Over recent decades, rapidly growing global demands for advanced electronics have exacerbated the need for certain Lanthanide metals (elements 57-71), due to their irreplaceable functions in various consumer electronic devices, including smartphones, computers, tablets, and more. Unfortunately, conventional methods for acquiring lanthanides from natural sources, primarily in the form of large-scale mining, frequently fail to meet commercial and environmental demands. Lanmodulin (LanM), a recently discovered lanthanide sequestering protein from *Thermoplasma*, offers a potential solution to both of these problems. LanM is capable of selectively sequestering many lanthanides from environmental and electronics sources. Accordingly, this research project is focused on the development of methods to optimize the scalable production of purified LanM as a first step toward developing efficient biomining strategies for lanthanides. To accomplish this, my project utilized lactose-based autoinduction of *E. coli* transformed with a plasmid encoded for a recombinant form of LanM containing a 6×Histidine (His6x) protein binding tag connected to the native LanM protein through a Tobacco Etch Virus (TEV) Protease cleavage sequence. Following expression and with a variable heat treatment (85°C), the His6x-tagged LanM was isolated using nickel-nitrilotriacetic acid (Ni-NTA) affinity chromatography. After cleavage of the 6×Histidine tag, we then compared the binding of lanthanides and transition metals to calculate the binding constants. Our systematic approach to isolate high purity His-tag LanM directly from Ni-NTA column fractions without a size exclusion chromatography step was successful. We confirmed that LanM purified using this scalable SEC-free method had a purity between >97% (by densitometry gel imaging). We will also present complementary selective metal binding results for Eu (III) and Fe(III) with LanM using data from a colorimetric xylenol orange back-titration approach.

Abstract Name: UV-Visible Spectroscopy and Electrochemical Sensing for Analytical and Comprehensive Characterization of Substances

Research was conducted to investigate the use of UV-Visible spectroscopy and electrochemical sensing. UV-Visible spectroscopy is an optical technique used to analyze the optical properties and characteristics of a sample. The spectroscopy provides a comparison of the absorption behavior between the liquid and dry substances. Multiple samples of liquid and dry substances were tested under different chemical conditions to test their wavelength and absorbance interactions with light. Electrochemical sensing is a technique that compares the voltage and current in a substance. This was conducted by using standard and gold plasma electrodes for sensitivity analysis. Using gold plasma electrodes is a more intensive process than using standard electrodes, due to their ability to enhance electrochemical responses. Both techniques are findings that aid in a more comprehensive and analytical characterization of substances. Both UV-Visible spectroscopy and electrochemical sensing are used in real world applications in the environmental, industrial, scientific, and medical fields. Both techniques are often combined in hybrid systems to further enhance quality (e.g., drug quality testing and heavy metal detection in water sources). Keyword: UV-Visible, Electrochemical, Gold Plasma

Abstract Name: Insert Coin: How the Console Wars prompted video game companies to “level up” from the 70s to the 90s

This project analyzes the competition between two major video game companies of the 80s and 90s, Nintendo and SEGA. This project uses the context of the American market, paired with the restraints of Japanese law and regulation to understand why these companies moved in the direction they chose, and how their competition affected the market for years to come. Secondary sources shed light on these elements and assist in contextualizing the market. The research methodology included library searches to find books and other scholarly sources to support the project. Primary sources were collected on translation websites, the internet archive, and in video form on youtube. The sources selected were chosen for their proximity to the relevant companies, such as first party magazines such as Nintendo power and SEGA visions, although third party fan magazines are also included. The translation websites are focused on interviews with important people involved with both companies who provide their insight and reasoning from their perspectives. The expected conclusion will reveal what happened during the third, fourth, and fifth console generations between these rival companies that shaped the industry as a whole. The elements that these companies shaped range anywhere from marketing and sales strategy to the design of their consoles and games.

Abstract Name: Mass of St. Gregory: Hybridized Art in Colonial Mexico

This research examines the hybridity of art in colonial Mexico by examining the featherwork of Mass of St. Gregory. First, this research will briefly discuss the colonization of Mexico, specifically the distribution of Catholic ideals during 1521-1540. Second, this research will formally analyze Mass of St. Gregory. Third, this research will textually analyze the formal elements and their religious, cultural, and social meaning. Fourth, the study will assert featherwork as an Indigenous visual language by providing references to other hybrid artwork from this period. This research will demonstrate Mass of St. Gregory's complex composition as hybrid art in relation to colonial power and Catholicism, created by the Indigenous peoples of Mexico who were active participants in the formation of visual culture under colonial rule.

Abstract Name: Sweet Mother-of-Pearl: Indigenous and Hybrid Shell Art of the Toltec and Bontoc Societies

This research investigates mother-of-pearl as a principal material utilized in the artistic expressions of the Toltec and Bontoc societies in the pre-colonial and colonial periods. While many scholars emphasize the similar effects of Spanish colonization on the Toltec and Bontoc societies, not many scholars emphasize their similar artistic exploitations of natural materials and contributions to hybrid art. Therefore, this research emphasizes the shared material practices of the Toltec and Bontoc societies and their endurance in material culture. This research will pose as synchronic and diachronic analyses of the shared artistic evolution involving mother-of-pearl and the artistic manifestations of colonialism between these transmarine communities. First, this research will highlight mother-of-pearl as an accessible material to the Toltec and Bontoc societies by examining Face Emerging from a Coyote's Maw (Toltec) and Fikum (Bontoc) as symbols of adornment and status. Second, this research will examine the 16th century Spanish colonization of the Toltec and Bontoc societies considering the transformation of sociopolitical structures and dissemination of Catholic ideals thus affecting the artistic production of the Toltec and Bontoc peoples. Third, this research will investigate The Virgin of Guadalupe (Toltec) and Colonial Philippines Baptismal Shell (Bontoc) as hybrid artworks that fuse Catholic imagery with Toltec and Bontoc material practices under Spanish colonial rule. This research emphasizes the shared artistic practices of the Toltec and Bontoc societies and demonstrates their similarities beyond Spanish colonization.

Abstract Name: Corazones Activos: Strengthening Resilience in Elderly Displaced Women Through Dance, Craft-Making, and Social Engagement

Elderly displaced women face increased risks of falls, chronic illness, and depression, often worsened by limited access to supportive health programs. Evidence shows that physical activity like dance and creative movement, can improve mobility, balance, confidence, and emotional well-being in aging populations. Despite these benefits, displaced older women remain underserved in community wellness initiatives. This service-learning program aims to improve mobility, reduce fall risk, and enhance quality of life. This service learning program assesses changes in mobility and quality of life over six weeks. Participants engaged in twice-weekly sessions incorporating adaptive exercise, modified dance, and creative social activities. Functional mobility was measured using the Timed Up and Go (TUG) test, and quality of life was assessed using the Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q-SF). Paired t-tests and Wilcoxon analyses were conducted to evaluate change. Seven individuals participated in the service-learning program. However, only 2 participants completed the pre- and post-assessments. Paired t-tests showed no statistically significant changes from pre- to post-intervention. Q-LES-Q-SF did not differ significantly [$t = (-1.889)$; $p = 0.310$], and TUG performance also remained non-significant [$t = (5.808)$; $p = 0.109$]. Wilcoxon tests confirmed these results, with no significant differences for both Q-LES-Q-SF ($p = 0.180$) and TUG ($p = 0.180$). Overall, the intervention produced no statistically significant improvements in either outcome measure. Despite the absence of significant quantitative changes, qualitative observations revealed increased energy, motivation, and social engagement among participants. The women demonstrated greater enthusiasm during sessions and more consistent involvement in movement and creative activities. These behavioral shifts suggest that community-based wellness programs may foster meaningful psychosocial benefits even when objective metrics remain unchanged. Future research with a larger sample and extended duration may clarify the program's full impact on functional mobility and well-being.

Abstract Name: The Moderating Roles of Ethnic-Racial Identity Components in the Association between Adverse Childhood Experiences and Cannabis Use: Exploring Ethnic-Racial Differences between Black, Asian, & White Students.

Cannabis is the most widely used illicit substance globally and remains a major public health concern, especially among young adults, whose use has increased significantly (Johnston et al., 2013). Understanding the factors influencing cannabis use during late adolescence and emerging adulthood is crucial, particularly the roles of adverse childhood experiences (ACEs) and ethnic-racial identity (ERI). Prior research links ACEs with higher cannabis use risk (Halpern et al., 2018), but little is known about whether ERI components, exploration, affirmation, and resolution, can buffer this relationship. ERI involves exploring one's ethnic-racial group, affirming positive feelings about it, and understanding its meaning (Umaña-Taylor et al., 2014). While some studies suggest ERI relates to lower cannabis use, its moderating role remains unclear. This study examined whether ERI components moderate the association between ACEs and cannabis use and whether these relationships differ across ethnic groups. Participants were 733 emerging adults (ages 18–22; 72.2% female) from a larger ongoing project, including Black, White, and Asian participants. Three moderation

models were tested in Mplus, each including one ERI component as a moderator. Results showed that ACEs predicted higher cannabis use among Black youth. ERI exploration significantly moderated the ACEs and cannabis relationship for Black and White participants, but not for Asian participants. Specifically, Black and White youth with low ERI exploration showed a strong positive association between ACEs and cannabis use. In contrast, for those with high ERI exploration, ACEs was no longer significantly linked to cannabis use. These findings suggest that ethnic-racial identity exploration may protect against the negative effects of childhood adversity on cannabis use, particularly for Black and White youth. The study highlights the importance of considering both adversity and ethnic-racial development in understanding and preventing substance use.

Abstract Name: Soft Tactile Endoscopic Probe (STEP) for In Vivo Real-Time Mechanical Mapping and Detection of Submucosal Colon Tumors

Colonoscopy is the primary tool for detecting colorectal cancer, yet standard visual inspection and surface biopsies often miss tumors hidden beneath the mucosal surface of the colon. We present a mechanically based diagnostic approach that uses soft contact mechanics to sense subsurface stiffness variations. Our device features a water-inflatable silicone probe tip that applies controlled deformation to the colon wall, allowing pressure measurements that reveal underlying mechanical contrast. Tests on artificial colon models and excised biological tissue show that regions with submucosal tumors produce elevated pressure responses, enabling stiffness-based detection up to 2 mm beneath the surface, beyond the reach of traditional methods. Because the probe integrates easily into existing colonoscopic tools, this technique offers a practical route to improving early detection of tumors that would otherwise remain hidden.

Abstract Name: Disarmament, Demobilization, and Reintegration and the Compensated Eradication Plan: The United States and NATO's Counternarcotics Strategies in the War in Afghanistan from 2001-2005

Starting in the late 1980s, Afghanistan became a major source of opium production, but with the ban on opium in 2000, Afghanistan's share in the world's supply of opium decreased. The United States' intervention in Afghanistan in 2001 removed this ban on opium, and the United States may not have been interested in stopping the narcotics trade since the task of counternarcotics fell to the British. The question then becomes whether these counternarcotics strategies were effective in curbing the Afghan narcotics trade, which may reveal the possible complacency behind the United States intervention in Afghanistan. Current research on this topic covers in detail the corruption and narcotics in Afghanistan, as well as the Western intervention in Afghanistan. This paper aims to understand what effect this Western intervention may have had on narcotics and corruption in Afghanistan. This paper examines academic sources that discuss the United States' apparent apathy toward the opium problem as well as Britain's failed counternarcotics experiment in Afghanistan,

which attempted to use compensated eradication to stop the decades-long habit of opium production and trade. Articles regarding Disarmament, Demobilization, and Reintegration (DDR) programs in Afghanistan and how DDR may have worsened the problem of corruption and narcotics in Afghanistan are also examined. This paper discusses the unintended consequences of counternarcotics and nation-building policies and examines the effectiveness of these policies, which may lead future policies to counter corruption and narcotics simultaneously. Answering these questions may add to the larger discussion surrounding the United States' involvement in foreign territory. Keywords: Afghanistan, Narcotics, US Intervention, DDR.

Abstract Name: Representation of Race in Medieval Fantasy: Creating Yoruba-inspired Concept Artworks

Due to its emphasis on marketability, medieval fantasy media often falls short of respectful and well-written representation of its Black characters. Main arguments against the inclusion of Black or non-European characters in medieval fantasy include discussions of 'realism', which fall back upon the incorrect belief that Europe was the center of the medieval world, debunked by the existence of powerful kingdoms and empires across the globe during the 5th to 15th centuries. The argument for realism also disregards the suspension of disbelief that comes with fantasy, the medieval concept of race, and the inaccuracy of most pop-medieval media. However, just including a Black character in medieval fantasy media set in Europe does not make it representative because of the way the genre talks about race metatextually. Authors Ebony Elizabeth Thomas and Helen Young have written about ways in which race is talked about indirectly in fantasy literature through narratives of "The Dark Other" and race being linked to morality. Africanfuturism (separate from Afrofuturism, coined by Nnedi Okorafor) provides a helpful starting point for an African focused, decolonial genre, and recent addition to the Pathfinder Universe, the Mwangi Expanse, is examined for its creativity and thought when depicting an African-inspired medieval fantasy region. Through explorative essay, masterwork copy sketches, character design, and concept painting, this project seeks to show how medieval fantasy outside of Europe (specifically in Yorubaland) can be depicted in a way that includes the most compelling elements of the pre-established Medieval fantasy and also disregards those that uphold inappropriate meta-textual narratives about race.

Abstract Name: Bodies, Politics, and Performance: Reproductive Justice and Activism in Neo-Burlesque Communities in the United States and France

Scholars of burlesque and performance studies have long noted the form's feminist and political potential, yet little research compares how national contexts shape its activist capacities. This project investigates how reproductive justice is embodied, expressed, and constrained within neo-burlesque communities in the United States and France. It asks: How do political, commercial, and community pressures shape neo-burlesque activism—its risks and its forms—across U.S. and French reproductive-justice contexts? Using a humanities-

based ethnographic method, this study draws on interviews, performance observation, and reflexive field notes. To analyze these narratives, I developed a framework distinguishing explicit activism (overt political storytelling), embodied activism (the political meaning of marginalized bodies onstage), and relational activism (backstage care networks and safety practices). Preliminary analysis of 13 interviews and nine observations shows that U.S. performers frequently engage in explicit activism, including abortion-rights fundraisers and protest-themed acts, while also experiencing bullying, backlash, and reduced bookings when their work becomes overtly political. French performers more often emphasize embodied activism, citing cultural norms of universalism that discourage naming racial, gendered, or reproductive injustice; for Black, disabled, queer, immigrant, and aging artists, visibility itself becomes a political act. Relational activism appears in both contexts through mutual aid, community protection, and collective care that enable performers to continue working amid political or interpersonal risk. By comparing these dynamics, this study demonstrates that activism in neo-burlesque is not inherent to the form but shaped by national ideology and performers' everyday negotiations of visibility, safety, and care. More broadly, it offers insight into how performance cultures adapt to shifting political environments and how the body becomes a site where reproductive politics are contested and lived.

Abstract Name: Prediction of Ovulation with Progesterone Patterns in individuals with and without PCOS

Understanding the menstrual cycle is essential for diagnosing reproductive disorders and improving fertility tracking, yet the natural variation in hormone patterns throughout the menstrual cycle is still understudied. Here we use data collected with the Mira ovulation tracker to analyze the Progesterone (PDG) pattern across the menstrual cycle, focusing on individuals with PCOS in comparison with healthy controls. Mira provides quantitative urine hormone measurements, and collects self-reported PCOS status, making this data well-suited for analyzing PDG patterns in this context. A common hallmark of PCOS is anovulatory cycles, or cycles in which ovulation does not occur. Confirming ovulation typically requires an ultrasound, but a spike in Luteinizing Hormone followed by a sustained rise in PDG can also indicate that ovulation has occurred. The main objective of this analysis is to assess how this hormone-based approach performs in both typical and PCOS-affected cycles. We first streamlined and structured hormone recordings, resolved multi-reading days, and aligned hormonal data to defined cycle phases. Then, by setting different thresholds and defining how many days a PDG rise must be sustained, we can assign each cycle a label of ovulatory or anovulatory. Preliminary results indicate distinct differences in the dynamics of PDG. Well-timed increases in PDG following the predicted ovulation window characterize baseline ovulatory cycles. In contrast, PCOS cycles are more often characterized by delayed or inconsistent PDG patterns, suggestive of lack of ovulation or irregular luteal phases. These distinctions make apparent a way in which hormonal data can enhance accuracy in the prediction of ovulation and provide a deeper understanding of cycle variability. This work demonstrates how tracking quantitative hormones in conjunction with methods in data science can support more personalized insights into reproductive health. Ultimately, it may help refine digital fertility tools and contribute to better screening for disorders such as PCOS.

Abstract Name: From Story to Science: Mentoring Creativity, Empathy, and Innovation Through Interactive Fiction Research

This mentor-led presentation explores the collaborative research journey between faculty and an undergraduate student in the design, development, and evaluation of an interactive fictional software tool created to teach empathy. What began as a creative concept evolved into a rigorous interdisciplinary research project that blended psychology, counseling theory, narrative design, and educational technology. Through close mentorship, the student became an active co-creator—developing scripts, shaping character perspectives, learning research methodology, and ultimately evaluating the very tool she helped design. This project highlights a model of mentorship in which students are not only researchers but innovators—learning how professional identity, creativity, and scientific inquiry intersect. The presentation will explore how the mentoring relationship supported skill development in coding logic, qualitative analysis, ethical research design, and professional collaboration, while also fostering deep student ownership and confidence. Findings from the tool’s evaluation suggest promising applications for empathy training in helping professions and educational settings. This work demonstrates how mentoring students in the creative research process can transform them into emerging colleagues while producing meaningful, socially relevant scholarship.

Abstract Name: When Research Is “Me-Search”: Mentoring Lived Experience, Family Systems, and Student Well-Being

This mentor-led presentation examines a deeply relational research partnership centered on the lived experiences of students from non-nuclear family structures navigating college life. Rooted in the shared personal experiences of both mentor and student, this project exemplifies how “research as me-search” can be both rigorous and transformative. Through sustained mentorship, the student developed a sophisticated qualitative research study examining how family transitions, institutional policies, and social supports intersect to influence student mental health, resilience, and academic persistence. The mentoring relationship itself became a powerful vehicle for growth, as both mentor and student navigated personal resonance, ethical reflexivity, and scholarly accountability. The project resulted in multiple conference presentations and competitive research recognition while also deepening the student’s professional identity as a future public health leader and advocate. This presentation highlights how mentoring grounded in authenticity, mutual respect, and shared meaning can amplify scholarly excellence, emotional insight, and long-term student success—demonstrating the profound impact of mentorship on both research outcomes and student/mentor development.

Abstract Name: : Colonial Erasure and Cultural Renewal: The Psychological and Spiritual Dimensions of Two-Spirit Identity in Southwestern Indigenous Communities

This research examines the historical and contemporary experiences of Two-Spirit individuals in Southwestern Indigenous communities, including Navajo, Pueblo, Apache, and Hopi peoples. Traditionally, Two-Spirit people held respected roles as healers, mediators, and cultural leaders. Colonialism, Christian missionary efforts, and boarding-school assimilation disrupted these roles, contributing to stigma, erasure, and psychological harm. Using a mixed-methods approach, the study integrates qualitative analysis of oral histories, literary texts, and archival materials with secondary quantitative data on mental health disparities among Indigenous LGBTQ+ populations. This framework highlights how Two-Spirit individuals navigate identity, belonging, and mental health challenges in the present day. The research emphasizes resilience strategies rooted in Indigenous cultural practices—including ceremony, storytelling, and language preservation—that support well-being and foster community connection. It also documents contemporary efforts to reclaim and revitalize traditional Two-Spirit roles, illustrating the ongoing cultural renewal within these communities. By centering Indigenous knowledge systems alongside Western psychological frameworks, the study aims to inform culturally responsive mental health care, support Two-Spirit identity affirmation, and contribute to broader efforts in cultural revitalization and advocacy.

Abstract Name: Spatiotemporal variation of plant phenology and forage quality and their effects on ungulate migration in the Greater Yellowstone Ecosystem

The seasonal migration of ungulates often follows peak vegetation growth throughout a region; however, with climate change affecting season durations, the different timing of peak vegetation may influence migration paths over time. In this study, we aimed to answer the questions: (1) How can Chlorophyll A content show seasonal variation in nutrient quality patterns? (2) How might the nutritional quality patterns shown by Chlorophyll be driving elk migration patterns in the Greater Yellowstone Ecosystem? By building effective methods in vegetation mapping, we will better understand ungulate migration patterns and how to manage migrating populations in an ever-changing landscape. The study area was broken into classes based on the average start of season growth rate and previous elk migratory movement to sample our data. These groups were classified into three groups by start of season growth and elevation, including early (1,231-2,134m), middle (2,134-2,438m), and late (2,438-3,453m). We then sampled from these groups in predetermined locations during June-September. Quadrant sampling methods were used to collect vegetative samples, which were subsequently prepared for Chlorophyll A analysis. Forage quality was determined using a spectrophotometer. We determined that there is a month-elevation interaction driven by the middle elevation class ($p = 0.0003$), while the changes in the early and late elevations were too subtle to detect. Our findings were consistent with the presence of delayed peak green-up, as the largest difference in Chlorophyll concentration occurs between June and September ($p = 0.0095$). With this, we can evaluate the behaviors of migrating elk. Elk may prefer to first stay on early elevations as the Chlorophyll content becomes stable early, then there may be a pull into the middle elevations. There may be fewer incentives for elk to move into high elevations, as there was no significant improvement in forage quality.

Abstract Name: Pre-clinical assessment of hRXFP1 agonists ML290 and 8394 as therapeutics for vascular calcification

Vascular calcification is the most significant predictor of cardiovascular disease and mortality, especially in patients with chronic kidney disease. Medial vascular calcification occurs when calcium phosphate deposits stiffen the arterial wall, impairing vascular function. Relaxin, a naturally produced hormone closely related to dilatation and loosening of muscles during childbirth, has been recently presented as a possible treatment for cardiovascular diseases. Relaxin despite being highly vasoprotective and antifibrotic has limitations due to its short stability and bioavailability in vivo, reducing its therapeutic potential. As an alternative, targeting the relaxin family peptide receptor type 1 (RXFP1) is being researched, as it allows to implement the hormones benefits while overcoming its drawbacks. ML290 and 8394 are allosteric agonists of the human relaxin family peptide type 1, both of which have demonstrated an ability to mitigate calcification progression and mineral presence in cultured vascular smooth muscle cells. This study aimed to determine if 8394 and ML290 (10mg/kg and 30 mg/kg dosages) can inhibit vascular calcification progression in an in vivo model of chronic kidney disease. Chronic kidney disease was induced in hRXFP1/hRXFP1; apolipoprotein E-deficient (ApoE^{-/-}) mice by administering an adenine-rich diet for 6 weeks, followed by a high adenine-high phosphate diet for the remaining 2 weeks of the experiment. Simultaneously, we will administer a daily dosage of either ML290 (10mg/kg), ML290 (30mg/kg), 8394 (10mg/kg) or vehicle through oral gavage. Results suggest a significant decrease in cardiovascular calcification progression in mice that received ML290 at 30mg/kg dosage, establishing it as a possible treatment for medial vascular calcification. However, there were clear sex-dependent differences between the female and male results, with females presenting less calcification overall, making the results of the treatment unclear for this demographic.

Abstract Name: Strengthening the Village: Maternal Mental Health, Parenting, and Youth Mental Health in Black Families

Caregiver mental health has been found to inform youths' mental health, such as depressive symptoms. This association demonstrates the intergenerational transmission of mental health challenges from caregiver to child; however, there is insufficient research on the factors that influence this relation. While experiencing mental health challenges, mothers may have difficulty engaging in positive parenting behaviors with their child, which may then affect their child's increased depressive symptoms. Additionally, not only is it

important to focus on mediators in this relation, but also potential protective moderators that may prevent negative effects in youths' depressive symptoms, such as social support. To our knowledge, no studies have tested this full moderated mediation model among Black children and their caregivers. To address these gaps, the current study tested whether the relation between mothers' depressive symptoms and supportive-engaged parenting was moderated by social support from friends and/or family, and whether supportive-engaged parenting, in turn, impacted youths' depressive symptoms. The current study included data from 128 Black children ages 5 to 11 and their mothers who participated in a larger study. Findings indicated that mothers' depressive symptoms predicted greater children's depressive symptoms, with various significant moderating and mediating pathways. Familial social support predicted greater supportive/engaged parenting, which was associated with youths' decreased depressive symptoms. Social support from friends moderated the relation from mothers' depressive symptoms to support-engaged parenting. Specifically, among mothers with high levels of social support from friends, they engaged in greater supportive-engaged parenting despite experiencing depressive symptoms, which was, in turn, associated with lower depressive symptoms among youth. Overall, our findings indicate that mothers' mental health, social support, and supportive-engaged parenting all play important roles in Black children's depressive symptoms, which could be used to bridge disparities that are prevalent among Black families in the United States.

Abstract Name: Empowering Community College Students with Access to Undergraduate Research Experience

Undergraduate research has significant beneficial impacts on students; yet many community colleges struggle to facilitate opportunities for students because of heavy teaching loads; limited infrastructure (lab space, equipment, limited funding for research, dedicated research office); a narrow traditional view of research; and institutional priorities that are focused on transfer pathways and workforce readiness. In this project we will talk about implementing first "Scholars Day", an undergraduate research conference intentionally shaped around the needs and realities of community college students at the Oklahoma City Community College. We are the 4th largest higher education institute at Oklahoma with more than 18,000 students. Many of our students are first generation college students, balance caregiving responsibilities, jobs, and financial stress, and some arrive with internalized beliefs that their voice does not matter. We had more than 60 research and scholarly projects presented at the Scholars Day. This included more than 500 participants for the event. We will outline the steps taken to create Scholar's Day, describe how we addressed the hurdles, and discuss the impacts on students. We will discuss how Using a practitioner action research approach, we designed and implemented Scholar's Day. Preliminary results suggest these types of structured, faculty-supported presentation opportunities, when implemented with the unique characteristics of the community college in mind, can increase community college students' confidence, academic identity, and sense of belonging. Our experience drives our commitment to help community college students develop voice, confidence, and belonging in undergraduate research.

Abstract Name: "Fled from the Harvester's Feet": Bird Populations and Conceptualizing Extinction Through the Lens of 19th Century Victorian Poetry

This project seeks to examine bird extinction through the lens of Victorian poetic expression alongside statistical data of bird populations in Britain throughout the Industrial Revolution. The literature of the Victorian period offers a unique perspective into thoughts surrounding extinction at its inception. The mid-19th century saw sensibilities of bygone Romantic poets clash with the growing mass of factories and commercial economy in urban British centers. Meanwhile, the new concept of Darwinism brought forth a body of thought around speciation; and the first theories of extinction appeared in Britain in the mid 19th century in relation to bird populations. While few poets were aware of the imminent environmental disaster these early signs heralded, anxieties in the works of poets such as Thomas Hardy, Mathilde Blind, and George Meredith express discomfort with humanity's encroachment on natural processes. The bird is a common subject that suffers at the hands of humans, the poet assuming the perspective of the avian creatures to reflect upon society itself. Alongside literary analysis of Victorian authors' poems, a quantitative analysis of avian extinction data in Britain over the industrial evolution is conducted and compared to awareness of the concept in popular literature to assess correlation between extinction events and awareness of them. Statistical tests are applied to see if a strong correlation between the two exists. We hypothesize that evidence of bird habitat disruption correlates with literary intimations of bird suffering, forming early roots of environmental awareness. Victorian poetry offers a lens through which people could process their changing world, and allows us to identify how species were conceptualized before modern ideas of conservation and extinction.

Abstract Name: Associations Between Testes Size and Polyandry in Illinois *Magicicada* spp.

Periodical cicadas (*Magicicada* spp.) are unique insects due to their 13–17-year life cycle and short adult emergence, during which reproduction takes place for 3–4 weeks. While their life cycles and behaviors are well-studied, relatively little is known about whether *Magicicada* have a polyandrous system. This study examined whether testes size in male cicadas reflects reproductive investment consistent with levels of polyandry by measuring absolute and relative testes area and dry mass in male *M. cassini*, *M. decula*, and *M. decim* from the 2024 Brood XIII. Linear regressions assessed the relationship between head width and testes size, while single-factor ANOVAs compared relative testes size among species. Relative testes size did exhibit variation, with *M. cassini* and *M. decim* resulting with proportionally larger testes than *M. decula*, suggesting higher sperm competition in these species. Weak correlations between body size and testes size indicate that reproductive investment is not solely determined by relative body size. These findings suggest that *M. decula* may experience lower levels of sperm competition compared to *M. decim* and *M. cassini*, reflecting potential differences in mating frequency among *Magicicada* species.

Abstract Name: Data Breach Effects On Firm Revenue and Consumer Sentiment

Data breaches are cybersecurity incidents where confidential, or at least sensitive, information is accessed without authorization, and are occurring at an increasing frequency across the world's firms. We examine the extent to which these events impact a company's revenue, which may additionally proxy for consumer sentiment. Our unique 15-year sample consists of 50 publicly traded companies that experienced data breaches, with several important industries represented. Methodologies include statistical hypothesis testing, linear regression, fixed effects regression, time series analysis, and (fixed effects) quantile regression. Results suggest that, at most, companies experience a two-quarter period of slower revenue growth following a data breach, with the differential most often being statistically insignificant. Thus, in contradiction to sensational press coverage, stories of boycotting behavior, and general belief, data breaches do not generally appear to have measurable impacts on company revenue or consumer behavior.

Abstract Name: Screen Time and Anxiety in an Understudied Community-College Population

Johnathan Haidt, in *The Anxious Generation*, argues that the rapid digitization of the lives of those in Gen Z (widely understood to be between the years of 1997 and 2012) has contributed to rising anxiety rates. Prior research established a correlational relationship between higher daily screen time and anxiety levels (Twenge, 2019). Community college student bodies are more demographically diverse, with more variations in age, financial backgrounds, and work obligations—yet they remain underrepresented in studies linking the digital behavior of college students to anxiety. This study asks whether total daily screen time predicts higher self-reported anxiety levels in community college students, an understudied group in existing literature. A sample of undergraduate students at Westmoreland County Community College will be obtained through email invitations, social media posts, and physical flyers. A non-diagnostic use of the Generalized Anxiety Disorder questionnaire (GAD-7) will be administered to measure self-reported anxiety levels. Scores will be correlated with participants' reported smartphone screen time data. Researchers will examine whether the relationship between screen time and anxiety found in prior research also appears in community-college students

Abstract Name: Leveraging AI in Nanomedicine Design

There is an ever-growing amount of research data available on nanomedicine, and consequently, the assessment of novelty and feasibility of proposed new designs is becoming more difficult. With advancements in performance and accessibility of AI tools, we hypothesize that AI can accelerate the nanomedicine research process by assisting with formulation suggestion, synthesis planning, and dose finding. To test this hypothesis, we used AI tools vetted by VCU, specifically Microsoft CoPilot, Google Gemini, and Google NotebookLM. Between September 2025 to December 2025 all available models within these tools were tested. The use case chosen for testing was the co-encapsulation of methotrexate with another drug in PLGA nanoparticles for treating endometriosis. All tested models had an associated cost (run time – ranging from 1 to 90 minutes, fees – ranging from \$0 to \$20 per month, verification time – ranging from 1 to 8 hours). The quick response required multiple prompts to retrieve the desired information. The deep research provided in-depth explanations and even full literature reviews, yet this led to longer verification time. Because the models save previous searches, the responses become more personalized with prolonged use, making generalization to other users difficult. Synonyms were not recognized unless initially prompted with the synonym first. Overall, the tools could suggest potential drugs to pair in a nanoparticle formulation and provide step-by-step protocols for synthesizing the nanoparticle, as well as reference pharmacokinetic data when the drug has clinical data available. However, additional prompting is needed to clearly link information with its sources due to citations either not associated with the information, not provided for the information, or, in some cases, not real. When the information attribution strategy improves in future versions of AI tools, we anticipate they will truly accelerate the research process in nanomedicine design.

Abstract Name: “A Trumpet Call of Victory:” Eleanor Roosevelt, the UDHR, and the Postwar World’s Reckoning with the Holocaust

The Universal Declaration of Human Rights was unanimously adopted by the newly created United Nations in 1948. The document outlined the basic standards of human dignity that the UN would seek to protect. There is great debate among historians and political scientists over the extent to which the violations committed in the Holocaust influenced the creation of the UDHR. Some argue that the horrors of the Holocaust shook the very foundation of the world order in a way that prompted the drafters to include articles in the declaration which were specifically intended to address Nazi atrocities. However, others claim that this narrative was constructed later to give the modern human rights regime legitimacy, and that the UDHR did not respond directly to the Holocaust. This project intended to assess both of these claims, specifically through the work and contributions of Eleanor Roosevelt, who chaired the Human Rights Commission that drafted the document. Through key primary source documents and scholarly critiques, this project re-examined the narrative around the creation of the modern human rights regime. Additionally, this study examined Roosevelt’s engagement with Holocaust survivors and her writings about her time on the commission. Ultimately, based on Eleanor Roosevelt’s work this paper concluded that the Holocaust did play a significant role in shaping the UDHR.

Abstract Name: Fourier Neural Operators for Excitable Media Dynamics in FitzHugh-Nagumo Systems

Fourier Neural Operators (FNOs) provide a strong framework for learning solution mappings of parametric partial differential equations (PDEs) by directly approximating operators between infinite-dimensional function spaces. While FNOs have demonstrated success in modeling of numerous physical systems, their application to reaction-diffusion systems, particularly in neuroscience, remains underexplored. In this work, we develop and implement FNOs for the parametric FitzHugh-Nagumo (FHN) system, a model of excitable media dynamics in neural systems. Our framework learns solution operators mapping initial conditions and system parameters to dynamics of the activator and inhibitor variables. We train the FNO model on a dataset of FHN solutions generated via a traditional numerical solver across a wide parameter space, aiming to create a strong resemblance of the numerical solver while achieving significant speedup in computation time. We evaluate our approach mainly on mean squared error (MSE) and coefficient of determination (R^2) between FNO predictions and ground truth solutions, as well as generalization to unseen parameter combinations and long time rollouts. Our results demonstrate that the FNO accurately captures the spatiotemporal patterns of the FHN system, achieving MSE under 2% for both activator and inhibitor variables, while providing several orders of magnitude speedup in computation time compared to traditional solvers.

