equities market through filings made to the US Securities and Exchange Commission, as well as financial data provided through Yahoo Finance. The data will be filtered to remove stocks with low risk-to-reward ratios. I plan to use the Efficient Frontier, as first presented in the Modern Portfolio Theory by Harry Markowitz, to provide optimal allocations for each security. The framework will adjust for industry overexposure by recommending the liquidation of specific positions to maintain appropriate diversification. The expected outcome is a framework that balances risk and reward while tailoring recommendations to individual investors, bridging theoretical portfolio optimization and practical application. This framework aims to empower individuals to make better-informed investment decisions, alleviating anxiety about market volatility by providing personalized, data-driven recommendations. Additionally, it can serve as a valuable complement to financial advisors, enhancing their ability to guide clients in optimizing portfolios for long-term growth.

Abstract Name: Functional analysis of the Insulin/IGF-1 signaling gene Bma-pptr-1 in the parasitic nematode *Brugia Malayi*

Lymphatic filariasis (LF) is a human disease caused by a parasitic nematode, *Brugia malayi*, as well as other related parasites. This mosquito-transmitted disease can be highly debilitating and is the second leading cause of permanent deformity and disability worldwide, following leprosy. The free-living nematode *Caenorhabditis elegans* is a widely used model organism for parasitic nematodes. *C. elegans* progress through four different larval stages during their development where each stage lasts between seven and eleven hours. However, under certain environmental conditions the nematode can enter a dauer larval stage and stay in this stage for up to four months. *C. elegans* dauer stage is hypothesized to be similar to the parasite infective stage. Dauer

stage is known to be regulated by the insulin/insulin-like growth factor signaling pathway in *C. elegans*. DAF-2 is the insulin receptor, and it is activated when insulin-like peptides bind to it. DAF-2 then sends a signal into the cell that activates a kinase cascade which includes PDK-1 phosphorylating and activating AKT-1. Activated AKT-1 can phosphorylate the DAF-16/FoxO transcription factor which deactivates DAF-16 and turns off genes important for dauer formation. However, a phosphatase, PPTR-1, can dephosphorylate AKT-1, and therefore activate DAF-16 gene function, turning on genes responsible for dauer formation. We are studying the pptr-1 gene in *B. malayi*. We have successfully cloned and sequenced a Bma-pptr-1 expression construct. We will be testing its function by expressing it in cultured cells. We will then use a reporter gene assay to determine if overexpression of Bma-PPTR-1 will activate Bma-DAF-16, as shown by an increase in reporter gene activity. This could lead to more research on how larval development is affected by Bma-PPTR-1 and will hopefully help drive further ideas for medicine used in the mitigation of lymphatic filariasis.

Abstract Name: Protective Role of GDAP1 in Maintaining Mitochondrial Calcium Homeostasis Under Oxidative Stress

Calcium signaling is essential for cellular function, with mitochondria playing a critical role in energy regulation and calcium homeostasis by absorbing and releasing calcium to maintain mitochondrial health. This process involves calcium uptake through the outer membrane protein VDAC1 and the inner membrane protein MCU, driven by mitochondrial membrane potential. Oxidative stress, induced by lipid peroxidation products like 4-Hydroxynonenal (4HNE), disrupts this calcium exchange, leading to mitochondrial dysfunction. Oxidative stress damages mitochondrial proteins, lipids, and DNA, impairing their ability to regulate calcium and produce energy efficiently. 4HNE modifies and inhibits VDAC1 and MCU, affecting calcium regulation. This study investigates whether GDAP1, a protein hypothesized to protect mitochondria by removing 4HNE modifications from VDAC1, can maintain mitochondrial calcium homeostasis under oxidative stress. We used flow cytometry and the calcium-sensitive dye Rhod 2 to monitor calcium levels in GDAP1-overexpressing HEK cells exposed to tert-butyl Hydroperoxide (tBHP) and Uridine Triphosphate (UTP). These compounds were used to induce oxidative stress and calcium signaling, respectively, to assess mitochondrial calcium dynamics under physiological and stress conditions. Additionally, ionomycin was applied to release intracellular calcium, allowing further observation of calcium dynamics. The data revealed that GDAP1 overexpression modulates calcium signaling under oxidative stress. In GDAP1-overexpressing cells, tBHP treatment significantly increased calcium levels, indicating elevated calcium under stress. The addition of UTP did not further increase calcium, suggesting GDAP1 helps stabilize calcium homeostasis during prolonged stress. Resting calcium levels increased with higher tBHP concentrations and then plateaued, highlighting the impact of oxidative stress on calcium dynamics. These findings suggest that GDAP1 plays a protective role in maintaining mitochondrial calcium balance and mitigating oxidative stress, potentially by preventing 4HNE modification of VDAC1. This protective mechanism may have broader implications for diseases characterized by oxidative stress and mitochondrial dysfunction, such as neurodegenerative disorders (Parkinson's and Alzheimer's diseases) and cardiovascular conditions.

Abstract Name: Parental Transmission, Italian Society, and Agency on Religious Identity of Individuals from Muslim-Catholic Families in Italy

With immigration increasing significantly in Italy, intercultural and interreligious family dynamics are crucial to understanding identity development in adolescents from these families. Adolescents from interfaith families may benefit from increased cultural capital due to exposure to diverse value, but also face potential internal turmoil in reconciling religious, national, and ethnic identities. This study explored whether interfaith and same-faith families differ in the strategies they use for religious transmission and the effectiveness of such strategies in facilitating a minority religious identity in a Catholic-dominated cultural context. Through a review of literature, the study examined key themes such as the variability of religious transmission strategies (active, passive, or absent) in interfaith families, the role of external societal pressures on second-generation Muslim immigrants' religiosity, and the increasing individualization of Islamic practices within Catholic-majority settings. Interfaith families that attempt to transmit both parent's religion may opt to choose passive transmission, allowing their children to be exposed to cultural references related to either religion and experience religious practices with extended family or peers. However, due to the dominance of Catholicism in Italian society, Islam may not be as effectively transmitted to children who are only passively exposed to Islamic teachings. The findings aimed to illuminate how Italian-Catholic cultural influences shape pluralistic identities and potentially weaken connections to minority religious identities, offering new insights into the intersection of intercultural relations, religious identity, and adolescent development.

Abstract Name: Dedupr: Streamlining Citation Deduplication in Evidence Synthesis

In evidence synthesis projects, removing duplicated citations from multiple databases is a critical but often time-consuming task. To streamline this process, we developed Dedupr, a user-friendly R package and Shiny web app. This tool automates the reliable Bramer's method for citation deduplication, significantly reducing the effort required in systematic reviews. By simplifying the removal of duplicates, Dedupr improves the accuracy and efficiency of research, ensuring compliance with PRISMA2020 guidelines. Dedupr is particularly valuable as it removes the need for users to know R coding, offering an accessible solution through a straightforward interface. Researchers can upload their citation files, deduplicate them, and export results quickly and easily. The tool's broader impact includes enhancing the accessibility of systematic reviews for professionals in fields like healthcare, public health, and academia. By providing a cost-effective and efficient solution, Dedupr empowers researchers, especially in resource-limited environments, to conduct high-quality evidence synthesis without extensive technical expertise.

Abstract Name: Genetic Diversity of Bird Species in Fragmented Forest Habitats

Understanding genetic diversity in isolated ecological communities sheds light on species abundance, evolutionary history, and community assembly processes. Isolated communities reveal how species respond to fragmentation and provide predictions for biodiversity under anthropogenic pressures. This study examines species abundance, genetic, and functional diversity in high-elevation forest fragments in Brazil, remnants of ancient rainforests isolated 13–15 thousand years ago due to climate-driven changes. These "forest islands," sustained by a rain shadow effect, offer a natural laboratory to explore biodiversity dynamics in fragmented ecosystems. Focusing on forest fragments in Areia, Ubajara, Araripe, and Baturité, the research targets birds and arthropods, analyzing four biodiversity dimensions: species abundance, genetic diversity, functional diversity, and phylogenetic diversity. Species abundance measures individual counts, genetic diversity assesses genetic variation, functional diversity examines ecological traits like diet and morphology, and phylogenetic diversity explores evolutionary relationships among species. Data integration addresses key questions on community assembly, such as whether environmental filters or competitive interactions shape species coexistence. Molecular techniques like DNA extraction and sequencing evaluate genetic diversity, while computational analyses leverage databases to assess abundance, traits, and evolutionary relationships. Results reveal that genetic diversity and species abundance are not positively correlated, with habitat size and isolation influencing abundance distribution. Genetic diversity appears shaped by historical isolation, while abundance reflects contemporary landscape configurations. Future efforts will expand genetic analyses and incorporate body size distributions to better understand functional diversity. Insights from this research enhance understanding of biodiversity dynamics in fragmented habitats, informing conservation strategies to preserve genetic reservoirs and ecosystem functionality. These findings underscore the significance of habitat characteristics in shaping biodiversity, offering valuable perspectives for managing isolated ecosystems worldwide.

Abstract Name: Space Exploration Through Orbital Data Analysis and Computational Techniques

How can the AKATSUKI orbiter provide key information on Venus's cloud cover and atmosphere? This research seeks to refine positional data from AKATSUKI's imaging using the NAIF-SPICE toolkit developed at the Jet Propulsion Laboratory. It is critical to have accurate knowledge of the planetary coordinates corresponding to the individual pixels in every image from the Akatsuki orbiter for better analysis of the Venus cloud cover properties. Using SPICE tools on the positional data from the spacecraft and Venus at the time the image was captured, I leveraged the pointing kernels provided by the Akatsuki project to develop a "forward" function in Python. This function translates each pixel coordinate in a Venusian image into its corresponding latitude and longitude on Venus. Typically the predicted location of the planet in the image and its actual position in the image do not coincide perfectly. By calculating the planet center location from the image data, I found the offset between the predicted center and the actual center in image coordinates. I then implemented that offset into my "forward" function to obtain accurate planetary coordinates for the image pixels on the planet. The forward function allowed me to convert to and from certain positions of Venus and

more accurately align the SPICE values of Venus with the corrected values for each pixel coordinate in every infrared and ultraviolet image captured by the AKATSUKI orbiter. This enables more accurate future investigations of cloud properties as well as atmospheric dynamics through measurement of cloud motions on Venus.

Abstract Name: Hostile Architecture: Ethics in the Urban Environment

This research investigates the impact of hostile architecture on user experience and public perception of urban environments, emphasizing its ethical implications in urban design. Hostile architecture refers to design elements that discourage specific behaviors, often marginalizing vulnerable groups such as the homeless. The study explores the societal consequences of these designs and their alignment with the principles of inclusivity and equity in public spaces. Hostile architecture raises significant ethical concerns as it often operates unnoticed, yet its effects on marginalized groups and the mental well-being of urban residents are profound. While some proponents argue that these designs address urban challenges pragmatically, they often perpetuate exclusion and societal divisions. This research is particularly relevant in today's context of growing urban populations, technological advancements, and heightened awareness of social justice, calling for a critical reevaluation of urban design practices. The study employs a qualitative and inductive methodology, combining case studies, comparative analyses, literature reviews, and stakeholder perspectives. Case studies of urban spaces where hostile architecture is prevalent will shed light on its design intent and social outcomes, while comparative analyses will highlight the differences in user engagement between inclusive and exclusionary designs. Insights from literature and stakeholders will provide a holistic understanding of the issue. Preliminary findings suggest that hostile architecture negatively impacts social cohesion, public trust, and mental health while reinforcing systemic inequalities. This research anticipates offering design alternatives that prioritize inclusivity and fairness, challenging the status quo and inspiring urban planners, architects, and policymakers to create more compassionate and equitable cities. By highlighting the broader societal implications of design decisions, this study aims to foster ethical urban design practices that serve all members of society, particularly marginalized communities.

Abstract Name: Elements of Belonging

This research sought to develop a model of student belonging at small private liberal arts universities. Using the lens of Bronfenbrenner's Ecological Model we hypothesized that the past research predicting student belonging from academic achievement and relationships with faculty and staff was insufficient as it left out important variables related to the individual student and the relationships with peers. Using archival data set

of over 90 students gathered in conjunction with the National Survey of Student Engagement (NSSE) we were able to refine the model of student belonging. By adding student mental health status and relationships with peers a linear regression model accounted for over 50% of the variability in students' self-reported belonging. The implications for college support services are discussed. Future research should refine the model by exploring the role of other factors such as cultural background and extracurricular involvement and examining the relationship between belonging and degree persistence and completion using larger and more diverse longitudinal samples.

Abstract Name: Candomblé, Capoeira, and Catholicism: Hybridity in Afro-Brazilian Religious and Cultural Practices

This summer, I had the opportunity to travel to Salvador, Bahia in Brazil for three and a half weeks through a Fulbright-Hays grant. While there, I engaged in participant observation of various Afro-Brazilian cultural and religious practices. I had the chance to attend a Terreiro De Candomblé and a Roman Catholic Mass, and I heard an Afro-Brazilian drumming rhythm called Ijexa in both spaces. I immediately recognized the rhythm because I had heard it and played it before during my previous ethnography of a Capoeira group in Atlanta, Georgia. I was immediately curious about why Ijexa appeared in these three practices, especially in the Roman Catholic Mass. This paper aims to share descriptions from my initial ethnographic encounters in Brazil combined with descriptions and research from my previous ethnography in Atlanta, Georgia to describe how I witnessed Ijexa function in a Candomblé Ceremony, a Capoeira Roda, and a Catholic mass. I am guided by my research questions: How does Ijexa function in a Terreiro De Candomblé, a Roman Catholic Mass, and a Capoeira Roda? What are the similarities within differences and differences within similarities of how Ijexa functions in these three spaces? What is the significance of hearing Ijexa, an Afro-Brazilian drumming rhythm in these three spaces?

Abstract Name: Squid RNA Editing in Hypoxic Environments

RNA editing is a phenomenon when adenosines on RNA molecules are edited into inosines, which are interpreted by ribosomes as guanosines. Depending on where in an mRNA transcript this edit occurs, it can result in the protein produced having variations in its amino acid sequence, that may be adaptive for their function under certain environmental conditions. All animals are capable of RNA editing, but coleoid cephalopods can edit their RNA to change their proteins orders of magnitude more than other organisms. It was recently found that cephalopods alter their RNA editing in different environmental conditions such as

temperature. We wanted to assess whether varying environmental oxygen levels also produce changes in RNA editing. During the summer of 2024, we conducted experiments at the Marine Biological Laboratory in Woods Hole, MA that investigated RNA editing in the squid *Euprymna berryi* that were exposed to hypoxic environmental conditions. First, we conducted experiments to determine the hypoxia tolerance of *E. berryi*. These experiments suggested they can tolerate ~33% air saturation without depression of aerobic metabolism. In our second set of experiments, the squids were kept either at air saturation or near their hypoxia threshold for seven days by regulating dissolved oxygen levels with a microcontroller. At the end of the experiments, we dissected optic lobes from the brain for RNA sequencing to quantify the abundance of RNA editing. To help determine a potential mechanism of hypoxia-induced RNA editing, we also examined in situ oxygen levels within the optic lobes of squids exposed to varying oxygen conditions. Our preliminary data showed that their brain oxygen levels change with the environmental oxygen conditions. We also observed that when squids exhibited jetting behavior there may potentially be a decrease in brain oxygenation. This study broadens our understanding of the acclimatory responses of cephalopods to environmental changes.

Abstract Name: NPCS mission to make safety culture in the child welfare system

Public child welfare system workers dedicate their time and hard work to improve the outcomes for children and their families. As a high-stake organization, there are possibilities for individuals to make mistakes that could range from minor missed case opportunities to critical incidents cases that push policy change. The National Partnership for Child Safety (NPCS) is a peer-to-peer learning and data sharing collaborative of over 35 child welfare jurisdictions in the United States, and members are focused on systems improvements. One goal the NPCS wants to achieve is to develop an efficient model of a safety culture to be followed for overall psychological safety. With a focus of critical incidents, the NPCS developed a safe systems improvement tool aimed to understand possible influences in case errors. The main objective of this study is to find a correlation between stress and work outcomes using employees within the NPCS jurisdiction as a sample. The methods of this study include surveys of child welfare workers reflecting on their critical incidents. Ultimately, the goal is to understand the different types of external stressors that impact child welfare workers and their target families. Currently, this study is through data analyzation; thus, conclusions are being developed. A full description of the database, study goals, and preliminary data will be presented at the showcase.

Abstract Name: A cultural analysis of Japanese and French Impressionist art through Hiroshige and Monet

The topic of this study is the cross-cultural comparison between Japanese-style ukiyo-e prints and French Impressionism, with a specific focus on thematic elements including bridges and the natural world. The study will compare the print *In the Kameido Tenjin Shrine Compound* by Utagawa Hiroshige and the painting

Water Lilies and Japanese Bridge by Claude Monet. Contrary to the myth, ukiyo-e prints were considered to be more than just wrapping paper for goods traded between Japan and France. Ukiyo-e prints were deeply admired by not only Japan but many other countries, especially France. With the introduction of the ukiyo-e prints to the rest of the world, France began to draw inspiration from these prints as seen in Monet's painting Water Lilies and Japanese Bridge. One example of this can be found in the imagery of bridges in the two compositions. The depiction of bridges held local importance to Japan and France but also had a shared cultural significance. While bridges held a more mythological and spiritual meaning in Japan, both Japan and France depict bridges to help convey human connection to the natural world. This is not the only relevant cultural overlap to be found within the two artworks. This comparison will highlight the similarities between Hiroshige's and Monet's respective works, in particular the use conceptual elements such as light and airiness, while expanding on specific differences such as the presence and lack of human subjects within these pieces. The information from this study was gathered from various printed academic sources. Knowing the inspirations and similarities in artworks such as these allows us to understand the cultural and global competence that is foundational for positive cross-cultural relations.

Abstract Name: The Efficacy of Differing Cryotherapy Modalities

Healthcare has become expensive so we endeavored to see if the increased expense was worth the results, where cryotherapy and compression treatments are in question. We tested three devices the GameReady 2.1 Pro (~\$4000), the NICE1 system (~\$4500), and an elastic bandage (FEB) with a non-stick coating on one side, soaked in water and frozen, (~\$4). Each was applied to cover 30.5-33cm of the lower leg, left on for 30 minutes of treatment, and removed for 25 minutes of rewarming. We used a pico-press on the lateral side of the calf to ensure consistent pressure throughout each treatment. We inserted a thermocouple into the greatest girth of the calf (1 ± 0.3 cm) deep to the subcutaneous fat. After each trial, we gave a survey to assess their satisfaction with the treatment. 24 subjects volunteered to participate (12 males, 12 females, age= 24.21 ± 2.87 yr, ht= 170.18 ± 7.45 cm, mass= 77.05 ± 18.79 kg.) There were statistically significant differences in intramuscular temperature between the three treatments over time ($F=10.75$, $p=.001$, observed power-0.987), there was a statistically significant difference ($p=.043$) in intramuscular temperature between the GameReady 2.1 Pro ($24.78 \pm 4.90^{\circ}\text{C}$) and the FEB ($28.07 \pm 2.82^{\circ}\text{C}$) at 25 minutes treatment. The surveys indicated a statistical significance ($\chi^2(2)=6.727$, $p=0.035$) in satisfaction with the treatment's ability to cool the leg, being more satisfied with the ability of the GameReady 2.1 Pro to cool compared to the FEB. These results indicate that the GameReady 2.1 Pro and the NICE1 system were the more effective treatments, with the GameReady 2.1 Pro having higher satisfaction with cooling. Future research should evaluate the cost-effectiveness and satisfaction results of other cryotherapy/compression modalities.

Abstract Name: African Orality as Ignored History

In this presentation I aim to explain how the structuralist movement in history created stigma and ignorance towards African Orality and Historiography calling them pseudo-history. The structuralist movement then attacks culture because of how important history, specifically oral history, is to the west african culture. In doing this they invalidated African Culture which has Orality and Family history deeply embedded within cultural values. I use two accounts of the epic of Sundiata, Sundiata: an epic of old Mali and La Maître de la Parôle to show how these historical stories told by griots have ties of culture and family history within them. These stories being exactly what structuralists found non-historical. Within this boasts a story of persistence and resilience, that with these invalidations, African Orality and Culture is still thriving in West Africa.

Abstract Name: Exploring the Mechanism of the Electronic Quenching of NO ($A2\Sigma^+$) With Acetylene and Benzene

NO is an important by-product of combustion and a prototypical free radical. NO is commonly quantified using laser-induced fluorescence (LIF) along its $A2\Sigma^+ \leftarrow X2\Pi$ transition band. Electronic quenching of NO ($A2\Sigma^+$) through interactions with other molecules provides alternative photochemical pathways that fluorescence must compete with. Previous experiments have demonstrated that acetylene and benzene are highly effective at quenching NO ($A2\Sigma^+$). Specifically, the room temperature electronic quenching cross sections for NO ($A2\Sigma^+$)+C₂H₂ and NO ($A2\Sigma^+$)+C₆H₆ are 62 Å² and 147 Å², respectively. The underlying photochemical pathways responsible for these large electronic quenching pathways remain unknown. In this poster, we describe our efforts to characterize the photochemistry of both NO ($A2\Sigma^+$)+C₂H₂ and NO ($A2\Sigma^+$)+C₆H₆ through the development of high-quality potential energy surfaces (PESs). The PESs are primarily calculated using the EOM-EA-CCSD/d-aug-cc-pVTZ//EOM-EA-CCSD/aug-cc-pVDZ and CASSCF/d-aug-cc-pVTZ//NEVPT2/d-aug-cc-pVTZ level of theory. These methods provide a balanced treatment of the valence and Rydberg electronic states while cleanly capturing the open-shell character of these systems. We additionally performed multireference electronic structure calculations to evaluate the role of electronic energy transfer from NO ($A2\Sigma^+$) to the low-lying electronic states of C₂H₂ or C₆H₆. Our work suggests that the harpoon mechanism, in which electron density shifts from NO ($A2\Sigma^+$) to the molecular partner, primarily drives the electronic quenching. While C₂H₂ and C₆H₆ have highly unfavorable electron affinities, attractive Coulombic interactions within the transient ion pair generated by the electron transfer allow the harpoon mechanism to be energetically favorable. Applying these computational methods helped us to compare the differences between the low-lying electronic states of C₂H₂ and C₆H₆. Overall, our work sheds new insights into bimolecular, open-shell photochemistry and will hopefully inspire new experimental studies on these interesting systems.

Abstract Name: An Examination of Degree Attainment on Reported Physical and Mental Health over Three Decades

Previous empirical studies have examined the relationship between education and health, notably finding that education leads to better health outcomes; however, it is not clear how education leads to improved health outcomes. This study seeks to examine the pathways through which obtaining a college degree mediates physical and mental health outcomes. Further, this study seeks to examine how degree attainment has mediated physical and mental health outcomes across time by using three different years (1998, 2008, 2018) of the General Social Survey. Multiple structural path models were examined, and results indicate that education has a positive impact across time. While the direct effects examined largely confirm findings from the existing literature, indirect effects indicate that these relationships are more complex. The findings from this study can be used to better understand the changing effect education has on health. Conclusively, the research offers support for the pursuit of higher education. Policy implications will be discussed.

Abstract Name: Survival Strategies in Monarch Butterflies: Cannibalism Increases When Resources Are Scarce

Butterfly enthusiasts often plant milkweed to support monarch butterflies (*Danaus plexippus*), but in South Florida, the nonnative tropical milkweed (*Asclepias curassavica*) is the predominant option available at nurseries, with limited exceptions. Tropical milkweed has smaller leaves compared to the native common milkweed (*Asclepias syriaca*), and monarch caterpillars may resort to cannibalism when food resources are depleted. While such behavior has been observed anecdotally, video documentation offers an opportunity to provide empirical evidence of these interactions. In this study, tropical milkweed was arranged in both low-density and high-density patches, with an equal number of caterpillars placed in each patch. Two experiments were conducted: one that allowed caterpillars to interact with natural predators, and another that excluded predators using netting. Video footage revealed that monarch caterpillars in low-density patches exhibited heavy cannibalism, whereas cannibalism was minimal in high-density patches. These findings suggest that monarch caterpillars experience a Malthusian trap, where cannibalism increases when resources are scarce. While predation by natural predators was relatively rare, caterpillars in low-density patches suffered significantly more losses compared to those in high-density patches. Plant density appears to influence both the likelihood of cannibalism and exposure to predators. This study demonstrates the utility of video cameras as a tool for remotely documenting monarch caterpillar behavior. Future research should explore the integration of artificial intelligence to streamline video analysis and reduce time spent reviewing footage.

Abstract Name: Bringing in The Bystander Program for prevention of sexual violence for LGBTQ+ community on Campus

LGBTQ+ (lesbian, gay, bisexual, transgender, nonbinary, queer) people face disproportionately high rates of sexual and relationship violence (SRV) and often lack access to inclusive prevention education on college campuses. To address this, our research focuses on implementing an LGBTQ+-specific adaptation of the Bringing In The Bystander (BITB) program, which promotes positive bystander intervention that is tailored to LGBTQ+ communities (BITB-LGBTQ+). BITB is the campus SRV bystander intervention with the most empirically replicated support and is used on college and university campuses across the United States and Canada. This project focuses on pilot testing BITB-LGBTQ+, a 100-minute in-person interactive small group educational program for LGBTQ+ college students. Throughout the program, participants will have a chance to elevate and equip themselves with skills that can result in effective and positive action when encountering and witnessing sexual violence and SRV situations. We evaluate the adapted intervention through outcome measures, measures of acceptability and feasibility, and semi-structured interviews. After evaluation through these interviews, we hope to adjust and make improvements to better facilitate the BITB program for future use. This study measure not only highlights the importance of prevention education but also contributes to efforts to reduce disparities in SRV prevention and provide equity and inclusion in educational settings. By adapting and testing the BITB program to address the unique experiences of LGBTQ+ participants, we hope to shift bystander attitudes, knowledge, beliefs, and behavior to create a more safe and supportive campus environment and, in addition, contribute to more inclusive SRV prevention strategies that are evidence-based and inclusive of everyone.

Abstract Name: The Effects of Aerobic Fitness on Bilateral Transfer in Younger and Older Adults

Bilateral transfer is the change of motor performance in one limb following opposite limb practice. Transfer between limbs in younger adults is typically asymmetrical, meaning a greater change is observed in one limb following practice with the other limb than vice versa. Asymmetrical transfer is associated with lateralized hemispheric control of movement parameters according to the dynamic dominance model. Older adults exhibit more symmetrical transfer caused by additional ipsilateral activation as a compensatory mechanism for de-lateralization. Aerobic fitness helps maintain lateralized hemispheric activation in older adults, suggesting asymmetric transfer could be retained. Previous research has shown high levels of reported physical activity influenced bilateral transfer performance in both young and older adults, with older adults maintaining asymmetric bilateral transfer. However, the effects of aerobic fitness on bilateral transfer have not been assessed. The purpose of this study is to examine the effects of aerobic fitness on bilateral transfer in younger and older adults. 50 young right-handed adults aged 18-35 and right-handed older adults aged 65-81 will be recruited. Prior to training, the Edinburgh Handedness Inventory will determine hand dominance. Individuals will then perform a 30° visual rotation drawing task assessing movement parameters. Pre-test of two trials with each limb will establish baseline performance, followed by 40 practice trials on the assigned limb. Post-tests mirror pre-tests assessing the transfer of motor planning parameters including movement time, normalized jerk, trajectory length, and initial direction error. Following the drawing task, aerobic fitness will be assessed through a 2-minute walk test to estimate VO2 max performance. Higher aerobic fitness is hypothesized to preserve lateralized hemispheric activation compared to those with low aerobic fitness. For

younger adults, higher aerobic fitness may positively influence bilateral transfer of movement parameters. For older adults, higher aerobic fitness could help retain lateralized hemispheric control.

Abstract Name: The Impact of Exercise on Sucrose Preference in Sprague-Dawley Rats

A prior study showed that 8 weeks of treadmill exercise blunts sucrose preference in Long-Evans rats. We seek to replicate those findings in Sprague-Dawley rats with the goal of using exercise to prevent changes in 'sweet' taste behavior and physiology resulting from early-life ingestion of low-calorie sweeteners. To that end, we subjected male and female Sprague-Dawley rats to moderate treadmill exercise (35-min sessions) 5 days per week for 6 weeks (n=7) or allowed them to remain sedentary (n=8) but exposed to the testing environment. The females ran 519m per day, and the males ran 365m per day. To assess taste-behavior changes, a 2-bottle preference test was employed, where 1 bottle of water and 1 bottle of 0.1 M sucrose solution were placed on each cage. Following exercise, fluid intake was measured at 15,30,60,120&240 min and at 24&48h after placements. At 24h, the bottles switched sides. Preference was calculated as the proportion of sucrose intake that made up total fluid intake. No significant differences in preference were seen between the exercise and sedentary groups in the mixed-sex cohort in a 2-way repeated measures ANOVA. However, the female rats, which were maintained on the more intense exercise regimen, showed lower levels of sucrose preference relative to those of their sedentary sisters at 30 and 240 min when the data were analyzed separately via t-test. We seek to extend this work by increasing sample size to further explore sex differences and increasing the duration of the exercise regimen to that used in the prior publication. Since exercise has the potential to change taste preferences, it may be a useful therapy to prevent changes resulting from early-life ingestion of low-calorie sweeteners.

Abstract Name: Serglycin Regulates Azurophilic Granule Formation in Neutrophils

Neutrophil granules are membrane-bound compartments that release their contents upon a stimulus in a process known as regulated secretion. Neutrophils contain three prevalent granule types, characterized by different protein compositions and capacities to fuse with the cell membrane: primary (azurophilic), secondary (specific), and tertiary (gelatinase) granules. The proper secretion and formation of Neutrophil granule proteins are important in protecting the body against infections, inflammation, and malignancies. However, the underlying molecular mechanisms of granule formation in neutrophils are poorly understood, limiting the treatment of neutropenic disorders. The process by which granule-destined proteins are sorted and subsequently packaged into nascent secretory granules has remained a scientific enigma. Primary granules are

the first granules formed during neutrophil differentiation and contain serine proteases, neutrophil elastase (Elane), and myeloperoxidases (Mpo). Previous studies suggested that serglycin, CD63, and Rab27a are required for the trafficking and function of primary granules. Our work confirmed the increased production of serglycin during the initial stages of neutrophil differentiation, corresponding with expression of Elane, indicating that serglycin is present during primary granule formation. Furthermore, imaging of differentiating neutrophils showed increased expression and colocalization of serglycin, Elane, Cd63, and Mpo during primary granule formation. To test if serglycin is a granule-forming protein, we ectopically expressed serglycin in U2OS cells, which lack native secretory granules. Serglycin was shown to induce the expression of Elane, Rab27a, and Cd63. In contrast, ectopic expression of Elane showed no impact on the expression. Our findings support the theory that serglycin regulates primary granule biogenesis by promoting the upregulation of cargo proteins (Elane) and trafficking machinery, including CD63 and Rab27a. With this work, we have provided a first mechanistic insight into the biogenesis of primary granules, setting the base for future investigations.

Abstract Name: Identifying Sex-Related SNPs in Eusocial Synalpheus Shrimps

Eusociality is a rare phenomenon that is characterized by a queen-worker relationship in which a single queen is responsible for breeding for the entire colony, while the workers defend the juveniles and the rest of the colony from predators. Synalpheus shrimps provide a unique opportunity to study the evolution of eusociality because both eusocial and non-eusocial species coexist in the same areas, and their multiple origins of eusociality occurred more recently than many eusocial insects. While the evolution of eusociality in shrimps has been explored to some extent, the mechanisms of sex determination in eusocial Synalpheus shrimps are still unclear. This study aims to use double-digest restriction site-associated DNA sequencing (ddRADseq) to identify the presence of sex-linked single nucleotide polymorphisms (SNPs) in Synalpheus shrimps. Genomic data was obtained from 384 individuals across 33 species of Synalpheus, including eusocial and non-eusocial representatives. We used reference samples (two species with 28 females and 19 males) to obtain (1) SNPs shared by both males and females and (2) SNPs that are unique to one sex. Then we tested these SNPs in the test samples (31 species with 334 females and 3 males) 746 and 49 SNPs were identified among the female and male reference samples, respectively. Among these SNPs, 205 and 19 SNPs had a major allele frequency close to 1 in the reference and the test samples for females and males, respectively. Furthermore, > 10,000 sex-specific SNPs were found in the reference samples but only a small proportion were found in the test samples (3.9% and 0.3% in females and males, respectively). These findings suggest the potential for localized genomic regions associated with sex-determination. Future work on this project would involve mapping identified SNPs back to reference genomes to identify sex-linked loci, which could provide insight into the evolutionary sex dynamics of eusociality.

Abstract Name: Connection Between Microbial Activity on Grocery Stores Shopping Cart Handles and Short-term Exposures to Ambient Temperature, Relative Humidity, Ultraviolet Radiation, and Wind Speed

Research question, purpose, and context: Shopping carts can harbor microorganisms, but limited research has been done on the microbial activity on cart handles when stored outdoors under varying conditions of ambient temperature (T), relative humidity (RH), ultraviolet radiation (UV), and wind speed (WS). We propose that certain outdoor factors, particularly UV exposure and T, may contribute to the natural decontamination of the carts if they are left outside for an adequate duration. This study aims to investigate this hypothesis. Methodology: Surface ATP levels were measured to assess microbial activity on shopping cart handles (n = 10 per test). When the luminescent enzymes are present, ATP released from microorganisms generates light. The intensity of this light was measured using a luminometer and expressed in Relative Light Units (RLUs). T, RH, WS, and UV were measured using a handheld environmental multimeter, and a handheld UV-AB light meter. Results: Preliminary results indicated the microbial loads on shopping cart handles after a 10-minute outdoor exposure to UV light, temperature, and wind speed significantly dropped ($p < 0.05$ in paired t-test). When analyzing half of the handles, the microbial loads were measured as 318.25 ± 234.74 RLU before exposure and 255.74 ± 202.75 RLU after exposure. The environmental conditions during the experiments were: UV intensity was 1.18 ± 0.95 mW/cm², temperature was $69.20 \pm 2.787^\circ\text{F}$, relative humidity was $51.33 \pm 20.40\%$, and wind speed was 2.75 ± 1.58 m/sec. The differences in microbial activity on low-UV days compared to high-UV days were noticeable. Conclusion: Based on preliminary data, we conclude that short-term outdoor exposure to ambient T, RH, WS, and natural sunlight UV can significantly reduce the microbial activity on shopping cart handles. This cost-effective decontamination method should be widely considered by business managers of grocery stores.

Abstract Name: Evaluating the Efficacy and Limitations of K-Nearest Neighbors in Imbalanced Datasets

The K-nearest neighbor (kNN) algorithm is a powerful and simple technique in machine learning. Its common purpose is to classify a query point into a class based on the classes of the K number of nearest neighbors. Due to the simplicity and effectiveness, it is used in a wide variety of applications such as data preprocessing, recommendation engines, finance, healthcare, and pattern recognition. Recommendation systems used in Netflix and Amazon, Climate forecasting, Stock price prediction, and prediction of a second heart attack are some of the real-world examples. However, it has drawbacks which makes kNN algorithm not applicable in certain scenarios. These disadvantages include large datasets which can potentially slow the system, large number of dimensions as it can increase errors and choosing the right value of K or number of nearest neighbors in order to proceed with the algorithm. As per previous knowledge, lower values of K can overfit the query points whereas higher K values can underfit the data. This research aims to display the limitations of kNN algorithm specifically with unbalanced datasets. It will examine the effect of number of neighbors or K on theoretical and experimental kNN algorithm's performance. At last, a better algorithm will be proposed to display the noise or pattern in imbalanced datasets, it will be compatible with large dimensions and is friendly with all K values.

Abstract Name: Symbology of the Feminine New World as Explored Through Art

The subject of this study is visual media emphasizing creation myths about female symbolism within the Americas, a place allegorically feminized in order to justify control and expansion by European colonists. The symbolism of a female figure has emerged out of colonized places time and time again for nation-building and mythologizing stories to justify later nation-states. As established in scholarship, the loving and forgiving woman of the New World accepts and unites this “New World” for the colonizers, but comparative studies on the topic are limited. This comparative study focuses on Pocahontas and La Malinche, and their mythologizing stories created by Europeans for colonial means. In addition, this study concerns the image of The Virgin of Guadalupe, one created through Spanish-Catholic and indigenous contact in Central America in the 1500s. The study further demonstrates key differences in the artistic representations of these three cultural symbols in the “post-colonial” world of what was once North America and Central America via a formal and symbolic study of each visual representation. Art as a visual medium, paired with cultural contexts will provide a unique dialogue in the national myth of The United States and Mexico. The importance of this study lay in the context of colonization; the US remains a colonized state, continuously reinforced by Pocahontas’s myth, whereas Mexico created a nation state out of independence from Spanish control where La Malinche is villainized, and exists alongside la Virgen de Guadalupe.

Abstract Name: Setup, Calibration and Implementation of a Pendulum Impact Machine Following ASTM Standards

This undergraduate research focuses on the setup, calibration, and implementation of a pendulum impact machine according to ASTM guidelines. Pendulum impact testing is a method used for evaluating the toughness and fracture resistance of materials which provides insights into their performance under sudden loading conditions. The project aims to ensure accurate and consistent impact test results by following the standardized procedures outlined in ASTM D256 and D6110, which specifies the requirements for Izod and Charpy impact testing. The calibration process, as detailed by ASTM, involves verifying the machine's alignment, pendulum release, and striking edge, as well as ensuring the accurate positioning of the specimen. The process also entails adjusting the pendulum's height and measuring any frictional losses that could influence the energy readings. Calibration plays a crucial role in minimizing measurement error, thereby increasing the repeatability and reproducibility of test results. Calibration results are then verified by testing a 3D printed polypropylene specimen with a known impact strength, allowing verification that the machine's energy readings align with expected values. This research contributes to understanding how careful setup and calibration of impact testing equipment can influence the reliability of material property data, helping ensure that engineering materials meet safety and performance standards in practical applications. After careful calibration is completed, the goal is to perform impact tests on 3D printed materials that have been infused with hemp fibers to assess how the addition of natural fibers affects the impact strength of the

material. The findings are intended to support future material testing initiatives by providing a framework for accurate impact testing.

Abstract Name: The Effects of Acute Psychosocial Stress on Alcohol Craving, Motivation to Consume Alcohol, and Physiological Correlates

Stress has been identified as an important risk factor for the onset and maintenance of Alcohol Use Disorder (AUD). Accordingly, the present study seeks to explore the link between stress and alcohol-related measures, specifically by analyzing how fluctuations in subjective and biological measures of stress affect craving and choice for alcohol. The present study utilizes a variation of the Trier Social Stress Test (TSST) to acutely induce stress in participants. Participants will be randomly assigned to complete either the TSST or a non-stress equivalent procedure which will serve as the control. Saliva samples will be collected in order to assess fluctuations in the stress biomarker alpha amylase in response to the TSST. Heart rate and heart rate variation will also be measured throughout the experimental session as an additional measure of the physiological stress response. Participants will be asked to fill out a series of questionnaires pertaining to perceived levels of stress, anxiety, and affect before and after completing the TSST. Upon completion of the TSST, participants will complete a series of alcohol-related questionnaires that measure: frequency of alcohol use, magnitude of alcohol craving, risk for developing AUD, anticipated effects of alcohol use, hypothetical alcohol choice behavior, occurrence of negative alcohol-related consequences, and level of engagement in non-drug related activities. We expect to see an increase in subjective and physiological markers of stress post-TSST, correlated with an increase in alcohol craving in those who are at-risk for developing AUD. The aforementioned measures will allow us to identify factors that may influence the decision to consume alcohol or engage in non-alcohol related activities. In turn, this would allow us to develop a more complete understanding of the relationship between stress and alcohol-related behaviors which may relate to the development of AUD.

Abstract Name: The Impact of Undergraduate Research Experiences on Student Communication Skills, Understanding of the Research Process, and Academic Achievement: a Cross-Disciplinary Scoping Review

Undergraduate Research Experiences (UREs) are increasingly recognized as an important component of higher education. They provide students with opportunities to apply theoretical knowledge to real-world problems, develop an array of academic and professional skills, and foster student interest in research-

oriented careers and graduate studies. Despite the recognized value of UREs, it is challenging to assess the extent of their benefits due to the diversity of research experiences and corresponding variety of assessment tools. To understand the impact of UREs across disciplines and formats, we systematically identified URE skills, outcomes, assessment tools employed, and their validation status. Systematic searches in MEDLINE, SCOPUS, and ERIC were performed and results were limited to English-language studies from Canada and the United States, published between 2019-2023. Inductive thematic analysis was conducted on the primary sources to categorize the skills and outcomes of UREs. Subgroup analysis was performed to explore themes associated with different characteristics of UREs including year of URE intervention, duration, format, discipline, and inclusion of historically underrepresented groups. Thirty-eight studies met the inclusion criteria and from these, four overarching themes for outcomes were identified—Academic Performance and Achievement, Research Achievement, Advanced Degree Enrollment, and Employment Outcomes—along with eleven subthemes. For skills, six themes were identified—Scientific Process Skills and Knowledge, Personal Gains and Development, Communication and Collaboration, Attitudes and Behaviors Towards Research, Career Preparation and Job Readiness, and Social and Cultural Competency—with twenty-five skill subthemes. The assessment methods used to evaluate skills and outcomes were separated into direct and indirect methods, each with their own advantages and disadvantages. Twenty studies used tools previously validated, fifteen used self-validation techniques, and eleven did not report validation. The identified skills and outcomes can guide creation of assessment tools and programs that capture the full range of skills developed through UREs, while ensuring accessibility and inclusivity for all students.

Abstract Name: Racial Equity Collaborative Database (RECD): Leveraging Solution-Based Resources to Advance Racial Equity and Address Systemic Racism on a Global Scale

The Racial Equity Consciousness Database (RECD) is a comprehensive platform designed to serve as a centralized repository for resources addressing systemic racism. Developed in collaboration with the United Nations Permanent Forum on People of African Descent (UNPFAD) and other partners, RECD is a database for individuals and organizations seeking racial equity solutions aligned with the United Nations Sustainable Development Goals (SDGs). Accessing resources to address systemic racism is notoriously difficult due to their fragmentation across multiple platforms, disciplines, and formats, which hinders collaboration and progress. A centralized database like RECD eliminates this challenge by unifying these resources into a single, easily accessible hub, enabling users to efficiently find the tools and information needed to drive meaningful action toward racial equity. In building this global database, we used a structured survey as a primary method of collecting and organizing research data from our student team. The team actively sought

out siloed data from professionals across various disciplines within the Pittsburgh region with the purpose of centralizing information for greater use. As such, we started within the University of Pittsburgh and created a novel pathway for students and universities to leverage RECD and our structured research methodology as the initial steps of an intervention mapping process in addressing racial issues. By organizing these resources under the SDGs, RECD bridges gaps in accessibility, provides actionable insights to tackle racial disparities across various sectors, and empowers users to engage with research, initiatives, and innovative solutions that promote equity and sustainability. Through our presentation at NCUR 2025, we aim to showcase the impact of RECD as a transformative tool for advancing racial equity, fostering collaboration, and driving meaningful social change.

Abstract Name: Real-time Seizure Detection from Intraoperative Files Using a Variational Autoencoder, Transformer, and Multi-Layer Perception

In neurosurgery, seizure detection is essential to patient safety during open brain surgery. The current standard of care relies upon continuous interpretations of EEG monitoring by clinical staff, a process made difficult due to the multiplicity of information that must be understood in real time. This study investigates the capability of machine-learning algorithms to evaluate intraoperative neuromonitoring data for real-time seizure detection to increase detection accuracy and reduce human error. This study uses a machine-learning technique using a variational autoencoder (VAE), transformer, and multi-layer perceptron (MLP) to interpret neurophysiological data from intraoperative monitoring files. The simultaneous recording of electrical activity across multiple electrodes placed on the scalp is known as “multi-lead data,” which provides complex data about brain activity. The VAE is utilized to extract latent representations of this data, identifying underlying signals in neurophysiological data. The transformer enables sequence analysis, revealing temporal relationships that are essential for the early diagnosis of seizures. The MLP then categorizes seizure-like activity based on these processed features. By automating the examination of multi-lead data, this integrated pipeline helps the surgical team receive real-time alerts while overcoming the problem of subjective detection delays. We anticipate an AI-powered seizure detection system leveraging a VAE, transformer, and MLP will perform better than traditional EEG interpretation techniques performed by clinical staff regarding detection speed and accuracy. Even with the variability of multi-lead data, preliminary research indicates improved sensitivity and specificity. This approach minimizes subjective interpretation and provides rapid alerts during critical events. Integrating AI into real-time seizure detection has great potential to enhance patient safety during surgical procedures by improving reaction times through better seizure detection. This technology will increase intraoperative safety by extending the window of action when a seizure is about to occur.

Abstract Name: Exploring the Perceived Impact of Farmers' Markets on Food Access: Insights from the Twin Cities Metro Area

Within the Twin Cities metro area in Minnesota, an estimated 12.5% of residents are food insecure, although some census tracts report food insecurity as high as 24%. Oftentimes these tracts are classified as food deserts, where significant portions of residents are low-income and are located more than ½ a mile from a supermarket. These factors impede access to affordable, healthy, and adequate food. We expanded on the literature around the Twin Cities' food environment. Our project assessed how shopping at farmers' markets may improve perceived food access. We investigated how perceived food access differs based on whether an individual is food insecure and/or utilizing food assistance programs including Supplemental Nutrition Assistance Program (SNAP), Electronic Benefits Transfer (EBT), Farmers' Market Nutrition Program (FMNP) and a "Market Bucks" program at farmers' markets that matches up to \$10 of SNAP-EBT spending. We developed a survey with questions about demographics, accessibility of the farmers' markets, food insecurity, use of food assistance programs, and perceptions of food access, and administered it at 17 farmers' markets across the Twin Cities metro area during June and July of 2024. Of the 239 respondents, 46 (19%) used food assistance programs at the farmers' market, 57 (24%) met the criteria for food insecurity, and 24 (10%) were food insecure and utilizing a food assistance program. Use of food assistance programs and food insecurity were each associated with statistically significant increases in agreement that farmers' markets increased respondents' food access in general and their consumption of healthy foods ($p < 0.05$). The data suggests those who use benefits felt they were able to access a greater variety of local nutritious foods and these markets and their use of food benefits increased the quantity of food food-insecure attendees were able to purchase.

Abstract Name: Optimization of Reaction Conditions for Green Synthesized ZnO Nanoparticles Using Microwave-Assisted Heating: Effects of Different Heating Times

Nanoparticles synthesized through green methods have garnered significant attention for their eco-friendly approach and potential applications in environmental remediation. Zinc oxide (ZnO) nanoparticles are known for their photocatalytic properties, making them suitable for the degradation of organic pollutants. The use of natural reducing agents like red mangrove (*Rhizophora mangle*) extracts offers a sustainable alternative for producing ZnO nanoparticles via microwave-assisted methods. Traditional methods of synthesizing photocatalytic nanoparticles often involve harmful chemicals, raising concerns about environmental impact. Optimizing green synthesis methods, such as using plant extracts and microwave-assisted processes, is critical for improving nanoparticle yield, reducing particle size, and ensuring scalability for environmental applications. Understanding the relationship between synthesis parameters and nanoparticle efficiency in degrading pollutants remains a key challenge. This study focuses on optimizing the reaction conditions for

the green synthesis of zinc oxide (ZnO) nanoparticles using microwave-assisted heating. Red mangrove leaf extract was employed as a sustainable reducing agent. A CEM 2.0 Discover microwave was used at a fixed power of 250 W, with heating times ranging from 5 to 25 minutes to evaluate their effects on nanoparticle yield and morphology. Characterization of the synthesized ZnO nanoparticles is being conducted to assess their structural, optical, and thermal properties, including efforts to optimize the synthesis process further. This research aims to investigate how microwave heating times influence nanoparticle formation, with a focus on reducing particle size and enhancing the yield of ZnO nanoparticles. The findings will provide insights into the potential of microwave-assisted green synthesis to improve the efficiency and scalability of ZnO nanoparticle production for environmental applications, particularly in the degradation of organic pollutants.

Abstract Name: Understanding Misinformation Susceptibility in Relation to Social Media Use and Media Literacy

As misinformation proliferation continues within social media environments, understanding how individuals engage with erroneous information has become an increasingly important area of focus in psychology and social sciences. However, media literacy may also influence susceptibility to misinformation. The purpose of this study aims to understand how social media use relates to misinformation susceptibility depending on an individual's media literacy level. This study mainly hypothesizes that greater social media use will be more strongly associated with susceptibility to misinformation when media literacy is low, while the relationship will be weaker among individuals with high media literacy. Up to 200 adult college students will be recruited to complete an online Qualtrics survey. Participants will provide consent and answer demographic questions before the assessment starts. Next, participants will begin the assessment by selecting social media platforms that are applicable to them and report their weekly average social media use. Then, complete a 26-item media literacy scale (covering need for cognition, locus of control over media, and knowledge of media structures), and finish with a 20-item Misinformation Susceptibility Test analyzing true or false news headlines. Data collection will occur from December 2024 to March 2025. Data will be exported from Qualtrics and analyzed using SPSS through a multiple regression model to assess the relationship between social media use and misinformation susceptibility based on media literacy levels. This study aims to understand the relationship between social media use and misinformation susceptibility depending on media literacy. This particular relationship has not yet been observed empirically. The results of this study will contribute to a further understanding of how misinformation and social media use are related to one another. Not only that, but this study would also make use of a fairly novel instrument that measures susceptibility to misinformation, which could further validate its use.

Abstract Name: Positive outcomes of $\alpha 7$ nicotinic acetylcholine receptor modulation and environmental enrichment on sustained attention and cholinergic neurotransmission after controlled cortical impact injury

Traumatic brain injury (TBI) is a leading cause of cognitive disability. Enhancing acetylcholine (ACh) transmission may ameliorate post-injury cognitive deficits, especially when combined with noninvasive rehabilitation. We predicted that NS-1738, an $\alpha 7$ nicotinic ACh receptor ($\alpha 7$ -NACHR) positive allosteric modulator (PAM), will improve sustained attention post-TBI, alone and with environmental enrichment (EE) housing, and improve brain markers of cholinergic transmission post-TBI in male and female adult rats. Blocking $\alpha 7$ -NACHRs with methylycaconitine (MLA) will attenuate the effects of NS-1738, confirming its mechanism of action. Additionally, we compared effects of 4BP-TQS, an $\alpha 7$ -NACHR allosteric agonist (ago-PAM), on attention post-injury. Rats trained in the 3-choice serial reaction time task (3-CSRT) prior to right parietal controlled cortical impact (CCI) or sham injury. Rats were randomized to NS-1738 (5 mg/kg, i.p.) or vehicle (saline), as well as daily EE (6h) or standard housing starting post-injury day (PID) 1. Male subgroups also received daily $\alpha 7$ -NACHRs blockade via MLA (3 mg/kg) injections. 3-CSRT retrials occurred on PID 14-24, when 4BP-TQS (1 mg/kg) was administered daily in one male cohort. Choline acetyltransferase (ChAT) immunostaining was performed in the basal forebrain. Statistical analysis utilized ANOVAs with repeated measures and Newman-Keuls post hoc tests. TBI rats of both sexes exhibited impaired sustained attention and increased distractibility versus shams ($p < 0.05$), with chronic NS-1738 improving accuracy in females and omissions in both sexes ($p < 0.05$). Daily EE was beneficial on 3-CSRT measures in male rats ($p < 0.05$), while NS-1738+EE rendered an additive effect on lowering omissions and reducing cortical cavitation ($p < 0.05$). All TBI rats reflected ChAT disruptions in the basal forebrain, improved by chronic NS-1738+EE housing in male rats ($p < 0.05$). Chronic 4BP-TQS was promising at restoring accuracy and premature responding. Our findings support benefits of $\alpha 7$ -NACHR PAM and ago-PAM compounds and/or EE treatment after TBI.

Abstract Name: The Impact of Oral Histories on Long-Term Care Staff's Perceptions of Patient-Centered Care

Background: The growing aging population, nursing shortage, and current landscape of understaffed long-term care (LTC) facilities collectively threaten quality patient care. Patient-centered care (PCC) is known to improve patient and staff outcomes by approaching care holistically through shared active patient/staff engagement in patient care and decision-making. When LTC staff engage with residents through stimulating and positive interactions, residents' mental and physical quality of life increase. Benefits to staff include increased job satisfaction and improved work performance through meaningful engagement and learning more about the residents' preferences. The literature describes the impact of conducting oral histories on LTC as a strategy to promote PCC with a focus on patient outcomes. However, there is a gap regarding the impact

of oral histories on PCC from the staff's perspective. A nursing student created a LTC initiative in which the findings of LTC residents' oral histories were summarized in posters and shadow boxes placed in the patient's rooms to promote patient/staff engagement. Purpose: to explore the perceptions and experiences of LTC staff regarding the impact of a LTC oral history initiative on PCC. Methodology: phenomenological qualitative methodology, utilizing thematic analysis of transcripts from semi-structured interviews conducted with LTC staff. Interview questions were created using the PeoPLe framework to address all six aspects of PCC. Results: Pending. Study has obtained IRB approval. Data collection is on track for completion in December 2024; thematic analysis will be completed January 2025. Expected Conclusion/Clinical Implications: Preliminary findings indicate oral histories show promise as an effective strategy to promote PCC in LTC, with meaningful mutually beneficial outcomes for patients, staff, and LTC facilities. Findings will be disseminated to the LTC facility and corporate stakeholders and disseminated in a peer-reviewed journal.

Abstract Name: Empowering Undergraduate Research: A Mentor's Guide to Practical Application and Success

Empowering Undergraduate Research: A Mentor's Guide to Practical Application and Success For over thirty years, my pedagogical philosophy has been deeply intertwined with the practical application of academic research. A central tenet of my teaching strategy is not only to equip students with foundational research concepts and practices but also to inspire them to translate these elements into actionable projects. This approach requires students to design a research study, collect and analyze data using SPSS, and disseminate their findings in public forums. Annually, I select 3-5 exemplary students to present their research at national or regional conferences. A notable instance from my recent intercultural communication class highlights this process. Several students excelled in their research designs and arguments, prompting me to recommend their work for our university's Diversity, Equity, and Inclusion Retreat. These three students adapted their class paper into a compelling presentation that resonated well with the audience, illustrating the dynamic and persuasive potential of well-guided undergraduate research. This engagement led to the university endorsing their participation in the Council on Undergraduate Research's Advocacy Program: Scholars Transforming Through Research (STR). Such opportunities exemplify the numerous instances throughout my career where student-initiated research projects have transitioned into significant learning and professional development experiences. Through my presentation, I aim to reflect on these experiences and distill essential principles that can enhance undergraduate research initiatives. By fostering an environment where research is seen not only as accessible but also as an enjoyable and beneficial pursuit, we can significantly influence students' academic and career trajectories. This session will explore strategies to cultivate a vibrant research culture that empowers students to thrive and succeed in their higher education journeys and beyond.

Abstract Name: Exploring and Mitigating Implicit Bias in Large Language Models: A Cross-Domain Evaluation Framework

Implicit bias in Large Language Models (LLMs) remains a significant challenge, particularly in high-stakes applications like healthcare, education, and hiring. Despite advancements in reducing explicit biases, subtle and unintentional biases rooted in societal stereotypes persist, influencing LLM-generated outputs even when demographic attributes such as race, gender, or age are not directly referenced. These biases can result in discriminatory outcomes, with potentially harmful consequences if left unaddressed. A comprehensive framework for evaluating and mitigating these biases is essential to ensure that LLMs produce equitable and contextually sensitive responses. The evaluation framework developed here assesses the influence of language associations and contextual cues on model outputs, focusing on how certain words and phrases can trigger biased responses. By comparing prompts with varying levels of context, from context-neutral to context-rich, the impact of prompt design on bias manifestation is examined. The framework further explores different mitigation strategies to determine their effectiveness across diverse domains and tasks, ensuring that solutions are adaptable without compromising the accuracy or fluency of generated text. Ethical concerns surrounding fairness, cultural sensitivity, and the potential reinforcement of harmful stereotypes are also addressed. Findings highlight the necessity of scrutinizing model outputs for implicit bias, especially in decision-making applications where fairness is critical. The proposed framework offers a scalable approach to identifying and mitigating bias in LLMs, with broader implications for improving AI systems' fairness and inclusivity in real-world applications. The insights gained aim to inform best practices in AI development, ensuring that LLMs contribute to more equitable outcomes and reduce the risk of perpetuating societal biases.

Abstract Name: Classification of Bilingualism and Performance on Cognitive Control Tasks

The bilingual advantage hypothesis claims that bilinguals' management of multiple linguistic systems provides additional cognitive flexibility relative to monolinguals. However, what is considered bilingual has varied markedly across studies, limiting the generalizability of results. There are two common approaches to grouping participants: categorical and continuous. With categorical grouping, participants are divided into groups (e.g., bilinguals, monolinguals) based on predetermined criterion. With continuous grouping, bilingualism is a continuous metric ranging along a spectrum. This study aims to close this gap by investigating how experimenter's choice of participant grouping influences the results of cognitive control tasks in a linguistically diverse group. Participants (N=54) completed a language history questionnaire (LHQ-3) asking about language usage patterns, family language backgrounds, and self-ratings of proficiency. The participants performed two tasks measuring cognitive control: the AX-CPT and the n-back task with lures. We used an aggregate L2-to-L1 dominance ratio score from participants' response data to either create a continuous index of bilingualism (continuous approach) or to split participants into monolingual and bilingual groups (categorical approach). For the continuous classification, individuals with no L2-to-L1 dominance scores were assigned a value of zero. For categorical classification, those with L2 experience, and thus L2-to-L1 dominance scores, were classed as bilingual (n=30) while other participants were classed as monolingual (n=24). We conducted a linear regression analysis on cognitive control measures from behavioral tasks to explore the influence of language experience on cognitive performance. No significant difference between bilinguals and monolinguals in cognitive control under categorical classification was found. Likewise, there was no significant relationship between cognitive control and the continuous language experience metric. While we note that the absence of a significant difference is not evidence of a significant absence, we believe

that these results call for more systematic standards of practice for investigation of the cognitive consequences of bilingualism.

Abstract Name: Cathodic Contact Glow Discharge Electrolysis: Characterization and Exploration of Applications for PFOA Degradation

Plasma technology has increased in popularity in recent decades due to its unique ability to produce chemically diverse species within a solution. Despite its increasing popularity, plasma is a niche area of research with wide knowledge gaps. The characteristics of different plasma types are broadly theorized but haven't been prominently studied. To bridge large deficits in knowledge surrounding plasma technology, this project focuses on characterizing the first-ever cathodic contact glow discharge electrolysis (CGDE) plasma jet to be built and operated in the United States. CGDE is a special type of plasma that's generated within the solution directly instead of being introduced to the sample afterward. This technology is spurred by the breakdown of normal electrolysis, causing deviations from Faraday and Ohm's laws to synthesize excess yields of valuable gases such as hydrogen and oxygen. To properly characterize the plasma, trials implementing different conductive salts were analyzed to identify the lowest breakdown voltage, indicating the generation of plasma at energy-efficient costs. Results indicated that 0.006M potassium sulfate, increasing the conductivity of the solution to 3000-3500uS, coupled with a small cylindrical cell (~35mm in diameter), produces plasma the quickest with minimal energy input. Once characterized, CGDE was used to degrade PFOA, an emerging carcinogenic water contaminant. In degradation trials using the standard conditions determined above, PFOA was treated in 25 mL, 20uM aliquots from zero to fifteen minutes. A Liquid Chromatography Mass Spectrometer was utilized to quantify PFOA degradation for each trial. Fifteen minutes of plasma exposure degraded PFOA by 75%. Preliminarily, 82% to 88% of PFOA is degraded when other reagents are implemented into the solution. Results highlight enhanced PFOA degradation compared to the current literature. This project has many probative avenues with the potential to further combat water contamination and create interdisciplinary solutions to previously unsolvable issues.

Abstract Name: The Impact of Jazz Education on Students' Musicianship: A Survey Study

It is undeniable the impact jazz has on culture both in the United States and around the world. However, there exists a need for further research on the importance of jazz education. By understanding the impact participating in jazz ensembles has on our collegiate and K-12 students, teachers can better prepare their music students for life beyond their classroom. Research regarding jazz pedagogy has informed us that jazz can benefit students' development of artistic identities (Robertson, 2023) and can help students' improvisation skills (Perlmutter, 2010). Further research is needed on how students' fundamental musicianship skills can

improve through participating in jazz band. The purpose of this study is to investigate the importance of participating in a jazz ensemble and to track the growth students have made by participating in such ensembles. A survey was created using the Qualtrics electronic program and was distributed via the ILMEA membership list, social media, and to colleagues. The survey was designed with branches so that each student received personalized questions based on their current level of schooling. The branch designed for teachers included questions they answered about their students. Current K-12 students, high school graduates, current college students, college graduates, and current K-12 teachers were invited to respond. The data will be used to analyze how participating in a jazz ensemble has affected students' rhythm counting skills, knowledge of scales and chords, playing technique, ability to improvise, confidence and ability to play their instrument in front of an audience, overall musicianship, and knowledge of the history and origins of jazz. Identifying the impact that playing in a jazz ensemble has on K-12 students will add to the body of research informing us of the effects that jazz education can have on students.