Abstract Name: Cultivating Scholars: Coaching and Mentorship for Belonging and Resiliency at a Hispanic-Serving Institution

Students from minoritized backgrounds often face barriers that limit access to advanced degrees and contribute to inequities in STEM and social sciences. Beyond academic preparation, fostering belonging is essential for persistence and success. This presentation highlights two innovative coaching models at the University of Puerto Rico Cayey: METAS+, an NIH-funded program supporting transitions from undergraduate to graduate studies in STEM and biomedical fields, and the Mellon-funded Resiliency Coaching Program, designed to strengthen retention and graduation among undergraduates. Although implemented at different stages of the BA degree—METAS+ during the final undergraduate year and first year of graduate school, and Mellon during earlier semesters—both models share common topics essential for academic and professional success: time management, networking, teamwork, perseverance, mentoring, and structured planning through the Individual Development Plan (IDP), the leadership wheel, and SMART goal-setting techniques. These strategies promote transferable skills while fostering a strong sense of belonging. Coaching sessions provide “acompañamiento” or accompaniment in a safe space that encourages active participation through interactive activities and peer-mentoring by graduate-level students. A distinctive feature of both programs is the creative presentation of each student’s IDP portfolio, which focuses on research opportunities and experiences as developing scholars, serving as a reflective and goal-oriented artifact at program completion. This presentation shares peer-mentorship insights and innovative group coaching practices that illuminate pathways for aspiring student researchers and strengthen professional development readiness. Evaluation results show significant gains in confidence, resilience, and clarity in

academic planning, as well as measurable improvements in NIH Hallmarks of Success for METAS+ participants and high retention and graduation rates for Mellon participants. Together, these initiatives demonstrate how coaching combined with peer mentoring can transform student trajectories by fostering belonging and resilience across critical academic transitions.

Abstract Name: Model Lunar Airlock for Space Training and Simulation

This project is being conducted in collaboration with Space Nation, an organization dedicated to advancing space education, training, and simulation to prepare individuals and teams for future extraterrestrial missions. Space Nation's mission is to make space exploration knowledge and preparedness accessible to everyone by creating realistic, scientifically grounded simulation environments. Our Model Airlock System is being developed as a scalable prototype for Space Nation's simulated lunar station, which forms part of their ongoing Moon Mission Simulation Program. The full-scale station is located at the Midland International Air and Space Port in Midland, Texas. I have personally visited the lunar station simulation site and conducted on-site measurements to ensure that our model fits within the parameters of the site. This collaboration not only strengthens the technical relevance of our project but also provides valuable experiential learning within an active aerospace research environment. The project aims to produce a fully functional, modular airlock system that demonstrates fundamental aerospace and mechanical engineering principles. The prototype will serve as a useful training tool for space and lunar simulation and incorporate many of the sounds, visuals and systems that an astronaut would encounter while operating a lunar airlock. The prototype will feature pressure sensors, temperature sensors, and a vacuum simulation zone. The system integrates sensors such as Pt1000 temperature detectors, VCT pressure transducers, and CDG vacuum confirmation sensors, along with timers, lighting, and onboard cameras for monitoring. Extensive material research led to the selection of aluminum for its durability, structural stability, and vacuum compatibility.

Abstract Name: History Curricula in Blue and Red States: How Varying Partisan Ideologies Impact Students' Political Opinion

Political Socialization is the process whereby individuals develop political opinions and affiliations. This results from social, political, and/ or economic values in an individual's environment. The attitudes and beliefs of an individual are most malleable during childhood, adolescence, and young adulthood, and are heavily impacted by social interactions and peer groups. Time spent in school can have a significant impact on political socialization through peer interactions and the inclusion of political ideals, values, or practices in curricula. Because state and local governments have the power to control funding, textbook adoption, and curriculum, and may adopt curricula based on partisan ideology, what is taught in history classes across the country varies state by state. This may suggest variation in how students in states of varying partisan

ideologies will vote in the future. Given their distinct partisan ideologies, Alabama and California differ in how they present the historical topics of Slavery, Reconstruction, and the Civil Rights Movement in late elementary and middle school curricula during the early 2000s. This has implications for millennial voting behavior today. After the review of literature and curriculum guides from each state, Alabama presents these historical topics in a more politically neutral manner, leaving out specific statements that addressed moral faults, and inadequately explaining the extent to which Slavery, Reconstruction, and the Civil Rights Movement negatively impacted Black Americans. In contrast, California adequately addressed these historical events, discussing both positive and negative outcomes. These states still contrast politically today, and millennial voters exhibit the partisan beliefs of the curriculum they were taught.

Abstract Name: Optimizing for Multitask Model Capabilities Using Machine Learning

The optimization of any process is an important but tedious task. While exhaustive searches guarantee an eventual set of optimal inputs, as systems become more complex, exhaustive searches lead to exponentially increased testing times and costs. Machine learning is used to try to optimize processes more efficiently. One approach is using a method called Bayesian optimization, which works by balancing exploration and exploitation through a probabilistic model, allowing optimal inputs to be found with far fewer tests than an exhaustive search. In our work, we are looking at multitask Bayesian optimization, optimizing a model to be able to handle multiple possible targets simultaneously. We believe that this will be more efficient than optimizing for individual targets separately. Our test system is quantum dot synthesis, where we're optimizing for being able to target multiple different colors. We are comparing multiple different unique batching methods to see which method converges the fastest. We will discuss the capabilities of each method, where they hit their limits, and how stable and consistent each batching method is. We plan to test all the batching methods over 100 unique runs, with each method having the same initial data points. In our smaller tests we have noticed that one of the methods we are testing did much better than expected. During our large batch testing, we will make sure to remove a potential source of improvement for that specific method that we believe may be the reason that that method did so well. We predict that most, if not all, of our multitask methods will be more efficient than individualized single-target optimization.

Abstract Name: From Partnership to Estrangement: The Impact of Sino-American Educational Exchange and Changing Diplomacy in Wartime China

Transnational education served as a critical bridge of diplomacy and cultural exchange between China and the United States during the early twentieth century. The Peking Union Medical College (PUMC), established by the Rockefeller Foundation from 1917 to 1951, exemplified how educational collaboration could shape

international relations through shared intellectual and humanitarian goals. Positioned within the broader history of global educational exchange, the PUMC operated not merely as a site of Western medical instruction but as a space of negotiation, adaptation, and mutual influence. Focusing on student perspectives—particularly those of Chinese women in nursing and medicine—this research reinterprets the history of the PUMC, which has long been dominated by Western faculty narratives. Drawing upon archival materials, memoirs, and institutional reports from the Rockefeller Archive Center, the analysis reconstructs how students understood and enacted the college's mission. Their experiences reveal a culture of unity, humanitarianism, and national service that transcended cultural hierarchies and political divisions. During the Second Sino-Japanese War, PUMC students mobilized their training for civilian and military relief, establishing clinics and refugee programs that embodied both professional rigor and transnational solidarity. The findings demonstrate that the PUMC functioned as a non-state instrument of diplomacy, fostering cross-cultural understanding even amid geopolitical conflict. Its legacy underscores the potential of educational exchange to build durable connections between nations—a historical model that illuminates how collaboration in learning can renew dialogue and empathy within contemporary Sino-American relations.

Abstract Name: Reevaluation of VlsE based diagnostic assays for canine Lyme disease

Lyme disease (LD), caused by *Borrelia burgdorferi*, is an increasing health concern for humans, livestock, and companion animals across the Northern Hemisphere. *B. burgdorferi* is transmitted to mammals through the bite of infected *Ixodes scapularis* (black-legged) ticks. Dogs are sentinel animals for Lyme disease providing surveillance for local exposure and signaling potential emerging public health risks. Accepted diagnostic testing relies on the detection of antibodies to the conserved C6 peptide region of VlsE. VlsE is a surface protein is a major contributor to the pathogenesis of the Lyme disease spirochetes. Current diagnostic testing presents significant limitations due to sequence variation in the C6 region of VlsE. The purpose of this study was to reevaluate the utility of VlsE and the C6 peptide as diagnostic antigens for Lyme disease in dogs. Towards this goal, we assessed the reliability of VlsE-based diagnostic performance by screening serum from experimentally infected and client-owned dogs. Several different VlsE variants were included in the analysis. The ELISA results revealed significant variability in antibody detection by diverse VlsE variants suggesting that current Lyme diagnostic tests lack specificity and sensitivity.

Abstract Name: The Hero, the Trickster, and the Shadow: A Jungian Reading of Gun Island

This paper analyzes Amitav Ghosh's 2019 novel, *Gun Island*, by examining the main character Deen's personal journey of self-discovery and growth. Drawing on the ideas of the psychologist Carl Jung, this study looks at the characters through recurring personality patterns, also known as "archetypes," to show the novel's ideas about skepticism, ancient myths, and environmental issues. Using a close look at the text, the paper

argues that Deen embodies the Hero archetype, transforming from a skeptical book dealer into a seeker of the unknown. He is guided by Cinta and Tipu, who act as contrasting guides, or Tricksters, whose different influences push Deen to change. Furthermore, the analysis suggests that Deen's love interest, Piya, represents his Shadow; the purely scientific part of himself that he must overcome, challenging his acceptance of the supernatural and intuitive world that he's newly introduced to. The essay concludes that Deen's personal awakening, rooted in the modern resurfacing of the Gun Merchant myth, highlights a broader need for humanity to re-engage and unite with its ancestral myths to better cultivate the depths of our collective psyche to confront modern ecological and psychological crises.

Abstract Name: Implementing Sustainability and Climate Resilience into the Undergraduate Science Curriculum

Climate and sustainability resilience are some of the most pressing challenges of the 21st-century. The effects of climate change such as higher amounts of extreme weather events, increase in atmospheric CO₂ levels, changes in ocean acidification, rising sea levels, have severe social and economic consequences, disproportionately affecting vulnerable populations and disrupting global economies. Despite this, there is a significant gap in undergraduate college curricula specifically designed around key issues related to sustainability and climate change. To address this gap, this project aims to implement sustainability and climate resilience into the development of scientific activities and laboratories for 5 undergraduate courses at West Chester University (WCU). These activities integrate Student Learning objectives (SLOs) with the goals of the WCU Climate Action Plan (CAP) and Strategic Plan 2025 by using the backwards design curriculum development approach to keep the goals of CAP, Strategic Plan 2025, United Nations (UN) Sustainable Development Goals, and student learning objectives at the center of an environmentally conscious course development project. Through this, our objective is to give students an in-depth understanding of sustainability, and address CAP curriculum goals by increasing sustainability education in general-ed courses by implementing learning objectives related to climate change. To do this, we have developed formative and summative assessments based around topics such as radio frequency interference, light pollution, ocean acidification, and AI model energy consumption to better prepare undergraduate students to drive climate resilience, sustainable solutions, and advocacy in post-graduate environments.

Abstract Name: Designing an Affordable Semi-Active EMG-Controlled Prosthetic Arm for Upper-limb Amputees in Ghana

The high cost and limited accessibility of advanced prosthetic devices are significant challenges to upper-limb amputees in low to middle-income regions like Ghana. Studies have shown that in low-resource settings, the number of amputees continues to grow, but the demand for prosthetic devices remains unmet. Amputees encounter daily struggles that are physically, emotionally, and financially draining. Additionally, other studies have demonstrated that electromyography (EMG)-controlled prostheses can achieve high accuracy using

multiple sensors and computational power. However, these studies have little to no focus on individuals in low- to middle-income regions, which calls for an investigation into how low-cost prosthetic devices can be made accessible to such individuals. Therefore, this project investigates whether an affordable, semi-active prosthetic arm can be developed using EMG to restore essential hand functions for such individuals. The methodology integrates hardware and software systems across three core sections: EMG signal acquisition and classification, actuation, and mechanical design. EMG data were obtained from the GRABMyo dataset using only three electrodes that targeted key forearm muscles. Then, a hybrid recurrent neural network (RNN) and long-short term memory (LSTM) model was used to classify four gestures: hand open, hand close, index and middle finger extension, and rest. The model achieved an accuracy of 84.97%, demonstrating that gesture recognition is feasible with limited electrodes. A spring-mass-damper model was applied to simulate finger dynamics and used to predict natural finger movement with less complex calculations. Simulation and experimental results showed responsive finger movement, and the total material cost of the device was approximately \$319.57, supporting the goal of affordability. Collaboration with a local prosthetics manufacturer helped refine weight, usability, and functionality. Hence, this work demonstrates that meaningful prosthetic innovation is achievable using accessible, low-cost technologies and offers a scalable framework for improving mobility for amputees in underserved regions.

Abstract Name: Transpiration-Enhanced Condensation Using Synthetic Trees

Natural trees are able to efficiently pump water from the soil to their leaves in a process called transpiration, where negative pressure in the leaves' nanopores suctions water upward through xylem conduits. Synthetic trees mimic this phenomenon, with partially-submerged tubes acting as the "xylem" water conduits and a nanoporous disc acting as the "leaf." This project seeks to investigate the ability of a synthetic tree to enhance the condensation process on a chilled plate in varying environmental conditions. Water condensed in a film on a vertical chilled plate will continue to grow until reaching an equilibrium thickness, which depends on the balance between gravity and water surface tension. The rate at which water vapor can condense on the plate is dictated by the thermal resistance of the system, which is dominated by the conductive losses across the film thickness. The thinner this film is, the lower the thermal resistance will be, resulting in more efficient cooling. The proposed method to reduce this thermal resistance is to use a synthetic tree to passively thin the film from approximately 3 mm to approximately 30 μm . The tree will be oriented perpendicular to the surface of the chilled plate, with the ends of its tubes submerged in the thin water film. As the tree transpires, water will be suctioned from the film, thinning it. At the time of writing, synthetic tree transpiration rates have been measured and experiments within a climate-controlled chamber are ongoing to determine condensation rate. The next phase of the project involves tuning these transpiration and condensation rates when the synthetic tree and chilled vertical plate are set up as described above, then measuring if film thinning occurs as hypothesized. If successful, these results will have exciting implications for reduced-energy cooling applications.

Abstract Name: Deep Neural Network Pose Estimation and Modeling of Butterfly Flight Performance

Seasonal morphological variations in *Zerene cesonia* (the Southern Dogface Butterfly) result in these butterflies having different wing colorations. *Zerene cesonia* exhibits two morphs: a winter morph and a summer morph. When *Zerene cesonia* are reared in winter conditions they have pink coloration on their wings, and when they are reared in summer conditions the entirety of the butterflies' wings are yellow. Moreover, the recent increase in the accessibility of high quality, neural network based, computer vision, pose estimation softwares like DeepLabCut allows novel approaches to animal behavior questions in biology. This research utilizes the novel application of DeepLabCut to assess how seasonal morphology in *Zerene cesonia* impacts flight efficiency. The first objective of this project will assess the ability of DeepLabCut to accurately monitor the climbing flight of *Zerene cesonia*. The second objective of this research is to utilize the pose estimations from DeepLabCut to approximate the flight efficiency of both the cold and warm morphs of *Zerene cesonia* in climbing flight. The third objective is to make a comparison of flight efficiency between the two morphs. Specimens of *Zerene cesonia* have been reared in conditions simulating the summer and winter conditions that naturally produce morphological variation. These specimens were flown in a flight chamber and videoed from two angles using RGB cameras. Then their flight data will be used to train a DeepLabCut model. DeepLabCut can use triangulation to project the butterflies' estimated position into 3-D space, thereby allowing for flight performance analysis.

Abstract Name: Comparing Consumer Dashboard Metrics to Research-Grade Accelerometry

With running at an all-time high in popularity, many levels of runners want to improve their exercise routines. Numerous companies have started developing running sensors to help analyze performance and identify areas for improvement. One key metric that runners use to monitor their performance is called impact, which an accelerometer can measure. The systems include a web-based dashboard for users to review their running data. However, the system is only reliable if the dashboard data accurately reflects the raw data. Our study aims to evaluate the validity of the dashboard information compared to research-grade sensors. We have been conducting experiments with numerous subjects of varying ages running on a treadmill. We begin by having the subjects, all runners aged 18-80 with no prior injuries, stand or sit so we can attach various sensors to their lower extremities. Next, we calibrate the sensors by having the subjects perform different poses to help the sensors identify their placement. Then, the subjects start running on a treadmill to help warm up. Data is recorded for about a minute during the middle of their run. Our data processing involves writing code to apply to the raw acceleration data from the research-grade sensor, producing raw Y, Z, and YZ resultant data points. We then compare the web-based dashboard data from the commercial-grade sensor with the raw data from the research-grade sensor to analyze differences and assess the validity of the dashboard data. Pearson product-moment correlations will be calculated to evaluate the relationships between the commercial-grade dashboard metrics (braking Gs(Y), impact Gs(Z), and shock(YZ resultant)) and the corresponding research-grade PPA(Y, Z, and YZ resultant)($p < 0.05$). In conclusion, our study aims to establish the validity of commercial-grade sensor dashboard information, helping runners of all levels improve their running more easily.

Abstract Name: Associations of Immigration Stress with Body Mass Index and Food Insecurity Among Rural Latino Adults

Background Earlier studies suggested that high stress levels can contribute to poor eating habits and an increased body mass index (BMI). This study examined whether immigration stress is associated with BMI and food insecurity among rural Latino adults. Methods Preliminary baseline data were analyzed from an ongoing pilot study on a health promotion project aimed at reducing cancer risk in Latinos living in rural and agricultural communities in Florida who have children between the ages of 6 and 12. Twenty participants completed a demographic survey, the Immigration Stress subscale of the Hispanic Stress Inventory v2.; the 2-item food insecurity screener; and had anthropometrics measurements collected (weight and height). Pearson's correlation and Mann-Whitney tests were conducted. Results Participants were all female, with a mean age of 36.4 ± 6.8 years. Nineteen participants (95%) were born outside of the U.S, with the majority

(68.4%) emigrating from Mexico. Eleven participants (55%) had at least some high school education. Seventeen participants (85%) had a household income below \$24,999. The mean time spent in the U.S was 15.0 ± 7.4 years. Immigration stress did not significantly correlate with time spent in the U.S., $r(20) = 0.110$, $p = 0.643$, or BMI, $r(20) = 0.200$, $p = 0.398$. Immigration stress was not significantly different between food insecure (11.2 ± 11.2) and food secure participants (10.8 ± 10.4 , $p = 0.876$). Conclusion Immigration stress was not significantly associated with BMI or food insecurity. These findings suggest that other structural determinants may play a more prominent role in influencing BMI and food insecurity in this population.

Abstract Name: Characterization of a Novel 3-Dimensional In-Vitro Co-Culture System for Human Secondary Acute Myeloid Leukemia Studies

Secondary AML (sAML) is a form of acute myeloid leukemia that appears in patients with a history of hematological disorders. The overall survival of sAML is 4.7 months in patients ≥ 60 years of age. The discovery of novel treatment strategies for sAML is urgently needed. The goal of this study was to establish and characterize a novel three-dimensional (3D) in vitro model for sAML. Human bone marrow mesenchymal stem cells (BM-MSCs) and SKM1 leukemia cells were co-cultured on 700 nm-diameter electrospun polycaprolactone plates for 96h. Control cells were cultured alone. Gene expression was investigated by q-RT-PCR, and the results were expressed as mean + standard deviation. Our results showed that CXCR1, CXCR2, TGF β , VEGF, ASXL1 and SRSF2 were downregulated in BM-MSCs after co-culture (CXCR1: control: 1.1 ± 0.0 , co-culture: 0.0 ± 0.0 , CXCR2: control: 1.1 ± 0.1 , co-culture: 0.0 ± 0.0 , TGF β : control: 1.0 ± 0.0 , co-culture: 0.1 ± 0.0 , VEGF: control: 1.0 ± 0.0 , co-culture: 0.0 ± 0.0 , ASXL1: control: 1.1 ± 0.1 , co-culture: 0.0 ± 0.0 , and SRSF2: control: 1.1 ± 0.2 , co-culture: 0.2 ± 0.1), while IL6R, SPP1, CCL2 and RUNX1 were unchanged after co-culture. In addition, we observed that IL6R, CXCR2, SPP1, TGF β , RUNX1 and SRSF2 were upregulated after co-culture in SKM1 cells (IL6R: control: 0.2 ± 0.0 , co-culture: 0.9 ± 0.6 , CXCR2: control: 1.0 ± 0.0 , co-culture: 1.8 ± 1.3 , SPP1: control: 1.0 ± 0.0 , co-culture: 3.2 ± 3.2 , TGF β : control: 1.0 ± 0.0 , co-culture: 1.5 ± 0.8 , RUNX1: control: 1.0 ± 0.0 , co-culture: 1.4 ± 0.3 , SRSF2: control: 1.0 ± 0.0 , co-culture: 1.4 ± 0.1), while CXCR1, CCL2, VEGF, and ASXL1 were unchanged after co-culture. Overall, our study supports the notion that a nanofiber-based 3D culture system may be useful for sAML studies. Abstract Name: Advancing AI Through Digital Twins and Embodied Intelligence

This work investigates how Large Language Models (LLMs) can be integrated into Digital Twin simulation environments to enhance situational awareness and autonomous decision-making in unmanned aerial vehicles (UAVs) and mobile robots. Although prior research demonstrates that LLMs can generate robotic actions from natural language prompts, performance deteriorates as task complexity increases, raising concerns regarding safety and reliability. Digital Twins provide a controlled, repeatable environment for validating embodied intelligence and supporting simulation-to-real transfer. Building on initial capability tests in Turtlesim, Gazebo, and RViz, we integrated Meta's Llama-3 with ROS2 to produce executable commands and operate in a closed-loop configuration with sensor feedback. Using NVIDIA Isaac Sim, we developed a high-fidelity Digital Twin of the Nova Carter robot, equipped with ROS2-based autonomy, safety interlinks, and multimodal sensing (LiDAR, RGB, IMU). In simulation experiments, Llama-3 successfully generated viable ROS2 scripts for assigned tasks but exhibited inefficiencies and hallucination as complexity increased. These observations informed refinements to our evaluation pipeline and training strategies. The Nova Carter Digital Twin demonstrated repeatable closed-loop navigation, obstacle detection and avoidance, and policy execution in cluttered warehouse environments, supporting transparent, safe, and iterative assessment of LLM-driven reasoning prior to physical deployment. Future work will focus on LLM fine-tuning to reduce hallucinations, improve computational efficiency, and increase dependability in more complex missions. Additionally, we aim to expand ROS2 integration and explore Extended Reality-based human-in-the-loop training to support multi-agent coordination and enable robust, privacy-preserving autonomy for UAVs and mobile robots.

Abstract Name: Temporal and Contextual Repeatability in a Novel Community Science Dog Cognition Task

Community science, where members of the public contribute to data collection, has the potential to expand the scale and diversity of canine cognition research by enabling participation from a wider range of dogs and owners. However, questions remain about whether tasks conducted in less controlled settings produce data as reliable as those implemented by trained researchers. This project focuses on developing and assessing a spatial reversal learning task designed to be used both by researchers in a daycare setting and by dog guardians at home. The study addresses whether performance on this task is repeatable within a single context and whether such an approach could support larger-scale, owner-implemented testing. Preliminary analyses indicate that dog performance on the researcher-implemented version of the task shows a weak positive correlation across two sessions, suggesting limited retest reliability to date. This may reflect environmental variability in daycare settings, small sample size, and the disproportionate influence of a few individuals whose performance differed substantially between sessions. Continued data collection will allow for stronger estimates and future analyses comparing researcher- and owner-implemented data. Establishing that a brief, accessible community science task produces repeatable results would provide evidence for its validity and contribute to the development of scalable methods for studying behavioral flexibility in companion dogs.

Abstract Name: Utilizing Generative Artificial Intelligence (AI) to Model Human Carboxylesterase (CES) Interactions with Fluorogenic Chemical Tools

Human carboxylesterases (CESs) are key enzymes involved in the metabolism of various drugs. The methods to study CESs have various limitations. To address this our group has been developing fluorogenic chemical tools to study CES activity in live cells. The development of highly specific and optimized fluorogenic tools typically requires in depth structure-activity relationships requiring the synthesis of large libraries of molecules. Recent advances in generative artificial intelligence (AI) has resulted in the development and release of Alfafold3 and fully opensource implementations including Boltz-2. These approaches allow for more efficient and accurate modeling enabling better understanding of the interactions of molecules with biomolecules. Here we seek to determine if Boltz-2 can be used to model interactions and binding affinities of fluorogenic chemical tools with the two major forms of human CESs. To achieve this, we will model the interactions of CES1 and CES2 with fluorogenic chemical tools that have had their binding affinities determined through experimental methods. Ultimately, successful validation of this approach will allow for in silico screening of chemical tools for CESs resulting in the development of more specific chemical tools for CESs. This will result in better methods to study the roles of CESs in human health and assists in the development of improved therapeutics.

Abstract Name: A Person or a Criminal? An Autoethnographic Study within a Public Defender Setting

This autoethnographic research examines how environmental, social, and systemic factors shape individuals' involvement with the criminal justice system. The study was conducted during a social work field placement with the Albany County Public Defender's Office and focuses on the lived experiences of people who are awaiting sentencing, on probation, or incarcerated. The project explores how relationships with individuals, families, communities, and systems influence criminal justice system outcomes. Qualitative data was collected through reflective journaling, client mitigation interviews, and informal conversations with public defenders and caseworkers. Data is organized into micro, mezzo, and macro categories, and examined to find how they impact the individual within the system. Preliminary findings indicate that involvement in the criminal justice system is less a product of individual behavior alone and more connected to their environment. Clients' legal challenges frequently intersected with mental health conditions and a lack of access to positive social and family support, stemming from an early age. This study highlights the value autoethnographies have in research focused on criminal justice and social work. By centering lived experiences within an ecological framework, the project emphasizes the need for structural reforms that address environmental factors that contribute to the criminal justice system. Findings will contribute to broader conversations on equity and empathy surrounding people involved with the justice system. By applying social work themes such as the use of self, strengths perspective, and ecological theory, the criminal justice experience can be observed through a lens that puts the person, not the criminal, first.

Abstract Name: No more dead mothers : Bridging the gap between maternal health services and black women in Virginia

The stark reality of maternal mortality rates in Virginia displays a significant disparity and lack of care faced by Black mothers. The maternal mortality rate for Black mothers stands alarmingly high at 47.2 deaths for every 100,000 pregnancies, which is more than twice the rate for white mothers, recorded at 18.1 deaths. This alarming statistic exposes systemic issues in healthcare and highlights the urgent need to address this disparity. My project firstly seeks to demonstrate historically recorded bias amongst physicians, where their racial bias affects their concern for certain patients based on skin color, including an inaccurate but widely held notion that Black Americans have higher pain tolerances than other races. This impacts maternal care for Black mothers, which displays an intersection between the disregard of women's health and antiblack racism. Second, this research will utilize historical data to present the variety of care that can help improve healthcare conditions and, therefore, the outcomes of childbirth for Black mothers in Virginia. For example, Petersburg, Virginia, a Black majority city struggling with poverty, had one of the highest maternal mortality rates in the state until alternative care was established in birthing facilities, like doulas fostered by Black grassroots. Organizations like Urban Baby Project and Birth in Color advocate for Black mothers and more community-centric care, such as opening birthing and postpartum care centers. Such efforts will be recommended as evidence-based interventions, as they have resulted in fewer maternal deaths, with the percentage dropping to a level never seen before in the region. Ultimately, the issue of Black maternal mortality has many layers rooted in racism and misogyny, but to address the current rate, providing attainable and community-oriented care for Black mothers will help Black mothers live after childbirth and further in postpartum.

Abstract Name: Backlash at the Ballot Box: Race, Framing Effects, and Public Support for Felony Disenfranchisement

One of the collateral consequences of a felony-level criminal record is felony disenfranchisement - restrictions on one's eligibility to vote in political elections. Scholarship has documented the level of support for these policies in the U.S., as well as some of the correlates of public support. However, research has yet to investigate what messages may be effective in altering public opinion of FD policy support. Previous scholarship on death penalty support has shown how racialized messaging frames can influence punitive policy support, and that race and racial attitudes can moderate these effects. Using a nationally representative survey we experimentally examine the effects of different messaging frames (racial, democratic, and partisanship frames) on respondent support for felony disenfranchisement policy. Overall, we find that messaging frames were ineffective in altering support for disenfranchisement policy. However, the effects of the racial and partisanship frames were moderated by racialized crime attitudes and political ideology respectively. Specifically, the partisanship message reduced support significantly amongst liberal respondents, and the racial treatment led to increased punitive support for respondents with high levels of belief that racial differences in arrest are due to dispositional factors. This research highlights the continued racialized foundation of public support for restrictive voting policy, and gives direction as to how social groups may respond in bifurcating ways to messages surrounding disenfranchisement policy.

Abstract Name: Synthesis of Metformin Organic Salts (GUMBOS) for Enhanced Transdermal Drug Delivery Using Alginate-Chitosan Hydrogel Patches

Metformin Hydrochloride (MTF_{HCl}) is a highly water-soluble, orally administered drug widely used in the management of type 2 diabetes mellitus. Literature has highlighted the potential of metformin to inhibit cancer cell proliferation by targeting the mammalian target of rapamycin complex 1 (mTORC1), a regulator of cellular metabolism. Herein, metformin HCl is utilized alongside six hydrophobic anions to synthesize a group of uniform materials based on organic salts (GUMBOS). Employing chitosan and alginate as principal biopolymers and novel GUMBOS, a proposed system to create MTF-based GUMBOS complexed within chitosan-alginate patches through a gelation process will allow for an extended and increased integration of metformin through a transdermal pathway. These metformin-based GUMBOS will be characterized through FT-IR, ESI-MS, ¹H- and ¹³C-NMR, amongst other techniques. Lipophilicity assessment is employed via a water-octanol partitioning sequence to estimate complexation of hydrophobic anions with metformin. Additionally, evaluation of the complex chitosan-alginate patches were conducted through SEM, TGA, FT-IR, and DSC. The secretion of hydrophobic MTF based drugs from the hydrogel patches will be conducted through an absorbance stepwise system evaluated at varying pH, temperatures, and salinity, among other factors. This will allow for an optimization of the drug encapsulated patches and assess the increased capacity for drug delivery through an in vitro system.

Abstract Name: Design and Synthesis of a Dual-Emission Fluorescent Probe for Early Detection of Amyloid Aggregates in Neurodegenerative Disorders

Neurodegenerative diseases such as Alzheimer's and Parkinson's involve the gradual accumulation of misfolded proteins known as amyloid aggregates, which disrupt neural communication and contribute to progressive cognitive decline. Detecting these aggregates early is challenging, as current imaging tools can be expensive, invasive, or lack the sensitivity needed to identify early-stage pathology. To address this gap, this project focuses on designing a novel dual-emission fluorescent probe capable of selectively binding amyloid aggregates and producing a ratiometric fluorescent signal. Ratiometric probes, which emit light at two different wavelengths, offer significant advantages because they self-correct for environmental factors such as pH, solvent changes, and probe concentration, making them especially useful in complex biological environments. This ongoing study integrates molecular design, computational modeling, and synthetic planning to develop an optimized small-molecule ligand for amyloid detection. Current work includes reviewing literature on fluorophores known to interact with amyloid species and evaluating structural

modifications predicted to enhance selectivity, photostability, and emission behavior. Molecular docking studies using AutoDock and UCSF Chimera are being prepared to model how the designed ligand interacts with amyloid- β aggregates, assess binding affinity, and predict energetically favorable conformations. These simulations will guide refinement of the ligand's structure before laboratory synthesis begins. In parallel, synthetic route development is underway, including selecting commercially available starting materials, outlining protection and coupling steps, and planning purification strategies. Once finalized, future work will involve synthesizing the designed ligand and characterizing its optical properties through absorption and fluorescence spectroscopy. By combining rational design and computational prediction, this project aims to establish the foundation for a next-generation fluorescent tool that can support early detection of amyloid aggregation and facilitate research on neurodegenerative disease progression. This work is conducted under the mentorship of Dr. Susantha K. Ganegamage and supported by the Office of Undergraduate Research at Lamar University.

Abstract Name: AOC: The Personality Profile of U.S. Representative Alexandria Ocasio-Cortez

This poster presents the results of an indirect personality assessment of U.S Representative Alexandria Ocasio-Cortez from the conceptual perspective of personologist Theodore Millon and the Millon Inventory of Diagnostic Criteria (MIDC), which assesses five personality attribute domains: expressive behavior, interpersonal conduct, cognitive style, mood/temperament, and self-image. The inventory consists of 12 scales congruent with Millon's taxonomy of normal and pathological personality patterns and yields 34 normal and maladaptive personality classifications congruent with DSM-III-R, DSM-IV, and DSM-5. The methodology informing the use of the inventory comprises three phases: data collection, scoring and interpretation, and inference. In the first phase, an indirect, at-a-distance psychological assessment of Ocasio-Cortez—a standard approach to the assessment of personality in politics—was conducted through extracting psychodiagnostically relevant data in the public domain from a broad range of biographic sources and media reports. Once collected, the data were coded to the 170-item MIDC. Each item was then classified as either affirmative (more than sufficient evidence), equivocal/affirmative or equivocal/negative (insufficient evidence to rate with confidence), or negative (no empirical support). Affirmatively classified diagnostic criteria were used to generate a personality profile with quantified scale elevations for each of the 12 personality patterns tapped by the MIDC and based on interpretive guidelines provided in the Millon Index of Personality Styles manual. Ocasio-Cortez's primary personality patterns were found to be Ambitious/self-serving and Outgoing/congenial, supplemented by a secondary Dauntless/adventurous pattern and subsidiary Accommodating/cooperative features. A descriptive label aligning with Ocasio-Cortez's personality composite is "Authentically Outgoing Challenger," largely based on the prominence of the Ambitious and Outgoing patterns. An individual with this personality configuration is self-confident, daring, cordial, and considerate. They may be prone to pursuing leadership positions, seeking attention, and taking calculated risks, which could lead others to view them as entitled and needlessly impulsive.

Abstract Name: The Therapy and Medicalization of Native-Hispanic Healing Practices

Many families of Native or Hispanic/Latino background seek the works and resources that come from healers. Healers have helped people heal from problems that have affected their mental and physical health by utilizing their knowledge with religious traditions, culture, energy work, spiritual understanding, their gifts, and natural resources from the Earth. Healthcare professionals can learn how to work with healers and clients to meet treatment goals. Those in our society can learn cultural competency and how to better understand how culture and medicine can be more effective. Based on interviews with healers, their clients, and a health provider in Texas, this paper argues that there is potential to incorporate culture into a clinical setting.

Abstract Name: The Association Between Ultra-Processed Foods and Chronic Kidney Disease in U.S. Adults From NHANES, 2001–2018

Ultra-processed food (UPF) consumption has been rising in the US and globally in the past decade and linked to a wide range of chronic diseases. UPF intake can contribute to the development of chronic kidney disease (CKD); however, the population level data remains limited. The objective of this study was to examine the association between UPF consumption and CKD among U.S. adults using the National Health and Nutrition Examination Survey (NHANES) (2001 – 2018). UPF intake was estimated using the NOVA classification system based on up to 2 days' 24-hour dietary recalls. CKD was ascertained using the recognized criteria for estimated glomerular filtration rate (eGFR) (based on the 2021 CKD-EPI creatinine equation) ≤ 60 mL/min/1.73 m². The association of UPF consumption and CKD was examined with reported odds ratios (aORs), and 95% confidence intervals using the weighted multivariable logistic regression models adjusted for demographic, lifestyle, and clinical covariates. We evaluated 39,512 U.S. adults (≥ 20 y, mean age = 50.3 $\pm$ 17.9), and found that the highest quartile of UPF, relative to the lowest quartile, is significantly associated with 40%-60% increased odds of CKD (aOR = 1.4 ~ 1.6, all $p < 0.05$) across all models. The dose-response relationship has been determined between higher UPF intake and higher CKD risk (ptrend = 0.0103), after adjusting for all covariates. These findings suggest that reducing UPF consumption is critical in CKD prevention.

Abstract Name: Invertebrate Host Species Shed Infective Zoospores Into Aquatic Environments at Varying Rates

Multihost pathogens are important in the spread of infectious disease. Using microwell enumeration, we

measured the rate at which invertebrate hosts release infective propagules into bodies of water, known as their shedding rate. We found that the mean shedding rate varies between species. Aquatic sowbugs were the most competent hosts in the shed of infective propagules. Frequency distributions showed a right skew, meaning some individual hosts contribute more to transmission than others. By exploring the relationship between shedding rate and invertebrate hosts, we can formulate an epidemiological model to predict the spread of infectious disease involving water-borne pathogens.

Abstract Name: Evaluating the effectiveness and viability of *E. coli* as a Marker of Sewage Contamination in Freshwater Beach Environments

Escherichia coli is a gram-negative, motile bacterium commonly found in gut microbiomes of warm-blooded animals and is routinely used as an indicator of sewage pollution in recreational freshwaters. However, *E. coli* is not always a reliable indicator of human health risk because it is abundant in environmental reservoirs (i.e., wildlife, sediments), making it difficult to determine potential sources. This uncertainty complicates beach management decisions, especially following precipitation events when fecal inputs originate from multiple sources. To better characterize origins of fecal contamination across beaches in the Milwaukee metropolitan area, a total of 221 water samples were collected from five beaches during the summer of 2025, targeting periods immediately following precipitation events. Samples were analyzed using standard microbial culturing methods to quantify *E. coli*. To identify potential fecal sources and compare alongside *E. coli* distributions, microbial source tracking (MST) assays were performed for the human-associated *Bacteroides* marker pBI143 and the gull-associated marker *Catellibacterium marimammali* (gull2). *Escherichia coli* concentrations across all sampled beaches ranged from 0 – 6,000 CFU/100 mL, with nearly 40% of measurements exceeding the beach action value (BAV) of 235 CFU/100 mL. During BAV exceedances, 75% of samples were positive for the gull2 marker, whereas 50% were positive for pBI143. Average *E. coli* and gull2 marker concentrations were highest at Harrington Beach, a site characterized by agricultural land use while average pBI143 concentrations were highest at Bender Park Beach, which is located ~2.3 km south of a wastewater treatment plant. pBI143 levels were also highest following combined and sanitary sewer overflow events, consistent with human wastewater contributions. These findings suggest that elevated *E. coli* levels at freshwater beaches are driven by bird-associated contamination rather than human sewage. Incorporating human-specific markers, such as pBI143, into routine monitoring could improve identification of sewage impacts to better inform beach management decisions.

Abstract Name: Decomposing the Post-Pandemic Gender Wage Gap in Finance: the Role of Work-from-Home

Despite substantial gains in women's human capital and wages since 1970, the gender wage gap remains, and

is the highest in finance among sectors. Contemporary research shows that the gap is driven by differences in job flexibility, specifically duration, particular timing, and location of work. Because women traditionally shoulder greater caregiving responsibilities, they place a higher value on job flexibility and sort into more flexible, lower paying jobs. The rise of Work-from-Home (WFH) policies during the COVID-19 pandemic improved flexibility in high paying sectors like finance, suggesting a potential link between working from home and the gender wage gap. This study investigates the post-pandemic gender wage gap in finance by assessing the effect of working from home and decomposing the gap. I use repeated cross-sectional data from the 2021-2023 American Community Survey (ACS) for individuals in finance aged 22 to 64, merged with O*Net occupational characteristics. I estimate a pooled log earnings model including a gender indicator and a gender-work-from-home interaction term with relevant controls to produce the conditional gender wage gap. I hypothesize that working from home narrows the gap, which would be represented as a positive interaction coefficient. I perform an Oaxaca decomposition through estimating separate log earnings equations for men and women and decomposing the mean gender wage gap into explained and unexplained components. This approach identifies the share of the gap attributable to working from home, and evaluates whether differences in average characteristics or market returns to those characteristics play a larger role. My findings will inform policy on work arrangements aimed at promoting gender equality in finance.

Abstract Name: Optimization of a Low-Cost Wildlife Surveillance Camera based on Raspberry Pi Technology

This study investigates the optimization of an existing Raspberry Pi-based camera system as a low-cost alternative for documenting predation of selected butterfly species in Miami, Florida. A significant challenge in this work is developing surveillance solutions that balance high-resolution image capture with affordability. Commercial outdoor videography systems are often expensive and designed for general use, making them unsuitable for applications requiring the successful recording of very small targets such as caterpillars. The system, built on a Raspberry Pi 5 with a compatible high-definition camera module and interchangeable CS-mount lenses, includes a customized Python code for camera control and data logging, along with ongoing evaluations of its thermal behavior to determine whether cooling solutions may be needed for continuous operation. Its performance will be assessed through controlled trials involving the capture of images of target species, or representative models, under daylight, dusk, and infrared-illuminated nighttime conditions at fixed distances while maintaining consistent camera placement. Metadata, including environmental conditions and internal enclosure temperatures, will be collected to support analysis. The evaluation focuses on three primary objectives: assessing the system's ability to capture clear images at multiple distances, comparing the sharpness and field coverage of different lenses, and determining the effectiveness of IR illumination for night-vision applications. Analysis will examine image quality, the feasibility of nocturnal monitoring, and thermal stability relative to manufacturer specifications. Ultimately, this work aims to refine and validate a cost-effective camera system capable of supporting extended field research within practical budget constraints. The results will be discussed in the context of improving wildlife-monitoring tools and identifying practical design considerations for low-cost surveillance systems.

Abstract Name: Fluorescence Spectroscopic Study of the Mechanism of HIV Replication

Untreated replicating HIV is the only way a patient may develop AIDS, a prominent disease taking approximately a million lives annually. It is proposed that the mechanism of HIV replication can be further understood when studying the interactions of the HIV Matrix protein (MA) with cellular proteins. MA has two binding sites for Calmodulin (CaM), and when CaM binds to MA it causes a conformation in the structure of MA, allowing it to become active and bind to other cellular sites. Research has shown that it is likely that decreasing the availability of active MA binding sites would decrease HIV replication in the cell. To further understand the interactions between CaM and MA, fluorescence spectroscopy was used on different CaM and MA solutions in various buffering systems.. At specific wavelengths of light, amino acids become excited and emit light themselves i.e. fluoresce. Tryptophan has the capability of being excited and fluorescing a certain wavelength of light, and this amino acid is found at the CaM binding sites of the MA structure. Since research has shown MA and CaM interactions are Ca^{2+} dependent, by studying the emission spectrum of the tryptophan as MA binds with CaM in different buffering solutions, a better understanding of HIV replication can be grasped. Understanding the mechanisms of HIV replication will be a step closer to treating millions of patients around the world.

Abstract Name: The Effects of Pre-exercise Feeding on Gastrointestinal Integrity Following Acute Resistance Exercise

Resistance exercise (RE) elevates intra-abdominal pressure, reducing splanchnic blood flow and weakening the gastrointestinal (GI) barrier, causing an increase in permeability and translocation of lipopolysaccharide (LPS), a common bacteria component. Previous studies have only examined these effects in fasted conditions. Our goal was to compare how fed vs fasted conditions influence GI distress and permeability. By using a randomized counterbalance crossover design, 10 recreationally trained subjects (5 males and 5 females, age = 20.7 ± 2.4 years, height = 171.6 ± 7.7 cm, mass = 80.3 ± 9.8 kg) underwent both fasted (8 hr overnight fast) and fed conditions on separate days. In each condition, they performed 5 compound RE at a load of 70% 1-repetition maximum for 3 sets of 10 repetitions. For the fed condition, participants consumed a standardized meal 30 minutes before the RE. Blood samples were collected before a standardized meal and RE (PRE), immediately after RE (POST), and 30-minutes after RE (P30). The samples were analyzed for intestinal fatty acid-binding protein (I-FABP) and LPS-binding protein (LBP) by ELISA. Markers were compared using two-way repeated measures ANOVA (condition x time). Our results indicated that I- FABP increased significantly from PRE to POST ($p = 0.009$) and P30 ($p = 0.048$), whereas no significant changes were observed in the fed condition. LBP displayed no significant condition x time interaction ($p = 0.81$) or main effect of condition ($p = 0.17$). However, there was a significant main effect of time ($p = 0.014$), with LBP decreasing from PRE (19.1 ± 1.5 $\mu\text{g/mL}$) to P30 (15.8 ± 1.3 $\mu\text{g/mL}$) across all conditions. This suggests that a pre-exercise meal may reduce exercise-induced GI epithelial damage, indicating a potential protective effect on eating before RE.

Abstract Name: Segmentation strategies in motor sequences: A real-world example using sewing

Motor sequence research has largely relied on tasks composed of brief, fixed-order events (e.g., keypress paradigms), which limit the ability to study how people flexibly organize longer, real-world actions. This project asked two linked questions: (1) Does increasing task complexity lead to more segmentation in a state-based motor sequence, and (2) does segmenting a sequence more finely actually make people faster, or can different strategies yield similar performance? To examine this, we used an industrially relevant sewing context that constrains the order of actions but still allows multiple temporal solutions. Participants were employees at an apparel manufacturing plant and were asked to perform two standardized sewing tasks using an industrial sewing machine - a straight stitch and a curved stitch. Performances were video-recorded, and the temporal sequence was coded into three different behavioral categories (Preparation, Alignment, and Execution) using BORIS. From these annotations, several strategy metrics were computed. The more complex curved stitch elicited reliably greater segmentation than the straight stitch, confirming that task demands push performers to interleave Alignment and Execution more frequently. However, segmentation was only weakly correlated with total completion time, indicating that operators could reach comparable performance through distinct strategy profiles, either with fewer, longer segments or more, shorter segments, provided their per-step pace was high. We argue that this sewing-based paradigm broadens sequence-learning research to behaviors with finite-duration states and demonstrates that variation in segmentation is not merely “noise” but a meaningful expression of individual constraints and trainable skill, with implications for adaptive instruction in industrial settings.

Abstract Name: Designing the Next gp120 Inhibitors: How Pocket Electrostatics Shape HIV Entry Blockade

HIV entry inhibitors targeting the envelope glycoprotein gp120 represent an important approach to block the virus attachment and fusion, but structural and electrostatic features of gp120 that enable small molecules to potently inhibit gp120 are poorly defined. gp120 undergoes a major conformational transition upon CD4 engagement, creating binding pockets of distinct local chemistry and residue composition. To evaluate how pocket electrostatics shape inhibitor activity and can guide future inhibitor design, molecular docking with AutoDock Vina was combined with electrostatic surface analysis and amino acid propensity mapping for residues within 5 Å of docked inhibitors. Two crystallographically validated Env states were considered: (i) the attachment inhibitor pocket in the closed gp120 trimer (PDB 5U7O), which is the reported target of temsavir and BMS-806; and (ii) the CD4 mimetic pocket captured in PDB 8FLY, modeling small molecules designed to interfere with gp120 engagement mediated by CD4 receptors. The ligand panel included the approved attachment inhibitor temsavir (-13.05 kcal/mol), the prototype inhibitor BMS-806 (-10.85 kcal/mol), and three experimental small molecules for which gp120 activity has been reported: FD028 (-8.07 kcal/mol), Compound 5660386 (-6.44 kcal/mol), and ARM-H (-6.11 kcal/mol). Amino acid propensity analysis revealed that the 5U7O pocket is strongly enriched in aromatic and hydrophobic residues, such as

phenylalanine, methionine, isoleucine, valine, and tryptophan, forming a packed non-polar cavity. The 8FLY pocket contained a higher proportion of acidic and basic residues that create a polarized electrostatic surface. These results align with generated electrostatic surface maps, indicating that next-generation gp120 inhibitors may need to reproduce the packed interactions with hydrophobic aromatics in 5U7O and engage acidic and basic residues in 8FLY. This suggests that matching local amino acid chemistry is a key requirement for next-generation entry HIV inhibitor design.

Abstract Name: Scalable Computing With Low Precision Floating Point Algorithms

The rising cost of artificial intelligence training and inference is projected to outpace our nation's energy supply. Current algorithms typically rely on full-precision floating-point arithmetic (FP32, 32-bit) on CPUs and GPUs. However, GPUs have begun supporting low-precision floating-point formats such as FP16 (16-bit), FP8 (8-bit), and FP4 (4-bit). These low-precision operations reduce energy consumption and improve execution speed but require careful use to preserve numerical accuracy. This paper explores mixed-precision floating-point data types in numerical methods for solving high-degree polynomials and transcendental equations. We implemented Newton's method using FP32, FP16, and FP8 for different steps of the algorithm. We hypothesize that the derivatives can be computed in lower precision as quantization errors tend to average out over iterations, but residuals should be kept in high precision because they directly determine the convergence criteria through delta updates, avoiding premature termination. Our experiments demonstrate that using lower precision (FP8 or FP16) for derivative calculations while maintaining higher precision for residuals (FP32) and medium precision for root updates (FP16) achieves accurate results with 33% less computation and 35% less energy consumption per iteration. One key finding is that stochastic rounding is essential to prevent oscillations when converting data to lower-precision FP8/FP16. Additionally, we applied the Ehrlich-Aberth (E-A) method, which adds a correcting term to the derivative, to compute all roots including multiple roots simultaneously, yielding significant improvements in convergence and accuracy. Our results for four equations from different fields show that FP8 is sufficient for derivatives with scaled coefficients in equations having real roots. However, FP16 is necessary for derivatives to maintain accuracy while still reducing energy and computation costs for equations whose roots are complex or when using the E-A method. These results confirm that mixed-precision floating-point methods are a promising approach for scalable computing.

Abstract Name: Relative Clause Structure in Chuj: Headed RCs, Headless Relatives, and Free Relative Constructions

This study examines the internal structure of relative clauses (RCs) in Chuj, specifically a dialect of this Mayan language spoken in San Sebastián Coatán in the Huehuetenango region of Guatemala, focusing on

headed RCs, determiner-headed headless RCs, and three types of free relatives. While Chuj RCs are post-nominal and formed without relative pronouns, little prior work has compared headed RCs, determiner-headed headless RCs, and the three types of free relatives found in this dialect. Through elicitation sessions with a native consultant, we constructed controlled RC pairs that varied subject type (full DP subjects vs. subjects expressed only through verbal agreement), WH-forms, determiners, and clause layering, while keeping tense, animacy, and lexical items constant. For headed RCs, we find a strong tendency for SVO word order when subjects are overt noun phrases, whereas RCs with agreement-only subjects surface as verb-only predicates that lack internal nominal structure. In multi-clause RCs, higher clauses pattern as SVO while lower clauses allow verb-initial alternations, suggesting structural compression in embedded domains. For headless and free relatives, determiner-headed forms behave like definite noun phrases (“the one that...”). WH-headed free relatives fall into three semantic types: maximal free relatives receive definite, uniquely identifiable interpretations; existential free relatives arise only under existential predicates such as *jax*; and free-choice relatives uniquely employ the operator *jalaaxa*. These findings clarify how Chuj uses WH-forms, determiners, and subject realization to encode meaning in different RC constructions, contributing to a broader understanding of how Mayan languages structure complex sentences.

Abstract Name: Constraining Tidal Parameter of Binary Asteroids

This purpose of this research is to better understand and constrain characteristics of asteroids, specifically their tidal parameters. Studying asteroids is key step in understanding the formation/evolution of the solar system, developing planetary defense technology and using resources from bodies other than Earth. Tides arise from the gravitational interactions between bodies in close proximity to each other, potentially causing physical distortions to the surface of asteroids and energy loss. Tidal parameters consist of two values, Q and K , which determine the efficiency of energy loss and the internal structure of the body, respectively. Tidal parameters are a key component of small body dynamics and long-term asteroid evolution, yet we are still lacking information about this property. This property is relevant to all asteroids, but this research looks at binary asteroids, which is when two asteroids are in orbit around each other. Being able to better constrain such a vital property can help improve future telescope technology as well as spacecraft navigation by advancing our understanding of how asteroids move in space. By utilizing observational data of certain binary asteroids, as well as existing models for these types of small bodies, we create and code a numerical function to emulate how the behavior of binary asteroid systems changes with different Q and K values. The results from this research can examine the effects of current tidal models to derive measurement requirements needed for future telescopes and spacecraft to effectively constrain these values. Currently, there is no way to constrain tidal parameters of asteroids when conducting observational research, relying on crude estimations of what the parameters should be. Ultimately, this helps to better understand a key property in asteroid dynamics as well as improve upon future technology.

Abstract Name: Optimizing a Green Anti-Convulsant Synthesis with Safe and Accessible Materials

Phenytoin was discovered in 1908 by Heinrich Blitz and has been used to treat epilepsy since the 1930s. It is on the World Health Organization list of essential medicines. There are several routes to phenytoin and phenytoin derivatives, but yields are typically low. By experimenting with different published experiments in lab and in research, we found that we can make phenytoin without solvent and with a variety of bases including sodium carbonate and calcium oxide. As we continue to optimize this green synthesis, our hope is that the milder conditions used in our synthesis can help make a wider variety of phenytoin derivatives easily accessible.

Abstract Name: Impact Of Maternal Drug Use On Fetal Development And Newborn Dependence Timeline

Maternal use of opioids, alcohol, cocaine, and methamphetamine during pregnancy can disrupt fetal growth and brain development, resulting in complications such as low birthweight, preterm birth, congenital abnormalities, and long-term neurodevelopmental delays. This study aimed to examine the effects of maternal drug use on fetal development across pregnancy stages and to identify the timeline for potential newborn dependence and withdrawal. A systematic review of peer-reviewed journal articles, government health reports, and medical guidelines published between 2020–2025 was conducted using databases including PubMed, Google Scholar, and ScienceDirect. Keywords included prenatal drug exposure, fetal development, and Neonatal Abstinence Syndrome (NAS). Data were organized into summary tables illustrating fetal vulnerability, dependence onset, and newborn withdrawal risk by drug type. Results indicate that fetal susceptibility to drug-induced harm is highest during the first and third trimesters, when organ systems are forming and later maturing for life outside the womb. Early exposure is linked to structural defects, neural tube abnormalities, miscarriage, and Fetal Alcohol Spectrum Disorders (FASD), while late exposure is associated with NAS, low birthweight, preterm birth, and early developmental delays. Opioids carry the highest risk of neonatal withdrawal, often appearing 24–72 hours after birth and requiring pharmacologic intervention. Stimulants such as cocaine and methamphetamine cause neurobehavioral dysregulation and cognitive impairments, whereas alcohol primarily results in irreversible neurodevelopmental damage rather than acute withdrawal. These findings emphasize that the timing, dosage, and type of drug significantly shape fetal outcomes and newborn dependence patterns. They support the need for early prenatal screening, nonjudgmental counseling, accessible treatment for substance use disorders, and long-term developmental follow-up for exposed children. By clarifying critical periods of vulnerability and drug-specific risks, this research provides actionable guidance for clinicians, public health professionals, and policymakers to improve outcomes for both pregnant people and their infants.

Abstract Name: Pearl Coffee Table for Luxury Modern Apartments That Integrate Sustainable Design Principles to Support and Raise Awareness of Ocean Health

Plastic pollution in the ocean is one of the most urgent environmental issues today, with millions of tons of waste entering marine ecosystems each year. Research shows that microplastics, chemical runoff, and degraded plastic particles directly harm oysters by clogging their filtration systems, reducing reproduction, and weakening the reefs they naturally build. As oysters struggle to survive, coastal ecosystems lose a key species responsible for filtering water, removing pollutants, and protecting shorelines. These impacts highlight the need for greater awareness of how everyday plastic use affects fragile marine organisms. This project explores how reclaimed materials, repurposed plastics, and low-emission finishes can be used to create a functional product that promotes sustainability and ocean protection for modern luxury apartment owners on the East Coast of California. The design centers on an oyster-inspired coffee table that symbolizes restoration and marine care. Soft curves and layered forms reflect the structure of oyster shells, while repurposed plastic components underscore the urgent need to reduce ocean pollution. Reclaimed materials and low-VOC finishes further reduce environmental impact and support healthier indoor air quality. By combining sustainable materials with symbolic, ocean-focused design elements, this project encourages responsible living and reminds users of the essential role oysters play in cleaning and protecting marine environments.

Abstract Name: Evaluating the Utility of the Family Nutrition and Physical Activity Screening Tool for Predicting Childhood Obesity in a Mid-Michigan Pregnancy Cohort

Childhood obesity can lead to serious long-term health consequences, including type 2 diabetes and cardiovascular disease (CDC, 2023). In 2020, 19.7% of children and adolescents were classified as obese, underscoring a critical public health concern. Early identification of at-risk children is essential for timely prevention. However, the influence of the home environment on obesity-related health behaviors remains unclear (Lindsey et al., 2006), and healthcare clinics currently lack standardized tools to assess these risks (Taveras et al., 2011). This study examined home environment risk factors associated with children's health behaviors using the Family Nutrition and Physical Activity (FNPA) screening tool. Our research question was: What is the association between FNPA risk scores and childhood obesity? We hypothesized that higher FNPA scores would be associated with lower BMI. We conducted a cross-sectional analysis using data from the Archive for Research in Child Health (ARCH), a prospective pregnancy cohort in Lansing, Michigan. FNPA scores were collected for 52 children aged 4–6 and 35 children aged 10–12. The tool assessed 10 subdomains of family routines and behaviors on a four-point scale, with higher scores indicating healthier environments. Child height and weight were measured, and BMI was calculated. Linear regression models evaluated associations between FNPA subscores and BMI, adjusting for sex, race, and age. Results showed that in 4–6-year-olds, the child activity subscore was significantly associated with BMI. Among 10–12-year-olds, both the healthy environment subscore and the overall FNPA score were significant predictors of BMI. These findings suggest that promoting physical activity, limiting screen time, and fostering supportive home environments may help prevent obesity. Incorporating family-based risk assessments, such as the FNPA, into

pediatric primary care could inform early prevention strategies. Future research should examine these associations longitudinally and across diverse populations to strengthen generalizability and causal inference.

Abstract Name: The Effects of Repeated High-Intensity Aerobic Exercise on Pain Sensitivity: A randomized control trial

Pain is a prevalent and complex condition that substantially affects quality of life, highlighting the need to better understand mechanisms that can inform chronic pain treatments¹⁻². Athletes typically demonstrate higher pain thresholds and tolerance, often attributed to repeated high-intensity training and the resulting exercise-induced hypoalgesia (EIH)³⁻⁵. However, the effects of high-intensity exercise on pain sensitivity in non-athletic populations remain unclear. This study tested the hypothesis that multiple high-intensity aerobic exercise sessions would reduce pain sensitivity more than a single session through enhanced descending pain inhibition. Twenty pain-free participants aged 18 to 50 were randomly assigned to either a Multiple Exercise Session (MES, n=8, 4 high-intensity interval training (HIIT) sessions) or a Single Exercise Session (SES, n=12, 1 HIIT session) over two weeks. Exercise intensity was individualized using a graded exercise test (GXT) performed at 90% of the participant's peak power output. Changes in pain sensitivity were evaluated pre- and post-exercise using Quantitative Sensory Testing (QST), including conditioned pain modulation (CPM), Heat Tolerance (HTO), and Heat Threshold (HT). ANOVA revealed significant main effects of time for Heat Tolerance ($F = 5.66$, $p = 0.022$, $\eta^2 = 0.130$), Heat Threshold ($F = 6.56$, $p = 0.015$, $\eta^2 = 0.143$), and CPM Efficiency ($F = 4.41$, $p = 0.042$, $\eta^2 = 0.104$). However, no significant group $\times$ time interactions emerged (all $p > 0.05$), indicating MES and SES resulted in similar changes across all QST measures. Conclusions: This pilot study, part of an ongoing clinical trial (NCT07083219), suggests that high-intensity aerobic exercise can acutely modulate pain sensitivity and enhance endogenous pain inhibition in non-athletic adults. Contrary to our hypothesis, a single session produced similar effects to multiple sessions, suggesting that acute bouts may effectively modulate pain sensitivity. These findings warrant further investigation with larger samples to inform exercise-based interventions for chronic pain management.

Abstract Name: Exploring the Impact of JSTEM on Mentors' Self-Efficacy and Self-Concept

In STEM mentoring, high self-efficacy and self-concept predict persistence in facilitating complex, inquiry-based learning. Self-efficacy refers to an individual's belief in their ability to successfully perform specific tasks, while self-concept reflects an individual's perception of themselves within particular domains. The Journalism, Science, Technology, Engineering, and Math (JSTEM) program is a month-long experience in which high school students design and conduct college-level research projects to address real-world problems. Mentors serve as facilitators, supporting students' project development, guiding inquiry processes, and encouraging connections between research and authentic contexts. This mixed-methods study included surveys and interviews to assess the impact of JSTEM participation on mentors' self-efficacy and self-concept. Quantitative analyses (survey) revealed self-concept was approaching significance ($p=0.08$), and while self-efficacy increased by 0.17 points, we found it was not statistically significant ($p=0.526$), likely due to the small sample size ($n=5$). However, qualitative data (interviews) revealed meaningful growth in mentors' perceived self-efficacy and self-concept. A chemistry mentor reflected, "I had to teach them that right then and there... I knew the content already, but I wasn't so sure if I [would] be able to teach it, and it worked out; in the end, they were able to understand." This demonstrates increasing confidence in her ability to apply prior knowledge in real teaching scenarios. An engineering mentor described a shift in understanding the nature of science, "science is not right or wrong. It's a process." This indicates growth associated with a stronger self-efficacy. A mathematics mentor shared, "And I want to keep on learning as well, because I know after this summer, I learned a lot, including science and its mathematics." This illustrates their emerging confidence outside of math, prompting a growth in self-concept. Mentors showed shifts in self-efficacy and self-concept through JSTEM participation, despite the small sample size.

Abstract Name: Role of Extra-Erythrocytic Bodies as Metabolic Suppliers of Cartilaginous Tumors

Zhang et al. recently described a mechanism for O_2 delivery to cartilaginous tissue, independent of blood supply, via endogenous cytoplasmic hemoglobin bodies that act as oxygen carriers (1). This mechanism permits the survival of chondrocytes in their avascular environment. Chondrocytes persist in an oxygen-deprived niche, requiring continuous O_2 delivery from surrounding tissue. In our practice as bone and soft tissue pathologists, we observe these eosinophilic hemoglobin bodies in cartilage-forming tumors, which are among the most common neoplasms arising in bone. These tumors develop through cellular reprogramming that results in reacquisition of proliferation and chondrogenic differentiation potential. Like benign cartilage, cartilaginous neoplasms lack the blood vessel-rich microenvironment seen in other tumors (2). As they grow, they recapitulate embryonic intramembranous or endochondral ossification, making extrapolation from embryonic to neoplastic tissue plausible. We report eosinophilic cytoplasmic bodies across benign and malignant cartilage-forming tumors. These hemoglobin bodies were present in tumor types recognized in the current World Health Organization Classification for Tumors of Bone and Soft Tissue (3). Across tumor subtypes, the bodies show similar spherical morphology, ranging from 5 to 20 μm . Although not widely emphasized, eosinophilic bodies in cartilage-forming tumors are not new in diagnostic pathology. Del Rosario et al. first noted these structures as "hyaline bodies" in the cytoplasm and occasionally the extracellular matrix (4). Their study did not include embryonic or proliferative tissues, which may explain their reported absence in normal cartilage. While the origin and function were not established, the authors proposed possible sources, including accumulated secretory products or red blood cell-derived proteins, the latter aligning with

current findings (1). These eosinophilic bodies represent endogenous hemoglobin complexes that provide oxygenation in neoplastic cartilage. Targeting these structures may offer therapeutic potential, supported by Lucas et al. (5), who showed that polymerized hemoglobin co-administered with cisplatin attenuated tumor growth.

Abstract Name: Unknown Microorganism from NJ Urban Runoff Exhibits Antibiofilm Hemolytic and Bactericidal Properties

Biofilms, communities of bacteria encased in an extracellular matrix, contribute to persistent infections and antibiotic resistance, posing significant challenges in healthcare. Identifying new antibiofilm agents is essential to address the growing problem of biofilm-associated infections. Natural antimicrobial compounds have been isolated from diverse environmental sources, including marine and soil bacteria. This study aimed to isolate microorganisms from urban runoff waters and evaluate their potential antimicrobial properties. Several unknown microorganisms were isolated, and antimicrobial activity was initially screened using the streak inhibition assay. Screening revealed one microorganism, designated N2, with notable antimicrobial properties. The streak inhibition assay showed variable inhibition of growth against several pathogenic bacteria, including *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Bacillus cereus*. N2 also displayed strong beta-hemolysis on blood agar plates, indicating the production of hemolytic factors. A cell-free extract of this isolate was further tested using a 96-well plate growth assay and antibiofilm assay. Results showed that N2 inhibited biofilm formation in *S. epidermidis* and *P. aeruginosa*, but enhanced biofilm formation in other bacteria. These findings suggest that N2 produces compounds with both inhibitory and stimulatory effects on biofilm development, along with hemolytic activity that may contribute to its pathogenic potential. Future studies will focus on identifying and characterizing this microorganism, as well as isolating the active compounds responsible for its antimicrobial activity.

Abstract Name: The Natures Nurture - Home Design for the Visually Impaired

Retinitis pigmentosa is part of a large group of hereditary retinal conditions involving one or several layers of the retina, causing progressive degeneration. The condition which involves both eyes is inherited and is generally diagnosed later in life. People with this progressive degeneration of the retina usually retain central vision until late in the disease, as the periphery slowly constricts. Individuals with RP will start to notice an increasing difficulty in night vision with progressive constriction of the visual field to tunnel vision of 20 degrees or less in the better-seeing eye, and total blindness eventually. When designing a home for those individuals with retinitis pigmentosa it is essential to consider wayfinding, contrast, lighting strategies, as well as how to create non-hazardous spaces with finishes and furniture placements. A great example of designing for visual impairment is the So & So Studio architects home design for their visually impaired client. Material options were taken into deep consideration with the play of different textures and how that

can help with wayfinding. The goal of this project is to create an environment where wayfinding and contrast serve as the top two foundational elements which guide all major design decisions for individuals with rp. A carpet tile and laminate flooring are used so the user can make her way through the home by feeling the different textures between the carpet and laminate. All finishes contrast within each other by using darker elements against lighter so the user can differentiate everything while navigating through her home. This design is meant to create a comfortable and safe space for the user. It will help them adapt to the new space which if they are led into legal blindness, they will know the space using materials.

Abstract Name: Supported Apartment Living for Individuals with Epilepsy to Enhance Independence and Safety

Epilepsy affects millions of people nationwide, and many young adults struggle with daily challenges such as stress, transportation barriers, and limited access to specialists. These issues can increase seizure risks and make independent living difficult. This project explores how a supported residential apartment community can create a safer and more stable living environment that promotes comfort, independence, and emotional well-being for young adults living with epilepsy. By understanding the spaces and services that best support their needs, the project seeks to provide a reliable and uplifting alternative to traditional housing options. This research draws on case studies of supportive living campuses, a literature review on living environments for people with neurological conditions, and an interview with a young adult who has epilepsy. Together, these methods highlight the daily experiences, common triggers, and safety concerns that shape the direction of the design. The project uses these insights to guide the development of an environment that strengthens independence while reducing triggers. The design focuses on creating a calm, safe, and supported environment. Soft flooring, rounded furniture, dimmable lighting, and simple pathways help reduce injury risks during seizures. Natural light, indoor plants, and outdoor walking areas support relaxation and lower stress. On-site services such as medical help, therapy rooms, fitness areas, recovery rooms, and private housing units give residents the support they need while still allowing them to stay independent. A dedicated nursing staff area supports continuous monitoring, quick response to medical needs, and consistent care for residents. A pool, small grocery store, and social areas support daily routines and offer safe places to relax and build community. By including supportive services, natural elements, and community-centered spaces, this project creates a living environment that builds independence and helps young adults with epilepsy live with more confidence, safety, and a better quality of life.