Abstract Name: Selfish Transmission of the Homogeneously Staining Region in Mice

Most animals have pairs of chromosomes harboring genes, one chromosome inherited from the female and the other from the male. Gene inheritance is largely considered random, consistent with Mendel's Law of Independent Assortment. However, some genes/chromosomes are "selfish," and their inheritance frequency is greater than 50%. Selfish gene inheritance can happen on the female's side, during oogenesis, or on the male's side, during spermatogenesis. One gene believed to be "selfish" during oogenesis is HSR, the homogeneously staining region, which maps to the first chromosome in house mice (*Mus musculus*). I will determine if the HSR chromosomal region is selfish and how it promotes its own inheritance. I will use heterozygous female mice for an HSR deletion (deletion/wild-type) and determine the frequency of inheritance of the deletion versus the wild-type chromosome by genotyping offspring. To determine the genotype of each offspring, I will use PCR (polymerase chain reaction) to detect chromosomes carrying the HSR deletion versus wild-type chromosomes. The PCR amplified DNA will be resolved via gel electrophoresis to detect PCR product presence or absence and product sizes. The study will determine if HSR is "selfish" by observing the frequency of inheritance of the HSR deletion.

Abstract Name: A Cross-Sectional Analysis of Financial Stress and Smoking Behavior: The Influence of Housing Costs, Mental Health, and Sociodemographic Factors Among US Adults.

The primary aim of the study was to assess the association between financial stress, specifically stress about paying rent, mortgage, or utility bills, and smoking tobacco, while accounting for mental health and sociodemographic variables. While there has been much study of the correlation between financial stress and smoking or smoking and mental health, a gap remains in the literature regarding the combined intersectional effect these variables have upon one another. This study utilized data from the 2023 National Health Interview Survey (NHIS). The weighted sample included 76,423,291 participants, and the data analyzed included sociodemographic variables such as age, race, ethnicity, marital status, educational level, financial stress, smoking behavior (every day or some days), and mental health as measured by the PHQ-2 and GAD-2. Findings indicate significant associations between financial stress, mental health, and smoking behavior. Participants experiencing financial stress had 53% higher odds of smoking (OR = 1.53, $p < 0.001$) compared to those without financial stress. Additionally, anxiety (OR = 1.38, $p < 0.01$) and depression (OR = 1.23, $p < 0.05$) were significantly associated with smoking behavior. Race, education level, and marital status also demonstrated intersecting influences on the likelihood of smoking. Non-Hispanic Black participants were more likely to smoke than Non-Hispanic White participants (OR = 1.40, $p < 0.05$), while higher educational attainment and being married were inversely associated with smoking. Interaction analyses revealed that Non-Hispanic Black participants with depression had lower odds of smoking than Non-Hispanic White participants (OR = 0.46, $p < 0.01$). These findings highlight the importance of considering intersectional factors, such as race and mental health, when designing smoking cessation programs, as well as addressing mental health alongside smoking cessation.

Abstract Name: Creating a Heparin-Binding, Hyper-Stable FGF1: Effects of a Targeted Two Mutation on the N-Terminus of a Hyper-Stable FGF1

Approximately 4% of Americans experience poor-healing foot ulcers due to diabetes, often leading to severe complications and amputations and costing millions in healthcare resources for intensive wound care. Fibroblast Growth Factors (FGFs), cell-signaling proteins critical for cell proliferation, metabolism, differentiation, and tissue repair, are key drivers of wound-healing processes. Recently, researchers have developed a hyper-stable FGF1 (hsFGF1) mutant that retains its diverse bioactivity while increasing its stability in isolation, eliminating repulsive electrostatic forces by mutating the amino acid sequence in the protein's C-terminus. While hsFGF1 represents a significant advancement in the protein's stability, no current modifications in literature exhibit complete loss of heparin-binding affinity. This leaves room for increasing the efficacy of wound-healing applications, completely eliminating anticoagulatory activity due to heparin's inhibition of thrombin, a biological coagulant. This project aims to investigate the heparin-binding functionality of the hyper-stable FGF1 by introducing two amino acid mutations in the N-terminus of hsFGF1. Prior research found five amino acids on the N-Terminal of FGF10, which has the highest heparin-binding affinity out of all of the FGF protein family, that are also found on FGF1 near its heparin-binding site. This project focuses on incorporating two of these five amino acids of FGF10 on hsFGF1 to investigate their effect on heparin-binding affinity. Investigation of this two-mutation recombinant hsFGF1 involves overexpression and purification techniques. The protein's structure and stability will be characterized using circular dichroism spectroscopy, fluorescence spectroscopy, and thermal assays. Biological activity will be compared to original hsFGF1 and wild-type FGF1 through isothermal titration calorimetry and bioactivity assays. After initial testing and analysis, it is anticipated that the two-mutation recombinant hsFGF1 will exhibit enhanced heparin-binding functionality and comparable biological activity to wild-type FGF1, while

retaining the stability of the hyper-stable FGF1. Implications include improved understanding on the development of optimal wound-healing treatments through chemically-engineered solutions.

Abstract Name: New Measurements for WDS 11329-4342 HJ 4448AB

The purpose of the project was to conduct astronomical research of double star (binary) systems. The research was conducted by student led teams using a network of small telescopes remotely controlled with locations all over the world. The goal was to provide insight into how scientific research may be completed and published in a timely manner within a community of practice that includes students, educators, and both amateur and professional astronomers. The research began with an overview of the essential astronomy relationships necessary to analyze and understand the binary star data. We then selected a suitable double star system from an existing database using specific criteria we learned at the beginning of the course. We utilized remote small telescopes stationed worldwide to capture images. We then analyzed these images, measuring angular distances and angles between stars. By comparing our findings with historical observations, sometimes spanning a century or more, we contributed a new data point to their orbital plots. This collaborative effort was finally synthesized into a research report using a simple yet professionally correct structure suitable for publication in a scientific journal. This seminar had a great deal of educational value: It enriched our understanding of fundamental astrophysical concepts; it fostered critical thinking skills; and, it will no doubt inspire future generations of astrophysicists. Specific to our research, we were hoping to find evidence that the double star system we selected was a true binary. Its nature was listed as "uncertain," so we assumed that more data was needed to make this determination. Unfortunately, the additional data we collected was inconclusive. But the true goal of the research seminar was achieved in October of 2024 when our report titled "New Measurements for WDS 11329-4342 HJ 4448AB," was published in the Journal of Double Star Observations.

Abstract Name: Breaking the Cycle of Abuse: The Role of Supportive Emotion Socialization in the Relationship Between Childhood Abuse and Later Parenting Behaviors

In 2022, there were 558,899 incidents and 1,990 deaths from child abuse/neglect. Childhood physical abuse survivors have the greatest risk of perpetuating child abuse through abusive/neglectful parenting, and childhood emotional abuse predicts unsupportive parenting behaviors. Both forms of abuse are associated

with poor emotion regulation, a key risk factor for abusive behaviors. Supportive emotion socialization promotes emotion regulation, especially for negative emotions, yet few studies have investigated its role in the relationship between childhood abuse and parenting behaviors. This study investigated whether supportive emotion socialization moderated the relationship between childhood emotional and physical abuse and adults' parenting behaviors towards their offspring. The sample included participants from Waves 4 and 5 of the Healthy Passages Study, conducted in Birmingham, Alabama. Wave 4 consisted of 1,273 participants (mean age = 19.7 years; 51.3% female) who reported physical and emotional childhood abuse and supportive parental emotion socialization of fear, sadness, and anger. Wave 5 included 317 participants with children (mean age = 28.7 years; 62.8% female) who reported their parenting behaviors (nurturance, inconsistent discipline, and harsh discipline). Multiple linear regressions demonstrated that supportive anger socialization moderated the effects of physical abuse ($\beta = -0.07$, $p < 0.05$) and emotional abuse ($\beta = 0.09$, $p < 0.01$) on inconsistent discipline. Simple slope analyses showed that greater physical abuse predicted more inconsistent discipline at low supportive anger socialization ($\beta = 0.26$, $p < 0.01$) but not at high supportive anger socialization ($\beta = -0.12$, $p = 0.27$). Emotional abuse predicted lower inconsistent discipline at low supportive anger socialization ($\beta = -0.22$, $p < 0.05$) and high inconsistent discipline at high supportive anger socialization ($\beta = 0.24$, $p < 0.05$). These results suggest that supportive anger socialization may lessen the negative impact of childhood physical abuse on later parenting but aggravate the effects of emotional abuse.

Abstract Name: Understanding Decision-making: Can Individual Differences Predict Dominant Decision-making Styles?

One question that remains ambiguous in decision-making research is whether it is possible to predict decision making styles. Previous research suggests that one element of that prediction may involve individual differences to measure an individual's tendency toward certain decision-making styles. This study explores whether it is possible to predict dominant decision-making styles based on the following individual differences: risk attitudes, personality traits, and cognitive styles. Also, this study investigates which variables may be stronger predictors for decision-making styles in an attempt to work toward an accurate and reliable model for predicting dominant decision-making styles. Data was collected via an online self-report survey and then analyzed using multiple regression statistical analysis. This study hypothesizes a correlation between the predictor variables of risk attitude, cognitive style, and personality traits and the dependent variable of decision-making style. Risk attitude is expected to be one of the strongest predictor variables due to the well-established connection between risk and the decision-making process. Results are expected to suggest that individuals with attitudes oriented more towards risk aversion are more likely to demonstrate either dependent or avoidant decision-making styles. The personality traits and cognitive differences predictors are expected to be statistically significant, but they are expected to be weaker predictors for decision-making style than risk attitude. The demographic factors are not expected to be correlated with decision-making style and are not expected to have a significant impact on the overall regression model. The results of this study may add to the psychological understanding of how individuals tend to make decisions and whether it is possible to predict those tendencies based on individual differences. If psychologists can make these predictions, they may be able to better understand the overall decision-making process as it relates to specific individuals and also why people make decisions in drastically different ways.

Abstract Name: Ideology and Social Classes in Francophone Theater

Shakespeare's Hamlet famously claimed that theater holds a mirror up to nature and in the 20th century Sartre called for an "engaged" theater that transforms its society. Does theater reflect pre-existing societal realities, or does it aim to profoundly reshape its society through its influence? This project explores the interactions between theater and society at large by showcasing the representation of social classes in francophone theater. Through an analysis of three works across francophone theater, this paper argues that playwrights consistently use theater to advocate and promulgate their own worldviews, with an emphasis on how they portray social class and defend their class interests. This paper examines *Le Jeu de l'amour et du hasard* (1730) by Marivaux, *Le Mariage de Figaro* (1778) by Beaumarchais, and *Les Belles-sœurs* (1965) by Michel Tremblay and analyses how they portray social classes and the ideological intent behind these portrayals. *Le Jeu de l'amour et du hasard* defends the place of the aristocracy in the Ancien Régime while also arguing for certain advancements within that class. *Le Mariage de Figaro* critiques the moral corruption of the aristocratic class and defends the ascendant bourgeoisie against both the aristocrats and the tiers état. *Les Belles-sœurs*'s portrayal of working-class women in Quebec during the Quiet Revolution shows the economic and moral disillusionment experienced by Québécois workers, and how it interacts with concurrent societal evolutions. All three plays demonstrate the fact that theater not only reflects but also, sometimes very directly, shapes the societal debates of their time. By engaging with the sociocultural issues of their day, each playwright affirms their own perspective and often attempts to influence their audience's values and perceptions through this engagement.

Abstract Name: From Isolation to Integration: Cross-Cultural Adaptation of International Students in a Northwestern Liberal Arts Setting

Here's a revised version of your abstract, condensed to 300 words while preserving the key elements: This study explores the cross-cultural adaptation experiences of international undergraduate students at a small liberal arts college in the northwestern USA. As globalization increases international student enrollment worldwide, understanding their unique challenges becomes crucial. The research aims to identify factors influencing adaptation and contribute qualitative data to inform institutional support mechanisms. Building on existing research, including Luo and Zhang's (2021) predictors of cross-cultural adaptation, Zhang and Li's (2022) exploration of initial transition effects, and Schwartz et al.'s (2010) call for expanded acculturation

operationalization, this study employs semi-structured interviews with 17 randomly selected international students. The research question guiding the study is: How do international students perceive their cross-cultural adaptation experiences? Grounded theory analysis of the interviews revealed a range of perceptions categorized as positive, negative, and mixed experiences. Positive aspects included participation in campus activities and personal resilience development. Negative perceptions highlighted the need for better support systems to address isolation and homesickness. Mixed experiences indicated that cultural adaptation is a complex, individualized process influenced by various factors. The findings underscore the importance of tailored institutional support to meet diverse student needs. Practical implications for small liberal arts colleges include implementing targeted support mechanisms such as orientation programs, mentoring, and increased opportunities for social integration. This study contributes to the broader understanding of international student experiences, offering valuable insights for educators and administrators. By providing a supportive and inclusive environment, colleges can help international students navigate cross-cultural adaptation more effectively, leading to a more positive and enriching educational experience. The research emphasizes the need for an expanded and nuanced approach to acculturation and cross-cultural adaptation within the context of higher education.

Abstract Name: "Stay Sexy and Don't Get Murdered": A Rhetorical Analysis of the True Crime Podcast My Favorite Murder

As the true crime genre grows in popularity, questions arise about how difficult cases are presented. The literature on true crime addresses concerns of insensitivity and commercialization of the genre. While the literature addresses problems of docuseries such as Netflix's *Monster: The Jeffrey Dahmer Story*, it does not consider the same concerns with true crime podcasts, including *My Favorite Murder*. There has also yet to be research that analyzes specific true crime podcast episodes. Adding to the conversation on the moral ambiguities of the genre, this project uses rhetorical analysis to analyze the Jon Benet Ramsey episode of *My Favorite Murder* titled "A Small Foreign Faction." The analysis of this episode reveals the two hosts purposefully use a lighthearted tone and gossip-like conversation to disconnect the audience from the severity of the crime that has been committed. The analysis also examines how the tone and language of the episode push ethical boundaries in hopes to draw in listeners. In addition to filling the gap in the literature, this project argues additional research should be completed over other true crime podcasts that further demonstrates the genre using sensitive stories for their own purposes.

Abstract Name: Quantitative Analysis of Epigenetic Influences by Gut Microbiota-Derived Short Chain Fatty Acids on RPI-1 Gene Expression in *C. elegans*: A Novel Investigation into Dyslexia and ADHD Related Pathways

Background: Nearly one in five individuals is diagnosed with dyslexia, while ADHD affects approximately 10% of the population. Both disorders however, lack effective, side-effect-free treatments. Recent research highlights the gut-brain axis's role in neurodevelopmental disorders, with SCFAs—gut bacteria metabolites—potentially modulating gene expression. However, no studies have yet explored the impact of SCFAs on dyslexia-related genes. This study addresses this gap by exploring the effects of SCFAs on the expression of the dyslexia-related gene DCDC2 and its ortholog, RPI-1, in *C. elegans*. **Procedure:** The experiment involved preparing Nematode Growth Media (NGM) agar plates seeded with *E. coli* OP50, treated with SCFA concentrations of 10 μ L, 20 μ L, and 40 μ L, while untreated plates served as negative controls. *C. elegans* were cultured on the plates followed by RNA extraction for cDNA synthesis. Gene expression levels were quantified using qPCR analysis, with ACT-1, which served as an internal control to normalize expression levels and by accounting for variations in RNA quantity and quality. **Results:** Statistical analyses, including ANOVA ($p < 0.05$) and Tukey HSD, confirmed significant reductions in RPI-1 expression at SCFA concentrations of 20 μ L and higher. Data simulations in Python 3.12.3 validated these results, ensuring reproducibility and robustness. Notably, no significant changes were observed in the expression of ACT-1, ensuring that the effects on RPI-1 were specific to SCFA treatment and not due to procedural inconsistencies or technical errors. Shapiro-Wilk tests confirmed a normally distributed dataset, further ensuring reliability of the findings. **Conclusion:** The results demonstrate that higher SCFA concentrations significantly reduce RPI-1 expression, suggesting a potential epigenetic mechanism by which SCFAs influence dyslexia-related gene expression. These findings provide preliminary evidence for the role of diet and gut health in managing dyslexia, with implications for developing scalable, non-invasive, and personalized lifestyle-based strategies for addressing neurodevelopmental disorders. **Keywords:** Dyslexia, ADHD, SCFAs, Epigenetics, Gut-Brain Axis, *C. elegans*

Abstract Name: Cell Selection of A Fully Modified Aptamer Against Human Transferrin Receptor

aimed to address limitations in traditional chemotherapy by using fully modified RNA aptamers as targeted cancer therapeutics. The primary step is to push the selection to select for an aptamer against human transferrin receptor (TfR) that does not compete with the human transferrin receptor ligand using the GL1 library. TfR contains a positively charge portion that produces a high affinity binding site for most aptamers since aptamers are negatively charged due to the structure of their backbone. Fully modified RNA sequence consists of modifications to the 2' position of the carbon ring. Cytosines are modified by adding a Fluro, while Guanine, Adenine, and Uracil are modified by adding O-Methyl groups. Cell internalization Systematic Evolution of Ligands by EXponential Enrichment (SELEX) is used to identify high-affinity nucleic acid sequences, such as aptamers, through multiple rounds of binding, selection and amplification. Cycle-course Polymerase Chain Reaction (PCR) is performed to determine the optimal amplification round number, at which the expected DNA product is clearly visible in gel electrophoresis without the significant presence of other non-specific products at various sizes. Past experiments showed that at cycle 16 and upwards, the significant presence of a large, non-specific DNA artifact was observed. Flow binding is used to test if a significant increase of aptamers that bind the TfR in the presence of competitive and non-competitive ligands is present. Currently, cell SELEX is performed for additional rounds on Jurkat cells to amplify the desired aptamers. The next step will be conducting an additional 1 to 2 rounds of selection and testing for binding to Jurkat cells. Additional steps involves sequencing the selected aptamers to identify which ones are binding, and then to optimize them via truncation and additional chemical modifications.

Abstract Name: Interdisciplinary Renewable and Environmental Collaborative REU Program at University of North Dakota

The Interdisciplinary Renewable and Environmental Collaborative (IREC) Research Experience for Undergraduates (REU) Program at University of North Dakota has been running for a couple of cycles. This NSF-supported program is jointly hosted by the departments of chemistry, chemical engineering and atmosphere science, and provides summer research experiences for undergraduates with priority to first generation college students, underrepresented minority students, and students from tribal colleges and other primarily undergraduate institutions. We emphasize the interdisciplinary and collaborative nature of renewable and environmental research by assembling a team of faculty mentors from various disciplines and working closely with graduate students. Typical research projects include cathode materials from lignite for battery applications, synthesis of degradable polymers, catalytic hydrogenation of CO₂, chemical characterization of pollen, hydrogen production from biogas, and carbon quantum dots from lignin. The professional training is centered around science communication with three main components: an initial 3-minute elevator pitch on research goals, a mid-term oral presentation of research progress and a final poster presentation. Faculty mentors lead the training sessions and experienced graduate students provide live examples, feedbacks, and help sessions. Students can apply these skills in two outreach activities targeting K-8 kids in the community. These activities are interspersed with tours to the local research facilities such as Energy and Environmental Research Center and UND Artificial Intelligence and Virtual Reality Lab. Overall the program provides an inspiring and enjoyable summer experience and continues to empower the next generation of researchers and scientists in the field of renewable and environmental studies.

Abstract Name: Ambition, Motivation, and Achievement among first generation college students in urban settings: An Analysis of the Factors that Contribute to Subjective Success

Within a city, how does the background of being a first generation student inform one's ambition and attitude towards college, desired income, and potential career? This paper aims to assess and explore how much of ambition is intrinsic, taught, and how much can be attributed to the individual. The currently existing research offers little consideration to an approach analyzing the perspectives of individuals themselves regarding higher education. Another previously lacking aspect is the application of an academic motivation scale to this specific group of students. This factor within the data sets of similar experiments prior presented a gap in the literature the study aimed to fill. In social psychology, the widely discussed topic of motivation has not yet focused on this group of underrepresented people. This research used the pre-existing AMS-C 28 validated scale that measured internal and external motivations in academia. It was a cross sectional design, controlling for 42 participant survey responses from demographic of first generation students. Responses were collected beginning on March 31st, 2024 through April 16, 2024. The results of the experiment revealed that their desires for academic achievement were often highly aligned with the utilized scale, and their motivations were indeed influenced by external factors. A potential direction for future research could be a more

expansive scale regarding how their communities and home lives impacted their perspectives on higher education and career choices in general. While the current research successfully yields responses regarding attitudes towards overall life achievement, it is evident that there is some career specific research to be conducted.

Abstract Name: Insecticide Resistance of the Mosquito, *Aedes aegypti* to Different Classes of Insecticides

Aedes aegypti is a key vector for diseases affecting millions globally. In the U.S., these mosquitoes are concentrated in southern and southwestern regions, increasing the risk of disease transmission. Mosquito management relies heavily on integrated pest management (IPM), which includes environmental, biological, and chemical control. However, the development of insecticide resistance, particularly in *Aedes aegypti*, poses significant challenges to these efforts. Insecticides such as pyrethroids and organophosphates (OPs) are commonly used for mosquito control, with pyrethroids being particularly effective. Unfortunately, resistance to these chemicals, often due to mutations in the voltage-gated sodium channel gene, has emerged. To investigate the evolution of resistance, researchers compared AeStA, a field strain, with insecticide-selected strains. Results showed that resistance to permethrin developed rapidly in *Aedes aegypti*, increasing resistance by 120-, 400-, and 650-fold after three generations. In contrast, resistance to malathion developed more slowly, with no cross-resistance observed between permethrin and malathion. Additionally, the F1534C mutation, caused by a T-to-G polymorphism in the sodium channel gene, was confirmed in resistant strains, indicating its role in pyrethroid resistance. These findings highlight the importance of alternating insecticides from different classes to delay resistance development, a strategy that can enhance the effectiveness of IPM programs for mosquito control.

Abstract Name: Eel-volution: Many Roads to a Slippery Shape

Vertebrates span a huge array of body shapes, and their degree of elongation is a major component of this diversity. Some animals are long and skinny, like snakes and eels, while others are stout or round, such as toads and pufferfish. Fishes are an excellent model system for studying this diversity because their wide-ranging body shapes can inform upon the unique adaptive advantages of differing morphologies. In this study, we examined Zoarcoidei, a suborder of fishes derived from a shared eel-shaped ancestor. While these fishes share an elongate history, the group includes several highly elongated species as well as one non-elongate species, making them an ideal model for the study of changes in morphology. We collected measurements of

anatomical features such as body length, depth, and vertebrae from x-rays of 71 zoarcoid species. Using these data, we then identified clusters of related species that have been drawn to distinct adaptive peaks. We found that extreme body elongation arose multiple times but through different sets of skeletal characteristics, such as an increased number of caudal vertebrae in the wolf eel versus increased numbers of vertebrae in both caudal and precaudal regions in the quillfish. These alternative shifts may indicate different adaptations for swimming efficiency in the challenging habitats that these species often inhabit. Interestingly, we also found evidence of adaptive peak shifts in skeletal form that were not associated with an overall shift in body shape; in these cases, subtle changes in the skeleton allow for adaptation to different environmental demands while retaining a similar moderately elongated body shape. These findings support the hypothesis that varying selective pressures—arising from different habitats, feeding strategies, and behaviors—drive not only body shape diversity but an even greater variety of underlying skeletal forms across fishes.

Abstract Name: Estuarine Eutrophication Risk and Urbanization

Anthropogenic eutrophication is a process by which the overapplication of nutrients by humans in a waterbody leads to algal blooms, hypoxia or anoxia, and the accompanying damage to living populations, water quality, and ecosystems in general. The objective of this study is to determine if there is a higher risk of eutrophication in more urbanized areas compared to less-developed locations and how eutrophication risk is affected by seasonality. We conduct monthly monitoring at three sites in Long Bay, South Carolina: the urbanized tidal creeks of White Point Swash and Singleton Swash, and the restricted-access Waties Island's estuarine Dunn Sound and open-ocean-facing beach. We collect salinity, temperature and oxygen data using a handheld meter-sensor ensemble in situ. We collect samples for the analysis of the nutrients nitrate, nitrite, phosphate, and ammonium, as well as chlorophyll by spectrophotometry and fluorometry. We evaluate eutrophication risk by comparing our data with the National Eutrophication Estuarine Assessment thresholds. We hypothesize that the urbanized locations will show higher eutrophication risk, as previous research concludes that urbanized areas tend to be exposed to more fertilizers than secluded areas. We also expect that risk will be higher in warmer months, since higher temperatures increase photosynthesis and respiration rates, leading to increased organic matter production but also oxygen depletion due to lower oxygen saturation concentrations. Our results will inform the degree to which urban development compromises coastal water quality as compared to undeveloped or protected coastal environments

Abstract Name: Developing a program to rehabilitate sex offenders

Sex offenses are among the most serious crimes in our society, causing profound harm to individuals and communities. Up to 24% of those convicted of a sex offense reoffend, according to the Center for Sex Offender Management (2007), though this figure may be an underestimate due to the underreporting of sex crimes. Individuals who commit sex offenses are often stigmatized and marginalized, yet there is limited research on effective interventions and systems to prevent these crimes and reduce recidivism. The purpose of this research is to adapt and develop a rehabilitation program specifically for individuals who have committed sex offenses. Currently, the ACTV (Achieving Change Through Values-Based Behavior) program, created by Dr. Amie Zarling, has demonstrated success in addressing intimate partner violence. This project seeks to revise and tailor the ACTV program to meet the unique needs of individuals convicted of sex offenses. To guide these revisions, I first reviewed existing rehabilitation models and programs to identify best practices and evidence-based approaches for this population. These insights will inform the development of a sex offender-specific adaptation of ACTV. The revised program will be piloted at the Civil Commitment Unit for Sexual Offenders (CCUSO) in Cherokee, Iowa, with the goal of creating a framework that can also be implemented at other treatment facilities. While sex offenses remain a societal challenge, this initiative seeks to provide a path toward rehabilitation, aiming to reduce recidivism and contribute to a safer society. By addressing this critical issue, we can support those committed to change and help prevent future harm.

Abstract Name: Agar Plate Methods for Assessing the Antibacterial Activity of *Zingiber officinale* (Ginger) and *Curcuma longa* (Turmeric) against *Bacillus cereus* and *Escherichia coli*

The proliferation and dissemination of antibiotic resistance among pathogenic microorganisms represent a critical global health concern. The excessive and inappropriate use of antibiotics has facilitated the development of resistance mechanisms, rendering many established antimicrobial agents ineffective against bacterial pathogens. Consequently, there is an urgent imperative to investigate alternative antimicrobial compounds, particularly those derived from natural sources, to effectively address the challenge of antibiotic-resistant bacteria. This study aims to assess the antimicrobial potency of *Curcuma longa* (turmeric) and *Zingiber officinale* (ginger) extracts, liquid and powder, against two prevalent bacterial pathogens, *Bacillus cereus* [BC] and *Escherichia coli* [EC] after 24 hours. The extracts, both in liquid and powdered forms, were prepared using 95% ethanol (EtOH) as the solvent, with appropriate dilution factors applied to facilitate accurate colony enumeration and ensure experimental reproducibility. Tetracycline, penicillin, and untreated control plates with [BC] and [EC] will serve as reference controls to benchmark the antimicrobial efficacy of the natural extracts.

Abstract Name: The Association between Mental Health and Self-Care Among People with Multiple Sclerosis

The intrusiveness and uncertainty related to multiple sclerosis (MS) can lead to the development of mental health symptoms. Prior research has suggested that fatigue and physical functioning were predictors of self-care among people with MS. However, less research has examined the role of psychological factors in predicting self-care behaviors in the MS population. The purpose of the study was to examine the extent to which depression and anxiety explain the variance in self-care when controlling for demographic and MS characteristics. 369 participants with MS were recruited from the National MS Society. Self-care was measured with two items of the 12-item World Health Organization Disability Assessment Schedule 2.0. Depression and anxiety were measured with the Patient Health Questionnaire-4. A three-step hierarchical regression analysis was carried out to examine the extent to which depression and anxiety explain the unique variance in self-care when demographic and MS-related covariates were controlled. Our results showed that in step 1, the amount of variance in self-care scores accounted by the demographic variables was not significant. In step 2, MS duration and subtype accounted for a significant amount of variance in self-care even after controlling for age, gender, and race. In step 3, depression and anxiety accounted for a significant amount of variance beyond that explained by the demographic variables, MS duration and subtype. The model explained 28% of the variance in self-care. Overall, our findings suggested that depression and anxiety were associated with self-care when controlling demographic and MS-related covariates. Findings provided implications for practitioners to incorporate mental health and self-care strategies that are relevant to client's needs and priorities during the rehabilitation process. When clients with MS can better manage their mental health symptoms, this can also facilitate the improvement of self-care behaviors.

Abstract Name: The Haunting of Female Gender and Sexuality in Gothic Literature

This research will analyze Gothic literature through the lens of Queer and Feminist Theory, explicitly focusing on gender performance/roles, gender identity, and homosexuality. Some of the novels analyzed will include, but are not limited to: *Dracula* by Bram Stoker, *Rebecca* by Daphne du Maurier, *Beloved* by Toni Morrison, *Mexican Gothic* by Silvia Moreno-Garcia, *Carmilla* by Sheridan Le Fanu, *Wuthering Heights* by Emily Brontë, *The Mysteries of Udolpho* by Ann Radcliffe, and *The Haunting of Hill House* by Shirley Jackson. These novels range from 1794 to 2020 and include five female authors, two authors of color, and a mix of American, English, and Irish authors. The list also consists of a blend of traditionally canonized and non-canonized Gothic texts. The selected novels embody characteristics of the Female Gothic, a subcategory of Gothic literature that predominantly focuses on female protagonists and their struggles against a patriarchal society, in addition to the haunting. As such the Female Gothic, represented by selected texts, is the perfect site to explore gender performance/roles, gender identity, and homosexuality. This analysis will focus on female gender expectations specifically, and how the selected Gothic narratives use ghosts or other sources of haunting, to challenge gender and sexual binaries. Ultimately it will be determined that the hauntings in these novels disrupt cis-heteronormativity, allowing female characters to explore homosexuality and differing gender identities and behaviors from what is typically allowed under patriarchal heterosexual cisgender conventions. While queerness has been discussed within Gothic studies, the emphasis on how the haunting generates queerness has not been fully discussed. Ultimately, it will be determined that the haunting in Gothic literature repressed heteronormative behavior while encouraging homonormative behavior.

Abstract Name: Exploring AI's Potential in Predictive Analysis for Student Essay Scoring and Real-Time Feedback

This research seeks to answer the question: To what extent can Artificial Intelligence (AI) be used for predictive analysis in student essay scoring and real-time feedback, and what are the implications for fairness, accuracy, and educational outcomes? AI has shown transformative potential in education, particularly through automated essay scoring (AES) systems and large language models (LLMs), which analyze patterns in prior essays to forecast scores and provide immediate, iterative feedback. To address this question, the study employs state-of-the-art (SOTA) models and rationale-based scoring approaches that align with human grading practices by generating rubric-based rationales. These methods are evaluated against traditional assessment systems to determine their effectiveness in assessing nuanced traits like creativity, argument coherence, and originality. The research also explores a hybrid human-AI framework to mitigate limitations such as bias, fairness, and privacy concerns. Preliminary findings indicate that while AI systems excel in evaluating surface-level features like grammar and organization, they face challenges with higher-order traits requiring subjective interpretation. The proposed hybrid approach combines AI's efficiency with human oversight, resulting in more reliable and equitable assessments. Additionally, the study highlights the critical role of diverse training datasets and advanced prompt engineering in improving model accuracy and inclusivity. This research contributes to the integration of AI in education by addressing its strengths and limitations, offering practical solutions for enhancing student outcomes, and reducing educator workloads. These findings aim to guide the development of equitable, effective AI systems for real-time essay feedback and predictive scoring.

Abstract Name: Course Based Undergraduate Research Experiences (CUREs) Strategies for Cultivating Undergraduate Research at the University of New Mexico-Valencia Campus, a rural 2-year Hispanic-serving Institution

Course-based Undergraduate Research Experiences (CUREs) can provide more students access to research, including those from rural areas, who might not typically have the chance to participate in novel research. CUREs at the University of New Mexico-Valencia Campus, a rural, Hispanic-serving 2-year institution, were developed and taught in two courses: Microbiology for Health Sciences Lab (Biol 2305) and Biotechnology I (Biol 2710). The end goal for each course was presentation of students' original research at the semester end campus-wide Research Day. Two strategies were used to cultivate vibrant research CURE experiences. In Microbiology lab CURE, students started with an overall research question, Is the overall health of an individual affected by their oral microbial diversity? Through the semester students completed a i. preparation phase to understand the background of human oral microbes, ii. a hands-on application phase in completing and analyzing experiments, and iii. presentation phase of presenting their findings to their peers and campus

community. In Biotechnology I CURE, students reached state-mandated course learning objectives focused on DNA manipulations by performing a novel research project in the field of cancer biology. They designed DNA oligos which code for shRNA (short hairpin RNA) targeting expression of TET1, a novel oncogene candidate that promotes malignancy of p53-mutated lung cancers. After synthesis, students cloned these oligos into pENTR expression vector via ligation, transformed recombinant constructs into competent bacteria, and obtained high yield of each vector via plasmid isolation. Sequencing data confirmed the correct structure of cloned constructs. These vectors will be used in functional studies on the effect of TET1 knock-down on lung cancer cell growth as a part of Biotechnology II class scheduled for the Spring of 2025. Research for both CUREs provides undergraduates with early opportunities to engage in high-quality science, enhancing their commitment to STEM and health sciences careers.

Abstract Name: I said alcohol not methanol: Italian alcohol policy and consumption habits regarding the 1986 wine methanol scandal

This project asks how Italian food and beverage policies had evolved after the 1986 methanol scandal to further protect the Italian wine consumer from wine adulteration. The 1986 methanol scandal was a case of wine adulteration in Italy where wine bottles were tainted with methanol as a means to raise the alcohol content, hospitalizing 90 people, and leading to the death of 23. Previous researchers explained the significance of wine adulteration on the wine industry in France, signifying adulteration as a worldwide problem affecting the global wine consumer. Additionally, past researchers explored German alcohol policies against wine adulteration, however, this project will investigate Italian alcohol policies in relation to the methanol scandal. I will conduct a historical case study analysis on the public opinion of Italian wine consumers in the years following the methanol scandal, as seen in Italian newspaper articles. I will then connect the public opinion with raw alcohol policy data in Italy both before and after the methanol scandal, detailing if and how the policies shifted after the methanol scandal, and the impact the policies had on the Italian wine consumer. The results will likely show a distrust between the Italian wine consumer and the Italian wine industry following the methanol scandal, leading to amendments in alcohol policies which prioritize the safety of the consumer. Understanding the results will explain how Italian consumer habits and wine culture have changed into what they are today and will also pinpoint how Italian policymakers prioritize the safety of Italian consumers.

Abstract Name: Development of excess extracellular collagen in biceps, subscapularis, and supraspinatus muscles following brachial plexus birth injury

Brachial plexus birth injury (BPBI) occurs when the nerve bundle innervating the shoulder is damaged due to excessive stretching of an infant's neck during childbirth. It occurs in about 0.9 of every 1,000 births, with 30-40% of those resulting in lifelong shoulder impairment, including musculoskeletal deformities, reduced range of motion, and muscle paralysis. These deficits vary by injury location (preganglionic vs. postganglionic), but the effect on underlying muscle composition is unknown. We hypothesize diminished muscle growth from BPBI is related to increased collagen content (fibrosis), impairing muscle function. We will examine the effects of altered passive muscle loading and active functional loading on collagen buildup between muscle fibers using four groups. Sprague Dawley rats underwent surgery on one forelimb at postnatal day 3-6: preganglionic or postganglionic neurectomy, forelimb disarticulation (n=8/group/timepoint), or sham surgery (n=6/timepoint). Contralateral limbs served as added controls. Biceps, subscapularis, and supraspinatus muscles were dissected at 2, 3, 4, 8, or 16 weeks post-injury, snap-frozen, cryosectioned longitudinally, and stained using Masson's trichrome. Muscle sections were imaged and analyzed as a ratio of collagen to muscle tissue. Fibrosis was compared across groups and timepoints using repeated measures ANOVA and Tukey's tests for multiple comparisons (GraphPad Prism 10, $\alpha=0.05$). Comparisons between injured and uninjured limbs in each group were assessed using paired t-tests. Preliminary data indicate greater fibrosis in postganglionic injuries than preganglionic. Collagen content peaked at 4 weeks in all muscles for postganglionic injured limbs and in the subscapularis and supraspinatus for disarticulation injured limbs. No significant differences have been found across timepoints in sham or preganglionic injured limbs. This is the first study characterizing fibrosis development and progression in glenohumeral muscles following BPBI. Understanding the progression of altered muscle composition throughout development following BPBI may inform treatment planning.

Abstract Name: Forced Marriage, Exhibition, and Prostitution: Uncovering the History of Trafficked Women in Lower Manhattan

This study has been conducted in the approach to and aftermath of the 2024 US Presidential election. It has formed concurrently with a political climate in which female autonomy is being relitigated. This study has also been conducted as a new slogan echoes among men – your body, my choice. By distorting the popular phrase, “my body, my choice,” that has served to empower women, this slogan suggests that a modern society is not removed from the female oppression that it posits as a feature of the distant past. This work therefore seeks to uncover the theft of women's autonomy, focusing on untold histories of early New York. It considers the evolving sociopolitical ideas on the purposes a woman's body should serve and her right to ownership of it. Since the beginning of the 21st century, attention to criminalizing human trafficking has spiked, but before progress was made, certain instances of this crime, especially involving women, have not been recognised as such. In this study, I will trace the history of women who were brought to this city in the 17th century, when the first enslaved women arrived in the Dutch colony, through the 19th century when the interest in human exhibitions reached its peak, until the early 20th century when forced prostitution became a widespread issue. Using archival research, this study asserts that unexamined forms of human trafficking, including forced marriage, exhibition, and prostitution, have compromised women's autonomy in ways not yet fully realised. This exploration ultimately seeks to discover why women could be trafficked without consequence, and how normalising female objectification in the past has informed ideas about women's bodily rights in our present.

Abstract Name: Breaking Barriers - Gender Law and Female Entrepreneurship

Our research aims to examine how laws can impact female entrepreneurship across different contexts. We use a new measurement from the World Bank's Women, Business, and the Law (WBL) index 2.0, focusing on legal systems in place to help female entrepreneurs. Specifically, we explore how gendered differences in legal access in the context of accessing credit, registering businesses, opening bank accounts, and laws relating to inheritance influence female entrepreneurship outcomes relative to males. We also want to distinguish between opportunity driven and necessity driven entrepreneurship across genders and whether differences in legal access can explain some of the gaps. The research will provide insights into how policymakers can enhance female entrepreneurship by improving legal frameworks, particularly in developing economies where women face significant financial and institutional barriers. We will also investigate potential moderating factors such as economic institutions and culture, which have been shown to affect female entrepreneurship outcomes. Empirical models like OLS, fixed effect, marginal effect plots, and matching models will be used to test our analysis. We will also present ideas for future related research, as the WBL index is fairly new and thus understudied. The contribution of our work is twofold: 1) we will examine the effectiveness of legal/policy frameworks as they relate to female entrepreneurship, and 2) we will examine how these systems interact with formal economic institutions and informal institutions such as culture. The latter will help to understand what frameworks must be in place for a nation to foster successful female entrepreneurs and promote an equitable entrepreneurial landscape.

Abstract Name: Voice of a Nation: Interviews of Nationalistic Terms in Japan

Nationalism in East Asia has been a recurring theme in Western research, particularly concerning Japan. This proposed study will conduct interviews with Japanese citizens to explore individual perceptions of nationalism and connect Japanese nationalism to the extant literature on the deconstruction of East Asian identity. While previous studies have deconstructed East Asian national identity and its connection to nationalism, much of the data used focuses either on the linguistic aspects of nationalistic terms or the direct analysis of identity construction and its influence on nationalistic tendencies. Therefore, this study will conduct interviews to explore how Japanese citizens perceive nationalistic terms. The results will show how certain demographics use the terms. This research aims to explore perceptions of nationalism and the connection between national identity and nationalist sentiment in East Asia, particularly in the context of Japan, by emphasizing the perspectives of Japanese citizens.

Abstract Name: Unpacking Microaggressions: Evaluating Word Meaning Through Public Perception

What do everyday people think the term “microaggression” means? Are people equally willing to use the term to describe different types of microaggressions (e.g., microassaults, microinsults, and microinvalidations)? While researchers, such as Sue et al. (2007), define the term “microaggression” in their published work, it is not clear whether the ways in which everyday people define this term align with such definitions. We seek to explore these questions by recruiting 200 adults within the United States and asking the extent to which they are familiar with the term “microaggression”: Those who indicate familiarity will be asked to characterize the meaning of the term using a semantic differential scale, and those unfamiliar with the term will be presented with a definition followed by the same semantic differential scale. Participants will then be shown six scenarios, three involving microaggressions and three involving pleasant interactions, and asked how sure they are that what the person in power said to the minority member was a microaggression on a scale of 1 (very sure it was not a microaggression) to 7 (very sure it was a microaggression). After each rating, participants will be asked an open-ended, follow-up question about their reasoning. We are interested to see the extent to which our participants are familiar with the term “microaggression” and whether the semantic differential scale ratings are different based on whether participants were provided a definition. We anticipate differences in ratings across the different types of microaggressions with participants being more confident that microassaults are microaggressions as compared to microinsults and microinvalidations. Finally, participants’ responses will be used to determine which factors are most important for everyday people when considering the term “microaggression.” These findings can be used to develop more effective strategies for reducing the frequency of microaggressions in everyday life.

Abstract Name: Politics of the Performance: Who Attends Theater, Why, and How Does It Matter for Politics?

Live theatrical performance, though used as political commentary across many cultures for millennia, has been less researched by social scientists in its potential impact on voting and civic life. Many often view theatre and its participants as leaning to the left of the American political spectrum. However, this assumption does not account for the wide array of theatrical performances in the United States. This study asks what are the demographic, social, and political factors associated with attending live performances. In turn, the research asks how live theatrical performance may influence the tendencies of theatergoers to be civically engaged or engaged with a particular political ideology or party. Using theoretical frameworks of media and politics research as well as the social capital literature, the research design employs surveys of United States residents from Pew Research Center (2018) and the General Social Survey (2016). Findings reveal that audiences in the United States are politically diverse with both Democrats and Republicans appearing

regularly in audiences. Theatergoers tend to be higher socioeconomic status and are more likely to be involved in their community than non-attenders. While the types of productions attended by Democrats and Republicans may differ in context, Democrats and Republicans alike attend theatrical performances to engage in political commentary and other social capital building. Overall, results are suggestive that theater attendance is one of many important contributors to civic involvement and socioeconomic class, rather than politics, is the primary differentiator in who attends theater.

Abstract Name: Childhood Rhythms: Perspectives on Music in Early Childhood Education

This project explores how music exposure influences the development and well-being of preschool-aged children, inspired by Dalcroze pedagogy. This capstone aims to address three key questions: (1) What is the comfort level of early childhood teachers in implementing music in their classrooms? (2) How does music exposure affect six core areas of preschool development — self-esteem and independence, interaction and cooperation, communication, discovery and exploration, physical capabilities, and artistic expression? (3) Which features of activities have the most positive valence for children? The project will use multiple methods of inquiry, beginning with teacher carousel brainstorming sessions and interviews to gauge their confidence in using music as a classroom tool. Small group music activities, inspired by Dalcroze techniques, will be introduced alongside regular classroom rhythms. At the end of the project, teachers will revisit the initial questions to reflect on changes in both their own comfort levels and in their classrooms, and teachers' impressions of the activities. The project not only highlights the developmental benefits of music exposure, but also emphasizes its role in fostering classroom wellness, promoting cognitive growth and physical development, and provides discussion of opportunities for teachers to include music in their classrooms.

Abstract Name: Deception, Fear, and Moral Value: Portrayal of Women in Horror in 19th Century America and Contemporary Japan

This study compares 19th-century American and Japanese supernatural stories, examines the connections between the two and how they relate, and explores the prominent role women play in horror. By analyzing myths, stories, and films from the past and present, I demonstrate how human psychology, fear, and cultural norms inspire the horror genre. Within this study, I look at *The Bell Witch* and *Kuchisake-Onna* as selections from American and Japanese horror literature. I analyze their shared themes of perverse womanhood and how they present this concept in different ways. By comparing and contrasting each story and connecting their ideas to modern horror literature and films, I find much to be learned about human psychology, internalized fears, and cultural and religious reflections within the genre. By observing the history of horror through these

stories and their relation to human psychology and societal differences, we can understand how modern forms capitalize on these ideals and further emphasize the intrinsically human aspects of the genre.

Abstract Name: Immigration in the United States – Displacement, Refugees, Border Crises, Healthcare, Economic Impact, and Education.

This research paper explores the complex socio-economic impacts of immigration in the United States, focusing on key issues such as displacement, healthcare, economic contributions, education, refugee challenges, and border crises. Immigration is both a catalyst for economic growth and a point of social and political contention, affecting diverse facets of American life. Drawing from an immersive experience on a Spring Alternative Break in Los Angeles that highlighted the intersection of immigration and homelessness, this study examines how immigrant populations shape urban landscapes and confront multifaceted challenges. Through fieldwork, community engagement, and comprehensive research, we delve into how immigrants, particularly refugees and those displaced by crises, navigate access to healthcare, education, and economic opportunities. The paper also assesses the border crises that further complicate immigration policy and advocates for policies that acknowledge and integrate immigrant contributions while addressing systemic barriers. My findings underscore the urgent need for reforms that support immigrant resilience, enhance their contributions to society, and address challenges through equitable solutions.

Abstract Name: Toward Open Domain Scientific Claim Verification: Baseline Results Using GPT-3.5

Online scientific disinformation misrepresents the findings of scientific papers and disseminates misleading or malicious information to internet users. Although fact-checking sites such as Snopes.com exist, manually verifying scientific claims is time-consuming and usually requires domain knowledge, and therefore does not scale to the massive number of claims spread on the internet. This leaves a pressing need for tools that can automatically verify scientific claims by labeling their credibility and providing a rationale for the labels. In this work, we investigate the capabilities of large language models in verifying scientific claims. As a pilot study, we explore baseline prompting methods including zero-shot, one-shot, and Chain-of-Thought (CoT) on GPT-3.5. Recent research on prompt engineering has shown significant improvements in accuracy when using CoT compared to few-shot or zero-shot prompting, and we aim to compare the three prompting methods within the context of two subtasks, namely, stance labeling and rationale annotation. To this end, we developed a new dataset by carefully selecting legitimate scientific claims from an existing dataset MSVEC. The new dataset consists of 138 scientific claims in 10 scientific domains. We performed extensive experiments by varying the prompts and domains and evaluated performances using the F1-score. We find

that zero-shot prompting performs the best on average in the stance labeling task. For the rationale annotation task, CoT outperforms zero-shot and one-shot and the performance improves in general with the number of examples. Surprisingly, the CoT performs better when out-of-domain examples are provided than when in-domain examples are provided. Our work sheds light on the potential of developing a fact-checking browser extension to assist internet users in identifying credible science news.

Abstract Name: Predicting Median Housing Price in New York State: Integrating Economic Indicators with Time Series Forecasting

This study presents a data mining model for predicting median housing prices in New York State, combining economic indicators and multiple forecasting models. Housing prices are critical for many including buyers, sellers, investors, and policy as they influence critical decisions across the real estate market and affect the overall economy. We created a dataset including the Federal Funds Rate, New York Unemployment Rate, 30-Year Mortgage rates, Gross Domestic Product (GDP), Consumer Price Index (CPI), New Construction Permits for New York, New York Population, New York Real Income, and a binary Pandemic Indicator. Additionally, lagged features and rolling statistics were created to capture the temporal dependencies as well as patterns and trends in the time series data. The initial forecasting method was a naive model which served as a benchmark for comparing the accuracy of more advanced models. Subsequently, Exponential Smoothing (ETS), ARIMAX (Autoregressive Integrated Moving Average with Exogenous Variable), and linear regression forecasting models were employed. Each model being chosen because of their different strengths in handling seasonality, trends and external economic factors. These models were evaluated using the key performance metric Root Mean Squared Error (RMSE). The results indicated that ETS and ARIMAX performed significantly better than the naive model because it was able to account for historical patterns and external influence, while the linear regression models offered a more interpretable model with competitive accuracy. This study demonstrates the value of using multiple forecasting techniques, feature selection, and the integration of lagged and rolling features to enhance predictive power of housing price models, providing valuable insights for anyone in the housing market and policy makers looking to anticipate future trends in the market and make informed decisions about the real estate market.

Abstract Name: Drugging *C. elegans* Worms to Study Cocaine Use Disorder

Cocaine Use Disorder (CUD) is known to cause molecular, cellular, and behavioral changes in neuronal plasticity, yet the underlying mechanisms remain largely unexplored. Most CUD research relies on model organisms with long developmental periods, limiting large-scale analysis. *Caenorhabditis elegans* (*C. elegans*), a model organism with rapid growth, a well-characterized nervous system, and established drug responses, offers a promising alternative. In this study, we investigated cocaine-induced behavioral changes in *C. elegans* mutant strains (CB112, RM2702, MT14984, DA509, ZR1, ZR2) by exposing each to acute and chronic cocaine treatments. Worms in the chronic exposure group received daily doses of cocaine until adulthood. At adulthood, both groups were placed onto plates with and without cocaine before behavioral tracking. Locomotion-based characteristics were quantified and compared to an established control baseline. All cocaine-exposed mutants exhibited decreases in speed and other locomotion parameters. These results suggest conserved pathways in cocaine response that may be linked to neural plasticity. We hope to use this pilot data as a framework for future CUD studies that explore *C. elegans* DEGs with human orthologs to further explore the potential mechanisms behind CUD-induced neural plasticity.

Abstract Name: A Network Analysis Approach for Improving Stock Market Predictions

Abstract—This work proposes the use of network analysis to improve stock market price prediction. Historical, daily adjusted closing prices are collected before being shifted daily and grouped weekly. Then, are used to calculate lagged, weekly correlation matrices between every pair of stocks. Weekly graphs are then generated with nodes as stocks, and edges as the correlation between the stocks. Furthermore, centrality measures are determined from the graphs and were utilized in the form of individual neural network models for each stock with and without exogenous variables (centrality measures). The results indicate that models without exogenous variables provide better and statistically significant results compared to those with exogenous variables. However, the significance can be debated based on the chosen p-value threshold. Of the centrality measures, PageRank and hubness score of Hyperlink-Induced Topic Search (HITS) were the most predictive of future prices. Although findings show that centrality measures are not beneficial features for predicting stock market prices, the nuance in optimization methods, like the use of genetic algorithm, opens the possibility for them to be more helpful than observed.

Abstract Name: Application of Quantum Dots in Layer-by-Layer Films as Pressure Sensors

Quantum dots are zero-dimensional nanocrystals with unique fluorescence capabilities, where the wavelength of light produced is dependent on its size. In previous studies, quantum dots have been proven to show altered light intensities when in proximity to metal nanoparticles (MNPs) compared to their fluorescence without the MNPs. Using the layer-by-layer self-assembly method, thin films with varying amounts of layers between the quantum dots and metal nanoparticles were used to produce fluorescence. The purpose was to measure the emittance wavelength as a function of separation. This research investigates the applicability of layer-by-layer (LbL) assembly and quantum-dot technology to be used in quantifiable visual analysis of pressure gradients across wings. This LbL film was designed to produce changes in fluorescence based on the air pressure present on the wing. Computational Fluid Dynamics (CFD) software was used to model a wind tunnel and simulate the flow parameters within the test section. The relative pressures on the surface were 76% of the total pressure of the tunnel through comparison of the inlet pressure and the pressure on the slide with an inlet velocity of 45 mph. In the future, the films will be tested in a physical wind-tunnel at velocities up to 250 mph and MATLAB software will be used to process the light intensity of the fluorescence of the films.

Abstract Name: Drinking Motives and Alcohol's Acute Effects in a Social Laboratory Setting

Background: Motivational models of alcohol use emphasize drinking motives—enhancement, coping, social, and conformity—as drivers of drinking behavior. Few studies have explored whether these motives influence acute alcohol responses, with prior research neglecting social motives, expectancy effects, and ecological validity. This pre-registered study addresses these gaps by examining how drinking motives relate to alcohol's effects on emotions and social facilitation using multi-modal assessments in a multi-participant alcohol administration study with placebo control. Methods: Heavy-drinking young adults (N=393; 50% female) completed the Drinking Motives Questionnaire-Revised and were assembled into 131 three-person groups of strangers. Groups consumed either alcohol (males: 0.82 g/kg; females: 0.74 g/kg) or placebo over 36-min. Social interactions were video-recorded, with facial expressions, speech, and laughter coded using Ekman's Facial Action Coding System. Participants also reported subjective responses to alcohol (e.g., affect, stimulation) and perceived social bonding after drinking. Results: Using multilevel structural equation modeling, results showed higher enhancement motives were associated with increases in positive affect and stimulation in both the alcohol and placebo conditions, and greater relief of negative affect and social bonding in the alcohol condition. Higher coping motives were associated with greater relief in both conditions with a significantly stronger effect in the alcohol condition, and was associated with increases in positive affect and stimulation in both conditions. Higher social motives were associated with increases in stimulation in both conditions, and increases in positive affect and greater relief in the alcohol condition. Finally, higher

conformity motives were associated with longer durations of social smiles in the placebo condition throughout the drinking session, and were associated with increases in positive affect, stimulation, and greater relief in the alcohol condition. Conclusion: These results highlight the importance of considering expectancy effects and more ecologically-valid laboratory drinking contexts in understanding how drinking motives may shape acute alcohol responses.

Abstract Name: Defining the Timing of Cytomegalovirus Acquisition in Infants with Prenatal Zika Virus Exposure: Insights into Fetal Immune Modulation

This study investigates the timing of Cytomegalovirus (CMV) acquisition in rhesus macaque infants, exploring whether prenatal exposure to Zika virus (ZIKV) alters the fetal immune system and influences functional immune responses, like the timing of CMV infection during childhood. CMV is a ubiquitous virus in human and macaque populations with nearly 100% seroprevalence by adulthood, with most individuals acquiring CMV in early childhood. Previous research indicates that exposure to other prenatal infections, such as HIV, leads to earlier acquisition of CMV infection in childhood. We hypothesized that prenatal exposure to ZIKV might have a similar effect. We tested banked blood samples from ZIKV-exposed and control infant macaques at 12, 18, and 24 months and corresponding dam samples at the time of infant birth for rhesus CMV DNA and antibodies. Our final sample size was 32 infants and 23 dams. We found a similar acquisition timing of CMV IgG antibodies across ZIKV-exposed and control infants, with ~20% having CMV IgG at 12 months, 60% at 18 months, and 100% at 24 months. CMV viremia was identified in 3 infants before 12 months of age. All the dams presented positive with rhCMV IgG, indicating this is a ubiquitous virus infection in macaque colonies. Our findings suggest that prenatal ZIKV exposure does not alter the timing of CMV acquisition and that prenatal ZIKV exposure may not significantly alter the development of the fetal immune response.

Abstract Name: Roots of Resilience: How Maternal Trauma Shapes Generational Identities in Black Communities

The purpose of this exploratory study was to understand the protective and risk factors for transmission of trauma across generations for Black women and their daughters. At this stage in the research, intergenerational trauma will be generally defined as the passing of the psychological effects of traumatic and/or racist experiences from one generation to the next. Specifically, this study seeks to answer the following

research question: What are the protective and risk factors of intergenerational trauma among Black women and their children? Research shows that trauma experienced by African Americans due to systemic oppression is transmitted across generations, particularly through maternal influence. Many Black Americans exhibit behaviors, such as hyper-vigilance and distrust, which become normalized and are often passed down as survival mechanisms. Identifying protective factors may inform interventions to strengthen resilience within affected communities. Preliminary data collection includes participants who were pairs of Black women and their daughters. Recruitment included purposive sampling, and to date 4 mother-daughter pairs have been interviewed. The data collection method included a semi-structured interview, approximately 35 minute in duration, one for the daughter and a separate one for the mother of each pair. Data collection will continue to saturation. Preliminary results indicate that daughters whose mother had coping mechanisms were more likely to pass on similar behaviors to their daughters. Validation strategies include rich thick descriptions and reflexive journaling. Implications of the results for future studies include designing interventions to enhance coping among mothers so that they can be socialized to the daughter/child, based on the findings of this study. The results of this study can contribute to the field of psychology and help initiate positive change for culturally relevant interventions for people of color.

Abstract Name: 3D-Printed Microneedle Device Design Optimization for Pain Reduction and Drug Delivery Efficiency

In comparison to traditional drug-delivery applications, microneedles have shown fewer adverse effects and reduced patient discomfort during transdermal drug delivery. Medical applications of these devices include vaccination, insulin delivery, and cancer therapy. Studies show that longer needles can increase pain by activating deeper skin receptors; yet it is often necessary to penetrate deeper layers to increase bioavailability and likelihood of reaching the target site. However, it is a challenge to balance drug delivery efficiency with low pain response. Literature lacks explicit reports that provide parameters for a microneedle array design that minimizes pain while efficiently administering the therapeutic agent. We seek to optimize a 3D printed microneedle design to address the need to reduce pain while maximizing drug delivery efficiency through the variation of design parameters. Cone-shaped, solid microneedles with various heights, diameters, and array sizes are designed using SolidWorks and fabricated by 3D printing. We assign the value of pain based on needle dimensions as reported in literature. A simulated drug is used to assess the impact of surface area on coating efficiency and drug release. The acquired data is examined to determine the needle design that effectively delivers drug with minimal pain. We strive to highlight the dependency of pain and delivery efficiency on the surface area. We aim to identify the optimal height, width, and array size to minimize pain and maximize drug delivery efficiency. The use of microneedles for transdermal drug delivery would greatly improve patient compliance, thereby reducing needle phobia. This research is expected to provide a guide for the design of next-generation microneedles by providing a deeper understanding of how microneedle designs can be optimized to cause the least amount of pain while delivering drugs efficiently.

Abstract Name: Storytelling for Success: The Effects of Preserving Campus Lore on Salisbury University's Admission and Retention Rates

Admission and retention rates at a university depend on the institution's reputation, which is then dependent on the university's image from the students' and community's perspective. Previous research has shown that when a university has a positive reputation, students are more willing to stay enrolled in their chosen institution through graduation and remain involved as alumni, while donors are more likely to make financial contributions to the university. To increase admission and retention rates at a given university, this paper focuses on how to improve reputation and make connections through the telling of campus legends and the preservation of the institution's history. Storytelling allows people to connect and provides a feeling of familiarity that can be applied to relationships between the students and the university, as well as between the university and its donors. To improve Salisbury University's admission and retention rates, this research recommends the incorporation of campus legends in Salisbury University's tours for students and donors on the physical campus through story signs. Doing so may spark a personal connection between the university and the audience, leading to increased feelings of loyalty and willingness to support the institution.

Abstract Name: Design and Development of Components for a Jumping-Type Dynamic Climbing Robot

Climbing robots have great potential to be used in various applications such as the inspection of vertical structures and the exploration of microgravity environments. There are, however, a few challenges facing climbing robots that limit their general utility. Most existing climbing robot designs can be described as quasi-static, as they climb by slowly taking one step at a time. These robots tend to climb at speeds unacceptable for time-sensitive applications and struggle to overcome discontinuous climbing terrain. Dynamic climbing robots, a relatively new sub-category of climbing robots, utilize momentum to propel themselves up vertical surfaces and have great potential to address these issues. The purpose of this research is to begin the development of a dynamic climbing system that can overcome discontinuous climbing terrain and traverse quickly by jumping between climbing holds. Two components were developed that may be used in a jumping-type dynamic climbing robot: a locust-inspired robotic limb theoretically capable of propelling a 4 kg total payload to a height of 1 meter, and a compliant micro-spine gripper. A simplified model of the power-amplification mechanism found in locusts was analyzed and used to design the robotic limb. The micro-spine gripper's design was largely inspired by the design of existing grippers for quasi-static climbing robots. Initial tests confirmed the functionality of the limb's power amplification system and demonstrated the gripper's ability to adhere to the climbing surface when dropped from a height of 1 cm. Further improvements in energy density of the power amplification mechanism, actuator speed, and gripper reliability are discussed as steps toward realizing a dynamic climbing robot.

Abstract Name: Capitalism, Consumerism, and the Contemporary Classroom

“MEDIA LITERACY IS DEAD!!!” has been the battle cry of many individuals across social media platforms in recent years. The response to this claim has been overwhelmingly one of agreement, looking at how there has been a decline of education in the United States of America, and how that has affected the understanding and consumption of every piece of media in our lives. Social media has also made many individuals more cognizant of America’s economy, with the realization that we are functioning under capitalism’s latest stages. In my research presentation, I want to explore how these two things are inextricably interlinked. Through personal primary research, compiled with research done by others, I will be able to demonstrate how capitalism has “killed” education in America. I will look especially at capitalism’s inherently racist upbringing that has led to the underfunding and defunding of English programs, which forces educators to not have the resources to make kids feel represented in literature. This movement has led to an increase in book bans of representational literature, primarily in red states like Florida. Because kids are not feeling represented, they are not caring about English classes and are not learning important contextualization and empathizing skills. I will take these conclusions and look at what educators and others can do to address these issues. By turning to the work of Adrienne Rich's groundbreaking essay, “When We Dead Awaken: Writing as Re-Vision”, I will suggest a framework for combating the damage capitalism has done to our education system. I will also interview current and future educators about what they see in real time, how capitalism – and its child, consumerism – has affected students and classrooms. Through these processes, I will develop a plan that educators can put into place to help potentially save education in America.