Abstract Name: B-Cell Activation is Increased Following Exposure to Freshwater Algal Toxin Microcystin and Anabaenopeptin-B

Cyanobacteria naturally occur in freshwater lakes; however, in recent years, increased climate change and excess nutrient runoff have led to uncontrolled growth of these organisms, resulting in harmful algal blooms.

When a cyanobacterial harmful algal bloom (CHAB) forms, there is a high potential for toxin release into the lake, which could harm people and the environment. The only algal toxin regulated by the EPA is microcystin. However, this toxin is just the tip of the iceberg of what we know exists in our freshwater ecosystems. Therefore, this study aims to understand better the potential human health impacts of these non-regulated toxins, starting with a toxin called anabaenopeptin. Our research focused on the immune cell activation effects of these toxins, using a B cell line maintained in the lab with sterile techniques. Maintaining cell health involved microscopy and other lab tools. We grew the cells in nutrient-rich media and split them every two days. Then, we exposed them to the algal toxins for two hours and proceeded to stain and record B-cell activation. Initially, we tested both microcystin and anabaenopeptin-B in a controlled environment to define the effects of these toxins on the B cell antigen receptor signaling threshold. The doses of the toxins tested were below the levels of the EPA intervention for adults. Dosages used to conduct the experiments were 100 mg/L, 10 mg/L, and 1mg/L. We found that B-cells exposed to anabaenopeptin-B and microcystin were overly activated compared to the control B-cells. In the context of human cells, if these results occurred in people, it could potentially reduce the threshold necessary for normal B cells to become activated. The consequences of such a state might be higher levels of inflammation and potentially an elevated risk of developing an autoimmune disease.

Abstract Name: Exploring Chalcone Scaffolds as Sunscreen Candidates: Undergraduate Synthesis and Spectroscopic Analysis

Chalcones are highly conjugated molecules with strong UV absorption, making them promising candidates for the development of more effective sunscreen agents. Because UV radiation contributes to skin damage, ideal sunscreen molecules must absorb efficiently in the UV region; therefore, Lambda max (λ_{max}) values and molar extinction coefficients are key indicators of a compound's protective potential. In this project, we explored how structural changes influence these photophysical properties by proposing and synthesizing our own chalcone derivatives using the Claisen–Schmidt condensation. Each compound was characterized by melting point and UV-Vis. spectroscopy to assess its UV-absorbing ability. We observed that electron-donating substituents, particularly methoxy groups, increased absorbance intensity and shifted λ_{max} to longer wavelengths. Our findings support chalcone scaffolds as promising UV- protective molecules and demonstrate the value of connecting organic synthesis with functional molecular design.

Abstract Name: Saul Bass and the Art of Simplicity

This paper discusses the design legacy and cultural impact of Saul Bass, a designer whose philosophy of “less is more” reshaped both film intro sequences and corporate branding. Beginning with his introduction to European modernism in the 1940s, Bass developed a style rooted in strong symbolism, simplified forms, and mixed-media experimentation. Influences from Cubism and Neoplasticism helped him find the visual language he became known for, with clean shapes that he intentionally “roughed up” to create something powerful and memorable. Bass carried this approach into film, where he completely changed the purpose of the title sequence. Before Bass titles were often simple typography slapped onto the screen, and he saw this as an opportunity to make them great. His collaborations with directors like Otto Preminger, Alfred Hitchcock, and Martin Scorsese led to iconic openings that are still widely remembered to this day. Outside of film, he brought this straightforward way of thinking into corporate branding, creating well-known logos for AT&T, United Airlines, and Warner Bros., and more. It also examines Bass’s quite flawed personality, as he could be stubborn, self-focused, and unwilling to credit the people who worked with him, while also recognizing how important his wife, Elaine, was to his work. Even with these flaws, Bass’s dedication to his craft shines in his work, inspiring both designers and filmmakers alike. In the end, the paper argues that Saul Bass did more than influence film and branding; he also changed the way designers understand visual storytelling as a whole.

Abstract Name: Wee Beasties: The Evolution of Tyrosine Kinase Activity and Chance, Contingency, and Necessity in Evolution

A central question in biology is the extent of predictability in evolutionary outcomes and the relative roles of chance and contingency on this predictability. Since we cannot directly observe the past, the effects of chance and contingency are unknown. However, we could infer their effects by comparing the outcomes of repeated evolutionary events. Chance predominating would cause independent evolutionary events to produce variable outcomes, while contingency predominating would cause variable outcomes to depend on where evolution started. If the outcomes of evolution were always the same, there is evolutionary necessity (the absence of chance and contingency) and there was a single route available to evolution. Unfortunately, most traits evolved once and this analysis has been inapplicable. The repeated and independent evolution of tyrosine phosphorylation activity offers an exception. Here, we determine the genetic and molecular basis for tyrosine kinase (TK) activity for one instance: the Wee kinase family. Using maximum likelihood analysis, we reconstructed a phylogeny of related kinases and mapped known phosphorylation capabilities onto it, determining when and how the Wee family gained TK activity. We refined our analysis using structurally validated sequence alignments. Future work will use this phylogeny to reconstruct the last common ancestor of Wee and related kinases and identify the genetic changes that conferred kinase activity. We will then compare the sequences and evolutionary mechanisms against those of TK activity in other kinase families, allowing us to determine the relative roles of chance and contingency in the evolution of acquired function for the first time.

Abstract Name: Increasing Sorafenib Efficacy in Hepatocellular Carcinoma via ECT2 siRNA Knockdown

This project evaluates if short-interfering RNA (siRNA) targeting the ECT2 oncogene can increase the vulnerability of hepatocellular carcinoma (HCC) cells to sorafenib (FDA-approved chemotherapy for liver cancer), thereby reducing the effective dose of the drug required for treatment. HCC is one of the most common and deadly liver cancers with only a 22% 5-year survival rate. Not only are the survival rates dismal, but chemotherapy treatment results in many side effects. Lowering the effective concentration of sorafenib required for treatment could greatly improve patient outcomes. siRNA provides a highly-specific mechanism for silencing the expression of unwanted genes by targeting only the mRNA it is programmed to bind to. ECT2 is an oncogene that is commonly overexpressed in liver cancers, causing tumor growth by inhibiting natural cellular processes like apoptosis and increasing cell proliferation. PP5 cells, a commonly studied liver cancer cell line, were grown and seeded into two 96-well plates. One of these plates was treated with ECT2 siRNA and one was left as a control. Then, a series of chemotherapy dilutions were used to treat individual columns in the plate. An MTS Assay was used to determine the concentrations of viable cells left in each well. Initial data shows that treatment of cells with combined sorafenib and siRNA significantly reduces the IC50 compared to treatment with sorafenib alone, indicating improved drug effectiveness at lower concentrations. Future experiments will test the treatment across multiple HCC cell lines to determine consistency of the treatment in a variety of genetic environments.

Abstract Name: Hematological and Cytokine Changes in a Rat Model of Spinal Cord Injury Post-Sepsis Survival

Spinal cord injury, also known as SCI, is a serious condition that leads to paralysis of both motor and sensory parts of the body. As time goes on, SCI will impact one's quality of life, as well as a decreased life span. Systemic infections, more commonly known as sepsis, is an infectious dysregulated inflammatory response, potentially leading to organ failure, tissue damage, and in severe cases, death. Populations of SCI had worsened symptoms due to a primary complication of sepsis, increasing the mortality rate. However, there is no experimental model studying the complications of post-sepsis spinal cord injury, which is what this study is aimed towards. Rats were divided into four experimental groups: sham, SCI, sepsis, SCI+sepsis. Spinal cord was contused at the T10 spinal level at 200 kDyn using an Infinite Horizon (IH) Impactor. At 15 minutes post-injury, sepsis was induced through injection of 3ml cecal slurry (i.p.). Animals were properly monitored, treated with antibiotics and resuscitated with fluids starting at 8 hours post-SCI/post-sepsis, continuing twice daily for the next five days. CBC analysis revealed a decrease in red and white blood cell counts, along with reduced hemoglobin levels, indicating impaired oxygen-carrying capacity following SCI, Sepsis, and SCI+Sepsis in a time-dependent manner, with a more pronounced effect in the SCI+Sepsis group. These findings align with increased inflammation observed in cytokine analysis of serum samples, which showed elevated levels of IL-6 and TNF- α . A detailed analysis of differential blood parameters is ongoing.

Abstract Name: Lost in Translation: The Hidden Gaps in ACS Data

Researchers frequently rely on the American Community Survey to study how the Affordable Care Act shaped health insurance coverage, particularly through Medicaid expansion, yet recent work shows that respondents do not always report their Medicaid coverage accurately and sometimes skip the question entirely. These gaps matter because missing or inconsistent data can distort estimates of coverage changes after major policy reforms. Despite extensive research on the ACA, no study has examined whether Medicaid expansion itself influenced missing Medicaid coverage data in the ACS. This project addresses that gap by asking how Medicaid expansion affected the likelihood that respondents left the Medicaid coverage question unanswered. Using ACS microdata from 2011 to 2018, I begin with descriptive visualizations comparing missingness trends in expansion and non-expansion states and then assess how missingness varies across groups defined by employment status, race and ethnicity, and citizenship. I then employ a difference-in-differences approach to estimate the causal effect of Medicaid expansion on missingness, taking advantage of variation in when states adopted the policy. Preliminary results show clear and consistent differences after 2014: missingness rises more sharply in expansion states, particularly among unemployed adults, individuals not in the labor force, and several Hispanic subgroups. These patterns suggest that Medicaid expansion may have changed how respondents interpreted or reported their coverage as eligibility rules and enrollment processes shifted. The findings point to an important but understudied consequence of major health policy reforms: they may reshape not only who becomes insured but also the quality of the survey data used to measure those outcomes.

Abstract Name: Synthesis of α -Substituted β -Nitroalkene Scaffolds for Use in Organocatalyzed Reactions

Chiral α - and β -amino acids and esters are widely found in nature and in pharmacological or biologically relevant molecules. Due to their importance, versatile and efficient syntheses of these chiral building blocks are of great interest in the pharmaceutical industry. Squaramide organocatalysts are alternatives to metal catalysts that can catalyze a wide range of reactions by taking advantage of noncovalent interactions to activate one or both substrates stereoselectively. We previously developed an enantioselective organocatalyzed reaction of masked acyl cyanides (MAC) to β -nitrostyrenes as a complementary method towards the synthesis of chiral β -amino acids and esters. Based on the high yields and high enantioselectivity of the prior reaction, we propose to extend this chemistry to α -substituted β -nitrostyrenes to probe the diastereoselectivity. Preliminary investigation using MAC addition to a cyclic α,β -nitrostyrene substrate favored one major diastereomer. We propose to study the applicability of this reaction through the synthesis of various cyclic and substituted nitroalkenes as scaffolds. These include the nitration of alkenes such as

cyclohexene, benzofuran, indene, 1,5-cyclooctadiene, norbornene, annulene, and 1,4-dihydronaphthalene. The future work will be to explore the conjugate addition of MAC to these scaffolds as a route to access chiral amino acids.

Abstract Name: Postpartum Mental Health and Wellness in African American Women

Postpartum mental health conditions (such as postpartum depression) affect up to 15 % of mothers. Rates in the United States are higher for African American women. Additionally, African American women are less likely to be screened for symptoms, less likely to have their symptoms identified even when they do complete a screening and therefore are less likely to receive care. This literature review and annotated bibliography focuses on postpartum mental health and specifically hones in on how it affects African American Women with the goal of exploring out what was causing that gap in the statistics, and to figure out how it could possibly be addressed in the future to impact positive change in these outcomes. The most important key findings of this research experience highlighted three themes that may contribute to these high rates and gaps in the statistics: historical trauma, superwoman phenomenon, and representation and shared identity. I plan to continue to further this research with Dr. Sara Moyer through the Spring 2026 semester putting to use training in qualitative research methods. After that, I plan to attend graduate school to become a Women's Health Nurse Practitioner and elaborate even further on this research in the role of a Women's Health Nurse Practitioner caring for postpartum women.

Abstract Name: How Lollard Theology Challenged the Church's Community in Early 15th-Century England

In this paper I will explore how Lollard theology, in the 15th century, challenged how the everyday person was expected to engage with their local community according to the standards defined by the medieval English church. Specifically, I will answer this question: how did Lollard theology create an alternative way of thinking about community in medieval England, and particularly in the Diocese of Norwich? The Lollards set themselves apart from societal normality with their radical (and therefore heretical) views resulting in some of their members facing an inquisition c. 1428-1431 held in the Diocese of Norwich; thus, providing documentation of particular theological views that they held. This paper will include the views and writings of John Wyclif, but not in exclusivity; therefore, expanding the scope to include the Lollard peoples once they had the opportunity to standardize their theology. Through this research, I show that the Lollards were able to challenge the community framework that the Church had established through their own theology. Through a comparative analysis of church court records, Lollard sermons, and key Lollard theological tracts, I will demonstrate core Lollard beliefs and the impact that they had on their community life. By concentrating on how the Lollards' views on the Church's sacraments differed with respect to their impact on community routines, I show how the Lollards' actions shaped behavior around baptism, marriage, and the annual cycle of

lent, confession, and participation in the Eucharist. In addition, I demonstrate how the Lollards' ideas of priesthood challenged the Church's sense of the community hierarchy, which they (the Lollards) deemed too worldly and too focused on ostentatious ceremony and earthly concerns.

Abstract Name: Integrating Social Determinants of Health in Undergraduate Medical Education: A Systematic Review of Teaching Approaches

Social determinants of health (SDOH) “are the conditions in which babies are born, grow, live, work, and age – including the wider set of forces and systems shaping the conditions of daily life,” as defined by the World Health Organization (WHO). These determinants have the greatest impact on a patient’s health and are responsible for most population-wide disparities in health, but undergraduate medical education has been slow to integrate these SDOH into its curriculum. This systematic review of the literature adhered to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 criteria while searching for successful teaching strategies that prepare medical students to address SDOH in patient care. A thorough search of the scientific databases PubMed and Scopus was carried out, resulting in 1,049 records. Out of the peer-reviewed publications within the last 15 years on medical students, with quantifiable outcomes related to SDOH and that met inclusion criteria ($n = 10$), all were included in the final synthesis. From this analysis, four teaching approaches are emphasized: experiential learning, longitudinal integration, interprofessional and reflective practice, and institutional capacity and faculty development. Data showed that multi-year, hands-on programs truly helped students build empathy, systems thinking, and advocacy skills. However, most medical schools still rely heavily on short, lecture-style SDOH teaching, despite its clear limitations. National survey data from Lewis et al. and Campbell et al. support that SDOH instruction continues to be predominantly lecture-based, variably integrated, and inconsistently evaluated throughout medical education. These results emphasize that ongoing, reflective, and institutionally sustained frameworks are necessary to adequately equip future physicians with the tools needed to address SDOH and promote health equity in clinical settings.

Abstract Name: Nurse Sharks’ Captive Care: How Changes to the Care Plans of Nurse Sharks May Increase the Suitability of Captivity for Marine Life in Commercial Aquariums in the United States

Ginglymostoma cirratum (nurse sharks) are one of the most prominent species of elasmobranchs kept in captivity due to the general notion that they are lower maintenance and more suitable for a captive environment. Given the diminishment of the natural habitat for many elasmobranch species, the research on sharks in captivity has become imperative to the understanding of their physiological make-up as well as the functions of their biological systems. This comprehensive review analyzes peer reviewed sources on the reproductive, dietary, and movement habits of nurse sharks in captivity and how it reveals aspects of their

physical and cognitive health. The health of species in captivity is important to be able to maintain them safely and with as much accuracy to their natural habitat as possible, in order to ultimately gather accurate data on their habits and their inhibitions to proper flourishing. This detailed analysis displays that more research is being conducted on the reproductive capabilities of sharks in captivity and how their diet and movement affects their ability to execute their natural physiological functions. This data may be able to exhibit how to properly feed sharks in captivity as well as what to feed them in order to optimize their livelihood and capabilities. These studies are additionally collecting data on more abstract ideas of care in captivity including sense stimulation and habitat construction that are new concepts within this field of study that could potentially further our understanding of the needs of an imperative but under-researched population. This thorough review studies the research on nurse sharks and other small, benthic sharks in captivity and develops a construct of how animal care experts could include new and different methods of care in order to best study and care for the sharks in their institutions.

Abstract Name: Milk Teeth (A Vignette Collection on Loss & Coming of Age)

The loss of milk teeth, otherwise known as baby teeth, is often associated with a transition from childhood to adolescence. Milk Teeth is a coming of age text centered on the reflections of a young Jamaican girl, Ciara, as she traverses childhood and adolescence. Milk Teeth serves to creatively highlight social issues impacting the lives of children within the Caribbean, particularly in Jamaica. The work explores prominent Black and Global Studies themes such as family dynamics, loss, identity, socioeconomic disparities and migration. A vignette (short literary passage) structure is utilized to encourage the reader to analyze the narrator's personal experiences and draw parallels between said experiences and broader ones within the Afro-Caribbean context. Vignettes in Milk Teeth are interrelated, with each one consisting of unique memories and observations, through which the main themes are reflected.

Abstract Name: Integrating Case-Based Learning into NMR Instruction with Real Antibiotic Examples

Rising antibiotic resistance underscores the urgent need to develop therapeutics effective against drug-resistant bacteria. Antibiotic misuse-particularly in low- and middle-income countries has accelerated the spread of antimicrobial resistance (AMR), rendering many once-manageable infections increasingly difficult to treat. Lolamicin, a recently developed Gram-negative antibiotic, exhibits potent activity against more than 130 multidrug-resistant clinical strains. Its pyridinepyrazole and pyridineimidazole scaffold, along with its unique mechanism of action, contribute to its selective activity and make it a compelling example for students learning how chemical structure relates to biological function. Following the discovery and synthesis of antibiotics like lolamicin, chromatography and spectroscopy techniques are essential for confirming structure

and purity. Although undergraduates are typically introduced to NMR as a tool for identifying unknown structures, they often lack exposure to the real-world examples used in the pharmaceutical industry. To address this gap, we developed a case-based learning activity designed to help students connect foundational NMR spectroscopy concepts to drug characterization encountered in research. In this case study, students use a benchtop NMR to collect and interpret spectra of lolamicin and levofloxacin, identifying functional groups, splitting patterns, integration values, and chemical shifts. The activity encourages students to apply chemical reasoning, compare structural features of two clinically relevant antibiotics, and explore how structural differences relate to mechanism and activity. In addition, the case study aims to strengthen students' understanding of antibiotic misuse and AMR, reinforce core NMR concepts, and highlight the interdisciplinary nature of drug discovery at the chemical biology interface. By analyzing spectra of both drugs, students determine key structural features and gain hands-on experience with techniques routinely used in modern pharmaceutical research, equipping them with skills that support undergraduate research and strengthen their overall career readiness in scientific and biomedical fields.

Abstract Name: Analyzing the Proteolytic Activity of the SPRTN-Nudix Domain

DNA-protein crosslinks (DPCs) is a common form of DNA lesions, which proteins covalently crosslink to DNA due to exogenous factors such as radiation or a chemotherapy drug, or as a by-product during DNA metabolism. Removal of DPCs is essential for cell survival as the blockages caused by DPCs can interrupt DNA activities such as replication and gene expression. SprT-like N-terminal domain or SPRTN (also known as Spartan or DVC-1) is a mammalian metalloprotease that selectively targets DPCs. Mutations in SPRTN are often deadly, leading to diseases such as Ruijs-Aalfs, a rare condition that causes early aging and hepatocellular carcinoma. Despite the critical role of SPRTN in cells, the regulatory mechanism that enables SPRTN to specifically target DPCs remains to be further studied. SPRTN has been found to contain a NUDIX Homology Domain (NHD) that is structurally related to the NUDIX motif but lacks ADP-ribose hydrolase activity. In this study, we examine the 4 specific amino acid sites within the NHD domain on poly-ADP-ribose (PAR) cleavage and its proteolytic activity on DPC removal. To study this, we aim to 1) introduce point mutations within the NUDIX domain via site-directed mutagenesis, 2) optimize expression and purification of the recombinant SPRTN wild-type, NUDIX, and four NUDIX mutants in E.coli, 3) conduct in vitro PAR degradation assays to examine the impact of the NUDIX mutant on PAR degradation compared to the NUDIX, and wild-type. Overall, this project provides insight on the biochemical mechanisms of SPRTN, potentially leading to new opportunities for researchers in the field and potentially life-saving treatments and technologies to be developed.

Abstract Name: Tibor Kalman: Hazard or Hero?

Tibor Kalman was celebrated as the “bad boy” of graphic design, with his striking, activism-driven works that set him apart as an influential designer, as well as a leader in activist movements against corrupt actions in the corporate world. This paper explores his journey, from his beginnings as a Hungarian immigrant, through his rise to the top through his very own magazines, M&Co. and Colors. The paper also explores how Kalman broke away from traditional design principles, taking a more radical approach for global awareness and critique of what he stood against, even going as far as rejecting unethical clients and directly confronting consumerist values and ideas. Tibor’s commitment to criticizing unethical and corrupt business practices earned him respect from fellow designers and activists alike, who admired how he used his work as a means for change. However, Kalman’s actions also caused him to be seen as a threat in the eyes of the companies he criticized, as their reputations relied on how the public saw them. This paper demonstrates Kalman’s design practices and how it worked as both activism and provocation of corporate entities, and ultimately argues that these practices are where Tibor Kalman’s legacy lies.

Abstract Name: Evolution and Conservation of Ice Crawlers

Ice crawlers are a rare group of cold specialized insects that inhabit montane areas, caves, lava tubes and canyons. These areas are typically characteristic of colder regions, which makes these environments and ice crawlers particularly vulnerable to past and present climate change. The goal of this proposal is to understand how climate change has historically affected the genetic differentiation of the ice-crawlers in the family Grylloblattidae through population genetics. Historical glacial periods have been hypothesized to have a significant effect on the biodiversity of ice crawler populations and contributed to present day levels of genetic diversity. Glacial expansion resulted in ice crawlers dispersing to higher altitudes. Due to their low vagility, isolation was prominent and is what likely resulted in the biological diversity of current Grylloblattidae populations. This study focuses on reconstructing responses of ice crawlers to glacial cycles in the vicinity of the southern Cascades Range. Samples will go through a reduced representation genome sequencing process to measure variation, estimate relationships and reconstruct demographic changes. The results will be correlated with glaciation events to understand the effects of past changes in climate on genetic diversity among ice-crawler populations. If speciation in phylogeny aligns with historical glacial cycles with low levels of efficient dispersal, then it can be concluded that glaciations impacted the diversification of Grylloblattidae populations. Understanding historical climate effects can provide insight into ice crawler genomics and would help to make predictions about the impact of future climate changes.

Abstract Name: Evaluating Machine Learning Approaches for Safer and More Reliable Autonomous Driving

Machine learning and deep learning have now become central in how an autonomous vehicle views the road, makes decisions, and communicates with other cars and infrastructure. Recent work has demonstrated strong progress in areas such as lane detection, object detection, trajectory prediction, traffic forecasting, and vehicle-to-vehicle communication, using models such as U-Net, YOLO, and CNN-based lane detectors, Deep Q-Learning, CNN-LSTM traffic models, and Random Forest-based security frameworks. When looking more closely across these studies, a number of consistent gaps appear. First, most of the models are trained on narrow datasets from specific cities, highways, or weather conditions, which makes it difficult to trust their performance on unstructured roads, developing regions, or under adverse environments, including heavy rain, fog, or night driving. Many studies focus on accuracy scores but give limited evidence of how the models perform in real time on vehicle hardware, how they cope with sensor faults, or how they respond to corrupted or malicious data. Perception, planning, connectivity, and security are also often treated as separate rather than as parts of one system that needs to work together in real time. To address these issues, this project examines a wide range of recent research and compares how different approaches tackle perception, control, communication, and safety. The aim is not only to summarize what the field has achieved but also to clarify where current methods fall short when applied outside controlled datasets and simulation environments. This project reviews recent research across these areas, identifies common limitations, and outlines directions for more generalizable, multi-sensor, and security-aware models that respect real-time constraints. The goal is to highlight what is missing today and what is needed next for safer and more reliable autonomous driving.

Abstract Name: Optimizing Health Insurance Costs through Quantitative Data Analysis for a Nonprofit Organization

Identifying and understanding the underlying factors that drive rising health insurance costs is essential for effective cost management, particularly within the nonprofit sector. Many nonprofit organizations lack the capacity to conduct in-depth analyses of health insurance claims data, which can hinder their ability to make informed decisions. This research, conducted collaboratively within a data analytics team, sought to determine the most significant cost drivers within a comprehensive insurance cost claims dataset through a structured process of data cleaning, data mining, and cost driver assessment. The analysis began with an extensive data cleaning phase to remove duplicate entries and claims containing missing or inconsistent values. Addressing these inaccuracies was critical, as such discrepancies could distort mean cost estimates, trend analyses, and subsequent interpretations. After establishing a reliable dataset, data mining techniques were applied using both Excel and RStudio to perform exploratory data analysis from multiple perspectives. Data mining served as a foundational step in uncovering hidden patterns, relationships, and anomalies that could suggest potential cost drivers. To further refine these insights, regression tree modeling—a recursively partitioning statistical method—was employed to identify and visualize the key variables most strongly associated with insurance claim costs. This model provided a clear structure of influential factors, enabling a deeper understanding of how specific variables interact to shape overall cost trends. The combined approach of data cleaning, exploratory data mining, and recursive partitioning produced data-driven insights highlighting the primary contributors to the nonprofit's health insurance expenditures. By integrating these

findings into strategic decision-making, nonprofit organizations can more effectively allocate resources, negotiate insurance plans, and enhance long-term financial sustainability.

Abstract Name: Improving Confidence and Self-Efficacy with the Unsung Creatives Project

This research investigates if completing and sharing creative work publicly can improve confidence and self-efficacy. Research was conducted through a literature review and a quantitative and qualitative study on the Unsung Creatives Project (UCP) – an original eight-week participatory arts program (PAP) created by the researcher to coach participants in completing a creative project, culminating with them sharing their work at a public showcase. Existing research on the relationship between sharing creative work and confidence and self-efficacy was limited, but did show that effectively designed PAPs and group coaching programs with an emphasis on creativity can improve confidence in participants. Further research into strategies to improve confidence and self-efficacy correlated with the qualities of effective PAPs and were integrated into the design of the UCP curriculum, which aimed to support participants in improving their confidence and self-efficacy through the creative process. The UCP strategies included cultivating a supportive group atmosphere, targeting “inner critic” thoughts with self-compassion and mental reframing, strengthening participants' relationships to their creative instincts as a way to build trust and belief in themselves, project management techniques, and more. The seven participants were given quantitative and qualitative surveys during weeks one, five, and eight to track their progress. Observational field notes were taken after each meeting to further record efficacy. The quantitative and qualitative data showed significant improvements in participants' confidence (+45%), self-efficacy (+28%), self-compassion (+43%), relationship to creativity (+63%), and mental well-being (+72%), and a significant decrease in self-doubt (-24%). The results of this study suggest that completing a creative project and sharing it publicly can improve confidence and self-efficacy, with additional transformative changes that support quality of life beyond the creative work. The quantitative findings will be presented alongside excerpts from the curriculum and film clips, participant quotes, and photos from the showcase.

Abstract Name: Family Engagement for Culturally Diverse Families in Special Education

Family engagement is a critical factor in supporting students with disabilities during the transition from high school to adult life. However, families from culturally and linguistically diverse (CDL) backgrounds often face barriers that make it difficult to stay involved during this process. This research answers the question “How can teachers’ improve family engagement with parents of students with special needs from multicultural backgrounds when transitioning from post-secondary school?” by exploring how educators and parents in New Bedford Public Schools (NBPS) experience family engagement during secondary transitions and how it might be improved. Fifteen educator interviews and fourteen parent interviews were conducted,

alongside surveys of post-school outcomes for students exiting special education. Interviews were transcribed, coded, and analyzed for themes. Results showed that both groups identified barriers such as language differences, communication that often only focused on problems, lack of training for educators, and time constraints. Parents also reported feeling unclear about their role in engagement. Both groups emphasized the need for more consistent, positive, and culturally responsive communication. Based on these results, a five-factor Family Engagement Model was developed: (1) Culturally & Linguistically Responsive Communication, (2) Balanced Communication Practices, (3) Shared School-Wide Responsibility, (4) Family Education & Empowerment, and (5) Student-Centered Engagement. This model provides realistic strategies to strengthen collaboration between schools and families, ensuring transition planning is more inclusive, empowering, and effective.

Abstract Name: Zodiac, Knights, and Miss Gay America: Discovering Queer History in the Coastal South

This research project examines the historical significance and cultural impact of House of Camelot, a Norfolk, Virginia based drag organization active from 1974 through the late 1990s and foregrounds the challenges of researching understudied queer histories. Although House of Camelot played a pivotal role in shaping the region's queer social landscape, it has received minimal scholarly attention, reflecting a pattern in which local queer communities, particularly outside major metropolitan areas and in the South, remain under documented. Consequently, this project reconstructs the story of House of Camelot and positions the research process as a case study in recovering local queer pasts. Methodologically, the project draws on community-based archives that recognize the fragmentary nature of queer material culture. Primary sources include Our Own Community Press, Norfolk's gay newspaper that publicized House of Camelot events, as well as surviving flyers, correspondence, photographs, and audiovisual materials from personal collections and informal archives. Since much of the group's documentation has been dispersed, damaged, or never formally preserved, the project relies on close reading of event descriptions such as the Miss Zodiac Pageant, benefit gong shows, and the Miss Gay USA pageant, to piece together the organization's cultural presence. This approach highlights both the limitations and the unique interpretive opportunities in researching marginalized histories whose traces persist in community memory and transient media. Preliminary findings indicate that House of Camelot functioned as a vital hub for creative expression, mutual support, and queer visibility during a period of intense social stigma. By documenting these histories, the project demonstrates that recovering local queer archives not only preserves overlooked narratives but also reshapes broader understandings of drag culture and queer community formation in the late twentieth century. Ultimately, this study underscores the importance of locally grounded research in illuminating the interconnected, community-centered nature of queer cultural production.

Abstract Name: Creating an Affordable Bioreactor to Expand Access to Cell-Based Treatments and Biomanufactured Medicines

This project aims to design and construct a low-cost, small-scale bioreactor using engineering components, including an Arduino control system and a culture vessel. Bioreactors are essential tools in biotechnology for growing cells, yeast, and bacteria for purposes such as creating enzymes or vaccines. Commercial systems are usually too expensive for students, early-stage researchers, and community laboratories. This project addresses that gap by developing an affordable yet efficient reactor that maintains sterility, provides controlled air flow, and enables monitoring of conditions necessary for cell growth. The overarching objective of this project is to streamline a process for creating transportable bioreactors that can be outfitted for different purposes. Although the initial prototype focuses on organisms like yeast and chlorella, the same framework can be applied to support other cell types grown, such as mammal cells used in manufacturing antibodies, insect cells used for producing vaccines, or engineered bacteria used for producing therapeutic proteins. Developing a reproducible, affordable system for growing and harvesting diverse cell systems contributes to a plethora of goals in biotechnology accessibility. Specifically, simplified bioreactor designs have the potential to reduce the barrier to producing materials like viral vectors, weak viruses used to deliver therapeutic genes in a harmless manner, and recombinant proteins, which are useful proteins made by genetically modified cells. This can make gene therapy research and training more attainable for smaller institutions. The methodology includes iterative prototyping, performance testing, and comparison of oxygen-transfer efficiency between bubble-column and airlift configurations. Expected results include demonstrating that a reactor, with a budget of \$500, can reliably sustain microbial cultures, achieve meaningful mixing, and support applications such as biomass production, wastewater nutrient removal, and preliminary biomedical research. This work will be presented in the context of expanding accessibility in biotechnology education and creating flexible tools for future bioengineering applications.

Abstract Name: Glutamate Receptor Modulation by Polysialic Acid in Hippocampal Synaptic Plasticity and Cognitive Function

Glutamate receptors, including the α -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA) and N-methyl-D-aspartate (NMDA), are essential mediators of excitatory neurotransmission and underlie synaptic plasticity, the fundamental cellular process that supports learning and memory. AMPA receptors generate rapid synaptic responses, whereas NMDA receptors serve as key modulators of activity-dependent synaptic strengthening. The neural cell adhesion molecule (NCAM), a transmembrane glycoprotein involved in neurite outgrowth, cell migration, and synapse formation, acquires enhanced functional capabilities when modified by polysialic acid (PSA), a negatively charged carbohydrate polymer. Although previous studies suggest a role for PSA in glutamatergic neurotransmission, its precise contribution to hippocampal long-term potentiation (LTP) and long-term depression (LTD) remains insufficiently defined. Methods: This investigation assessed the concentration-dependent impact of PSA on hippocampal synaptic plasticity. Field Electrophysiological analyses were performed to determine the effects of PSA on LTP and LTD induction, and single-channel recordings were used to quantify changes in synaptic AMPA receptor-channel function. Results: Our data demonstrate that PSA significantly enhanced LTP and decreased LTD. These effects were associated with a dose-dependent increase in the probability of synaptic AMPA receptor-channel function,

indicating a critical role for PSA in modulating synaptic strength. Conclusion: These findings position PSA as a key regulator of neuronal plasticity and highlight its potential as a novel therapeutic for enhancing cognitive function. By elucidating the molecular mechanisms that support learning and memory, this work underscores PSA's promise for treating cognitive impairments and other disorders characterized by synaptic dysfunction.