Abstract Name: Identifying Hidden Ideals in Partially Ordered Sets

We study the problem of identifying hidden ideals in partially ordered sets (or posets). In this problem, we query members of the poset one at a time for membership in the hidden ideal with a given limited number of positive queries allowed. We provide an efficient search strategy for this problem and prove that this strategy finds the hidden ideal in a number of queries bounded by an explicit function of the height and degree of the poset. Moreover, we show that for the case of complete n -ary trees, this strategy is of the same order as a hypothetical optimal strategy. This result has applications in various situations, such as the famous ‘marble drop problem,’ identifying sources of pollution in water systems, and searching for corrupt data in computer science.

Abstract Name: Significance of Telomeres on Aging

This research project looks at the process of aging at a cellular level. The shortening of telomeres is what causes aging. Telomeres are repeating DNA sequences that erode as cells divide. Telomerase is an enzyme found in gamete cells that can help mitigate telomere erosion. In order to slow the process of aging, a study has found a way to use modified RNA that encodes for TERT. TERT is a protein component of telomerase. With more TERT, there is more telomerase and a slowed rate of telomere erosion. This treatment can help slow the aging of patients with Hutchinson-Gilford progeria syndrome (or progeria) who experience accelerated aging at a very young age. This research project also discusses the consequences of potentially immortalizing cells and the development of cancer as a result of it. This project brings attention to possible treatments for progeria patients. While it is not a cure, we can be hopeful that it can improve the quality of life for these patients.

Abstract Name: Development and Preclinical Evaluation of Glypican-3 Antibody Fragments for Targeted Cancer Therapy

This study investigates the production and preclinical evaluation of single-chain variable fragments (scFvs) derived from the Glypican-3 (GC-33) antibody to advance targeted radiopharmaceutical therapy (RPT) for hepatocellular carcinoma (HCC). Glypican-3, a heparan sulfate proteoglycan overexpressed in HCC cells, is a promising therapeutic target due to its critical role in tumor progression and limited expression in normal tissues. However, the prolonged half-life of full-length GC-33 antibodies presents challenges for combination RPT and immunotherapy, including risks of systemic lymphodepletion, off-target toxicity, and impaired anti-tumor immune responses. To address these limitations, smaller antibody fragments—diabody (Db), minibody (Mb), and scFv constructs—were engineered to optimize pharmacokinetics, therapeutic specificity, and clinical applicability. Constructs were cloned into *Escherichia coli* for periplasmic expression, exploiting the bacterial disulfide-bond formation machinery to ensure proper folding. The fragments were purified using HisTrap™ HP columns, and their purity and molecular weights were confirmed through SDS-PAGE analysis. Surface plasmon resonance (SPR) experiments demonstrated high binding affinities, with scFv GC-33 exhibiting a K_d value of 16.3 nM, highlighting its robust target specificity and binding functionality. The successful production, purification, and validation of these antibody fragments establish their suitability for targeted RPT applications. This study provides a foundation for future biodistribution, pharmacodynamic, and radio-labeling studies, aiming to optimize these fragments for in vivo performance. Planned murine model trials will deliver critical data on safety, efficacy, pharmacokinetics, and translational potential, setting the stage for clinical applications in HCC treatment. This research represents a significant advance in targeted cancer therapies, addressing key limitations of conventional approaches while offering new strategies to enhance combination RPT and immunotherapy. By overcoming pharmacokinetic challenges, this work

improves therapeutic precision and paves the way for broader applications in treating other cancers where Glypican-3 plays a pivotal role.

Abstract Name: Is Cognitive Intrusion Associated With Delayed Discounting and Pain in Individuals With Substance Use Disorder and Chronic Pain?

Background: The presence of chronic pain is associated with substance use disorders (SUD). Research shows that those in SUD recovery with chronic pain have a shorter temporal window. However, little research has focused on whether the cognitive intrusion of pain (i.e., the extent to which people experience pain that interrupts their thinking) plays a role in this relationship. **Objective:** This study aimed to (1) investigate the relationship between chronic pain and delay discounting (DD; a measure of one's temporal window) and (2) examine whether the cognitive intrusion of pain is associated with chronic pain and DD among individuals in SUD recovery. **Methods:** Participants ($n = 209$) were recruited from the International Quit & Recovery Registry and completed a monetary DD task, demographics questionnaire, chronic pain questions, and the Experience of Cognitive Intrusion of Pain. Linear regressions with model selection were used to test the aforementioned associations. The model with the lowest BIC was used. **Results:** No differences were observed in DD rates between those with and without chronic pain ($p = .469$). Those with chronic pain reported having higher cognitive intrusion of pain ($p < .001$). Additionally, cognitive intrusion of pain was not associated with DD rates ($p = .178$). **Conclusion:** The study did not find associations between chronic pain and DD, and between cognitive intrusion and DD. We found that chronic pain was associated with higher scores on the cognitive intrusion scale. This may potentially lead to attempts to stop thinking about the pain, which might lead to relapse.

Abstract Name: Imagining Our Futures in the Red Cedar Watershed

Conventional agriculture, defined here as planting a limited crop rotation, regular tilling, and use of chemical pesticides and herbicides, has been identified as a cause of nutrient pollution, soil degradation, and, when coupled with farm consolidation, social inequality. In contrast, greater implementation of regenerative methods, specifically rotational grazing would help restore biodiversity and enhance forage production. This project explores the viability of expanding permanent agriculture in the Red Cedar Watershed, examining what an ideal future looks like to residents and possible changes that can be made today. Eighteen interviews

with farmers and community stakeholders were conducted, transcribed, and coded for themes. This data revealed that interviewees linked farm consolidation with poverty increase, environmental degradation, and rural population decline in the Red Cedar Watershed. Residents desired clean water, economic development, and sustainable agriculture, but had different visions of possible agricultural paths. Some believed that large-scale, industrialized agriculture can be more sustainable due to advanced technology and stricter regulations. Others advocated for more grazing-based farms in order to restore habitat and mitigate climate change. Interviewees agreed that actions taken to ensure profitability in the dominant system and community divisions are barriers to agricultural transformation. Farmers are currently financially incentivized to follow potentially environmentally harmful practices. Ideological differences can also hinder cooperation between various farmers or farmers and conservationists. Reformed government subsidy programs and farmer-led learning networks could encourage changes in agriculture, including more grazing. These recommendations could, in turn, improve overall social and environmental well-being in the Red Cedar Watershed.

Abstract Name: Sentiment Analysis on Twitter Dataset Using Apache Spark and H2O Machine Learning Framework: A Comparative Study

Sentiment analysis, an integral part of natural language processing, holds significant importance in understanding public opinion and sentiment trends, especially in the era of social media dominance. This paper explores sentiment analysis on Twitter data, focusing on the challenges posed by the platform's dynamic nature and informal communication style. Leveraging Big Data technologies and PySpark's machine learning framework, we address the complexities of sentiment analysis by developing robust models capable of accurately categorizing tweets based on sentiment polarity. Our study delves into various machine learning algorithms, feature engineering techniques, and model optimization strategies, utilizing a Twitter dataset comprising 1,600,000 annotated tweets. Through a comprehensive literature review, we highlight existing methodologies and advancements in sentiment analysis, including classical machine learning and deep learning approaches. Additionally, we categorize relevant research papers to provide insights into the diverse methodologies employed in sentiment analysis on Twitter data. Our findings contribute to the advancement of sentiment analysis techniques, emphasizing the significance of Big Data utilization in overcoming the challenges inherent in analyzing social media data.

Abstract Name: Teaching in the Age of GenAI: Social Media Insights on Opportunities and Challenges

Generative Artificial Intelligence (GenAI) is evolving rapidly, with sophisticated models being increasingly utilized by students. This swift adoption poses both opportunities and challenges for educators, necessitating a deep understanding of their responses to adapt effectively. Traditional methods like interviews and surveys

are often too slow to capture the rapidly shifting landscape of GenAI, risking obsolescence before studies conclude. This study addresses the need for timely insights by analyzing unstructured data from social media platforms such as X (formerly Twitter) and BlueSky, focusing on posts by educators discussing GenAI. The analysis aims to uncover real-time reactions to GenAI's role in education, track sentiment evolution since the use of GenAI became widespread, and identify categories of barriers to classroom adoption and adaptation to challenges. To achieve this, we collected and preprocessed over 1,000,000 posts across platforms that related to the field of GenAI. This data was filtered to only include posts from educators and students to provide firsthand accounts of GenAI use in education. Advanced text-mining techniques such as topic modeling and sentiment analysis were applied to extract patterns, sentiments, and recurring themes in the discourse. Our findings reveal key insights into educators' perceptions, including the benefits, risks, and challenges associated with integrating GenAI into educational practices. These results offer valuable guidance to both the educational community and GenAI developers, enabling the design of tools and strategies that better align with educators' needs and address the complexities of GenAI in learning environments.

Abstract Name: Bridging the Gap: A Communication Privacy Management Approach to Student-Faculty Interaction in Higher Education

This study examines the criteria undergraduate students use to develop privacy management rules when deciding whether to share personal struggles and stress with their instructors, guided by Communication Privacy Management Theory (CPM). CPM highlights individuals' belief in owning their private information and the rules they create to regulate its disclosure, emphasizing the vulnerability in sharing personal matters. High-stress levels among college students have documented impacts on academic performance, mental health, and well-being; while faculty-student relationships and social support have been shown to alleviate stress, the factors that shape students' decisions to confide in faculty remain underexplored. This qualitative, interpretive study employed semi-structured interviews and focus groups with 40 undergraduate students to investigate which criteria students use to develop privacy management rules with instructors. Data analysis, grounded in CPM, revealed four main themes influencing students' privacy management decisions: (1) Culture—norms of higher education and past experiences inform disclosure choices; (2) Motivations—help-seeking for academic support and relationship-building and reciprocity with professors; (3) Context—factors such as course policies, physical environment, relevance to class content, and the professor-student relationship influence openness; and (4) Risk-Benefit Assessment—students weigh potential stigma, face risk (embarrassment), and role risk to social and professional standing. By understanding these CPM-informed factors, educators can better support student well-being and enhance academic success through informed communication practices.

Abstract Name: Utilizing beneficial microbes to enhance plant growth under limiting conditions

Providing sufficient nutrients to crop plants in a sustainable way is an issue in both agriculture on Earth, with the financial and environmental cost of fertilizer, and developing agriculture in spaceflight or extraterrestrial environments, with the challenge of developing bio-regenerative life support systems. Species of rhizobacteria that support crop plants in various ways have been identified as a potential method for alleviating plant nutrient deficiencies and maintaining yields while minimizing fertilizer application. *Azospirillum brasilense* has been shown to be beneficial to crop plants under deficient conditions. This project explores the ability of two *Azospirillum* bacteria strains to improve growth under limited nitrogen and limited phosphorus conditions through synthetic auxin production, nitrogen fixation, and phosphate solubilization. Various plate and soil experiments are being conducted, and data is being collected on root development and nutrient, pigment, and hormone content. Preliminary data shows potential benefits to the model plant, *Arabidopsis thaliana*, and differences in the two bacteria strains. Adding to the growing knowledge of plant-growth-promoting bacteria aids in the continued development of solutions for sustainable agriculture and space exploration, so conclusions will be placed in the context of agricultural improvements and future research directions.

Abstract Name: Green Hydrogen for Sustainability

This research explores the design and feasibility of a trigeneration plant for sustainable ammonia production in the Imperial Valley, Southern California, with an emphasis on renewable energy integration and advanced air separation technologies. Ammonia, a vital component for agricultural operations, is synthesized using a process that combines solar energy and biomass-derived resources with innovative nitrogen production techniques. At the core of this system is the air separation unit (ASU), which employs cryogenic distillation to produce high-purity nitrogen required for the ammonia synthesis process. This study focuses on modeling the ASU as a key subsystem, simulating its performance to optimize energy use and operational efficiency. The ASU model incorporates dynamic parameters, including cooling demands and process flow rates, to align with the variable energy inputs from renewable sources. In addition to nitrogen, the ASU generates oxygen, which is utilized in other plant processes to enhance system integration and overall energy efficiency. The plant's design integrates solar-driven allothermal gasification to convert biomass into syngas, minimizing emissions compared to conventional fossil fuel methods. A solid oxide fuel cell (SOFC) complements the system, providing hydrogen for ammonia synthesis and electricity for plant operations, enabling a self-sustaining framework. Together, these technologies enable the simultaneous production of ammonia, power, and heat in a carbon-neutral manner. Through comprehensive modeling and analysis, this research demonstrates the feasibility of coupling an ASU with a trigeneration system powered by renewable energy. The findings highlight the potential of decentralized ammonia production to support local agriculture while addressing global challenges of energy efficiency and carbon footprint reduction. This study serves as a foundation for future innovations in integrating advanced separation technologies with sustainable energy systems for industrial applications.

Abstract Name: The Vitamin C Content in Organic Versus Canned Fruits

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available products and food items using titration techniques. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the highest concentration of vitamin C, a crucial antioxidant that plays a vital role in human health. The experimental approach involves titrating the samples, employing 2,6-dichloroindophenol (DCIP) as the titrant, chosen for its ability to exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. The goal of this project is to find if there is a nutritional Vitamin C concentration difference between organic and canned fruits. Canned fruits tend to be cheaper and more affordable for families, so if there is similar Vitamin C concentration, families could utilize canned fruit more in their diets. Samples of organic fresh and canned fruits were obtained and liquified in a blender. The vitamin C concentration was determined by titration using a 2,6-dichloroindophenol sodium salt solution.

Abstract Name: The Vitamin C Content in Fresh Versus Canned Fruits

It is presumed that fresh fruit and canned fruit contain different levels of vitamin C. The purpose of this project is to analyze the vitamin C content in fresh fruit versus canned fruit. In this project, we used a titration technique on canned and fresh versions of mandarin oranges and pineapples to determine the difference in vitamin C levels. Our results demonstrated that fresh fruit contains more vitamin C compared to the canned version. These findings suggest that preservation methods used for canned fruits may affect vitamin C retention. This also supports the higher economic value of fresh fruits compared to canned fruits.

Abstract Name: Building of prototype real-time sub-80-nm airborne nanoparticle characterization instrument for research of ultrafine aerosol effects on human health and the environment

Ultrafine airborne nanoparticles, similar to viruses in size, significantly impact public health due to remarkably high surface-area-to-mass ratios. Typical manufacturing processes already produce an influx of such particles into the environment, such as metallic waste nanoparticles from high-temperature metal working. While the rise of interest in nanotechnology brings excellent promise in advancing vital fields, such as cancer treatment in medicine, the deliberate production increase of these materials poses a significant occupational and environmental risk if not understood from a cradle-to-grave perspective. Differential mobility analysis (DMA) is widely used to characterize particle size distributions rapidly. However, traditional instruments fail to reach adequate resolving power for particles smaller than about 80 nm in diameter. Using a prototype nano-DMA column under low-pressure, high-flow operation, we will investigate the viability of this prototype to provide real-time characterization of these particles. We are integrating a nano-DMA column into a custom instrument with a recirculating sheath flow, aerosol electrospray source, and aerosol electrometer detector. We expect to present a transfer function characterizing the relationship between sheath flow rate, particle size, and instrument voltage. We expect the high-flow operation, ranging from 100 to 1200 liters per minute, to provide significantly finer resolution than traditional DMAs, bridging the gap between DMA and mass spectrometry techniques. It is anticipated that this work will advance the research of how ultrafine aerosols impact human health and the environment with the aim of eventual local implementation in the Inland Empire to study the effects of the worst air quality in the nation, especially on low-income communities.

Abstract Name: The Role of RRM2 in Aberrant Hippocampal Neurogenesis: A Potential Therapeutic Target For Epilepsy

Epilepsy is one of the most common neurological diseases worldwide, affecting over 50 million people. While many factors can cause epilepsy, brain insults, such as seizures, in otherwise healthy individuals are among the leading causes of this disease. Recent studies show that brain insults specifically disrupt adult neurogenesis, resulting in the ectopic migration of immature adult-born granule cells (abGCs) into aberrant compartments within the dentate gyrus of the hippocampus, potentially leading to epilepsy. We hypothesize that these brain insults affect gene expression within immature abGCs, contributing to their development into aberrant abGCs and ultimately leading to spontaneous recurrent seizures (SRS), a hallmark of epilepsy. To test this hypothesis, we induced seizures in wild-type C57BL/6 mice via pilocarpine injection. We then compared these mice to another group that, in addition to pilocarpine, received an hM4Di, a designer receptor

exclusively activated by designer drugs (DREADDs), and clozapine-N-oxide (CNO), a designer drug that activates hM4Di, to silence these immature abGCs. Bulk RNA sequencing of these groups identified Rrm2 as one of the top differentially expressed genes; it was upregulated during seizures and downregulated during abGC silencing with hM4Di and CNO, showing gene expression dynamics specific to seizure activity and immature abGCs. To determine the role of Rrm2 in aberrant abGC development in the pilocarpine model of epilepsy, we used triapine (3-AP) to knock down Rrm2 gene expression after pilocarpine-induced seizures in wild-type mice. Our preliminary data show that treatment with 3-AP reduces SRS and ectopic migration of abGCs in pilocarpine-induced seizure mice compared to untreated controls. These findings suggest that inhibiting Rrm2 expression prevents aberrant neurogenesis and reduces seizures. This work highlights a novel approach to gene regulation and underscores the role of Rrm2 in aberrant abGC neurogenesis, which could lead to treatments that lower the risk of epilepsy following brain insults.

Abstract Name: Evaluating the Efficacy of and Satisfaction with On-Campus Student Support Systems at California State University, Fullerton

This assessment seeks to understand which on-campus support systems (Counseling and Psychological Services, Disability Support Services, and TitanMED) are used by students at California State University, Fullerton (CSUF) and how they may improve mental health, physical health, and academics. Services like these aim to improve student retention, health outcomes, and academic success. CSUF has a high rate of students who take longer to graduate than expected, and it is imperative that support systems be in place to assist students in their academic journey. Thirty-three students were recruited via convenience sampling to participate in a non-experimental survey study. The Qualtrics survey included questions measuring participant demographics, knowledge of on-campus support systems, use of these systems, and overall satisfaction of the systems. Many questions to assess satisfaction were on a Likert scale of 1-6 (Strongly agree to Strongly disagree) followed by open-ended text boxes for participants to expand upon their answers. Students find Counseling and Psychological Services helpful, but would appreciate more availability and online options to combat barriers to care. Some, however, noted they were under satisfied with the quality of providers. Those needing physical health or academic support services tended to not use TitanMED or Disability Support Services; yet, these services are deemed generally supportive by those who use them. Findings suggest that more publicity of services may be necessary due to the lack of awareness about how to access them on campus. CSUF and other universities may benefit from this information by altering their programs and/or increasing advertising.

Abstract Name: Generating Student Curriculum Plans with Local Large Language Models

The rise of Large Language Models (LLMs) has demonstrated their potential across various applications and user requests. Businesses and universities are increasingly exploring how AI-based chat models can streamline operations, save time, and free up resources. One promising area is the automation of administrative tasks using the Natural Language Processing (NLP) capabilities inherent in LLMs. This project aims to evaluate the viability of using LLMs to generate accurate and individualized curriculum plans for college students to support their academic journey. The focus is on how well LLMs, from various sources and configurations, can follow a series of instructions to create a schedule-based format of courses based on students' transcripts. Effective prompt engineering is crucial in enhancing the accuracy and reliability of these models. The correctness of the outputs is reviewed based on course prerequisites and semester availability constraints. LLMs such as Bard, ChatGPT (versions 3.5, 4, and 4o), and the locally hosted Hermes are initially tested. In addition, models such as Gemini, Mistral, LLaMa 3, Phi-3, and Gemma 2 are also tested. Furthermore, Retrieval-Augmented Generation (RAG) will be implemented to enhance the performance with local models by identifying unique data points. Chroma and Acorn are two proposed resources. The research will evaluate outputs using test cases, inspecting a student's year, relevant prerequisites, major, and recommended semester for each course. While LLMs offer wide-ranging applications, their stability in following complex instructions remains a concern. Inconsistencies in accuracy highlight the need for careful consideration before implementing LLMs for tasks like curriculum planning. Future work will expand the scope to include a full 4-year degree program schedule and develop a user interface and script for customizable prompts, alongside continuous testing of new models.

Abstract Name: Massimo Vignelli: A Revelational Designer

Massimo Vignelli was one of the design world's most influential designers. He had a profound impact on graphic design, typography, corporate logos, product design, fashion, and furniture design. When Vignelli is brought to mind his minimalist and modern design style is often affiliated with his work. Vignelli revolutionized design communication, especially through his work with the New York Subway map in the 1970s. Using techniques such as grids, Vignelli achieved an elegant and effective method of organization in his work. This paper explores how Vignelli's work became a symbol for modern design through his use of the font, Helvetica. Using direct sources of information from Vignelli himself, the paper explores the identity of Massimo Vignelli both as a designer and as a person. Vignelli's work continues to impact the design world today, proving that effective design is not just about aesthetics but about conveying meaning with purpose and discipline.

Abstract Name: Parent Money Talk During Pretend Grocery Shopping with Toddlers and Preschoolers

By the time children enter kindergarten, they already show significant individual differences in math skills. For example, children from higher socioeconomic status (SES) backgrounds tend to perform significantly better in math than their peers from lower SES backgrounds. Additionally, prior research has shown that the early home learning environment is vital to the development of children's math skills, but it is unclear if and how the home learning environment contributes to SES differences in math. The current study seeks to describe how parents of toddlers and preschoolers talk about money during pretend grocery shopping and examine potential age-related and SES-related differences in parental money talk. Data come from an ongoing longitudinal study in which parents and their preschooler ($n = 300$) or toddler ($n = 300$) were filmed in their homes playing with pretend grocery store toys. Conversations will be coded for all instances of utterances related to money talk (e.g., "Can I have five dollars?" and "I need change."). I expect parents of older children to engage in more talk about money. However, I do not have any expectations regarding the frequencies of different types of talk about money and their associations with SES. It is possible parents from lower SES will use more money talk as they are used to talking about money with their children. Alternatively, it is also possible that they may engage in less or similar amounts of money talk as parents from higher SES backgrounds. Understanding children's exposure to conversations about money can inform our understanding of the opportunities young children experience to learn math. This knowledge can guide educational policy and early math intervention programs.

Abstract Name: Characterizing the healthcare experiences of Karen migrants to Middle Tennessee

The Karen people are an ethnic group originating from the Karen/Kayin state of present-day Myanmar. For decades, the Karen have been entangled in conflicts with the central government which is led by the Burmese ethnic majority. Civilians have fled to refugee camps primarily located in the Thailand border regions. Some Karen refugees have been resettled in Middle Tennessee, living and forming community here for nearly twenty years. There are countless external and personal factors which can influence an individual's experiences managing their health and receiving healthcare. Previous research suggests that refugees bring carry a heavier burden on their mental and physical health, and migrants from Asia may experience barriers to health related to language and understanding of the systems in place here. Asian Americans are observed to engage in complementary and alternative medical practices either in addition or in place of Western medical care. Thus, a combination of social, cultural, and individual factors may influence healthcare experiences. This interview study seeks to identify common themes related to health management and the healthcare experiences of individuals identifying as Karen. We want to learn what resources and actions are already being helpful and what resources and actions might still be needed. Additionally, we seek to identify the role of culture and community in managing personal health among this particular group. The proposed outcome of this study is to publish and share a list of recommendations for healthcare providers on maintain or improve quality of care for individuals in the Karen community and others who share similarities with them.

Abstract Name: ATP: An alternate role of an energy currency

ATP is well established as an energy currency in all organisms, yet its concentration in the intracellular environment is vastly greater than that needed to perform metabolic function prompting inquiry into supplementary roles of ATP. Recent in vitro studies on two isozymes of malate dehydrogenase, mMDH and cMDH, revealed that ATP increases the kinetic parameter K_m in the dehydrogenation reaction much more in mMDH over cMDH. Microsecond molecular dynamics simulations of the two isozymes (with and without ATP) were performed in a periodic water box with NaCl at 300K to analyze ATP interactions and how the dynamics are affected. In both isozymes, the RMSF fluctuation and entropy were different between the ATP and non-ATP systems. In cMDH, ATP consistently formed hydrogen bonds along the mobile loop of the isozyme and affected the isozyme by lowering the RMSF fluctuation and decreasing the entropy of the mobile loop. In mMDH, there was a reversal of these observations. These results support ATP serving a regulatory role beyond its use as an energy currency as there is a differential effect between the two isozymes, but do not explain the much higher value of K_m in mMDH under the presence of ATP. Future research will involve replicate simulations to confirm the prior results. Additionally, simulations including substrate and cofactor will be performed to investigate ATP serving as a competitive inhibitor

Abstract Name: Nitrate Pollution in Dunn County: Perceptions and Solutions

Nitrates are the most common groundwater contaminant in Wisconsin. Blue baby syndrome, gastric cancer, elevated heart rates and headaches are cited as health consequences of consuming nitrates at high levels. My project aims to address the following questions: What are state, county and township policies on nitrate pollution? What are the perceptions that Dunn County residents hold about nitrate pollution? How do various stakeholders perceive the results of the Dunn County 2023 Groundwater Sampling Report and the issue of nitrate pollution? I used interviews and public opinion surveys to answer my research questions. Interviews of stakeholders at the township, county and state level showed nitrate pollution is an important issue for public officials and the 2023 Groundwater Sampling Report is seen as a baseline for further testing and policy initiatives. Survey responses indicate most respondents are aware of the County's nitrate pollution program and are at least somewhat concerned with drinking water quality. However, when looking at respondents who get their water from private wells, proper well testing protocols were only followed by a small fraction of well owners. This indicates that the public is aware of nitrate contamination but maybe not how to combat the problem. My project ends with suggestions for public engagement to raise awareness of nitrate pollution and water testing in Dunn County.

Abstract Name: Black Artivism: The Revolution of Black Creative Expression for Social Liberation

Black art is defined as cultural-politically charged art expression by and for black communities. The creative practice encompasses a cultural socio-political identity, employing factors of the black experience that have catalyzed social change. The intersection of art and activism has contested systemic injustices that persist within society advancing black social movements across generations. Beginning in Harlem, New York during the eminent Harlem Renaissance, black art and artists such as Langston Hughes, Alice Walker, and Jean Michel Basquiat reshaped the narratives around black identity countering systemic oppression and stereotypes. Social movements like the Civil Rights Movement and the Black Arts Movement amplified this legacy promoting art entrenched in Black culture, community, identity, and life. These instrumentally historical black movements have revolutionized contemporary black movements like Black Lives Matter (BLM). Black artists such as Titus Kaphar and Kara Walker employ visual art to confront systemic contemporary issues like police brutality while correcting historical knowledge and fostering solidarity. From the Harlem Renaissance to BLM, black art's transformative potential has challenged societal structures, fostering community and social reform. An examination of black art's role across social movements can uncover significance in its ability to pilot social-political development while affirming the black experience. This study examines the role of Black art within social movements during the 1960s and its impact on social advancement. Using a methodology of historical analysis and artistic practice involving the creation of original digital designs I will capture and identify themes, aesthetics, and political messages associated with black social movements. Furthermore, these designs will reflect diverse styles such as realism, modernism, and abstraction to connect past and present black social movements effectively. Lastly, this study hopes to recommend studying the continuity of Black art as a powerful agent for confronting injustice, asserting identity, and establishing an equitable future.

Abstract Name: Effects of NSD3 on Neural Crest Migration in Chick Embryos

Neural crest cells are migratory embryonic cells present in vertebrates. Neural crest cells are precursors for a wide variety of cell types and bodily structures including the peripheral nervous system, heart outflow tract, and craniofacial structures. NSD3 is a protein modifying enzyme with a well studied role in regulating gene expression and is commonly studied in research involving other migratory cell types, most notably metastatic cancer. However, despite the possible link between migratory cells and NSD3, its impact on neural crest development is understudied. While previous research has demonstrated that NSD3 is required for neural crest migration, the molecular mechanisms involved remain unclear. To isolate the effect of NSD3 inhibition on neural crest cells, cell cultures were made from the dissected neural folds of chick embryos. The cultures were exposed to one of two experimental conditions, one group contained an NSD3 selective inhibitor, and the other contained a chemically similar negative control. The migration distance and morphology of the cells were compared between the two groups. Migration distance was measured by taking the total dispersal area

of the cells in each culture, and two measurements were used for morphological analysis: aspect ratio, the length vs width of a cell, and circularity, a mathematical representation of how circular a cell is on a 0 to 1 scale where 1 represents a perfect circle. The cells in experimental conditions migrated less on average, were significantly more circular, and had significantly lower aspect ratios than cells under control conditions. These results suggest that NSD3 plays an important role in the regulation of neural crest migration, and future research should explore why NSD3 inhibition leads to these cellular changes and seek other molecular mechanisms that affect neural crest cell migration.

Abstract Name: Graph Coloring with Restricted Colors

Graph coloring is a well-studied problem in the mathematical field of combinatorics. A (mathematical) graph consists of a set of vertices, some of which are connected by edges. As a real-world example, we could think of the vertices as being a set of cities and the edges as airline flights. Then we could say that two cities are connected if there is a non-stop flight between them. To color a graph means to assign a color to each vertex such that no two connected vertices are assigned the same color. One then asks the question: if there are only some number n of available colors, how many ways are there to color the graph? If we ask this question for the same graph, but different values of n , it turns out that there is a nice formula (which depends on the specific graph) that will give the answer no matter what n is. This formula is called the chromatic polynomial of the graph, and it is well-known how to calculate it. In this project, we will study the problem of finding the number of ways to color a graph when each color is only allowed to be used a limited amount of times. We will begin with the situation where each color can be used at most twice, and study the problem for several different categories of graphs. For graphs in these categories, we hope to find explicit formulas for the number of colorings in terms of the number of available colors. It is known that this problem is computationally hard in general, but we hope that by narrowing our scope, we will be able to find formulas for those types of graphs. Where possible, we will also attempt to prove results for different restrictions on the number of colors.

Abstract Name: The Effect of Sense of Agency on Voluntary Motor Action

The Libet paradigm (Libet et al., 1983) demonstrated that brain activity (indicated by an ERP component, the readiness potential, or RP) precedes the conscious decision to act by 500 msec, indicating that neural activity, rather than “free will” causes voluntary acts. Recent research has examined the influence of free will beliefs (FWB) on the RP. For example, Rigoni et al. (2011) found that amplitude of RP’s was lower in a group that had diminished FWB. Although previous research has established that amplitude of RP’s can be influenced

by FWB, scientific literature has yet to determine how sense of agency (SoA) may affect RP's. SoA, or perceived control over our environment, helps maintain psychological stability and flexibility when faced with challenges. The purpose of this study was to determine whether one's SoA affects amplitude of RP's. Participants completed a motor task adopted from Libet et al. (1983). An analog clock was presented to participants on a monitor. Participants watched as one clock hand made a full rotation every 2 seconds. Participants were instructed to press a button to stop the clock hand when they felt the urge. This task was repeated for 50 trials while brain activity was recorded with a 32-channel EEG system. Participants completed a Sense of Agency Scale (SoAS) before and after completing the task. The SoAS is used to quantify each participant's SoA. It was hypothesized that amplitude of RP's would differ between individuals with varying SoA. Specifically, we predicted that participants with a low SoA would have a smaller RP than participants with a high SoA. The results of this study will provide a better understanding of how SoA relates to motor acts, a broader context for understanding the nature of consciousness, and the potential to inform future investigations of the relationship between mind and brain.

Abstract Name: A Machine Learning-Based Multilevel Approach to Identify High Risk Dementia Prediction

Dementia is a chronic, progressive, and degenerative condition that causes a decline in brain function due to disease or impairment, becoming a major health concern among the elderly. The continuous rise of dementia cases due to the aging population has made it a critical to provide accurate, timely diagnosis, and adequate care for patients with dementia. Recently, several advancements have been introduced using machine learning techniques to analyze neuroimaging and other computer-aided data to enhance diagnostic accuracy and early detection. However, many studies lack a focus on identifying specific high-risk factors or gender-specific influences that could improve early detection and personalized care. This research aims to fill these gaps by identifying important variables associated with dementia with two main objectives utilizing data sourced from Kaggle's Open Access Series of Imaging Studies (OASIS-2), which includes 373 Magnetic Resonance Imaging (MRI) scans from 150 subjects. The study has two primary objectives: (1) examining features to identify high-risk factors of dementia including gender-specific factors, and (2) developing a multilevel predictive model. To achieve these objectives, a step-by approach is taken. First, missing values are imputed to handle incomplete data. Second, categorical variables are transformed using one-hot encoding method. Third, a feature set is generated to present relevant information by calculating time-weighted averages, differences, variability, cumulative sum, cumulative rate change, etc. Finally, machine learning techniques are applied to identify dementia and predicting their mini-mental state examination (MMSE) score. The performance of the model will be evaluated using accuracy, precision, recall, and F1-score metrics.

Abstract Name: The persistence of poverty among U.S refugees: Exploring the Intergenerational Poverty Cycle Among U.S. Refugees and the Barriers to Effective Integration.

The cycle of poverty in U.S refugees is consistent and ongoing, passing from generation to generation with no indication of improvement. This research seeks to understand the social, economic, and policy barriers that perpetuate and contribute to this trend in poverty. By highlighting the systematic issues faced by refugees, the research aims to give voice to refugees' experiences and provide actionable recommendations to improve policies in support of refugee integration. Through an analysis of existing literature and data, the research examines barriers faced by refugees such as unrecognized credentials, insufficient housing options, and lack of legal accessibility. These issues faced by displaced persons are often overlooked and neglected in the United States. Refugees are often overqualified for their current job position due to foreign credentials that are unrecognized and undervalued. Furthermore, the evidence provided in this analysis showcases the lived experiences of housing managers in government resettlement agencies. This insight explores the living conditions and lack of available housing units for families. Additionally, refugees are faced with a daunting series of challenges in our legal system that often keeps displaced individuals and families in exile for ten to fifteen years. This state of legal limbo reinforces poverty by restricting their access to stable employment, housing, and essential resources, making it increasingly difficult to escape economic hardship. These compounded barriers create a cycle of poverty that spans generations, with each new wave of refugees facing the same struggles without significant opportunity for advancement. Without policy change, refugees will continue to be trapped in a system that hinders their ability to break free from poverty. This research calls for a reevaluation of current policies to address these systemic issues and provide refugees with the necessary tools to escape the cycle of poverty and build a better future for themselves and their families.

Abstract Name: The Caputo Fractional-Order Derivatives of Standard Real-Valued Functions

In calculus, whole-number derivatives and integrals of functions are simple to interpret geometrically: the derivative is the rate of change of a function, whereas the integral is the area between a function and the x-axis. In a letter to L'Hospital in 1695, Leibniz raised the possibility of generalizing the operation of differentiation to non-integer orders. What would a half-derivative or half-integral mean? Despite this early interest in fractional calculus, it was not until 1974 that fractional calculus became the object of specialized mathematics conferences and texts. In recent years, applications to chemistry and physics have increased the interest in fractional calculus. Within these applications, competing definitions for the fractional integrals have been proposed: the Riemann-Liouville, Weyl, and Caputo fractional derivatives being the three most prominent. Unlike with ordinary differentiation, the fractional derivative of a function depends on which definition for the fractional derivative is chosen; in other words, the fractional derivative of a function is not unique. The focus of this research was on analytically finding and graphically showing the continuous interpolation between elementary real-valued functions and their first derivatives, as α varies continuously from 0 to 1 for the Caputo fractional derivatives. The elementary functions under study include constant functions, rational powers of x , and exponential functions. The contribution of this research was two-fold. First, it provided a record of the derivation of the Caputo fractional derivatives for elementary real-valued functions. Second, it provided the graphical interpretation of these derivatives by presenting the constant interpolation between the function and its first derivative. This research also addresses a gap in the mathematics literature identified by Machado: there is no elaboration of the simple concepts from fractional

calculus that are approachable to undergraduates and could easily be incorporated into existing third-semester calculus courses. This research provides such concepts and examples.

Abstract Name: The Effect of Beta-Hydroxy-Beta-Methylbutyrate on mTOR Expression During Limb Regeneration

Regeneration, the replacement of lost or damaged tissue, is essential for understanding tissue repair and organ regeneration. The axolotl, *Ambystoma mexicanum*, is a widely used model organism for studying this process due to its ability to regenerate complex structures like limbs and organs. A key regulator of this process is the mechanistic target of rapamycin (mTOR), a serine/threonine kinase that forms the mTOR complex 1 (mTORC1). This complex activates early in axolotl limb regeneration, facilitating cellular proliferation and differentiation. mTORC1 integrates external signals like nutrient availability and growth factors to regulate protein synthesis, a key process in tissue repair and regeneration. β -hydroxy- β -methylbutyrate (HMB), a metabolite of leucine, enhances protein synthesis in humans and other mammals through stimulation of the mTORC1 pathway. Despite HMB's established effect in other systems, its impact on mTOR expression during axolotl limb regeneration remains unexplored. This study aims to determine if HMB supplementation increases mTOR expression during axolotl limb regeneration and enhances the regenerative process. To test this, 24 axolotls were divided into 3 groups of 8, and assigned a specific treatment: high HMB, low HMB, and no HMB (saline). Limb amputations were performed, and each axolotl was injected with its assigned treatment. Limb tissues were collected at two time-points: non-regenerating (T0) and regenerating (T72). mTOR expression was quantified by qRT-PCR. mTOR expression significantly increased from T0 to T72 across all treatment groups. However, no significant differences in mTOR expression were observed across treatment groups within T0 and T72, indicating that HMB supplementation did not further enhance mTOR expression. These findings suggest that while mTOR is critical during regeneration, HMB supplementation may not directly influence mTOR expression in axolotls. Future research should prioritize long-term studies of HMB supplementation and its interactions with other pathways to optimize nutrient-based approaches for enhancing regeneration.

Abstract Name: Exploring Incentives and Barriers to Cybersecurity Education

Recent research highlights the pressing need to address the growing cybersecurity workforce shortage; a 2024 study revealed a 4.8 million personnel gap in cybersecurity skills globally. This underscores the importance of analyzing attitudes toward cybersecurity education among STEM students. Our study aimed to identify the

barriers and incentives affecting cybersecurity learning, with the goal of exposing students from diverse academic backgrounds to an interdisciplinary application of cybersecurity skills. Our team conducted a comprehensive survey engaging students from multiple majors to understand their perceptions regarding cybersecurity education. By analyzing their responses, we identified strategies for interdisciplinary cyber education and proposed actionable changes applicable to the College of Business, Security, and Intelligence (CBSI) at Embry-Riddle Aeronautical University-Prescott, including the introduction of new cybersecurity courses tailored to different fields of study. Additionally, we suggested revised course sequences that would help students gradually build a solid foundation in cyber-related knowledge and skills. We also considered employer perspectives, noting the need for a workforce equipped with foundational cybersecurity knowledge. Discussions with industry representatives highlighted the growing demand for employees who understand cybersecurity's practical implications across fields. By combining insights into student motivations with employer needs, we gained a clearer sense of how educational institutions can improve cyber-related curricula. Our research revealed the need to restructure courses and integrate cybersecurity-related content into non-cybersecurity majors, showing connections to their primary studies. In response, our team restructured a cybersecurity course and proposed its integration into a non-cybersecurity major flowchart. By making cybersecurity education accessible, this approach equips students across disciplines with essential skills, preparing them for evolving cybersecurity challenges in diverse organizations. Moreover, it could serve as a model for other institutions, demonstrating the potential for widespread interdisciplinary cybersecurity education to enhance workforce readiness across sectors.

Abstract Name: The Role of Neuroscience and Data Analytics in Understanding the Impact of Beverage Advertising on Perceptions of Women

This research investigated the portrayal of women in alcohol advertisements and explored the broader societal implications of these representations. Although these ads often depicted women in glamorized, idealized ways, the reality for many women in the alcohol industry was far less glamorous, with numerous challenges, including the risk of physical and sexual harassment. The research methodology included a voluntary survey where participants shared their perceptions of women's portrayals in alcohol advertisements, the themes used in these ads, and the analysis of MRI scans highlighting related brain activity. Participants were also asked to explain what stood out to them the most in these advertisements and how they felt about the content they observed. It was hypothesized that the data would reveal differences in how men and women perceive these portrayals. Specifically, men were anticipated to view the depictions more positively, while women were expected to interpret these portrayals more negatively. Additionally, it was hypothesized that alcohol advertisements would often reinforce traditional gender roles, depicting women in more submissive or passive roles, thereby contributing to harmful societal norms. Certain themes and stereotypes associated with women in alcohol advertisements were also expected to reflect a more submissive role. Overall, the results supported these hypotheses based on survey findings. These findings suggested that the portrayal of women in alcohol advertisements, as well as the marketing strategies employed by companies, were perceived differently by the public, reflecting underlying gender biases in advertising.

Jasmine Eubanks

Abstract Name: Childhood Independence in Japan and Canada: How Cultural Differences Influence Development and Esteem in Children's Artwork

In most Japanese preschools, children are given tasks and positions of leadership that instill a sense of autonomy and community, allowing them to create their own classroom rules and solve problems when there are issues amongst them. In addition, Japanese parents put more emphasis on collectivism rather than individualism, while still allowing children walk to school without parental supervision and run errands on their own. In Canada, however, children lack opportunities to develop their autonomy due to narcissistic and helicopter parenting that isolates children from opportunities to learn from their peers and extended family members. This study explores the difference in the two parenting styles and classroom management, through the quality of children's artwork. This exploration of children's artwork demonstrates Japanese children's greater observational skills of the outside world, since they are given more freedom and responsibilities. The difference in observational skills is highlighted when looking specifically at landscape artwork from children of each culture. By quantifying the amount of detail in each artwork, this study shows that Japanese children tend to create more detailed and developed artwork, and this can be connected to the freedom and independence those children experience at home and in the classroom. This research is crucial for western educators, as it covers the positive developmental outcomes of Japanese teaching and parenting strategies.

Abstract Name: Experimentally Guided Computational Investigation of Reactivity of Isomeric Butanol on TiO₂/Au(111)

Biofuels such as butanol can be utilized to minimize global fossil fuel reliance while contributing to a carbon-neutral cycle. Developing a deeper understanding of the fundamental thermal catalysis processes of butanol over heterogeneous model catalysts can aid in the design of more efficient catalysts. Temperature-programmed desorption (TPD) experiments demonstrate differences in both reactivity and selectivity for butanol isomers with 1-butanol showing little reactivity and only elimination products while 2-butanol shows both oxidation and elimination. To gain an atomically-detailed perspective on these processes, density functional theory (DFT) was used to investigate energetic trends and identify comparisons between 1- and 2-butanol as they adsorb on Ti₃O_x nanoparticles supported on a Au(111) surface. There are two favorable interactions between the butanol and the catalyst material; the oxygen on butanol covalently bonds to the nanoparticle and the alkane chain interacts with the gold surface through dispersion forces. Initial conclusions determine the adsorption energies of both 1- and 2-butanol to be less dependent on coordination number of the Ti and more dependent on gold surface interactions. Preliminary results indicate that there are more active sites available for 2-butanol to interact favorably with both the nanoparticle and the gold surface compared to 1-butanol, potentially influencing reactivity and selectivity. DFT calculations to further investigate the reaction pathways for 1- and 2-butanol elimination and oxidation are ongoing.

Abstract Name: In the Public Eye: Focus Group Insights on Policing and Safety in Morgantown

In contemporary America, policing has become as divisive as political debates. While much research has focused on understanding this in urban areas, rural communities like Morgantown, WV, remain largely overlooked. Despite rising crime rates and growing discontent with law enforcement, little effort has been made to address these issues at a local level. Our research seeks to fill this gap, providing much-needed rural representation by exploring public perceptions of safety and the role of the Morgantown Police Department. Using a Community-Based Participatory Action Research (CBPAR) approach, we engaged key stakeholders—including police officers, advocacy groups, the unsheltered population, businesses, and more—through focus groups to capture a diverse range of viewpoints. Early findings reveal evolving expectations of police roles, with participants emphasizing the need for law enforcement to balance consistent enforcement with community engagement. Citizens expressed a desire for greater collaboration and transparency, while concerns were raised about whether the police mission aligns with community needs. Recommendations included improving communication, increasing police visibility, and fostering stronger community-police partnerships. By centering these perspectives, we aim to inform actionable, inclusive reforms tailored to Morgantown's unique challenges.

Abstract Name: One Condemning Decision: Reader Perpetuated Trauma and Misrepresentation of Helen of Troy and Chaucer's Criseyde

Words have the ability to define who we are to ourselves, the world, and generations to come; they have the power to elevate us or to condemn us. Two women, in particular, continue to feel the villainizing power of words that can stain one's reputation beyond easy or foreseeable repair. One of these women is Helen of Troy, whose story is told by Colluthus in "Rape of Helen" and Homer in *The Iliad*; the other is Criseyde, from Chaucer's work *Troilus and Criseyde*. Both Helen and Criseyde are criminalized for their part in betraying the men in their lives; however, the picture that we have crafted of these women as unfaithful and conniving traitors unfairly treats two women silenced and abused, made victims of their society. Both Helen and Criseyde are condemned for one decision: Helen for leaving and Criseyde for never returning. Yet, readers' assignation of heavy blame and a negative reputation to each woman—which fails to consider the factors surrounding each woman's choice—is wrongful. Responding to readers' unjust assignation and perpetuation of blame on Helen and Criseyde, I analyze and expand upon the Greek rhetorician Gorgias' *The Encomium of Helen* (a rhetorical defense of Helen). Engaging with Chaucerian, Greek, Psychology, and rhetorical scholars, I then extend Gorgias' defense to Criseyde, a woman, I argue, whose position in society, experiences with the men in her life, and victim-blaming relationship with readers parallels that of Helen. In doing this, I

demonstrate how Helen and Criseyde have endured centuries of abuse for the reputations that readers have wrongfully assigned them. I conclude by discussing the common literary depiction of women as despicable and untrustworthy. Addressing this normalized negative reputation of women in literature, I open up a conversation about victim blaming and actions for survival within a patriarchal society.

Abstract Name: The Female Power to Create Unity: Subverting Freudian Paradigms in *To the Lighthouse*

JaneMaree Maher and Nini Fang have argued that Lily Briscoe's character in *To the Lighthouse* exemplifies the central ideas of Kleinian psychoanalysis, which emphasizes the importance of a powerful maternal presence as the center of an individual's universe. It presents such an influence as necessary for proper development and family unity. Maher and Fang argued that in the novel, Mrs. Ramsay's maternal attributes make her valuable to all and especially desirable to Lily for her abilities to embody power and to create. Likewise, Nadia Fusini believed not only that Lily desires to be like the maternal, powerful Mrs. Ramsay, but that Woolf was suggesting that all women should strive to emulate Mrs. Ramsay. While Woolf herself admitted that *To the Lighthouse* was written with psychoanalytic motivations, this Kleinian view of the importance of maternalism overlooks the specifically Freudian psychoanalytic ideology exemplified in both characters, and undermines Lily Briscoe's radical character. Reading with the Freudian lens allows one to understand a central character tension in the novel between Mrs. Ramsay and Lily Briscoe and to discern the significance of its resolution. Throughout the novel, Virginia Woolf depicts Mrs. Ramsay as Freud's ideal female with an inferior, submissive attitude towards men and a whole-hearted embrace of the nurturing image of a mother. On the other hand, Lily's lack of passivity, powerfully active creativity, and rejection of the accepted female role characterizes her as Freud's definition of a neurotic female. This essay argues that Virginia Woolf implicitly criticizes Freudian psychoanalysis by reframing female "neurosis" into a norm for women to pursue: creativity, activity, and a rejection of the assigned female role. Throughout the novel, Woolf shows her desire for women to possess these traits through Lily Briscoe's success, and Mrs. Ramsay's failure, to achieve permanent, all-encompassing social and aesthetic unity.

Abstract Name: Navigating Justice: Gender Perspectives on AI's Role in Court

Many have stood by the judicial system and many have criticized it. These opposing perspectives have raised the question of whether people really believe if the judicial system is fair? This question of fairness has led many to wonder if A.I could perhaps have a role in some processes within the judicial system. In order to answer these questions, I wrote a 16 question survey and distributed using Amazon Mechanical Turk to individuals 18 and over across the United States. Specifically, I wanted to test two hypotheses. First, is there a statistically significant difference between gender and the views of fairness of the Judicial System; and

second, is there statistically significant differences on the incorporation of A.I into the Judicial System. I used IBM SPSS to analyze the data and found that there is a statistically significant difference between gender and the views of fairness, with 19% of males indicating that the judicial system is very fair whereas only 4.8% of women believe the system is very fair. Additionally, 87% of respondents believe AI should be incorporated into the judicial system, with no significant difference between males (89%) and females (87%). In conclusion, my research shows that people are open to AI in the judicial system, paving the way for future studies on how it could be implemented.

Abstract Name: Morphology Analysis of iPSC-derived BCAT1 Deficient Neurons

Branched chain amino acid metabolism disorders are rare, inborn disorders associated with devastating neurologic dysfunction. Within the metabolism of branched chain amino acid, branched chain amino acid transaminase 1 (BCAT1) is an enzyme that catalyzes the reversible transamination of branched chain amino acids. Although BCAT1 deficiency has been associated with cellular dysfunction, the role of BCAT1 in neurodevelopment has not been elucidated. Thus, we aimed to study how BCAT1 mutations affect neuronal morphology over maturation. To study neuronal morphology, we built a lentiviral system with myristoylated tdTomato to sparsely label cells with high resolution. The lentiviral system was first transfected into mouse neuroblastoma cell line to ensure successful labeling of ultrastructure with the system. Then, the lentiviral system was transfected into a patient-derived induced pluripotent stem cell line (iPSC), and these cells were differentiated into induced neurons (iNeurons) and collected on Day 2 and Day 7 of differentiation. Finally, ImageJ Simple Neurite Tracer was used to process images, trace cells, and run Sholl and branch analyses. We found that there were subtle delays in BCAT1 diseased iPSC differentiation. Additionally, sparse labeling showed more variable morphology in BCAT1 diseased iNeurons compared to the wildtype (control) iNeurons throughout maturation. Neuronal tracing and Sholl analysis also showed varying morphology between the BCAT1 diseased cells and the wildtype cells. Moreover, branching analysis established a significant difference between genotype at Day 2 of maturation, yet normalized by Day 7 of maturation. Ultimately, these analyses suggest that the BCAT1 diseased iNeurons mature slower and with different morphology than the wildtype iNeurons, and understanding the morphology of BCAT1 diseased neurons over maturation is a step towards elucidating the role of BCAT1 in neurodevelopment.

Abstract Name: Using Fluorescent Tools to Detect the Regulation of Sugar Cycling Enzymes in Cellular

In the last twenty years, despite overall cancer incidence decreasing, hyperglycemic-related cancers have continued to rise. In the Feh1 Lab, we are interested in how cancers utilize sugars to develop and grow. One sugar of interest to us is the glucose-derived N-Acetylglucosamine. (GlcNAc) GlcNAc is used to modify proteins post-translationally, becoming O-linked β -N-acetylglucosamine, and can impact a protein's localization, stability, and activity. O-GlcNAc levels have been shown to increase in cancer but decrease in neurodegenerative disease significantly. As such, our cells must carefully regulate O-GlcNAc modifications. The study of O-GlcNAc regulation is currently limited, however, as only two enzymes modulate the addition and removal of O-GlcNAc, O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA), respectively. These enzymes constantly cycle O-GlcNAc on and off proteins to maintain a basal O-GlcNAc modification level. However, relatively unknown mechanisms shift this regulation towards high or low O-GlcNAc in varying disease states. One mechanism behind O-GlcNAc regulation is the complexation of OGA and OGT in vivo. It is theorized that when GlcNAc concentration is relatively stable, these enzymes will inactivate each other; likewise, when GlcNAc levels vary, these enzymes will dissociate and regain their activity. Several studies have confirmed that OGA and OGT form a complex in vitro, with a crystal structure released in recent years. However, to our knowledge, this complex has not been confirmed in vivo. We aim to verify the interaction of OGA and OGT in vivo via Förster Resonance Energy Transfer (FRET). This technique uses fluorescent microscopy to confirm protein-protein interactions in live cells. We have successfully designed our system to tag OGA and OGT with light-releasing tags, and our FRET experiments are underway. We are confident that confirmation of an in vivo OGA and OGT complex would provide a key regulatory mechanism behind O-GlcNAc cycling in various disease states.

Abstract Name: Mental Health Treatment Choice in a Queer Population

People who identify as queer - members of gender and/or sexual minority groups - face unique stressors in society both on a personal and political level. Increased incidence of anxiety, depression, and PTSD in the queer population due to novel stressors like discrimination or dysphoria can lead to complex problems. First-line treatment options, which are those that are considered standard options by mental health professionals, may not be the best suited interventions for these issues. Previous studies have looked at the barriers to accessing therapy that queer people face, but few studies have looked at individual perceptions of different interventions despite it being an important factor in therapeutic success. This study sought to assess queer people's perceptions of and preferences for mental health interventions whilst also examining their relationship with and perception of mental healthcare. Participants (n = 112) were recruited through snowball sampling and our university's online participant pool (SONA). Status as a gender or sexual minority group member was self-reported. Our survey assessed demographic information, anxiety, depression, PTSD symptomology, interest in mental health interventions, and attitudes towards seeking counseling. A list of mental health interventions was developed that was organized by first-line (empirically validated and approved options, considered standard options by mental health care professionals), alternative (conditionally approved for treatment by the APA), and experimental (interventions that are still seeking empirical validation) treatments. Brief summaries of the treatment options were provided and participants were then asked to indicate their willingness to participate in each treatment. Data suggests that queer individuals tend to prefer first-line and alternative treatments, with interventions that medicalize mental illness being the most unpopular. Results could inform clinicians who work with queer populations on possible attitudes that exist towards different interventions.

Abstract Name: Optimizing Solar Energy Efficiency Using Machine Learning Models

The global shift toward renewable energy is critical for combating climate change and ensuring sustainable energy supplies. Solar energy systems, as one of the most promising renewable energy sources, face challenges in optimizing efficiency due to complex dependencies on environmental conditions and energy output. This research aims to address these challenges by applying machine learning models to predict solar energy output and identify the key factors affecting efficiency. The study utilizes plant-level data from the California Energy Commission, including variables such as plant type, geographic location, and energy production metrics. Environmental datasets, including solar irradiance and weather patterns from the National Renewable Energy Laboratory, are integrated to identify trends and relationships. Machine learning models—such as Linear Regression, Decision Trees, and Random Forest—are utilized to develop predictive models and evaluate the influence of environmental variables on energy efficiency. While the primary focus is on California plants, the research may expand to other regions depending on data availability and relevance. By combining machine learning techniques with comprehensive datasets, the study aims to generate actionable insights into optimal solar panel configurations and strategies to improve energy output. Anticipated outcomes include a predictive model capable of estimating solar energy output under varying conditions, as well as recommendations to reduce inefficiencies, enhance system reliability, and support the widespread adoption of renewable energy. These findings will provide valuable contributions to advancing global sustainability efforts and addressing the pressing challenges of climate change.

Abstract Name: Leveraging Transfer Learning for Pneumonia Detection: Fine-Tuning a Deep Neural Network Model for Medical Imaging

Recent developments in Artificial Intelligence and Machine learning have enabled more efficient and precise medical diagnosis. Still, the development of these AI and ML models from scratch is expensive and time-consuming. An alternative to creating these models from scratch is fine-tuning pre-trained models. Attempts were made to create such models for pneumonia detection. Tensorflow with Keras API was used as the framework. Resnet-50 weighing ImageNet was used as the pre-trained Convolutional Neural Network model and fine-tuned to detect pneumonia in X-rays collected from children ages 1-5 visiting Guangzhou Women and Children's Medical Center. Multiple data augmentation and preprocessing modifications were applied to the training dataset including `rescale=1./255`, `shear_range=0.2`, `zoom_range=0.2`, `horizontal_flip=True`, `rotation_range=15`, `width_shift_range=0.1`, `height_shift_range=0.1`. Batch sizes containing 16 images were used for training, validation, and testing of the model. Class weighting was used as a method to compensate for imbalances between the number of pneumonia and normal classes. Only the last 10 layers of the ResNet50 model were set to be trainable. GlobalAveragePooling2D was used to reduce the dimensionality of

feature maps. The dense layer had 128 neurons with relu activation and regularized via L1L2 regularization, dropout rate for this layer was set at 0.3. The final dense layer contained 1 neuron with sigmoid activation. Adam was used as the optimizer for this model with an initial learning rate of 10^{-4} subject to modification by the ReduceLROnPlateau function. Binary-cross-entropy was used as the loss function. 25 epochs (training rounds) were used to train the model. The fine-tuned model was able to detect normal and pneumonia cases with a precision of 0.89 and 0.97 and F1 scores of 0.92 and 0.95, respectively. These findings demonstrate the promising use case of transfer learning in creating efficient and effective deep learning models for medical image classification.

Abstract Name: Use of Eggshell Waste to Neutralize Low pH Water and Wastewater

This research explores the feasibility and benefits of using eggshell waste (ESW) as a cost-effective and environmentally sustainable alternative for neutralizing acidic waste streams. Due to mining activity, rocks containing sulfur and other compounds can become exposed to air and water, creating acidic runoff. This contaminated water can harm plant and animal growth, and in extreme scenarios damage human infrastructure. Current methods of acidic wastewater treatment include the addition of limestone, which adds operating costs and can further the environmental burden. ESW is largely made up of the same material as limestone, calcium carbonate (CaCO_3). CaCO_3 is important as it is the primary chemical that performs the adsorption. In addition, using ESW can provide use for materials that are often landfilled. This research explores both batch and fixed bed processes to test the neutralization capacity of different sizes, types, and preparation methods of ESW. With this, testing ESW's in various acids was performed to analyze its effectiveness in industrial settings. In multiple experiments, ESW has demonstrated neutralization performance similar to limestone, and recent work has started to investigate performance in fixed beds. Beyond the immediate economic advantages, such an approach underscores a broader commitment to resource efficiency and environmental stewardship. By capitalizing on the inherent value of food waste and promoting circularity in resource utilization, this innovative solution holds promise for advancing sustainability objectives across diverse industries and geographic regions.

Abstract Name: Art that Makes a Statement: A Comparison of Art in Relation to the Vietnam War

This study will examine how the Vietnam War impacted art in both the United States and Vietnam with a specific emphasis on the artists Peter Saul, Martha Rosler, and Tiffany Chung. Though there is a large amount of writing about the Vietnam War and its impacts, there is little research done through the artistic perspective.

I argue that the artistic representation from all sides is crucial in understanding the extent of this war's societal impact. This argument will be supported through national archives, refugee biographies, artistic references, and art historical writing. First, I will briefly discuss the background of the war and its tragic consequences on Vietnamese people and humanity in general. Then, I will provide references to the direct impact and influence of the war in American artworks, focusing on Peter Saul's and Martha Rosler's works. Following will be a description of the impact of the war on the Vietnamese people, as revealed in art. I will provide examples through the work of contemporary artist and Vietnam refugee, Tiffany Chung. This study holds value because this war caused a great division between two nations as well as within the nations themselves. Because of this division and conflict, both societies have been changed, which was inevitably reflected through an artistic lens.

Abstract Name: Effects of brachial plexus birth injury on muscle spindle quantity in biceps, supraspinatus, and subscapularis muscles

Brachial plexus birth injury (BPBI) is a neuromuscular injury that occurs in about 1 out of every 1,000 live births, often causing lifelong shoulder muscle paralysis, reduced range of motion, and musculoskeletal deformities. Deficits depend on severity and location of injury (preganglionic vs. postganglionic), resulting in different effects on functional mobility and neuromusculoskeletal signaling that disrupt muscle and bone development. Muscle spindles are stretch sensory organs located within skeletal muscle responsible for afferent (sensory) signaling pathways and can be denervated following injury. We hypothesize muscle spindle quantity will be lower in injured limbs and higher in uninjured limbs to overcome limitations in injured limb muscle function. Sprague Dawley rats underwent surgery on one forelimb at 3-6 days postnatally: preganglionic neurectomy (n=8/endpoint), postganglionic neurectomy (n=8/endpoint), forelimb disarticulation (mimicking disuse without nerve injury, n=8/endpoint), or sham (n=6/endpoint). Biceps, supraspinatus, and subscapularis muscles were dissected for injured and uninjured limbs at 2, 3, 4, 8, or 16 weeks post-injury, snap-frozen, cryosectioned, and stained using hematoxylin and eosin. Muscle sections were imaged, and muscle spindles were counted. Limb comparisons were made using paired t-tests, and group comparisons were performed with Kruskal-Wallis tests (GraphPad Prism, $\alpha=0.05$). Analyses are ongoing to understand the progression of altered muscle composition following BPBI. Preliminary results indicate that muscle spindle quantity was greater in the uninjured biceps muscles following postganglionic neurectomy than following forelimb disarticulation at 3 weeks ($p<0.05$), tended to decrease in injured and uninjured biceps and supraspinatus muscles from 2 to 16 weeks following sham neurectomy ($p<0.1$), and decreased from 2 to 16 weeks following forelimb disarticulation ($p<0.05$). This study is the first to characterize progressive changes to muscle spindles after BPBI injury, which may inform optimal treatment timing, as well as potential mechanisms underlying muscle detriments following BPBI.

Abstract Name: When Trauma Lasts: How The Histories We Carry Shape Us

How does trauma, experienced over generations, impact identity – both individual and familial? This study aims to explore how intergenerational trauma occurs, functions, and interacts with family history, collective memory, and concepts of identity within the matrilineal line of a family. As a case-study utilizing oral history interviews with family members across three generations, the project aims to explore the family history of intergenerational trauma to then be analyzed and synthesized with existing research. Trauma experiences within the case study include immigration, parental abuse, domestic violence, familial estrangement, disability, and religious abuse. Unlike most existing research, the methodology utilizes oral history as the primary vehicle for data collection with interdisciplinary focuses on the conversation between family history, identity, and collective memory under familial intergenerational trauma. The results will inform the fields of family history, public history, memory, and mental health, among others. Specifically, the study will provide holistic analysis on the transmission, perceptions, and impacts of intergenerational trauma on the family history narrative and familial relations. The study emphasizes the opportunity of future work to promote empowerment over silence when grounding one's identity against family history.

Abstract Name: Addressing Mental Health Barriers Among Ethiopian-American Youth in the Dallas-Fort Worth Metroplex

Mental health challenges among Ethiopian-American youth remain underexplored, particularly in the Dallas-Fort Worth (DFW) metroplex, home to one of the largest Ethiopian diasporas in the United States. This study investigates barriers inhibiting mental health resource utilization among Ethiopian-American young adults aged 16-30. Cultural stigma, lack of awareness, and financial barriers are critical factors discouraging individuals from seeking care. Employing mixed methods, the research gathers quantitative data through surveys distributed among youth via Ethiopian Orthodox Tewahedo Church networks and East African student associations. Qualitative data is collected through focus groups and interviews with Ethiopian-American youth, church leaders, and healthcare providers to explore cultural attitudes and potential interventions. Findings will inform culturally sensitive solutions, including the development of faith-integrated workshops and community programs designed to destigmatize mental illness and improve access to mental health care. The study emphasizes the critical role of the Ethiopian Orthodox Church, leveraging its trusted position within the community to bridge the gap between mental health resources and those in need. Additionally, collaboration with mental health professionals ensures that proposed interventions align with both cultural and clinical standards. This research not only aims to uncover systemic barriers but also to provide actionable recommendations for fostering a supportive environment where Ethiopian-American youth can seek mental health care without fear of judgment or stigma. By addressing these barriers holistically, this study contributes to improving the mental well-being of this underserved population while offering a model for similar immigrant communities.

Abstract Name: Puromycin Resistance and Transfection Challenges with Primary Glioblastoma Stem Cells

Glioblastoma (GBM) is a highly aggressive malignancy, with its complex and adaptive tumor microenvironment (TME) contributing significantly to therapeutic resistance and rapid progression. A critical focus in understanding GBM biology is characterizing the extracellular matrix (ECM), a glycosylated network of proteins and glycans that is profoundly remodeled in tumors. Efforts to manipulate the ECM, such as targeting glycosaminoglycan biosynthesis through gene knockdown (e.g., XYLT1), are promising but face substantial technical hurdles. Transfection of primary patient-derived glioblastoma stem cells (GSCs) presents unique challenges compared to immortalized cell lines. These challenges include low transfection efficiency, variability in cellular viability post-transfection, and difficulties in achieving stable gene knockdown or overexpression due to the heterogeneity and sensitivity of primary cells. Furthermore, patient-derived GSCs frequently exhibit resistance to antibiotics, such as puromycin, which are used to select successfully transduced cells. This resistance complicates the screening process, as higher concentrations of antibiotics are required, often compromising cell viability and limiting the scalability of experiments. Optimizing antibiotic selection conditions, such as balancing puromycin concentration to achieve effective selection without excessive cytotoxicity, has proven particularly difficult in our studies. Additionally, primary GSCs often show variability in viral transduction efficiency, necessitating rigorous optimization of lentiviral titers (transfecting units, TU/mL) and infection protocols. For example, generating viral particles to efficiently knock down XYLT1 in these cells while maintaining their viability requires extensive trial and error, especially when combined with the challenges posed by antibiotic resistance. Future work must address these technical challenges through innovative approaches to enhance transfection efficiency, refine antibiotic selection strategies, and ensure the reproducibility of functional assays in patient-derived models. Overcoming these obstacles is essential for advancing ECM-targeted therapies and evaluating their potential to disrupt tumor progression and therapeutic resistance in GBM.

Abstract Name: The Relationship Between Culture and Parenting Styles on Young Adult Intimacy

This study examined the interconnections between cultural orientation (individualism vs. collectivism), childhood parenting styles, and their combined influence on intimacy in adulthood. While prior research has explored these factors separately, few studies have integrated parenting style and cultural orientation to investigate their joint impact on intimacy and relational dynamics. Meta-analytic findings suggest that authoritarian parenting is more prevalent in collectivistic cultures, where group harmony and collective well-being are prioritized over individual needs and autonomy. Additionally, studies show that authoritative parenting—marked by a balance of structure and responsiveness—has been associated with higher levels of intimacy, particularly in friendships. Though research on romantic relationships remains limited, existing evidence suggests that authoritative parenting promotes greater overall intimacy, which may extend to romantic contexts. Conversely, collectivistic cultures are often associated with lower intimacy levels compared to individualistic cultures, possibly due to reduced autonomy, a critical factor in fostering secure

attachments and intimacy. This study sought to address these gaps by examining these variables in tandem. A convenience sample of 34 undergraduate students from Eastern Connecticut State University participated in the study by completing validated self-report measures: the Parental Authority Questionnaire, the Individualism-Collectivism Interpersonal Assessment Inventory, and the Personal Assessment of Intimacy in Relationships-Revised. The study hypothesized that (1) collectivism would positively correlate with authoritarian parenting, (2) authoritative parenting would positively correlate with intimacy, and (3) collectivism would negatively correlate with intimacy. Using Pearson's r correlation, results confirmed significant relationships between collectivism and authoritarian parenting; participants who experienced authoritarian parenting were more likely to come from collectivistic cultural backgrounds. However, no significant correlations were observed between parenting style and intimacy or between culture and intimacy. These findings highlight the complexity of these relationships and underscore the importance of further research with larger, more diverse samples.⁴

Abstract Name: Lectin Profiling of Altered Glycosylation in Severe Traumatic Brain Injury Lesions

Severe traumatic brain injuries (sTBI) lead to chronic secondary neuroinflammation, which often culminates into brain tissue atrophy and volume loss, and is associated with poor clinical outcomes. Changes in N-glycosylation (Asn-linked glycans to glycoproteins) on immune cells have been shown to play a critical role in inflammation. High-mannose N-glycans on endothelial cells can facilitate immune cell adhesion to inflamed tissues. However, changes in mannosylated N-glycan signatures on brain-resident cells after sTBI, have not been characterized. We hypothesize that sTBI leads to the upregulation of high mannose N-glycans on activated microglia and reactive astrocytes. We used a controlled cortical impact-suction ablation (CCI-SA) model to induce sTBI in Sprague Dawley male rats. Sham animals ($n=4$) underwent craniotomy without injury, while CCI-SA animals received craniotomy and CCI on Day 0, followed by suction ablation (SA) on Day 2 ($n=4$). Animals were euthanized 5 weeks after sTBI and brain tissue was flash frozen and cryosectioned. Immunohistochemical analysis was performed to stain for mannosylated N-glycans using Concanavalin-A (Con-A), ionized calcium-binding adaptor molecule 1 (IBA1) to label activated microglia, and glial fibrillary acidic protein (GFAP) to label reactive astrocytes. Our results revealed a significant upregulation of IBA1+ activated microglia in CCI-SA tissue, compared to Sham controls ($p<0.001$). An increase in IBA1+ cells corroborated with significant upregulation in Concanavalin-A (Con-A) expression ($p<0.0001$). We observed a significant correlation between IBA1+ microglia and Con-A expression ($p<0.0001$). Additionally, GFAP+ reactive astrocytes were significantly upregulated, bordering sTBI lesions ($p<0.0001$). Although Con-A expression showed an increasing trend around the perilesional area in CCI-SA animals ($p=0.0525$), there was a significant correlation between GFAP and Con-A expression ($p<0.0001$). These findings suggest that activated microglia and reactive astrocytes could contribute to elevated high-mannose glycans after sTBI, highlighting their role in chronic inflammation and altered glycosylation following brain injury.

Abstract Name: Evaluation of Distance-Related Emission of Radiation From Tablets and Laptops

The wide usage of electronic gadgets such as tablets and laptops in daily life has aroused concerns about exposure to electromagnetic radiation generated by these devices. This study is intended to measure the level of such radiation coming from a tablet and laptop while powered off and on as a function of distance. Through the use of standardized measurement protocols and equipment, we performed experiments to measure the intensity of radiation from various laptop and tablet models as they were positioned at different distances from the devices.

Abstract Name: Bioreduction of Copper-Contaminated Wastewater using *Shewanella Oneidensis* MR-1

Copper contamination in water poses significant environmental and health challenges due to its toxicity and persistence. > This experiment explores the use of *Shewanella*, a metal-reducing bacterium, as a bioremediation tool to reduce copper concentrations under aerobic and anaerobic conditions at different time intervals (24 hours, 1 week, and 1 month). Copper acetate solutions of varying concentrations (1, 2 & 4 mM) were treated with *Shewanella*, and copper levels were measured before and after bioremediation using spectrophotometric methods. > Results showed a significant decrease in copper concentrations in the long term after the bioremediation process. There was no significant reduction in the copper concentration after 24 hours of the bioremediation process, while the 1-week process showed a significant decrease only for the 1 mM concentration. In the following, it took one month to reduce high copper concentrations of 2 & 4 mM significantly. > These findings highlight *Shewanella*'s potential for eco-friendly copper remediation and provide a foundation for future applications in cleaning metal-contaminated water.

Abstract Name: Adolescent Type 1 Diabetes Mellitus and Self-Efficacy

AbstractBackground: Type 1 Diabetes Mellitus is a common disease affecting adolescents. This is a chronic condition that continues throughout life, requires supplemental insulin, and necessitates close monitoring of blood glucose to prevent complications. Adolescents are at a developmental stage focused on preparation for young adulthood, including increased independence. This independence becomes a sensitive issue when factoring in a chronic illness such as type 1 diabetes. Many researchers have identified barriers to adolescent diabetes self-management, and many have tried and failed to implement interventions to improve self-efficacy. The most effective modalities included family, nurses, and technology. Family systems theory assumes that all family members play a part in how each member of the family relates to each other and how the systems erupt as a whole. Nurses must understand the system as a whole to understand individual functioning within it. There is a need for research into the family systems of adolescents with diabetes and family perception of intervention effectiveness. **Purpose:** The study aims to evaluate the effectiveness of family-centered interventions compared to other intervention modalities for the outcome of improved self-efficacy. **Methods:** The study will survey participants using a qualitative design with open-ended responses using both Family Systems Theory and The Adolescent Autonomy Questionnaire (AAQ). **Conclusion:** Many barriers to adolescent self-efficacy exist, and these barriers are not entirely understood. The research chosen will uncover the complexities of this issue and provide insight to guide future interventions. **Keywords:** Adolescents, Diabetes, Self-efficacy, Family, Management

Abstract Name: Understanding the Stateless Rohingya Refugee Community in Buffalo: Resettlement Experiences and Educational Aspirations

This research explores the lives of stateless Rohingya refugees resettled in Buffalo, focusing on their resettlement experiences and the educational aspirations of the Rohingya youth. Given the lack of scholarly literature on the Rohingya in the U.S., this study aims to fill a critical gap by providing insights into the unique challenges faced by this community, particularly after the end of the U.S. resettlement support program, which only lasts for the first three months. The study employs a mixed-method approach, including interviews with Rohingya adults and surveys of Rohingya students and resettlement agencies. Findings suggest significant barriers due to illiteracy, lack of a written language, ongoing trauma, and lack of continuous support, which exacerbate difficulties in adapting to life in the U.S. They struggled with life-and-death situations most of their lives and never got the opportunity to understand the value of education. The research highlights the need for improved support systems, especially tailored to the unique linguistic and cultural needs of the Rohingya. The study suggests that a Rohingya-led organization could greatly benefit the community in the long run as it will allow the community members to receive the services in a language that they understand, and it can also play a major role in helping the Rohingya students pursue their further education by exposing them to careers that they never thought existed. The implications of this study could inform more effective resettlement strategies and advocate for better educational pathways for Rohingya youth. The project also opens avenues on refugee studies, education in underserved communities, and trauma in displaced populations and contributes to ongoing discussions about creating sustainable support networks

within refugee communities. More research is needed to understand these experiences longitudinally and qualitatively.

Abstract Name: Sleep Quality, Physical Activity, and Healthcare Utilization Amongst Adults with Chronic Kidney Disease (CKD)

Proper sleep efficiency and physical activity are common concerns in those with chronic diseases, including chronic kidney disease (CKD). High levels of physical activity have been associated with less healthcare utilization in the general population, while markers of poor sleep efficiency (insomnia) have been associated with greater healthcare utilization. Though there has been previous research on the risk factors for both poor physical activity and sleep efficiency in those with CKD, little research has drawn associations between these two measures and other patient-reported outcomes. The current study therefore sought to answer the following question: “Are sleep quality and physical activity associated with healthcare utilization by adults with CKD?” In this investigation, patients from CKD advocacy groups were recruited via an online survey for remote sleep and step data collection over 8 weeks utilizing a Fitbit watch. Participants also completed a Demographics survey, a Healthcare Utilization survey, and an abbreviated Kidney Disease Quality of Life Instrument during data collection. Descriptive statistics were used to summarize demographic data, and logistic regression models were used to determine the associations between participant characteristics and sleep efficiency, and healthcare utilization. Linear regression was used to assess the association of patient characteristics and step counts. Adjusted and unadjusted logistic regression modeled the association between step count and sleep efficiency with healthcare utilization. It was observed that greater sleep quality (defined as $\geq 90\%$ mean sleep efficiency) and higher step count (defined as ≥ 5450 steps per day) were associated with less healthcare utilization (defined as ≤ 5 doctor visits within 1 year) in both unadjusted and adjusted models. This data can be used to implement advantageous changes for patients in healthcare practice and policy, such as future interventions that improve sleep quality and step counts, thereby lessening healthcare utilization and the financial burden of healthcare for patients.

Abstract Name: Voting Behavior of Minorities in Panama and Peru

Many scholars have attempted to estimate minority support for political parties in various countries worldwide. These measures can help researchers understand the extent to which minorities are included in government and the institutions that can promote minority inclusion. This project contributes to this research by estimating the voting behavior of ethnic minorities in Peru and Panama. For Panama, I used data from the 2019 election and the 2023 census. For Peru, I used the 2021 election and the 2017 census. Much of the focus

was on gathering and cleaning census and election data from Panama and Peru, focusing on ethnic populations and party vote totals from each political unit. Separate R programs had to be developed to organize the raw data into files that could be quickly sorted by political unit and minority group. I could then use this data to perform ecological inference analysis, which gave estimates of the percentage of each ethnic group that voted for a political party. In general, minority groups in Panama, including indigenous groups and Afro-Panamanians, voted at relatively similar rates to non-minorities. In Peru, the situation was different—the Free Peru party, the winner of the 2021 election, saw much more significant support from indigenous groups than the rest of the population. These results suggest that minorities in Panama vote based on values and interests much more aligned with the rest of the population than minorities in Peru. However, more research should be done to fully understand the implications of these results on minority inclusion.

Abstract Name: Influence of Shared Ancestry on the Expression of Traits in Tissues

Like all living things, cells and tissues have an evolutionary pathway that has led to their genetic and physical makeup. The concept of evolutionary history has been used commonly in ecological frameworks when studying species and organisms but is frequently missing from medical research. This has led medical research to treat diseases like cancer as individual occurrences or populations, rather than having relatedness through their shared ancestry. In this research, we extensively reviewed the literature to create an accurate phylogenetic tree portraying the developmental pathways of human tissues from the point of fertilization to the point of viability. With this phylogeny, we analyze the shared ancestry of tissues and their relationship to traits, such as genes, material properties, cancer risk, and stem cell divisions, to determine whether their expression is phylogenetically patterned. We use BayesTraits, a phylogenetic analysis program, to calculate the phylogenetic signal, Lambda, to determine the importance of shared ancestry on how the trait is expressed across our phylogeny. Then, we compare traits at set phylogenetic signals, among other tests, to determine the best-fit model, recommending that trait for future research. Through this project, we hope to highlight the non-independence of tissues and emphasize the importance of evolutionary lineages in studying medical topics. Additionally, we hope to find traits that significantly link to cell phylogeny for future research, in our lab or elsewhere, to help find cures for diseases like cancer.

Abstract Name: Cardiopulmonary and Neuroendocrine Involvement in Sleep Disturbance in People with Dysautonomia

The autonomic nervous system (ANS) regulates many physiological processes that occur during sleep such as

blood pressure (BP), heart rate (HR), and respiratory rate (RR). Cardiopulmonary and neuroendocrine functions vary from wakefulness to sleep states and during different parts of sleep. Given the involvement of the ANS in physiological processes that occur during sleep, it is not surprising that sleep disorders and non-restorative sleep are a common complaint by people affected by autonomic dysfunction. The goal of this study is to describe the occurrence of disturbed sleep in dysautonomia, focusing on the effect that dysfunction of the autonomic nervous system has on cardiopulmonary and neuroendocrine physiology during sleep. To this end, we conducted a literature review to synthesize the known physiological mechanisms that are regulated by the ANS during sleep. We found that the ANS may improperly regulate cardiopulmonary parameters such as HR, BP, and RR during different sleep stages but also the inhibition or activation of hormones involved in the control of stress growth, development, and many other neuroendocrine parameters. The parasympathetic ANS maintains the body in a calm state, especially in non-rapid eye movement (NREM) sleep, decreasing HR and RR. During REM sleep, which is when dreams occur, the sympathetic ANS increases the cardiovascular reflexes (i.e., control mechanisms) similarly to the state of wakefulness, increasing HR, RR, and BP. Future studies should aim to improve our understanding of sleep disturbance in dysautonomia, including its prevalence and impact on quality of life.

Abstract Name: Aquí y Ahora: The Role of US Spanish-Language TV News in Financial Vulnerability

In today's world, the news we watch often does more than inform us; it can shape how secure or insecure we feel about our future. In this paper, I examine the extent to which an individual's consumption of particular Spanish-speaking TV news channels contribute to their sense of financial vulnerability. Using an original data set of responses to the questions in the 2022 American National Election Studies (ANES), I find a moderately strong relationship between the television news channel Aquí y Ahora, and the degree to which they are worried about their financial situation. While it is true that various factors such as employment status, household size, and marital status contribute to this financial worry, a person's choice of television station can be an indicator of an increased sense of financial insecurity. This suggests that watching Aquí y Ahora, especially for immigrants and first generation Americans, may influence financial distress, leading to a tense relationship with personal finances, economic uncertainty, and low financial confidence. Therefore, it is highly important to recognize media biases within the Spanish-speaking television networks to address the urgent need for informing the immigrant and first-generation Hispanic population on how news may influence their opinions. Ultimately, this highlights how critical it is to be cognizant of communication rhetoric in Spanish-speaking television networks to accurately inform the Hispanic population while setting them up for upward financial mobility.

Abstract Name: Probing the Structure of the Serotonin Transporter by Crosslinking and Mass Spectrometry

Serotonin is a neurotransmitter that improves mood and mental wellness. The serotonin transporter (SERT) re-uptakes serotonin from the synapse back into pre-synaptic neurons. Selective serotonin reuptake inhibitors (SSRIs) target SERT and are used for treating anxiety/depression but are not always effective. We propose to better understand SERT structure to facilitate more effective therapeutic design. To do this, SERT was tagged with the mutation L406C in an extracellular loop to contain a single Cystine residue that can be targeted by crosslinkers. Overexpressed SERT was purified, reconstituted, and crosslinked with methylthiosulfonate-benzophenone. After photoactivation, SERT was isolated by gel-electrophoresis and proteolyzed for bottom-up mass spectrometry (MS) to identify crosslinked residues in the vicinity of the introduced mutation. In the future, MS/MS will be performed to identify specific residues that are crosslinked within mass-shifted peptides. Further refinement of SERT structure will allow for subsequent design of more effective and selective SSRIs in the future.

Abstract Name: The Lightbulb Tunicate: A Study of Climate Change, Invasion Ecology and Risk Assessment

Clavelina oblonga, also known as the lightbulb tunicate, is an ascidian species native to the Caribbean. Over the last 80 years, it has invaded throughout western Europe and on the eastern seaboard of the United States from South Florida to portions of South Carolina and, most recently, Beaufort, NC. This isolated invasion has putatively occurred as a result of ballast water in shipping. Our research involved hand sampling docks along the North Carolina coast to observe occurrences of this species and map how far it has spread since it was first observed in the state in 2014. We have combined this data with citizen science and museum data to generate comprehensive maps using GIS software. These maps demonstrate the current geographic distribution and environmental conditions. We also modeled the location of suitable habitats across the globe. Using these results, we evaluate the threat that this species poses in North Carolina and beyond.

Abstract Name: Determining Casual Relationship Between COVID-19 and Acute Kidney Injury Using Mendelian Randomization

Acute kidney Injury (AKI), previously known as Acute Renal Failure (ARF) is characterized by a sudden loss of the ability to filter blood. AKI has been observed in over 20% of COVID-19 hospitalizations, occurring at twice the rate among patients admitted to intensive care units. Approximately 10% of these cases require dialysis, and AKI is linked to high mortality rates even after hospitalization. While these clinical associations have been documented, the causal relationship between COVID-19 and AKI remains unclear due to potential confounding factors and mediators. To address this, we conducted a Mendelian randomization (MR) analysis to investigate the causality of relevant quantitative traits. MR is a statistical method used to infer causal relationships between risk factors (exposures) and outcomes using genetic variants as instrumental variables (IVs). These genetic variants are assumed to be randomly assigned at conception, mimicking a randomized controlled trial and mitigating confounding and reverse causation. This analysis utilized a combined dataset of genome-wide association studies (GWAS) summary statistics from multiple COVID-19 studies across different hospitalization levels, integrated with GWAS summary statistics for AKI for European populations. By applying robust MR methods, such as inverse-variance weighted (IVW) analysis, MR-Egger regression, and weighted median estimation, we aimed to address potential pleiotropy and ensure reliable causal inference, shedding light on the genetic interplay between COVID-19 severity and AKI risk.

Abstract Name: Addressing Educational Disparities and Strengthening Community Cohesion: A Multi-dimensional Study

This study examines the intersection of socioeconomic status, public perception of government policies, and community development programs in shaping educational equity and community resilience at the University of Central Oklahoma (UCO). Using a mixed-methods approach, the research employs a large-scale survey targeting approximately 10,000 UCO students to assess their perspectives on access to educational and community resources, financial barriers, and perceived equity in institutional support. The findings will be compared with state and national data to contextualize UCO's environment within broader educational trends. Grounded in Social Capital and Educational Equity theories, this research highlights how systemic barriers and community networks influence student outcomes. Preliminary insights suggest significant disparities tied to socioeconomic factors, underscoring the critical role of localized policies and community programs in addressing educational inequities. The study concludes with actionable recommendations for UCO administrators and policymakers, emphasizing the need for enhanced financial aid, expanded support services, and strengthened community partnerships to foster resilience and equity. This research aims to contribute to a deeper understanding of how targeted interventions can bridge gaps in educational access and support sustainable community development.

Abstract Name: Exploring The Role of Shame In The Relation Between Cannabidiol And Problematic Alcohol Use: A Randomized Double Blind, Placebo-Controlled Trial

Background: For millions of Americans suffering from clinically relevant alcohol use problems, evidence-based treatments can be difficult to access (Kranzler & Soyka, 2018); thus, novel therapeutics are necessary. Cannabidiol (CBD) presents broad therapeutic potential (Blessing et al., 2016). Data suggest that CBD has the potential to reduce problematic alcohol use (Viudez-Martinez, 2020); however, no work has examined the role of shame in this context. Shame is a complex emotion involving a negative evaluation of the self (Dearing et al., 2005) and is related to problematic alcohol use (Luoma et al., 2019). From a theoretical perspective, trait shame may be expected to attenuate the effects of CBD on alcohol-related problems. The current study aims to assess the effects of 300mg CBD versus placebo administered daily for 3 weeks on alcohol-related outcomes as a function of shame proneness. Methods: 34 participants (Mage = 24.43; SDage = 6.26) who met criteria for hazardous drinking (along with a set of eligibility criteria ensuring participant safety and reducing scientific confounds) were randomly assigned to condition (300mg CBD or placebo) and instructed to self-administer the product daily for 3 weeks. The Test of Self-Conscious Affect (TOSCA; Tangney et al., 1989) was administered to assess trait shame at baseline, and the Alcohol Craving Questionnaire (ACQ; Singleton et al., 2014) was administered to assess alcohol cravings at three weeks. Results: Preliminary findings suggest that there were no main effects of condition ($b = -0.23$, $t(30) = -0.16$, $p = .875$, $\eta^2 = 0.004$) or trait shame ($b = 0.005$, $t(30) = 0.16$, $p = .872$, $\eta^2 = 0.003$) on alcohol craving. Additionally, there was no condition by trait shame interaction ($b = 0.003$, $t(30) = 0.07$, $p = .943$, $\eta^2 = 0.0002$) for alcohol craving. Conclusions: Given the small sample size of the current study, more work is needed to discern the effects of CBD on alcohol-related indicators.

Abstract Name: Total synthesis of cevanine-type Veratrum alkaloids

A strategic total synthesis that aims to access members of the Veratrum family of cevanine-type alkaloids. The Veratrum family of alkaloids all share a unique C-nor-D-homo [6-6-5-6] steroid skeleton and can be divided into three subtypes based on the connectivity to its piperidine ring with the cevanine-type being the largest subtype. The synthetic approach explored utilizes an asymmetric synthesis of a propargyl-substituted piperidinone fragment and an enantioselective synthesis of a bicyclic diyne fragment. After the unification of these two fragments an intramolecular [2+2+2] cycloisomerization reaction is performed creating three additional rings to offer total access to the Veratrum steroidal alkaloid family.

Abstract Name: Induction of Secondary Metabolites in Bat-associated Bacteria using SAHA to Fight White-Nose Syndrome

Bat populations in North America are in decline due to the fungus *Pseudogymnoascus destructans*, the species that causes White-Nose Syndrome (WNS). Over 7 million bats have died in the last decade from this disease, greatly harming ecosystems and agriculture. Fortunately, some caves are still WNS free, leading scientists to explore how bats living in these caves obtain protection from this disease. In a recent study, 632 bacterial isolates from WNS-free bats were isolated, 36 of which had antifungal activity against *P. destructans*. Interestingly, the compounds responsible for this activity were not identified. A pilot study on 18 bioactive strains from this study identified a set of target metabolites with putative antifungal activity. The most bioactive bacterium, *Streptomyces buecherae* AC536, was chosen for scale up growth for targeted isolation studies. Unfortunately, upon scale up growth, the target metabolites stopped being produced, most likely due to a lack of required environmental triggers in a laboratory setting. Bacterial biosynthetic pathways are under strict transcriptional regulation so that energetically expensive products are only formed when they provide a competitive advantage. To activate these silent biosynthetic pathways, we varied growth conditions by adjusting temperature, light exposure, carbon source, and/or chemical additives. Interestingly, growth of AC536 in the presence of the histone deacetylase inhibitor suberoylanilide hydroxamic acid (SAHA) led to significant upregulation of secondary metabolites. We have identified six compounds that are reproducibly upregulated or completely unique to SAHA-treated cultures compared to controls and putative identifications of these compounds made using mass spectrometry data. Due to the success of the SAHA treatment, 10 of other bat-associated bacteria have been treated with SAHA and mass spectrometry based metabolomics analyses are underway to identify new and upregulated products.

Abstract Name: Exploring the Cytotoxic Effects of Fungal Secondary Metabolites on Human Cancer Cells

Fungi are eukaryotic cellular organisms that compete with other microorganisms to survive in a niche environment. They do so by releasing chemical defensins, some of which are toxic to competing fungi. In this work, fungi were collected from trees and leaves and isolated to generate pure specimens. A Kirby-Bauer disc diffusion assay was used to select specimens that exhibited bioactivity against other fungi. We hypothesized that fungi exhibiting bioactivity against other fungi may also have a bioactive effect on cancer cells. Those fungi that exhibit bioactivity were selected and grown in pure culture using potato dextrose media. After growth their secondary metabolites were extracted using sonication followed by ethyl acetate treatment. The samples were further concentrated and the final extract recovered in dimethyl sulfoxide (DMSO). Human cancer cells were then challenged by the extract in a colony survival assay. Several cancer cell lines were grown using appropriate growth media and standard cell culture techniques. Cancer cells were plated uniformly in triplicate and challenged with the fungal extracts using DMSO treatment as a control vehicle. Several fungi showed a strong cytotoxic effect against cancer cells. We then hypothesized that fungi that showing cytotoxicity in a pure growth environment may show heightened cytotoxicity when grown in a competitive growth environment with another fungal strain. Fungal plugs from two different specimens were placed three inches apart from one another on a potato dextrose agar plate. When fungi were one-inch apart, specimens were collected from each strain and processed as described. Cancer cells will be treated with

extracts derived from fungi grown in isolation compared to those grown in a competitive environment to measure if there is an increase in cytotoxicity.

Abstract Name: Silent Soundscapes: The Instruments, Musicians, and Scores that Defined Storytelling in Silent Cinema

Our modern world of film has been characterized by blockbuster movies and elaborate soundtracks. This is a stark contrast to the humble beginnings of the film industry. Early film music served as a form of entertainment for the audience that allowed them to be more engaged with the production. During the 1920s, however, film music progressed from being mere entertainment to becoming a crucial part of defining characters and evoking emotions, actions, and narrative contexts. The diverse group of performers and instruments used in silent film music highlights the technical development that the music experienced through the decade. As the 1920s continued and silent films grew in popularity, early methods of scoring that relied on pre-existing musical materials gave way to scores specifically developed for large-scale productions. These scores were meticulously crafted to highlight the action on screen and to influence the emotions of the audience. This research analyzes the history of the silent film era in order to interpret the role music has in storytelling. Film scores, motifs, leitmotifs, and sound effects are examined to understand how they have influenced the way in which society assigns meaning to music. More specifically, this project analyzes how we have come to connect with certain themes and motifs as descriptive of emotions and actions. By examining the history of music in silent films, we can see how musical works have become synonymous with specific film genres and how we have come to view music as descriptive of the action on screen.

Abstract Name: Effect of Food Preparation on Vitamin C Concentration in Fruit

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available products and food items using titration techniques. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the highest concentration of vitamin C, a crucial antioxidant that plays a vital role in human health. The experimental approach involves titrating the samples, employing 2,6 dichloroindophenol (DCIP) as the titrant, chosen for its ability to exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one

color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. The goal of this team's project to find out how different food preparation affects Vitamin C concentrations in fruits. We will be testing this on three different fruits; pineapple, orange and lemons. The preparation techniques include boiling, freezing and dehydration. Samples of juice from the fresh fruits were tested in both the as obtained and processed condition. The analysis technique consisted of titration using a 2,6-dichloroindophenol sodium salt solution.

Abstract Name: The Elephant in the Room: Being Maasai, Tourism, and Conservation

This research investigates how the boundaries between indigenous religion, culture, and species conservation intersect through the lifestyles of the Maasai people in southern Kenya. Focusing on Maasai interactions with African elephants, the research examines how Maasai spiritual and cultural practices shape conservation efforts in a rapidly changing ecological landscape. The presentation explores four central arcs: 1) the influence of indigenous religious beliefs on Maasai perspectives toward land use, wildlife, and conservation; 2) ethical questions surrounding conservation responsibilities and the Maasai's role in land protection; 3) the often-overlooked role of animals in anthropocentric land-use decisions; and 4) the impact of tourism on conservation efforts. Drawing from ethnographic data collected through narrative inquiry and direct observations during fieldwork, this essay analyzes the complex interplay between religion and ecology and considers how social mobility—across geographical, cultural, and ethical boundaries—shapes conservation in this region.

Abstract Name: Automating Calibration of Colorado's Zephyr Meteor Radar Network with ADS-B Data

The upper mesosphere/lower thermosphere (MLT) acts as a middle ground between space weather's influence on the upper atmosphere and terrestrial weather. Understanding this region provides insights into how different layers of the atmosphere interact. It is difficult to collect atmospheric data in the MLT, as its high altitude makes dense in-situ sampling methods infeasible. The MLT is largely neutral, without electromagnetically reflective media for most remote sensing techniques. Meteors act as tracers of opportunity, enabling remote measurements of the MLT by analyzing returned radar signals. The Zephyr meteor radar network observes meteors by transmitting signals which reflect off the meteor trail and are

collected by the receiver. Interferometry and other techniques can be used to determine the meteors' precise location and environment. Small errors in antennas phase center can cause drastic errors in the estimated position of the meteor. These errors can be minimized by calibrating the network, achieved here by using objects with a known location, calibrating all system components at once. Airplanes are reflective targets that broadcast their location and velocity via ADS-B and are used here as known calibration targets, but the process so far is labor intensive. This project aims to automate the calibration process of Zephyr, reducing the need for human involvement. ADS-B data of planes traveling over Zephyr will be acquired through external sources and used to determine each plane's position. The expected phase for each transmitter receiver link will be computed based on the known location of the plane. This will be compared to received data from Zephyr. For each transmitter-receiver link, an offset is calculated so that the received phase matches the predicted phase. Extending this research, this project aims to determine guidelines of what makes a flight good for calibration and automate collecting flight data which meets those guidelines.

Abstract Name: The "No Bed Syndrome" in Ghanaian Tertiary Hospitals

The current global scarcity of hospital beds, especially in the developing world, is a major concern to human health. This paper explores Ghana's No Bed Syndrome, which is a phenomenon that describes the shortage of hospital beds. The hospital bed-to-1000 population in Ghana is 0.9 in 2021, which is extremely lower than the World Health Organization's (WHO) recommended minimum of 5 beds per thousand population. The main research question aims to understand how the lack of adequate hospital beds in Ghana affects access to quality healthcare and the interventions that can be adopted to address this problem, focusing on tertiary hospitals. This research enhances the study of public health by offering insights into the challenges faced in healthcare delivery in Ghana, contributing to the subject of healthcare infrastructure in developing countries. Although past studies establish the extent of global bed scarcity, this research studies system contributors in the Ghanaian context, including resource allocation, systemic issues, and patient behavior, further promoting high hospital overcrowding and delayed treatment. The study uses a sequential mixed-method approach, with qualitative key informant interviews with selected healthcare providers and quantitative data analysis to quantify the findings. Key findings reveal that "bed capacity" involves physical beds and the necessary resources to make them functional, including staff and equipment. Furthermore, the hierarchical healthcare structure in Ghana encourages decentralization, but inadequate resource distribution causes patients to bypass lower-level facilities and overburden tertiary hospitals. The results underscore the complex interaction between resource shortages, healthcare system inefficiencies, and patient behaviors, exacerbating the No Bed Syndrome. Effective interventions, such as increasing bed numbers and establishing Bed Bureau Offices, are already showing promise. The study concludes with recommendations for systemic reforms, including collaborations with key government ministries, public education, and resource allocation to lower-level healthcare facilities.

Abstract Name: The Political Economy of Climate Finance in Ghana

Climate finance has emerged as a critical subject in the global fight against climate change. This study provides insights into the political economy of climate finance in Ghana and how political factors impact the mobilization and allocation of climate finance resources. It highlights key political drivers such as policy measures, government engagement, international conventions like the Paris Agreement, intergovernmental organizations, and funding bodies. These drivers are crucial in influencing national strategies and the impact of climate finance policies such as the Ghana National Climate Change Policy (GNCCP). While climate finance is a critical tool for developing countries to combat climate change, the intersection of governance, international commitments, and local politics often complicates its mobilization and allocation. This research contributes new insights into these dynamics within the Ghanaian context. Some identified challenges include inadequate domestic resources, weak institutional capacity, cumbersome donor processes, corruption, absence of information, and lack of synergy among all stakeholders. The study provides a comprehensive understanding of the political facilitators and barriers to climate policy implementation. This study also adopts a qualitative research approach, using primary data collected through semi-structured interviews of participants within the categories of mid-level officials in the Ministries of Finance and Environmental, Science, Technology, and Innovation (MESTI), local government environmental officers, NGO, academics and researchers, private sector, international development organizations and donor agencies, and journalists. It employs thematic analysis, which involves the identification, analysis, and reporting of patterns or themes within data to analyze data. The study emphasizes that governance structures, institutional settings, and coordination play a significant role in enhancing the climate finance mobilization and allocation system. The study also offers policy implications such as enhanced domestic resource mobilization, enhanced institutional capacity, and strengthened transparency and accountability.

Abstract Name: Flood Disaster Declarations and Warnings in FEMA Region Five

Climate change is expected to increase the significance of floods over the next 25 years. Because of an increase in flooding, disasters will lead to more widespread economic damage. An example of this occurred in the Wisconsin Driftless area during the historic 2018 flood. Around 12 inches of rain fell in about six hours and was not retained by five out of 23 dams. This caused about \$14 million in public infrastructure damage in Vernon County, and approximately \$3 million in damage to homes and businesses in Coon County. With this in mind, the spatial and temporal relationship between flood disaster declarations and flood warnings in FEMA Region 5 are being examined. The ultimate purpose of this project is to identify if trends in flood disaster declarations and flood warnings are increasing in states comprising FEMA Region 5. Flood disaster data was collected from the Open FEMA Data Set v2. All disasters in the US are organized from Present-to-1953. Filtering of the data was required to categorize floods in FEMA Region 5 from 2023-1974. The total number of flood declarations were recorded, as well as each flood event by state and the number of counties affected by each incident. Analysis includes completing summary statistics to examine trends in flood hazard incidents, investigating changes in cost of impact over the 50-year period, and looking at precipitation amounts to see if any major changes have occurred during this time. Initial results show that Minnesota is

steadily increasing in the number of flood disaster declarations and counties affected, Wisconsin is subtly increasing in both, and Ohio is increasing in the number of counties impacted despite its decreasing flood declarations. With further examination we expect to see a seasonal correlation between these events, as well as economic damages increasing.

Abstract Name: State Sex Education Legislation as a Predictor of Sexual and Relationship Health

Recent research suggests there is an association between comprehensive sex education and improved sexual health—as demonstrated by lowered rates of STIs and teen pregnancy, as well as higher rates of contraceptive use in states with comprehensive sex education as compared to states without comprehensive sex education. Some further research suggests that gender equality education programs are related to lower levels of intimate partner violence, however there is still an overall dearth of literature regarding the association of sex education legislation and relationship health. This project aims to provide further insight into how sex education legislation is associated with this and other relationship health indicators by examining the relationship between legislative requirements such as consent education and medically accurate curricula and relationship health outcomes such as intimate partner violence rates, sexual health measures, and sex life satisfaction. The association between the requirement of consent education and intimate partner violence rates and the correlation between medically accurate curricula and sexual health will be computed as point biserial correlations; the association between statutory requirements and sex life satisfaction will be computed as a point multiseriate correlation. Finally, exploratory regression analyses will be carried out to determine which combination of legislation requirements best predicts each indicator of sexual health (teen birth rates and STI rates). By exploring existing health data sets, this study aims to clarify the relationship between relationship health variables, sex education, and legislation in the United States. These results can inform policy development around sex education in a direction that promotes higher-quality public health outcomes.

Abstract Name: Degrowth through a Psychological Lens

Degrowth is a socioeconomic ideology that recognizes the benefits that can come from a drawback from a mass-producing, over-consuming way of living. Our society has been mass-producing goods non-stop since the Industrial Revolution, which has only made the economy grow larger and larger in line with greater supply and demand. In recent years, the effects of these advancements have led us to the poststructuralist question: How has something that was initially better for our world turned against us? Many interpretations and critiques have been made in regard to the concept of degrowth. Some theorists believe, in fact, that we may reach a point where degrowth will be the inevitable result of extreme recession if we do not collectively

proceed with the movement ourselves, putting our materialistic values aside. Degrowth implies a regression from capitalizing off of ourselves for the sake of our own prosperity. It calls for a return to consuming goods from local businesses rather than continued investment in large corporations that already have ownership over most of the brands we buy. Perhaps most importantly, in regard to human psychology, degrowth can lead to enhanced community-building, where there is less emphasis on individualistic (self-reliant) living. This presentation will explore the societal and individual benefits of degrowth through the lens of critical-community psychology and psychoanalysis. It will consider the roots of growthism through a psychoanalytic lens, considering the following questions: How are our capitalist tendencies shaped by certain aspects of human nature? How do they influence and create our desires? Recent research has begun to pose these questions in response to not only the circumstances of today's world, but to those of our looming future. Ultimately, this presentation will consider the potential for strategic degrowth as a means of developing more promising directions for societal development.

Abstract Name: Business Case: People with Disabilities

This paper aims to determine whether a potentially causal relationship exists between the inclusion of people with disabilities in a company and that company's revenue, sales, profit, and market valuation. As such, this paper contributes to the academic literature examining the effects of corporate social responsibility (CSR) on firm outcomes. Most of this literature finds a positive correlation, but doesn't focus on the disabled population. To test this hypothesis I use the Disability Equality Index, assembled by the American Association of People with Disabilities and Disability:IN, to identify companies where people with disabilities are not structurally marginalized. I merge this index with financial and other firm level data obtained from Standard & Poor's Compustat for the years 2015 to 2019. Although the dataset goes up to 2023, I limit the timeframe of this paper to avoid the economic shock caused by the pandemic. The finalized dataset consists of longitudinal data on over 200 firms. First, I structure the index into a dataset sorted by year and firm. Because firm name usage varies (e.g., EY vs Ernst and Young) by year, I employ STATA's fuzzy matching technique to identify a firm's presence. Then I merge the resulting dataset with the Compustat data. However, not all firms in Compustat are in the index. Consequently, I use propensity score matching to obtain a more homogeneous control group. Lastly, I estimate a two way fixed effects model to test my hypothesis and use event study analysis to check for dynamic effects. These models control for industry, capital expenditures, number of employees, assets and survey year, to test if firms scoring over 80% on the index enjoy greater revenue, sales, profit, and market valuation. Preliminary interpretations indicate that results are sensitive to model specification, but there appears to be a strong relationship.

Abstract Name: Strengths and Challenges of School-Based Health Centers in South Carolina: Findings and Insights from Assessment

A host of barriers ranging from individual to macrosystem factors can prevent youth and adolescents in the United States from accessing timely healthcare. School-based health centers (SBHCs), can mitigate common barriers to care by providing primary care services directly to students in school settings. Despite the importance of SBHCs for youth and families, the capacity of these healthcare organizations to serve youth, particularly youth mental/behavioral health, is not well understood. In October 2024, the Youth Access to Psychiatry Program administered a state-wide asset and needs assessment to understand the landscape of school-based health (SBH) programs and centers in South Carolina. The assessment was distributed via an online survey to all identified SBH program administrators within South Carolina (n=17 SBH programs representing 292 SBHCs). Twelve SBH programs responded (71% response rate), reflecting 254 SBHCs. The assessment examined a variety of organizational factors, including operational and clinical characteristics. Results revealed that 86% of programs offer behavioral health services, 57% offer vision, 7% offer oral, and 57% offer health education resources. The majority of SBH programs (93%) indicated that they had access to mental health professionals within their program. Among telehealth programs offered, oral health care emerged as the sector with the greatest gap in service delivery across SBHCs. Barriers to care included limited client interest (58%), low-quality internet (50%), and a shortage of dedicated telehealth providers (50%). In this poster session, additional findings will be discussed along with implications for youth access to health services in school settings. Findings from the needs assessment are essential in evaluating the current strengths and growth edges across SBHCs.

Abstract Name: Mitotic Abnormalities in HPV+ Integrated Cervical and Intestinal Carcinomas by Histopathological Evaluation

The majority of cervical cancers are caused by the human papillomavirus (HPV), which also plays a major role in the development of various other cancers, including those of the head and neck, anal, vulvar, and penile regions. HPV causes chromosome instability through abnormal mitosis, leading to genomic instability, which is crucial for cancer development. This study sought to determine the spatial distribution of mitotic aberrations in HPV-positive integrated cervical carcinomas and compare chromosomal instability (CIN) caused by HPV to CIN in HPV-negative intestinal tissues, as CIN is a common feature of tumors. Through histological assessment. HPV-positive intestine and cervical tissues were used as controls. When compared to HPV-tissues, a comparative examination showed that HPV+ tissues exhibited a notably larger quantity of mitosis cells and aberrant mitotic events, such as multipolar mitosis, lagging chromosomes, and misaligned metaphase. These abnormalities suggest that normal cell division mechanisms are disrupted and there is an increase in genomic instability in HPV+ tissues. The study found that the viral oncoproteins E6 and E7 were important in causing these aberrant mitotic processes, which in turn led to the cells' malignant properties. The work effectively delineated the tissue regional distribution of mitotic aberrations using Hematoxylin and Eosin (H&E) staining and high-resolution scanning techniques, offering important insights into the processes of HPV-driven carcinogenesis. This study clarifies the significant influence of HPV integration on the mitotic cycle and cellular changes, which advances our knowledge of HPV-related cancer development

Abstract Name: Exploring the Axioms of Reality: A Comparison of Parasite (2019) and The Dark Forest (2008)

Liu Cixin's renowned sci-fi novel The Dark Forest introduces readers to two axioms of cosmic sociology. The first axiom is survival is a primary need of civilization, the second axiom is civilization continuously grows and expands. These two axioms operate following two important concepts, which are chains of suspicion and the technological explosion. Drawing from the novel's social cosmological theory, this presentation offers a reconsideration of Bong Joon-ho's directed film Parasite (2019), which portrays two families of drastically different status and their positions in the class system in Korea. The Kim family's house in the film is also an example of society's class system. While the wealthy high class is ever-growing and changing. The lower class is repressed and made to stay in the same poverty cycle, never able to break the cycle. [good; generational poverty] The lower class can never "go up the stairs" without fearing for their life. Because they might be discovered for what they really are. While the wealthy upper class can bask in the sun, buy new things, and not worry about life. At the end of the movie, Ki-woo says that he wants to make enough money to save his father and let him out of the basement. This imaginative arrangement in the son's mind however fosters multiple and sometimes conflicting interpretations. Both audiences from middle and upper-middle class and grassroots background can relate to the characters, and find a way of eliciting moral message from it. The film does not simply portray the Park family through the lens of victimized and marginalized social members, but focuses on the seemingly irreducible distance between different social classes. As the ending of the film shows, for the Park family, their struggles of living in poverty and the lower class are generational and perpetual.

Abstract Name: Investigation into the effects of Pseudomonas aeruginosa bacteriophage on cytokine expression in macrophages in vitro

Antibiotics have long been the go-to therapy for bacterial infections, but the rise of antibiotic-resistant bacteria makes for a reduction in both the effectiveness and quality of antibiotic treatments. Both healthcare and the economy are seeing the harsh reality that comes with antibiotic resistant bacterial infections, an alternative or coupled therapy is needed. Bacteriophages which are viruses that infect and lyse bacterial cells, offer a promising alternative. Discovered in the 1900s by Felix d'Herelle, phage therapy was initially viewed as a potential for bacterial infection therapy, however interest in phage declined after antibiotics emerged in the 1940s. Phage therapy has regained interest recently due to an increase in antibiotic resistance. Recent clinical trials show promise, but more research is needed to understand the immune system's impact on phage therapy. This project utilized bacteriophage of Pseudomonas aeruginosa, which are opportunistic pathogens common in hospitals. Most often seen as secondary infections to immunocompromised individuals. Pseudomonas aeruginosa resistance has spread to a large proportion of antibiotics on the market. This project

examines pro- and anti-inflammatory cytokine production in macrophage cells exposed to varying concentrations of *Pseudomonas aeruginosa* phage. Phage stocks were endotoxin-purified to remove contaminants that could trigger an immune response. Macrophage cells (RAW264.7) were incubated with phage for 24 hours, and total RNA was isolated to study cellular responses. DNase treatment conditions were tested and optimized before cDNA synthesis, using GAPDH primers as a control for RT-PCR. Current work focuses on analyzing pro-inflammatory cytokines (TNF α , CXCL5, IL-1B, IL-1A, and CXCL1) using RT-PCR to monitor their regulation. This analysis aims to provide insights into the immune responses of macrophages to bacteriophage exposure.

Abstract Name: The Role of Experiential Avoidance in Disordered Eating Attitudes and Behaviors and Alcohol and Nicotine Consumption in College Students

Young adulthood is a high-risk developmental stage for multiple potentially harmful behaviors including disordered eating, alcohol misuse, and nicotine use. Experiential avoidance refers to the tendency of an individual to avoid or control distressing psychological experiences. Experiential avoidance has been used to understand why individuals, such as college students, engage in high-risk behaviors. Some individuals may use alcohol or nicotine to avoid or control distressing psychological experiences, such as disordered eating attitudes and behaviors. Experiential avoidance may play a mediating role between disordered eating attitudes and behaviors and alcohol and nicotine use. Much of the previous research has focused on these relationships in women; this study includes college students of all genders and utilizes updated assessment measures validated in all genders. This study explores the relationships amongst disordered eating attitudes and behaviors and alcohol and nicotine consumption, and how these behaviors could be mediated by experiential avoidance.

Abstract Name: The Economic Burden of Obesity in the Elderly

Prescription anti obesity medications offer potential benefits for improving health outcomes but access to these medications is limited due to high out-of-pocket costs and limited insurance coverage. This issue is of importance for the elderly, who do not have guaranteed access to these medications because they are not fully covered by their insurance. Currently, there are very few studies of obesity costs in the elderly and most

published studies were from before recent developments such as Ozempic of diabetes. This paper will estimate the potential cost savings and benefits of the elderly having better access to anti obesity medications using more recent data. The study will use 2008 - 2019 data from the Medical Expenditure Panel Survey which has information from large scale surveys of Americans, their families, medical providers, and employers. It is an ongoing study focused on the use and spending on healthcare conducted by the Agency for Healthcare Research and Quality. I will subsample to elderly adults aged 65 and older. I will estimate a regression model to analyze the relationship between BMI and healthcare expenditures for elderly adults. My models will control for individual demographics, insurance type, employment and retirement, and other health conditions. I will use the model to perform a cost benefit analysis for newer anti obesity medications; costly but effective medications which studies have shown have a weight loss effect of about 15%. I will compare predicted medical spending for high BMI individuals to their predicted spending at lower levels of BMI reflecting the weight they could lose were they to take the new anti obesity medications. Based on the efficacy of these drugs and their impact on overall healthcare spending, I will provide insights for policymakers to improve drug access and address socioeconomic disparities in obesity treatment for the elderly.

Abstract Name: The Impact of Racial Representation in Educational Spaces

A general sense of belonging established within educational spaces is crucial to the success and motivation reflected among students. This may be especially true and important for racially minoritized students, who have historically faced marginalization and lack of inclusion in the dominant narratives of schooling and knowledge. This study aims to evaluate the presence of racial representation within multiple educational media and its influence on Black female students in both elementary and high school settings. This evaluation will help establish how these forms of media impact individual identity development and perceptions of other identities students are exposed to through educational content. This study takes place within a unique university and public school partnership in a large Midwestern city. This study documents experiences across elementary and high school contexts as part of a single educational campus. Data will be collected through ethnographic methods, observations, and in-situ interviews with teachers and students in elementary and high school contexts. These observations will investigate what material realities, figures, texts, people, and more exist in these spaces and how they shape the identities of students engaging in learning in the space. In this in-work-in-progress study, I anticipate uncovering potential positive impacts of the racial concordance students find within different demonstrations of racial representation and the simultaneous positive impacts of accessing content that contrasts with their individual identities. I also anticipate the various racially representative aspects of these educational settings will reflect the individual connections students have with this media. Furthermore, educational motivation, perceptions of learning, and sense of belonging in different educational spaces and domains will be investigated. Ultimately, I foresee this study continuing to uncover the significance of diverse media embedded within the two school settings in relation to the positive development of student identity, motivation, sense of belonging, and perceptions of the world.

Abstract Name: Infection Rates of Chytrid Fungus and Ranavirus in Amphibians from Southeastern and Central Ohio

Amphibians are the most threatened group of vertebrates due to emerging infectious diseases and other human impacts. *Batrachochytrium dendrobatidis* (Bd), a chytrid fungal pathogen, and Ranavirus (FV3), a deadly virus infecting amphibians and reptiles, have been implicated in serious declines and extinctions although little is known for the Midwest region of the United States. The goal of this research is to evaluate the prevalence of both Bd and Ranavirus at the Primmer Outdoor Learning Center (Logan, OH) and Highbanks Metro Park (Westerville, OH). Amphibians were hand-caught and live-trapped during three sessions at the streams and wetland at Primmer and a pond at the Dragonfly Day Camp at Highbanks during Fall of 2024. Swabs and tissue samples were collected from 22 individuals including pickerel frogs (*Lithobates palustris*), northern green frogs (*Lithobates clamitans melanota*), American bullfrogs (*Lithobates catesbeianus*), and southern two-lined (*Eurycea bislineata*) and dusky (*Desmognathus fuscus*) salamanders. To date, DNA extraction and duplex real-time qPCR testing has been completed on 14 oral swab samples from Primmer and 2 oral swab samples from Highbanks. Taqman-based assays were run in duplicate and consisted of forward and reverse primers with probes labeled with FAM-MGB and VIC-MGB, TaqPath BactoPure Microbial Detection Master Mix, and RT-PCR water. Negative controls and a gBlock designed positive control containing both targets were serially diluted and included on each plate. Preliminary results showed that 14% (2/14) of samples from Primmer were positive for both Bd and Ranavirus from an American bullfrog tadpole and a Northern green frog tadpole with 0% (0/2) from Highbanks. Additional fieldwork at three Metro Park sites in Central Ohio and qPCR testing is planned for February-March 2025. This research is important to better understand threats to biodiversity in amphibians as well as aid in conservation efforts in Ohio.

Abstract Name: The Effects Skill-building has on Self-esteem and Self-Efficacy

Art therapy is a new field, as it develops new models and methods should be developing through research. Taking a skill building focus and examining the relationship between mental health and learning new skills is a new approach this research seeks to develop The purpose of the research is to observe the relationship between skill building and increased self-esteem and self-advocacy, With the goal of using the information gathered to form new methods of art therapy. Participants will build the chosen skill in this study creating watercolor paints from scratch was chosen for its simple but engaging processes. The participants will take a survey before and after the workshop for data on initial self-esteem and post self-esteem. Using the data collected researchers will infer whether there is a positive correlation or not. It is anticipated that the workshop will make people feel better about themselves and have a positive impact on self-advocacy. If there is a confirmed positive correlation, this will open opportunities to expand research on the topic. Developing new models within art therapy will expand the kinds of treatment plans available to clients and expand the overall knowledge of art as therapy.

Abstract Name: Examining Interactions between the Default Mode Network, Executive Control Network, and Salience Network

The triple network model proposed by Menon et al. plays a major role in many psychiatric illnesses, including anxiety disorders, schizophrenia (SCZ), and autism spectrum disorder (ASD). The triple network model involves the interplay of activity between the Default Mode Network (DMN), which plays a role in mind wandering, creativity, and social cognitive processing, the Executive Control Network (ECN), which plays a role in working memory, decision making, and goal-directed behavior, and the Salience Network (SN), which is proposed to play a role in modulating the activity between these two networks. While research has explored the applications of the triple network model, the dynamics upon which these three networks interact is still relatively unknown. In this study, we will use transcranial Direct Current Stimulation (tDCS) aimed at the Posterior Cingulate Cortex (DMN), dorsolateral Prefrontal Cortex (ECN), and the Anterior Insula (AI) to modulate activity between the three networks. As part of the study, we will verify the stimulation of these networks with a modified version of the Multi-Source Interference Task (MSIT), incorporating a Stop Signal Task (SST) into the trials. We predict that stimulation of the DMN would result in a decrease in performance at the MSIT, stimulation of the ECN would lead to an increase in performance at the MSIT, and stimulation of the SN would result in an increase in performance at the MSIT as well as the SST.

Abstract Name: Final Steps of Torreyunlignan D Total Synthesis

Our research group has investigated the synthesis of the Torreyunlignans A-D, a family of natural products isolated from *Torreya yunnanensis*. These compounds have shown high affinity for inhibition of the phosphodiesterase 9A (PDE9A) enzyme, decreasing the degradation of cyclic guanosine monophosphate (cGMP), a known treatment for various heart conditions, diabetes, Alzheimer's disease, and other neurodegenerative diseases. Retrosynthetic analysis revealed a synthetic route for formation of these compounds by coupling phenylpropanoid fragments. Previous work on a model compound developed this pathway for a practical synthesis. Recently, work has focused on the final synthetic steps for Torreyunlignan D: a Pd-catalyzed Tsuji-Trost coupling reaction, a diastereoselective and lithium aluminum hydride (LAH) reduction, and acetal formation. The Tsuji-Trost coupled the first two phenylpropanoid units, after attachment of an allylic acetate and β -keto ester. A cerium-promoted reduction gave a selective yield towards the targeted anti-diastereomer. Then the LAH reduced this diastereomer from a β -hydroxy ester to a diol compound. The final step in this total synthesis was attachment of the final phenylpropanoid (2-methoxycinnamaldehyde)

using tosylic acid to drive acetal formation. Completion of the synthesis of Torreyunlignan D provides insight to the successful formation of the other three natural products, as well as supports investigation into the biological activity and medicinal application of this family of compounds.

Abstract Name: The Impact of the COVID-19 Pandemic on Tropical Crop Cultivation in Eastern Thailand

This research sought an understanding of how the COVID-19 pandemic impacted tropical crop cultivation in Eastern Thailand, primarily in the Chanthaburi province, a critical agricultural hub. The province supplies goods domestically as well as internationally, emphasizing crops such as durian, rambutan, and mangosteen. Globally, the COVID-19 pandemic brought unprecedented challenges to agricultural systems. Despite ongoing research on the pandemic and its impacts on global systems, there is a need to investigate changes implemented that remain or are expected to shift long-term practices. This research was conducted on farmer adaptations and lasting consequences identified through in-depth interviews and farm visits in Eastern Thailand. The research team completed structured interviews with 52 farmers and 10 in-depth interviews with key stakeholders. Data collection took place between June and July 2024. The research found that the region faced three primary challenges: labor shortages due to disrupted migrant worker flows, shifts in market demand and channels from changes in consumer behavior and supply chain disruptions, and evident mental shifts partially due to a lack of government support. Agricultural producers in the Eastern region of Thailand responded to pandemic disruptions at the national and international levels by pursuing new efficiencies on their farms, seeking out new markets, attending more to health and hygiene, and crop diversification to build self-efficiency. Many of these shifts continue post-pandemic in ways that produce lasting consequences for environmental, social, and economic systems. Our results provide insights into social system changes produced by shifting relations between consumers and producers, farm owners and farmworkers, farm-to-farm cooperation, and economic system changes in the expansion of online markets and value-added goods. These findings have important implications for agricultural policy and resiliency planning, informing other regions with similar agricultural systems, and contributing to understanding sustainable food systems and adaptation in the face of global challenges.

Abstract Name: The Adsorption of Per- and Polyfluoroalkyl substances (PFAS) using Zeolite

Per- and poly-fluoroalkyl substances (PFAS) are persistent organic pollutants commonly found in water, linked to serious health issues such as cancer and birth defects. Due to their environmental persistence, effective methods are needed for PFAS removal. One potential solution is the use of Zeolite Beta, a porous

silicon crystal with known adsorption properties. While some research has explored Zeolite Beta's ability to adsorb PFAS, there is limited understanding of how its hydrophilic or hydrophobic properties influence PFAS removal. This study aims to investigate the impact of varying hydrophilicity/hydrophobicity on PFAS adsorption by Zeolite Beta. The hydrophobicity arises from siloxane (Si-O-Si) groups, while hydrophilicity is due to silanol (Si-OH) groups that interact with water via hydrogen bonding. The goal is to synthesize Zeolite Beta with different degrees of hydrophilicity and hydrophobicity and evaluate its PFAS adsorption performance. Experimental conditions, including adsorption time, temperature, pH, and Zeolite varieties, will be tested. Aqueous PFAS solutions will be analyzed before and after treatment using Liquid Chromatography-Mass Spectrometry (LC-MS). Preliminary trials with Zeolite Beta (CP814E) and PFOA show promising results. This study will address key gaps in understanding the optimal conditions and properties of Zeolite Beta for efficient PFAS removal, contributing to improved water treatment strategies.

Abstract Name: Providing Winter Warmth in Flagstaff Arizona: Providing Health Education and Resources to the Local Community

Project Purpose: The purpose of our health intervention was to assist in lessening the impact of lack of access to winter warmth resources and education; as well as researching and reducing any associated health disparities and determinants. We used the diverse, centralized, and well-representative population of Flagstaff Family Food Center (FFFC) as our basis for intervention. **Background:** Coconino County has a poverty level of 16.9% and a below-average overall health score, with a score of 42 out of 100. FFFC serves thousands of people in our community and distributed 6.7 million pounds of food in 2023. In addition to addressing food insecurity, FFFC also addresses risk factors and related issues (such as winter warmth), due to lack of access to resources. The city of Flagstaff receives over 100 inches of snow per year, and access to affordable housing and shelter can be an issue. **Methods:** Our intervention was based on the Health Belief Model. We addressed perceived susceptibility and severity, reduce barriers, and increase self-efficacy around winter warmth. We organized, promoted, and facilitated a clothing drive with a local church and additionally created winter relief kits. These included gloves, lip balm, hand warmers, lotion, and paper infographics outlining winter relief resources, tips, hygiene/skincare, and more. We then distributed educational materials along with winter kits to clients at the food center and collected paper surveys to evaluate our intervention's effectiveness. **Conclusions:** Overall, 60% of participants indicated high levels of self-efficacy around winter warmth after our intervention. We found that the participants were very receptive and grateful for our intervention through the use of our survey. 100% of participants reported they would use at least one of the resources provided. They also expressed an understanding of the resources provided and offered suggestions for future kits.