Abstract Name: The Ethical Dilemma of AI Sex Bots and Artificial Intimacy on Interpersonal and Human Relationships

Artificial Intelligence is one of the most controversial topics of the last several years, and those who defend it plead that AI isn't going anywhere or that it's simply a helpful tool for tedious tasks. But what happens when that "helpful tool" turns into a replacement for physical and emotional intimacy? With the rise of more sophisticated AI tools created by companies like Realbotix, AI is no longer just a software that creates outlines and solves equations— it can serve as an interactive, customizable sex robot. In the last 10-15 years, AI algorithms have been combined with life-sized sex dolls to create interactive AI "sex bots." Through an analysis of the history of sex dolls, the current state of more evolved sex dolls, and the algorithms used in AI sex bots, I examine whether these technologies pose a threat to human intimacy and the other ethical issues that arise within the domain. Additionally, I look at the underlying ideologies that current sex devices elicit about gender roles and the fetishization of underage women. My research consists of a literature review of several texts, including *The Desirable Body: Cultural Fetishism and the Erotics of Consumption* by Jon Stratton, *AI Love You* by Yuefang Zhou and Martin H. Fischer, and an examination of user reviews for AI sex bots. I also reference a study titled "Are We Ready for Sex Robots?" conducted by researchers in the Human-Robot Interaction Laboratory at Tufts University. Through the desirable traits that are embedded in the algorithms of AI sex bots, I also dissect the concept of whether pedophilia is subliminally encouraged by the intense customization of a manufactured sexual partner. With the historical context of sexual devices and the future of AI, it is crucial to understand the threats it may pose to our interpersonal relationships.

Abstract Name: Rapid Screening of Dirhodium Complexes for Biomolecule Binding

One important and interesting chemical property of transition metal complexes is their ability to bind biological molecules and affect the growth of cells. Cisplatin, a simple transition metal complex with a platinum ion at its center, is a widely used anti-tumor drug that is known to bind to DNA as part of its mechanism of action. Cisplatin, however, is not effective against all cancers and has some severe side effects. In an effort to identify new transition metal complexes that can affect cancer cell growth, this work focuses on complexes with rhodium atoms at their core which have potential for anti-tumor activity. To screen multiple metal complexes for their ability to interact with biomolecules, we have streamlined a method to measure the interactions of rhodium complexes with either double-stranded DNA or the serum albumin protein. Reactions were monitored in 1 mM sodium phosphate buffer, pH 6.8, with 3.0 mM NaCl, in the dark at 37° C. Filtering devices were used to separate a portion of each reaction, allowing the small transition

metal complexes to filter through but retaining the much larger biomolecules. The volume of reaction that was allowed to filter through the devices was at or below 10% of the total portion volume, such that the concentration of the reaction was not significantly affected by the filtration. The concentration of rhodium metal in retentate (top) and filtrate (bottom) layers was measured using an atomic absorbance spectrometer (AAS), and differences in these concentrations indicate rhodium interaction with the biomolecule. The expected result is that some transition metal complexes may bind to the biological molecules within the first 24 hours of reaction, perhaps indicating potential for better antitumor activity and leading to more rapid identification of promising cancer cell killing compounds.

Abstract Name: Influence of Domain-Specific Working Memory Load on Temporal Error Monitoring Abilities

Error monitoring involves the ability to keep track of one's own errors without receiving external feedback. This ability is often investigated within perceptual decision-making tasks where performance takes binary correct/incorrect forms. Recent studies demonstrated that error monitoring ability can be observed in metric domains capturing temporal, spatial, and numerosity errors, where errors have both a magnitude and direction with respect to a target. Albeit distinct from perceptual decision-making, error monitoring abilities are correlated across these metric domains, suggesting a domain-general mechanism consistent with A Theory of Magnitude (ATOM). Previous findings demonstrated that increased WM load in a dual-task paradigm, where the secondary task involved mental alphabetization, impaired error monitoring in a perceptual decision-making task. However, this effect did not extend to temporal error monitoring (TEM). This result may be due to domain-specific WM load effects, where the mental alphabetization task may not have engaged the metric characteristics required for a diminishment in TEM abilities. We investigated this possibility in two separate dual-task experiments. In both experiments, participants performed temporal reproduction as the primary task, where they evaluated their own performance in terms of magnitude and direction relative to a target duration on a trial-by-trial basis. Depending on the experiment, the secondary task involved alphabetization of a letter sequence (mental alphabetization, Experiment 1) or calculating numerical equations (mental arithmetics, Experiment 2). Experiment 1 showed that magnitude monitoring ability depends on the WM accuracy, where the secondary task was alphabetization. However, this effect did not apply to other WM load indices, including the number of letters or sorting difficulty. Interestingly, this diminishment was not observed in Experiment 2, where metric characteristics of WM load matched TEM. Together, these results indicate that the sensitivity of TEM to WM depends on relative load indices that selectively capture magnitude monitoring.

Abstract Name: Capacity Coaching and Its Effect on Patients with End-Stage Kidney Disease

Patients with end-stage kidney disease (ESKD) undergoing dialysis face substantial treatment burden, major life disruptions, and emotional distress. Capacity Coaching is a supportive intervention that helps patients build the abilities needed to adapt, endure, and function well alongside illness and demanding treatments. We hypothesized that patients with ESKD who completed at least three Capacity Coaching sessions would experience reduced treatment burden and less anxiety/depression compared with those completing fewer sessions. We conducted a pilot randomized controlled trial with 33 adults receiving in-center or home dialysis, randomized to Capacity Coaching or usual care. The intervention was considered complete when participants attended at least three coaching sessions. Participants were followed for six months, with treatment burden, anxiety, and depression assessed at baseline and every three months. No statistically significant differences were observed between groups for treatment burden, anxiety, or depression. However, a downward trend in treatment burden was noted in the intervention group compared with controls. As a pilot study, the limited sample size prevented a full assessment of efficacy, and a larger, adequately powered trial is planned. This study demonstrates the feasibility of integrating Capacity Coaching into dialysis care, even within a highly complex clinical population. Future research with larger samples, longer follow-up, and standardized post-intervention protocols is needed to determine whether Capacity Coaching can meaningfully reduce treatment burden and improve emotional well-being among patients living with ESKD.

Abstract Name: Early Maladaptive Schema (EMS) Formation in Transgender Women: A Diathesis-Stress Application

This study proposes an application of the diathesis-stress model to examine early maladaptive schema (EMS) formation in transgender women to elucidate psychopathological precursors in queer populations. Though researchers frequently explore EMSs' ability to predict various psychological disorders, few studies utilize a diathesis-stress lens to examine EMS development. The diathesis-stress model is chosen to achieve a baseline understanding of both preexisting vulnerabilities (diatheses) and environmental variables (stressors) responsible for EMS formation in transgender women. Following a semi-meta-analytic review of EMS literature, several thematic areas are identified then categorized as either diatheses or stressors. The analysis classifies personality traits of neuroticism, low agreeableness, negative affectivity, psychoticism, and detachment as diatheses alongside the stressors of interpersonal problems, abuse, trauma, depressive symptoms, and minority stress. Scholarly findings based on Hankin & Abramson's (2001) cognitive vulnerability-transactional stress theory are also employed to highlight the bidirectional relationships between EMSs, depressive stressors, and depressive symptoms. Lastly, Ilan H. Meyer's (1995) minority stress theory is applied to contextualize the model within queer and minority-focused literature. Overall, the aforementioned stressors identified by the study are numerous and varied while only select personality traits are identified as diatheses. This finding suggests the formation of EMSs in transgender women may be tied to a wider variety of environmental variables, though it should not be assumed a larger number of stressors equates to greater predictive validity. Further research should include an evaluation of resilience factors in EMS formation, potentially utilizing diathesis-stress expansive models, to further inform schema therapy interventions.

Abstract Name: Preventing Green Gentrification in Frederick County: Policy Strategies for Equitable Urban Greening

Minority communities have historically been excluded from green amenities, prompting the movement of environmental justice by expanding access to green space and environmentally sustainable infrastructure. However, green space creates a green gap in which developers can capture increased rent, displace long-term residents, and lead to gentrification, excluding the very people these projects were aimed to include. Therefore, it is important that policymakers are conscious in their decisions to not only improve environmental justice through increased accessibility but also to mitigate and prevent the effects of green gentrification in plans and policies. This project examines Frederick County as a case study, which has a strong initiative to improve environmental justice through new and renovated parks, sustainable buildings, and other green amenities. However, nothing is being done to prevent the gentrification that may come from this. By reviewing past literature on green gentrification in combination with Frederick County's plans and policies, this study identifies opportunities to improve environmental equity through conscious urban planning. It argues that meaningful community engagement, implementing anti-displacement policies, and coalitions among nonprofits, the municipality, and private stakeholders are vital to ensuring that greening efforts reach all residents of Frederick County. This work calls for deliberate decisions to be made surrounding urban greening in Frederick County to create a more socially and environmentally sustainable county.

Abstract Name: Enhancing pharmacy student skills through AI-driven patient counseling simulations

AI chatbots can be trained on a variety of user-provided materials for specific interactions across a range of settings. The goal of this project is to develop and assess an AI-based chatbot designed to support pharmacy students in building essential patient counseling skills within the three-year Dispensing and Patient Care (DPC) course series. The pilot text-based chatbot will initially be created for third-year (P3) students in PHA 489 Dispensing and Patient Care III to simulate a realistic patient interaction and provide objective feedback based on the course patient counseling rubric to help students improve communication skills and patient counseling proficiency. Data collection will include chatbot session transcripts, rubric scores, and self-assessment surveys, and will be compared across all pharmacy pathways (Omaha, Distance, and Phoenix). Results will inform the potential expansion of chatbot-based practice opportunities across all levels of the DPC course series. Expected outcomes include increased student confidence in patient counseling, greater readiness for fourth-year experiential rotations, and potentially a broader adoption of AI tools in the pharmacy program.

Abstract Name: Do Freshwater Turtles Stabilize Maryland Wetlands?

Given the dire situation of turtles - over 60% of species are either threatened or recently extinct – it is vital that we understand their impacts to ecosystem functioning and advocate for increased protections. Omnivorous, freshwater turtles can reach high densities and biomass/hectare (among the highest ever recorded for vertebrates) and therefore, may be particularly impactful to their wetlands, pond, and lake food webs around the world. Here, we posit that omnivorous turtles increase the stability of freshwater food webs through several mechanisms: 1) by subsidizing their diet with terrestrial foods, 2) by relying on both green and brown food webs within water bodies, and 3) by undergoing ontogenetic diet shifts and distributing predatory and herbivory pressure among many species. We test these predictions using a community of six turtle species captured in ponds and wetlands of Bowie State University and the nearby Patuxent Research Refuge in 2021-2025. Terrestrial food consumption was quantified using metabarcoding of eDNA and d34S in turtle claws, while participation in brown vs. green food webs was inferred from stable d13C. We used a regression of turtle claw d13C and d15N against straight carapace length to detail a potential shift in turtle diet with age. Overall, we found support for two of our three predictions. While we observed no evidence of ontogenetic diet shifts in three turtle species, we found that the most abundant turtle at our sites - painted turtles (*Chrysemys picta picta*) - frequently fed off both green and brown aquatic food webs as well as from terrestrial food webs. Overall, our study suggests that painted turtles have broad diets that likely increase stability of their food webs.

Abstract Name: Detecting Deepfakes Using Machine Learning: A Comprehensive Literature Review

Deepfake technology, which uses machine learning to synthesize and manipulate audio, video, and images, poses escalating threats to media authenticity, identity security, and public trust through political misinformation, financial fraud, and non-consensual synthetic media. As generative models evolve rapidly current detection systems frequently overfit to legacy benchmarks and fail under real world conditions, which in turn create a critical gap between laboratory performance and practical deployment. This literature review looks at how effective current machine learning approaches are for deepfake detection across different modalities and whether they can perform reliably in real world settings. We synthesized recent benchmark studies (2022-2025) examining machine learning approaches for deepfake detection across image, video, audio, and multi modal modalities. These include classic machine learning algorithms, deep learning

structures, specific detection approaches, and modern assessment methods. Key findings show that, while traditional machine learning has high interpretability and Vision Transformers excel at global feature capture, multimodal audio-visual fusion consistently outperforms single modality approaches, and specialized methods using biological signals perform exceptionally well in controlled settings. However, a critical gap emerges when models encounter modern deepfakes with diffusion artifacts, selective manipulations, and diverse linguistic content, with commercial detectors showing only marginal improvements over open source baselines and human listeners demonstrating unreliable detection abilities. This research concludes that achieving reliable real world deepfake detection requires substantial advancement beyond controlled laboratory settings toward strong, broad architectures and layered human-in-the-loop verification protocols that acknowledge the limitations of both automated systems and human judgment.

Abstract Name: Lost in Translation: Linguistic Barriers to Nagorno-Karabakh's Lasting Ceasefire

Stability of interstate agreements hinges not merely on geopolitics but also on language itself. While translations of such documents aim to bridge cultural barriers to a comprehensive understanding, translation itself can also serve as an impediment to agreement. This article seeks to better understand the role of translation in the stability of interstate treaties, specifically investigating how discrepancies between state-sanctioned and independent translations of the 2023 Nagorno-Karabakh ceasefire declaration challenge its interpretation and hence implementation. Following scholarly traditions in the lineage of Skopos and translation studies, the paper applies close reading and source analysis—comparing the Armenian and Azerbaijani translations against the original Russian document—and explores blind spots, biases, and linguistic limitations that may distort the peace process. The research on hand aims to bridge the gap between translation studies and the understudied Nagorno-Karabakh conflict. Current literature discusses the Russian language as a post-Soviet tool of subjugation, and this paper aims to expand that scholarship by presenting the Russian language, mediating the precarious Nagorno-Karabakh ceasefire, as an imperial one in the South Caucasus. This research ultimately concludes that the inability to adequately translate semantics directly from Russian to either Armenian or Azerbaijani results in a final text not entirely reflective of the original terms agreed upon by the parties. Furthermore, the article highlights that a translator's personal background and intended audience heavily impact the document's interpretation in translation, demonstrating how translation may be distorting the peace process between Armenia and Azerbaijan. "Lost in Translation: Linguistic Barriers to Nagorno-Karabakh's Lasting Ceasefire" has been recently published in the 22nd volume of Aleph, UCLA's Undergraduate Research Journal for the Humanities and Social Sciences.

Abstract Name: Machine Learning Analysis of Maternal Health Risk Factors

This Research uses machine learning to study maternal health risk factors and predict whether a pregnant woman is at risk of complications. The purpose of the study is to explore how clinical data can support early detection and better decision making in maternal health care. The dataset includes 1,015 records collected

from hospitals, community clinics, and maternal health centers in rural Bangladesh. It contains six clinical features age, systolic blood pressure, diastolic blood pressure, blood sugar, body temperature, and heart rate which were used as coding categories for model development. The study is guided by the research question: How can machine learning techniques be applied to maternal health data to accurately predict risk levels and support early intervention? This project connects to earlier research by Sheakh et al. (2023) and Efeoğlu (2023), who showed that machine learning models such as Random Forest, Decision Trees, and Adaboost can successfully identify risk patterns in maternal datasets. Their findings support the use of technology to help improve maternal health monitoring, especially in underserved rural areas. In this analysis, five models were tested: Logistic Regression, Decision Tree, KNN, Random Forest, and Gradient Boosting. The Random Forest model achieved the strongest performance, with an AUC of 0.945 and the highest precision recall score. Gradient Boosting also performed well. Confusion matrices showed that these two models produced the fewest misclassified cases. Feature importance analysis revealed that blood sugar was the most influential risk factor, followed by systolic blood pressure and age. The results show that machine learning can effectively identify high risk pregnancies using simple clinical measurements. These findings may help support the development of low-cost decision-support tools to improve early intervention and reduce maternal health complications in low resource communities.

Abstract Name: Physics-Informed Neural Networks To Estimate Soil Thermal Properties

Accurate estimation of soil thermal properties is critical for sizing ground heat exchangers in ground-source heat pump (GSHP) systems. At a Lexington, Virginia research site, temperature sensors were installed at multiple depths (surface to 10 meters) and logged at 15-minute intervals, yielding a detailed dataset of subsurface temperature dynamics. This study compares two approaches for inferring soil thermal properties from these data. The traditional method uses a one-dimensional heat equation model, where layer-specific thermal parameters are calibrated by minimizing the error between simulated and measured temperatures through sequential numerical optimization. While effective, this approach is computationally intensive and can struggle to uniquely identify all relevant parameters. In contrast, we implement a physics-informed neural network (PINN) that embeds the governing heat equation into the training process, allowing simultaneous estimation of specific heat capacity and thermal conductivity for each soil layer. The PINN leverages automatic differentiation and combines data-driven and physics-based losses to improve efficiency and enforce physical consistency. Our preliminary results indicate that the PINN can recover plausible layer-specific properties and temperature profiles. This work presents the PINN formulation, training strategy, and early comparisons with the benchmark numerical approach, with a focus on exploring the opportunities and potential of state-of-the-art AI for subsurface thermal characterization in GSHP applications.

Abstract Name: A Three-Year Study of Offline Digital Library Use in Lesotho Schools: Extending Behavior Change Theory From COM-B to COMBO

This study introduces COMBO: a practical framework for understanding how educational interventions create lasting change, particularly in low-resource settings where evidence of long-term impact is critical. COMBO expands upon the COM-B behavior change model by incorporating Outcomes to support post-implementation evaluation. While COM-B identifies Capability, Opportunity, and Motivation as drivers of Behavior, COMBO captures the resulting impacts of that behavior change. Over a three-year period, we applied this framework to a qualitative study of an offline digital library intervention in rural Lesotho. Drawing on 60 participant interviews, we found that changes in teacher behavior were enabled by increased digital and information literacy capabilities, supportive environments, and both reflective and automatic motivation. These shifts led to observable student outcomes, including academic gains, digital skill development, and increased engagement. As positive outcomes reinforced motivation, a feedback loop emerged, deepening and sustaining teacher behavior change.

Abstract Name: Improving Deep Tissue Imaging Through Dye-Enhanced Polarization Imaging

This project aimed to enhance deep tissue imaging through polarization imaging combined with absorbing dye molecules, like tartrazine, to enhance penetration depth. Current optical imaging methods, like Mueller Matrix Imaging, are affected by light scattering, which reduces imaging depth and resolution. By combining polarization imaging with dye, light scattering was reduced, which improved tissue transparency and increased the imaging penetration depth. The study used an experimental approach, using biological tissue samples, such as chicken breast or ex vivo mice tissue, treated with tartrazine and imaged using a polarization-sensitive camera system built in-house at 605 nm. We analysed the polarized-light data by breaking it into four parts: how much the tissue favored one polarization state (diattenuation), how much it shifted it (retardance), which way the fibres pointed (orientation) and how much the polarization was lost through the tissue (depolarization). Comparative analysis with other, more common imaging methods assessed how image quality improved tissue visibility. The biomedical significance of this research lies in its ability to enhance non-invasive medical imaging techniques used for diagnosing. By improving imaging depth and contrast, this approach was able to improve the diagnostic capabilities of different medical instrumentation, particularly in prenatal healthcare, which is explored through MPL's Portable Preterm Imaging System (PPRIM). The ability to assess cervical collagen networks and their integrity with greater accuracy facilitated the detection of pregnancy complications, leading to better maternal and infant health outcomes. If successful, this technique contributed to the broader field of biomedical and clinical diagnosing and enhanced medical diagnostics technology.

Abstract Name: Testing the Plant Vigor Hypothesis on Oak (*Quercus* spp.) and Heath (*Ericaceae*) Leaves in the Pinelands National Reserve, New Jersey

Fires are becoming more frequent and severe due to anthropogenic climate change. The Plant Vigor Hypothesis predicts that after fires, plants will invest more energy into growing rapidly, and subsequently, will invest less energy into their structural and chemical defenses making them more vulnerable to herbivore attack. Therefore, we predict that oak and heath leaves from our fire sites will (1) grow more rapidly and (2) have more insect herbivore damage compared to our unburned sites. We collected 20 oak (*Quercus* spp.) leaves and 20 heath (*Ericaceae*) leaves from wildfire, prescribed fire and unburned sites every week throughout the season between May to September in 2018, from the Pinelands National Reserve (PNR), New Jersey. We then measured the leaf area and counted various insect herbivore damage from each leaf to collect data to test our hypotheses. Next, we used a Generalized Additive Model (GAM) and a Generalized Linear Model (GLM) to test if the Plant Vigor Hypothesis will be supported from the PNR. In total, we collected 1,904 oak leaves and 1,902 heath leaves from our study sites. We found that the fires significantly affected the leaf growth rate, however, leaves from our fire sites were smaller than leaves from our unburned sites. Additionally, we found that there was significantly more insect herbivore damage on oak leaves, but there was significantly less insect herbivore damage on heath leaves. Therefore, our first hypothesis was rejected and our second hypothesis was supported for oaks and rejected for heaths. Our findings suggest that fires affect plant-insect interactions differently between taxonomic plant families and functional feeding groups of insects. Our current research is now testing the structural and chemical (tannin) defenses of our leaves.

Abstract Name: Development of Novel Small-Molecule Calcium Sensitizers for Cardiac Troponin C

Currently, congested heart failure is one of the leading causes of death globally. Even though it has a high mortality rate, current medicines are ineffective due to mobilizing the calcium in the system causing hypocalcemia and other side effects. Calcium sensitizers solve this problem through increasing the hearts sensitivity to calcium versus taking in more calcium into the system. Our research builds on the work of [1] where a possible small molecule calcium sensitizer was found to have a more effective calcium binding affinity of $1.45 \pm 0.09 \mu\text{M}$, which is the highest at the time of the study. Our objective was to synthesize a small molecule with a lower binding affinity. This was done by modifying the base small molecule and changing the functional groups. The current best small molecule synthesized has a calcium binding $\sim 0.5 \mu\text{M}$ which is 3-5 times more effective compared to the original small molecule that the new molecule is based on. If the small molecule is implemented in new medicine, it would make the current inotropes more effective in preventing heart failure in patients. However, continued synthesis of new compounds are needed to continue increasing the effectiveness of the calcium binding affinity.

Abstract Name: Earth's Epidermis & Ours: CFC-Driven Ozone Depletion & Its Health Implications in Northern Spain

Stratospheric ozone depletion driven by chlorofluorocarbon emissions has intensified the penetration of ultraviolet radiation at Earth's surface, generating growing public health concerns. This research analyzes how heightened ultraviolet exposure has influenced population health in Northern Spain, focusing on Santander, a mid latitude coastal region where climatic conditions, tourism dynamics, and behavioral patterns converge to shape UV vulnerability. Positioned at the intersection of climate science and public health, this interdisciplinary study investigates how ozone-driven increases in ultraviolet radiation have affected vitamin D status, skin cancer incidence, and broader health indicators. The project integrates quantitative datasets, including ultraviolet index records from AEMET, long range projections from the IPCC Sixth Assessment Report, and national epidemiological trends in melanoma and non-melanoma skin cancers. Qualitative analysis draws on national sun exposure surveys and peer reviewed research in UV photobiology, enabling a comprehensive assessment of shifting environmental pressures and human behavioral responses. Findings indicate a multifaceted health burden. Although summer UV levels are high, winter irradiance remains inadequate for vitamin D production, contributing to widespread deficiency among Spanish adults. Concurrently, melanoma incidence has risen steadily from 1990 to 2019, with the most pronounced increases in older populations. Additional evidence suggests that individuals with higher serum vitamin D levels, often linked to high sun exposure, may exhibit increased susceptibility to non-melanoma skin cancers. Behavioral surveys reveal frequent exposure during peak UV hours and inconsistent sunscreen use, amplifying cumulative risk. Conclusively, it was illustrated how climatic change and human behavior jointly influence UV related health outcomes. These results underscore the need for integrated public health strategies that balance safe sunlight exposure with effective photoprotection as environmental conditions continue to evolve.

Abstract Name: The Sun's Influence: Exploring Vitamin D's Role in Paclitaxel and Menadione Sensitivity in Breast Cancer Cells

The most common cancer in women is breast cancer. In the U.S, it is the second leading cause of death in women after lung cancer. 1 in 8 women in the U.S will develop breast cancer in their lifetime. MDA-MB-231 is a triple-negative breast cancer cell line that lacks estrogen and progesterone receptors, while MCF-7 is estrogen-positive and has estrogen and progesterone receptors. Studies have shown that there could be an association between higher vitamin D levels and increasing breast cancer survival rates. Cholecalciferol (vitamin D3) is linked to cancer prevention because of its ability to promote apoptosis and regulate cell growth. In order to evaluate the successes of chemotherapy with Vitamin D, Paclitaxel, and Menadione will be tested. These Results will be measured using Alamar Blue assay to track cell survival.

Abstract Name: Why Parental Alienation Studies Should Be Taught at U.S. Universities

Parental alienation (PA) is a silent epidemic with devastating consequences. It is a form of psychological abuse and maltreatment of children in which one parent manipulates children through lies, false allegations, and manipulation, to fear and hate their non-abusive, non-violent, emotionally available, other loved and loving, parent and entire side of family with whom they have had always a healthy relationship. Despite its documented history dating back to the 1800s, PA remains under-recognized in legal and mental health fields. PA studies are urgently needed in U.S. university curricula, particularly within counseling, psychology, social work, family law programs, and careers that will interface with children and families. My research details the devastating emotional toll of PA on children, targeted parents, and extended family members and how PA can lead to real-world tragedies which culminate in murder-suicide by a parent with child victims. Educational reform and awareness are essential steps toward early recognition, trauma-informed care and preventing family tragedy. Currently, professional gaps in knowledge, empathy, and understanding are retraumatizing parents seeking help. This perpetuates cycles of grief, misdiagnosis, and systemic failure, while delaying justice for children who lose a major attachment figure, and for parents whose children are abruptly taken from their lives, causing generational chronic traumatic stress and long-term, ambiguous grief without closure. Educating professionals on the Five-Factor Diagnostic Model will help Professionals identify PA and prevent parents from mistakenly being accused of PA. Universities must lead the way in educating future professionals, validating lived experiences, and fostering early intervention. Once this education is in place, lives may be saved, loving parents will remain together and much-needed policy reform can begin.

Abstract Name: Shepherds in the Great War: The Evolution of the U.S. Army Chaplaincy and the Service of Malcolm Taylor in World War I

From its beginnings in 1775, the U.S. military chaplaincy has been a vital but often overlooked component of the American military experience. Though the specific duties and regulations for U.S. chaplains have evolved over time, the heart of the chaplaincy is rooted in sacrificial service, a ministry of presence, spiritual leadership, and moral guidance. The American entrance into the Great War in 1917 marked a period of exponential growth for the military chaplaincy as it faced unprecedented demand and growing professionalization. In this paper, I examine the professional development of the U.S. Army chaplaincy during World War I, focusing on the growth of standardized qualifications for chaplains, the establishment of chaplain training schools, the creation of the General Headquarters Chaplains' Office, and the ways individual chaplains fulfilled their duties by embracing muscular Christianity and interfaith cooperation. The personal letters of Chaplain Malcolm S. Taylor further illuminate the everyday conditions and forms of service chaplains provided to American troops overseas. The personal accounts and correspondence of American chaplains, like Chaplain Malcolm S. Taylor, reveal how chaplains navigated their newly expanded roles as they conducted professional spiritual leadership within the U.S. military and provided a ministry of service within the demands of modern warfare.

Abstract Name: Increasing Inflation, a Regressive Tax structure, and Globalization: Dollarization in the 1970s and Increased Housing Costs for the Middle Class

The root cause of the housing crisis currently faced by the United States middle class needs a proposed potential solution that may successfully mitigate the symptoms of the problem. Rising housing prices and housing inequality are currently a significant problem faced by the middle class in the entirety of the United States and the present analysis is an examination of the potential root causes of this problem. A comprehensive review of sources relating to rising housing inequality, rising wealth inequality, rising inflation, the effects of currency pegging, and the effects of a progressive taxation system on wealth inequality were explored to determine the root cause of rising housing inequality and a potential solution. The results suggest that the root cause of the current housing crisis is the United States global economic strategy relating to dollarization which led to a large amount of inflation, increasing inequality, and as a result, increasing housing inequality. The implementation of a progressive taxation system can offset wealth inequality and as a result offset housing inequality between wealth levels. A progressive taxation systems has may have the potential to offset the root causes of wealth inequality and as a result afford the middle class the ability to buy homes at previous home buying levels.

Abstract Name: Emotion-Aware Speech Analysis for Mental Health Support Using Whisper

Emotional Self Awareness (ESA) refers to a person's ability to understand and identify their own emotions. Low ESA is associated with depressive and anxiety disorders, while increasing ESA is associated with a reduction in symptoms of these disorders and greater emotional regulation. Depression and anxiety are widely experienced, debilitating conditions that represent leading causes of disability and reduced quality of life worldwide. Methods to reduce the symptoms of these disorders have critical impacts on public health and individual well-being. Self-monitoring approaches for emotional states are often used with other psychotherapy techniques to treat mental health disorders with the intention of increasing ESA. However, many people struggle to pinpoint exactly how they feel, when those feelings started, and why. Manual self-monitoring imposes a daily obligation onto the user and is limited by the individual's own self-awareness and ability to reflect honestly. Providing continuous, automatic, and objective emotion tracking would address these shortcomings, yet no current methods to do so exist. In this work, we developed a system to solve this problem using automatic, AI/ML powered emotion monitoring through speech and textual emotion classification. The privacy module continuously transcribes a user's speech while removing all other speakers from the analysis. Within the classification module, OpenAI's Whisper is used to perform a multi-modal

analysis using both audio and text to classify the user's emotions and produce daily emotion tracking reports. Automatic tracking removes the individual's responsibility of logging entries, creating accurate and consistent mood trends. This system will increase ESA by allowing users to better recognize emotional triggers and long-term patterns without relying on subjective self-reporting or burdensome questionnaires. By analyzing the user's day and transforming everyday speech into data driven insights, this project demonstrates a novel and cost-effective approach to improving emotional well-being.

Abstract Name: How the Page Remembers: Written Monuments of Forgotten Pasts

This project examines how literature and novels manifest as a counter-monument of cultural memory. The landscape of monuments we see focuses on a fixed and unyielding perspective where voices and histories are censored from public view, leaving them erased in public spaces. Cultural memory, a collective possession of memories relating to past events that transmit through generations, serves as another form of public space within historical knowledge, wherein literature creates a different form of monumentality that contrasts rigid structures, leaves emotional residue, and uncovers unwritten pasts. This study offers a subversive perspective on how literature questions and challenges dominant historical ideologies unlike static, fixed, and structural monuments. As traditional monuments reinforce hegemonic narratives, I investigate how literature provides a defiant, intimate, and dynamic space to preserve suppressed histories and reconceptualize the perspective of our memory by challenging what is remembered and why. This project illuminates how literature serves as a form of resistance and rebellion against oblivion for marginalized voices. Through close readings of *Beloved* by Toni Morrison, I re-examine how literature offers a critical reimagination of erased pasts by reshaping the architecture of memory. *Beloved* examines the devastating trauma and horrors of slavery through Margaret Garner's infanticide and the haunting legacy it imprints on familial history, which confronts erasure within racist and colonial histories by reclaiming silenced perspectives, and traces cultural memory across time and place. I examine how literature functions as a living and haunting archive for cultural memory and how these works become counter-monuments through emotional residue. I research monuments as cultural repositories and explore how symbolic power in historical monuments is reframed in literature. I study this phenomenon to emphasize the importance in the everlasting emotional impact of counter-monuments, to reconsider storytelling's role within the construction of memory, and to uplift marginalized voices through cultural memory.

Abstract Name: Successes and Challenges of an Emerging Undergraduate Research Program: Developing a Community College Research Culture

Truman College, a small community college within the City Colleges of Chicago, is in its third year of developing an undergraduate research and creative activity initiative, SERCA @ T (Student Experience in Research and Creative Activity at Truman). As faculty director, I will discuss the mentoring approaches, faculty initiatives, and cross-departmental collaborations SERCA @T has developed to offer students,

particularly from underrepresented backgrounds, access to academic mentoring and opportunities for research and creative activity. From these efforts, a small but thriving research culture is emerging; I will also share plans to overcome obstacles and actualize new goals. The key to SERCA @T's initial success lay in weaving together strong resources already in place Truman: partnering with existing campus centers; harnessing a group of professors and departments already practicing undergraduate research, particularly in Chemistry and Biology; and coalescing multidisciplinary faculty who are eager to explore inquiry-based learning in their classrooms. As a result, SERCA @ T has helped expand the number of independent research courses offered in various departments and the number of faculty mentoring students to create independent research and creative projects. In addition, this emerging research culture has led some faculty to fund or enhance their work with students through grants or partnerships with NASA Community College Network, the National Endowment for the Humanities, the Pulitzer Center, and the Alliance for the Great Lakes. Showcasing this research culture through student presentations has generated interest among students, faculty, and staff: SERCA @T has hosted two college-wide annual student symposia, featuring projects from the laboratory sciences and computer science to art, English, theater, and music. These symposia, in turn, have stimulated further teaching innovations. Through dialogue with session participants, I hope to generate ideas for building upon these activities and setting future directions for SERCA @T.

Abstract Name: Understanding Career Readiness in Public Media: A LIWC-22 Analysis of NACE Career Readiness Competency Language

As career readiness skills become an increasingly visible expectation for higher education, there remains limited evidence about how these competencies surface in large-scale public and online discourse. Many colleges and universities have adopted the National Association of Colleges and Employers (NACE) eight Career Readiness Competencies: Communication, Critical Thinking, Teamwork, Equity & Inclusion, Professionalism, Technology, Leadership, and Career Self-Development. Existing analyses of career readiness language have largely focused on student services interactions, institutional messaging, or demographic subgroups, leaving large-scale public discourse unexamined. To address this gap in knowledge, we used automated linguistic inquiry and word count (LIWC-22) to analyze large datasets from traditional news, blogs, and social media. We constructed a custom dictionary for LIWC-22 by transforming NACE's definitions into keyword stems and supplementing them with high-frequency terms drawn from workforce-readiness discourse. The presentation will report patterns in the frequency and distribution of NACE competency language across media sources. Additionally, we will highlight emerging relationships among the eight competency categories within the corpus. Overall, the study provides a large-scale linguistic profile of how career readiness is represented in the public and online media. The resulting dictionary offers a replicable and scalable method for measuring the presence of career readiness constructs in natural language. This work demonstrates the potential of computational text analysis to enhance our understanding of workforce preparation narratives and provides a methodological foundation for future studies examining career development.

Abstract Name: Association between TNF- α and hippocampal volume in overweight cognitively unimpaired adults and Amyloid- β status

Introduction: Obesity is a risk factor for Alzheimer's disease (AD), though mechanisms remain unclear. Higher body mass index (BMI) is linked to hippocampal atrophy and chronic inflammation. TNF- α , an inflammatory plasma biomarker often elevated with higher BMI, has been associated with brain atrophy and amyloid-beta (A β) accumulation. We hypothesized that higher plasma TNF- α in cognitively unimpaired older adults would be associated with smaller hippocampi, particularly in those with higher BMI. Methods: We analyzed data from 1,580 cognitively unimpaired adults from the HABS-HD cohort. Linear regressions were conducted to examine the associations between plasma TNF- α and 3T MRI-derived hippocampal volume, covarying for age, sex, education, and intracranial volume. Analyses were stratified by BMI category and A β status (florbetaben PET), correcting for multiple comparisons (false discovery rate; FDR). Mediation analysis assessed whether TNF- α mediated the BMI-hippocampal volume relationship in overweight/obese adults. Results: TNF- α levels were not related to hippocampal volume in the full sample (β = -0.050; FDR p = 0.246) or among underweight/normal participants ($BMI < 25$; β = 0.010, FDR p = 0.863). Among overweight/obese participants ($BMI \geq 25$; $n = 1,228$), higher TNF- α was linked to smaller hippocampal volume (β = -0.060; FDR p = 0.019). This persisted in the A β subgroup ($n = 762$), with A β positivity included as a covariate (β = -0.067; FDR p = 0.072). Among A β + individuals ($n = 141$) the association was stronger (β = -0.160; FDR p = 0.084) than in A β - participants ($n = 619$; β = -0.047; FDR p = 0.172). The interaction was not significant ($n = 777$; β = -0.050; FDR p = 0.152). TNF- α did not mediate the BMI-hippocampal volume relationship (ACME p = 0.172). Conclusions: In cognitively unimpaired overweight/obese participants, higher TNF- α levels were linked to smaller hippocampal volume, particularly in A β + individuals, suggesting inflammation may contribute to early AD-related atrophy.

Abstract Name: Tikkun Olam and La Causa: The Impact of American Jews on the United Farm Workers Union

Throughout its most successful years, the United Farm Workers (UFW) union, headed by a Mexican-Catholic named Cesar Chavez, was deeply pluralistic. While most of the farmworkers that the UFW represented were Hispanic, and largely Mexican-Catholic, supporters and leaders of the union came from a diversity of ethnic and religious backgrounds. In particular, Jewish Americans propelled the union's success. This fact is apparent throughout the literature on the UFW, as examples of Jewish involvement and support have amassed in great numbers. However, scholars have almost always compiled these examples in pursuit of some other, broader analysis of the UFW or a related topic. As such, no scholarly work analyzes Jewish Americans' impact on the union's success for its own sake. This paper begins to fill this gap in the literature by asking the question, "What was the unique impact of Jewish Americans on the success of the UFW from the mid 1960s through the late 1970s?" Pulling from archival sources from Wayne State University, Yale University, Hebrew Union College, and Amherst College, as well as online repositories hosted by the University of California San

Diego, oral histories with former UFW leadership, and the existing scholarly literature, this paper argues that American Jews contributed most to the UFW's success over the period in question in three respects. First, American Jews had a strong presence throughout the union's ranks, with Jewish support playing an especially outsized role in union leadership. Second, Jewish support provided important institutional backing for the union, which was especially crucial through the mid 1960s, when such institutional support was needed to sustain the union through its infancy. Third, Jewish growers were key to the union's success, as Jewish leaders in agriculture were consistently the most willing to stray from their fellow producers and sign breakthrough contracts with the union.

Abstract Name: Synthesis and characterization of β -mannanase and α -galactosidase encapsulated PLL-g-PEG nanoparticles as an efficient viscosity breaker in fracturing fluids used in oil reservoirs

Hydraulic fracturing is a key technique used to extract oil from low permeability reservoirs. This process involves injecting highly viscous fluids containing guar gum polymers at high pressure to fracture rock formations. It is essential to remove or degrade these highly viscous fluids to allow efficient oil or gas flow. Controlled release of enzyme breakers is crucial to avoid premature degradation or formation of filter cakes in oil wells. This research focuses on developing an efficient enzymatic breaker for guar gum-based fracturing fluids by utilizing α -galactosidase and β -mannanase encapsulated poly-L-lysine graft poly(ethylene) glycol (PLL-g-PEG) co-polymer nanoparticles (NPs). PLL-g-PEG copolymers were synthesized using various grafting ratios of PEG including 2%, 5%, 10%, and 15%. Proton NMR and FTIR data confirmed successful co-polymer synthesis and PEG grafting onto PLL. Dynamic light scattering data showed the appropriate size of NPs for oil field applications. The encapsulation efficiency of α -galactosidase and β -mannanase within NPs was evaluated using sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE) and the data confirmed both enzymes were successfully encapsulated, though not at 100% efficiency. Preliminary rheometric studies on guar gum solutions in PBS buffer were performed to determine the zero-shear viscosity of guar gum using the Carreau-Yasuda regression model. Our ongoing work focuses on the ability of encapsulated enzymes to degrade guar gum polymers. Rheometric measurements are used to monitor time-dependent viscosity changes in guar gum treated with nanoparticles containing β -mannanase and α -galactosidase.

Abstract Name: Comparison of Borderline Personality Disorder Symptom Severity Between Male and Female College Students.

Borderline personality disorder (BPD) is a severe and poorly understood disorder that is often associated with women in clinical samples. However, in community samples, recent literature conflicts with this finding, with varying rates of prevalence in community samples ranging from equivalence between genders to higher relative prevalence in men. Presentation of BPD shows differences in gender, with relative rates of alexithymia being higher in women, and alcohol abuse and impulsivity in men. This study aims to provide additional data on the prevalence and severity of BPD symptoms in men and women, along with an investigation of whether alexithymia, alcohol abuse, and depression are predictive factors of BPD symptom severity in a community sample. A community sample of college students from a Maryland university will be asked questions regarding BPD symptoms & behaviors, alexithymia, alcohol abuse, and depression in an online survey. Students will also be questioned about additional comorbidities and any family mental health history. We expect to find a rate of 9.7% above the cutoff point for presenting BPD symptoms. Regression analyses will be used to create separate predictive models of symptom severity for both men and women. For men, we expect alcohol abuse to be particularly predictive, while for women, we expect alexithymia to be predictive. We anticipate depression scores will positively predict BPD symptom severity in both men & women.

Abstract Name: What the Amphorae Tell Us: Mapping Transport Amphorae from the Bay of Cádiz to Study Food Movement in Roman Maritime Trade

This research uses a Microsoft Access database and Google Earth Pro to synthesize the published amphorae from the area of Roman Gades (modern Bay of Cádiz) and create a queryable mapping tool for analyzing amphorae spatial distribution around the area's harbors. Amphorae were among the most common transport vessels for food used in maritime trade in the Roman empire, and by drawing on data such as vessel forms and residue analysis it is possible to identify an amphora's date and food contents. Archaeologists have excavated the many harbors and neighborhoods surrounding the Bay of Cádiz throughout the past century, documenting their work through brief excavation reports, individual residue analysis studies, and regional pottery catalogues. This project compiles this information into a database and creates a map of amphora find spots in order to situate excavated amphorae in their broader context and search for trends. The author anticipates that filtering the database and map by various amphora contents, dates, and shapes will reveal diachronic trends and patterns of spatial distribution, which the paper will illustrate using Google Earth mapping software. More broadly, by showing how these theories and methods can be applied to a single Roman port area, this project seeks to demonstrate the potential for these types of amphora databases and maps to answer complex research questions and provide a holistic view of food networks. Conducting and integrating similar studies at other locations has the potential to create more accurate reconstructions of ancient food networks and expand archaeology's understanding of maritime trade.

Abstract Name: The Evolution of Organic Residue Analysis and its Applications for Studying Maritime Trade in the Context of the Theoretical and Scientific Development of Archaeology

What drives theoretical and methodological innovation in archaeology, and how do these changes impact research into ancient human food networks? This study found that as archaeology increasingly aims for a holistic view of the past, progressively sophisticated research questions necessitate new forms of data and drive scientific and methodological innovation; these developments steadily push organic residue analysis (ORA) toward actualizing its potential to revolutionize our understanding of ancient food production and trade through reconstructing food networks. In the absence of a comprehensive, comparative history of ORA's use in archaeology, this study constructed one, evaluating ORA case studies from England to Egypt from the past 150 years to examine the nature of theoretical and scientific development in classical archaeology. This analysis illuminates areas of past growth, those needing further development, and those holding exciting possibilities for the future of the field. ORA opens new avenues of inquiry for studying trade and reconstructing food networks by fostering interdisciplinary collaboration and a more holistic understanding of history, but such complex research questions necessitate vast amounts of consolidated, searchable data. Therefore, the author calls for the creation of a largescale, diachronic ORA research database which archaeologists could query to map food distributions and suggest trade routes for past civilizations such as Rome. As society increasingly questions the value of historical research and archaeology becomes ever more interdisciplinary, this sort of digital humanities project could facilitate data-driven discussions about food production and access in the past as well as ideas for the future.

Abstract Name: Reacting to Another's Feelings: The Association of Cognitive and Affective Empathy with Emotional Reactivity

Both empathy and emotional reactivity play important roles within couples' interactions. Empathy aids in understanding another's situation and partaking in their feelings. Emotional reactivity is the spontaneous reaction to good or bad stimuli, including social ones. However, there is little literature on whether two types of empathy, cognitive and affective empathy, relate to emotional reactivity to a partner's distress. The present study aims to determine whether cognitive and affective empathy independently relate to emotional reactivity in the context of couples listening to each other's troubles. By exploring this impactful facet of couples' interactions, this study can provide insight for interventions seeking to improve couples' everyday lives. 204 participants (N = 102 couples) were recruited online using social media, community events, and flyers. Each completed the 14-item Interpersonal Reactivity Index, which operationalized cognitive and affective empathy. Both before and after listening to their partner's disclosure of a distressing event, each participant indicated their emotional state via a mood scale. Emotional reactivity was operationalized using the changes between the baseline emotional state and the emotional state at post-task. Currently, data analysis is still in progress. However, given the findings in previous literature, we expect to find that cognitive empathy will have a negative relationship with emotional reactivity. Conversely, we expect that affective empathy will be positively related to emotional reactivity. Multiple regressions will be performed to control for demographics and analyze the hypothesized relationships. In the first regression model, cognitive empathy will predict emotional reactivity, controlling for age, gender, and baseline negative emotion. In a second model, affective

empathy will predict emotional reactivity and control for the same covariates. In the third model, both cognitive and affective empathy will be included along with the covariates.

Abstract Name: Adwa and the Awakening of Ethiopianism: Resistance and the Birth of a Collective Consciousness

The Battle of Adwa is one of the most consequential events in African history. In the late nineteenth century, the Italian monarchy, ruled by Umberto I, attempted to invade Ethiopia and subdue Emperor Menelik II. Ethiopia remains one of the only nations on the African continent to successfully avoid colonization by a European power. However, Italy's desire for global legitimacy and territorial claims to the Suez Canal prompted the nation to invade. Many scholars believe that Ethiopia was successfully able to repel the invasion only because of an innate territorial and geographical advantage. However, there are many emerging perspectives of the Battle of Adwa that challenge this narrative and attribute Menelik II's victory to superior strategy and execution. Italy's defeat sent shockwaves through nations in both Europe and Africa. Menelik II's victory challenged European imperialism and invited African's to resist subjugation. Following the Ethiopian's victory, leaders around the world called into question their imperial ambitions, with some claiming that establishing new colonies in Africa would be impossible. Adwa also inspired an intellectual movement in the United States among Pan-Africanists, who paid homage to Menelik II. Prominent activists like Marcus Garvey and Dr. Benito Sylvain relied heavily on Ethiopia's victory to develop their Pan-African ideology and invite the African diaspora to resist imperialism. Ethiopianism specifically has a connection to scholars like W.E.B. Du Bois and Booker T. Washington. While Adwa was not the end of a long saga of conflict on the African continent, it ignited an intellectual movement and demonstrated that resistance to subjugation was possible.

Abstract Name: Sex-Specific Differences in P2X7-Mediated ATP Responses in Mast Cells

Allergic diseases like asthma are more common and often more severe in females than males. One cause of these disparities can be how the immune system responds to common inflammatory stimuli. Extracellular ATP is increased by cellular damage, including damage caused by allergens. Once released from cells, ATP functions as a damage associated molecular pattern (DAMP), causing inflammation by coordinating an immune response. We used mast cells, a key immune cell involved in allergic inflammation, to investigate sex differences in ATP-mediated inflammation. After ATP stimulation, we used ELISA to measure cytokine secretion and flow cytometry to analyze cell-surface receptor expression. We find that female mouse mast cells release more inflammatory cellular granules and greater amounts of inflammatory cytokines in

comparison to males. Our results showed consistent female-dominant responses to ATP across two genetic backgrounds. We found that the ATP receptor, P2X7, is necessary for both male and female mast cell responses and that females do not express greater amounts of P2X7 than male cells. Work in progress will help understand the underlying mechanisms for female-dominant ATP effects. This work reveals fundamental differences in inflammatory diseases that exhibit sexual dimorphism and could lead to better interventions.

Abstract Name: Til Death Do Us Part: Narrative of Death in Jane Austen's Marriage Plots

The works of Jane Austen are hardly known for their portrayal of death. On the contrary, many critics of Austen's work have focused on the "light, and bright, and sparkling" stylistic elements that attract readers some two hundred years after publication. While Austen's works are far more light-hearted than those of many of the women authors who came before her, death exists in everything Austen writes, even though scholars of Austen's work have tended to overlook this darker side of Austen's writing. In this paper, I show how the many instances of death in Austen's juvenilia and novels work to underscore the overarching theme of their respective works. Building on the scholarship of Gillian Dooley, I show how death in Austen's novels and juvenilia are also used to speak to instances of character reform and as tools of satire. Both death through the inheritance plot and death as satire, I argue, present death rather unseriously even as these same instances speak to major thematic strains. It is only the inclusion of death as character reform that tends to receive serious treatment by Austen's narrators, serving to reinforce gentility. This paper focuses on these three delineations of death and their connections to the texts' larger themes, demonstrating how an author best known for her marriage plots covertly handled more somber material to a variety of narrative ends.

Abstract Name: Exploring Maize Root Microbiome Engineering by Optimizing *Bacillus Subtilis* for Metagenomic Library Expression

As populations rise and new environmental stressors negatively impact plants, food security will become one of the world's largest obstacles in the future. Plant root microbe engineering enhances certain plant functions and may help increase crop yields. Despite the potential to revolutionize treatment of crops, this approach remains complex with vast knowledge gaps. Metagenomic libraries allow for expression of DNA sequences from microbes that are not culturable and discovery of genes critical to plant function. Plasmid libraries carrying unique DNA fragments are transformed into bacteria, and grown on plant roots. Functional screening identifies which sequences of DNA confer advantages or are important to microbial interactions on plant roots. *Bacillus subtilis* is a Gram-positive bacterium commonly found in soil. As a metagenomic library host, it could broaden heterologous gene expression, increasing chances of discovering novel interactions between microbes and maize. Initial research shows *B. subtilis* strain 168 has high potential in transformation,

however, lacks the ability to produce tryptophan, and cannot persist upon maize roots. Our goal is to optimize *B. subtilis* strain 168 for metagenomic library expression by engineering the strain, optimizing the library plasmid, and improving the transformation process. Using technologies such as molecular cloning, DNA sequencing, and bacterial transformation we will hope to use an integrative vector to stably express the *trpC* gene in *B. subtilis* 168, remediating tryptophan auxotrophy, and testing in minimal media with appropriate controls. We will use molecular cloning techniques to optimize our library plasmid, by testing different components such as promoters, origin of replication, and plasmid size, and evaluating effects on bacterial transformation efficiency. By varying electroporation variables like buffers, wall weakening agents, voltages, and recovery times, we will optimize our transformation method. Our results will aid in the discovery of novel genes significant to plant microbiome engineering applications.

Abstract Name: Simulating a Presentation Attack Using a Fake Finger to Evaluate Spoofing Detection and Prevention Capabilities of Digital Persona Fingerprint Reader

Fingerprint authentication, a widely used biometric security method, is vulnerable to presentation attacks (spoofing). These involve an attacker using a fake finger to trick the sensor into granting unauthorized access, raising concerns about the security, privacy, and reliability of biometric systems. This research project investigates the spoofing resistance of the Digital Persona U.are.U 4500 fingerprint reader. The study will test whether a fabricated fingerprint is rejected or authenticated, while documenting the fabrication process and evaluating the ridge-level quality (L1–L3 features) of the fake print. It will also compare similarity scores between real and spoofed fingers using fingerprint recognition software. The goal is to analyze not only whether spoofing is possible but also how effectively the sensor detects or prevents such attacks. This work will provide evidence about the strengths and weaknesses of consumer-grade fingerprint readers and create a reproducible framework for studying spoofing in academic settings. By relating results to prior literature, the findings will offer practical insights into biometric system security.

Abstract Name: The Influence of the axis of astigmatism on stereopsis across spatial frequencies

Purpose. Uncorrected astigmatism can profoundly reduce stereoacuity. However, previous studies have used tests that are broadband in their spatial frequency content. Here we developed a new stereoacuity test using

narrowband Gabor stimuli to evaluate depth perception at different spatial scales, ranging from coarse to fine stereopsis. This study aimed to characterize how the axis of astigmatic blur alters the spatial frequency tuning of stereopsis. **Methods.** Stereoacuity was measured across spatial frequencies (1.25-20 cpd). Binocular disparity was introduced by shifting the two Gabor targets in opposite directions, and a haploscope was used to enable binocular fusion. The visual task was to determine the stereoscopic depth of the Gabor target relative to four Gabor references. Four young adult observers with normal vision were tested. Positive cylindrical lenses were used to induce various types of astigmatism in each of the two eyes: +1.00 DC x 180 for with-the-rule astigmatism, +1.00 DC x 45 for oblique astigmatism, and +1.00 DC x 90 for against-the-rule astigmatism. **Results.** In general, stereoacuity was more severely degraded by against-the-rule astigmatism than by oblique astigmatism across spatial frequencies, while with-the-rule astigmatism had the least effect. Inducing astigmatic blur degraded stereoacuity more selectively and substantially at higher spatial frequencies for with-the-rule astigmatism and at medium-to-high spatial frequencies for oblique astigmatism. Stereoacuity at lower spatial frequencies was also reduced by against-the-rule astigmatism - the optimum frequency tuning gradually shifted to lower spatial frequencies as the power meridian of astigmatism rotated from 0° to 45° and then to 90°. Notably, stereopsis for low spatial frequency targets was relatively less affected in all three astigmatic conditions. **Conclusions.** Using a narrowband stereoacuity test, we characterized the effects of astigmatic axis on depth perception across different spatial scales. These findings provide new insights into the stereopsis deficits in amblyopia associated with different types of astigmatism.

Abstract Name: Psilocybin Treatment for Alcohol Addiction and Reduction of Harm: Implementing Treatment for Low Socioeconomic Status Individuals in the United States

Alcohol Use Disorder (AUD) is a continuing problem in the United States that causes a high number of deaths and harm but lacks sufficient treatment methods, resulting in individuals with the disorder having an inability to receive treatment or experiencing high rates of relapse following treatment. Individuals at a lower socioeconomic status are currently facing the highest amounts of negative consequences, including, but not limited to, mortality, liver issues, and psychological issues, creating an alcohol harm paradox. In this review, the use of psilocybin in AUD treatment was evaluated to assess its effectiveness in remediating the disorder, and it was found that psilocybin treatment significantly reduces heavy drinking days, drinks consumed per day, and likelihood of relapse while increasing the likelihood of abstinence, most notably through the similarities in neurotransmitter pathways between psilocybin and alcohol and the mystic effects of psilocybin, including ego-dissolution. The factors that contribute to the inability of individuals at a low socioeconomic status to receive treatment were studied, including insufficient funding, lack of insurance, and lack of resources. Using this information, a plan was drafted that utilizes government grants to bring psilocybin treatment to areas of low socioeconomic status to alleviate the harm paradox.

Abstract Name: Apple Versus Spotify

The focus of this project was to analyze consumer preferences between Apple Music and Spotify to help improve each platform's online marketing strategy. Our survey included both Likert-scale and demographic questions to better understand how users perceive each service based on key features such as Spotify Wrapped, AI driven recommendations, podcast availability, pricing, and overall functionality. The goal was to prove that users preferred Spotify over Apple Music and why, and to identify what featured mattered most when choosing a music streaming service. Using Qualtrics and in person distribution, we collected 290 usable responses from our target population. We analyzed the data using SPSS to identify patterns in user preferences and develop meaningful conclusions and recommendations. Approximately 69.4% of respondents Agreed or Strongly Agreed that Spotify Wrapped is a feature they look forward to at the end of each year. This led to a recommendation that Spotify continues their 'Wrapped' feature. T-Tests showed that female respondents showed a significantly higher score than male respondents on the importance of a free- with ad version of Spotify. Spotify should continue to emphasize the free version with ad features they offer to the public. Regression analysis showed that overall satisfaction of Spotify's music streaming platform was dependent on the importance of the Spotify Wrapped feature, how knowledgeable the respondents are of Spotify's platform, and the number of hours a week used. Another regression showed that respondents would recommend Spotify over Apple Music due to the importance of the "jam session" feature, the \$5.99/month Student Plan pricing, and the importance of having the Apple logo on their music app. Recommendations included that Spotify make more marketing efforts towards males. Spotify should extend their efforts to catch males' attention in the Spotify Wrapped feature, the variety of podcasts, and the free with ad version.

Abstract Name: Design, synthesis, and biological evaluation of novel quinoline-based colchicine-binding site inhibitors

Cancer remains a major health problem worldwide, driven by genetic changes that disrupt normal cell growth and spread. Advanced cancers are often treated with drugs like paclitaxel and docetaxel, which target microtubules. Microtubules are components of the cytoskeleton that are required for maintaining cell shape, intracellular transport, and, most significantly, chromosomal segregation during mitosis. Their ability to switch between polymerization and depolymerization, known as dynamic instability, is closely regulated in healthy cells. Cancer disrupts this regulatory balance, causing malignant cells to divide uncontrollably. Because microtubules are essential for mitotic spindle formation, compounds that disrupt their function have emerged as an effective treatment for cancer. However, many existing microtubule-targeting drugs, like paclitaxel, have major drawbacks, such as off-target toxicity, low solubility, metabolic instability, and multidrug resistance. These shortcomings highlight the need for novel scaffolds that can bind tubulin more selectively, overcome resistance, and sustain potent antiproliferative activity. We report that the initiative attempts to overcome some of these challenges by developing a new class of phenyl(quinoline)methanone analogs designed to bind to the colchicine-binding site (CBS) at the interface of $\alpha\beta$ -tubulin, a well-established groove that inhibits tubulin polymerization when occupied. The quinoline core provides a versatile foundation for synthetic modification, allowing for comprehensive adjustment of electronic, steric, and hydrogen-bonding properties to increase tubulin binding and improve the potency of the molecules. Using structure-based molecular modeling, ten compounds were synthesized that could potentially optimize interactions with CBS and ensure drug-like properties. These compounds were then tested on cancer cells to determine their potency. A few of these compounds proved to have IC₅₀ values below 1 μ M, indicating that further modifications can lead to more potent and selective compounds. These molecules would be further

evaluated for their mechanism of action studies and their ability to induce apoptosis (programmed cell death) in cancer cells.

Abstract Name: Undergraduate Public Health Facilitation of Open Airways for Schools: Educational Benefits for Children and College Students

This project examines how a college student-led implementation of the American Lung Association's Open Airways for Schools (OAS) program can strengthen asthma management education for elementary-aged children while simultaneously building professional skills for Public and Community Health undergraduates. OAS has been implemented by nursing students and school nurses, this project is the first to train undergraduate Public and Community Health students to deliver the program. We sought to determine whether this model created reciprocal learning benefits for both the children receiving instruction and the college students facilitating it. Childhood asthma remains a major public health concern, and education-focused interventions consistently improve symptom management, self-efficacy, autonomy, and long-term health outcomes. OAS is an evidence-informed curriculum that has demonstrated past success. School nurses in Ithaca face increasing demands that limit their capacity to implement such programs. Training Public and Community Health students offers a practical solution: children continue to receive high-quality asthma education, college students gain hands-on experience, and school nurses experience reduced burden. Limited research has explored how non-nursing undergraduate health students can effectively deliver asthma education, making this project a unique contribution to community health pedagogy and school-college partnerships. Selected Public and Community Health students were supported by a student ambassador and faculty. The ambassador coordinated OAS training with the American Lung Association, scheduled school sessions, prepared instructional materials, and supported classroom management. Caregivers completed consent and asthma surveys prior to participation. Children completed pre-tests and post-tests measuring asthma knowledge. Data was collected over two years in two schools. Findings showed improvements in children's post-test scores, increased confidence in asthma self-management, and anecdotal reports of calmer responses during asthma episodes. College students demonstrated growth in behavior management, professionalism, and confidence in program delivery. Results suggest that Public and Community Health students can effectively implement OAS while gaining valuable experiential learning.

Abstract Name: New Crusades, Old Problems: Crusade as Cognitive Space in the Billy Graham Library

From 1949 to 2005, American evangelical preacher Billy Graham led more than 400 multi-day revivals around the world, reaching more than 200 million people. He called these events "Crusades," drawing upon language that had long been used among early 20th-century American evangelical Christians. Among those

living in historically Christian countries, “the Crusades” are typically understood as a series of military campaigns led by European Christians from the 11th to 14th centuries in Asia and the Middle East. The use of “Crusade” by Graham evokes this medieval history and the popular notion among some evangelical Christians that their faith needs to be defended against ethnic or religious “others” (i.e., Muslims, Jews, liberal Christians). In this presentation, I explore what, if anything, Graham's twentieth-century Crusades have to do with their medieval predecessors. I argue that these Crusades function as a recontextualized conceptual space through which evangelical Christians imagine their work in terms of journeying to exotic places to fight for their faith and bring about the reign of Christ as described in the Book of Revelation. I demonstrate this through an analysis of the Billy Graham Library, focusing on exhibit captions and spatial layout. This paper contributes to a longer project on the use of crusades by White Christian Nationalists (WCN), a religious-political movement that incorporates crusader imagery into new calls for Christians to take up arms against Muslims and other imagined opponents. The larger project analyzes the way two sites, the Billy Graham Library and Rosslyn Chapel in Scotland, employ Crusade language or history and how these sites are interpreted by WCN.

Abstract Name: The Humane Finish Line: Fixing the Horse Racing Industry

The cruelties plaguing the United States' racehorse industry are deep-rooted, fueled by systemic and ethical failures that profoundly affect equine athletes' well-being. This paper examines the industry's inhumanity, focusing on the story of CeCe, a retired Thoroughbred who, due to industry abuses, lost her left eye. It presents statistics from October 17, 2025, showing that since 2014, the on-track death count has reached 11,671. I drew on veterinary medicine and welfare research, highlighting critical deficiencies within the industry. The first study reviewed was a collaborative effort by Colorado State University, the University of Sydney, and the One Welfare Institute. Their research reveals how high-concentrate, low-forage diets contribute to an 80-100% prevalence of gastrointestinal diseases. It also discusses how close confinement in small stalls for 23 hours daily leads to bone density loss and psychological distress. Additionally, the study shows that intensive training before full musculoskeletal maturity is associated with a higher injury rate. The industry's dependence on cruel behavioral-modifying equipment and medications to mask pain is also highlighted. I then examined a study by the UC Davis School of Veterinary Medicine and the University of Melbourne's School of Veterinary Medicine, which assesses the risk of Catastrophic Musculoskeletal Injuries (CMIs) associated with preexisting medical conditions, indicating that horses with multiple preexisting conditions face a high risk of CMIs, with a history of lameness being the most significant predictor. Based on research, I developed a comprehensive five-domain solution including: improving the living conditions of racehorses, banning drugs and prosecuting those who administer them, delaying training until musculoskeletal maturity, ensuring access to quality, independent veterinary care, and establishing a Federal Racehorse Cruelty Prevention Law providing legal protection and ensuring accountability across the industry. This law would mandate end-of-career options, dismantling the devastating race-to-slaughter pipeline and ensuring a humane finish line for all.

Abstract Name: The Impact of Social Use and Cognitive Factors on Language Learning, Retention, and Attrition in Multilinguals

Language attrition refers to the gradual loss of language proficiency that may occur after a language has been acquired. Attrition can occur with an individual's first language (L1) or second language (L2), and it is typically not a process that individuals plan or desire to experience. Language attrition in multilinguals is shaped by social factors, including patterns of language use, cultural values, and emotional identity, as well as cognitive factors related to memory, attention, and neurological processes. The purpose of this research was to explore how these factors contribute to language attrition. This research entailed examination of scholarly research from academic databases on themes such as language attrition, language loss, language maintenance, language retention, and language preservation. This research allowed for the comparison of theoretical perspectives and identified common patterns across age groups, environments, and cultural contexts. It was expected that these findings would provide insight into how multilingualism is acquired and supported, offering strategies for supporting language preservation through educational opportunities and sociocultural experiences. Language preservation holds significance in our society as it strengthens individuals' language skills, which allows linguistic communities to maintain their culture and collective identity. This promotes diversity and inclusion of people from a variety of backgrounds and supports the transmission of cultural knowledge across generations. Strengthening language preservation also enhances society's capacity for cross-cultural communication and to meaningfully interact with others. Overall, the findings may help deepen our understanding of social and cognitive factors that impact multilingualism to inform education and efforts for supporting language preservation in our global society. By recognizing the importance of linguistic diversity, this research aims to build this skill in our global multilingual population and deepen understanding of how these processes occur.

Abstract Name: Quantification of the Collaterals Originating from the Corticospinal Tract to the Subthalamic Nucleus and Zona Incerta: A Comparative Study Between Mouse and Monkey

The corticospinal tract (CST) is the major neuronal pathway that travels from the primary motor cortex (M1) to the spinal cord (SC) and allows for voluntary muscle movement of the body and limbs. On their way to the SC, CST neurons are known to send collaterals, side branches of axons, to subcortical structures of the brain. These structures include the subthalamic nucleus (STN) and zona incerta (ZI), which are involved in movement modulation and integration of different information modalities, respectively. Importantly, collaterals from the CST transmit efferent copies of outflowing movement-producing signals to these structures. This collateralization may vary across species due to evolutionary specializations. We thus employed a comparative study between mouse and rhesus monkey to analyze the level of innervation that the STN and ZI receive from CST collaterals. We injected an AAV-GFP retrograde tracer in the arm region of the SC in both species to label CST neurons that send outputs to the arm region of the SC as well as collateral branches that terminate onto STN and ZI. We used immunoperoxidase staining to visualize the GFP from this injection. Digital images of the brain sections were taken using light microscopy (LM) and electron microscopy (EM). For LM images, we will visualize and calculate the spatial density of labeled terminals using MATLAB/Imagej algorithms. For EM images, we will identify labeled elements (e.g., terminals, dendrites, etc.) and measure their area to assess the level of influence collaterals have on the structures. The

results of this study will further our understanding of CST neurons in the arm region across species, thus evaluating the relevance of these species for the study of normal and diseased states, and as models of movement disorders such as Parkinson's Disease, a disorder in which fine hand motor control dysfunction is prevalent.

Abstract Name: Modular Road, Lane, and Traffic Object Segmentation for Autonomous Driving

This project develops a modular image segmentation pipeline for low-speed autonomous driving. Instead of learning steering commands directly, the system focuses on understanding the road scene by labeling each pixel as drivable road, lane marking, or traffic-related object. The primary goal is to design and demonstrate a pipeline that cleanly separates these classes in driving images so that future controllers can rely on clear, interpretable inputs. To achieve this goal, the approach combines existing open-source vision models into three main stages. First, a multi-task deep network composed of YOLO-based object detectors and a YOLOPv2 lane and drivable-area model takes camera images and produces initial proposals for road, lane lines, and key objects such as vehicles and pedestrians. Second, an automatic mask-generation stage built with the Segment Anything Model (SAM) and OpenCV refines these proposals into dense training labels, reducing the amount of manual annotation needed. Finally, a compact U-Net-style segmentation network is trained on a mix of public road-scene datasets and a custom image dataset collected around the California State Polytechnic University, Pomona campus. This network learns to output separate masks for drivable road, lane markings, and traffic-related objects. Initial qualitative tests on the campus dataset show that the model can produce coherent, continuous road masks and clear lane markings, while failure cases still appear under strong glare, deep shadows, and unusual lane configurations. Because the pipeline is still being refined, ongoing work includes quantitative evaluation, systematic comparisons to simpler baselines, and exploration of adding LiDAR and overlapping sensor data to further improve robustness in more challenging conditions.