Abstract Name: Hostile Architecture in Philadelphia Public Spaces: Producing a Physical and Social Deterrent for Unhoused People

Cities across the globe have enforced hostile architecture and other forms of defensive design implemented through urban design methods, such as Crime Prevention Through Environmental Design (CPTED) and the "broken window model of policing." Defensive design methods seek to combat crime and poverty in an attempt to improve the image of cities. The emergence of hostile architecture is prevalent in Philadelphia, Pennsylvania through the addition and removal of amenities; including proper seating, accessible pathways, and raised surfaces; to exclude groups such as the unhoused and skateboarders. This comprehensive literature review aims to evaluate hostile architecture within Philadelphia that attempts to render public spaces unusable to facilitate the relocation of unhoused individuals from those public spaces. The locations of public spaces

within Philadelphia will further narrow to Center City and surrounding areas that experience an influx of tourists. The analysis of peer-reviewed studies on hostile architecture internationally finds that implementing defensive design discourages social connectivity within spaces and encourages crime. This review examines public opinion regarding anti-homeless design through architecture, social, and environmental journals. The goal of this review is to highlight the necessity of certain measures of hostile architecture within Philadelphia, including the intent behind ground spikes and inaccessible seating implemented by the city of Philadelphia. Cities may attempt to disguise the reason for defensive design installation by arguing that hostile architecture may provide increased accessibility for the elderly. These findings contribute to a larger understanding of hostile architecture and discussion of apparent and implicit defensive fixtures within Philadelphia and larger metropolitan cities.

Abstract Name: the impact of population heterogeneity and migration on vaccination strategies and disease dynamics in mpox

Mpox is a viral zoonotic disease, a member of the Orthopoxvirus genus, and is characterized by rashes or skin lesions primarily on the face, palms, and soles. In 2024, a significant outbreak occurred in the Congo, involving a new strain of the virus. Previous modeling efforts commonly assumed a population divided into two distinct groups without migration and, from an epidemiological perspective, treated population heterogeneity as negligible. In such simplified frameworks, neither interactions nor transmission rates depended on an individual's group. Yet, in realistic populations, interactions are inherently heterogeneous—individuals may have different contact patterns and risk exposures depending on their group affiliations, geographic settings, or socio-economic factors. This heterogeneity can produce differing disease burdens across subpopulations, as seen in the greater prevalence of Mpox in urban areas relative to rural ones. Utilizing structured population approaches, which incorporate age-stratified mixing patterns, we can enhance our game-theoretic framework to more accurately display these complex relationships. The work presented here extends existing game-theoretic models by incorporating migration between groups, heterogeneous transmission rates, and scenarios where vaccines may have limited efficacy or transmission rates are high. We analyze a system of ODEs to characterize disease-free and endemic equilibria, using game theory to identify Nash equilibria of vaccination strategies under realistic conditions. Analytical expressions and sensitivity analyses reveal how migration rates, interaction heterogeneity, and vaccine efficacy influence long-term disease outcomes. Numerical MATLAB simulations will validate these findings, showing how parameter variations and heterogeneity affect equilibrium vaccination behavior and disease prevalence. By incorporating these changes into our modeling framework, we aim to show how realistic population structures and interaction patterns can lead to multiple Nash equilibria that shape disease trajectories and guide more effective public health interventions.

Abstract Name: Precise modelling of the B_s^0 invariant mass distribution in the B_s^0 decays to $J/\psi(\mu^+\mu^-)\Phi(K^+K^-)$ channel using data from the ATLAS experiment at the LHC

A model of the B_s^0 meson mass is being developed using data from decays in the channel $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\Phi(K^+K^-)$ using information from the ATLAS experiment at the LHC. The data were collected during Runs 2 and 3. Measurement of the $B_s^0 \rightarrow J/\psi(\mu^+\mu^-)\Phi(K^+K^-)$ decay probes CP violation due to interference between a direct decay and a decay with B_s^0 – anti B_s^0 mixing. Precise fits of peaking and combinatorial backgrounds will be applied. Assessment of the stability of the reconstructed mass over time is an essential contribution to the understanding of the systematic error of the measurement of the branching ratio.

Abstract Name: Flexibility within a Framework: Engaging Undergraduate Students in Cancer Research

Engaging undergraduate students in independent scientific research presents unique challenges, including teaching advanced laboratory skills and helping students grasp background literature deeply enough to develop meaningful experimental questions, all within limited a time frame. I developed a research system that addresses these challenges by providing students with guided flexibility, allowing them to explore personalized research questions within a structured framework. In this work, students investigate the potential synergy between traditional chemotherapies and readily available supplements on cancer cells. Students are empowered to tailor their projects by selecting a cancer type, a chemotherapeutic agent, and a supplement of their choice. Despite this flexibility, all projects follow a shared experimental flow. Initial experiments assess the effects of single agents and their combinations on cancer cell proliferation, establishing baseline efficacy. Follow-up studies are conducted to explore mechanistic outcomes, including cell migration, tumorigenesis, and apoptosis. The streamlined process facilitates efficient management of multiple student projects and encourages collaboration and troubleshooting within the research cohort. To demonstrate the success of this approach, I have compiled results from four different student projects that examine a variety of cancers, chemotherapies, and supplements and demonstrate varying degrees of synergy. This research strategy offers a scalable model for facilitating student project ownership within a manageable framework.

Abstract Name: The Role of Company Culture in Employee Retention: A Focus on Generation Z

This paper examines company culture's profound role in employee retention while emphasizing Generation Z's unique needs and expectations as they enter the workforce. The literature review explores the different definitions of company culture, its impact on employee satisfaction, productivity, and turnover, and the values and challenges of Gen Z workers. An analysis of employee insights and customer reviews was conducted using Organizational Commitment theory to analyze two local coffee shops in Kenosha, Wisconsin: Harborside Common Grounds and Anna's on the Lake. These contrasting businesses demonstrate how cultural practices impact retention and overall business success. The results of this study suggest that aligning company culture with the evolving expectations of Generation Z will result in workplaces that retain talent and drive long-term success for organizations.

Abstract Name: CubeSat Payload: Thermal Regulation Applications of E-Ink for Small Satellites

This research explores the effectiveness of E-paper as a potential thermal management system for small satellites. E-paper is an electronic display that consists of a film filled with a clear fluid and charged ink particles. When a field is applied to the film, it pushes or pulls the charged ink particles to or from the screen, where it will remain in that state when the field is released. When the pattern shown on the screen is not being changed, it draws negligible leakage current. Satellites in low earth orbit go from an extremely cold environment (-65°C) to an extremely hot one (125°C) within the course of 4 hours. Typically, satellites are fitted with thermal control systems. However, thermal regulation can be a high consumer of energy for electronics that must operate at consistent temperatures. These electronics are typically heated by surrounding heating element systems. Implementing a low energy thermal controller will allow for the constant thermal regulation of electronics that must operate at consistent temperatures while minimizing the power consumption of the thermal regulation system. This research presents the thermal characterization of E-paper, using a system consisting of a metal plate and an E-paper module at steady state, in which the thermal impact of radiation on the screen can be quantified. The experimental results were used to create a mapping function between the pattern shown on the screen to the coefficient of emissivity. The implementation of this lays the foundation for autonomous variable thermal control on a small satellite; usage of this low-power thermal system in orbit may improve the battery economy of small satellites.

Abstract Name: Synthesis of Mesoporous Titania-Silica Catalyst for Polyolefin Upcycling

In today's society, there are more than 7.3 billion metric tons of plastic on Earth, which has caused significant environmental pollution that is detrimental to human and ecological health. Conventional plastic recycling methods need to be revised to address this challenge because they degrade the properties of the plastic and result in a product with limited uses. An alternative to plastic recycling is chemical upcycling, which converts plastic waste into other value-added chemicals. Previous studies show mesoporous silica catalysts can upcycle plastics via catalytic hydrogenolysis. This research project aims to create a new, porous catalyst composed of titania and silica to break down polyolefin plastics into products such as lubricants, solvents, jet fuels, and diesel fuels. The checkpoints of this project are creating a desired catalyst made of titania and silica, inserting metal nanoparticles into the titania-silica structure, and testing the catalyst's performance in the hydrogenolysis reaction. We predict this new catalyst will have a higher catalytic potential because titania is more reactive than silica.

Abstract Name: Evaluating Bias and User Perceptions of Generative AI Chatbots at a Liberal Arts College

This study investigates the biases of generative AI chatbots and examines how individuals interact with these tools at a liberal arts college. Generative AI is widely used for text generation and problem-solving through platforms such as ChatGPT, Google Gemini, and Microsoft Copilot. While these technologies offer significant utility, they are susceptible to spreading misinformation due to biased programming or reliance on unreliable sources. The objective of this research is to analyze the biases in chatbot outputs and assess user perspectives on their accuracy, helpfulness, and overall trustworthiness. The research employed two surveys targeting the student body at Texas Lutheran University. The first survey collected student opinions on 20 sociopolitical issues, including topics like presidential elections and firearm regulations. These responses were compared with answers generated by the three AI chatbots to identify patterns of agreement or divergence. The second survey explored students' usage of AI, focusing on the frequency of engagement, purposes for using chatbots, and their perceptions of chatbot reliability and effectiveness. The findings reveal that chatbot responses generally aligned with student opinions across most topics. However, significant deviations were observed on controversial issues, particularly those related to government policies. Students found chatbots useful for addressing straightforward queries but noted that their performance diminished when handling sensitive subjects. Additionally, the second survey highlighted that most students engage with AI tools sparingly, with many expressing a cautious approach toward the accuracy of the information provided. These results underscore the dual role of generative AI as both a valuable tool and a potential source of misinformation, emphasizing the need for critical evaluation by users. This study contributes to ongoing discussions about the ethical implications of AI and its integration into educational and societal contexts.

Abstract Name: Toward Personalized Virtual Reality Gait Training System for Full-Body Obstacle Avoidance Using Real-Time Motion Analysis

Human motion tracking is essential for medical evaluations, activity monitoring, and rehabilitation. When combined with virtual reality (VR), it creates safe, controlled environments to simulate real-world scenarios, making it ideal for gait training and obstacle navigation. However, current VR gait training systems often overlook the complexity of full-body obstacles and lack real-time performance assessment, limiting their utility for personalized rehabilitation therapies. This project introduces a VR system for personalized gait training with full-body obstacle avoidance. Built in Unreal Engine 5, the system simulates real-world obstacles such as branches, rocks, and logs to mimic natural environments. Sony Mocopi sensors capture full-body motion at multiple key points, while the Meta Oculus Quest 2 provides an immersive VR interface. A real-time motion analysis module employs a decision tree algorithm to classify user movements into ducking, stepping over, side-stepping, or combinations of these from body position changes and validated, personalized gait characteristic thresholds derived from rigorous data analysis collected from multiple users. To successfully avoid tree-like obstacles, the user must duck their head at least 12 cm below their initial standing position. Stepping over obstacles requires the foot to rise at least 11.5 cm above their general walking range, determined during the initial simulation phase. Side-stepping is indicated by hip sensor data: a negative value corresponds to stepping left, while a positive value signals stepping right. The decision tree first checks for ducking, followed by stepping over, distinguishing between left and right foot movements. If stepping over is not detected, the algorithm assesses side-stepping behaviors. Combinations, such as ducking while stepping over or side-stepping, are classified accordingly. Initial tests demonstrate the system's ability to detect obstacle-avoidance strategies with high accuracy in real time. Future work includes a user study, and developing machine learning models to predict optimal strategies to support personalized gait rehabilitation.

Abstract Name: c-Abl inhibition as a therapeutic to reverse existing atherosclerotic plaque

Despite the advent of therapies that have lowered risk, cardiovascular disease remains the global leading cause of death. This “residual risk” likely exists due to a lack of therapeutics that reverse late-stages of disease, especially in atherosclerosis where plaques develop undetected as fats deposit in the arterial wall. In atherosclerosis, fat accumulation drives inflammation and promotes remodeling within the arterial wall, which increases the risk of plaque rupture and subsequent acute vascular complications. Vascular calcification, late-stage remodeling characterized by bone-like mineral formation, also contributes to plaque rupture by generating significant mechanical stress. Abelson tyrosine kinase, referred to as c-Abl, is a non-receptor tyrosine kinase involved in cell proliferation and signaling, and it has recently been identified as a leading contributor in activating inflammation pathways. c-Abl also phosphorylates caveolin-1 (CAV 1), a plasma membrane scaffolding protein involved in vascular calcification. Given its known role in modulating both inflammation and calcification, we hypothesize that c-Abl inhibition could target the two key drivers of late-stage atherosclerosis. Our collaborators at the National Center for Advancing Translational Sciences

(NCATS) recently developed allosteric c-Abl inhibitor Neurotinib, which has enhanced pharmacokinetic and pharmacodynamic properties that make it well-suited for drug development. This study aimed to determine whether Neurotinib could prevent and reverse late-stage atherosclerosis. Neurotinib was administered to the Apoe^{-/-} murine model of atherosclerosis, where the subjects were placed in an untreated control group, a group receiving exclusively Neurotinib to assess prevention, or a group that received Neurotinib after development of atherosclerosis to assess reversal. To study associated mechanisms involved in calcification, Vascular Smooth Muscle Cells (VSMCs) were cultured and exposed to osteogenic media, inducing vascular calcification in vitro. These VSMCs were treated with Neurotinib at different concentrations (0.5 μ M and 1.0 μ M) and endpoint analyses assessed mineral formation and the elaboration of inflammatory cytokines.

Abstract Name: The Impact of Language Barriers on Therapy-Seeking Behavior Among Bilingual Immigrant College Students

Language barriers can significantly affect therapy-seeking behavior among bilingual immigrant college students, limiting access to critical mental health resources. This study combines a comprehensive exploration of existing research with an empirical approach to address the mental health needs of this population. By integrating prior findings with newly collected data, the project aims to provide actionable solutions to reduce these barriers. The research focuses on designing and conducting surveys at Miami Dade College, starting with the Eduardo J. Padrón Campus. These surveys will assess bilingual immigrant students' mental health needs, their likelihood of seeking therapy if offered in their native language, and perceived obstacles to accessing mental health care. Insights gathered will inform the development of a multilingual text message crisis line as a scalable and accessible resource tailored to the needs of diverse student populations. The findings aim to demonstrate the critical importance of culturally competent mental health services and advocate for systemic changes, such as increasing the availability of bilingual therapists and expanding training opportunities for mental health professionals. This project emphasizes the role of language accessibility in fostering stronger therapeutic relationships, improving emotional expression and identity, ultimately encouraging students to seek the support they need in the more appropriate, comprehensive, flexible ways. By integrating existing literature with new data, this study contributes to a broader understanding of therapy-seeking behavior among bilingual immigrant students and underscores the need for innovative, linguistically inclusive mental health solutions in multicultural communities like Miami.

Abstract Name: Reducing Pathogens in Built Environments: Ethical and Responsible Translational Activities

We are working to implement a new safety tool using the bacterium *Bacillus subtilis* to reduce pathogens in built environments, such as hospitals. Antimicrobial resistant (AMR) pathogens, more prevalent in healthcare settings, pose significant health risks like diseases and infections. *Bacillus subtilis* can aid in pathogen reduction, and our interdisciplinary team is integrating it into 3D printing technology to create probiotic surface materials. While developing this technology, it is important to investigate healthcare staff perceptions of integrating this technology into their workplaces, and to communicate common themes to the biotechnology team to help refine the technology and ensure successful implementation. We conducted qualitative research, interviewing seven healthcare and lab professionals—including administrators, graduate students, and clinic managers—to gain insights into their concerns and suggestions. We then analyzed six of the transcribed interviews and used Google Sheets and MAXQDA to make a codebook, then identified common themes. Participants expressed key concerns regarding safety, cost, and effectiveness. There were significant worries about the potential risks associated with the technology, and many asked if it complied with hospital regulations. Questions arose about the initial investment for purchasing and installing the technology and potential hidden expenses such as maintenance and repair. Participants sought a clearer understanding of how the technology operates and its benefits. Ensuring the technology is safe for users, affordable, and proven effective would be crucial in gaining public trust and acceptance. Moving forward, we plan to conduct additional interviews with hospital staff, including doctors, nurses, and janitors, to assess their comfort with working in an environment where this technology is present and to understand its potential impact on their routines. Additionally, we aim to advance to the next phase by testing the technology in a hospital setting, allowing us to observe its real-world application and gather more comprehensive data.

Abstract Name: Advancing Dosimetry for Radiopharmaceutical Therapy with a Novel Ionizing Quantum Imaging Detector

Radiopharmaceutical therapy (RPT) shows promise for improving survival for patients with metastatic prostate cancer. However, the characterization of RPT radiation dose, known as dosimetry, is underdeveloped and poorly understood. Further RPT advancement will require novel tools that can precisely measure RPT dosimetry. This project aimed to benchmark a novel system for measuring RPT dosimetry: the Ionizing Quantum Imaging Detector (iQID). The scintillator-based iQID maps individual alpha or beta emissions on a $10 \times 10 \text{ cm}^2$ detector. We tested spatial resolution by measuring the full width at half maximum (FWHM) of a collimated ($5 \mu\text{m} \times 5 \text{ mm}$) alpha-emitting source (5 mCi , ^{210}Po). We repeated the spatial resolution test for two scintillator materials (ZnS:Ag and Gaddox) and at 17 positions on the detector surface. To ensure placement reproducibility, a custom holder was designed and printed on a Bambu Lab X1-Carbon printer. We tested variations in FWHM with position via Bonferroni-corrected Spearman's Correlation ($\alpha=0.02$). The number of alpha particles detected from a $50.2 \pm 1.1 \text{ Bq}$ source (^{243}Am , ^{242}Pu , and ^{239}Pu) over 48 hours quantified sensitivity. Finally, we quantified uniformity via the variation in total particles detected from 200 Bq of ^{210}Po at 17 positions on the detector surface. The FWHM averaged $57.35 \pm 4.36 \mu\text{m}$ with ZnS:Ag and $57.29 \pm 4.78 \mu\text{m}$ with Gaddox. FWHM was insensitive to position on the detector ($p \geq 0.03$). The sensitivity measurement

yielded 4,241,627 counts, representing 48.69 ± 0.02 Bq and 97% sensitivity. Uniformity tests revealed a significant variation in counts detected with radial distance from the detector center with a loss of 450 counts/mm from the center. Our results revealed the novel iQID can identify individual alpha emissions with high sensitivity at spatial resolutions approaching the cellular scale. However, corrections for non-uniform response may be needed. With advanced RPT dosimetry, precision RPT can offer optimal cancer management to patients with metastatic prostate cancer.

Abstract Name: Associations Between Trace Eyeblink Conditioning and Hippocampal Subfield Structure in 4-to-6-Year-Olds

The brain is integral for learning and memory, with no region more important for learning facts and events than the hippocampus. This region develops slowly and is linked to academic success. Understanding functional development will have important consequences on academic achievement and life outcomes for many children. No reliable and valid measure to assess hippocampal function in very young children is currently available. Trace eye-blink conditioning (EBC) is a well-established task with a clear link to hippocampal function and has been extensively used to investigate associative learning in children as young as a few months old. Previous work by our group has shown a relation between trace EBC and hippocampal development. The current study aims to re-examine the relation between trace EBC and hippocampal development by replicating our prior findings in a larger sample and extending our results to consider the subfields of the hippocampus. The hippocampus' cornu Ammonis (CA) region is made up of four main subfields: CA1, CA2, CA3, and dentate gyrus (DG). In general, these are thought to have different functional attributions with the DG/CA3 being important for fine-grain memories. As part of a larger study, we collected structural MRI and trace EBC from 4–6-year-olds. We preprocessed and analyzed the structural data to extract volumetric information of the hippocampal subfields. We anticipate that DG/CA3 subfield will be associated with greater percentage of conditioned responses and more accurate response latency timed to the unconditioned stimulus. These results will be important because they will offer further proof of the relation between hippocampal structure and performance on trace EBC – thereby providing a task to assess hippocampal function in very young children.

Abstract Name: Pitch Perfect: Gender Doesn't Matter, but a Great Story Does

There is a growing desire for more gender representation in business, especially in entrepreneurial startups and the venture capital industry. Various studies have explored why there is a gap between male and female entrepreneurs who receive funding for their businesses, and many have explored gender- or sex-based biases

as potential causes. Other studies have examined that narratives are useful tools for persuasion. This experimental study explores the potential of these topics through an online survey with a national sample (N = 276), testing the effect of storytelling on the participant's willingness to fund an entrepreneur. Treatment included stories where the gender of the entrepreneur was specified, and the control condition which used the same story but with an unspecified gender. In the results of our study, the gender of the respondents was not significant, which is different from previous assumptions. Instead, the results showed that a person's level of intuition and attitude towards the story were most influential when it came to the decision to fund an entrepreneur. More research is needed, but findings indicate that storytelling can close the funding gap between male and female entrepreneurs.

Abstract Name: The Role of Category Formation in How Infants Distinguish Between Object Features

Words are often used to refer to categories, rather than individual objects. For example, the word 'house' does not just refer to your home, but also your neighbor's house or a dollhouse. When learning words, infants are tasked with the challenge of identifying which objects belong to which categories. How do infants accomplish this task? One possible strategy is for infants to focus on the commonalities between objects labeled with the same word to form the correct category. For example, infants might notice that all objects called houses have doors. The current study investigates this possibility using a novel word-learning task where infants are familiarized with a series of novel objects such as shapes with different colors, patterns, and symbols on them, that are each labeled with the same novel word (e.g., "This is a boff!"). The design includes two conditions: the Common Feature and the Distinct Feature condition. All novel objects in the Common Feature condition share a commonality: a swirl symbol in the middle. In the Distinct Feature condition, the symbols of the novel objects are all different. Then using an eye-tracking test, we measured which features babies remembered about the novel objects. We hypothesized that infants would focus on the features common among the objects to help them learn the category. Results from pilot data are consistent with this hypothesis. Looking-time measures indicated that infants remembered the commonalities between objects but forgot differences. Therefore, these data reveal that when learning new words, for example, "house," babies focus on common features across objects labeled with the same word (e.g., doors and windows for "house") and ignore differences (e.g., size, shape, color, etc.) to successfully form the correct category.

Abstract Name: Solid waste management in smart cities: the case of Medellin-Colombia and Seoul-South Korea.

Inadequate solid waste management contributes 5% of global greenhouse gas emissions. In Medellín, the situation is critical, with 55% of landfills near the end of their useful life and the main landfill, La Pradera, at risk of collapse. This research compares Medellín and Seoul, two leading cities in the IMD Smart City Index, focusing on their approaches to urban waste management. While Seoul utilizes advanced waste-to-energy technologies and smart pricing systems, Medellín relies on manual waste separation and informal recycling actors, highlighting the need for sustainable solutions. Key differences emerge in education and technology. Medellín aims to implement solid waste management education programs but struggles with conceptual unification. Seoul, in contrast, has integrated environmental education into its school system, creating a structured framework for effective waste management. Technologically, Medellín is conducting feasibility studies for biogas collection and flaring at La Pradera landfill. Meanwhile, Seoul uses biogas from landfills to generate electricity for 43,000 residents, significantly reducing CO2 emissions. This comparative study employs a descriptive qualitative methodology, utilizing primary and secondary sources. It reviews technological advances, plans, and projects in both cities to identify best practices and propose strategic recommendations. The findings aim to enhance waste management in Medellín, integrating technological innovation and policy frameworks for smarter, more sustainable cities. Ultimately, these measures can positively impact the environment, health, and quality of life for Medellín's residents.

Abstract Name: From Puddles to Policies: Public Perceptions of Actions Surrounding Urban Runoff

Urban runoff is one of the hardest sources of pollution to mitigate and regulate. This is especially true in rural communities, where there are limited resources and a greater focus on problems regarding agricultural runoff. Dunn County, Wisconsin faces water quality degradation in Lakes Menomin and Tainter. Most blame these water quality issues on agricultural runoff, but with both lakes also being surrounded by residential and urban areas, other factors are at play as well. My project focuses on Dunn County residents to determine their awareness of urban runoff issues, local government action regarding urban runoff, and if opinions of sustainability and political ideology impact awareness. To understand awareness, I used survey and interview data. Surveys of Dunn County residents indicated awareness of urban runoff, behaviors designed to limit use of lawn chemicals, and views of sustainability that see it as policies directed towards preservation of local resources and environmental health. Interviews with government officials found that policy preferences and public outreach depended on their positions, with County officials centered on agricultural runoff and Local officials on runoff from construction projects and city infrastructure. My project ends with recommendations for both County and Local governments regarding public education and policy proposals.

Abstract Name: Trans experience, community, and healthcare; inexorable pieces of one puzzle

The focus of this visual display is the interaction between social transgender community building and healthcare, primarily stemming from marginalization of the community through limited access to selective lifesaving procedures specifically related to identity, rather than a lack of access to healthcare altogether. The piece draws attention to the identity-focused nature and specificity of gender-affirming healthcare, whether hormones or procedures, and the resulting difficulty in acquiring either of these. The resulting collage claims that a significant aspect of social interaction for transgender people in the early days of mass media was the distribution of medical information and the acquisition of healthcare, and that it is an example of a marginalized community attempting to fill the gap left by traditional medical systems. The art piece, still in progress, is a handmade and sized-up zine- an easily distributable and copiable collection of information typically collaged and copy-printed on cheap poster paper for self-publish- featuring cutouts and collage with cultural and medical information from historical and modern magazines and newspapers. It will be 2-3 pages, possibly only one sided but ideally double, and the title page, if possible, will be mounted on a piece of wood, which has a braille image translation laser-cut into the back of it for ease of access. The creation of the zine necessitated medical research to gauge the complexity of procedures completed in the 60s and 70s, consistent utilization of the Hillman historical archives, and the use of laser cutters in a student creative space. It will also require reaching out to the university network to ensure the image description translations have been checked and are all correct.

Abstract Name: Determination of antibiotic resistance patterns isolated from Canadian Geese in Central Ohio

This study investigates the role of Canadian geese in the spread of antibiotic-resistant bacteria in urban parks in Columbus and Dayton, Ohio. Urban wildlife, particularly waterfowl like geese, are increasingly recognized as potential vectors for antibiotic-resistant bacteria due to their frequent interaction with human-impacted environments such as sewage systems, agricultural runoff, and public parks. These environments can harbor bacteria that carry antibiotic resistance genes, which can then be disseminated by geese through their feces. Fecal samples will be collected from geese in urban parks, and bacteria will be isolated and tested for resistance to antibiotics using the Kirby-Bauer disk diffusion method. The antibiotics tested will include amoxicillin, penicillin, naproxen, and tetracycline. Bacterial isolates showing resistance will undergo further molecular analysis to detect specific resistance genes, such as tet A, tet B, and tet C, using Polymerase Chain Reaction (PCR) and gel electrophoresis. Previous studies have demonstrated that waterfowl can harbor resistant strains of *E. coli* and *Enterococcus* and play a significant role in the spread of resistance genes across ecosystems. This study builds on that work by exploring the presence of resistance in urban Canadian geese and their role in disseminating resistant bacteria in human-populated environments. Identifying phenotypic resistance and genetic markers will provide critical insights into how these bacteria are spread in urban ecosystems, with implications for public health.

Abstract Name: Plant-based Diets: A Demographic and Sociological Analysis

The adoption of plant-based diets has continued to rise in recent years driven by environmental, ethical, and health related concerns. However, those who follow plant-based diets remain a small portion of the population, and widespread adoption still faces significant barriers. This research examines the demographic groups most likely to adopt a plant-based diet and seeks to answer the question: Why are these demographics more likely to adopt a plant-based diet, and how do factors such as cultural norms, socioeconomic backgrounds, and ethnic identity impact these choices? Existing data suggests that younger generations, women and gender-nonconforming people, and BIPOC are more likely to adopt plant-based diets, while residency location and income play roles in adoption and accessibility. My research also investigates the influence of cultural factors such as, religious practices related to vegetarianism and the role of plant-based diets as a part of social justice movements in marginalized communities. My analysis uses a synthesis of existing scholarly works and demographic data to identify trends and the disparities in plant-based diet adoption between groups. My findings highlight key barriers in plant-based adoption including; accessibility and affordability in rural and underserved areas, cultural and social stigma, and lack of education surrounding plant-based diets. Conclusions from my analysis highlight the deep interplay between cultural, social, and economic factors in demographic trends affecting plant-based diet adoption. This underscores the importance of addressing barriers to adoption and making plant-based diets more inclusive.

Abstract Name: The Use of Statistical Analysis and Convolutional Neural Network as Tools in Predicting Alzheimer's Patients

Alzheimer's is a neurodegenerative disease that affects millions of people every year. Further research is being done to identify early stage Alzheimer's and its progression over time. Our objective is to analyze if different perspectives are accurately able to evaluate the development and presentation of patients with Alzheimer's disease through statistics and deep learning using Convolutional Neural Networks (CNN). Data from the AIBL (Australian Imaging Biomarkers & Lifestyle) was used for statistics while magnetic resonance imaging scans were used for the machine learning. From AIBL, 92 patients from 3 groups, for a total of 276 patients, were statistically analyzed. Clinical Dementia Rating Scale scores and biomarker levels were evaluated. From the Alzheimer's Neuroimaging Data Initiative (ADNI), 306 patients' magnetic resonance imaging (MRI) scans were used. The CNN model will output two confidence scores between zero and one, each corresponding to the model's guess of whether the patient has or does not have Alzheimer's disease, with zero being the least confident and one being the most confident. Another dataset of MRI brain scans of non-Alzheimer patients will be used and the two datasets will be mixed to create a dataset to train and test a CNN model. Statistically significant differences were observed with the results of the analysis of Clinical Dementia Rating scores between normal and Alzheimer's groups. Some biomarker levels displayed

statistical significance between groups. Data is being prepared, so there are no new findings yet as to whether a CNN model can be an effective way of predicting if a patient has Alzheimer's disease. Further evaluation is required to know if CNN is enough to accomplish our goals or if we must find another hybrid method.

Abstract Name: Hydrology, Water Quality, and Invasion in the Sabie-Sand River Catchment

The rivers of Kruger National Park, South Africa are critical water resources for downstream communities and support the biodiversity of the park. Three rivers in the park, the Olifants, Sand, and Sabie, are endangered to various extents. This is a risk to both the biodiversity in these waters and to the surrounding areas that are dependent upon these rivers. The purpose of this experiment was twofold to determine the water quality and invasive species presence in the Sand River to contribute to the Park's river health assessments and determine the status of the alien crayfish invasion. The first was to assess the water quality with standard water quality measurements. The second was to determine the presence of invasive crayfish in the Sand River. Water quality was assessed by physicochemical measurements and benthic macroinvertebrate surveys by the South African Scoring System (SASS) along several sites along the Sand River. Finally, Promar traps were set along three different locations, in multiple habitats in the river to determine the presence of crayfish. The physicochemical water quality parameters were within acceptable limits for ambient water quality. The SASS scores were above the threshold in the two sites surveyed. Two crayfish were found in the Sand River, which indicates that a possible crayfish invasion has not fully set into the Sand River. There is no conclusive data on the habitat of the crayfish as the amount found was so few, but there are potential correlations that open the topic to further study. Additional studies are needed to determine if crayfish in the Sand River came from upstream, whose headwaters is within protected natural areas, or downstream in the Sabie River, where similar low numbers of crayfish have been observed.

Abstract Name: Investigation of Bioactive Compounds Derived from Cinnamon and Vanilla

Finding new, plant-based bioactive compounds with antioxidant, anti-inflammatory, and antimicrobial activity is an important part of scientific research and drug discovery programs. Both cinnamon and vanilla are known for their therapeutic properties. The goal of our research was to obtain the essential oil from cinnamon and vanilla, identify and isolate their major organic compounds, create derivatives of these compounds, and finally test those compounds for their antioxidant and antibacterial qualities. We used techniques such as hydrodistillation and Soxhlet extraction to obtain our essential oils which we purified using column chromatography and then reacted using oxidation, reduction, and Schiff-base forming reactions. Our initial results indicate that some of the compounds showed observable activity in both antioxidant assays

and antibacterial assays. In particular, our data indicates that the phenol moiety plays a key role in reducing radicals in the antioxidant assays. Further experiments involving additional Schiff-base derivatives as well as their coordination complexes could prove interesting.

Abstract Name: Examining Gender Differences in Financial Risk Tolerance and Attitudes Toward Economic Security

Research shows that men and women often have differing levels of economic education, shaped by societal expectations and disparities in financial exposure. Men tend to encounter financial concepts earlier and more thoroughly, building confidence in handling financial risks. In contrast, women, who may receive less formal economic education, often adopt more conservative financial approaches, prioritizing stability over risk, especially during economic uncertainty. Observing these gender differences in financial attitudes around me, I became interested in examining if these patterns held true on a broader scale. My goal was to explore how gender impacts attitudes toward economic stability and investment risk and to investigate if educational differences in gender contribute to this divide. Data was collected via Amazon Mechanical Turk, with 153 participants answering questions about their willingness to invest in volatile markets and perceptions of financial security. I hypothesized that men would show a higher tolerance for financial risk, while women would prioritize economic security. The results confirmed my hypothesis with the data being statistically significant at the 1% level. The findings confirmed this, with 31.1% of men displaying high levels of willingness to investment risks while only 12.7% of women display those same risky investing styles. These findings highlight the need for financial literacy programs that address gender-specific needs, helping to close educational gaps and support informed financial decision-making for people of every gender.

Abstract Name: Investigating the Potential Protective Mechanism of Probiotics in Mitigating Cadmium-Induced Hair Cell Death and Reactive Oxygen Species Production in Zebrafish

I will be investigating whether probiotic administration in zebrafish may mediate toxic effects of cadmium on hair cells. In the current literature, there's been investigation into the effects that heavy metals have against sensory cells, yet little is known about the capacity for protecting against these insults. I will use zebrafish to investigate this as they have hair cells on their surface that are easily accessible and biologically conserved, which makes them prime targets to look for protective agents against cadmium. Interestingly, an area yet to be investigated is whether probiotics, commonly used to lessen body-wide inflammation in human and animal models alike, may be protective in sensory/peripheral systems as opposed to the previously established protection in the gut-brain axis. Even further, it is unclear what mechanism probiotics may use to

initiate these protective measures, so levels of reactive oxygen species (ROS), along with levels of endogenous antioxidant activity will be measured to determine the role of oxidative stress in cadmium toxicity and potential protection from probiotics. I will address these questions through three aims, first by administering cadmium and probiotics to fish and then assessing for endogenous GSH activity, then by carrying out a dose response curve of cadmium along with probiotics to test for protection against cadmium-induced toxicity, and finally by using an ROS indicator dye to investigate ROS levels between treatment groups. I hypothesize that the results of these experiments will show a protective capacity of probiotic treatment in combination with cadmium administration, and that ROS and GSH levels correlate directly to ototoxic insult from cadmium exposure and subsequent protection from probiotics. The goal of this study is ultimately to fill the gap surrounding the mechanistic possibilities of probiotics in the quest to ameliorate heavy metal toxicity.

Abstract Name: The Relationship Between Relationship Satisfaction, Communication, and Intimacy

This study observed the correlation between an individual's relationship satisfaction, communication, and intimacy in their current romantic relationship. Research has shown greater levels of relationship satisfaction in couples experiencing elevated levels of emotional intimacy. Additionally, the literature has found that attaining relationship satisfaction lies heavily on responding constructively, by expressing care and appreciation for one's partner. Though research on the association between intimacy and couple communication is limited, it does show that those who experience lower perceived responsiveness and higher perceived punishment from their partner, experience lower feelings of intimacy. This study aims to evaluate these variables from a young adult's point of view. A convenience sample of 30 undergraduate students from Eastern Connecticut State University completed the Romantic Partner Conflict Scale (RPCS), the Relationship Assessment Scale (RAS), and the Personal Assessment of Intimacy in Relationships (PAIR). The first hypothesis of this study was that intimacy and relationship satisfaction are positively correlated, thus the more intimacy in a relationship, the more satisfaction. The second hypothesis stated that communication and intimacy have a positive relationship, therefore the more communication in a relationship, the more intimacy. The third hypothesis declared that communication and relationship satisfaction have a positive correlation, thus the more communication, the more relationship satisfaction. This study used Pearson's r correlation to assess results from hypothesis two and Spearman's Rho correlation for hypothesis one and three. There were significant findings for the relationships between relationship satisfaction and intimacy and the relationship between relationship satisfaction and communication. However, there were no significant findings for the relationship between communication and intimacy. Future researchers could explore using sexual orientation as an additional measure to examine how these variables would change within the LGBTQ community.

Abstract Name: Hungry, Hungry Snails? Importance of Hippo Dung and Potential Overloading in the Mara River, Kenya

Hippopotami play an important role in the Mara River ecosystem, where they spend most of their lives in the water, adding high amounts of dung into the river. Previous research showed that aquatic invertebrate diversity and abundance benefit from hippo dung. With current hippo population declining, we want to understand why hippo dung is important to invertebrates and if the amount of hippo dung matters. Twenty experimental streams in Florida contained one of three types of hippo dung: blended dung (to determine if dung was an important food source for invertebrates), boiled dung (to determine if hippo dung was structurally important for invertebrates), or unprocessed dung (food and structure). The amount of dung in each stream ranged from 0g to 240g for each dung type. These amounts reflected concentrations observed in the Mara River, except the 240g concentration. This high concentration of dung helped us determine if overloading of dung can be a problem. After 3 weeks, invertebrates were collected from each stream and we identified, counted, and measured them this past summer. Our results showed that hippo dung is important not only as a food source but also as a habitat, providing safety against abiotic (flooding) and biotic (predators) factors. Across treatments, the abundance of invertebrates increased as the amount of dung increased. However, concentrations of hippo dung higher than what has been documented in the Mara River (240 g) showed declines in invertebrate abundance. This indicates that more dung is not always better. Additionally, dominating snails, which are algal grazers, had the highest abundance in all samples. This was attributed to higher algae as a result from hippo dung providing fertilizing nutrients, and structure complexity where algae can grow on.

Abstract Name: Exploring CD38's Role in NAD Metabolism and Circadian Regulation

Nicotinamide adenine dinucleotide (NAD⁺) metabolism has been implicated in regulating transcription, metabolism, and healthy neuronal aging. Fluctuations in NAD⁺ levels are also rhythmic and closely tied to the oscillations of circadian rhythms in both the brain and peripheral tissues. The availability of NAD⁺ is primarily regulated by sirtuins (SIRT1s), poly ADP-ribose polymerases (PARPs), and CD38. Interestingly, CD38 accounts for 90% of NAD⁺ conversions and plays a crucial role in converting NAD⁺ to ADPR, adenine diphosphate ribose, with the byproduct nicotinamide (NAM) providing energetic precursors necessary for neuronal function. It is known that CD38-deficient mice have disrupted circadian rhythm behavior, such as shorter period lengths and loss of siesta during nighttime. Our preliminary results also show that CD38 deficient mice have elevated NAD⁺ levels and NAD/NAM ratios, increased poly (ADP-ribose), (PAR) modifications, and decreased sirtuin deacetylation in the midbrain and striatal tissue. To demonstrate the effect of CD38 on molecular clock function, we used organotypic cultures from Cd38^{-/-}:Per2Luc ^{+/+} mice and found an increased amplitude of PER2::LUC rhythmicity, further suggesting that elevated NAD⁺ may increase the strength of clock-controlled gene expression. Ongoing experiments will focus on measuring cellular PER2::LUC amplitude, period, phase, and cell-cell synchrony in Cd38^{-/-}:Per2Luc ^{+/+} mice and determining whether the expression of CD38 is rhythmic in astrocytes. Together, this could elucidate the mechanism of circadian disruption in CD38 deficiency and implicate CD38 as a key regulator in NAD⁺ metabolism and in age-related circadian disruption.

Abstract Name: The Efficiency of Financial Literacy Programs Across Demographic Groups: Addressing the Gaps in Low-Income Communities

Financial literacy programs are crucial for improving financial stability and economic outcomes, particularly in low-income communities. However, research indicates that the efficiency of these programs often varies across different socioeconomic, geographic, and demographic groups. This project explores how the effectiveness of financial literacy programs differs based on community characteristics such as income level, educational background, and neighborhood context. Through a review of existing literature, the study highlights key findings related to socioeconomic factors influencing the success of financial education, the barriers to program utilization in marginalized communities, and the role of community engagement in enhancing program impact. Studies have shown that financial literacy programs that are tailored to local contexts, integrate psychosocial support, or are community-led tend to produce better results. However, barriers such as distrust in financial institutions, lack of access to financial services, and the challenges posed by financial scarcity persist. The research also addresses why free financial literacy programs, despite being available, are often underutilized by low-income populations. By identifying gaps in existing research, the study aims to provide a deeper understanding of the challenges faced by these communities and the structural barriers hindering the success of financial literacy interventions. The findings of this study will inform the design of more effective financial literacy programs that can be adapted to different community needs, particularly in underserved areas.

Abstract Name: GPU-Accelerated Collision Detection for Spherical Particles

Discrete collision detection is the problem of detecting if two geometric objects intersect with each other. It is important to various areas of computing, including rendering, physical simulations, and virtual reality. Naive algorithms solve this problem in quadratic time by examining every pair of geometric objects for collisions. Previous works have accelerated collision detection for circular particles in two dimensions by dividing objects using a grid data structure and indexing efficiently with parallel algorithms running on GPU hardware. In this work we present an extension of this accelerated detection algorithm into three dimensions, allowing fast collision detection between spherical particles. By indexing particles into a 3-dimensional grid based on their location, the required search space is reduced to just neighboring cells. To quickly partition particles, we extend a cumulative sum algorithm that uses GPU hardware to compute particle counts in parallel. When running a discrete element method (DEM) simulation of thousands of particles, we can

simulate free-falling objects using just 3.8x the time used for the same amount of particles in two dimensions, demonstrating a low performance overhead despite the additional dimension of simulation.

Abstract Name: The Association Between Enrollment Duration and Perceptions of Social Determinants of Health Among Community Service Providers

This study investigated the association between the duration of a community service provider's enrollment within their organization and their perceptions of the importance and impact of social determinants of health (SDOH; e.g., the conditions in which people are born, live, work, and age). Health and social service providers from local and regional organizations (e.g., Area Agency on Aging, Prisma Health System, among others) were invited to participate in mobile outreach health and resource fairs (MOHRFs) conducted at various locations (2 low-income housing facilities and 1 community center) targeted towards lower-income, and rural- and urban-dwelling older adults. Prior to participating in the MOHRFs, providers were asked to complete a survey that employed a Likert-Scale ranging from 1 (strongly disagree) to 5 (strongly agree) to evaluate vendors' perceptions of 9 questions related to their attitudes, beliefs, awareness, and understanding of SDoH. The survey also included an item that asked the provider for the length of time they have worked for their organization. Data was collected from 12 providers, with varying lengths of tenure ranging from 4 months to 25 years. Pearson correlations revealed that longer-tenure within an organization was significantly associated with reporting greater agreement with the importance of the impact of SDoH ($r = -0.50$ to 1.00 , $p < .05$). These findings provide insights into how duration of engagement within an organization may influence vendors' beliefs, attitudes, awareness, and understanding of social determinants of health, potentially strengthening relationships with vendors by aligning organizational goals with the greater social and health-related needs of the communities they serve. These results are preliminary, and further research with larger samples should be conducted to identify whether observed findings are consistent across health and service providers and the potential influences for why length of time engaging in this activity impacts providers' views on SDoH.

Abstract Name: Does Experience in Multiple Contests Affect Cricket Exploration Behavior?

Previous experiences strongly influence animal behavior, particularly in response to social interactions. In this study, I investigated how sequences of positive and negative outcomes in aggressive contests influenced exploration and latency behaviors in male house crickets (*Acheta domesticus*). I divided crickets into five experimental groups: two wins (WW), two losses (LL), win-loss (WL), loss-win (LW), and a control group (CG) without contests. I measured behavioral responses both before and after the contests and conducted additional observations on subsequent days to evaluate lasting impacts. I assessed exploration by recording movements between defined areas in a test arena, and I measured latency by timing how long crickets took to exit a shelter. I analyzed behavior in a designated thigmotaxis area, a zone near the arena walls, to evaluate anti-predatory responses such as stress and risk aversion. I staged aggression contests by pairing crickets with either larger or smaller opponents to produce specific outcomes. The staged contest design allowed me to examine how winning or losing, as well as the sequence of these outcomes, influenced key behavioral metrics. I hypothesized that the most recent contest experience strongly influenced exploration, latency, and time spent in the thigmotaxis area. I expected patterns to vary based on the sequence and proportion of wins and losses. Crickets experiencing predominantly negative outcomes likely displayed more pronounced and prolonged behavioral changes than those with positive experiences. This research highlighted the ecological importance of behavioral plasticity and demonstrated how social experiences dynamically shaped behaviors critical for survival, including dispersal, mating, and predator avoidance.

Abstract Name: Accessing group 13 and 14 Azadipyrrromethene chelates via alkali salt precursors for applications in optical contrast material

As the medical field continues to progress, doctors are looking for more efficient ways to treat and diagnose patients. One of the best methods used to accomplish this is medical imaging, this technique gives medical professionals the ability to quickly visualize abnormalities in the body without using other invasive procedures. Real-time fluorescence imaging is an approach to medical diagnostics that utilizes an optical contrast material that can highlight internal anatomical features such as vasculature and organs. These contrast materials need to be moderately inexpensive, harmless to living tissue, and have emission and absorption wavelengths in the near-infrared range. These NIR wavelengths are capable of being absorbed into the body without causing extensive damage to surrounding organs and anatomy, and benefit from a higher penetration depth relative to higher energy photons. There are currently three FDA approved optical imaging contrast agents for real-time fluorescence imaging: methylene blue, indocyanine green, and Fluorescein. All of these agents are fairly toxic in large doses, and due to their photophysical properties it is often required to use close to the LD50 in order to obtain the necessary signal response in medical applications. While these contrast agents are available commercially, the medical community needs move towards less toxic alternatives. Azadipyrrromethenes, (Aza-DIPYs) are a class of compounds that emit between 600 – 1500 nm and have a molar absorptivity high enough that in very low concentrations an optical response can still be detected. In previous studies, we have assessed the behavior of a series of Aza-DIPY chelates of group 13 elements, specifically to investigate the effects of ligand substitution on the photophysical properties of the resultant compounds. In this investigation, a novel Aza-DIPY core is synthesized and chelated to various group 13 elements with the intention of probing the effect of oxidation state on these properties.

Abstract Name: Functional analysis of candidate genes for converting lysergic acid amides in *Aspergillus leporis*

Ergot alkaloids are a family of chemicals including lysergic acid derivatives that are produced by fungi and can be used in pharmaceuticals to treat dementia and migraines. Understanding the genes and enzymes that control formation of lysergic acid derivatives will facilitate their production. Several fungi, including *Aspergillus leporis*, produce the ergot alkaloid lysergic acid α -hydroxyethylamide (LAH). In some fungi LAH is relatively stable but in *A. leporis* much of it is converted to ergine and then later to lysergic acid. The hypothesis that the relatively rapid conversion in *A. leporis* is enzymatically catalyzed was supported by studies with fresh versus autoclaved extracts from the fungus. Fresh extracts rapidly converted LAH to ergine along with some lysergic acid, whereas extracts inactivated by autoclaving catalyzed minimal conversion of LAH. Since genes involved in ergot alkaloid synthesis are typically clustered, we hypothesized that genes adjacent to one of *A. leporis*'s ergot alkaloid synthesis clusters might catalyze one or both of these reactions. We identified two such genes: *easU*, encoding a Zn-dependent beta-lactamase-like enzyme, and *easV*, encoding an amidohydrolase, and used a CRISPR-Cas9 approach to mutate them. Cas9 complexed with sgRNA targeted to *easU* or *easV* was introduced into *A. leporis* along with a gene conferring resistance to pyrithiamine. Pyrithiamine-resistant transformants were screened for mutation at *easU* or *easV* by PCR primed from positions flanking the target site. Transformants with amplicons varying in length relative to the wild type were chosen for Sanger sequencing of the target locus. One transformant contained a mutation at *easU* and four independent transformants contained mutations at *easV*. Future chemical analysis by high performance liquid chromatography will determine whether mutation of the candidate loci affect the formation of ergine or lysergic acid. The ability to control formation of different lysergic acid derivatives may aid in pharmaceutical development.

Abstract Name: Simulation Based Mastery Learning and its Effect on Undergraduate Nursing Students' Psychomotor Skill Competencies

Errors stemming from inadequate knowledge, skills, and/or education pose a significant challenge in healthcare. Mastery Learning, an educational approach designed to enhance competencies through deliberate practice, has demonstrated effectiveness in improving skill acquisition. However, its application in undergraduate nursing education remains underexplored. This study aims to evaluate the impact of Mastery Learning on the psychomotor skill competency of undergraduate nursing students, focusing specifically on Foley catheter insertion, central line dressing changes, and suctioning an open system tracheostomy. The research question guiding this study is: What is the effectiveness of mastery learning curricula in improving

psychomotor skill competency among undergraduate nursing students in Foley catheter insertion, central line dressing changes and suctioning an open system tracheostomy. This retrospective quasi-experimental study analyzes data from undergraduate nursing students at the University of Tennessee College of Nursing, Class of 2024. Competency changes were assessed using a pre-test/post-test design, and convenience sampling was employed. Data analysis revealed a statistically significant improvement in students' competencies from the pretest to the first posttest, suggesting the effectiveness of education and deliberate practice. Furthermore, no statistically significant differences were observed between the first posttest and the second posttest, indicating that students successfully retained their mastery of the skills over time.

Abstract Name: Bridging the Gap: Comparing Motor Task Performance in Lab and Home Environments for Stroke Rehabilitation

Recovering motor function after a stroke is a journey that extends beyond the clinic, where the familiar walls of a lab can't fully mimic the dynamic, unpredictable environments of daily life. This study bridges that gap by comparing biomechanical data from stroke patients as they perform movement tasks in controlled lab settings versus their own homes, aiming to uncover how real-world surroundings influence rehabilitation outcomes. The objective was to assess how environmental context influences the quality and execution of motor tasks, providing insights into the feasibility of remote monitoring for rehabilitation. Data was collected from stroke patients performing 360-degree turning and sit-to-stand tasks under varied conditions—eyes open, eyes closed, on foam, and on foam with eyes closed. For the turning tasks, completion time, peak acceleration, and peak angular acceleration were measured. For sit-to-stand tasks, movement time was divided into segments: initiation to peak flexion, peak flexion to peak extension, and peak extension to termination. Additional metrics, including peak flexion, peak extension, seat-off, acceleration initiation, and termination, were analyzed. Data from both environments were compared for each metric. Differences in movement dynamics were observed between lab and home environments, particularly in acceleration and timing metrics. These results suggest that patients perform movement tasks differently outside a controlled setting, emphasizing the impact of environmental factors on rehabilitation monitoring and outcomes. This study highlights significant variations in motor task performance between lab and home settings, underlining the need to consider the environmental context in remote patient monitoring. These findings support further investigation into the design and application of home-based monitoring tools for effective stroke rehabilitation tracking.

Abstract Name: The Velocity of a Squirrel

Picture this: a squirrel, dashing effortlessly across the campus of Bowie State, whose movements appear purposeful yet spirititic. Now, let's use technology to our advantage by using a tracker to precisely monitor its movements against the context of its natural habitat. Tracking technology allows us to study a squirrel's movements across Bowie State's campus, revealing insights into its velocity, mass, and kinetic energy. These measurements tie into concepts like kinetic energy and velocity from our physics course. By analyzing how these factors shape the squirrel's motion, we enhance our understanding of physics principles and uncover the intricate relationship between theoretical knowledge and real-world observations. Additionally, we can deepen our understanding of these fundamental concepts we have learned throughout the semester.

Abstract Name: Examining Elevation Adjustments and Altitude schools Impact on the Number of Athletes Qualifying for NCAA Regionals and Nationals

This study examines how NCAA elevation adjustments impact the qualification rates of track and field athletes from altitude schools compared to non-altitude schools for regional and national championships. Using NCAA data from 2010 to 2023, we analyzed athlete qualifications from 125 West region and 215 East region schools, focusing on trends across sprint, distance, and hurdle events. The purpose of this research is to assess whether elevation adjustments effectively promote equity in collegiate athletics by mitigating geographical advantages associated with high-altitude training environments. The analysis revealed a significant increase in qualification rates for distance events among athletes from altitude schools. Interestingly, most altitude school athletes qualified for NCAA championships at lower elevation venues, where they did not receive elevation adjustments. This finding suggests that the physiological benefits of high-altitude training may enhance performance even when competing at sea level, contributing to their success. These results demonstrate how elevation adjustments and high-altitude training collectively provide athletes from smaller, budget-limited schools with a fair opportunity to compete at the highest levels. This study highlights the importance of NCAA elevation adjustments in promoting fairness and inclusivity in collegiate track and field. The policy not only levels the playing field by balancing geographical disparities but also ensures representation for athletes from underfunded and geographically disadvantaged programs. Future research should investigate the broader impacts of elevation adjustments on non-distance events and examine how high-altitude training influences athletic performance across different competition settings. By exploring these dynamics further, this work underscores the importance of continuously evaluating NCAA policies to support fairness, diversity, and athletic excellence in collegiate sports.

Abstract Name: Exploring the Role of Calpain Proteases in the Disassembly of Talin Condensates

Focal adhesions are large protein assemblies that allow cells to attach to the extracellular matrix and are vital for cell migration during embryonic development, wound healing, and the immune response. Misregulation of focal adhesions also contributes to the metastasis and invasion of cancer cells highlighting their clinical and biological significance in disease progression. While the assembly of focal adhesions has been extensively studied, the disassembly of these complexes has not been as well-characterized or understood. Liquid-liquid phase separation is one of the driving forces for the formation of these focal adhesions, enabling dynamic assembly. Thus, focal adhesions are an example of a biomolecular condensate, cellular compartments that form through phase separation driven by interactions between macromolecules. Talin plays an important role in the focal adhesion complex, acting as a scaffold to link together various other proteins in the complex. Purified talin undergoes phase separation in its open, uninhibited conformation, forming micron-sized liquid-like condensates in vitro. Calpain2, a calcium-dependent protease, has previously been shown to cleave talin at specific residues, and calpain2 protease activity is required for efficient focal adhesion disassembly in cells. Thus, we sought to test the effect of calpain2 on talin condensates. Here we show that calpain2 can disassemble preformed talin condensates. This implies that calpain2-mediated cleavage of talin specifically disrupts talin phase separation. Our results suggest that calpain2 protease activity is sufficient to disassemble talin condensates. Our study improves our understanding of the mechanism of cell migration by addressing the question of how calpain2 promotes focal adhesion disassembly.

Abstract Name: Forward and reverse genetic screens to identify genes that participate with H4K20 methylation in controlling cell proliferation in Drosophila

Control of cell proliferation is essential for organismal development and survival and occurs through a series of steps called the cell cycle. During the cell cycle, the genome is copied before the cell divides and, if this process is compromised, DNA damage and death can result. The ability to effectively replicate DNA and therefore control cell proliferation is affected by chromatin structure and accessibility, which is influenced by post-translational modifications to histone proteins including methylation. Data suggest that cell proliferation is compromised when H4K20 methylation is disrupted. However, the exact mechanism behind a requirement for H4K20 methylation in the cell cycle is still unknown. Our goal is to identify genes on the third chromosome of Drosophila that regulate cell proliferation through H4K20 methylation. Using a histone deletion on the second chromosome and a transgene on the third chromosome that expresses either wild type or H4K20R mutant histone, we are utilizing the FLP/FRT system to create histone mutant clones in the adult eye. Wildtype cells are marked with GFP and histone mutant cells with RFP, and the size of histone mutant clones relative to wildtype clones are determined with fluorescence microscopy. To identify genes that interact with H4K20 methylation, we are simultaneously performing screens with Set8-interacting proteins and 3rd chromosome deficiencies. Set8 is the only known H4K20 histone mono-methyltransferase in eukaryotes, and the action of Set8 is required for subsequent di and tri methylation of H4K20. The size of histone mutant clones is analyzed when heterozygous loss of function mutations in genes encoding Set8-interacting proteins or 3rd chromosome deficiencies are introduced. Initial results have identified a deficiency

of interest and further analysis of annotated genes within this deficiency will be performed to pinpoint the gene(s) that interact with H4K20 methylation to control cell proliferation.

Abstract Name: Addressing Oral Health Among the Unsheltered Community of Flagstaff, Arizona

Purpose: This project focused on addressing the oral hygiene needs of the unsheltered population in Flagstaff, Arizona, with the partnership of Willow Bend Environmental Education Center. Based on our needs assessment, a portion of this population experiencing chronic homelessness were faced with health disparities related to oral hygiene. We aimed to improve the oral hygiene of this population by providing accessible hygiene resources and education on proper oral hygiene practices. **Background:** According to a 2018 survey, a portion of the unsheltered population in Flagstaff includes Native Americans (44.1%) and White, non-Hispanic individuals (47.5%). Additionally, 45.8% are considered chronically homeless, meaning they have been experiencing homelessness for a long time, often facing various health issues like oral related illnesses. Unsheltered people are a transient population that don't live in one place permanently. They can transition from residing in shelters, hospitals, jails, hotels, streets/camping, with friends or family, etc. Due to the fluctuating stability in their living situation, they experience a lack of access to necessary facilities and resources to perform proper oral hygiene. **Methods:** The event was modeled using the Health Belief Model and the constructs self-efficacy, perceived severity, perceived benefits and perceived barriers. This model was used to develop event activities for oral hygiene awareness, oral cancer screening instruction, distribution of hygiene kits and meal incentives to encourage participation. Our evaluation plan included pre- and post-surveys, which determined effectiveness of the activities. While strategies for longevity aimed to integrate awareness into existing community programs like Willow Bend and the CATS engagement bus. **Conclusions:** The results saw an increase in confidence levels in understanding and identifying oral related risks. Similarly, there was an increase in the likelihood of continued use of provided resources. Overall, the intervention succeeded in increasing participant knowledge on oral health and resource awareness in Flagstaff.

Abstract Name: Experimental Determination of Parameters Affecting Backflow During Infusion into Agarose Gel from a Stepped Catheter

Direct drug infusion into the brain via convection-enhanced delivery (CED) has been a promising therapeutic

pathway for the treatment of various neurodegenerative diseases since the 1990s. CED allows for targeted treatment of small sections of brain tissue using drugs that are not typically able to be administered by conventional intravenous delivery. A major limitation of CED is the backflow of infusate up the outside of the catheter used to deliver the drug, resulting in the infusate being distributed along the length of the catheter rather than forward from the tip of the catheter towards the targeted tissue. One of the most promising solutions for this problem is the use of a stepped catheter in which a large step in outer cannula diameter occurs a length from the catheter tip. Despite previously demonstrated effectiveness of stepped catheters to limit backflow, there does not exist a major parametric study that determines how the geometric parameters of stepped catheters limit backflow. This study focuses on the main parameters presumed to have an effect on backflow during CED, that being: tip length, step width, inner cannula diameter, and infusate flow rate. This study will provide a rigorous correlation between these parameters and backflow, which may be used in the optimization of catheter designs for clinical applications.

Abstract Name: Geographic distribution patterns of *Arcobacter cryaerophilus*, a common microbial resident of sewer conveyance pipes

Wastewater conveyance systems are colonized by a robust and diverse microbial community. Previous research has focused primarily on microbial communities of wastewater treatment plants, but few have focused on the resident bacteria within conveyance systems. Our lab has shown a high abundance of *A. cryaerophilus* in wastewater systems. In this work, we examined the phylogenetic relationships of these organisms across a broad geographic area and their metabolic potential to cause detrimental effects. One major issue is sulfur cycling throughout the wastewater system which creates harmful byproducts that can cause corrosion, infrastructure failure, and wastewater treatment issues. We tested *A. cryaerophilus* isolated from sewer conveyance systems in geographically distant cities including Sydney, Honolulu, and Milwaukee (two distinct systems). We screened these isolates using different PCR assays to confirm the genus, then select samples were sequenced for the 16S rRNA gene, and phylogenetic trees were constructed. We also amplified and sequenced the sox genes of isolates of the different sewage systems. We found *A. cryaerophilus* from Sydney and Honolulu were more similar than those from Milwaukee. We further examined phylogenetic relationships based on temperature and location within a single city. We found the sox genes, which are part of sulfur oxidation pathways, which are often linked to sewer corrosion, were present in these species as core genes. We also examined if the sox genes followed the same phylogenetic patterns across the isolates to confirm the geographic patterns found with analysis of the 16S rRNA gene. This work gives us a better understanding of the wastewater ecosystem and provides more information about the sulfur cycle in these systems which could help us understand how infrastructure failures occur in sewage systems and how these cycles may vary across city and geographical scales.