Abstract Name: Identification of Drug Resistance Mutations in *Mycobacterium bovis* Isolates causing Zoonotic Tuberculosis

Background Zoonotic tuberculosis (zTB), caused mainly by *Mycobacterium bovis*, remains an underrecognized cause of human tuberculosis, particularly in regions with close human-animal interaction. Infection occurs through consumption of contaminated animal products or inhalation of infectious aerosols. A major clinical challenge is the intrinsic resistance of *M. bovis* to pyrazinamide due to the *pncA* His57Asp mutation. Whole-genome sequencing (WGS) enables phylogenetic analysis to trace lineage circulation and detect drug-resistance associated mutations. However, systematic regional comparisons of lineage diversity and resistance profiles in human-derived *M. bovis* isolates remain limited, highlighting critical surveillance

gaps. Methodology Publicly available human and animal *M. bovis* isolates were retrieved from NCBI. As preliminary analysis, 109 African genomes were analyzed using SNP-based clustering and phylogenetic reconstruction to assess lineage sharing and geography-specific patterns. The current dataset includes 706 human *M. bovis* genomes: North America (570), Europe (112), Africa (3), Asia (6), Oceania (4), and South America (11). Ongoing drug resistance profiling includes genome assembly, annotation, and variant calling using the Bacterial and Viral Bioinformatics Resource Center. Drug resistance-associated mutations, spoligotypes, and lineage classification are being performed using Mykrobe and TB Profiler. Results The regional analysis identified one human isolate clustering with cattle derived isolates from Uganda (~37 SNPs), suggesting shared lineage ancestry. Transmission clusters (<12 SNPs) were detected among cattle in Nigeria and Ethiopia, and wildlife in South Africa. High genomic diversity in Morocco, Uganda, and Ethiopia contrasted with lower diversity in Zambia. These findings provide quantitative evidence of regional heterogeneity and cross-species lineage circulation. Discussion This study will integrate lineage and resistance profiling to support regional genomic surveillance of human *M. bovis*. Findings to date demonstrate geographically structured diversity and human-animal lineage overlap reinforcing the need for One Health-aligned strategies to monitor and control zTB.

Abstract Name: Detection and Quantification of Facial Symmetry Using Computer Vision Methods

Background: Upper and lower facial droop are early signs of stroke. However, subjective evaluation of the subtle changes is difficult to detect. Landmark analysis through computer modeling provides insights to quantify the severity and depth of facial asymmetry. This study aims to develop an asymmetry index (AsI) and establish a score range to reduce subjectivity in neurological assessment. Methods: This instrument development uses portable, self-contained system to quantify facial asymmetry via 3D facial landmark analysis. Asymmetry methods from credible research were evaluated to compare accuracy against manual measurements and landmark detection with algorithmic outputs using the same asymmetry formulas. Key landmarks (eyes, nose, mouth) were tested independently and combined into an AsI. Baseline comparators for stroke-patients were developed from 100 neutral-expression human face images averaged to generate a population AsI reference value. System robustness was established from faces with glasses, makeup, scars, and using varied lighting and conditions. Clinically relevant human subject data from patients admitted with stroke will be obtained in early 2026. Results: Early results from referenced studies support a hypothesis that healthy individuals will demonstrate low AsI values with narrow variances. Similarly, mouth and eye regions contribute most significantly to asymmetry in facial palsy. The composite AsI will reflect trends to remain stable across repeated image capture, accounting for environmental variability. Conclusion: This novel device will provide an accurate and reliable AsI in real time. The study contributes meaningful advances towards an objective method to identify facial asymmetry via computerized algorithms. Further testing and trials will provide data to refine the AsI.

Mateo Gomez Bedoya

Abstract Name: Supporting high school students' language learning through culturally responsive teaching and funds of knowledge

This project aimed to use funds of knowledge to inform culturally responsive teaching to support high school English learners' language learning. Further, this study was conducted in a suburban high school of 1,500 students and in an English as a second language (ESL) program. The classroom involved 12 students at the entering level. The students came from various Spanish-speaking countries. The primary goal of this research was to focus on content literacy and move them from one Language level to the next one. The study had 4 different theoretical concepts. The first one was using students' cultural and linguistic strengths to make learning meaningful. The second one was teaching language through content with scaffolded instruction. The third one was using academic language like repetitive vocabulary and structures. The fourth one was partnering with families and communities to strengthen support for learners. These theoretical concepts came from Souto-Manning (2010), Jimenez et al. (2015), DelliCarpini and Alonso (2013), Janzen (2008). Equally important, the study focused on a qualitative method and different data sources including: lesson plans with materials (lesson plans, culturally responsive texts, manipulatives, word banks, etc), journals, video and audio recording of classroom discussion, student work samples, and a funds of knowledge survey. The goal of this project was to identify different changes and patterns in students' language that were affected and supported by this teaching approach. They were able to develop their reading skills and made connections with the culturally responsive texts that incorporated historical events, cultural traditions, and professions which were chosen for guided and independent practices throughout the unit. Finally, another conclusion drawn was that after implementing students' funds of knowledge and culturally responsive teaching practices, teacher modeling, helped students understand how to clearly write more complex sentences in English, use repetitive vocabulary, and further their writing skills.

Abstract Name: Alcohol Abstinence Effects on Anxiety-Like Behavior, Drinking Behavior, and BNST in Mice

Alcohol abstinence is associated with increased anxiety-like behavior and neuroadaptive changes in the bed nucleus of the stria terminalis (BNST), a critical region for affective regulation. Past studies demonstrate that females are more likely to drink alcohol and relapse to alleviate psychological distress. This study investigates sex differences during and after alcohol abstinence periods by measuring drinking behavior, anxiety-like behavior and brain activity. Male and female mice underwent a two-bottle choice alcohol paradigm for 6 weeks. The mice had continuous free access to two bottles, one with water, and one with 10% ethanol. The bottles and animals were weighed every 48h to measure how much ethanol they consumed. After the first 6 weeks of drinking, they had a 2-week abstinence period. Next, they were exposed to the novelty suppressed feeding test (NSFT) to measure anxiety-like behavior. The bottles were placed back for 6 weeks, followed by another 2-week abstinence period where the mice were exposed to a stress restraint test and a second NSFT. Ninety minutes after NSFT the animals were perfused, and the brains were harvested. The brains were sliced, and immunohistochemistry was performed for protein expression of C-FOS, a neuronal marker for brain

activity. Next, a water-control cohort underwent the same experimental timeline (i.e., no ethanol exposure). Results showed females consumed more alcohol before and after abstinence compared to males. Drinking was increased post-abstinence compared to pre-abstinence, an effect driven by males. In the second abstinence, the second NSFT showed that history of restraint stress increased anxiety-like behavior in males and not females. Our conclusion is that both females and males are sensitive to abstinence, with females consuming more alcohol and males showing increased anxiety. To determine differences in neuronal activity between males and females, images of the BNST are currently being analyzed for C-FOS expression.

Abstract Name: Principia Scientia et Mathematica de Christvs/Archonos Q-CAS Economic Engine

The present invention relates to a hybrid computational and economic infrastructure system integrating quantum computation, classical processing, photonic signaling, and adaptive distributed consensus. The system enables coordinated computational processes, ledger validation, and autonomous governance functions across heterogeneous hardware types including quantum processors, photonic devices, and conventional computing substrates. The architecture incorporates a quantum-classical autonomous system (Q-CAS) capable of dynamic task allocation, operational continuity, and protocol evolution without full-system interruption. The system further includes a cryptographic token engine, a multi-layer ledger framework, and a scalable communications fabric supporting terrestrial, distributed, and remote deployments. Energy independence modes are supported through compatibility with renewable, off-grid, and emergent power systems. The system is designed to maintain functional integrity across present and future computational paradigms, including post-classical or neuromorphic implementations. This invention provides a generalized platform enabling secure computation, distributed recordkeeping, and self-optimizing operational control. Successor technologies demonstrating substantially equivalent functionality are considered within the scope of the invention.

Abstract Name: Key Predictors of ICE Arrests in 2025

From the start of President Trump's second term, Immigration and Customs Enforcement (ICE) has moved aggressively to restrict immigration activity. These restrictions have led to a dramatic increase in ICE arrests throughout the country. This study investigates the following research question: what are the key predictors of ICE arrests and the percentage growth from 2024 to 2025 across the states? The independent variables in this study are percentage Latino population, seasonal migrant workers, percentage Trump vote, whether or not a state borders Mexico, sanctuary vs. non-sanctuary states, and region. The dependent variables are ICE arrests in 2025 and the percentage growth in ICE arrests from 2024 to 2025 for each state. This study utilizes correlation and multiple regression analyses as well as ANOVA. The findings indicate that percentage Latino population, seasonal migrant workers, and Trump vote were positive and significant predictors of ICE arrests in 2025. Furthermore, the data analysis reveals that states with a higher population of seasonal migrant

workers also experienced significant growth in ICE arrests from 2024 to 2025, while Latino population and Trump vote percentage were not as significant in this area. Interestingly, non-sanctuary states experienced higher arrest rates than those with sanctuary policies in place, contrary to public belief of Trump targeting those states. The ANOVA revealed that the highest ICE arrest rates were evident in the South and lowest in the North Central region. Future research should explore city-level or county-level data, racial attitudes, and socioeconomic factors. The growth in ICE arrests remains a flash point for media coverage, public opinion, and the growing political polarization in the United States.

Abstract Name: You Need Redundancy: Weight Decomposition for Homogeneous Cyclic Monomial Inequalities in Lean 4

Many algebraic inequalities, especially those involving cyclic homogeneous expressions, are typically proved through ad hoc manipulations or some combination of known inequalities, becoming an art of its own. This paper develops a general method for proving such inequalities whose terms are nonnegative monomials by decomposing them into a conic (nonnegative linear) weighted sum of simpler inequalities with unknown scalars; each corresponding to a cyclic rotation of variables. The idea is to enforce a single auxiliary inequality on one rotation of the variables and use the AM-GM inequality to compare monomials. By matching the exponent patterns term by term, we derive a linear system that, if solved, yields the desired inequality. This work is formalized in the Lean4 proof assistant, and code fragments are presented throughout the paper. Formally, each monomial in the auxiliary inequality places a linear constraint on the weights, and the entire set of constraints can be expressed as a matrix equation $M \cdot w = y$. The matrix M encodes how the exponents shift under cyclic rotation, while the vector y represents the exponent combination of the monomial we want to dominate using AM-GM. If this system has a solution with nonnegative entries, then the target cyclic inequality is a nonnegative linear combination of valid auxiliary inequalities, and therefore is itself valid. A key focus of this paper is identifying structural conditions on the matrix M that guarantee the existence of such nonnegative solutions without explicitly computing the weights. This includes invertibility, sign patterns, and positivity-preserving properties. The framework provides a systematic and potentially automatable way to prove entire families of cyclic inequalities.

Abstract Name: Title: Inhibition of MDA5 by the Nodamura virus dsRNA-binding protein B2

Viral RNA sensing by the human protein MDA5 is a key innate immune function in the interferon pathway. The specialized RNA-dependent ATPase is a pattern-associated molecular patterns in the form of viral double-stranded RNA (dsRNA). Activation of MDA5 by viral dsRNA binding leads to transcription of genes encoding type I interferons, responsible for antiviral immunity by coordinating cellular immune responses to

viral infection. Viral genomes encode proteins that inhibit or weaken the type I interferon response pathway by inhibiting RLRs. Here, we aim to identify whether Nodamura virus protein B2 (NoV-B2), a viral dsRNA-binding protein, inhibits MDA5 signaling of the type I interferon response pathway. MDA5 and NoV-B2 were expressed in *E. coli* and purified by affinity and ion exchange chromatography. The RNA-dependent ATPase activity of MDA5 was measured in vitro by the colorimetric Malachite Green Phosphate Assay using poly(I:C) as a viral dsRNA mimic. NoV-B2 was included to determine if it inhibits this function. Future directions of this project include (1) investigating the mechanism of inhibition by making a mutation in NoV-B2 to abolish dsRNA binding, and (2) testing other viral proteins that may inhibit MDA5. Findings of in vitro inhibition of MDA5 by poly(I:C) may indicate an in situ inhibition of MDA5 ultimately contributing to impaired signaling of the type I interferon response pathway during viral infection.

Abstract Name: The Student Network for Amphibian Pathogen Surveillance (SNAPS): Incorporating a citizen science project and independent research into an undergraduate curriculum

The Student Network for Amphibian Pathogen Surveillance (SNAPS) is a North American citizen-science initiative that integrates authentic research experiences into undergraduate education while generating high-value data on wildlife disease. SNAPS supports more than 60 institutions with shared protocols, centralized DNA testing for amphibian pathogens, and pedagogical resources—including lesson plans and attitudinal surveys—to strengthen student learning and engagement. Students collect skin swabs from wild amphibians during coursework or summer research, and samples are screened via qPCR for the fungal pathogens *Batrachochytrium dendrobatidis* (Bd) and *B. salamandrivorans* (Bsal). Faculty at Hampden-Sydney College and Longwood University joined SNAPS in 2023 and have contributed samples from 75 frogs and 6 salamanders collected by students during three courses (Ecology, Wildlife Biology, Conservation Biology) and one summer research project. Although no Bsal detections have occurred at any participating site, 7–10% of our samples within a surveillance period tested Bd-positive. Participation in this large collaborative network has provided faculty and students with experience in an authentic, large-scale research project with conservation significance, streamlined data sharing, and access to essential supplies and high-quality teaching materials. The project has also provided additional summer research in expanded laboratory training and enabled deeper inquiry for selected students. Overall, SNAPS has enhanced curriculum-wide engagement with authentic science practices while broadening opportunities for students to participate in ecological and molecular research. We will continue our participation in SNAPS in our 2026 Ecology course and will expand our summer research programs to include laboratory work on the amphibian microbiome and additional pathogens. We hope that involvement in this citizen-science program will provide all students with hands-on field skills and increase engagement by enabling them to contribute to a broader scientific effort. Students who join the summer projects will gain advanced research experience, including data management, molecular techniques, and scientific communication.

Abstract Name: Impact of Dam Intake Depth on the Outflow water Conditions: A Case Study of Walker Lake, Snyder County, PA.

Lake stratification strongly influences downstream water quality, particularly in reservoirs where discharge depth determines the physical and chemical characteristics of released water. Stratified lakes develop three layers: the warm, oxygen-rich epilimnion; the rapidly cooling metalimnion; and the cold, oxygen-poor hypolimnion. Because each thermal layer contains distinct temperatures, oxygen levels, nutrient loads, and metal concentrations, the depth of water withdrawal plays a major role in shaping downstream ecology. Walker Lake, a reservoir in Snyder County, Pennsylvania, historically released cold, low-oxygen hypolimnetic water, which significantly affected the water quality of Middle Creek. By 2025, management changes shifted the outflow to the epilimnion, resulting in warmer and more oxygenated discharge. Although the effects of dams on water quality are well documented globally, few studies have examined how changes in withdrawal depth within the same lake alter downstream conditions over time. This study evaluates whether Walker Lake's shift from hypolimnetic to epilimnetic discharge from 2018 to 2025 has influenced downstream water quality and biological communities. A multi-metric comparison of upstream and downstream data from both years, including temperature, dissolved oxygen, nutrient and ion concentrations, and benthic macroinvertebrate communities, revealed that the depth of discharge intake does influence conditions in Middle Creek.

Abstract Name: Investigating the Role of Regnase-2 in Glioblastoma Multiforme Tumor Growth Using Astrocyte-Targeted GEARBOCS Knockout

Background: Glioblastoma Multiforme (GBM) is a primary brain cancer, characterized by a unique immunosuppressive tumor microenvironment that promotes chronic neuroinflammation with persistently active pro-inflammatory cytokines that support tumor growth. Members of the Regnase family (Zc3h12A-D) are ribonucleases (RNase) that regulate neuroinflammation by degrading mRNAs encoding pro-inflammatory cytokines. In a healthy brain, Regnase-2 is highly expressed while Regnase-1 shows little expression. Under prolonged neuroinflammation, Regnase-2 expression is downregulated while expression of Regnase-1 is increased. However, Regnase-2's role in GBM is less understood. This project utilizes gene editing in astrocytes based on CRISPR/cas9 system (GEARBOCS) to target and knockout Regnase-2 in astrocytes and evaluate its effect on GBM growth and progression. Methods: gRNAs were designed, ligated into the GEARBOCS vector, and transformed into stbl3 bacteria. Colonies were selected, the plasmids were isolated, purified, and verified via SapI restriction enzyme digestion to confirm gRNAs insertion. Hek293T cells are cultured with complete DMEM and grown to approximately 80% confluency in T175 flasks. Cells are transfected with the generated plasmid and the helper plasmids (php.eb and pΔf) to package the construct into the functional AAV virus. The cells were harvested and lysed to release viral particles. The viral particles were purified using iodixanol gradient, ultracentrifugation, and filtration techniques. The AAV was tested in vitro for Reg-2 knockout efficiency using a western blot. Following verification, the AAV will be delivered retro-orbitally into mice, and effects on tumor growth will be analyzed. Expected Results: We anticipate that GEARBOCS-mediated knockout of Regnase-2 in astrocytes will significantly affect the growth and progression of glioma. Our data should provide evidence that through deletion of Reg-2, increased amounts of its target, Reg-1, will occur specifically in astrocytes. We expect to significantly alter the microenvironment of glioma and thus affect its growth and progression.

Abstract Name: Automated Volumetric Assessment of Hounsfield Units Using a Deep-Reasoning Learning Model: A Validation in Lumbar Vertebrae

Accurate evaluation of spinal bone density is critical for assessing bone health and guiding preoperative planning. Conventional manual approaches to Hounsfield unit (HU) measurement rely on single-slice regions of interest, limiting reproducibility and precision, particularly in patients with severe vertebral deformities. We hypothesized that a novel deep-reasoning and learning model (DR-AI) could fully automate volumetric spinal bone density assessment, providing strong correlations with bone mineral density (BMD) obtained from dual-energy X-ray absorptiometry (DXA), as well as with T- and Z-scores. A cross-sectional study was conducted on patients who underwent lumbar spine BMD assessment and lumbar CT imaging within one year. The DR-AI model was applied to analyze the soft-tissue window of lumbar vertebrae CT scans. Spearman correlation coefficients were calculated to evaluate relationships between volumetric HU values and DXA-derived BMD, T-, and Z-scores for each vertebra. Eighty-four patients met inclusion criteria (67 females, mean age 74.1 ± 10.3 years; 17 males, mean age 68.1 ± 12.4 years). Correlation analyses across L1–L4 demonstrated significant positive associations ($p < 0.0001$), with the strongest correlation observed at L2 between HU and BMD ($\rho = 0.75$). These findings suggest that DR-AI provides a reliable, efficient, and precise method for automated volumetric HU assessment, offering a promising alternative to DXA in spinal bone health evaluation.

Abstract Name: Defining Normal Variation in the Pediatric Spine to Enhance Clinical Decision-Making

The pediatric spine undergoes complex developmental changes, yet defining what constitutes “normal” anatomy remains a challenge due to limited reference datasets and variability across age groups. This study will explore normative spinal features by analyzing pediatric chest, pelvis, and abdomen CT scans obtained for non-spinal indications, leveraging existing imaging to minimize additional radiation exposure. The project aims to characterize vertebral dimensions, alignment, and overall morphology across developmental stages, with findings stratified by age and sex to highlight growth-related trends. While specific analytic methods are still being refined, the overarching goal is to establish baseline parameters that distinguish typical variation from pathology. By providing age-stratified reference values, this work will contribute to improved diagnostic accuracy, inform surgical planning, and support future research in pediatric orthopedics and radiology. More broadly, defining a “normal” pediatric spine through accessible imaging data has the potential to enhance

patient care, reduce uncertainty in clinical decision-making, and create a foundation for multidisciplinary collaboration in understanding pediatric musculoskeletal health.

Abstract Name: Synthesis and characterization of Ni- and Co- Based Catalysts for CO₂ methanation

As the world ramps up its efforts to minimize the impact of carbon emissions, converting CO₂ from industrial flue gas into synthesized methane gas presents a promising method to accomplish this task. Using power-to-gas systems via methanation, efficient reductions are possible allowing for carbon capture and storage of renewable energy. Nickel- and cobalt-based catalysts have demonstrated successful conversion, however, there are limitations. These systems show reduced performance at lower temperatures, uneven metal distribution and catalyst instability. Additionally, the support material and metal-support interactions are not completely understood which impacts the catalytic performance optimization when it comes to the CO₂ methanation. This study focuses on the development of cost-efficient catalytic systems to convert carbon dioxide into synthesized methane gas through the methanation process. Nickel and cobalt catalysts with varying metal loadings were synthesized on silica and zirconia supports via incipient wetness impregnation. The catalysts are characterized by BET surface area analysis, H₂-temperature programmed reduction (TPR), CO₂-temperature programmed desorption (TPD) and transmission electron microscopy (TEM) to assess the effect of support material on metal dispersion, reducibility and interactions between the metal and the support. The influence of metal loading, the surface area of the support and the metal reduction protocol on catalytic activity and stability are examined. The findings of this research will allow the development of the catalytic systems capable of efficiently transforming CO₂ emissions into valuable energy sources. This advancement could significantly contribute to the transition towards repurposing and reduction of industrial combustion products.

Abstract Name: Resiliency and Critical Incident Exposure as Predictors of Police Officer Stress Across City and County Departments

Background/Objectives Police officers experience over 150 critical incidents (i.e., violent crimes, serious accidents) during their careers, compared with only 3-4 for the average person. This repeated exposure contributes to stress, though resiliency can buffer its effects. Less is known about how organizational context interacts with these factors. City and county police departments differ in jurisdiction size, resources, and frequency of critical incidents, which may shape stress experiences. This study examined whether resiliency,

critical incident exposure, and departmental context (city vs. county) are associated with police officer stress. Data were drawn from a Bureau of Justice-funded project (15PBJA-22-GG-00143-BRND). Methods From February 2022 to November 2024, 47 city and 130 county officers from Virginia completed the 10-item Connor-Davidson Resilience Scale-2, the DSSQ-3 State Questionnaire (measuring work disengagement, distress, and worry), and the Critical Incident Exposure Questionnaire. Regression analyses with $p < 0.05$ tested associations. Results The majority of participants were male (county: 78.4%; city: 75%) and aged 40 or under (county: 71%; city: 89%). Work disengagement was significantly associated with resiliency and critical incident exposure, while distress and worry were not. Critical incident exposure explained 4.7% of variance in work disengagement ($p < 0.05$), departmental context (city vs. county) explained 7.4% ($p < 0.05$), and resiliency accounted for the largest share at 14.1% ($p < 0.05$). Together, these factors explained 26.2% of the variance ($p < 0.05$). Conclusion Resiliency, critical incident exposure, and departmental context each predicted work disengagement, with resiliency being the strongest predictor. Officers' departmental setting (city vs. county) also significantly influenced work disengagement, suggesting that organizational structures may shape stress responses. Future research should explore organizational structures, such as workload, resources, and community demand to guide interventions that strengthen resiliency and reduce work disengagement among police officers.

Abstract Name: Disrupting The Mosquito Mind-Body Link: How Proprioceptive Mutations Impair Locomotion and Host Seeking in *Aedes Aegypti*

Mosquitoes pose a substantial threat to human health due to their ability to transmit parasites and viruses including malaria, yellow fever, and dengue. The control of mosquito-borne pathogens has become increasingly difficult as mosquitoes develop increased resistance to popular insecticides. To address this issue, we are investigating a novel class of insecticides (IRAC Group 9) whose effectiveness against mosquito populations is unknown. IRAC Group 9 insecticides include neurotoxins, such as pymetrozine, that disrupt the function of mechanosensory neurons known as chordotonal organ (CO) neurons. CO neurons are critical for hearing, walking, and navigation in a variety of insects. We aim to ascertain how these mechanotoxins disrupt CO neuron function in *Aedes aegypti* and how this disruption may alter mosquito walking behavior and overall fitness. Towards this end, we have developed an assay to compare the walking behavior of wildtype mosquitoes to mosquitoes exposed to pymetrozine. We are also assaying the walking behavior of mosquitoes with genetically ablated CO function via a mutation of the TRPVa ionotropic receptor, a mechanosensory channel responsible for regulating CO neuron activity. We recorded videos of walking mosquitoes via high-cameras. To assess step length, motor coordination, and body position, the mosquitoes' limb positions were tracked frame-by-frame using DeepLabCut, a machine learning algorithm. We find that disrupting CO neuron function, either through pymetrozine exposure or a lack the TRPVa channel, results in slower, less coordinated walking. Our results suggest that CO neurons play a significant role in neuromuscular coordination and targeting these pathways could interfere with the locomotive aspect of host-seeking behavior, pointing towards novel strategies to control the transmission of mosquito-borne diseases.

Abstract Name: Tachycardia Heart Monitor Sensor Abstract

Many energy-limiting conditions, such as POTS, chronic fatigue syndrome, and fibromyalgia, significantly impact quality of life. Heart arrhythmias are common across the U.S., affecting more than 14 million people. Current sensors on the market are expensive, commonly inaccurate, and lack the necessary data for users. The purpose of our project is to develop a rechargeable and wearable heart sensor that can detect tachycardia events. Alongside the sensor, an app companion will be designed to display data from the sensor to the user. The companion app will display up-to-date pulse calculations and will be capable of compiling data into a PDF for the user to print as a report. Our prototype utilizes a PPG sensor connected to an Arduino Nano ESP32 circuit to track voltage readings from the user's bloodstream. The Arduino Nano has internal Bluetooth capabilities, allowing it to transfer voltage values directly to a companion app connected to the cloud. This companion app handles our computations, including any calculations, physically graphing our pulse wave, and utilizes Swift to detect heart arrhythmias such as ventricular tachycardia and atrial fibrillation. In future work, we plan to scale down our circuit; we are currently researching other possible solutions as well. With this scaled-down version of our circuit, we are looking at potentially developing a wearable alternative device that users could utilize to track their cardiac activity at a more affordable price, accurately. We will be implementing a neural network to make our app more personal and adaptive to each user. This will allow us to more accurately detect arrhythmias and fatal cardiac activity since users have varying lifestyles. Additionally, we are developing a template that will import all trends and data for the user to print out as a report for doctors and health professionals.

Abstract Name: Culture, Tradition, and Gender Inequality: A Historical and Religious Analysis of Female Genital Mutilation/Cutting in 21st Century Egyptian Society

Female Genital Mutilation/Cutting (FGM/C) is a form of gender based violence continually perpetuated in Egypt based on religious beliefs and cultural tradition. Deeply entrenched in patriarchal structures, FGM/C is a manifestation of gender inequality permitted to continue by historical and religious societal aspects. This interpretive work identifies social and cultural factors that have aided in defining FGM/C as a religious requirement and allowed for its widespread prevalence. It has been undertaken to better understand the large role Islamic and Christian religions have played in the continuation of the practice. Most Egyptian girls undergo FGM/C on the basis of religion and culture; thus, it is imperative to examine how these factors have evolved and influenced the practice in modern-day society. This reinterpretation aims to contribute to the academic field of history while using literature review and textual analysis to collate source material. Knowledge activities undertaken to produce this interpretive work include detailed reading and close examination of primary and secondary sources, along with sacred texts from the Qur'an and the Bible. The outcome of this work demonstrates how FGM/C has been misconstrued in Islam and Christianity as a practice rooted in and required by such religions. Aspiring to control female sexuality, patriarchal structures in Egypt

have historically created socio-cultural factors hidden under the guise of religion to ensure the practice of FGM/C.

Abstract Name: Rope Sponge Diversity and Health Status in Roatán, Honduras

Sponges play essential roles in Caribbean reefs through filtration, nutrient cycling, and habitat formation, and their abundance has increased where coral cover has declined. Rope sponges such as *Aplysina cauliformis*, *Aplysina fulva*, and *Amphimedon compressa* are common in this region, and two emerging diseases have been reported in the Caribbean. *Aplysina* Red Band Syndrome (ARBS) affects *Aplysina* spp., while Sponge White Patch Disease (SWPD) affects *Amphimedon compressa*. ARBS is characterized by a rust-colored band of necrotic tissue that is later colonized by algae and microorganisms, while SWPD presents as irregular white patches with sharply defined boundaries from the surrounding red tissue. Both conditions can reduce sponge biomass and habitat structure. A paucity of data on rope sponge populations and disease status in Roatán limits the ability to detect and respond to future outbreaks. This study was conducted to assess rope sponge diversity and disease prevalence in Roatán, Honduras. Data were collected from 27 to 30 May 2025, using belt transects (BT) and the Randell–Robertson Marine Survey Technique (RRMST). A total of 220 rope sponges were recorded. The most abundant species were *A. cauliformis* (n = 78), *A. fulva* (n = 48), *Niphates amorphus* (n = 37), *Niphates erecta* (n = 30), and *Amphimedon compressa* (n = 24). Most sponges were healthy (85.9%), but ARBS (3.6%), SWPD (1.8%), physical damage (3.2%), and unknown disease (5.5%) were present. Lesion material from ARBS was identified by microscopy as filamentous cyanobacteria (*Lynxbya sordida*) and red algae, with expert confirmation. Chi-square tests showed that species composition differed significantly among sites for both methodologies. Disease patterns were species-specific: ARBS affected *A. cauliformis* and *A. fulva* (8/126; 6.3%), whereas SWPD occurred only in *Amphimedon compressa* (4/24; 16.7%). These findings confirm the presence of sponge disease in Roatán and provide baseline data for monitoring and reef management in Caribbean reefs.

Abstract Name: Engineering Clean Water: The Pure Water Project

After earthquakes devastated Haiti in 2010, a team of Embry-Riddle students and faculty built and installed a solar-powered water purifier to improve both the environmental and human health concerns created by the lack of infrastructure, clean water, and sanitation. Since then, the group Pure Water Project has installed 10 water purifiers in orphanages, clinics, schools, and community centers in Haiti and the Dominican Republic. The group relies on its partner selection criteria and local contacts to determine the installation site for the purifier. The fall and spring semesters leading up to the installation trip in May are spent designing, building, and testing the purifier. This process incorporates mechanical, electrical, and hydraulic design. The Mechanical Team designs and constructs the purifier frame, including cutting and welding metal, designing 3D printed brackets, and plumbing the PVC system. The Electrical Team designs and wires the electrical box in charge of powering the purifier. The Water and Sanitation Hygiene (WASH) Team develops learning activities to teach the local community personal hygiene practices and help them set up a micro-business to sell purified water. Profits from the micro-business ensure the ongoing maintenance and operation of the system. In May 2025, Pure Water Project students and faculty installed the purifier in Rincón De Yuboa, Dominican Republic, to accomplish the group's overall goal: using engineering principles to provide purified water to areas lacking reliable access to clean water.

Abstract Name: Evaluation of Structure-Property Relationships in Cotton-Bound Photocatalysts for Synthesizing Pharmaceutical Drugs

Traditional synthesis of pharmaceutical drugs relies on the use of toxic metals which poses limitations in sustainability. Currently, homogeneous photocatalysis, which uses light illumination to drive organic reactions, has been shown as a solution. However, the sustainability of reactions with these catalysts is poor as there are challenges with their recovery and reuse. In this work, I propose the development of photocatalyst-bound cotton that will exhibit higher reaction yields, selectivities and effective recovery and reuse in organic syntheses. The photocatalyst-bound cotton is synthesized by covalently attaching molecular photocatalysts to the primary hydroxyl groups on the surface of cotton fabrics. This is done through a two step process. The first being, a silanization reaction to covalently attach (3-aminopropyl)triethoxysilane (APTES) to cotton. In the second step, a nucleophilic acyl substitution reaction between APTES-functionalized cotton and perylene-3,4,9,10-tetracarboxylic dianhydride. These photocatalyst-bound cotton samples will be characterized using colorimetry, a common technique in the textile industry used to quantify color. Furthermore, the applicability of these photocatalysts will be tested through their use in the oxidation of sulfide to a sulfoxide group, a functional group present in many pharmaceuticals. We will use nuclear magnetic resonance spectroscopy (NMR) to monitor the reaction kinetics, yield and selectivity for the sulfide oxidation reaction. With this NMR analysis and the colorimetry results I will merge the textile and chemistry fields to develop a calibration curve to offer an easy comparison between the shade of the photocatalyst and the rate of reaction. In addition, I will investigate how the heterogeneous nature of our photocatalysts will offer ease of recovery and reuse via the separation technique of filtration. Overall, this work will serve as a foundation in the development of low cost textile-bound photocatalysts in sustainable and efficient synthesis which can be applied to pharmaceutical drug syntheses.

Abstract Name: Mapping LEO Satellite Internet Performance Using Mobile Starlink Deployment

High-speed, low-latency internet connectivity on the move is a critical challenge for applications in connected vehicles, disaster response, and remote education. While terrestrial networks such as 4G or 5G are widespread, they lack coverage in remote or rural geographic areas. Low Earth Orbit (LEO) satellite constellations, such as SpaceX's Starlink, promise global high-bandwidth, low-latency internet. However, their performance is well-documented in stationary scenarios, while data for *mobile* applications is scarce. This project explores the feasibility and real-world performance of LEO satellite internet while in motion. To capture real-world data, the team designed and deployed a mobile measurement system by mounting the Starlink satellite on a vehicle. This system captured GPS data simultaneously with connectivity metrics, including upload/download speeds and latency. First, throughput was tested on standard Wi-Fi and 5G mobile hotspots using iperf3 to establish a control group. A Python script using Dash was developed to render collected data as geographic heatmaps, facilitating the identification of spatial performance patterns. Two main tests are in the active collection stage, the first attempting to verify claims by previous studies that Starlink's global scheduler reallocates satellites roughly every 15 seconds. By obtaining RTT times and isolating to the second recorded, we aim to determine the impact this transition has on connectivity. The second main goal is to compare critical connectivity metrics between traditional wireless phone services and Starlink's satellite connectivity. As of now, data on several mobile carriers is being collected in tandem with Starlink data to help determine the feasibility of Starlink over a traditional mobile data plan. Data collection will be expanded to include weather, travel speed, and location type (e.g., urban or rural). At the project's conclusion, we aim to have a clear picture of Starlink's advantages and disadvantages and the contexts in which it is best applied.