Abstract Name: Feeling at Home: Exploring Third Places and University Student Belonging

Students are often torn between their academic obligations and time taken to relax and socialize. In university settings, third places are defined as places that foster socialization and allow students to be a part of a community (McLane & Kozinets, 2019), as opposed to first (home) or second (work/academic) places. Third place characteristics include a neutral, regularly accessible location that fosters a playful mood where conversation is the main activity and can act as a home away from home (Oldenburg, 1999). Our research aims to understand how students use third places on campus, and how third place use influences their sense of belongingness and community at the university. Elmhurst University students will be recruited to complete an online Qualtrics survey about their use of third places on campus and multiple measures related to belongingness and sense of community. We expect positive correlations between time spent in third places and psychological variables. As a majority commuter school, other important comparisons will be between commuter and residential students, as well as 4-year and transfer students. Literature leads us to believe that we will find a greater sense of belongingness and community among our residential students and our 4-year students, as they have had more time and access to third places compared to their counterparts (Alcozer Garcia et al., 2019; Holloway-Friesen, 2018; Lester et al., 2013). We will also get a sense of which third spaces are used most frequently on campus, an actionable piece of information for campus policy. We hope to have a greater understanding of the role of third places on campus and be able to create a greater sense of community by looking into how third places available at Elmhurst University can be enhanced.

Abstract Name: Enhancing Human-Robot Collaboration in Smart Manufacturing: “Natural Language-Driven Navigation Framework” - Autonomous Drone Navigation with Natural Language Processing for Intuitive Control

Smart manufacturing represents a transformative approach in the manufacturing sector that integrates advanced technologies into manufacturing processes. In smart manufacturing, Human-Robot Collaboration (HRC) serves as a core concept creating interdependent interactions between human operators and robotic systems. This collaboration is designed to enhance the strengths of both humans and robots, combining human creativity, problem-solving abilities, and adaptability with the precision, speed, and endurance of robots. Within this framework, Unmanned Aerial Vehicles (UAVs), commonly known as drones, have emerged as versatile robots for HRC. Drones can be used in smart manufacturing for emergency operations, infrastructure maintenance, logistics, and warehouse management. As a result, studies are conducted to navigate drones autonomously using localization algorithms and virtual simulation. Despite the potential, challenges such as obstacle avoidance, explosion risk, collision avoidance, and reliance on human supervision result in low adaptation rates. To overcome these challenges, this research proposes the ‘Natural Language-Driven Navigation Framework,’ which includes low-cost computation path-planning algorithms and Visual Integral Navigation Systems (VINS), integrated with Natural Language Processing (NLP). This novel approach to using natural language commands in drone navigation minimizes the need for training and supervision in drone piloting. The proposed solution calculates the gradient only at necessary waypoints while using VINS to enable remote visualization of the environment. The algorithms are executed as ROS (Robot Operating Systems) packages, and they provide safe trajectories with reasonable smoothness and precise coordinates of localization. Furthermore, the integration of natural language processing is achieved by

using the Open AI API large language model with the PX4 (Pixhawk) Chat module. Results show that path-planning algorithms successfully map the trajectories in indoor navigation environments. The natural language integration was conducted in the PX4 simulation environment. Simulation results demonstrated that the OpenAI API can successfully enable drone navigation through text and voice commands expressed in everyday language.

Abstract Name: Improvement of Mental Health in High School Students by Stress Management

Project Purpose: Our intervention aimed to improve the mental health of students enrolled in an alternative high school utilizing stress reduction. The main objective was to provide the students with the knowledge and self-efficacy to manage their stress more effectively, by providing them with techniques and resources they can complete on their own time. **Background:** High school students face high levels of stress in their lives, which is detrimental to their mental health. These stresses range from peer pressures, academic pressures, home environments, and a sense of not belonging. Alternative high school students are the most at risk, as statistics show they have higher rates of anxiety and depression. **Methods:** Three different types of interventions were used during this practice, each one being a way to help cope with stress and a way to potentially reduce stress. The first intervention was targeted at the benefits of outdoor physical activity, the second focused on the benefits of team collaboration, and the third focused on the benefits of mindfulness. During each day of the intervention, we had small presentations to help educate the students on the benefits and different things they can do themselves to reduce stress that may have been different from our activities. **Conclusions:** During the intervention, a pre-survey and post-survey were conducted that asked about their personal stress self-efficacy and coping mechanisms. Overall, there was a 46% increase in confidence to manage stress in a positive way. The results also showed that 70% of the students started to do physical activity and went on hikes to help reduce their stress. Most students reported that they have been less stressed in their lives and that they were using new techniques learned during the intervention to help with stress management. Word count: 289

Abstract Name: Understanding EcR Transcriptional Control of Glial Cell Development

Ecdysone (20E) signaling plays a crucial role during *Drosophila* development. In particular, the third instar stage, to make sure the tissue grows synchronously. Transcriptionally, 20E binds to its receptor, Ecdysone Receptor (EcR), activating or repressing transcriptional targets. Studies have shown how impactful it is for wing disc and salivary glands, but not for glial cells which are structural brain cells. The EcR transcriptional mechanism for glial cells is not yet understood. This study aims to understand how the ecdysone receptor

transcriptional control affects glial development during the third larvae stage. We developed tools that allow us to disrupt the binding partners of EcR. We created a transgenic fly EcR-LBD that when expressed disrupts the binding between EcR and 20E and other proteins. We then introduced a point mutation A483T, EcR-LBD-A483T, which cannot bind to the repressor Smrter. To test the transcriptional mechanism of EcR, we expressed our tools in glial cells using the GAL4 driver, repo-Gal. We analyzed the brain tissue volume and also if flies made it to adulthood. Together, this work helps understand the crucial role of ecdysone for glial development. Our preliminary survival data shows that Ecdysone signaling in glial cells is critical for the survival of the animal. Loss of Ecdysone signaling in glial cells caused by the expression of EcRLBD resulted in fewer adult *Drosophila* compared to adults. Interestingly, while some animals still died, expression of the EcRLBD-A483T did show as severe as a phenotype, suggesting that Smrter repression of EcR target is important for glial development and survival. Future work includes generating qualitative data to determine if brain volumes change with loss of EcR signaling in glial cells.

Abstract Name: Leveraging AI to Empower Neurodivergent Individuals: Maximizing Strengths and Minimizing Challenges in Education and the Workplace

The UM Neurodiversity Project aims to build a neuro-inclusive university environment by exploring pathways to support and empower neurodivergent communities. This research focuses on how artificial intelligence (AI) can be used to empower neurodivergent individuals by maximizing their unique strengths and minimizing challenges in educational and workplace settings. While neurodivergent individuals, including those with autism, ADHD, and dyslexia, often possess unique strengths such as creativity and attention to detail, they often face barriers in traditional environments. Additionally, many individuals remain undiagnosed, limiting the understanding and tailored support for this population. To address these challenges, this study explores how AI can be tailored to meet neurodivergent needs by enhancing accessibility, personalization, and usability for neurodivergent users. Using qualitative and quantitative methods, including interviews, surveys, and case studies, the research examines AI-driven strategies to reduce cognitive overload, simplify navigation, and provide personalized support. Initial findings demonstrate the potential of AI to personalize learning experiences, streamline content, and create sensory-friendly educational environments. In workplaces, AI-enhanced tools can improve task management, productivity, and inclusivity through tailored systems and inclusive hiring practices. One aspect of this study includes collaboration with the University of Michigan IT department to assess the role of AI in improving accessibility for student and staff facing websites. Given the size and diversity of the neurodivergent population, addressing accessibility gaps and leveraging AI to enhance neurodivergent strengths while reducing challenges could be significantly impactful by informing real world practices that help facilitate a more inclusive, supportive, and empowering future for neurodivergent communities.

Abstract Name: Seizures in a Bang-Sensitive Epilepsy Model Impact Associative Learning in *Drosophila* Larva

The seizures associated with epilepsy may impact learning and memory and are associated with early cognitive decline, however, the mechanism of how the seizures themselves lead to these deficits is not clear. *Drosophila* mutant flies that have seizure phenotypes has been used as a model for human epilepsy. In this study, we tested whether seizures induced in *Drosophila* *parabss* mutants, a mutation in fly sodium channel gene, affect learning. We used both rewarding and aversive stimuli to test associative learning in *Drosophila* larvae, similar to the methods developed by Apostolopoulou et al. (2010) and Pauls et al. (2010). Third instar larvae were collected from CS (wildtype) and *parabss* laid bottles. In rewarding stimulus task, larvae were trained 3x by pairing an odor (octanol or amyl acetate) with a reward (fructose). Larva then tested for movement towards the odor they were trained on, in a choice assay. In aversive learning tasks, a brief shock was paired with odor as training and then movement away from the trained odor was determined. We found that these odors were not neutral as described in the literature. Control experiments, octanol was repulsive in our assays while amyl acetate was attractive. And so, octanol was used to train in a positive associative learning task and amyl acetate was used in aversive assays. We could demonstrate associative learning using larva in assays with both odors and that *parabss* learned well as compared to wildtype using both rewarding and aversive stimulus tasks. To test the impact of seizure, larvae were exposed to the cold between the training and testing trials, which cause the *parabss* mutant larva to seize. Seizure in the mutant larva disrupted the rewarding and aversive associative learning. Similar to results we obtained previously in an adult courtship assay, seizures in *parabss* mutants can disrupt learning.

Abstract Name: Agency and Creation of Space; Empowered Women in the Gothic Fictions: Mexican Gothic and Build Your House Around My Body

This paper examines how two 21st-century gothic novels, *Mexican Gothic* (2020) by Silvia Moreno-Garcia and *Build Your House Around My Body* (2021) by Violet Kupersmith, represent women with more agency and as more developed characters than their 19th to mid-20th-century counterparts. Feminist and postcolonial analysis reveals how both authors have developed their complex female protagonists and modified traditional gothic motifs to bring their women into the 21st century. Drawing on the feminist positions of Roxane Gay, Jane Mitchell, Sandra Gilbert, and Susan Gubar, the paper establishes the traditional gothic motifs and examines how the authors alter them to show change in the gothic mode. This section will focus on the reconfiguration of relationships between men and women, and of relationships among women; on the rejection of the traditional gothic ending of either marriage or death; and on the re-situating houses in which

the women are trapped, with houses shifting from inanimate and unyielding structures to a hybrid of living and non-living, gaining sentience. Drawing upon Ignacio M. Sanchez Prado, Homi K. Bhabha, and Sharae Deckard's postcolonial and ecocritical positions, this paper also focuses on how these modern gothic novels reject and alter traditional masculine Eurocentrism, critiquing the patriarchal and imperial dominance of earlier novels. This section also reveals the authors' re-figuring of colonial gothic space, both manmade and natural. In these ways, the representations of women in gothic fiction have now changed to characterize women with more agency and complexity than in earlier gothic novels.

Abstract Name: Radiation Emission from Cell Phones

This study aimed to investigate the radiofrequency (RF) emissions of commonly used cell phones to assess potential exposure levels. A total of 2 cellphones from various manufacturers and models were tested using standardized methods to measure RF radiation levels. Measurements were taken at different distances from the devices, simulating various usage scenarios. The electromagnetic radiation that a cell phone releases in order to communicate with cell towers is known as its radiofrequency (RF). It's critical to comprehend RF exposure because excessive and prolonged exposure to RF radiation may have negative impacts on one's health. Researching RF technology in-depth is the first step in this project, which includes learning about the several RF bands, modulation methods, and communication protocols that are frequently found in mobile phones. Finding opportunities for innovation or improvement can be facilitated by analyzing the RF systems and technologies used in phones today.

Abstract Name: Developing an Interactive Data Dashboard for Strategic Neighborhood Revitalization in Lafayette, IN, Neighborhoods

The city of Lafayette, Indiana, has identified above-average levels of transiency in the neighborhoods of Lincoln, Hanna, Vinton, Monon, St. Lawrence McAllister, and Historic Jefferson. Despite the availability of funding for community development projects, the city lacks consistent and updated data to inform its proper usage to spur neighborhood revitalization in the target neighborhoods. This study aims to utilize the Polk Directory, Property Condition Surveys, and US Census data to help the city council identify target areas for funding and support. The Polk Directory is an online database housing demographic and socioeconomic data on the residents of Lafayette. Data contained in the Polk Directory provides the city of Lafayette with important context surrounding the well-being and lifestyle of its citizens including spending habits, income, and assets and liabilities. Property Condition Surveys are hand-collected at the behest of the city council of Lafayette. Using randomly sampled houses in each of the six neighborhoods, the Property Condition Surveys construct a holistic overview of the state of houses, roads, and amenities in each of the neighborhoods.

Finally, the US Census data is used to analyze aggregate trends in education, poverty, and demographics shared among the six-neighborhoods. The data from the Polk Directory, Property Condition Surveys, and US Census will be mined and analyzed to discover factors and trends that contribute to transiency and/or neighborhood revitalization. To combine these different avenues of data, an interactive data dashboard will be created and will present city officials with holistic and detailed socioeconomic trends across the six target neighborhoods. The city of Lafayette will be able to access visualizations about each neighborhood detailing the conditions of houses, average income of residents, and percentage of residents on government welfare, etc, allowing them to propose targeted policies for each neighborhood to reduce transiency and promote neighborhood revitalization.

Abstract Name: Quantitative Analysis of the Changing Collagen Fiber Organization During Tissue Loading

Collagen, the main structural protein in biological soft tissues, is crucial for maintaining the strength and integrity of the extracellular matrix. Therefore, knowledge of the relationship between the organization of collagen fibers and the mechanical function of soft tissue organs such as arteries and the bladder, is vital for understanding diseases affecting these organs. Such knowledge is also needed for creating structurally informed constitutive models. Collagen organization can be imaged using multiphoton microscopy (MPM). However, commercial software often faces challenges in accurately identifying collagen organization in these MPM datasets due to the high density and waviness of collagen fibers. We developed a semi-automatic tracing method and custom postprocessing code to precisely analyze collagen fiber orientation and tortuosity in MPM datasets. In this study, we applied this approach to MPM datasets from human cerebral arteries under various stretch conditions. We subjected cerebral vessels to uniaxial testing under MPM, allowing simultaneous mechanical response assessment and imaging of collagen fibers at prescribed stretch levels. Our semi-automated approach was then used to analyze tortuosity, defined as the ratio of the fiber's length to the straight-line distance between its endpoints, and orientation of each fiber. A collagen fiber was considered recruited to load-bearing if its tortuosity fell below a specified threshold of 1.02. Fibers in the adventitia exhibited a tortuous, bimodal orientation distribution before stretching. As stretch increased, recruited fibers became more numerous, and the bimodal distribution of fiber orientations gradually transitioned into an unimodal distribution. Eventually, this unimodal distribution centers around a zero-degree angle, reflecting the alignment of fibers in the direction of the applied stretch. With our method, we have successfully enhanced the analysis of collagen fiber orientation and tortuosity in human cerebral arteries enabling a structurally based understanding of the mechanics of cerebral arteries that can be applied to other collagenous tissues.

Abstract Name: The effect of disease-induced mortality and imitation dynamics on population vaccination rates for Mpox

The work presented here examines vaccination dynamics in the context of Mpox, a historically neglected tropical disease that gained global attention during its 2022–2023 outbreak, followed by the emergence of a new strain in 2024. Although vaccines are available, inequities in distribution and heterogeneous perceptions of relative vaccination costs have led to suboptimal vaccination uptake. To address these challenges, we extend existing game-theoretic frameworks in two key directions: incorporating disease-induced mortality and incorporating imitation dynamics. First, we allow infectious individuals to experience elevated mortality compared to the natural death rate, capturing how increased severity influences both personal risk assessments and collective vaccination decisions. Second, we shift from a static equilibrium approach to an imitation dynamics framework, which might be appropriate for diseases not yet fully endemic. Under this approach, individuals adapt their vaccination strategies over time by imitating others perceived to have more favorable payoffs. We analyze the resulting system of ordinary differential equations to characterize disease-free and endemic equilibria, using techniques from dynamical systems and the next-generation matrix approach to determine the basic reproduction number R_0 . We derive analytical expressions for equilibrium conditions and examine parameter sensitivities to understand how cost distributions, disease-induced mortality, and imperfect vaccine efficacy interact to shape long-term outcomes. To confirm and complement our analytical findings, we implemented numerical simulations in MATLAB, exploring how different parameter values, cost ratios, and imitation rates influence equilibrium vaccination levels and population health. By incorporating disease-induced mortality and exploring imitation dynamics within this modeling framework, we aim to clarify how realistic mortality assumptions and adaptive behavioral strategies may shape vaccination decisions and disease trajectories, which can then enhance our theoretical understanding and inform more effective public health interventions.

Abstract Name: A (MAD)der World: Practiced Nuclear Deterrence or Lip Service?

To determine the applicability of Mutually Assured Destruction (MAD) in today's geopolitical landscape, this study will observe and analyze the evolution of nuclear-use doctrines across the Cold War administrations (1945-1991) of the United States and the Union of Soviet Socialist Republics (U.S.S.R.). This study will catalogue nuclear doctrines throughout the Cold War to determine whether MAD kept state actors within the rational guardrails of deterrence, as well as highlight the similarities and differences of the nuclear doctrines across administrations. I review written and rhetorical communication of Cold War presidents and Soviet premieres from 1945-1991 using primary and secondary sources to determine if MAD is being communicated as an operating doctrine. I also examine weapons system development programs of Cold War presidents and Soviet administrations. Examining publicized doctrine and weapons advancement and stockpiling can uncover the dissonance between the language of executives and the weapons and militaristic proliferations. If

I observe dissonance, it tells us that MAD was used more as a smokescreen as opposed to a practiced nuclear doctrine. This finding compels us to reconsider the current relevance and application of MAD.

Abstract Name: Jumbo Shoo: A Cost-Effective System for Human-Wildlife Harmony

Human-wildlife conflict is a significant challenge in rural Namibian communities, where elephants, essential to biodiversity and ecotourism, frequently disrupt village life by damaging crops and water sources. Despite their ecological and economic importance, the increasing overlap between human settlements and wildlife habitats calls for innovative and sustainable solutions to mitigate conflict. The Jumbo Shoo project addresses this issue by developing a cost-effective, low-maintenance system that autonomously deters elephants from crop areas while preserving their access to vital water sources. This project integrates detection and deterrence mechanisms to provide a scalable and humane approach to wildlife management. The system employs a two-layer detection mechanism. The first layer uses a seismograph to detect elephant motion at a distance, triggering the second layer, which utilizes cameras and object detection software to confirm their presence at close range. Once confirmed, the system autonomously activates deterrents tailored to daylight or nighttime conditions: in daylight, an infrasound alert is deployed, while at night, a strobe light sequence is activated. This dual approach ensures high reliability and adaptability to varying environmental conditions. Solar panels power the system, providing energy and enabling time-of-day assessments, supported by a battery backup for continuous operation. Designed for ease of use, the system requires no specialized training and is scalable to form networks of interconnected devices, enhancing protection over larger areas. The Jumbo Shoo team hopes to further optimize the system to improve the reliability of the detection and deterrence states. The team will return to Namibia in May of 2025 to conduct field testing of the prototype in rural communities, collecting data to refine its performance and integration. Additionally, efforts will focus on expanding the system's applicability to address other human-wildlife conflict scenarios, supporting broader conservation goals.

Abstract Name: Examining the Mediating Roles between Gratitude and Life Satisfaction in People with Multiple Sclerosis

This study aimed to examine the cumulative mediating effect of perceived stress and mental health between gratitude and life satisfaction among people with multiple sclerosis (MS). Prior research has discussed gratitude as a source of human strength that enhances well-being while increasing the likelihood of experiencing positive emotions that facilitate happiness. While research has previously found benefits of gratitude on life satisfaction in people with MS, there is limited research on the associations among psychological distress, mental health, and well-being in the MS population. This cross-sectional design study, a serial mediation analysis was performed to investigate the mediating roles of perceived stress and mental health symptoms between gratitude and life satisfaction. Findings demonstrated that gratitude was negatively associated with perceived stress and mental health symptoms, and was positively associated with life satisfaction. Perceived stress was positively associated with mental health symptoms, and was negatively associated with life satisfaction. Mental health symptoms were negatively associated with life satisfaction. The findings demonstrated that the relationship between gratitude and life satisfaction was partially mediated by perceived stress and mental health symptoms in individuals with MS. These findings provided preliminary support for the effect of gratitude on life satisfaction through perceived stress and mental health symptoms in people with MS. Findings also provided implications on integrating gratitude interventions when working with people with MS. By increasing gratitude levels in MS, this may lead to reduced perceived stress and mental health symptoms, which can enhance their life satisfaction.

Abstract Name: Culturally Relevant Exercise Interventions: Improving Balance, Gait, and Quality of Life in Hispanic Elderly Populations

Balance and muscle strength decline with age, leading to decreased physical independence and an increased risk of falls and related injuries, which are major concerns for elderly populations. Physical activity, especially exercises targeting lower body strength and balance, has been shown to significantly reduce fall risk and improve mobility, balance, and quality of life (QoL). Group-based exercise interventions further enhance socialization and emotional well-being, which are vital for maintaining high QoL and addressing health disparities among the elderly. This study examines the effects of a structured, culturally relevant exercise program on balance, gait, and QoL in Hispanic elderly populations. Participants aged 70+ completed a five-week exercise program, held twice weekly for one hour per session, focusing on balance, mobility, and flexibility. Outcomes were assessed using the Timed Up and Go (TUG) test, Tinetti Balance and Gait Assessment, and Quality of Life Enjoyment and Satisfaction Questionnaire–Short Form (Q-LES-Q-SF). Pre- and post-intervention measures evaluated changes in balance, gait, fall risk, and QoL. Results showed a statistically significant improvement in TUG performance ($t(9) = 2.438, p = 0.037$), with pre-intervention times (mean = 14.07, SD = 2.39) exceeding post-intervention times (mean = 11.86, SD = 2.34). Improvements approached significance for the Q-LES-Q-SF ($p = 0.054$) and Tinetti Gait Assessment ($p = 0.056$). Participants also reported enhanced mobility, gait, and confidence, highlighting the importance of exercise in promoting health and independence. A longer intervention with a larger sample size could yield more robust statistical improvements across all measures. This study highlights the value of culturally tailored

exercise programs in fostering active aging, reducing fall risk, and enhancing QoL among Hispanic elderly populations.

Abstract Name: Religious Placemaking: Community and Pertenencia Fluyente - A Midwest Case Study of the Latinx Diaspora at the Catholic Church of San Miguel Arcángel

How has the Latinx diaspora utilized the Catholic Church as a space to construct an environment of “home”? To answer this question, I draw upon five semi-structured ethnographic interviews conducted with parish members and leadership at the shared parish of San Miguel Arcángel, situated in the Upper Midwest. Understanding that community exists partly due to parish members' distinct methods of community cultivation over the last twenty years, I question if belonging inherently follows. Analysis of interview responses shows that community, belonging, and tensions coexist within the parish. Puerto Rican scholar Felix Padilla's 1985 study utilizes the term “situational identity” while Peruvian American scholar Susan Oboler labels this same shifting actuality of belonging and expendability as “temporary sense of belonging.” In employing the terms, Padilla and Oboler attempt to highlight how minoritized communities are at times belonging and at other moments seen as dispensable in the eyes of dominant society. The transient implications of these two terms do not fully encompass the multifaceted and fluctuating Latinx experience at the case study parish. The Latinx sector of the parish of San Miguel Arcángel has transcended the unequivocal understanding of community and belonging, breaking the norms of temporality. To better describe their unique experience, I propose the concept of “Pertenencia Fluyente” (in English: “Fluid Belonging”). Understanding how community manifests within Latinx religious institutions is a launching point for learning from each other and nurturing solidarity.

Abstract Name: Effectiveness of a Medication Safety Checklist on Final-Semester Nursing Student Competency

Purpose: To determine the effectiveness of a medication safety checklist on nursing students' medication administration competency. Background: Medication errors in hospitals occur at a rate ranging from 5% to 41.3%. To minimize these errors, nursing programs emphasize the "Five Rights" of medication administration (right medication, right patient, right dose, right route, right time). Despite this training, many students continue to struggle with this fundamental skill. In one study, only 30% of nursing students in their final semester verified the right dose during a simulation. Yet, nurses are expected to perform safe medication administration in professional practice 100% of the time. In Fall 2024, a nursing program implemented a new simulation lab course for final-semester students, integrating medication administration competency into each simulation. Methods: Quantitative outcomes were measured utilizing a medication administration safety

competency checklist grounded in best practices. Prior to each simulation, students received education and a pre-briefing session. Following each simulation, faculty reviewed student performance and provided feedback. Education materials were adjusted based on performance patterns. Student competency will be analyzed in SPSS using repeated measures of ANOVA. Expected Results: Data collection was completed on December 5, 2024, and analysis will be completed in January 2025. Preliminary findings indicate that students' competency checklist scores improved over time. The results will be utilized for data-driven decision-making across the curriculum, and future studies will explore student progress across all four semesters.

Abstract Name: Youth Perspectives on the School-to-Prison Pipeline: Phenomenology from Colorado Public Schools

The school-to-prison pipeline (STPP) refers to the policies and practices that push students, particularly those from marginalized backgrounds, out of schools and into the criminal justice system. This research seeks to explore the development of the STPP in Colorado, and interview youth on how they have experienced these systems have shaped their lives. The STPP has its roots in various social, political, and legislative actions. These policies arose during the Reagan administration's "War on Drugs" and "tough on crime" policies and contributed to the rise of zero-tolerance approaches within education. In Colorado, the Columbine High School shooting significantly reshaped school security. Following the shooting, schools across the state increasingly adopted heightened policing measures, such as the expansion of school resource officers and isolative punishment, embedding a punitive approach to punishment within educational settings. This study investigates how these policies have impacted the lived experiences of students in relation to the STPP. This study poses the questions; How do school disciplinary policies and practices, such as zero-tolerance policies and the presence of school resource officers, affect the incidence of students becoming involved in the pipeline? How does that experience impact their education? Using a phenomenological approach, this study draws on snowball sampling to reach students who have directly interacted with systems involved in the STPP. Open-ended interviews are used to explore their encounters with school disciplinary practices and law enforcement. Data is currently being gathered from 10 youth participants with experience in a large urban school district in Colorado. The goal of this project is to interview youth (ages 18-25) on their stories and collect their narratives on the impact of the STPP.

Abstract Name: Supporting Spanish-Speaking Immigrants in Accessing Healthcare

Spanish-speaking Immigrant populations in the United States, especially undocumented individuals, face significant barriers to accessing healthcare, including language barriers, lack of insurance, and exclusion from

government programs. These challenges often lead to poorer health outcomes, such as delayed care, undiagnosed conditions, and increased reliance on emergency services. This presentation will explore the role of a volunteer Spanish interpreter in bridging this gap, particularly in the community, from a medical setting. Drawing from my experience as a Spanish interpreter in a community clinic, I will highlight how this role goes beyond simply facilitating communication between patients and providers. The interpreter's role is crucial in ensuring patients understand their diagnosis, treatment options, and healthcare rights, by also creating a welcoming and supportive environment. The task involves navigating cultural nuances, fostering trust, and ensuring patients feel understood. Interpreters face linguistic, cultural and diverse dialects they have to solve professionally and in a reliable manner. The presentation will explore how interpreters must use inclusive language and be sensitive to the linguistic diversity within Spanish-speaking communities, adapting to various dialects and communication styles to ensure more effective care. Furthermore, by providing language support and cultural insight, volunteer interpreters help overcome systemic barriers that often prevent immigrant patients from receiving adequate care. The interpreter's role is to understand the unique needs of each patient, recognizing that every experience is different, and to avoid generalizing or misrepresenting the patient's voice. Through this presentation, I will argue for expanded language services and increased resources to improve healthcare access for Spanish-speaking immigrants, ultimately fostering more equitable healthcare outcomes.

Abstract Name: Investigation regarding the physiological effects of cobalt on physiological functions in *Drosophila*, crayfish, and crab: behavioral, cardiac, neural, and synaptic properties

Cobalt, a metallic element found naturally in the earth's crust, is essential to survival. It is the active center of cobalamins such as vitamin B12 and is also a micronutrient for bacteria, algae, and fungi. The effects of cobalt (II) chloride (CoCl_2), the inorganic form of cobalt, are dependent on the dosage. High dosage or chronic exposure to CoCl_2 can have negative effects, such as carcinogenic properties, intoxication, and "beer drinker's cardiomyopathy." This investigation was designed to test the effects of acute, high-concentration cobalt exposure on physiological functions in *Drosophila*, crayfish, and crab, particularly in terms of behavioral, cardiac, neural, and synaptic properties. When exposed to 1 mM of CoCl_2 , decreased neural transmission was observed at the neuromuscular junction (NMJ) of both crayfish and *Drosophila* larvae. Within the crayfish proprioceptive organ, no conclusive changes in activity were observed due to the high variability among individuals, but activity was observed to increase in the crab proprioceptive organ after 10 minutes immersion the CoCl_2 . In larval *Drosophila*, heart rate decreased to near-cessation, though the in-situ preparations were able to recover regular heart rates after sufficient saline rinsing. Systemic injections of CoCl_2 into crayfish hemolymph produced no significant effects on heart rate or tail flip response. In larval *Drosophila* that had consumed food tainted with CoCl_2 , no effects were observed on behavior, mouth hook movements, or body wall movements; however, this led to adults bearing a slightly decreased lifespan, which indicates that 1 mM CoCl_2 has differing effects by tissue and organism.

Abstract Name: The Hidden Curriculum in Gross Anatomy – Fostering Humanistic Values in Health Sciences Students Through Anatomy Pedagogy

Cadaver dissection is the gold standard for anatomy education in health sciences. In addition to content knowledge, dissection may have added benefits for developing professional and clinical skills. This study explores how the “hidden curriculum” of a gross anatomy course fosters humanistic values such as altruism and respect, essential professional skills for clinical interactions. In this first iteration, occupational therapy (OT) students enrolled in gross anatomy were purposively sampled to participate in a pre-post, mixed methods study. An adapted version of the Human Dissection Questionnaire was administered twice at the start of the semester: once before entering lab and once after the first week of dissection activities. Surveys will be completed again at the end of the semester. The Likert scale survey focuses on emotional preparedness and perceptions about dissection and the donor body. Open-ended questions were added to the second survey but have not been analyzed yet. Descriptive statistics were calculated for student perceptions and readiness for dissection. Paired t-tests were run to assess change in these areas after the first week of lab. 100% of students agree dissection is fundamental for learning anatomy, and 90% agree they are excited for the process of discovery via dissection. A significant change ($p < 0.05$) in “readiness to make an incision” was found after the first week, along with preference to refer to the donor by their name. Students agree they want to know about the donor’s life and believe they can do so via dissection. However, they feel neutral about developing connections and identifying with the donor. OT students are excited to interact with and learn from cadavers through dissection. Early results suggest lab activities can be designed to foster humanistic values, including altruism and respect, which are critical soft skills for healthcare practitioners.

Abstract Name: Queer Belonging on Campus: The Call For Institutional Transparency

Roughly 17% of college students identify as Queer. Compared to their peers, Queer students are more likely to face harassment and discrimination on campus and experience a lower sense of belonging, which is associated with decreased retention and increased mental health issues. The Campus Pride Index (CPI) provides a nationally benchmarked database of campuses that have come out to improve the academic experience and quality of campus life for Queer students. As such, it is a fundamental tool for prospective students to identify campuses where they will feel safe and supported. Because the CPI does not capture the lived campus experiences of Queer students, it recommends campuses to conduct and report findings of cultural climate surveys. To determine if this occurred, the websites for a census of colleges and universities in the CPI database ($N=214$) were searched. Ninety institutions (42.3%) reported having conducted a cultural climate survey, and an independent t-test indicated they had a statistically higher CPI score. However, of those who reported having conducted a cultural climate survey, less than half (46.7%) reported the results publicly. An independent t-test indicated these institutions had a significantly higher CPI score than those who did not publicly report their findings. Additional analyses revealed that residential campuses had a

statistically significant difference in CPI scores and a moderate positive association with campus size. There were no statistically significant differences in CPI scores by region, religious affiliation, or minority-serving status. To provide Queer students with the support and safety they need, campuses need to conduct Cultural climate surveys and have them easily accessible to the public. Such transparency of the results demonstrates their commitment to creating and fostering an inclusive environment.

Abstract Name: Investigation of Capillin and Its Effects Microbial Growth using *Artemisia absinthium* from Wormwood

The Center for Disease Control and Prevention (CDC) estimates that at least 2.8 million antimicrobial-resistant infections continue to occur in the United States each year, killing more than 35,000 people. Globally, the World Health Organization projects that these infections will cause up to 10 million deaths annually by 2050 if new antibiotics are not developed. Capillin is an organic compound known for its cytotoxic properties, which can induce cell apoptosis. It also exhibits antitumoral, antibacterial, antimicrobial, and antifungal activities. This study investigates the inhibition of bacterial growth using *Artemisia absinthium* extract from wormwood, isolating capillin as a key active component. By examining the antibacterial effects of capillin, this research contributes to the understanding of natural compounds in medicine, offering insights into anti-microbial-resistant patients through the development of novel treatments and therapeutic options. The research findings support our hypothesis that the extract displays antibacterial properties, as evident through our preliminary bacterial growth trials. Our future studies will involve using GC-MS and HPLC techniques to verify capillin purity and concentration. Furthermore, we will investigate the mechanism of capillin in inhibiting bacterial and fungal growth.

Abstract Name: Exploring Demodex Mites on Captive Lemurs (Class: Arachnida)

Mites (Class Arachnida) are arthropod ectoparasites living on hosts. Demodex mites are a genus of mites that are normally benign, typically only causing dermatological issues when the host is immunocompromised. Mites have been extensively investigated in mammals such as humans and dogs, yet few studies have

examined mites on lemurs. Therefore, to study mite presence on lemurs, the Duke Lemur Center (DLC) provided lemur hair samples on slides taken from six facial and eight limb regions during routine vet procedures. These samples were examined under compound light microscopes using 10x and 40x objective lenses. Novel objects were then photographed and later reexamined in order to determine whether it was a mite. Mites were identified based on morphology. Data gathered from analyzing samples were organized by lemur characteristics (e.g., species, sex, age, etc.). Hair slides were examined from a total of 59 lemurs belonging to ten species, with mites being found on eight of the lemur species. Thirty-seven potential mites were found with most of the mites looking like they belong to *Demodex*, a mite genus commonly found on dogs. At least one of the mites found could potentially be a new species. This study marks the first systematic sampling of *Demodex* mites performed across lemur species. In the future, genetic analyses should be conducted to identify the specific mite species found. Studying the presence of mites on lemurs will provide insight into the largely unstudied relationship between ectoparasites and lemurs, and if / how ectoparasite frequency in lemurs can be indicative of population health.

Abstract Name: Cryptic Diversity of *Ligia novizealandiae* Isopods from Te Ika-a-Māui / North Island of Aotearoa New Zealand

Ligia are a globally distributed genus of isopods mostly found in the intertidal region of rocky coastlines. Due to their poor dispersal capabilities, *Ligia* in isolated locations often harbor highly unique genetic lineages. In some instances, these lineages have been shown to represent cryptic species (i.e., two or more morphologically similar species recognized as a single species). High levels of cryptic diversity within *Ligia* have been reported from the Hawaiian Islands, the Caribbean region, Southern Africa, the Seychelles, amongst others. We used molecular methods to characterize populations of *Ligia novizealandiae* from Aotearoa New Zealand and thus determine if cryptic diversity is found within this remote region of the Southwest Pacific. We extracted DNA from individuals collected in six localities from Te Ika-a-Māui / North Island of Aotearoa New Zealand. Three mitochondrial genes (CO1, 16S rDNA, 12S rDNA) and two nuclear genes (NaK, 28S rDNA) were sequenced from each individual. Phylogenetic reconstructions indicate the presence of three distinct and well-supported *L. novizealandiae* lineages: (a) one found in four localities on the western coastline, (b) another found at Moa Point at the southern end of the island, and (c) a lineage found at Waiwera Beach in the northeast. These lineages are highly divergent, as estimates of evolutionary divergence between 16S rDNA sequences using the Kimura 2-parameter amongst genetic range from 13.5% to 29.7% and exceed those reported for comparisons between *Ligia* species. To further our understanding of cryptic diversity within Aotearoa New Zealand, additional sampling will need to be conducted on the east coast of Te Ika-a-Māui / North Island and on Te Waipounamu / South Island. Further analysis will need to be completed to identify any additional lineages and determine whether these lineages represent new species.

Abstract Name: The Experiences of Incarcerated Postpartum Women: A Comprehensive Literature Review

The majority of women in prison are of reproductive age; currently, there are an estimated 55,000 pregnant women in jail, the majority will continue to serve their sentence after childbirth and be separated from their child within 24 hours. Postpartum women have significant physical and emotional needs, these needs are complicated by: isolation, mother-child separation, and non-standardized care within prisons. Prisoners typically receive substandard care that fails to address the unique needs of postpartum women. This study offers an overview of the experiences of incarcerated postpartum women who have participated in supportive programs. Postpartum care programs are defined as programs focused on maternal and infant care that include women from delivery to one year after birth. A comprehensive literature review of qualitative studies will be used to understand the perceptions and experiences of women who are in postpartum programs while incarcerated. This study will include articles that are peer-reviewed, English, published between January 1, 2000 and November 1, 2024, and from the databases: CINAHL, PubMed, & PsycINFO. Studies will be evaluated using the JBI Critical Appraisal Checklist for Qualitative Research. Preliminary findings have shown that imprisoned postpartum women feel significant grief due to infant separation and lack of support. Postpartum programs modestly improve the health outcomes of mothers. Programs can help mothers by providing opportunities for improved lactation, nutrition, and crucial maternal-infant bonding. There are limited programs focused on psychosocial health. Postpartum and maternal support is minimal in prison, however, prison programs help improve outcomes and should be more widely implemented throughout the prison system.

Abstract Name: SignalVerse: Harnessing LLMs to Revolutionize Traffic Signal Management

The optimization of traffic signal systems is a critical challenge in urban transportation planning, requiring quick and reliable access to precise and context-specific information. Despite advancements in adaptive signal control technologies and performance measurement systems, a gap remains in integrating these technologies effectively and making their knowledge widely and quickly accessible. To address this gap, we introduce SignalVerse, a specialized chatbot designed to support traffic engineers by providing reliable answers to complex queries about traffic signal operations and management. SignalVerse employs a dual-response system that merges information from a custom-built knowledge base—comprising specialized traffic signal documents—with responses sourced globally. This allows users to compare the relevance and accuracy of different sources of information. Our methodology involved continuous user feedback to refine its' responses, ensuring they meet the real-world needs of traffic engineers. The results indicate that SignalVerse provides highly satisfactory and contextually relevant answers, significantly aiding traffic signal optimization tasks. While SignalVerse shows great promise, it has limitations, such as the initial scope of its knowledge base. Future research focuses on expanding the knowledge base, enhancing natural language processing techniques, and exploring broader applications in traffic engineering. In conclusion, SignalVerse represents a significant advancement in the field, offering a practical solution for traffic engineers to access specialized knowledge quickly and reliably. By addressing the critical need for efficient information retrieval in traffic signal management, SignalVerse contributes to safer and more efficient urban transportation systems. Abstract Name: Human Neuroblastoma Cancer Stem Cells (SH-SY5Y) Differentiation using Retinoic Acid: A Potential Therapeutic Strategy

ObjectiveTo test if retinoic acid (RA) can induce differentiation of Human Neuroblastoma cancer stem cell line (SH-SY5Y) into normal neurons and offer a chance for cure for patients with Neuroblastoma.
Background:Neuroblastoma is a neurological malignancy with high relapse rate and mortality in young children despite optimal treatment.Retinoic acid (RA), a compound of vitamin A, can induce cell differentiation. It is used as treatment in acute promyelocytic leukemia by inducing differentiation of cancer cells. Whether RA can induce differentiation of Neuroblastoma cancer stem cell line SH-SY5Y is unknown.
Material and methods SH-SY5Y human neuroblastoma stem cells. RA, 1.25, 2.5, 5 and 10 micromolar (mm) concentrations, prepared along with 2% and 10% Fetal bovine serum (FBS) media. Cells are plated in wells of 2% and 10% FBS and incubated for 24 hours. RA concentrations from 1.25 to 10 mm added to wells with 2% and 10% FBS. Media replaced daily for 5 days. Plate fixed using phosphate buffered saline. Stain for neurons using 0.1% Triton X-100 TUJ1 primary antibody and secondary antibody mIgC129 added. Cells imaged for differentiation into neurons under fluorescent microscope
ResultsRA incremental concentrations from 1.25 to 10 mm concentration were tested with FBS of 2% and 1 %. FBS poor media resulted in cell death. Concentration of RA below 5 mm did not induce optimal cell differentiation.The optimal concentration of 10 mm retinoic acid and 10% fetal bovine serum effectively induces the differentiation of neuroblastoma stem cell lines into neurons, presenting a potential therapeutic strategy.
Conclusion: Neuroblastoma is a high-risk malignancy in children. This study suggests that retinoic acid, in combination with the optimal concentration of fetal bovine serum, can induce differentiation of the SH-SY5Y human neuroblastoma stem cell line. Testing retinoic acid in vivo should be considered, as it may offer a potential chance for cure for neuroblastoma patients.

Abstract Name: Identification of genes that dictate spatiogenetic structure formation in *Pseudomonas fluorescens* colonies through random and directed mutagenesis

The spatial organization of individual cells within a densely structured bacterial population profoundly impacts their survival and adaptation. In a colony model of *Pseudomonas fluorescens* Pf0-1, rsmE mutants spontaneously and repeatedly emerge as localized patches by solving the problem of overcrowding. These mutants use extracellular secretions that are consequently de-regulated by the altered post-transcriptional

regulator RsmE to form a dominant spatial structure. Through random transposon mutagenesis, 14 distinct genes were identified to impact spatial structure formation. We are currently validating our initial findings by constructing deletions of the candidate genes in the wildtype *P. fluorescens* Pf0-1 strain and a rsmE mutant and competing individual knockout isolates against the wildtype to assess their relative fitness and changes in spatial structure formation. Here, we report the results of the transposon mutagenesis screen and our current progress on the validation efforts. The mutant set includes genes that are bioinformatically predicted to encode extracellular secretions, signal transduction components, and proteins of unknown function. Mechanistic insights into the molecular architecture and regulation of bacterial community organization could provide a new path of discovery toward optimizing biotechnological processes and developing therapeutic strategies against chronic bacterial infections.

Abstract Name: The Interplay of Policy Content and Institutional Dynamics in Legislative Behavior: Insights from Cosponsorship and Roll Call Networks

Does the content of bills explain cooperation among US Senators? How do policy, partisanship, and institutional roles shape legislative behavior in the US Senate? This paper addresses these questions by examining cosponsorship and roll call voting behavior during the 117th Congress using Exponential Random Graph Models (ERGMs). This study incorporates two networks: a cosponsorship network that includes senator-level attributes (e.g., party, seniority, leadership) and edge-level covariates (e.g., text similarities of sponsored bills) and a roll call voting network that includes party affiliation, bill similarity, and cosponsorship behavior. A unique aspect of this study is the use of Bi-LSTM processed BERT embeddings to quantify the textual similarity of bills sponsored by each senator, capturing the influence of policy content on legislative decision-making. My findings demonstrate that policy alignment significantly affects cosponsorship ties, surpassing traditional factors such as partisanship. In contrast, roll call voting behavior is more strongly influenced by prior cosponsorship patterns and party affiliation, though policy alignment also plays a minor role. Together, these findings explain the drivers of legislative networks, highlighting the interconnected yet distinct drivers of cosponsorship and voting behavior in the Senate.

Abstract Name: Fear and Fascination: A Computational Analysis of Personal Safety Discourses within the Subreddit r/TrueCrime

True crime has become an extremely popular genre of media and is more widespread than ever, with countless stories being adapted into biopics, documentaries, podcasts, TikTok series and more. As true crime becomes more popular, there is a scramble in Hollywood to make the best and scariest renderings of the most heinous crimes. This morbid fascination can be viewed as simple consumption of enjoyable media, but I

hypothesized that watching and listening to true crime stories can have real life emotional implications that can be detrimental to how consumers interact with the world around them. Recent research on the true crime genre suggests that consumption of true crime content is connected to increased feelings of fear. In this study, I aim to further answer the research question “Do those who consume true crime perceive a heightened sense of danger in the real world?” I performed a computational topic analysis—an automated technique for identifying language-based clusters within a sample of texts—of the subreddit message board r/TrueCrime via Communlytic to analyze the emotional responses of true crime consumers. I chose the subreddit r/truecrime to focus the study on heavy consumers of true crime content and limited my sample to posts featuring keywords related to personal safety. The topic analysis generated 10 clusters of Reddit posts, and I am currently in the process of analyzing them to develop categories describing how r/TrueCrime members understand and describe personal safety. Ultimately, this study underscores the real life implications of violent stories sensationalized for the purpose of entertainment.

Abstract Name: The Cellular Role of par-1 in the Development of the *C. elegans* Male Tail

The par-1 gene codes for PAR-1 kinase protein, which contributes to cell polarity during cellular development in *C. elegans* and other organisms. The human orthologs of par-1 have been found to contribute to the progression of Alzheimer’s Disease through phosphorylation of Tau protein in the brain. Previously, PAR-1 has been found to play an essential role in the development of the *C. elegans* vulva with a post-embryonic RNAi silencing approach. Several new worm strains were created in order to visualize development of the tail cells with GFP reporters. Post-embryonic RNAi treatment of par-1 was used to study the development of *C. elegans* male tails. Worms that underwent RNAi treatment showed visible defects in male tail rays and cuticle shape. Visualization by DIC and epifluorescence microscopy shows that par-1 plays a role in the development of the *C. elegans* male tail.

Abstract Name: Increasing Bystander CPR Training in Latino(x) Communities

Latinos in Los Angeles receive bystander CPR at about half the rate of White residents, a disparity linked to barriers such as cost, limited Spanish-language training, fear of liability, and lack of bilingual 911 dispatchers.

Researchers surveyed attendees at health fairs in predominantly Latino neighborhoods to better understand CPR knowledge and utilization in the local Latino community, including the Vision y Compromiso conference and the Latino Student Health Project Health Fair. Eighty-two participants completed a 30-question survey assessing CPR knowledge and identifying barriers to learning and performing CPR. The survey results revealed that while 77.3% understood CPR's purpose and 88.9% had some knowledge of it, only 58.0% felt comfortable demonstrating CPR techniques. Additionally, 74.4% had attended a CPR course, but only 45.3% held an active certification. Key barriers to obtaining certification included cost (39.3%) and lack of Spanish-language courses (25.0%). Barriers to performing CPR in emergencies included language barriers (75.0%), fear of legal consequences (53.2%), and uncertainty about when CPR is needed (41.6%). The findings highlight the need for low-cost, bilingual CPR training programs in Latino communities. These programs should address Good Samaritan laws to alleviate liability concerns and include guidance on recognizing cardiac arrest to improve confidence in performing CPR. Enhancing CPR accessibility and knowledge in the Latino community is vital to increasing bystander CPR rates and improving cardiac arrest outcomes.

Abstract Name: Identifying the Chemical Composition of Kombucha Tea

Kombucha tea has gained popularity for its reported antimicrobial properties, antioxidant content, and polyphenol content. These properties are attributed to acetic acid production during fermentation, which subsequently lowers the pH of kombucha and contributes to the production of kombuchas' proposed health benefits. In this study, eight different types of herbal kombucha-fermented teas (HKFTs) were studied over a two-week fermentation period, during which the chemical profiles of these different HKFTs were analyzed. Colorimetric assays such as DPPH and the Folin-Ciocalteu assay resulted in a positive increase of both antioxidants and polyphenols as fermentation progressed in all HKFTs. The antimicrobial properties of the HKFTs were also measured against *Escherichia coli*, resulting in partial antimicrobial properties of the different teas regardless of the pH value of the HKFTs. The results suggest that the chemical profile of kombucha changes throughout the fermentation process and is dependent on the organic material used to brew the tea.

Abstract Name: Optimizing Mentor-Mentee Pairing: A Linear Programming Approach for Diverse Business Majors

This paper presents an optimization framework for mentor-mentee pairing using a linear programming approach. The model incorporates multiple weighted attributes, such as the alignment of mentor industry backgrounds with student majors and the Euclidean distance between their profiles. By maximizing

compatibility and minimizing total weighted distances, the proposed solution effectively addresses the challenge of pairing mentors and mentees across diverse business disciplines. This research highlights the power of mathematical optimization techniques in enhancing undergraduate research experiences and fostering meaningful mentor-student relationships.

Abstract Name: Exploring the Integration of Cybersecurity Tools in Software Development Pipelines: A Literary Analysis and Research Proposal

As cyber threats increasingly target software development processes, integrating cybersecurity tools into CI/CD pipelines is essential for minimizing vulnerabilities. This research explores the effectiveness, integration points, and costs associated with various commercial and open-source cybersecurity tools within CI/CD pipelines. Through a comprehensive literature review of scholarly articles, industry reports, and case studies, this study categorizes tools—such as OWASP ZAP, Veracode, and GitLeaks—by their application points, assessing their effectiveness and integration challenges. Additionally, hands-on testing with a GitLab CI/CD pipeline will be conducted to validate findings and evaluate the tools' real-world applicability. The study adopts a mixed-methods approach, combining literature analysis, empirical testing, and professional interviews with cybersecurity experts. Expected outcomes include a detailed catalog of tools, best practices for integration, and practical recommendations for small to medium-sized organizations seeking cost-effective security solutions. The catalog will cover each tool's integration costs, points of application, and performance in vulnerability detection. By bridging the gap between development speed and security needs, this research offers actionable insights for developers and security professionals, equipping them to make informed decisions about cybersecurity investments and pipeline protections. This work contributes to the broader DevSecOps movement, providing foundational guidelines that can help organizations enhance their CI/CD security frameworks effectively and affordably.

Abstract Name: Impact of Tumor Treating Fields Therapy on Patient-Derived Glioblastoma Models with Varying Radiation Sensitivities

Glioblastoma (GBM) is the most frequently occurring malignant primary brain tumor in adults. Current standard of care includes maximal safe tumor resection, chemotherapy with temozolomide (TMZ), and radiotherapy followed by adjunct TMZ and Tumor Treating Fields. Tumor Treating Fields (TTFields) delivers low intensity, intermediate frequency alternate current electric fields to tumors by transdermal application. TTFields has been shown to broadly induce autophagy, cell membrane permeability, DNA replication stress,

and anti-mitotic and anti-migratory effects. Despite clinical evidence in support of the benefits of TTFIELDS for GBM, prognosis remains poor. GBM shows an inherent and acquired resistance to TMZ and radiation, driven in part by brain tumor-initiating cells (BTICs), and a more thorough understanding of the effects of TTFIELDS in radiation-resistant GBM is needed. Patient-derived xenografts (PDX) were previously developed through subcutaneous implantation of patient GBM cells into immunodeficient (nu/nu) mice, and acquired radiation-resistant PDX were generated through serial in vivo radiation. We assessed the survival of PDX with varying radiotherapy sensitivities by cell viability assay Cell Titer Glo five days post-radiation. PDX were cultured on geltrex-coated coverslips under serum-free conditions. TTFIELDS was administered to PDX with the Novocure inoventro™ in a cooling incubator to maintain a 37°C sample temperature in the device ceramic well plates. Results showed that TTFIELDS provided varying growth inhibition across GBM PDXs depending on radiation sensitivity or resistance.

Abstract Name: Cholera and Colonization: The Racialization of the Philippine-American War

Increased disease outbreaks are noted with a greater frequency during times of conflict. Most studies on cholera focus on peacetime, removed from periods of war, yet its highest casualties are noted in the immediate aftermath. The annexation of the Philippines and its preceding conflicts coincided with the height of jingoism and were driven by the belief in the inherent supremacy of white America over the Orient. American expansion emphasized the idea of benevolent assimilation: the idea that colonialism existed not for the subjugation but rather domestication for acceptance into the broader American empire. Successive wars in the Philippines at the turn of the 20th century created one of the highest civilian mortality combat rates at the time. V. cholera, already present and endemic within the Philippines, is especially proliferative in conditions that arise immediately in the years post-war. Through the analysis of American martial law, first-hand accounts of the Philippine-American war, and the availability of 20th century bacteriology, I argue that the destruction of local public health infrastructures, hypermobility of troops and refugees, importation of and co-infection with disease, and destruction of food systems during the Philippine-American war enabled the spread of cholera during the 1902-04 epidemic in the Philippines.

Abstract Name: Expression, Purification, and Characterization of NMA1

According to the National Council of Aging, 94.9% percent of adults aged over 60 have at least one chronic medical condition. During aging, an essential coenzyme found in all our cells known as nicotinamide adenine dinucleotide (NAD⁺) decreases, which causes functional and metabolic decline. NAD⁺ is used in many cellular redox reactions for energy metabolism and involved in biological processes, such as DNA repair, calcium-dependent signaling pathways, chromatin structure, lifespan extension, and age-associated diseases. It also fuels another important regulator of our metabolism, the deacetylase enzymes sirtuins, that assist in

delaying cellular senescence and extending lifespan. As a result of the NAD⁺ levels diminishing with aging, researchers have been trying to increase NAD⁺ levels. One method is targeting the biosynthetic pathways that produce NAD⁺. The three major ones are the de novo, nicotinamide (NAM) salvage, and nicotinamide riboside (NR) salvage pathways. NMA1, a homolog of human nicotinic acid mononucleotide adenylyl transferase (NMNAT), is found in yeast and is a key enzyme in the NAD⁺ salvage pathway. I aimed to purify NMA1 to help facilitate further studies on producing enzymatically active NAD⁺ analogues in the laboratory and shifting from synthetic production. After several weeks of expressing our NMA1 protein with a His-tag from transformed Rosetta DE3 cells and purifying it with nickel column chromatography, I isolated the protein as indicated by the SDS-PAGE gels. For further purification of NMA1 protein from the impure fractions, I cleaved the His-tag with thrombin, which didn't prove to be efficient. By performing an enzymatic assay with the NMA-1 protein without the His-tag, I found that our purified NMA1 can successfully convert NMN to NAD⁺ as an enzymatically active protein, which can be a valuable therapeutic intervention against aging.

Abstract Name: The Disconnect Between the American Dream Ideology and the Evolving Work Culture of Younger Generations: A Study of Changing Values, Economic Realities, and Career Expectations

Abstract The concept of the American Dream has long been associated with the belief in upward social mobility and the idea that hard work can lead to success. For generations, this narrative has shaped individual's aspirations in the United States. However, this traditional ideology is increasingly viewed as outdated, often disconnected from the realities of modern economic challenges. This study seeks to explore the disconnect between the traditional ideals of the American Dream and the evolving work culture of younger generations, particularly Generation Z, as they enter the workforce. In an era marked by rising student debt, economic insecurity, and the decline of traditional career paths, young workers' values and expectations are shifting dramatically. This research examines how younger workers are rethinking key aspects of the American Dream, including job security, financial stability, and personal fulfillment, alongside issues such as work-life balance, career goals, and definitions of success. Through open-ended surveys, interviews, and an analysis of current demographic trends, this study aims to offer a deeper understanding of how changing work dynamics are reshaping the American Dream. The findings will contribute to discussions around organizational policies, economic inequality, labor market reforms, and strategies to reduce burnout, ultimately guiding organizations in adapting to the needs and values of the new workforce. Keywords: American Dream, work culture, economic challenges, cultural shifts, generational values

Abstract Name: Water Quality of Spring Brook Creek in Southeast Wisconsin: Implications for Cravath Lake

The Southeast Wisconsin Regional Planning Commission (SEWRPC) is working with the city of Whitewater, Wisconsin to develop a Lake Management Plan for Cravath Lake. In cooperation with SEWRPC, a study was organized to establish monthly (June-November) indicators of water quality on Springbrook Creek that can be used to better understand the environmental conditions in the watershed. Five sampling sites were identified. At each site water temperature, pH, conductivity, dissolved oxygen, total dissolved solids, and water clarity were examined. At the most downstream location water samples are collected for total phosphorus, reactive phosphorus, total kjeldahl nitrogen, ammonia, nitrate + nitrite (as N), chloride, and total suspended solids. Initial results show total phosphorus levels were much higher in June (0.511 mg/L), July (0.120 mg/L), and August (0.117 mg/L) than the 0.075 mg/L criterion identified by the Wisconsin DNR for Cravath Lake. Reference values of total phosphorus for streams of similar size in southeast Wisconsin are 0.03-0.04 mg/L. Nitrate + Nitrite (as N) averaged 5.0 mg/L during June, July, and August, which is double the reference values for sampled streams in southeast Wisconsin. The high values of total phosphorus entering Cravath Lake is concerning. Samples are currently being processed and when complete, will provide a more detailed examination of nutrients entering Cravath Lake.

Abstract Name: The Russo-Ukrainian War and Implications for the Western Balkans

The Russian sphere of influence extends far beyond the borders of the former Soviet Union—as seen through events as varied as the Russian military operations in Africa and the growing Russian media presence in Latin America. In Europe, Russian influence outside of the nations of the former Soviet Bloc has appeared most aggressively in countries of the former Yugoslavia, where Russia has used military, political, religious, and media pressure to expand influence over European territory. This continued influence makes the Western Balkan region a particularly fruitful region for study. The Yugoslav successor states and Albania are at risk of experiencing negative spillovers from the ongoing Russian invasion of Ukraine. In the context of the Balkans, these developments could feature increased nationalist sentiment and an enhanced desire for autonomy or sovereignty of independence movements (both of which may lead to violence) as a result of ethnic tensions, heightened by factors like EU and NATO integration. My research question asks how the Russian war on Ukraine — usually seen outside of the Ukrainian theater as a confrontation between Russia and NATO — might affect the nonaligned countries of the Western Balkans. My research gathers data from interviews with local actors, building off my work this past spring in Bosnia and Herzegovina with the Post-Conflict Research Center an NGO active in the area, to better understand how Russian actions hundreds of miles away in Ukraine, combined with the preexisting Russian influence in the region, have destabilized events on the ground in the Western Balkans. The present research also asks what this sustained influence could mean for the Balkans depending on the outcome of the war in Ukraine. This understanding is crucial for the prevention of violence and for exploring the interconnected nature of threats to European security and peace from Russian aggression.

Abstract Name: On the Verge of a Flood: An Investigation of High Hazard Dams in Rural Kentucky

There are approximately 300 Kentucky dams considered high hazard dams by the state, and two-thirds of these threaten communities. Many Kentucky dams were built in the early 20th century; most of them have experienced deferred maintenance and are used beyond their limits. The issues and safety hazards posed by these dams are only escalating, especially as the populations increase and weather patterns change. Funding is difficult, grants are scarce, and it often falls on citizens of rural communities to pay for the upkeep. This research will explore the five most critical condition dams and evaluate threats, societal impacts, and possible solutions. Using archival records from a dam engineering consultant, as well as current-day interviews and prediction mapping, dams will be analyzed by considering their past, present, and future. The Hiram J. Graham papers, 1915–1950, at the University of Kentucky Special Collections Research Center contains reports, photographs, and planning documents for numerous dams in Kentucky, focusing on the numerical data. This research will be inspired by his documentation and will provide a unique analysis of hazardous dams by considering engineering, political, and humanitarian viewpoints. This research calls for greater awareness of the growing flood issues and the lack of support for dam upkeep, particularly in rural areas. As a result of this research, an easily accessible guide written for community members—not engineers—will inform the communities affected by potential dam flooding and highlight the humanitarian impact that is usually forgotten within technical reports.

Abstract Name: The Impact of Faculty, Staff, and Student Perceptions of Campus Accessibility on Academic and Social Outcomes for Students with Disabilities

This project seeks to examine the question: Does faculty/staff/student perception of campus accessibility impact academic and social outcomes for students with disabilities? College student success is a heavily talked about and researched topic. Interactions in the various student populations are what creates an individualized environment for each student. For students with disabilities, this environment and the individuals within are crucial to their ability to thrive. Students with disabilities are statistically less likely to achieve a bachelor's degree with a completion rate of 41% in the United States alone. This isn't due to a lack of ability as students with disabilities have been shown to have the skills to achieve the same goals and tasks as students without disabilities. Research suggests that the accessibility within the environment and support systems for students with disabilities heavily impact this achievement. Accessibility refers to access to not only the physical space, but the academic learning environment. Students with disabilities face challenges related to accessibility including, but not limited to, medical challenges, financial difficulty, and stigmatism from university staff and students. Many students are hesitant to receive the support they need because of stigmatism from disability disclosure and its impact on peer and faculty interactions. For this project, a mixed-method approach was employed. Data were gathered and analyzed using a systematic literature review in conjunction with a survey that will be completed by faculty, staff and students at a state university in Pennsylvania. The expected conclusions will explicate how perceptions of campus accessibility for persons with disabilities by the university population in this particular setting can impact how a student with disabilities will manage and achieve success. This study will help further identify challenges for this setting and present solutions for improving academic and social outcomes for students with disabilities in this setting.

Abstract Name: Developmental Dissection of Neuroanatomical Disruption Following Early Life Adversity

In the United States, over 36 million individuals live in poverty, with millions of children affected by domestic violence and prenatal substance exposure. These adverse experiences are forms of early life disturbances that can have debilitating effects on brain development or predispose individuals to psychological disorders. While research has shown that genetic and environmental factors influence brain development and adverse environments have harmful effects, exactly how early life disturbances change the brain's growth, maturation, and impact behavior later in life is still not well understood. Existing research has demonstrated that early life adversities (ELA) can result in altered neural activity, however no one knows how the developmental programs that lead to those changes emerge. The goal of my research is to understand how early life adversities affect neuroanatomical changes throughout development, such as changes in size and structure of key brain regions. Recent research has demonstrated that zebrafish subjected to ELA as larvae, induced by random pulses of mild electric current, have elevated stress-like responses in later life. In this study fish will be exposed to shock then grown and tested at different time points, 7dpf, 28dpf, and 60dpf. Fish will be imaged using advanced microscopy with tERK as a neuroanatomical marker. These images will be registered to the larval or novel juvenile/adult brain atlases. Differences in whole-brain neuroanatomy will be performed using the CobraZ platform for analysis. We hypothesize that regions traditionally associated with stress like the amygdala and hippocampus will differ in size between ELA and control fish. This research will provide valuable insights into how ELA affects the brain anatomically and the timeline in which that occurs. The regions found to be affected and the time points in which they occur provide a strategic roadmap for future research investigating the exact molecular mechanisms causing the changes.

Abstract Name: THE EFFECT OF CAFFEINE ON ALCOHOL CONSUMPTION IN ADOLESCENCE

Caffeine and alcohol are two of the most widely consumed drugs worldwide, and their combined consumption is becoming increasingly popular among adolescents. When caffeine and alcohol are consumed together, caffeine can increase hazardous behaviors associated with alcohol consumption. Although this trend is growing, there is still limited understanding of the potential effects of mixing these substances on the developing adolescent brain. The purpose of the present experiment was to assess the effect of caffeine administration on alcohol consumption when the two substances were not administered on the same day. Ethanol consumption in male Sprague-Dawley rats was measured via intermittent-access two-bottle choice (IA2BC) procedure, wherein 20% ethanol was placed on the home-cage for 24 hours, every other day, for a 20-day period (water was continuously available). Rats were randomly assigned to one of four treatment conditions: ethanol and caffeine, ethanol and vehicle, water and caffeine, or water and saline. Water served as

the control for ethanol, and saline served as the control for caffeine. On days when ethanol was unavailable to the ethanol group, all rats received an intraperitoneal (IP) injection of either caffeine or saline. Preliminary findings suggest that caffeine attenuated ethanol consumption, specifically on days p40 to p45. This raises the question of whether this period of development is more sensitive to the effects of drug use. Future research in this field could explore the effects of this adolescent exposure on adult ethanol consumption, as well as anxiety-like behavior. Caffeine is known to mimic the somatic symptoms of anxiety or panic attacks, prompting the question of whether caffeine exposure during adolescence would affect anxiety-like behavior after rats develop into adulthood.

Abstract Name: Studying the Bending Mode of Carbon Dioxide in Ionic Liquids

Ultrafast multidimensional spectroscopy, or 2D-IR spectrometry has been used to study CO₂'s asymmetric stretch to further the understanding of the interactions between CO₂ and ionic liquids. This interaction is important because ionic liquids are a promising method of carbon capture. The current laser setup in Prof. Sean Garrett-Roe's lab is optimized to study this interaction through the asymmetric stretch of carbon dioxide. Unfortunately, the current laser spectroscopy setup is incapable of examining the bending mode of CO₂. This bending mode is important because observing it would provide greater insight into the molecular mechanism involved in carbon capture. This research project is working to develop a new spectroscopic method that would generate data about carbon capture from the bending mode in various materials. This has involved modeling and building a modified laser setup which will provide a new means of testing the central hypothesis developed by the lab, and that predicts the interactions between CO₂ and ionic liquids. This hypothesis is based on previous experimental results collected in Sean Garrett-Roe's lab as well as collaborations with the Corcelli group (University of Notre Dame). To test this hypothesis, an optical parametric amplifier (OPA) was built. This is a laser setup that uses many optics and crystals to modify the light from the lab's existing laser to the specific wavelength of light needed to interact with the CO₂ bending mode. This modified setup was designed in FreeCad and the crystal behavior was modeled using Select Nonlinear Optics (SNLO) to determine which crystals would be ideal for generating this wavelength of light. The project will continue to work construct a 2D-IR spectrometer to record data on the interactions between CO₂ and ionic liquids.

Abstract Name: Bridging the Gap: Enhancing Access to Dental Care in Low-Income Communities Through Mobile Dentistry

Millions of children in low-income communities face significant barriers to accessing basic healthcare

services, including dental care, which can lead to health concerns that negatively affect overall health, education, and social development. The question is: how can children's access to dental care in underprivileged areas be enhanced? This study investigates the efficacy of mobile dental care as a solution to improve access to dental care for adults and children. The methodology for this research involved a comprehensive review of existing literature related to the implementation, cost-effectiveness, and outcomes of mobile dental clinics in low-income communities. A detailed analysis was conducted on the prevalence of dental care access, community needs, and the financial impact of providing mobile dentistry services in economically disadvantaged regions. This included reviewing data on the availability of dental care, as well as assessing the effectiveness of mobile dental units in overcoming geographic and financial barriers to care. Data was gathered on the financial strategies used to support mobile dentistry programs and the potential for long-term sustainability. The study evaluated outcomes such as the reduction in untreated dental issues, improvements in oral health, and the overall impact on children's health and educational performance following treatment in mobile clinics. Research suggests that mobile dentistry not only increases access to dental care but leads to improvements in children's general overall health. The study concludes that mobile dental clinics have the potential to bridge the healthcare access gap in low-income communities. The research emphasizes the importance of investment in mobile dentistry, advocating for policy changes, securing funding, and conducting further studies to refine the delivery of care. These efforts are essential to ensure that all children, regardless of their socioeconomic background, receive the dental care necessary for a healthy future and a healthy smile.

Abstract Name: Evaluating Google and ChatGPT 4o as Patient Information Repositories Regarding Bone Grafting

The aim of this study is to demonstrate the impact of search engine information and comparing that quality between Google and Chat GPT4o in regards to the categories of questions, readability of responses, source analysis, and precision for frequently asked questions in regards to bone grafting. Analyzing this difference in information would be vital to understanding knowledge gaps between Google and Chat GPT4o in terms of patient education, since these gaps would be able to lead to confusion and anxiety in patients about commonly performed dental procedures. Through this analysis, we determined that the quality of answers from Google and ChatGPT4o had significant differences for readability. This is proven through scales like the Flesh-Kincaid and Flesch Reading Ease score ($p < 0.01$). The questions that were asked were similar between the two search methods. This is shown through the Rothwell grading system, which shows that questions were almost equally divided between value, fact, and policy questions. In addition to responses, we found significant differences in source quality between the search methods, which is illustrated by the JAMA source criterion ($p < 0.05$). ChatGPT4o was shown to provide higher quality and more reliable sources with higher JAMA scores. We also measured Automated Readability Index scores and saw that ChatGPT had a significantly more difficult reading score than Google ($p < 0.05$). Further research must be done to find ways of improving the quality and ease of information recovery for patients, with a focus on credible sources, easy to read articles, and in-depth information.

Abstract Name: Balancing Efficacy and Safety: Chlorhexidine, Sodium Hypochlorite, and Ozone Therapy as Endodontic Irrigants

Root canal therapy, a dental procedure, includes removing infected pulp, sealing canals, and covering the tooth with restorations such as a crown. Endodontic irrigation, a major step of this procedure, is used to eliminate bacteria and biofilm within the canals with the use of a disinfecting agent. After irrigation, the root canals are sealed to prevent reinfection, usually with gutta percha, a rubber substance, which is then followed by a crown restoration. Usually, sodium hypochlorite (NaOCl) is used as a common irrigant for its antibacterial properties but can lead to detrimental side effects like tissue and gum damage. Chlorhexidine (CHX), with its effectiveness against *Enterococcus faecalis* - a common cause of caries and periodontitis - is a safe alternative but may alter dentin's properties and doesn't erode organic material as well as NaOCl. A newer alternative, ozone, has powerful oxidizing qualities, minimal toxicity, and a wide range of antimicrobial effects, but only reaches full bactericidal potential when administered in conjunction with other irrigants. Our study evaluates these agents by comparing their antimicrobial mechanisms, efficiency, organic material erosion, and toxicity. Through such analysis, 2.5% sodium hypochlorite followed by ozonated liquid rinse were shown to be successful in eliminating bacteria like *Enterococcus faecalis* and getting rid of decay, while not posing serious risks to the patient or side effects. Further research is required to explore the possible benefits of combining ozone and sodium hypochlorite while minimizing toxic effects, as well as research on outside factors like temperature and moisture and their impact on antibacterial effects.

Abstract Name: A Chemical and Mathematical Analysis of Agave Spirits

Produced in Central America, tequila is a very well-known spirit that has historic links to the fermented drinks of Aztecs, pulque and maguey, which were made from the sap of agave plants. The Spaniard influence and industrialized distillation processes have modified these historic beverages to create the tequila that is available today. To prepare tequila, agave plants are carefully grown and the heart of the plant is removed, steamed, shredded, and milled to yield agave juice. This juice is then fermented with yeast, distilled, diluted, aged, and bottled to create a final 80 proof beverage. Variations in the aging process give rise to several

classifications of tequila: blanco, joven, reposado, añejo, and extra añejo. Not surprisingly, these different aging conditions yield alcohols with very distinct and different taste profiles. While the coloration of each product can serve as a preliminary method to characterize these spirits, a more sophisticated analysis of the chemical profile is often helpful. In this work, nearly 30 different agave spirit samples having a variety of classifications were analyzed by Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES) and Gas Chromatography Mass Spectrometry (GC-MS) to examine the levels of metal ions and volatile organic compounds, respectively, in the alcohols. Approximately 17 metal ions and 85 volatile compounds have been identified and trends in the major components were used to generate a chemical fingerprint to differentiate one tequila from another. To examine the patterns in the data in more detail, more sophisticated mathematical methods (Principal Component Analysis and Linear Discriminant Analysis) were employed to characterize and categorize the tequila samples.

Abstract Name: Digital Validation to Clinical Recognition: Mapping the Evolution of Adult Autism Diagnosis

Adult autism diagnoses have increased significantly over the past decade, sparking extensive debate within both public discourse and professional psychological communities. While popular narratives often reduce this phenomenon to simplistic explanations, the reality encompasses a complex interplay of shifting diagnostic paradigms, emerging self-advocacy movements, and diverse pathways to recognition. This study examines how these interconnected factors shape an adult's diagnostic journey, investigating the systematic elements and individual experiences that influence access to and understanding of autism diagnosis. This study investigates the rise in adult autism diagnosis through three connected research approaches. Document analysis provides the foundation, examining ten years of clinical literature and healthcare policies from 2014-2024, with specific focus on how diagnostic practices have affected women, racial minorities, and people from different economic backgrounds. Social media discussions and online communities reveal firsthand accounts of adult diagnosis experiences, showing how marginalized groups have reshaped our understanding of adult autism. Examination of case studies then explore individual diagnostic journeys, demonstrating how gender, race, and economic status influence access to diagnosis. This research structure allows for examination of both systemic barriers and personal experiences in adult autism diagnosis, while highlighting traditionally overlooked voices in autism research. This research expects to demonstrate that marginalized voices fundamentally reshape our understanding of adult autism diagnosis through three key findings: first, how diagnostic criteria have historically overlooked diverse presentations particularly in women and minorities; second, how online communities have created alternative spaces for recognition and validation; and third, how economic and social barriers continue to impact access to diagnosis. These findings will be contextualized within broader healthcare policy implications and recommendations for more inclusive diagnostic practices. By examining both systemic barriers and personal narratives, this study aims to contribute to a more nuanced and equitable approach to adult autism diagnosis.

Abstract Name: An Imposter at the Palace Door - A Poetry Collection

An Imposter at the Palace Door is a creative inquiry and a testament to the common experience of not understanding your own identity. This poetry collection seeks to tell multiple intertwining stories—contradictions that can simultaneously be true. Given the delicacy of this topic, this collection has a fantastical aspect woven into it. I look to formally publish this collection of poems. This poetry collection is a tribute to the life path I have chosen for myself. Growing up in a multicultural New York suburban household, with one immigrant parent and one first-generation American parent, my lifestyle was unique from those around me. Along with that, I was diagnosed at a young age with a chronic illness that I still struggle with. The emotional turmoil I felt growing up has followed me into adulthood, yet I have learned from this experience that surrounding yourself with accepting people is healing. Pouring your soul into art is healing. This collection is about learning to trust your own body and judgment, to lean onto those around you for support, and to never let your imagination and spirit die. To understand that you do not need to fit fully into a group in order to have a valid existence. The beginning of this poetry collection contains many poems of journal entries, lists, and other forms to express the anxiety of day-to-day life. The familiar stress of being away from loved ones, of feeling misunderstood, of not understanding yourself and your purpose. This bleeds into more upbeat poems exploring the mundane joys of life, and closes in a hopeful conclusion. My goal with this poetry collection is to help others feel seen in ways I have struggled in the past and to resonate with people. After all, that is what the human experience is wholly about.

Abstract Name: Understanding the role of HD5 in Colonic Epithelial Cell Death

Inflammatory bowel disease (IBD) is an autoimmune disorder that occurs when an individual's immune system attacks healthy tissue. IBD can occur in both adults and children, describing Ulcerative Colitis (UC) and Crohn's Colitis (CC). Our lab studies human alpha defensin 5 (HD5), an antimicrobial peptide that normally aids in immune defense by keeping the small intestine sterile. However, in CC patients, HD5 is overexpressed in the colon. Preliminary data from our lab indicates that colonic cell death increases in the presence of HD5. The main aim of this project is to determine if HD5 triggers cell death through apoptosis and, if so, to explain the exact mechanisms involved. To this end, we will test if the suppression of caspase enzymes with a pan-caspase inhibitor reduces cell death triggered by HD5. We will use two methods: the MTT assay, which assesses cellular viability while avoiding the autofluorescence problems we encountered previously, and Western blotting, which aids with detecting specific caspase activation. These methods will allow us to verify if HD5 triggers cellular death via caspase-dependent apoptotic pathways and which are affected. We expect that cellular apoptosis will be reduced upon treatment with both HD5 and the caspase inhibitor, and we hope to prove by Western blotting which caspases are activated by HD5. The findings will specify the mechanism HD5 mediates cell death and its role in CC. This is an important study since it will extend knowledge showing that HD5 induces apoptosis in colonic epithelial cells. Using non-fluorescent techniques, we aim to eliminate some of the limitations seen in earlier studies and clarify the effects of HD5 in more detail. The results will provide new insights into the impact of HD5 on gastrointestinal health and inform future approaches to treating inflammatory bowel disease.

Abstract Name: TLE-1 Promoter- Role in Gene Regulation

The central dogma explains how genetic information flows from DNA transcribing into RNA and translating to protein. In gene regulation, genes are activated or repressed in response to external stimuli which is mediated by transcription factors – proteins that bind directly to specific DNA sequences called transcription factor binding sites. Transducin Like Enhancer of Split 1 (TLE-1) is a transcriptional corepressor that interacts with transcription factors, playing a critical role in the regulation of gene expression. TLE-1 exerts its effects by binding to transcription factors and modulating their ability to activate or suppress target genes. This study aims to identify specific transcription factor binding sites within the TLE-1 promoter region that are critical for regulating TLE-1 gene expression. The putative promoter region was amplified using polymerase chain reaction and then directionally cloned into the pGL3-basic, a promoter-less vector containing a luciferase gene which allows for the quantification of gene expression to provide insight into the regulatory elements of the TLE-1 promoter region. After directional cloning, deletion constructs of the TLE-1 promoter will be generated by Site Directed Mutagenesis to shorten the TLE-1 promoter region to identify the role of the regions using luciferase expression. Newly constructed plasmids will be transfected into Human Embryonic Kidney cells and analyzed using a dual luciferase assay to identify the key regulatory elements responsible for TLE-1 activity. Investigating the dynamic regulation of transcription factor binding sites and coactivator recruitment can provide insights into gene expression.

Abstract Name: Understanding Asthma Symptom Management: The Intersection of Routines and Socioeconomic Status

Background: Consistent routines have been associated with better asthma management among children, as medication adherence increases with reliable routines. Similarly, children from higher socioeconomic backgrounds tend to demonstrate better asthma management than those from lower socioeconomic backgrounds, likely due to healthcare access. To better understand the relationships between protective and risk factors, this study examines how child routines may moderate the association between socioeconomic status (SES) and asthma symptoms. Methods: Data were collected from the Asthma in the Lives of Families Today 2.0 study, involving youth with asthma (N = 72, Mage = 13.34, SD = 2.18, range 10–17, 49% female, 85% African American). Youth participants completed the asthma functional severity scale (AFS), where lower scores indicate fewer symptoms. One parent of each participant also completed questionnaires documenting their child's routines (Child Routines Inventory, CRI) and reported their household income (SES). Results: Using multiple linear regression, we ran separate models investigating the relationships across the four CRI subscales and total score. We found no significant main effects for the total CRI, Discipline, Daily Living, or Homework routine subscales. However, more frequent household routines were significantly associated with lower asthma symptoms ($p = 0.024$), and higher income was significantly associated with lower asthma symptoms ($p = 0.038$). No interaction effect between household routines and household income ($p = 0.077$) was observed. Conclusion: Our findings highlight the role of socioeconomic factors and certain domains of routines in asthma symptom management among African American youth. While household routines demonstrated a significant main effect on asthma symptoms, other routine domains did not. Further research should explore the characteristics of routines that improve symptom management and emphasize the potential for routine interventions across all SES backgrounds.

Abstract Name: The Blind Robot, Implication of reinforcement learning into control systems

Research Purpose This project developed a robot navigation algorithm using reinforcement learning (RL) to assist visually impaired individuals in navigating unfamiliar environments with minimal sensory feedback. The aim was to create a system that could effectively operate in dynamic, obstacle-laden scenarios, mimicking how humans use intuition and other senses for navigation. Background Reinforcement learning integrates machine learning and optimal control to enable robots to navigate by maximizing rewards, such as reaching a target while avoiding obstacles. RL has proven successful in autonomous vehicles and multi-agent systems, demonstrating its real-world navigation potential. This research focuses on applying RL to a small

robotic vehicle for simplified navigation. Relevant Scholarly Work Since 2019, RL has gained significant attention for its applications in autonomous systems. Companies like Tesla and OpenAI have used RL in autonomous vehicles and multi-agent systems, showcasing its ability to replicate human-like decision-making and learning. RL has been applied widely in decision-making and pathfinding across institutions like Purdue University and the University of Toronto. This project builds on these advancements, applying RL to autonomous systems where robots navigate uncertain environments. Methodology The robot, equipped with a LiDAR sensor, collected data processed by a Raspberry Pi to detect obstacles. An RL algorithm adjusted the robot's movements, controlled by an Arduino Due, to reach a target while avoiding obstacles. The robot's performance was evaluated by testing its navigation in obstacle-filled environments. Findings Initial results showed that the RL algorithm effectively guided the robot to its destination without complex control systems, validating RL's potential in autonomous navigation for assistive technologies. Future Work and Impact Future research will explore multi-agent systems to improve collaborative navigation. The broader impact includes potential applications in autonomous vehicles and other areas requiring pathfinding, contributing to enhancing mobility and independence for individuals with disabilities.

Abstract Name: Investigating the Impact of Sacrifice Ideology on Help Seeking Patterns in Vietnamese Mothers

In Vietnam, research has shown that mothers are disproportionately suffering from mental health problems, while the Vietnamese population as a whole is underutilizing mental health services. This study seeks to investigate what factors play a role in Vietnamese mothers' willingness to seek help. Specifically, we want to investigate mothers' conceptualization of motherhood and the sacrifice ideology that so often comes with it. We also explore how mothers deal with distress, and how they imagine themselves within a network of social relationships and social support. By delivering surveys (N = 120) and semi-structured interviews (N = 20), we hope to have a holistic insight into how sacrifice ideology impacts help-seeking behavior in an Asian context. Qualitative data shows that mothers envision motherhood as a responsibility and as a sacrificing process, but they also create meanings and enjoyment from this identity. Further findings show that mothers often find support in themselves, in self-coping mechanisms, and to a lesser extent their romantic partner, rather than seek social support from their family members.

Abstract Name: Non-response of *Quercus agrifolia* to drought

With the impacts of anthropogenic greenhouse gas emissions on the global climate, models predict radical fluctuations in the hydrological cycle. These extreme weather events and fluctuations in water availability

have negative impacts on local vegetation, particularly in specialist plants adapted to niche environmental conditions, because water is a limiting factor to plant growth and carbon assimilation. California has already experienced this – chronic drought events have decimated ecosystems in recent years. *Quercus agrifolia*, the California live oak, is noted for its drought tolerance in such an arid region, so it is of interest for water stress studies. Between specimens acclimated to mesic or xeric conditions, stress indicators and physiological responses to low water availability were compared. Increased synthesis of the amino acid proline is also a ubiquitous plant stress response, so concentrations of proline as a specific osmolyte were assessed. Total leaf osmolarity was also assessed since plants osmotically adjust in response to low water availability and increasing osmotic pressures. Specific leaf area (SLA), a measure of area density associated with both drought acclimation and photosynthetic capacity, was also examined. For all metrics, no significant differences were found between mesic- and xeric-conditioned groups, but high variance overall was noted, as was stability in water content relative to leaf mass. This could mean that *Q. agrifolia* may be more resistant to future climate change-induced drought than other species, especially when compared to public datasets. The remarkable phenotypic diversity within the species is also of interest for future studies, and may play a role in this drought resistance through lack of physiological and stress responses.

Abstract Name: Paclitaxel and Vitamin D's Effect on MDA-MB-231 Breast Cancer Cells

Breast cancer is a leading cause of cancer death in women, it is estimated that 42,240 women will die from cancer in 2024. MCF-7 is a breast cancer cell line that is estrogen-positive and has estrogen and progesterone receptors while MDA-MB-231 is a cell line that is triple-negative and lacks estrogen and progesterone receptors. Cholecalciferol (vitamin D3) is a pro-hormone with numerous health benefits. Individuals with higher Vitamin D levels have been found to have improved breast cancer survival rates. The ability of Vitamin D to improve the effectiveness of the chemotherapy Paclitaxel will be measured using an Alamar Blue assay to track cell survival.

Abstract Name: Surviving the Heteropatriarchy: Mary Wollstonecraft's "The Wrongs of Woman"

The Romantic Era (the late 1700s to early 1800s) was extremely concealed in queer studies, erasing the history of queer people, due to things such as heteronormativity (white, straight, etc.) being perceived as the “right” and “normal” way of living. Feminist scholarship of the Romantic Era remains an understudied area within queer studies, with gaps in the scholarship that focus on the queer-coded relationships within the novels by different Romantic Era women writers, such as Mary Wollstonecraft. By examining the primary

text of Mary Wollstonecraft's *The Wrongs of Woman*, I contribute to this gap in feminist scholarship by examining texts through a queer analytic lens. I have noted and pulled quotes from each literary work that allude to female companionship as a relief from heteropatriarchy. Given the concealed nature of non-heteronormativity during this era, I argue that there is evidence in Romantic Era literary works of women writers that demonstrate queerness in female companionship despite the heteropatriarchal mainstream culture. This includes narratives such as 1. The bond between Wollstonecraft's main character Maria with fellow asylum member Jemima, 2. The posthumous ending of *The Wrongs of Woman*, in which Maria and Jemima raise Maria's child together, and 3. the tragic short ending of the male character Darnford. Together, this proves further the importance of companionship in the face of oppressive patriarchal systems. These findings suggest that female companionship plays a role in going against heteropatriarchy despite the chains and weights placed on women at the time.

Abstract Name: Heads: Reintroducing the Work of Jerry Rudquist

This presentation offers a look into the worlds of art documentation and curating as they pertain to the work of Minnesota artist Jerry Rudquist (1934-2001). Living, working, and creating during the second half of the 20th century, Rudquist produced a body of work that spans materials, styles, subject matter, and decades. In the twenty-three years since Rudquist's passing, new goals surrounding the updated documentation and reintroduction of his collection have emerged. My work with Rudquist's collection includes developing a system for documenting and digitizing hundreds of his artworks and curating an exhibition that explores his head studies and self-portraits. The former objective aims to preserve the artist's work in a digital archive reliant on upgraded technology; the last archive was created in 2014. The latter relates to reintroducing the work of a prolific local artist to a broader public and will augment a separate joint exhibition curated by Monica Rudquist, Jerry's daughter and clay artist. In order to document and digitize Rudquist's work, I have captured high-resolution photographs, gathered metadata including measurements and medium for Rudquist's paintings, prints, and drawings, as well as created a database to house the images and metadata. Curatorial work is ongoing and will culminate in the opening of an exhibition in February 2025. At this time, the curatorial process includes selecting the artworks, conducting oral history interviews with those who knew Rudquist and his work best, and considering how archival materials can be integrated into the exhibition. Both goals - documenting and curating - aim to make Rudquist's work newly accessible and add to conversations surrounding the artist's life and work. In addition to aiding the preservation of Rudquist's artwork and legacy, this project provides insight into the relationship between art documentation and curation, and how the former is a necessary part of the latter.

Abstract Name: The Roles of stk32a and gpr156 in Zebrafish Sleep Regulation

Despite being vital for survival, the genetic mechanisms that govern mammalian sleep regulation remain largely undiscovered. Zebrafish (*Danio rerio*) are a convenient sleep model because they sleep during natural night and exhibit similar sleep behaviors to mammalian sleep. The human gene STK32A (serine/threonine kinase 32a) was identified as a candidate sleep gene in a genome-wide association study, and has a zebrafish ortholog of unknown function. When the zebrafish *stk32a* gene is mutated, the fish are less active and sleep more at night. One location where *stk32a* is expressed is the neuromasts of the lateral line system, a system that spans the length of the dorsal midline. Neuromasts are composed of sensory hair cells and identify water flow changes that help the lateral line confer environmental sensitivity. *Stk32a* and *gpr156* (a G protein-coupled receptor) are two genes that function together in the same pathway to provide hair cell orientation. We hypothesize they are implicated in zebrafish sleep regulation by altering lateral line function and consequently, arousal threshold. Utilizing high-throughput behavioral assays in conjunction with molecular biology techniques and fluorescence imaging, we investigated two inquiries: 1) if the *stk32a* mutant sleep phenotype results from atypical lateral line function and 2) if *gpr156* mutant fish exhibit a disordered sleep phenotype. Work is ongoing to determine if any additive behavioral effect to the *stk32a* mutant sleep phenotype will result from lateral line disruption. We found that mutations to *gpr156* result in decreased activity and increased sleep at night, similar to the *stk32a* mutant phenotype. Additionally, we discovered that *stk32a* and *gpr156* are coexpressed in the hair cells of the lateral line. These findings suggest that *stk32a* affects sleep via interaction with *gpr156* in the hair cells, and thus they act in the same pathway within the lateral line to regulate zebrafish sleep.

Abstract Name: Women in Virginia Manumission

The general dismissal of women's rights and political influence from the 17th to the 19th centuries greatly underestimates the power of women in the public and economic spheres in Virginia's history. Women who participated in Virginia's slave and manumission system, though more limited in scope compared to men, influenced society in ways that are under recognized. In the realm of manumission or the voluntary freeing of slaves, women supported anti-abolition efforts, women slaveholders procured and carried out manumissions, and black women fought for self and familial liberation. There were also many women who used their enslaved for their own economic gain or resorted to manumission out of fear or obligation. As women generally held the responsibility to advocate morality in society, the role of women in manumission allows a better understanding of the ethics behind race relations in Virginia before federal emancipation. In this paper, I explore the wide range of roles women played in Virginia manumission as abolitionists, slave owners, administrators, manumitters, and enslaved individuals to present an accurate and diverse perspective of women in the process of manumission. Primary sources including wills, deeds of emancipation, letters, and court cases reveal the influence and prevalence of women in Virginia manumission. These documents indicate varying points of view that highlight the diverse beliefs and positions of women on slavery and manumission in Virginia.

Abstract Name: Covid-19 School Closures in North Carolina and the Effect on Adolescent Emergency Department Visits for Mental Health

Suicide is a leading cause of death among youth and along with worsening mental health, poses a critical public health problem. The onset of the Covid-19 pandemic only made this problem worse, especially with school closures and the increase of social isolation during the lockdown. The purpose of our study is to investigate if and how school learning modalities (remote, in-person, hybrid) during the pandemic period were associated with risk for mental health crises among school-aged youth in the state of North Carolina. State-wide data sources that provide information on school closures (COVID-19 School Data Hub) and emergency department visits (North Carolina SHEPS data) will be merged to determine if a remote learning modality was associated with an increased risk for seeking emergency medical care for a mental health crisis. We will assess if the proportion of ED visits due to mental health reasons each month is correlated with the learning modality that the school district was operating under. Implications of our study findings and suggestions for interventions will be discussed.

Abstract Name: C. elegans as a Model Organism to Study the Effects of Acute and Chronic Cocaine Exposure

Cocaine Use Disorder (CUD) is a prevalent issue affecting more than 1 million people in America. Currently, there are no therapeutics or effective clinical interventions for cocaine addiction or overdose making CUD's biological mechanisms of particular interest. We are working to establish C. elegans as a model organism to explore cocaine's molecular implications due to its short developmental timeframe, well-documented genotype, and conserved neurotransmitter pathways. An effect that can be easily quantified is the worm's pharynx. This behavior provides insight into the underlying molecular mechanisms and neural pathways cocaine exposure affects. We hypothesize that the characterization of pharynx behavior under cocaine exposure will identify neurons of interest for future cocaine studies. Using automated tracking software, I was able to record and analyze videos of adult C. elegans' pharynxes under different cocaine exposure patterns. Preliminary data has trends suggesting a decrease in the pharynx pumping rate of chronically and acutely exposed worms when on cocaine which indicates that the dosage paradigm is having a molecular effect on the C. elegans. The observation of decreased pharynx pumps provides a foundation for further pharynx pump analysis in both wild-type and mutant strains to further explore cocaine's molecular level effects that induce these behavior changes.

Abstract Name: Understanding Ecosystem Interactions: Microbial Dynamics in Leaf Litter Decomposition

Leaf degradation plays a significant role in ecosystems by supplying a rich nutrient source to plants and animals. Once decomposed, with the help of microorganisms and environmental factors, leaves enrich the soil with carbon, influencing the growth of future plants. While the importance of leaf degradation is well-established, the effects of environmental factors and tree species on microbial communities during the decomposition process are not fully understood. This research aimed to identify the organisms found in and on leaf litter at various stages of decomposition and to investigate how native and invasive tree species influence microbial composition. To achieve this, leaf litter samples were collected bimonthly from both native Sycamore and invasive Knotweed species and analyzed using DNA extraction and sequencing to track changes in bacterial and fungal community composition over time. An in vitro experiment was also conducted to isolate and study microorganisms present on leaf matter, with a focus on those capable of digesting cellulose. Colony morphology was documented, and biochemical testing was performed to better understand their functional capabilities. This study revealed diversity in microbial community composition across different phases of leaf decomposition, tree species, and environmental conditions. Similarities were also observed in samples from similar environmental conditions and tree species. The identification of cellulose-digesting microorganisms and their biochemical capabilities provides a better understanding of the organisms contributing to leaf decomposition. These findings enhance our understanding of how environmental conditions and tree species influence microbial composition and nutrient cycling in ecosystems.

Abstract Name: Stones to Hearts

Stones to Hearts. This piece gave me the physical vehicle to demonstrate the struggle and battle in showing one's emotions. The work also focuses on the struggle that one cannot always control when it comes to one's emotions. The music that I picked, Made of Stone, by Matt Corby, allowed me to create a dance that brings music and concept true partnership. I believe that both move my initial narrative forward. Throughout the creative process, I worked closely with the music to create dynamics within the movement and to portray a variety of emotions that the dancers presented physically. Through a collaborative process, I was inspired by how my cast interpreted my ideas and overall concept. This allowed me to bring forth better ideas. Some of the musical moments that we explored included moments of silence, slow or fast tempo, and areas that were only instrumental. This music structure allowed me the ability to explore and push my choreographic skills. This piece of music has been integral to my choreography. It has acted as a backbone to the piece and my creative process. The overall process has allowed me to better understand the issue of sharing emotions. This experience has paved way for me shed light on a topic that we seldom like to discuss. Dance is so much more than just beautiful movement. Through it we are able tell stories and communicate feelings. Through this dance I hope to bring empathy and a better understanding between people.

Abstract Name: Language as Power: Hungarian Language Policy and Education in Romania

Historically, the Hungarian population in Romania has faced discrimination in many aspects. My research focuses on the complicated challenges that Romania's language policy environment creates for the Hungarian ethnic minority, specifically in regard to education. As well as how these language policy power dynamics are reinforced via the education system for Hungarian-speaking students, and the effects this has on Romanian society at large. A large percentage of the Hungarian population in Romania lives in exclusively Hungarian areas within the Transylvania region where they have established their own Hungarian language institutions, namely schools. When it comes to language policy, the official language, and thus the institutional language, of Romania is Romanian, leading to a lack of support for the Hungarian ethnic minority. Hungarian-speaking schools lack proper resources, despite policies that supposedly promise equality for all minority languages in the Romanian school systems. Mandatory graduation exams require great proficiency in Romanian, even if students only speak Hungarian. University acceptance and success in the job market are also dependent on proper Romanian-language knowledge, placing Hungarian students at a significant disadvantage. This language policy environment continually reinforces the power dynamic between Romanian speakers and Hungarian speakers in Romania, as Hungarian speakers must mobilize significantly more energy and resources to get to the same place where Romanian speakers begin.

Abstract Name: Chasing Settlement Activity from the Chloroform Partition of *Padina* sp. on Surface Bacteria

Climate change is lowering the pH and increasing the temperature of the ocean which effects both the surface microbiome of macroalgae and oceanwide calcium equilibrium. These environmental changes could lead to an increase in pathogenic bacteria creating revisors of harmful bacteria in the food chain. *Padina* sp. is a particularly interesting brown algae as it is one of the few algae able to deposit CaCO_3 inside its thallus (body) thereby creating a fan-like calcified structure. This process helps mitigate climate change by removing CO_2 from the water. This alga is also known to produce a suite of bioactive compounds with anticancer and antioxidant activity. Algal samples were collected from the Florida Keys in 2022; the surface of the algae was swabbed and plated onto a variety of agar. The surface associated bacteria (SAB) were then isolated on A1 (starch, yeast, peptone, and synthetic ocean salts) and cryopreserved for later use. The algae sample was frozen, lyophilized, and extracted using 50% ethyl acetate in methanol. The extract was concentrated and partitioned between hexane and water; the hexane partition was further partitioned between chloroform and 30% aqueous methanol. The chloroform partition from *Padina* sp. inhibited 79% of all SAB isolated from 3 different algae (42 strains total) in a 96-well plate assay tested at 100 $\mu\text{g/mL}$ of algal extract. This partition was then fractionated using high-performance liquid chromatography (HPLC) to generate 6 fractions.

Settlement assays will demonstrate which fraction(s) modulate SAB settlement. Further isolation will allow us to determine the structure of the active metabolite. Identifying the compound(s) responsible for this activity will elucidate the role of specific metabolites in modulating the surface microbiome.

Abstract Name: Analyzing the Correlation Between Practicing Self-Compassion and Using Maladaptive Coping Mechanisms to Treat Anxiety and Depression

With anxiety and depression prevalent worldwide, but especially among undergraduate students, many have developed an interest in mindfulness. One avenue within meditation is practicing self-compassion, which is defined as supporting yourself during hardship and treating yourself with kindness. Literature has found that self-compassion can be an emotional regulation strategy and improve anxiety and depressive symptoms. Additionally, many individuals tend to develop maladaptive coping mechanisms in response to their declining mental health. This study focused on assessing the relationship between amounts of self-compassion, anxiety, and depression. Another goal was to focus on two common coping strategies: substance use and unhealthy attachments to family and friends. The survey consisted of basic demographics and validated self-report questionnaires to measure anxiety, depression, self-compassion, substance use if applicable, and attachment styles. The survey was uploaded to Prolific to recruit seventy-five participants globally, and an online platform (SONA) to recruit eighty-three undergraduate students. Among Prolific responses, anxiety and self-compassion were not significantly related, $r(73) = -.042$, $p = .725$; depression and self-compassion were also not significantly related, $r(73) = -.0179$, $p = .127$, while anxiety and depression were positively correlated, $r(73) = .600$, $p < .001$. Of the attachment styles subscales, level of closeness ($r(73) = .288$, $p = .013$) and feelings that others can be depended on ($r(73) = .271$, $p = .020$) were both positively correlated with self-compassion while attachment anxiety and self-compassion were negatively correlated, $r(73) = -.410$, $p < .001$. It was also found that substance use and level of self-compassion were not related, $r(11) = -.131$, $p = .670$. Data from undergraduate students will be analyzed next, and it is anticipated that there will be significant correlations between anxiety, depression, and self-compassion since college students tend to have worse mental health than other populations.

Abstract Name: Rhythms of Resistance: The Migration of the Argentine Tango and Political Dissent

This is a study about culture. More specifically, cultural exchange. The Argentine Tango is undoubtedly a cultural phenomenon that shook the world, but then dynamically transformed in New York City. In this study I will track the Tango's journey through the world, specifically from Buenos Aires over the Atlantic to the Vatican, Berlin, and London and across to New York City. Then, focus on the fluid relationship between New

York City and the Tango, and highlight the impact New York City had on Tango's culture. I tell this story of the Tango because, I am descended from Argentina – and if we do not grab onto our heritage, our culture, our history, we lose it in translation, and the importance of the authentic art we made is forever displaced. The time span covers the early creation of the Tango in the alleyways of 1880's Buenos Aires and follows the dance as it migrates, eventually landing on the stage of 1910's New York City. While exploring the migration of the Tango, this study focuses on answering how the Tango serves as a form of political dissent while influencing New York City's social and cultural landscape and, in turn, how New York City influenced the Tango. This study uncovers the dichotomies between the Tango in its home of Argentina and the Tango around the world. As the dance progresses and expands, this study highlights the nuanced ways the Tango serves as political pushback, how the complexities of the Tango's journey contributes to New York's evolution (while focusing on the cultural relationship between New York City and the Argentine Tango), analyzes the anglicization of the Tango, and asks how artistic culture can reshape political climate.

Abstract Name: Tested Kinship: The Generatively Messy and Multidirectional Relationship Between Black Gay Men and Black Women

Dominant discourse focuses on HIV transmission from Black Gay Men (BGM) to Black Women (BW) by way of “down-low” culture when considering the relationship between BGM and BW. I seek to intervene and Blacken the culture of white centered queer discourse and research by investigating through a multidirectional lens how BGM and BW navigate their relationships while negotiating with systemic forms of oppression like misogynoir, patriarchy, and queer antagonism. To investigate this further, I've proposed research questions: What are the dynamics of relational patterns, interdependence, and symbiosis between Black gay men and Black women, considering the impact of cultural representation and identity formations? And how do these communities navigate queer antagonism and discourse on “femmes” while also fostering mutual support and solidarity, encompassing various aspects of social, familial, and political life? These connections encompass family dynamics, notions of brotherhood, intimacy, and the shared experience of navigating a patriarchal system that is both white-adjacent and inherently hostile to various expressions of Black femininity. To research these relational pattern expressions, I'll contextualize their experiences through frameworks: Queer of Color Critique, Black Feminist Thought, and Intersectionality. In applying these frameworks, I'll be using a qualitative method, specifically a Dyad study. This method refers to the study of two participants who share a close relationship. Dyad studies are crucial in exploring the web of convergent and divergent points in interdependent relationships between these different communities. I'll be interviewing 15 - 20 BGM and BW. I'm currently finalizing my IRB Application (all sections completed), to begin this study in early spring.

Abstract Name: Feminine Not Feminist: How Conservative Young Women See Themselves in 2024

In the last ten years, misogyny and anti-feminism have been on the rise, especially within the American conservative political movement. Despite evolving societal understandings of gender, some young women in the conservative movement advocate for returning to traditional gender norms and gender roles. Although there is scholarship on women's involvement in conservatism and anti-feminism, too often, scholars have sought to explain such involvement as due to a lack of awareness or intelligence, negating the agency of women who identify as conservative or anti-feminist. This research project focuses on how women perceive themselves and the roots of their beliefs to more accurately portray conservative women as agentive individuals. It illustrates how conservative young women narrate their identification as conservatives and perceive feminism in 2024. With notable exceptions, literature on women's affiliations with the conservative and anti-feminist movements is outdated. It focuses on women in their thirties, excluding women in their teens and early twenties who associate with the movements. Thus, this research seeks to expand the scholarship's understanding of the people, specifically young women ages 18-26, who occupy the ever-changing ideological landscape of political conservatism and right-wing political thought. Young women between 18 and 26 are critical to study, as their political attitudes and affiliations will likely shape the future political landscape. Through semi-structured interviews with conservative young women in the summer of 2024, this research reveals that many form their political identities based on their childhood experiences with politics and their religious views. Using qualitative textual analysis, I found that in narrating their views, many viewed the left as enforcing harmful gender views. This research illustrates why young women join right-wing movements and how they understand themselves and their political views, which holds implications for future research on young women's political affiliations and attitudes.

Abstract Name: Effects of Aging and Vasopressin Receptor Agonists on Water Reabsorption in the Mouse Urinary Bladder

Aim: Nocturia is a common condition among the elderly where the need to urinate multiple times at night disrupts restful sleep. This may be a consequence of deficient endocrine arginine vasopressin (AVP) signaling and poor water reabsorption by the kidney collecting ducts during sleep. However, we have demonstrated that AVP is produced in the bladder and is involved in altering urine/blood osmolarity to decrease bladder volume. AVP receptors were recently demonstrated in the bladder as intraluminal desmopressin (dAVP, synthetic AVP) promotes bladder smooth muscle relaxation in a mucosa-dependent manner. Therefore, we investigated whether the age-associated rise in nocturia is linked to decreased water and salt reabsorption in mouse bladders and the therapeutic benefits of exogenous AVP/dAVP. **Results:** In absence of AVP/dAVP, female mice exhibited a two-fold age-related decline in water reabsorption. AVP/dAVP significantly increased water reabsorption in adult female and aged male mice in the first 30 minutes. In adult males the effect was more prominent with dAVP than AVP. At 15 minutes post instillation, AVP/dAVP doubled the absorbed dose in aged males compared to 60% with AVP in aged females ($p < 0.0001$). dAVP was more efficacious than AVP in both adult and aged females at 15 minutes while neither had significant effects in adult males. AVP/dAVP raised water reabsorption 5 fold (2 to 10 mL/min) with saline in aged animals. **Conclusion:** We demonstrated aged male/female mice exhibit significantly less bladder water reabsorption compared to adults which may be linked to impaired AVP signaling and contribute to nocturia in aging.

Abstract Name: The Brief Attitudes Toward Solo Masturbation Scale: Exploratory Factor Analysis

Solo masturbation is common across adulthood, with 12-52% of women and 28-69% of men having masturbated alone in the past month. For some, masturbation is a source of pleasure, joy, relaxation, and fulfillment. For others, masturbation is seen as wrong and immoral, which can lead to feelings of shame and spiritual turmoil. Past research on whether solo masturbation is associated with health and well-being vs harm and poor health has yielded mixed results. Years of social psychological research has shown that attitudes towards a behavior can predict the experience of that behavior. Thus, understanding individuals' attitudes towards solo masturbation could disentangle mixed findings on the association between solo masturbation and well-being. The most widely used measure of masturbation attitudes, created in 1975, has limitations from current standards of scale development: the 1975 measure is too long, uses dated language, and does not distinguish between positive and negative attitudes. Therefore, the goal of this study is to develop a psychometrically sound and brief scale of attitudes toward solo masturbation. Data will be collected via a 10-minute online survey of 1500 adults. Participants will respond to a pool of 24 newly written items assessing positive and negative attitudes towards solo masturbation and report on related constructs. These 24 attitude items will be reduced to a 10-item scale of positive and negative attitudes using exploratory factor analysis. Convergent and divergent validity will be assessed with Pearson's correlations between the new attitude scale and related constructs to be presented by a colleague, Gabriella Loreda Marquez. We expect these positive and negative subscales to be correlated with the old attitude measure, religiosity, attitudes towards sex, masturbation frequency, and masturbation pleasure. Thus, this new measure will shed light on why solo masturbation is associated with positive well-being for some, and negative well-being for others.

Abstract Name: Power Naps to Improve the Performance of Consolidated Learning

In the context of training deep neural networks (DNNs), continual learning (CL) methods reduce model inaccuracies resulting from a model "catastrophically forgetting" previous knowledge learned when updated offline. In humans, memory consolidation has been found to be related to sleep phases. The wake-sleep consolidated learning (WSCL) model proposed in Sorrenti et al., 2023 successfully improves CL performance. In this research, we propose a novel approach that utilizes the biological effect of power naps as being an influential aspect of memory consolidation. We build on the Sorrenti et al. 2023 framework to incorporate napping into the DNN training process to reduce catastrophic forgetting. In our approach, the interaction between the DNN and buffer represent the relationship between the neocortex and hippocampus, which work together to consolidate memories and facilitate human learning. As memory consolidation occurs in the neocortex, hippocampal-dependence decreases such that the hippocampus encoding capacity is restored

for the next wake period, meaning the neocortex has learned the stored information. We model this interaction by breaking the WSCL wake phase into wake-nap cycles that handle chunks of task data, where fast adaptation occurs before NREM sleep. We demonstrate that including power naps improve aspects of model performance using simulations. This indicates that the information stored during a nap may be learned more deeply. We compare our approach to 6 state-of-the-art CL methods (namely, DER++, ER, ER-ACE, and WSCL combined with each of these) using important performance measures. Our preliminary results indicate our approach outperforms the state-of-the-art-methods we compare to in terms of backward transfer and computational efficiency. It has comparable performance to WSCL in terms of forward transfer and catastrophic forgetting. Our future work will experiment with different memory models to further reduce the catastrophic forgetting in our wake-nap framework.

Abstract Name: Using eye-tracking technology to understand how visually appealing elements in skincare product packaging attract consumer attention.

The skincare industry has become competitive in domains like packaging, natural ingredients, product development, market presence, and customization. With multiple brands trying to connect with consumers, effective product packaging is the first point of contact through which brands can capture attention and establish a communication channel with potential buyers. In this study, we will use eye-tracking technology to understand how visually appealing elements in skincare product packaging attract consumer attention. For data collection, we have selected three skincare products that stand out with their unique and distinctive visual allure. All three products are liquid in texture, with prices varying from \$42 to \$600. We will recruit around 50 participants who will first be asked to view each skincare product individually, followed by a simultaneous presentation of two products, and finally, all three products together, each display lasting ten seconds. The eye-tracking device will be used throughout the process to monitor the heat map and gaze plot. Afterward, participants will be asked to complete a questionnaire based on visual appeal, colors, imagery, typography, illustrations, and the likelihood of purchase based on these elements. It will also help researchers correlate responses with the eye-tracking data. After data collection, we will examine how color, typography, imagery, and illustrations enhance product packaging and help gain consumer attention. This research can help brands understand the relationship between visual appeal and consumer attention. The study can be used to aid in the development of brand identity, awareness, and visibility. Brands can enhance their packaging design to increase engagement and optimize product placement, garnering consumer attention and influencing purchasing decisions. The findings could contribute to larger discussions about the role of visually appealing elements, providing insightful concepts for brands and marketing professionals in the makeup and skincare industry.

Abstract Name: It's All Latin to Me: Uncovering the Local and Liturgical Customs of a Monastery in Seville, Spain

This project will investigate the context surrounding a fifteenth-century manuscript from Seville, Spain that resides in West Virginia University's rare books collection. It is a large choral gradual which would have been used by a choir to sing various parts of the Mass at different times of the liturgical year in the Catholic Church. It is recorded that it comes from a Dominican monastery, however this requires further research as there does not appear to be any history of a Dominican monastery in Medieval Seville—only Dominican convents. In conjunction with its provenance, the gradual's content will be studied to discern its relevance to the Mass; this will be done by cross-referencing with other Medieval liturgical sources, as well as some ecclesiastical translation databases to assist in interpreting the Latin. It is currently suspected that it contains music only for major feasts and does not pertain to the ordinary time of the year. A part of the project will also include thorough research on the materials used in the book, primarily in the inks and the binding. This will be done by exploring the details in a handwritten note that contains information about its commission, as well as a survey of local materials in Seville. In addition, a mock-up demonstrating the Medieval book-binding technique will be constructed using modern materials to reveal the masterful technique hidden under the leather spine to provide an opportunity for research to future students interested in Medieval book-binding. Overall, the main goal is to contextualize the history of this book simultaneously in the local setting of Seville, Spain, in the rich tradition of the Catholic Church, and in the historical methods of book-binding. Promoting further understanding of this fifteenth-century choir book will better facilitate our relationship with the ancient traditions associated with it.

Abstract Name: Packing the Torus with Squares

At some point in our everyday lives, we pack objects into a finite space, for example putting books into a bookshelf or food into a grocery bag. The problem of packing objects into a confined space is not new, in fact, it is a topic in discrete geometry. In the 17th-century a mathematician/astronomer named Johannes Kepler came up with a mathematical conjecture about the optimal way of packing spheres into a three-dimensional space. Kepler's Conjecture was finally proved in 2014. In our study, we focused on packing the surface of a torus of area one with congruent isothetic squares. More precisely, for any given square S of a fixed size, we present the exact optimal number of non-overlapping parallel and congruent copies of S that fit in the torus. This is joint work with the members of the CSUN Combinatorics Research Group.

Abstract Name: Selections from the GramLee Collection

For this project, I created a catalog and set of hand-made artist books based on artifacts from the WVU Gramlee Collection of Commercial Wood Engravings. These wood engravings and related materials from a flour sack manufacturer and printer represent a specific moment in printing history when illustrations and multi-color graphics were engraved using end-grain wood. I focused on a small sampling of printer's proofs for my exploration. Used by the print shop to check for accuracy before running on the press, these proofs were made on low-quality paper that has severely deteriorated over time. After scanning torn fragments, I pieced them back together in Photoshop, preserving the folds and creases from the originals. I wanted to focus more on the graphics and typography rather than digital restoration. The catalog will be made through the Newspaper Club and will follow their tabloid size of 289mm by 380mm and will feature 20 proofs that have been digitally restored. In my research on strategies to document posters in a publication, I came across explosion books made from folded pages that expand when the book is opened, creating an explosion of content. Because of this, I felt I could also display the details of the proofs to create floods of color and form. So, while the catalog shows the full proofs, the explosion book focuses on the details of the type and imagery to have a more up-close look at the proofs. In my research, I used *Before Rosebud was a Sled* by Clifford Harvey. There is little published scholarship around the Gramlee Collection so I hope that this project can add to the body of knowledge by showcasing a small corner of the collection and adding interest in this particular part of commercial printing history.

Abstract Name: Synthesis of 1,2,4 triazolidine N-heterocycles through the [3+2] cycloaddition

Nitrogen containing heterocycles have repeatably displayed interesting biomedical properties, inspiring interest from synthetic and medicinal chemists. This has led to a strong drive to create novel pathways for synthesizing N-heterocycles, as an important step for drug discovery and manufacturing. Our project focuses on efficiently generating various N-heterocycles through a [3+2] cycloaddition of tertiary amine N-oxides. More specifically, emphasis is placed on synthesizing 1,2,4 triazolidines via azobenzene precursors. Synthesis of azobenzene derivatives with varying functional groups on the ortho, meta, and para positions of the compound are generated using manganese oxidation, followed by a [3+2] cycloaddition to afford triazolidine compounds. Thin layer chromatography and NMR were used to monitor reaction progress and confirm purity of intermediates and products.

Abstract Name: Vigorous Physical Activity Correlates with Mental Health Related Cognition

Mental health continues to be a pervasive problem in college aged students, now more than ever. Past

research has described a positive correlation between maladaptive thought behaviors (e.g., rumination, perseveration, and worry) and depression and anxiety. A large body of literature has also established the affective benefits of exercise in the context of anxiety and depression. However, the relationships between exercise and maladaptive thought behaviors have yet to be elucidated. The present study sought to determine the associations between physical activity and the aforementioned aspects of mental health through the assessments of various survey measurements. During the study, 133 undergraduate students ($M_{age}=20.1\pm1.3$, range=18-24; 33% male) responded to 6 previously validated questionnaires, assessing physical activity (IPAQ-SF), rumination (RRS), perseveration (PTQ), worry (PSWQ), anxiety (GAD-7), and depression (PHQ-9). A series of univariate linear regressions confirmed that rumination, perseveration, and worry were each significant predictors of anxiety and depression ($B's \geq .142$, $p's < .001$). Spearman's correlations revealed weak to moderate inverse relationships between vigorous physical activity (VPA) and each of the 5 psychometric constructs: $r=-.348$; $p < .001$ (rumination), $r=-.332$; $p < .001$ (perseveration), $r=-.278$; $p=.002$ (worry), $r=-.281$; $p=.002$ (anxiety), $r=-.313$; $p < .001$ (depression). In initial separate univariate linear regressions, VPA was a significant predictor of rumination, perseveration, and worry ($B's < 0.018$, $p's < .001$). These analyses replicated the finding that higher levels of physical activity engagement relate to lower levels of anxiety and depression. Novel to this investigation, vigorous exercise engagement was also related to lower levels of rumination, perseveration, and worry. Future research will further examine the predictive role of VPA in the context of mental health, as well as the potential for vigorous exercise to serve as a tool for addressing maladaptive thought behaviors.

Abstract Name: Police, Nonprofits and the Carceral Web: A Study of Police Nonprofits in Los Angeles

In the past 28 years, the United States has seen a dramatic rise in police nonprofits— an emerging category of tax-exempt organizations that work with police departments to raise private dollars. Despite this spike in police nonprofits throughout the US, research has only recently begun to consider how these organizations pose problems of governance and accountability with respect to promoting private interests. This project explores the symbiotic relationship between the nonprofit industrial complex (NPIC) and the police state. By examining their board compositions and organizational outputs (e.g., services, programs, partnerships), I investigate how “police nonprofits”, or nonprofit organizations that directly or indirectly support the police, engage in practices that reinforce the carceral apparatus. I employ an abductive approach to a digital archive of police nonprofits compiled by the UChicago Justice Lab. To demonstrate cross-sectoral police influence and collaboration, I explore the police affiliations of board members who serve on multiple nonprofit boards between 2014-2019 (i.e., former police officers who are board members). Additionally, I draw on (5/10) semi-structured interviews with police nonprofit organizations in Los Angeles City. This project bridges the literature on police with that on nonprofits, then contributes to a body of scholarship still in its infancy: police nonprofit studies. With recent activist-efforts and calls to defund/abolish the police, I hope that this project will illustrate the magnitude of the police-carceral state, allow for a political economy critique, and help us reimagine public safety.

Abstract Name: Crisis at the Stand and on the Streets: Understanding the Intersections Between Mental Illness, Substance Abuse, and Criminalization in Competency Outcomes Amongst People Experiencing Homelessness

The criminalization of homelessness is a phenomenon that took root in the United States during the late 20th century, making people experiencing homelessness more likely to face legal issues. Because people experiencing homelessness are more likely to experience a myriad of mental health problems, they sit at the intersection of the criminalization of poverty and of mental illness. As such, when they make contact with the criminal justice system, they may have more involvement with competency to stand trial (CST) cases— an evaluation used to determine if a defendant is able to defend themselves and to comprehend the charges they face. This is one of the factors hypothesized to contribute toward the national competency crisis— where there are too few evaluators for the number of CST cases. This study aims to investigate the relationship between homelessness, CST referrals, and CST outcomes. Using the Odyssey Public System, this study had access to a population of over 4000 CST evaluations in one Midwestern state and sampled 200 of these evaluations for the current research question. Using mycase.in.gov, student research assistants coded additional data about the case (including specific charges, whether the defendant was homeless, and the outcome of CST in those cases). This presentation will review the background of this growing problem, identify how many CST evaluations involve homeless individuals, and examine the outcomes of those cases. The study anticipates that people experiencing homelessness will both be more likely to experience CST referrals and incompetent evaluations.

Abstract Name: Comparing Symptom Severity in Parkinson's Patients on the Protein Consistent and Protein Redistribution Diets

Parkinson's Disease (PD) is a progressive neurological disease affecting almost 6.1 million people worldwide. Currently, the most effective treatment is Carbidopa Levodopa (Ldopa), a pharmacologic for symptom management that controls motor fluctuations (MF) in PD patients. Previous studies on Ldopa's bioavailability show it is reduced by dietary protein, creating the need for strategic timing of protein intake and Ldopa schedule. The only clinically recommended treatment to address this interaction is the Protein Redistribution Diet (PRD), but by limiting protein intake to the evening meal, the risk to older adults with PD is the progressive loss of muscle health and function. The overall aim of this five-week randomized crossover pilot trial was to explore the effects of a Protein Consistent Diet (PCD) versus PRD diet on symptom severity using the Movement Disorder Society's Unified Parkinson's Disease Rating Scale (MDS-UPDRS). Participants received meal plans, recipes, and instructions to follow each diet for two weeks with a one-week washout period between the two diets. Participants were assessed pre and post-diet included the full MDS-UPDRS assessment. Preliminary data in this pilot study was collected from 11 total participants, and analyzed via paired t-tests using the SPSS 30.0. Results demonstrate that both the PRD ($p=0.187$, 95% CI [-2.81, 12.63]) and PCD ($p=0.493$, 95% CI [-5.08, 9.92]) were shown to reduce MDS-UPDRS, indicating symptom improvement from both dietary patterns. Though the diets did not have significantly different effects, This data shows the need to design future studies to test both diets' effects on symptom severity with a larger sample size, eventually leading to more individualized nutritional recommendations for PD patients.

Abstract Name: To Seek or Not to Seek? Understanding the Barriers and Facilitators to Adolescent Help-Seeking Behavior for Suicide Prevention

Suicide is a leading cause of death among adolescents, yet rates of suicide-related help-seeking remain low among this population. The proposed study seeks to identify the key barriers and facilitators to adolescent help-seeking for suicidal ideation. Previous research has investigated the barriers for general mental health disorders, but few studies have explored barriers specific to suicide-related crises. Additionally, research on the facilitators to help-seeking for suicide-related crises is practically nonexistent. The proposed study will analyze existing survey data from California high school students who participated in a school-based suicide prevention program. Analyses of close-ended survey responses will approximate rates of help-seeking behaviors in this sample. Analyses of two open-ended survey items will be conducted to identify common themes regarding barriers and facilitators to suicide-related help-seeking behavior. Preliminary coding suggests barriers such as social judgment, burdensomeness, and fear of disclosure, with facilitators being social support, attentive listening or validation, and external check-ins. The results of this study will guide current school-based suicide prevention programs on optimal methods to reduce barriers and leverage facilitators to help-seeking. Additionally, they may inform the development of new interventions designed to bolster identified facilitators. By addressing critical literature gaps, this study aims to improve the comprehensive understanding of adolescent help-seeking behaviors for suicide-related issues, with implications that will hopefully reduce suicide rates.

Abstract Name: Growing Up in “The Pile”: The Effect of Mild to Moderate Hoarding Disorder in Parental Figures on Children’s Development

Growing up in a household dominated by parental figures with mild to moderate hoarding disorder alters childhood development. There are various avenues of ways children’s lives and development are affected by an overly cluttered home and unsanitary environment. By investigating what these effects are and how they manifest throughout the impacted children’s lives, trauma and psychological effects can be addressed. Understanding the experiences of children who grew up in these environments and referencing studies that have identified trends due to these household environments allows further analysis of the significance of where a child grows up. Parental figures creating an abnormally cluttered home environment negatively impacts a child’s emotional state, social development, early maturation, and mental health. These children take in excessive stress and anxiety due to the overwhelmingly chaotic environment that is intended to be their safe place: home. This dysregulation leads children to mature early by taking on adult responsibilities to clean up the clutter and lessen the anxieties it causes them. Furthermore, children become ashamed of their

household, preventing them from inviting friends over to socialize and grow bonds. The children become isolated from their peers and develop self-esteem issues because of their shame. Being unable to maintain a routine in a disorganized environment leads to developmental difficulties pertaining to personal organization and space to participate in age-appropriate activities crucial for reaching milestones. Understanding the various ways these impacts manifest in children is crucial in best supporting their futures through treatment and recovery from this environmental impact. When parental figures exhibit mild to moderate hoarding behavior their children develop within an abnormal environment leading to significant changes in behavior and mental health throughout their life.

Abstract Name: The Modulation of Natural Killer Cells by Macrophage-Secreted TGF β 1 in Ovarian Cancer

While immune checkpoint inhibitor (ICI) therapy has had success in treating many types of cancer, its effectiveness remains low in ovarian cancer (OvCa) due, at least in part, to an immunosuppressive tumor microenvironment (TME), typified by a high infiltration of M2-like macrophages. TGFBI, an extracellular matrix interacting protein, is present in the TME and has been correlated with reduced anti-tumorigenic immunity and poor OvCa prognosis. We have demonstrated that macrophage-secreted TGFBI is highly expressed in ICI-resistant tumors and inhibits the tumor killing activity of natural killer (NK) cells. However, its mechanisms of action have yet to be identified. TGFBI is known to bind β -integrins found on cancer cells, modulating their differentiation and migration, and thus we hypothesized that TGFBI also binds to β -integrins on NK cells, similarly inducing changes in cell behavior. Using co-immunoprecipitation, we found that TGFBI potentially binds integrins β 1 and β 3 on NK cells isolated from ovarian tumors. Furthermore, in vitro experiments revealed that stimulation of healthy splenic NK cells with rTGFBI inhibits the activation of Src and PI3K, two factors important for NK cell maturation and cytotoxicity. To assess the role of macrophage-secreted TGFBI on tumor growth and immune response, we will conduct an in vivo experiment using a syngeneic mouse model of OvCa. Specifically, we have silenced the expression of TGFBI in the RAW264.7 macrophage cell line (TGFBI-KO RAW264.7). A 1:1 co-culture of ovarian tumor cells (TC) and TGFBI-KO RAW264.7 will be injected into mice. As a control, mice will receive a co-culture of TC and control RAW264.7 cells. We expect that mice injected with TC/TGFBI-KO RAW264.7 will have diminished tumor growth and an increased immunostimulatory TME. Thus, our studies provide preliminary evidence that TGFBI may be an effective therapeutic target for ovarian cancer patients undergoing ICI therapy.

Abstract Name: ANALYZING TRENDS AND VARIATIONS OF NITROGEN DIOXIDE POLLUTION (2005-2024): USING DATA FROM PANDORA SPECTROMETER, EPA, AND OMI SENSORS

Nitrogen oxides ($\text{NO}_x = \text{NO}_2 + \text{NO}$) are a class of highly reactive gases primarily emitted from fuel combustion processes, including vehicle emissions, power plants, and off-road equipment. Monitoring the concentration of these compounds is vital because they are of significant concern due to their environmental and human health impacts. This study investigates nitrogen dioxide (NO_2) levels in Houston, TX, from January to November 2024, using data collected by the Pandora spectrometer. A comparative analysis is conducted with NO_2 levels from Austin, TX, during the same period. Additionally, Environmental Protection Agency (EPA) ground-based data are utilized to examine long-term NO_2 variations across five major cities. Furthermore, NASA satellite data are analyzed to explore NO_2 trends before and during the COVID-19 pandemic.

Abstract Name: An Analysis of Climate Change Adaptation Planning in California Counties and their Unincorporated Communities

The State of California has been a pioneer in planning for climate change and enacting legislation. However, recent studies have shown that adoption and implementation of state-mandated climate change adaptation planning has varied results. Furthermore, county plans—and unincorporated communities by proxy—have been neglected in research. This content analysis aims to identify high-vulnerability communities by referencing California Disadvantaged Communities and assess their resilience to climate change based on county plans and examples of substantiated implementations.

Abstract Name: Development of Non-Aggregated Cyanine Fluorophores

Heptamethine Cyanine (Cy7) are a class of polymethine dyes that absorb light in the near-infrared (near-IR; 750-900 nm) region. This region is of great biomedical interest because light penetrates deeper into tissues due to reduced absorption and scattering by the tissue. Cy7 fluorophores can be conjugated to biomolecules such as carbohydrates, lipids, nucleic acids, and proteins. An ideal Cy7 fluorophore should exhibit high photostability and minimal aggregation in aqueous solutions. However, Cy7 tends to aggregate due to π - π stacking of its symmetrical fluorophores, which can quench fluorescence and result in low signal-to-background ratios. There are limited methods to synthesize non-aggregating Cy7. Consequently, there is an urgent and unmet need to construct a general synthetic scheme for non-aggregating Cy7. We hypothesized that unsymmetrical heptamethine cyanines could help prevent π - π stacking and inhibit aggregation. To test

this hypothesis, we modified the polymethine chain (composed of alternating dienes) by introducing a phenyl group at the C4' (symmetrical) and C3' (unsymmetrical) positions to create a novel Cy7 dye. We evaluated the photophysical properties (absorbance, emission, quantum yields, and photostability) of these modified dyes in organic solvents and aqueous buffer solutions. We have developed a general method for synthesizing Cy7 fluorophores. We conducted bioconjugation experiments using the NHS ester conjugating it to lysines of IgG1 at pH 8.5 at varying concentrations. The degree of labeling (DOL) ranged from 1 to 8 and increased with higher equivalents of the unsymmetrical dye. These results demonstrate, for the first time, that unsymmetrical Cy7 fluorophores do not aggregate in aqueous conditions and that the unsymmetrical dye can be effectively used for protein labeling. Our findings suggest that this novel approach to designing unsymmetrical Cy7 fluorophores could be extended to other polymethine fluorophore systems, potentially advancing the development of more stable and effective dyes for various biomedical applications.

Abstract Name: Interactive English as a Second Language Teaching Resources

This project helped students learn basic English concepts, continue to develop their language skills, and express themselves in English as their second language through a variety of didactic material and culturally responsive activities that cover the four domains of language through the interaction between speaking, reading, writing and listening. Further, the research focuses on high school students and understanding that if a student can not manipulate academic and social English, they will fall behind, not be able to go into regular, honors, AP courses, and not have an opportunity to further their educational careers. The goal of this research was to make the ESL program much more efficient, engaging, and culturally responsive by creating engaging activities at the different ESL levels. Further, the key concepts of culturally responsive pedagogy were implemented to help students reach academic success, be culturally competent, and develop critical consciousness. It is important to note that one way to address the effectiveness of ESL classes is by implementing culturally responsive practices and content which has pointed to language development and success. Gloria Ladson-Billings, Sonia Soltero, Danling Fu, Sonia Nieto, and Laurie Olsen are academics that informed this project. They look at effective ways on how to teach ESL, the challenges immigrant students face in the public school system, and the solutions that can transform language learning. Equally important, this empirical research focused on the use of different teaching resources with the purpose of students acquiring the English language, and teachers assessed the students to see results. Finally, one conclusion that is drawn from the research is that the use of interactive and culturally relevant activities enhanced learning to the fullest in English as a second language. Results included students completing all activities designed for their ESL level and achieving better academic results in the classrooms.

Abstract Name: Author Intention & Reader Interpretation Through a Queer Lens

Historically, television, film, and literature have lacked greatly in diversity. Yet, the same cannot be said for the audiences consuming such content. Underrepresented communities have learned to adopt stories and characters as representations of themselves based on themes, ideologies, or mannerisms because it is in our nature to want stories we can see ourselves in. As a Queer Latino, I related to Voltron: Legendary Defender's Lance McClain, who I was certain was also Queer; yet this was never confirmed. My Queer/Trans peers have said they felt the same towards Nick Carraway from Great Gatsby, or even Franz Kafka's Metamorphosis. I tried to think of why I felt sure Lance was Queer, aside from my desire to have the perfect representation of myself; I asked peers why they felt that same kinship towards different stories or characters, but for many, there wasn't a direct answer besides speculation. Thanks to social media, underrepresented communities have become closer than ever, and here we find that it is a common practice to examine texts that aren't considered Queer and find representation in it. There has been some research as to how cultural or historical contexts may affect an audience's interpretation of a text, especially regarding Queer/Trans themes, but we typically pay less attention to the process by which creators' visions are translated to the texts we encounter on page or screen. Drawing on archival research surrounding the creation of specific texts such as Looney Tunes or The Adventures of Sherlock Holmes, I explore how audiences sometimes identify and/or resonate with themes that circulate more subtly in these texts. Through my presentation, I hope to answer the following questions: How do LGBTQ+ audiences find Queer/Trans themes in texts that lack explicit representation? How intentional may that interpretation be from creators?

Abstract Name: Alcohol Abstinence Effects on Anxiety-Like Behavior and Drinking Behavior in Mice

Background: Alcohol abstinence is associated with increased anxiety-like behavior and neuroadaptive changes in the bed nucleus of the stria terminalis (BNST), a critical region for affective regulation. Past studies demonstrate that females are more likely to drink alcohol and relapse due to alleviate psychological distress. Objective: This study investigates sex differences during and after alcohol abstinence periods by measuring drinking behavior and brain activity. Methods: Male and female mice (n=30) underwent a two-bottle choice paradigm (2BC) for 6 weeks. The mice had continuous free access to two bottles, one with water, and one with 10% ethanol. The bottles and animals were weighed every 48h to measure how much ethanol they consumed. After the first 6 weeks of drinking, they had a 2-week abstinence period. Next, they were exposed to the novelty suppressed feeding test (NSFT) to measure anxiety-like behavior. The bottles were placed back for 6 weeks. Next, they had a 3-week abstinence period and were exposed to a stress restraint test and a second NSFT. Results: Females consumed more alcohol before abstinence compared to males. In the first NSFT, there was no difference in anxiety-like behavior between males and females. After abstinence, only females consumed more alcohol than before. In the second abstinence, the second NSFT showed a history of restraint stress increased anxiety-like behavior in males and not females. Overall, females preferred and consumed more alcohol than males before and after abstinence, and repeated restraint increased anxiety in males. Our conclusion is that both females and males are sensitive to abstinence, with females consuming more alcohol and males showing increased anxiety. Next, we will look at their brain activity, focusing on the participation of the bed nucleus of the stria terminalis (BNST), given its central role in abstinence-induced anxiety.

Abstract Name: Explaining the mind-body problem present in the Monist philosophies of ancient China

Medicine during the classical period was deeply influenced by metaphysics, and the Shen Nong Bai Cao Jing provides insight into ancient Chinese beliefs about the relationship between the natural world, the body, and the human soul. In traditional Chinese medicine, the chrysanthemum flower is commonly used to treat inflammation, while dragon bones—less frequently used—are believed to have properties akin to the human soul. A section of the Bai Cao attributes the medicinal qualities of dragon bones to their composition, which is thought to be similar to the soul. According to traditional Chinese thought, the human body is composed of Yang, which forms after Tai Chi separates the original Qi, while the human soul is formed from Qi which remains undivided by Tai Chi. This distinction between the material substances invites deeper exploration, raising questions about when the human soul is formed and suggesting the possibility of its immortality. Given this potential, a close reading of the sections regarding the use of chrysanthemum flowers and the dragon bones could potentially reveal how the mind-body dualism can exist paradoxically within a monist metaphysical framework, and enlighten us about the ancient Chinese's belief concerning the nature of human's body and soul. In this project, I will examine the ancient Chinese interpretation of the mind-body problem through the lens of medicine, aiming to reconcile these views with contemporary philosophical perspectives, such as those of Daoist thinkers and the Yin-Yang school.

Abstract Name: Banning the Best Practice: The Dangers of Restricting Gender-Affirming Care For Youth.

Gender-affirming care (GAC) has become a target for many laws and restrictions in the United States notwithstanding GAC's proven positive outcomes in reducing depression and suicidality levels as well as its endorsements by leading world and national health associations and organizations like the World Health Organization and the American Academy of Pediatrics. Although transgender and nonbinary (TGNB) children make up such a small portion of the population, they often face extraordinary stigma which has manifested itself in laws restricting their rights and the rights of their families across the country, as well as disparities in mental health when compared to their cisgender peers. This literature review will examine the stigma TGNB and other queer children experience by examining pieces published by leading health organizations, peer reviewed-research, and primary queer sources. It will illustrate how the stigma TGNB people experience manifests itself in our current legal system and will explore the topic of GAC to demonstrate how it is life-saving supportive care for those who need it. I will demonstrate that these laws are not made to protect children, as many leading politicians and voices in favor of restricting this form of healthcare would purport that they do. Instead, they are designed and implemented to limit the rights of the LGBTQ+ population and their families by making life-saving healthcare more difficult or impossible to access.

Abstract Name: On the isomorphisms and representations of geometric lattices.

Geometric lattices have been extensively studied over recent decades, with two prominent examples being the lattice of partitions of a finite set and the lattice of subspaces of a finite-dimensional vector space over a finite field. This paper investigates the conditions under which these two lattices may be isomorphic. To explore this, we begin by examining the cardinalities of the respective sets and comparing them as a preliminary step towards verifying potential isomorphisms. Leveraging the well-known result that every finite lattice can be embedded into a partition lattice of a nonempty set, we further analyze the structure of the lattice of subspaces and the characteristics of their representations. We also discuss some practical applications of our results.

Abstract Name: ON THE ASCENT OF ALMOST AND QUASI-ATOMICITY TO MONOID SEMIDOMAINS

A commutative cancellative monoid is atomic if every non-invertible element factors into irreducibles (also called atoms), while an integral domain is atomic if its multiplicative monoid is atomic. Notions weaker than atomicity have been introduced and studied during the past decade, including almost atomicity and quasi-atomicity, which were coined and first investigated by Boynton and Coykendall in their study of graphs of divisibility of integral domains. The ascent of atomicity to polynomial extensions was settled by Roitman back in 1993 while the ascent of atomicity to monoid domains was settled by Coykendall and the second author in 2019 (in both cases the answer was negative). The main purpose of this paper is to study the ascent of almost atomicity and quasi-atomicity to polynomial extensions and monoid domains. Under certain reasonable conditions, we prove the ascent of both properties to polynomial extensions (over semidomains). Then we construct an explicit example illustrating that, with no extra condition, quasi-atomicity does not ascend to polynomial extensions. Finally, we show that, in general, neither almost atomicity nor quasi-atomicity ascend to monoid domains, improving upon a construction first provided by Coykendall and the second author for the non-ascent of atomicity.

Abstract Name: LOCALIZATION OF UNIQUE FACTORIZATION SEMIDOMAINS

A semidomain is a subsemiring of an integral domain. Within this class, a unique factorization semidomain (UFS) is characterized by the property that every nonzero, nonunit element can be factored into a product of finitely many prime elements. In this paper, we investigate the localization of semidomains, focusing specifically on UFSs. We demonstrate that the localization of a UFS remains a UFS, leading to the conclusion that a UFS is either a unique factorization domain or is additively reduced. In addition, we provide an example of a subsemiring S of the reals numbers such that $(S, \cdot)$ and $(S, +)$ are both half-factorial, shedding light on a conjecture posed by Baeth, Chapman, and Gotti.

Abstract Name: Connections between empathy and the feeling of beauty elicited by sad songs

Music can evoke a variety of emotions. A study by Eerola et. al. (2021) indicated that unfamiliar sad and low-arousal music can potentially give rise to pleasurable experiences. The Interpersonal Reactivity Index was used to analyze how empathy levels can predict feelings related to the feeling of beauty (Eerola et al., 2021). Eerola et al. (2021) found that high-empathy individuals reported increased positive mood and higher ratings of being moved in response to sad music. Concerning these findings, a study was conducted at Bethel College where participants analyzed 13 excerpts of sad music. The IRI was used to assess the different levels of empathy of the participants. An analysis of the data highlighted a moderately positive relationship between feelings of sadness and the feeling of beauty. However, further research was needed to examine how other factors, such as different lengths of music excerpts, influence the relationship between beauty and sadness in response to sad music. The present, between-groups study, investigates the effects different lengths of sad music excerpts have on aesthetic emotions relating to beauty and how empathy levels can be used to predict these feelings. Participants are first asked to complete the IRI to collect information regarding empathy levels. Following this, participants are randomly assigned to a survey that has them listen to four sad music excerpts that are either 5 or 60 seconds in length. Aesthetic emotional response to the music is measured using AESTHEMOS (Schindler et al., 2017). Familiarity with the song is also measured along with demographic information such as age, gender, and ethnicity/race. Based on previous work from Eerola et al. (2021) feelings related to the concept of beauty and being moved are likely to be better predicted by empathy levels in the longer songs than the shorter song excerpts.

Abstract Name: Picture-Perfect Pain: Educating Tattoo Artists about the Overlaps between Self-Harm and Tattooing among Women

Research shows that there is a lack of education for tattoo artists on how to properly help women who obtain tattoos as a form of self-harm. Although some tattoo artists might be aware of these correlations, many are not or do not know what conversation needs to be held, how to recognize signs, and what resources to recommend to struggling women. The research conducted for this project indicated that there are alarming similarities between engaging in self-harm and obtaining a tattoo among women. Both of these acts can make women feel powerful, allow them to draw satisfaction from a painful experience, help them cope with emotional distress, and provide an outlet for underlying psychiatric disorders. The survey conducted as a part of this project was distributed to tattoo artists and studied their familiarity with the correlation between getting tattoos and engaging in self-harm among women. Based on the results 44.4% of tattoo artists responded “not very well” when asked how well they understand the similarities between tattoos and self-harm among women. The survey also indicated that 88.9% of the tattoo artists would be willing to have an educational pamphlet on this topic in their shops. Research shows that pamphlets can be an effective way to display information. The goal of this project is to create a pamphlet that will familiarize tattoo artists with the similarities between self-harm and tattoos among women. In addition, the pamphlet will provide guidelines to tattoo artists on how to communicate with women about such sensitive topics and a list of helpful resources that they can share with women. In this way, the pamphlet will serve as a valuable resource for both tattoo artists and women. It will help protect the artists’ reputation and career and will provide much-needed help for females struggling with self-harm.

Abstract Name: 1970s & Modern-Day Sitcoms: The Evolution of a Stagnant Genre

Situational comedies have addressed social and women’s rights issues in their content for decades. U.S. sitcoms often reflect the political climate of the time, but how have previous decades of social conservatism and liberalism affected women in the modern-day sitcom? The research explored the connection between 1970s sitcoms as well as second-wave feminism and analyzed their effects on modern-day sitcom female representation. The research also analyzed feminist critiques of modern sitcoms to understand the multiple ways in which current situational comedies have progressed or remained stagnant compared to their 1970s counterparts. Previous research and history revealed that modern sitcoms are similarly confident in discussing and exploring women’s rights as 1970s sitcoms. The contemporary sitcom has, however, fallen into regressive tropes such as childfree women ending up pregnant, women being belittled by male coworkers, and the inability to acknowledge the social dynamics that allow workplace misogyny. Most of these tropes are found in shows with generally progressive premises, which may relate to the theory of post-feminism and the concept of feminism being no longer needed. Stagnant female representation in sitcoms may also relate to the current rise in American conservatism, specifically the conservative rights revolution. This may have influence on how sitcoms often frame systemic issues relating to misogyny as individual problems rather than systemic. The research suggests that a lot of work still needs to be done for sitcoms to accurately depict the lives and struggles of modern-day women and could be helped by creating more narratives where women’s lives are not immediately or automatically changed because of the inclusion of men. Female representation could also be improved through the acknowledgement of larger societal problems when it comes to narratives addressing misogyny, sexism, and other struggles affecting women.

Abstract Name: Comparing Alcohol Use Questions in National Questionnaires Through Compiling an Alcohol Use Repository

Objective/ Background: The aim of this study was to create a repository of alcohol use measures from national epidemiologic studies, identify key characteristics of the measures, and organize the repository by characteristics. Compiling measures into a single, easy-to-use repository can make it easier for individuals who are interested in future alcohol-related measurement and/or use of survey results (e.g., students, researchers, local public health officials) to find the information they need. Methods: Alcohol-specific measures were collected from 5 national surveys and put into a database. Three members of the research team reviewed the database to identify measure characteristics. Once key domains and subdomains were agreed upon, items were individually coded by each team member. The team met to discuss and reconcile any coding discrepancies. Results: Measures were organized within two primary domains: time and content. For time, four subdomains were identified: most recent, past month, past year, and lifetime use. For content, eight subdomains were identified: any use, age of onset, frequency, quantity, peak drinking, heavy drinking, drinking context, and other drinking-related behaviors. The past month was the most commonly measured timeframe (4 out of 5 surveys). Frequency of use and other drinking-related behaviors were the most commonly covered content areas (4 out of 5 surveys). Conclusion: As an undergraduate student, the experience of compiling a measures repository helped us to gain research experience including: searching for information; entering data; and qualitative data analysis. Our next step will be to document details related to the accessibility of data from these surveys.

Abstract Name: Neurodevelopmental Characterization of the TcMAC21 Mouse Model of Down Syndrome

Down syndrome (DS) is caused by the triplication of human chromosome 21 (Hsa21). DS affects approximately 1 out of every 700 live births and causes neurodevelopmental and cognitive deficits. Individuals with DS are affected by alterations in motor coordination, spatial learning, and memory, which impact their daily functioning. Commonly used DS mouse models show similar phenotypes as individuals with DS but contain non-orthologous triplicated genes. TcMAC21 mice carry a freely segregating Hsa21q arm to establish trisomy in that model without non-orthologous genes. Neurodevelopmental deficits seen in

TcMAC21 mice have not been widely studied, and characterizing these deficits may further substantiate this DS mouse model. Using TcMAC21 and control female and male mice, we performed a series of behavioral tests sensitive to altered hippocampal and cerebellar function, beginning at postnatal day 45 (P45) through P70. We hypothesize that trisomic TcMAC21 mice would exhibit increased activity levels during locomotion testing and impaired spatial learning and memory, along with altered motor coordination and gait, when compared to euploid mice. For locomotor testing, preliminary results show differences between euploid and trisomic mice when examining total time spent in the center, but there are no differences seen in total distance traveled. Gait analysis shows trends of increased step width and distance but a decrease in step angle in female and male trisomic mice. Deficits in spatial learning and memory are observed with both male and female trisomic mice combined. These preliminary results indicate that the TcMAC21 mice exhibit genotypic deficits and potentially exhibit differences due to sex.

Abstract Name: The Significance of the Concurrent Expression of Rare Pathogenic Variants ATM and CHEK2: A Case Report on Double-Negative Breast Cancer.

Ataxia-telangiectasia (ATM) and Checkpoint Kinase 2 (CHEK2) are the most common non-BRCA pathogenic or likely pathogenic variants. A 51 year old female patient with a unique history was referred to a breast oncologist for the purposes of exploring the clinicopathologic characteristics of breast cancer developed by ATM and CHEK2. The patient previously underwent genetic testing and was confirmed ATM and CHEK2 positive, although not having breast cancer. The patient's sister tested positive for ATM and is undergoing treatment for breast cancer. The patient's children were advised to undergo genetic testing, after which it was confirmed that the three children individually tested uniquely for each variant. A double mastectomy and breast reconstruction was performed on the patient to decrease the risk of breast cancer in the future due to the presence of ATM and CHEK2 variants. This case report illustrates the potential for genetic testing playing a preventative role in health enabling individuals to adopt tailored health strategies and preemptive interventions. The objective of this clinical case report is to highlight the clinical aspects of breast cancer and underscore the importance of genetic testing, mastectomies, breast reconstruction, nipple sparing, and mammograms.

Abstract Name: The Intersections of American Empire: MINUSTAH, GILEE, and AFRICOM

The United States of America is one of the wealthiest countries in the world. Occupying much of the landmass of North America, it is also one of the largest- yet its true size does not end there, as in order to accumulate and safeguard this economic prosperity it has its reach in each hemisphere. This oral presentation pursues to exemplify the reality of this situation through the case studies of the United Nations peacekeeping missions to Haiti (known as MINUSTAH); the Georgia International Law Enforcement Exchange (GILEE), otherwise known in the left-wing activist lexicon as "Cop City"; and the U.S. Department of Defense's Africa Command (AFRICOM). The presentation focuses on the critical role America plays in the lives of Africans- whether in the first black republic, within the United States itself, or in their home continent. The racist framework of colonialism and neocolonialism will be explored through a deeper understanding of how the executive force of states continues to perpetuate the practice of domination and exploitation against a diverse people. The implications of these three institutions cannot be downplayed for their volatile impact on the success of America, destabilizing developing countries and further impoverishing economically downtrodden communities. Their history, maintenance, goals, and future must be understood for the creation of a more just and equitable world in which all individuals can truly have a role.

Abstract Name: Analysis of pro-melanoma metastasis factor, galectin-8, as a promoter of melanoma cell adhesion to vascular endothelium

Melanoma is a deadly skin cancer responsible for most skin cancer-related deaths, with over 300,000 new cases diagnosed annually worldwide. The prognosis for advanced melanoma (Stage 4) remains poor, with a 5-year survival rate of about 30%, highlighting the need to better understand melanoma metastasis and find curative treatments. Our laboratory focuses on uncovering the molecular mechanisms of melanoma metastasis and has identified that metastatic melanoma cells lack pro-metastatic endothelial (E)-selectin-binding glycans, sialyl Lewis X and A (sLeX/A), commonly found on circulating tumor cells. Instead, melanoma cells exhibit elevated levels of linear poly-N-acetyllactosaminyl glycans that bind with galectin-8 (Gal-8), a glycan-binding protein elevated in metastatic melanoma patients. To explore Gal-8's role in melanoma cell attachment, we performed parallel-plate flow chamber assays under physiologic shear stress conditions. Human A375 melanoma cells were exposed to recombinant Gal-8, control buffer, or Gal-8 inhibitor lactose, then tested for adhesion to vascular endothelial cells (ECs) under shear stress conditions mimicking post-capillary venules. The results showed significantly increased melanoma cell adhesion in the presence of Gal-8 compared to controls or Gal-8 inhibition ($p < 0.001$), indicating Gal-8 enhances adhesion and shear resistance of melanoma cells to ECs. Our findings suggest Gal-8 acts as an adhesion molecule promoting melanoma cell retention in blood vessels, identifying Gal-8 as a potential anti-metastatic therapeutic target.

Abstract Name: Screening Partition: Violence Against Women in Partition Films and Its Intersection with Communal Violence (1970-1999)

This research aims to answer the question of “whether and how violence against women in films on the Partition play impacts the movement of Hindu Nationalism in India from 1970-1999?” Most of the previous literature concerning films on the Partition as it connects to Hindu Nationalism see the idea of film as historical remembrance, where nationalism impacts Indian films, or Indian films creating Hindu nationalism, where film impacts nationalism. My research explores this as a mutually constitutive relationship where Hindu nationalism impacts film and vice versa. The way I do this is by looking at violence against women as a lens to examine film and changes in newspaper coverage from the corresponding period. I am looking if this maps onto changes in coverage of Hindu nationalism over time. The Partition of 1947 was the single largest displacement of people in history, forcing approximately 15 million people from their homes during the creation of modern-day India and Pakistan. The taboo around the Partition has led to limited memorialization, reinforced by self-censorship. One-way that narratives from the Partition have been represented is through fictional cinema. With this research I employ a narrative analysis of films on the Partition to examine the portrayals of violence against women in Indian films on the Partition from 1970-1999 and connect it to changing perception of Hindu nationalism in the country by using historical newspapers to examine changing rhetoric. The timeframe of 1970-1999 is used because that is before India had a globalized film industry, and when Hindu nationalism was on the rise. These findings are then put into the larger historical context to examine the beginning of the rise of Hindu Nationalism in India.

Abstract Name: Exploring the Factors that Shape Refugee Adolescents' Perspectives and Experiences with Substance Use

Adolescent substance misuse is a prevalent issue within refugee communities and has been attributed to the traumatic experiences associated with forcible displacement. Current research has drawn a syndemic correlation between the post-traumatic effects of forcible displacement and risk factors for substance misuse. Accessibility to substances, pre- and post-migration experiences, and socialization with peers have been identified as the main risk factors for refugee adolescent substance misuse. The heavy reliance of refugee services on the nonprofit sector due to financial limitations has created an ineffective treatment model. Community resources have been reported to be unorganized, repetitive, and fragmented due to multiple independent organizations and the separation not only between mainstream and refugee-specific services but also between mental health and substance misuse services. This fragmented model is overwhelming to navigate and prevents individuals from receiving holistic treatment. Language barriers and cultural stigma around seeking support are other reported prominent barriers. This study sought to learn more about the experiences and perceptions of refugee adolescents in order to propose how prevention and treatment programming can be better catered to newcomer populations. An anonymous, intentionally open-ended questionnaire was given to students within a local refugee youth mentoring program in Albany, NY, asking them about their perceptions of substances, views on substance misuse within their communities, and thoughts on the resources provided by their schools. Current literature emphasizes how traumatic experiences and cultural factors promote substance use and prevent adolescents from seeking treatment. Not only does this framing place the blame for substance misuse within refugee communities, but it also causes programming to be more reactionary than preventative. Resources for refugee adolescents must shift their focus to positive youth development and address substance misuse not as a solo experience but rather within the context of one's community.

Abstract Name: Environmental enrichment is not a prophylactic for traumatic brain injury

Environmental enrichment (EE) reliably produces behavioral and histological benefits when initiated after experimental traumatic brain injury (TBI). However, no benefit or prophylactic effect was revealed in a recent study where EE was provided for 2-weeks before a single controlled cortical impact (CCI) impact to the right hemisphere. The lack of protection with Pre-TBI EE may have been due to limited exposure and thus to verify this possibility, the current study utilized a 4-week Pre-TBI EE paradigm to test the hypothesis that pre-TBI EE can exert a prophylactic effect. A group receiving EE before and after TBI was included to determine whether Pre-TBI EE affects the robust effectiveness of Post-TBI EE. After 4 weeks of EE or standard (STD) housing, anesthetized adult male rats were subjected to a right hemisphere CCI injury (2.8 mm deformation at 4 m/s) or sham surgery and then randomly assigned to post-operative EE or STD conditions. Beam-walk agility and acquisition of spatial learning were assessed on post-operative days 1-5 and 14-19, respectively. The Post-TBI EE groups performed better than the Post-TBI STD groups ($p < 0.05$) but did not differ from each other ($p > 0.05$). However, despite 4 weeks of EE prior to TBI, no prophylactic effect was observed as there were no differences between the STD-housed TBI groups regardless of whether they received EE or STD housing before surgery ($p > 0.05$). These data reproduce previous findings showing that EE post-TBI is effective and replicate a recent report that providing EE prior to TBI does not confer protection.

Abstract Name: Structure Formation in PK-4 Microgravity Experiments

Complex plasmas can self-organize into various crystalline and liquid structural states, providing an exceptional platform for modeling fundamental processes relevant to materials science. Recent experiments conducted aboard the International Space Station in the Plasmakristall-4 (PK-4) facility have revealed that dusty plasmas in microgravity can form filamentary structures resembling electrorheological materials or liquid crystals resulting from an anisotropic interaction potential. Here we analyze video data from two PK-4 experiments. In the first we observe changes in the filamentary structure as we manipulate pressure and current. In the second we analyze the changes in large-scale structure for fixed plasma conditions but changing dust densities through compression. The goal is to assess the coexistence of structural states in microgravity dusty plasma – simultaneous existence of a hexagonal lattice, square lattice, and a disordered (liquid-like state). The existence of a triple point in dusty plasma was reported in 2023 through ground-based experiments [1]. To determine the structure types, we use the bond-order parameter for different symmetries. Also employed is disorganization concentration, which allows us to assess the rigidity of the domains.

Abstract Name: From Pearl Necklaces and Picket Fences to Bell-Bottoms and Briefcases: Fashion Movements of the Housewife to the Working Woman in Mid-20th Century Sitcoms

The American feminist legacy is one that spans nearly two centuries of dynamic history. From early feminist leaders Elizabeth Cady Stanton and Lucretia Mott, who first declared the call for feminine equality, to modern activist bell hooks, the portrayal of the ideal woman has been a subject of much controversy and evolution. The divide between the historical image of the pristine housewife and the modern working woman have further driven this discussion. These two distinct, but common perceptions of the perfect American woman have been only exacerbated by the media presented to consumers. This study analyzes the differences in the portrayal of the ideal woman in two mid-20th century television productions: The Donna Reed Show and The Mary Tyler Moore Show. The use of costume design to convey the ideal woman was analyzed in tandem with the cultural developments of the second and third feminism waves. Donna Reed, a product of the 1960s, was largely influenced by post-WWII regression to traditionalism. In contrast, Mary Tyler Moore made strides in the path of 1970s sexual liberation and work-place independence for women. From pearl necklaces and picket fences to bell-bottoms and briefcases, the evolution of the concept and presentation of ideal women undoubtedly shifted with time. Now more than ever, in a world where the rights and position of women are in constant flux, this research shines a light on the lessons of the past and the promises of the future. History has manifested a tendency for media to shift between one ideal and the next without consideration for the reality of womanhood. It is important for this research to inspire modern feminists to take charge of their own story, so that one day a world may exist in which they can be any version of themselves that they aspire to be.

Abstract Name: Thinking Under Stressful Conditions: Multi-National Research on the Influence of Social Ecology on Cognitive Complexity

Does social-ecological context influence individual thought complexity? While cognitive complexity has been a highly studied construct since the 1950s, little is known of the connection between cognitive complexity and social-ecological stress. Previous studies have found relationships between harsh distal environmental factors and preference for authoritarian leadership structures, but no work directly evaluates the degree that the surrounding features of the local environment influence individual thought complexity. Thus, the social and environmental mechanisms that contribute to individual thought complexity remain largely speculation. The present two studies fill in this gap by examining the relationship between social-ecological factors as measured at the cultural level (e.g., resource scarcity and diversity/inequality) and integrative complexity in political speeches as measured at the individual level (with the highly validated Natural Language Processing tool AutoIC). Study 1 used state-level markers of resource scarcity (e.g., poverty) and inequality (e.g., GINI Index) from US states to predict the integrative complexity of individual governor speeches for State of the State and Inaugural addresses over a 20-year period. Study 2 used similar nation-level markers of resource scarcity and inequality to predict the integrative complexity of individual political leader speeches for State of the Union-style speeches in eight nations over a 30-year period. Results from both studies revealed that state/national resource scarcity and income inequality produced individual leaders with lower integrative complexity. This complexity-reduction effect was larger and more robust for resource scarcity across US states, whereas it was larger and more robust for inequality across nations. Additional analyses on complexity subtypes further suggested that difficult ecological environments reduced individual thought complexity due to a stress reduction effect. Taken together, these results importantly reveal the connection between the social-ecological contexts within which humans live and the individual cognitions they produce.

Abstract Name: Equilibria. - Student & Young Professional Connection Center

This study explores the growing mental health challenges among young adults and examines how thoughtful design can support self-care, academic success, and overall well-being among rising academic and financial pressures, social challenges, and the impact of technology. The research focuses on designing a Student Wellness Center that fosters a supportive and restorative environment for mental and physical health. Data collection includes surveys of college students on stress levels, coping mechanisms, self-care practices, and preferences for study and social spaces. Findings reveal a preference for private study rooms and collaborative lounges, emphasizing the importance of constructive feedback in shaping self-image. A literature review underscores the correlation between mental health, social support, and academic persistence, highlighting the role of community and personal growth initiatives. The design incorporates principles of accessibility, community, comfort, physical fitness, and mental health while integrating modern wabi-sabi aesthetics through natural materials and textures. Accessibility is ensured with features like wheelchair-accessible facilities, Braille signage, and inclusive restrooms to create a welcoming space for all users. Community is encouraged through collaborative study areas, lounges, and informal gathering spaces that promote social interaction and peer support. Comfort is prioritized with ergonomic furniture, WELL Building Standard principles, and the use of natural materials like wood, stone, and organic textiles to create a serene, harmonious environment. The wabi-sabi influence embraces imperfection and authenticity, creating spaces with textured finishes, muted tones, and organic forms to promote mindfulness and balance. Physical fitness amenities include a gym, yoga studio, and meditation rooms to encourage activity, while counseling offices, group therapy rooms, and quiet spaces provide essential mental health support. By integrating these elements, the Wellness Center aims to enhance well-being, resilience, and academic success in a modern and nurturing setting.

Abstract Name: Enhancing Cultural Competence Through an International Collaborative Project Exploring the Experiences of Asian Indian Immigrants in Patient-Centered Rehabilitation

Changing demographic profiles of the US necessitate that speech-language pathology (SLP) students be aware of the perspectives of immigrants regarding disability, rehabilitation, and family/patient-centered practices. International inter-university projects allow students to collaborate with peers from various cultural and linguistic backgrounds. These initiatives enable students from each country to serve as cultural informants, helping their counterparts gain insights into the socio-culturally informed perspectives on disability and rehabilitation prevalent in their local context. Such collaboration enhances understanding of how these perspectives influence family roles and expectations regarding rehabilitation services, including speech-language therapy. It also provides an excellent opportunity for SLP students to develop cultural sensitivity about the local culture and contributes to their journey of developing cross-cultural competence. An undergraduate SLP student at Moravian University, US, and another at Manipal University, India, conducted a collaborative autoethnography on their development of cross-cultural awareness through participation in an advocacy video project focused on highlighting the unmet rehabilitation support needs of Asian Indian immigrants and the necessity for a more diverse rehabilitation workforce. For the advocacy video project, the students performed a thorough literature review on immigration trends and the racial and ethnic diversity within the rehabilitation workforce. They also interviewed a first-generation Asian Indian individual with disabilities, who is a disability studies scholar, a family member of a child with disability, and an SLP to gather insights on the necessary changes to ensure equitable services. Throughout the project, the students maintained detailed reflection notes. Their independent reflections, WhatsApp group chat messages, and group discussions served as the primary data set for the collaborative autoethnography. Analysis and coding of these reflections and discussions reveal that this inter-university international project provided a valuable learning opportunity. The results underscore exposure, observation, and critical reflection are essential to one's cultural competence and humility journey.

Abstract Name: Promoting Early Identification of Speech Motor Delays in Autistic Toddlers Using a Novel Clinical Assessment

Motor impairments have been increasingly identified as common, persistent, and as having cascading impacts on other domains of development in people living with autism; yet they often go undiagnosed. Additionally, speech motor delays often occur in autistic children. These delays not only impact speech sound production skills, but also phonological memory and awareness, which are directly related to learning and literacy. Delays in speech motor development may be evident in the first two years of life. Therefore, it is vital that speech-language pathologists assess for delays in motor control. However, observational measures of early motor control are currently unavailable. This study examines the diagnostic utility of the Early Motor Control Scales (EMCS) a novel observational measure of speech motor, arm, and hand control that is designed to be scored during a standardized assessment of communication and play. Two trained student researchers scored the EMCS from video recordings of 40 autistic toddlers, toddlers with developmental delays, and toddlers with typical development at a mean age of 20 months.

Abstract Name: Refugee Resettlement Responses: Explaining Discrepancies in U.S. States' Refugee Resettlement Funding

In analyzing U.S. refugee policy, there are discrepancies in the refugee resettlement funding amounts each state receives. Each additional refugee that resettles in a state isn't correlated with a uniform increase in refugee resettlement funding to assist that refugee. This paper will document these discrepancies and explore why differences in refugee resettlement funding amounts between states exist. While refugee resettlement is initialized on a federal level through collaboration done with one of ten Voluntary Agencies (Volags), most refugee resettlement funding and services is actualized on a state level. Past literature examines state-level geographic distributions of refugees as well as the impact of social services on refugees' lives and outcomes, but there's yet to have been a state-level analysis of refugee resettlement funding and infrastructure. In a large-scale, quantitative analysis of 50 states from the years 2013-2022, this research tests four different independent

variables representing state refugee resettlement infrastructure; the number of unique Volag affiliate partners, the number of refugees and asylees eligible for resettlement funding, the average hourly wage of translators, and the number of people served by refugee resettlement funding from the prior year. The analysis will control for the refugee cap, the limit on the number of refugees that can enter the country each fiscal year, and political affiliations of U.S. states. Through work in cross-tabulation and linear regression, this analysis will interrogate why some states receive more funding than others and how each state utilizes its funding. The findings from this research will help policymakers make informed decisions about the best routes for refugee resettlement in the United States. This study could also provide a window into the lobbying interests that Volags hold and the ways in which refugee resettlement funding is influenced by capitalist interests.

Abstract Name: Assessing Species Delimitation Performance with Metabarcoding Data

This study aims to increase efficiency and accuracy of metabarcoding for use in worldwide biodiversity documentation. Biodiversity supports our society through medicinal breakthroughs, ecotourism, mental health benefits, and more. To conserve biodiversity, we must understand what species exist and their distributions across the globe. One tool used for biodiversity assessment is metabarcoding where species information is recovered from DNA sequenced from environmental samples like soil or water. Species delimitation methods that computationally decide the cutoff between interspecific and intraspecific diversity based on DNA sequence data are often used to assign DNA sequences to species. While these methods are widely used with DNA barcoding data (single species sequencing), knowledge of their performance with metabarcoding data is limited. We will assess the accuracy of four common molecular species delimitation methods in estimating species from these types of data. First, the current literature was used to define simulation parameters for 1000 metabarcoding DNA sequence datasets. Next, we will subset the simulated data to model various scenarios including different taxonomic ranks, different patterns of missing data, and data skewed towards a few common species. We will then apply the species delimitation methods to each dataset and compare the expected species richness to the species richness estimated by the method. This will allow us to assess the strengths and weaknesses of each method under the different scenarios and determine what is the best protocol for using species delimitation with metabarcoding data. Pinpointing the advantages and disadvantages of the different species delimitation methods will allow for a better use of metabarcoding data and in turn increase the efficiency of biodiversity documentation across the globe.

Abstract Name: Factors Impacting Education Students' Choice To Attend MSU

The purpose and aim of this research project is to investigate the factors that influence education students' decision to choose Midwestern State University. This research will be beneficial because it will identify ways to attract more people to MSU and possibly keep the students who are already here. The recruitment and retention rate data collected through MSU shows that there is a 14% decrease in enrollment in West College of Education. Many students have no interest in becoming teachers which leads to a teacher shortage. Through this study, we can see the factors that bring students who want to major in education to MSU. From this, we will be able to adjust the factors that can lead to an increase in retention and recruitment for not only West College of Education but also for the college of MSU. We are using a Quantitative methodology for this research study. This research seeks to identify the factors influencing students who attend Midwestern State University. To do this, an online form will be constructed and completed by students enrolled in education classes. We will survey students using questions from Borst Conti (2022). Participants will include students of different classifications enrolled in education classes. The expected findings of this research will include the identification of the factors that influence students to choose Midwestern State University. This research can be useful for future recruitment strategies to increase student enrollment at Midwestern State University.

Abstract Name: Girl Math, Girl Dinner; "Girl" as A Modifier in Noun Phrases

The feature selected for this study is the conversion of the noun "girl" into a modifier, as in phrases such as #girlmath and #girlmath. Samples were collected from Tik Tok posts during 20xx-20xx from twelve speakers, all female, the majority U.S. speakers of American English and aged 18-30. The specific research question investigated was what constraints (grammatical and semantic) best predict "girl" acting as a modifier rather than a standard noun phrase (NP). Methods of data analysis included constructing a table of phrases collected from social media, then sorting them based upon the function of "girl" as either a modifier or part of an NP. The cases in which "girl" behaved as a modifier were confirmed by means of a qualifier test (Lobeck & Denham 2014). Results indicate that common and countable NPs are most likely to be modified by "girl", and that in these cases, girl ____ becomes an NP that can further receive other modifiers.

Abstract Name: CRISPR editing Human Glioblastoma Cells for Glypican 1 removal

Glioblastoma (GBM) is an aggressive type of brain cancer with an incident rate of 3.19 cases per 100,000 people per year. Due to its location in the brain, GBM has limited treatment options like chemoradiation, immunotherapy, and surgery. Interestingly, glypican-1 specifically plays a role in multiple cellular pathways of the GBM tumor cells. There are six glypican members of the heparan sulfate proteoglycan family that are all present on the cell surface and are involved in cell proliferation, cell motility, and cell signaling. Since treatment options for GBM patients do not consider glypican levels on the GBM tumor cells, we have used clustered regularly interspaced short palindromic repeats (CRISPR) technology and clonal expansion to create a functional knockout of glypican-1 in human GBM cells. Briefly, we designed a single guide RNA (sgRNA) molecule to guide the Cas9 endonuclease to target the glypican-1 gene in the GBM cells. Then we employed cell culture for clonal expansion to achieve a clonal cell line harboring the CRISPR edit for glypican-1 knockout. The genomic DNA was isolated from the GBM cells and sent for Sanger Sequencing to determine the knockout score (glypican-1 removal) of the clonal cell lines. With the glypican-1 knockout cell line, we plan to investigate how glypican-1 impacts GBM tumor progression as well as treatment approaches.

Abstract Name: Classification of subsurface water flow paths using cave drip time series clustering

Cave drip water response to surface meteorological conditions is complex due to the heterogeneous nature of water movement in the karst unsaturated zone. Therefore, we aim to understand infiltration water hydrology in the Cretaceous karst formation of south-central Texas. This project utilizes the spatial survey of 20 automated cave drip loggers installed in Natural Bridge Caverns. Drip loggers were set up in approximate transects throughout the cavern from higher to lower elevations and have been monitored since May 2023. We analyzed drip time series for one hydrological year from all 20 sites taking advantage of an ensemble of drip loggers to extract common properties by clustering. A combination of multidimensional scaling and clustering by k means was utilized to classify similar drip types based on time series analysis. We used the coefficient of variation (COV) across different sampling frequencies (15 minutes to monthly) to determine the optimum sampling frequency that minimizes sampling artifacts while maximizing the capture of natural variability. The clustering reveals four unique drip regimes for better characterization of the limestone environment where flow occurs via fractures and storage. We found COV decreases with lower sampling frequency for all four cluster groups. We concluded that both daily and weekly sampling frequencies give the minimum COV, which does not change significantly with a finer sampling frequency and therefore we used one day as the optimum sampling frequency. By analyzing COV and cluster groupings, we discovered that age of limestone formation affects infiltration water flow pathways in heterogeneous karst formation.

Abstract Name: Taphonomy of the Gastropods, *E. acuta* and *E. livescens* from the Mukwonago River, Wisconsin

During the 48-day summer collection period, the gastropods *E. acuta* and *E. livescens* were gathered from the Mukwonago River at WSNA #417. We aimed to answer how anthropogenic impacts shape the live-dead composition of gastropods in the Mukwonago River and what insights this provided into the vulnerability of Pleurocerid gastropods. In the current study, dead and live specimens of all gastropods were sampled with 20-minute timed collections of surface-exposed live specimens plus ~2500 cm³ of sediment in the Taphonomically Active Zone (TAZ). The mean stream temperature, pH, and electrical conductivity are; 23.3°C, 8.80, and 578.3 µS, respectively. In preparation, all sediment and organisms were immersed and saturated in ethanol to preserve their shells during euthanization, then sieved using 4 mm and 2 mm mesh sizes. All specimens were classified into preservation categories, ranging from 1 (live with no skeletal damage) to 4 (only the central columella remaining). Shell length (mm) was measured for categories 1, 2, and 3. Size data was used to determine biomass (B); utilizing the equation $B = 0.331 \cdot \text{Length}^{2.851}$. Histograms of size frequencies were produced for *E. acuta* and *E. livescens* through live (1), and dead (2, 3) samples based on numerical abundance, with the same being calculated with biomass. Preliminary results on *E. acuta* include: 1) dead specimens were more abundant than live for all data, with only one exception, confirming published taphonomic studies of mollusks; and 2) more biomass was preserved than numerical abundance for both live and dead specimens because larger specimens preserve better in the TAZ. Future research on the Mukwonago project will incorporate tumbling fresh shells of *E. acuta* and sediment to provide an experimental study of the order of shell degradation related to time.

Abstract Name: Perceived Effectiveness of NSSI in Predicting Next Day Ability to Resist Suicide

Non-suicidal self-injury (NSSI) is a significant health concern among college students, that is characterized by the intentional act of harming oneself without the intent to die. Many individuals report using NSSI as a coping mechanism to manage suicidal thoughts and urges. Research suggests that an individual's belief in NSSI's effectiveness in achieving these functions is associated to the severity of their self-injury and suicidal ideation, which may increase the likelihood of suicide attempts. This study aimed to examine individuals' perceived effectiveness of NSSI on the ability to resist suicidal thoughts and urges concurrently and the next day. A total of 132 participants (Mean age = 19.44, SD = 1.43, 88% White, 70% female) with a recent history of NSSI and suicidal ideation completed a 28-day daily diary protocol assessed engagement in NSSI, perceived effectiveness of the NSSI, suicidal urges and the ability to resist suicide attempts. Multi-level dynamic structural equation analyses will be conducted with individual responses mean-centered to capture within-person differences across days. Data analyses are underway and will be completed in time for the conference. It is anticipated that on days participants perceive their NSSI as effective, they will report lower concurrent suicide urges and greater ability to resist attempting suicide the next day. This would support the role of NSSI as a coping mechanism and suggest that suicide risk may increase if NSSI effectiveness lessens over time and may become a potential marker for proximal risk. Additional clinical implications of the results will be discussed.

Abstract Name: A Qualitative Study of the Experiences of Parents Navigating the Educational System During Transition

PURPOSE: Under IDEA parents must be involved in the transition process from early intervention (EI) to school-based services. The process includes families, service providers, and agencies working together to decide the best course of action for the child. This study explored the perspectives of parents of children transitioning from EI to an educational setting. This study addressed the underrepresentation of this group in the literature answering 1. What are the experiences, perceptions, and needs of parents and their families as they transition to school-based services? 2. What actions do parents identify as being needed as they enter and navigate the system? DESIGN: This phenomenological study utilized purposive sampling. Inclusion criteria were parents of children ages 2.5-6 currently in the transition process. METHOD: Semi-structured interviews were conducted with 14 participants. Interviews were recorded and transcribed. Open and axial coding was completed by 4 researchers supported by MAXQDA® software. RESULTS: Eight themes emerged: 1. Navigating the System 2. "You're the expert" 3. Are we connected? 4. Making it happen 5. The parent's educational journey 6. Family Centered Care 7. "It's kind of like starting over" 8. There is no crystal ball. CONCLUSION: Results indicate that parents experience a range of emotions during the process. The impact of collaboration, the parents learning curve, and navigating the system were key indicators of success. Current literature supports these findings describing a successful transition as a process of development and parental empowerment. Teams should address collaboration, emotional support, communication, and education on the transition continuum. Impact Statement: An understanding of the parent perspective provides occupational therapists the tools to support family centered care during the transition process.

Abstract Name: How is excitatory/inhibitory balance impacted in the Shank3B heterozygote mouse model of Autism?

Shank3B mouse models tend to show autism spectrum disorder (ASD)-like behaviors that are compulsive, repetitive and aggressive, including: self-injurious, repetitive grooming, abnormal social interactions, deficits in recognizing social novelty, anxiety-like behaviors at juvenile age, atypical auditory processing and robust learning impairments. The SHANK family of proteins are responsible for synapse formation and synaptic plasticity at glutamatergic synapses. Shank3B codes for key post-synaptic density proteins that are part of the glutamate receptor protein complex that physically links ionotropic NMDA receptors to metabotropic mGlu5 receptors, a linkage necessary for induction of plasticity. Based on this, our research explores the behavioral impact of heterozygosity of SHANK3B in a sex dependent manner. We also use immunohistochemistry to describe the protein expression of ion channels regulated by glutamate and associated with neurodevelopment in the heterozygote. This research will further our understanding of the role of SHANK3B in development.

Abstract Name: Tuning Optical and Structural Properties of Lanthanide-Doped Calcium-Fluoride Nanocrystals

Lanthanide-based nanoparticles have potential applications in biomedical imaging, drug delivery, optoelectronics, and catalysis. Our research focuses on developing synthetic methods for producing high-quality Europium-doped calcium fluoride nanoparticles in aqueous phase using a previously optimized, closed-vessel microwave reaction. This synthetic method introduces high quality and reproducible nanoparticles. In this work, Europium-doped Calcium Fluoride nanoparticles were prepared using ethylenediaminetetraacetic acid (EDTA) as the surface coating agent, ensuring an environmentally safe synthetic method, as well as varying lanthanide-doping percentages. Among the parameters affecting performance, doping percentages play a pivotal role in tailoring the photophysical and structural characteristics of these nanomaterials. Comprehensive characterization techniques, including photoluminescence spectroscopy, X-ray diffraction (XRD), and transmission electron microscopy (TEM), were used to analyze the structural and optical properties of the synthesized nanoparticles. By optimizing doping percentages, we demonstrate significant enhancements in quantum yield and tunable emission profiles for advanced application.

Abstract Name: Antagonism of Inflammatory Signaling by NLRX1 During SARS-CoV-2 Infection

During the SARS-CoV-2 infection, there is an overactivation of the innate immune response due to uncontrolled production of cytokines otherwise known as the cytokine storm. These unchecked cytokines cause increases of inflammation and damage host tissue leading to a more severe disease progression. Prior studies have shown NLRX1, a PRR involved in innate immunity, is able to modulate NF- κ B and interferon signaling during an influenza infection. These pathways are involved in inflammation signaling and regulation of cytokine production, impacting the cytokine storm. Notably, preliminary data shows NLRX1 to be downregulated in patients during a SARS-CoV-2 infection indicating that NLRX1 is involved in modulation of the cytokine storm. We hypothesize that NLRX1 acts to antagonize inflammatory signaling to dampen the immune response and reduce damage to the host during SARS-CoV-2 infection. Using patient derived data, Nlr1^{-/-} mice, and transduced human airway epithelial cells, we worked to profile NLRX1's role in the cytokine storm. We found a positive correlation between upregulation of inflammatory cytokine expression and viral replication in SARS-CoV-2 positive patients. In murine models devoid of NLRX1, we saw a prolonged production of pro-inflammatory cytokines following SARS-CoV-2 infection, compared to WT mice. To further understand this phenotype, Calu3 cells transduced to overexpress NLRX1 were challenged with SARS-CoV-2 proteins and decreased expression of proinflammatory cytokines were observed. We also observed a protective nature of NLRX1 against the SARS-CoV-2 infection with increases in viral titer and inflammation of airways in Nlr1^{-/-} mice. However viral titer decreases in NLRX1 overexpressed Calu3 challenged with SARS-CoV-2 (MOI 0.05, 0.1). Our data indicates that NLRX1 is acting against inflammatory signaling to prevent the cytokine storm and has a protective nature against SARS-CoV-2 infection. Examination of the differentiation of cytokine expression due to NLRX1 could indicate a potential drug target.

Abstract Name: Connecting Clinically Observed Metabolic Deficiencies to Protein Structure and Function

Human fumarase (FH), an enzyme in the citric acid cycle, is an essential component in this metabolic pathway that fuels cell throughout the human body. Previous research indicates that mutated FH enzyme (R444G) results in a decreased quality of life likely caused by the deficiency of FH function. The relationship between the structure and function of this mutation and how this impacts the decreased FH activity observed is not well understood. Circular dichroism, non-denaturing gels, and Michaelis-Menten kinetics were utilized to better understand the specific impacts that this mutation has on the structure and function of FH. These experiments demonstrated that this variant had quaternary structure, which is crucial to enzyme functionality. However, exploring several additive screens, which encompass chemical compounds that are similar to FH substrate in shape and size, showed there were observed structural changes in the R444G mutation compared to the normal FH. Additionally, kinetic experiments showed this variant also had a 47.3-fold decrease in overall catalytic ability in comparison to the normal FH enzyme. This decreased catalytic ability results in a buildup of fumarate in cells which may cause decrease cellular functions such as DNA repair. Overall, this demonstrates the importance of conserved structure and function for essential metabolic enzymes in the human body and these mutations compromise this structure.

Abstract Name: Unfolded Protein Response in Early-life stress Mediated Depressive Behavior

Early-life stress (ELS) has been implicated in the onset of major depressive disorder later in adulthood. Recent studies suggest that the unfolded protein response (UPR), a cellular response to stress, could be a precipitating factor in depression and depressive symptoms. The present study examined the expression of genes commonly associated with UPR in the prefrontal cortex and the hippocampus. The male rodent model of depression (ELS model), specifically maternal separation (MS) was utilized with or without the inclusion environmental enrichment (MS-E). Altered expression of UPR genes was determined through quantitative polymerase chain reaction (qPCR). Of six UPR genes (Atf4, Atf6, Chop, Grp94, Xbp-1, and its spliced variant sXbp-1), Atf6 was significantly upregulated in the prefrontal cortices of MS male rats and drastically downregulated in MS-E male rats. In the hippocampi, Atf6 and sXbp-1 exhibited significant changes between control and MS male rats. In contrast, a drastic change in Atf6 and sXbp-1 was identified when comparing MS and MS-E male rats. Since Atf6 and sXbp-1 are transcription factors that execute a critical role in the regulation of genes involved in inflammatory pathways, especially the UPR, the present data suggests the

possible involvement of Atf6 and sXbp-1 in the inflammatory regulation of depression. Further examination of the regulatory factors for Atf6 and sXbp-1 would allow for a greater understanding of the activation of the UPR and its role in ELS-mediated depressive behavior.

Abstract Name: Developing a Low-Cost Arduino-Based Colorimetric Soil Tester for Precise Nutrient Analysis

Precise fertilization based on accurate soil testing is crucial to mitigate nutrient runoff. Several soil test methods and tools targeting the fundamental macronutrients (Nitrogen, Phosphorus, and Potassium - NPK) have been introduced, but most of them are from laboratory environments and require a certain amount of time and budget. A few recently introduced portable commercial electric current sensors return estimated values by referring to pH-based equations without providing actual nutrient levels for each NPK. We discovered a commercial colorimetric digital tester (in short, CCDT) capable of evaluating nutrient levels and assigning them to one of five categories: Surplus, Sufficient, Adequate, Deficient, or Depleted. However, the letter-based grading system cannot provide precise quantitative data regarding fertilizer needs or nutrient surpluses. To overcome these challenges, this study introduces an Arduino colorimetric soil tester that utilizes the AS7431 Spectral Color Sensor with 8 visible spectrum channels (in short, ASDT). Since the CCDT's chemical reagent represents the phosphorus level with a primary color (blue), we first calibrated ASDT to classify the wavelength readings of phosphorus into the five grades (e.g., $\lambda < 1188$: surplus; $\lambda < 1510$: sufficient; etc.) by referring to CCDT's color panels. We prepared solutions of the soil-distilled water mixture (pH 7.0, 70°F) to have different levels of richness according to CCDT's guide (e.g., 100 ppm: surplus, 50 ppm: sufficient; etc.). We also designed a 3D-printed test tube container to prevent external light interference and reflections from the test tube's surface. ASDT returned the expected wavelengths (e.g., $\lambda \sim 900$; $\lambda \sim 1400$; etc.), while CCDT provided unexpected grades (e.g., all adequate or alternating between two grades over time), confirming ASDT's better accuracy. CCDT's representing colors of the other two nutrients are not primary colors, and our next goal is to calibrate the multiple wavelengths for these nutrients' grades.

Abstract Name: The Fabrication and History of Bowl with Scenes of the Four Seasons

Imperial workshops in China produced decorative porcelain wares throughout the Ming and Qing dynasties. The Imperial kilns of Jingdezhen, located in southeastern China, are some of the most famous and robust areas for the production of these goods, made in the thousands. As such, many pieces in museums display similar styles and decorative coloration. This paper investigates one Qing dynasty tea bowl entitled Bowl with Scenes of the Four Seasons created in the Imperial porcelain factory in Jingdezhen between 1821-1850. Once used in the palace of the Forbidden City by the Imperial court, this work is part of the Asian Art museum in San Francisco, California (Object #: B60P1450). Research on this project includes a detailed visual analysis of the Peking bowl's four medallions, small landscape vignettes depicting the seasonality of China. The paper will also explore the methods used to produce the object including the use of petunse and kaolin, techniques associated with incision, overglaze, and enamel, and an understanding of the famille jaune and rose red color preferences in these types of enamel wares. The paper will investigate the social context of the vessel, including a discussion of the use of the Daoguang mark on the bottom of the vessel, and a deeper consideration of the lifecycle of the work from its production in Jingdezhen, the enamel decoration work completed in Beijing, and finally, its delivery to the Forbidden City and use during the Qing dynasty. Bowl with Scenes of the Four Seasons contains specific details indicating its importance and status that are representative of the Qing dynasty's ceramic production methods and aesthetic preferences during the 19th century.

Abstract Name: Acoustic Startle Response in a Zebrafish Model of Human Autism

Synapses are sites of information transfer between nerve cells. Less-effective or unneeded synapses should be removed through synaptic pruning. Studies have shown that individuals with the autistic phenotype have impaired synaptic pruning mechanisms relative to the "neurotypical" phenotype. Auditory sensitivity is commonly seen in the human autistic phenotype. Individuals often seek to remove sources of auditory stimuli. We hypothesize that this is because of an excess number of synaptic contacts in the parts of the brain processing auditory information. Normally, complement proteins of the innate immune system such as C3 and C4 help in synaptic pruning. Drugs and/or genetic variations may alter the function of C3 and C4 proteins. Valproic acid (VPA) controls epileptic seizures, but if taken during pregnancy increases the incidence of the autistic phenotype. It has been hypothesized that this is (at least in part) because of the effect of VPA on C3 and C4. Our lab has used the VPA-treated zebrafish model of autism, which should reveal universal synaptic pruning mechanisms that operate across all vertebrate species. Zebrafish are treated from 0-48 hours post fertilization with 50 μ M VPA. Control fish are raised in a medium without VPA. Both groups are then raised using normal animal husbandry procedures. Once zebrafish are 30 days old, they will have developed their Weberian apparatus, which detects vibrations (sounds). At this age, the fish can be tested using a 1000 Hz auditory stimulus. This frequency evokes the so-called "C-startle response" in which fish curl into a "C" shape as an instinctual reaction to an aversive stimulus. We will measure differences in the C-startle response at 30 days post-fertilization, comparing VPA-treated to untreated control fish. We expect to see a higher number of C-startle responses in the VPA-treated fish group.

Abstract Name: Strength in Numbers: Investigating the Role of Peer-to-Peer Motivation in First-Year Student Success

The transition to college represents a critical juncture in students' academic journeys, often accompanied by challenges that can impact their overall success. This proposal investigates the research question: 'Why is peer-to-peer motivation important to first-year student success?' Recent literature highlights the significance of social support and peer interactions in fostering academic engagement and persistence among first-year students (Tinto, 2017; Gopalan & Brady, 2020). Studies suggest that peer relationships can enhance motivation, reduce feelings of isolation, and promote a sense of belonging, which are essential for academic achievement (Astin, 2018; Wilcox et al., 2019). To explore this phenomenon, a mixed-methods research design will be employed. Quantitative data will be collected through surveys administered to first-year students at a mid-sized university, measuring levels of peer motivation, academic engagement, and self-reported success indicators. Additionally, qualitative interviews will be conducted with a subset of participants to gain deeper insights into their experiences and perceptions of peer influence on their academic journeys. This dual approach will allow for a comprehensive understanding of the dynamics at play. The intended outcomes of this research include identifying key factors of peer-to-peer motivation that contribute to first-year student success and providing actionable recommendations for institutions to enhance peer support programs. By emphasizing the importance of peer relationships in academic settings, this study aims to inform strategies that foster a supportive learning environment, ultimately improving retention rates and student satisfaction.