Abstract Name: Cherokee Women and the Continuity of Traditional Culture Under Assimilation in the Nineteenth Century

The back-and-forth between attempts to assimilate the Cherokee through "civilizing" programs and pressures for their removal drove major Cherokee cultural change. From early land encroachments before American independence, then U.S. "Civilization" programs with mission schools in the early 1800s, followed by brutal removal policies in the late 1830s, and later policy-based approaches to assimilation in the 1880s. The roles and powers of "traditional" Cherokee women—vital to Cherokee society, culture, spirituality, politics, war, and diplomacy—were increasingly questioned as distinct changes in Cherokee culture started to shift the roles of Cherokee women, starting in the post-American Revolutionary era. Historiographical narratives often describe this period as the beginning of cultural loss and erasure, as well as the loss of Cherokee women's traditional rights, roles, and powers. Other, more contemporary Scholars, such as Robert J. Conley and Theda Perdue, understood the Cherokees' motives for adopting parts of Euro-American governance and religion as demonstrations of resilience, not loss, of culture, against the external threats of settler-colonialism. However,

while it is important to show how Cherokees used and adapted Euro-American teachings to fight for political sovereignty, this paper argues that, while Cherokee women indeed experienced the wrath of Euro-American concepts of womanhood, by reanalyzing historiography and methodological practices and applying them to primary sources, important continuities in women's powers, roles, and traditions in the nineteenth century are revealed. These continuities can be used to recognize strategies employed to maintain traditional culture, as Cherokee resistance was also rooted in the continuation of their own "traditional" cultural practices. Thus, we gain a more complex view of Cherokee culture, its resistance, its persistence, and its reactionary changes to Euro-American assimilation and removal.

Abstract Name: The ontogeny of trabecular bone in the macaque (*Macaca mulatta*) hand

Differences in locomotion among primates have led to observations about their impact on bone composition. Modes of locomotion change throughout the lifetime of the macaque monkey (*Macaca mulatta*), particularly between arboreal juvenile years and terrestrial adulthood, which in turn decreases the variability of hand position and movement between the two age groups. Although there have been studies on how different factors impact bone composition in primates, there is a gap in the study of trabecular bone in Macaques, particularly how directionality of the trabeculae (considered an indicator of loading variability and measured as degree of anisotropy) might change through life. This study assesses the differences in trabecular bone between juvenile and adult Macaque fifth metacarpals, gaining a better understanding of the changes that occur in trabecular bone through ontogeny. Previously microCT scanned bones will be processed and segmented using Dragonfly and FIJI, while isolated volumes of interest for trabecular bone analysis will be segmented in Volume Graphics StudioMax. Permutation tests will be carried out in R Studio to determine the statistical difference between juvenile and adult samples. We predict that degree of anisotropy values in juveniles will be significantly lower (less directional) than in adults, as they engage in more variable hand positions and locomotion. These findings will expand our knowledge on the effects of locomotion and hand position on trabecular bone development in primates and could also be used to draw parallels with humans.

Abstract Name: Effectiveness between two caustic paste brands when disbudding dairy calves

This study aims to evaluate the pain-related behaviors in dairy calves following the application of caustic paste brands when used for disbudding. Although a popular way to disbud dairy calves, the evaluation of pain related behaviors has not been researched. The live animal experiment was completed at a commercial dairy farm using 84 Holstein calves. Calves were managed according to farm protocols and if their passive transfer of immunity was successful (5.5 mg/dL serum total protein), they were enrolled into this study. Treatments include 0.2 or 0.4 mL Dr. Naylor's caustic paste, 0.2 or 0.4 Dr. Larson's caustic paste, or a sham application of petroleum jelly. Individual cameras were focused on each calf above their pen and recorded continuously for

four hours following the application of the treatments. After all live animal work was finished, video recordings were downloaded into Boris (Turin, Italy). An ethogram was developed to monitor signs of pain behavior in dairy calves. This ethogram included the frequency and duration of pain-associated behaviors including head shaking, head rubbing, ear flicking, tail flicking, foot stamping, leg raising, and lying transitions. The collection of this visual data supports the evaluation of pain to determine if differences exist between caustic paste brands. Although we have finished the recording of ethogram based behaviors from the video data, the analysis of this data is ongoing and will be completed by March 2026. Results from this study will provide insight into the welfare implications of dairy calves when using various caustic paste disbudding products. Our conclusions will provide farmers insight into which caustic paste proves to be least painful for dairy calf disbudding.

Abstract Name: Temperament, Archetypes, and Memory Bias: Historical Lineage of Personality Psychology

How is it possible for two people walk the same trail yet remember entirely different worlds, one filled with sunlight and wonder and the other marked by danger and unease? This question has guided a long intellectual tradition aimed at understanding how personality shapes memory. This paper traces the historical development of that inquiry by examining how psychologists from the nineteenth to the twenty-first century conceptualized the relationship between temperament, archetypes, and memory bias. The discussion begins with Wilhelm Wundt, whose structuralist framework proposed that memory is filtered through subjective “mediate experiences” that arise from an individual’s temperament. Wundt’s Two-Axis Theory characterized personality as a combination of emotional strength and changeability, which influenced the aspects of experience that were most likely to be encoded and later recalled. In contrast, American functionalist William James emphasized the practical functions of consciousness. His distinction between the active “I” and the experiential “Me” presented personality as a fluid system of tendencies, in which dominant components of the self influence memory formation. We then explore the significant theoretical shift to psychoanalytic theory, introduced by Carl Jung in the twentieth century. Jung located the source of memory bias not in conscious temperament but in unconscious archetypes. Through dream analysis and cross-cultural comparison, he argued that inherited psychological patterns structure perception and selectively encode memories that align with one’s archetypal orientation. Across these developments, a consistent conclusion emerges. Memory is not a neutral recording device; it is continuously shaped and constrained by personality. By connecting this historical trajectory to contemporary personality psychology like HEXACO and The Big Five, this proposal continues to expand upon these foundational ideas. These findings suggest that future progress will involve identifying the neurological mechanisms that link individual personality to the memories that define subjective experience.

Abstract Name: Consciousness as Computation: Representations under the Lens of the Hard Problem

Why does a perfectly functioning robot, capable of computing its own internal states, fail to experience phenomenology as we humans do? This question frames my inquiry into whether the Computational Theory of Mind (CTM) can illuminate the central mystery of consciousness. I begin by situating CTM within Marr's three levels of analysis, emphasizing how representational architecture enables cognitive systems to encode and transform information. I then connect this framework to philosopher David Lewis' "Mad Pain and Martian Pain," which identifies pain with the physical state that fulfills the appropriate causal role. While Lewis articulates the functional structure of pain, he does not address why these states possess an intrinsic "what it is like" quality. This is the phenomenon philosopher David Chalmers terms the Hard Problem. To deepen this analysis, I examine models that distinguish between first-order representations (encoding sensory input) and higher-order representations (the system representing its own states). This hierarchical framework provides a promising naturalistic entry point for understanding phenomenal consciousness: when a system represents its own processing, it appears to generate a unified, first-person perspective. Finally, I consider how CTM contributes to ongoing debates about the nature of conscious experience. By clarifying the mechanisms through which cognitive systems encode, integrate, and monitor information, CTM offers a framework for theorizing about how subjective perspectives might arise from complex computational organization. While it does not yet provide a complete account of consciousness, it remains a powerful tool for articulating the structural and functional underpinnings of mental life.

Abstract Name: Investigating Gut-Brain Interactions in Alzheimer's Disease Through the Zebrafish Model

Currently, 7 million Americans aged 65 and older are affected by Alzheimer's disease (AD). Despite its prevalence, the underlying causes of AD are still debated, and the need for effective model organisms for studying this disorder is essential. Recent studies have highlighted the potential role of the gut microbiome in neurological diseases through the gut-brain axis. The disruption of the microbiome is thought to be involved in the onset and/or progression of AD. Zebrafish are an effective model for studying the gut-brain axis because they possess both similar brain and gastrointestinal structures to those of humans. Moreover, they possess genes *appa/b* and *mapta/b*, which are homologues with the human genes APP and MAPT associated with AD in humans. Zebrafish, however, have not yet been utilized to study the role of the gut-brain axis and its impact on AD. This study investigates the relationship between gut dysbiosis and AD using zebrafish as a model organism. We hypothesize that gut dysbiosis contributes more significantly to the onset of AD. This study will be conducted by (1) chemically inducing AD in zebrafish before inducing gut dysbiosis and (2) inducing gut dysbiosis before chemically inducing AD. Behavioral assessments will be performed to measure cognitive decline, and molecular analyses will be used to assess changes in AD-related genes. This study aims to confirm the zebrafish as a successful model organism for studying gut-brain interactions in AD, as well as to further elucidate the role the microbiome plays in the progression or onset of AD.

Abstract Name: A Targeted Prosociality Intervention for Previously Incarcerated Populations

Personality interventions for recidivism and re-offense continue to be scarce, with many interventions focusing on clinical counseling or forms of punishment. However, prior research shows the importance of prosocial behavior in personality change models, which could be of use in reducing the well-known link between negative personality traits (e.g., Dark Triad) and (re)offending. In a single six-wave longitudinal study, we examined the effect of a set of prosocial behavioral tasks (e.g., holding the door for someone) and the motivations to change on shifts in Dark Triad traits in previously incarcerated individuals (N = 245; control n = 84; experimental n = 161). When comparing changes in self-reported personality traits between the experimental group and a control group, results from the study found that, within the experimental group, participants reporting higher motivation to change their “darker” personality traits had significantly lower Dark Triad scores compared to their scores at the study’s onset. This study gives promising preliminary evidence for a low-cost behavioral intervention to support the reduction of antisocial traits which contribute to recidivism rates.

Abstract Name: : Identification and gene expression analysis of Auxin Biosynthetic Pathway genes in Duckweed (*S. polyrhiza*)

Plant growth development is an important phase of a plant’s life and studies are crucial to determine the environmental factors impacting the growth responses. Auxin, mainly Indole-3-acetic acid (IAA)- the predominant naturally occurring auxin, is an important plant hormone and has been widely identified for its role in plant growth and development. While IAA biosynthesis is well characterized in higher plants, there is no information available in aquatic plants. In this project, we aimed to identify the genes involved in auxin (IAA) biosynthesis pathway and quantify the gene expression of auxin (IAA) biosynthesis encoding genes in growth and/or stress conditions. IAA is mainly biosynthesized from tryptophan by two sequential enzymatic reactions consisting of TRYPTOPHAN AMINOTRANSFERASE of ARABIDOPSIS 1 (TAA1) and YUCCA (YUC) of the indole-3-pyruvic acid (IPA) pathway. TAA1 converts Tryptophan to IPA, and YUC catalyzes the oxidative decarboxylation of IPA to produce IAA in the IPA pathway. In duckweed genome, three TAA gene homologues are present-SpTAA1, SpTAA2 and SpTAA3. Further, we have characterized the gene expression of these three gene homologues-SpTAA1-3 in copper induced growth inhibited model. Our results indicate that the genes encoding for Auxin biosynthesis pathway are present in duckweed plants and their gene expression indicates the functionality of this pathway.

Abstract Name: IoT Powered Multi-Agent Machine Learning Testbed for Cybersecurity Research

The evolving field of generative Artificial Intelligence (AI) poses unprecedented cybersecurity risks and attack vectors in Internet of Things (IoT) applications. To explore and combat these new risks, this research developed a physical testbed, which is equipped with a Multi-Agent Machine Learning Framework powered by IoT devices. These IoT devices are Raspberry PI modules that can collect sensor data and act as Machine Learning (ML) agents that execute on-device ML models. The testbed also hosts a main server that retrieves data from the ML agents' outcomes and can be intentionally infected to simulate a cyber-attack by native generative AI models such as Generative Adversarial Networks (GANs) and Autoencoders. The goal of this research is to utilize this testbed to analyze the cybersecurity risks that arise with possible new AI-driven attack vectors on outcomes of the ML agents. Therefore, on top of the developed testbed, an IoT-based industry lab safety application is implemented and tested. Each of the ML Agents contains a program that retrieves data from sensors such as CO, temperature, and humidity data, which is then evaluated with the respective on-device ML model to classify lab environment safety measures from 0 to 3 labels. In particular, random forest and linear regression models are alternatively implemented in each IoT agent to analyze the sensor data and return lab environment safety labels. This information is then transmitted to the compromised main server. This application of the testbed simulates an infected network and creates an ideal sandbox for testing and analyzing the hazards and vulnerabilities proposed by these proprietary methods of generative AI cyber-attacks. Experimental results show that the autoencoder can recreate the ML agents' outputs with very high precision, with an average data loss of approximately $1.0325e-10$, indicating an almost perfect reconstruction of the original outcomes and higher risk of attacks.

Abstract Name: Harnessing Like-Charge Interactions: Lipid-Functionalized Gold Nanoparticles for Bacterial Inactivation

Bacterial infections pose a significant global health challenge, necessitating innovative treatment strategies beyond conventional antibiotics, especially as antibiotic resistance increases. This study explores the development of an inactivation approach for *Staphylococcus epidermidis* (*S. epidermidis*) utilizing lipid-coated gold nanoparticles (AuNPs). Unlike traditional antibacterial methods that rely on uncontrolled inactivation mechanisms and contribute to antibiotic resistance, this strategy employs biomimetic lipid encapsulation to enhance specificity and minimize cytotoxicity. Lipid-coated AuNPs were synthesized and characterized for stability, surface properties, and antibacterial performance. The lipid membrane consisted of varying concentrations of DOPS, a negatively charged lipid. Characterization revealed that AuNPs functionalized with DOPS exhibited a pronounced negative surface charge of approximately -35 mV, improving biocompatibility in biological media due to electrostatic similarity with cell membranes. Binding trials demonstrated strong like-charge interactions mediated by monovalent counterions, resulting in immobilization of the AuNPs on the surface of *S. epidermidis*. This phenomenon was not attributed to

bacteria-specific binding, as similar results were observed when trials were repeated using negatively charged polystyrene beads with similar dimensions to those of *S. epidermidis*. Future directions include leveraging the photothermal properties of gold in conjunction with charge-based targeting, enabling localized heating to damage bacterial membranes while reducing cytotoxicity and improving efficiency. Additionally, this approach could be adapted to incorporate increasingly biomimetic AuNPs and broaden its application to diverse pathogens, given its reliance on electrostatic interactions rather than membrane-specific binding.

Abstract Name: Understanding the Role of Wild Suids in *Mycobacterium bovis* Transmission in Multi-host Systems: A Systematic Review

Mycobacterium bovis is the main cause of animal tuberculosis in livestock and wildlife, which can also infect humans causing zoonotic tuberculosis. The issue surrounding this mycobacterium lies with spread and control of animal tuberculosis at the wildlife, livestock, and human interface, presenting a global economic and public health challenge. Maintenance hosts are species that sustain a pathogen in an area regardless of whether there are other species present that can disseminate the pathogen. Wild suids (i.e., wild boar [*Sus scrofa*] natively and invasive wild pigs [*S. scrofa* x *domesticus*] elsewhere) serve as *M. bovis* maintenance hosts. A thorough understanding of the factors promoting maintenance host status is necessary to improve disease control. In this study, we aim to define the epidemiological, ecological, and behavioral factors that promote wild suids as maintenance hosts for *M. bovis* transmission. We conducted a systematic review, following the Preferred Reporting Items of Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines and utilizing the Population, Exposure, Comparison, and Outcome (PECO) search method for determining keywords. These keywords were used to systematically pull references from several databases. A total of 1,517 references were identified through our initial search. Utilizing Rayyan, duplicates (n=551) were removed from the literature collected, leaving a total of n=1,219. Once initial abstract screening was complete, n=127 references were left. Of these, 88 met the inclusion criteria and were included for analysis. We identified 42 variables of interest in these references divided into the following categories: Diagnostics, Demographic, Behavioral, Environmental, Ecological, and Epidemiological. A meta-analysis is being performed to determine the risk factors underlying *M. bovis* infection (based on prevalence) in wild pig populations stratified by diagnostic test used. This study will allow us to address *M. bovis* transmission in wild suid populations globally, informing guidelines applicable to different regions for efficient prevention and control.

Abstract Name: El Lissitzky and His Impact on Design

This essay will examine El Lissitzky's contributions to the art and design field, and how he dove deeper into the possibilities of using design for visual communication in post-revolutionary Russia. From the struggles as a Jewish artist facing discrimination to later making collaborations with avant-garde artists from all over Europe, El Lissitzky shows a modern design that is founded through geometric shapes, abstraction, functionality, and social purpose. His most popular piece is the Prouns series, which bridged the gap between architecture and painting and was a turning point to him becoming the lead figure of Constructivism. Today, his influence and signature pieces continue to inspire designers in all aspects of design. By pioneering a new relationship between art, society, and technology, Lissitzky played a crucial role in shaping the visual systems that define modernity.

Abstract Name: Fractional Vertex Cover Reliability of Graphs

A graph is a collection of objects, called vertices, where if two vertices are related to each other there is an edge connecting them. Let G be a graph and let $0 \leq p, q$ and $p + q \leq 1$. Suppose that each vertex of G gets a weight of 1 with probability p , $1/2$ with probability q , and 0 with probability $1 - p - q$, and vertex weight probabilities are independent. The fractional vertex cover reliability of G , denoted by $FRel(G; p, q)$, is the probability that the sum of weights at the end-vertices of every edge in G is at least 1. In our research, we first constructed various computational formulas for $FRel(G; p, q)$ considering general graphs, basic graphs and graph operations. Secondly, we determined the graphs which maximize $FRel(G; p, q)$ for all values of p and q in the classes of trees, connected unicyclic and bicyclic graphs with fixed order, and determined the graphs which minimize it in the classes of trees, connected unicyclic graphs with fixed order. Our results on optimal graphs extend some known results in the literature about independent sets, and the tools we developed have potential to solve the optimality problem in other classes of graphs as well.

Abstract Name: “Show Me the Incentives and I Will Show You the Results” Ethics, Economics, and Ecology in AI Usage

The economic impacts of AI have been long since researched, as well as the ecological detriment this new technology brings. However, with the United States stock market investing so heavily in this new technology, it begs the question: how can AI be used ethically? If it is contributing to the problem of climate change, can it also be a solution? What are the incentives needed to change the results? This essay will examine a more ethical usage of AI with respect to climate change, and how economics can be used to incentivize this.

Abstract Name: Exercise Expectations: Can the Placebo Effect Boost Exercise’s Effects on Mood and Cognition?

A single session of aerobic exercise can improve mood and cognitive function. However, little is known about whether expecting exercise to enhance brain function can influence these outcomes. The purpose of this study was to examine whether psychological expectations about exercise benefits can amplify changes in mood and cognition beyond the physiological effects of exercise itself. Twenty-three full-time undergraduate students (mean age=20.7±0.9 years; 70% female) were randomly assigned to either an Expectation–Benefit (n=11) or Control (n=12) condition using a between groups pre-test/post-test experimental design. All participants completed a pre-test battery including a visual analog scale of expectancy and familiarity with the brain benefits of exercise, the Abbreviated Profile of Mood States (POMS), and a flanker task to assess inhibitory control. Participants then viewed one of two short videos: either a brief educational video describing how exercise enhances brain function (Expectation-Benefit), or an unrelated video on volcanoes (Control). All participants then completed a 25-minute moderate-intensity treadmill walk, maintaining 60–70% of their age-predicted maximum heart rate. Post-test measures were identical to pre-test. Data collection is ongoing (target N=40), and planned analyses include repeated measures ANOVAs to compare pre- and post-test scores between groups for expectancy and familiarity scores, POMS domain scores, and flanker task accuracy and reaction time. Results from this study may provide valuable information about the ways in which expectations about exercise’s benefits can be leveraged to improve mood and/or cognitive performance.

Abstract Name: Living Histories: Curating the Continued Negative Health Effects of 9/11 at the 9/11 Museum

The 9/11 Museum's rotating exhibition space has displayed the exhibition, “Dust: Illness and Advocacy after 9/11,” since 2023. It tells the story of the health effects and healthcare advocacy battles that began to surface post-9/11. This exhibition shows that the 9/11 Museum—a contemporary history museum—does not treat 9/11

as an event of the past but as an ongoing history. How, then, do contemporary history museums and their curators tell histories anchored in the present? To break apart this exhibition and clearly analyze what it tells us about memorial museums, I apply what Amy Sodaro suggests are the three main criteria to look for when discussing memorial museums. First, the museum function. This refers to the museum's ability to use objects, ephemera, and personal accounts to show the history to an audience. Second, the memorial function. This determines how well the institution provides the audience with a space to grieve and remember those affected by the event. Finally, the ability to communicate “never again” to an audience. This criterion is important given that many memorial museums are founded with this message of education and moral learning at their core. How can an ongoing history represent the idea of “never again”? By looking at this exhibition through this lens, I found that, though the exhibition works in the museum as an educational tool, it lacks the distance from the event to truly become a memorial. Something that is still happening cannot be memorialized. “Never again” cannot be applied. My research proves that contemporary histories require a new set of curatorial methods to represent the ongoing as well as the recent past. Furthermore, it opens up a discussion on how to present living, current histories that project into the future.

Abstract Name: Pathways and Career Explorations in STEM (PaCES): Advancing Equity and Persistence for Community College Students

The Pathways and Career Explorations in STEM (PaCES) program was a collaborative initiative between Los Angeles Valley College (LAVC), Los Angeles Pierce College (LAPC), and the University of Southern California (USC). PaCES addressed persistent equity gaps in STEM by improving retention and transfer rates among community college students, with a focus on Biology majors. Over three years, PaCES engaged 176 students through a two-tiered structure combining academic coaching, mentorship, and experiential learning. Tier 1 emphasized academic support and exposure to diverse STEM careers, while Tier 2 provided immersive research experiences at USC’s Wrigley Institute and courses designed to strengthen STEM networks and prepare students for competitive internships and transfer applications. Guided by two research questions: what factors influence STEM persistence and how to enhance educational experiences at two-year institutions. PaCES implemented evidence-based interventions, including early research opportunities, faculty and near-peer mentorship, and community-building activities. Mixed-methods evaluation (pre/post surveys and focus groups) informed iterative improvements and contributed to broader educational research. Program outcomes demonstrated significant impact: 71% of participants earned STEM degrees, two-thirds transferred to four-year institutions, and 8% enrolled in graduate programs. Post-program engagement remained high: over 35% of participants worked in scientific laboratories, 86% attended or presented at scientific conferences, and at least 34% participated in community outreach, including mentoring and volunteering at schools and museums. Additionally, 38% completed summer internships or research experiences, further solidifying their commitment to STEM. PaCES also established sustainable academic structures, including workshops and new for-credit courses, and strengthened institutional partnerships to expand access to STEM resources. By fostering persistence and success, PaCES offered a replicable model for community colleges nationwide. Its long-term impact extends beyond individual achievement, contributing to a more inclusive STEM workforce and advancing strategies to support diverse learners in higher education.

Abstract Name: Anticoagulants Safety In The Geriatric Population

The earth's population is currently shifting towards a demographic that includes an increased number of geriatric citizens. With this influx of elderly citizens, we have yet to see an increase in the research that surrounds their care. Anticoagulants are among the most commonly prescribed medications within this age group; however, their overall effect on both the health and safety of this community is less understood. This study investigates the frequency and type of adverse events patients suffer from while being on or recently discontinued from anticoagulant medications. In order to study this population, patient data were selected and blinded from Careline Health group's patient population. Charts were then divided into those discontinued from anticoagulants and those who remain on them within a six-month time frame. Information such as indication for use, type of medication, patient sex, and patient gender were also collected as variables within the data set. From here, we performed various odds-ratio tests for significance while comparing different variables from our data. Through this, we determined if patients who remain on anticoagulants experience significantly more adverse events than those who are discontinued from them. Following statistical testing, we found no significance between being discontinued from anticoagulants and a decrease in adverse events; however, results showed that being discontinued from an anticoagulant medication made patients five times less likely to suffer significant injury from a fall. This study provides critical information about the safety of anticoagulant medications within the geriatric population. Knowledge of this nature could allow future physicians to make more informed recommendations about one of the most administered medications for this age group. If we want to adjust and grow our understanding of the fastest-growing demographic within our society, studies such as this will edge us closer to achieving that goal.

Abstract Name: Aid or Ailment: The Effect of Foreign Aid on Sub-Saharan African Democracies

After a period of democratization in the 1990s, many Sub-Saharan African states have experienced democratic backsliding. Scholars have debated the causes of this trend, from both internal and external standpoints, with no clear consensus emerging. In this study, I contribute to this debate by arguing that 1) "distracted" international donors and 2) increased foreign aid allocation lead to democratic backsliding. Following the end of the Cold War, donors focused on democratization; however, after September 11, 2001, donor priorities shifted away from democratization, and illiberal actors utilized the "moral hazard" to misuse increased aid to consolidate power. It was expected that democratic backsliding would emerge as donors became distracted after 2001 and increased aid to the region. To test this hypothesis, this study used Freedom House, V-Dem's five high principles and clientelism as measures of democracy and Official Development Assistance to measure foreign aid. The study was broken into two time periods of 1990-2001 and 2002-2019 to reflect donor distraction. Linear regressions were run on all three of the dependent variables for the forty-nine countries in the region. The results suggest that the proposed theory is largely unsupported, with only a minor effect observed on the outcomes. Specifically, the evidence from this study does not support the claim that increased aid causes democratic backsliding. However, minor negative effects of distractedness on Freedom House rankings and V-Dem scores suggest that the predicted effect of distracted donors is somewhat supported. Nonetheless, minor R² values for all variables indicate that the explanatory capacity of the proposed theory is limited at best.

Abstract Name: "One of Everything": A technosignature search of the Exotica Catalog with the Allen Telescope Array

The Search for Extraterrestrial Intelligence (SETI) is a sub-field of astrobiology which searches for technologically-capable life in the universe. Some "technosignature" searches have focused on traditional astrobiological targets of Sun-like stars or Earth-like exoplanets, but it is also important to cast a wide net to search for "life as we don't know it". Breakthrough Listen's "One of Everything" Exotica Catalog helps us define this wider net of targets. We present an observing campaign of the approximately 648 observable targets in the Catalog, which spans from solar system objects to large cosmological structures. This novel exploratory search, focusing on bands 1.000-1.672 GHz, 1.672-2.344 GHz, 4.200-4.872 GHz, and 8.000-8.672 GHz, is conducted using 28 of the Allen Telescope Array's 42 6.1m dishes at Hat Creek Radio Observatory. By broadening our search for extraterrestrial intelligence with this "One of Everything" catalog, we hope to set the stage for future science and SETI projects and set strong upper limits of some of the most extreme and understudied environments in our universe.

Abstract Name: The Health Hut & Henry: Making Complex Medical Information Accessible

The complexities of medical and public health information make visual communication a vital tool for communicating clearly and effectively to diverse audiences, regardless of language or educational differences. This poster describes the illustrative process and development of an educational campaign for The Health Hut of Ruston, a free clinic that serves residents throughout Lincoln Parish. The Health Hut serves a population of non-native English speakers and people with little or no health insurance. The language barriers and, in some cases, the limitations in education, provide an opportunity for a partnership between Louisiana Tech University's VISTA Center and the staff at the Health Hut to create more personalized and meaningful medical educational materials. Through client consultation and review by providers and patients, four handouts were created with information about blood pressure, blood sugar, nutrition, and counseling services, each offering vital basic health information and ways to connect with the Health Hut. In addition, through the creation of the materials, a mascot was born: Henry the Health Hut Helper. Henry provides a secondary opportunity to communicate with the community as a character readily identifiable to Health Hut patients, helping humanize the brand and make health care more approachable. The creation of the Health Hut's illustrative campaign and mascot advertised affordable healthcare options and crucial health education information. Ultimately, this collaboration between Louisiana Tech University's VISTA Center and the Health

Hut not only allowed students to give back to the community by enhancing public health communication for underserved populations but also provided them with invaluable professional, real-world experience in using design to have a meaningful social impact.

Abstract Name: Project Henry: Making Complex Medical Information Accessible

Given the complexities of most medical and public health information, visuals have become a vital tool for communicating important health information clearly and effectively to diverse audiences, regardless of language or educational differences. This poster is a deep dive into the illustrative process and development of the poster Campaign for a local medical Non-Profit, The Health Hut of Ruston. The Health Hut is a free clinic in Ruston, LA that serves a population of non-native English speakers and people who have little or no health insurance, making it difficult for them to afford routine primary care providers. The language barriers and, in some cases, the limitations in education, provide an opportunity for a partnership between Louisiana Tech University's VISTA Center and the staff at the Health Hut to create more personalized and meaningful medical educational materials. Through client consultation and review by patients, four handouts were created with information about blood pressure, blood sugar, nutrition, and counseling services, each offering vital basic health information about each subject and a route of connection to the health hut to learn more. In addition, through the creation of the materials, a mascot was born. Henry, the Health Hut Mascot, provided a secondary opportunity as a character readily identifiable to the patients at the Health Hut, helping humanize the Health Hut brand, which can clear many negative stereotypes and fears associated with the medical field. The creation of the Health Hut's illustrative campaign and Mascot, advertised affordable healthcare options and crucial health educational information. These concerns are most prevalent in specific requests made by clients to improve the readability and approachability of the pieces, using calmer colors, larger typefaces, and even constructing a mascot to make the poster campaign more friendly and welcoming to the community.

Abstract Name: The Effect of Wastewater Sources and Thermal Hydrolysis Pretreatment on Biomethane Yield in Anaerobic Digestion

Anaerobic digestion is a process that breaks down organic waste without oxygen to produce biogas, a renewable energy source primarily composed of methane. Because methane yield varies depending on waste type and treatment, improving production reliability is critical for sustainable energy applications. This in-progress study compares methane and total biogas production from two different wastewater sources and evaluates how yields change after thermal hydrolysis pretreatment (THP), a heat-based method that breaks down complex waste structures before digestion. A microbial inoculum-only control was included to provide a baseline for gas production and composition without wastewater feedstock. This means the inoculum control contained only the methane-producing microbes and no added wastewater, allowing us to measure how much gas those microbes produce on their own for comparison. Wastewater samples were collected, homogenized for consistency, and added into batch anaerobic digesters inoculated with mixed microbial cultures. Digesters were maintained at 37 °C, a common moderate temperature used in real-world biogas systems. Gas collection systems enabled daily measurement of cumulative biogas volume, while methane concentration and organic breakdown were tracked over 45 days. All other experimental conditions were held constant to isolate the effects of water source and THP. Results show that both wastewater source and THP influence methane and gas production. THP increased total biogas output for both sources, indicating improved waste accessibility for microbes. The inoculum-only control produced the lowest gas volume but the highest methane proportion, highlighting that pretreatment and feedstock affect both gas quantity and composition. These trends suggest THP is a promising method for improving wastewater-to-energy systems, though optimization may need to be source-specific. Future work will refine methane quantification and test THP intensity to further enhance biomethane reliability for scalable energy production.

Abstract Name: The Relationship Between Stigma and Help-Seeking Intention: How Masculinity and Social Support Affect the Likelihood of Reaching Out

Recent data indicates over 65% of college students are reporting poor mental health negatively affecting their academic performance on a weekly basis. Yet, the number of students who seek care has not been rising at the same rate. Emerging adulthood is a pivotal period where one's concept of self, including concepts of gender norms, evolve independently from parental guidance. Exposure to new people can build a larger social circle, but can also increase exposure to negative public stigma. Masculinity can reduce help seeking behaviors, but buffer social support. However, there has been a lack of research on social support and masculinity post COVID-19. COVID stopped the socialization of most adolescents over 2020-2021. As a result, the way young adults perceive self-stigma within their social circles could have changed, but this has not been fully

explored despite how prevalent the shift is. The aim of this project is to address these gaps by examining the relationship between self-stigma and help-seeking behaviors alongside masculinity, in a post-COVID sample. Sample size is projected to be ~400. College students will complete a web-based survey measuring stigma, masculinity, social support, and mental health intention. We will utilize simple linear regression to examine the relationship between self-stigma and mental health help-seeking intention. Subsequently, we will run two moderation models to examine the buffering role of perceived social support and a hypothesized enhancing effect of masculinity. We hypothesize that higher self-stigma will predict lower help-seeking intention. Furthermore, we hypothesize that masculinity enhances this relationship, while social support will act as a buffer. This research will improve our ability to better understand factors influencing help-seeking and create personalized outreach for individuals who may be unlikely to seek help due to masculinity intrapersonal barriers. Results will also inform future directions for researchers and interventionists.

Abstract Name: An Exploration of Non-Voting Behaviors among Gen Z Consumers: Beyond the Impact of Social Media

Generation Z is one of the most politically aware yet under-engaged demographics in the U.S. Despite strong social media use and interest in social issues, about half (53%) of Generation Z voters did not participate in the 2024 U.S. presidential election (CIRCLE, 2005). While research often examines how social media mobilizes voters, less is known about how it discourages participation. This study explores factors contributing to non-voting among eligible Generation Z individuals, including social, societal, and systemic influences, as well as feelings of helplessness, lack of control, and limited knowledge about voting procedures. Results show that non-voting was strongly associated with feelings of helplessness and distrust in the electoral system, with 61% of respondents feeling their vote did not matter and 57% viewing the system as unfair. The study highlights how social media and systemic factors shape disengagement and suggests strategies to boost political participation among young voters.

Abstract Name: Exploring Geochemistry of Pseudotachylyte in the Homestake Shear Zone to Test the Utility of Handheld XRF in the Field

In this field study, handheld XRF was utilized to compare the geochemistry of two contrasting pseudotachylyte domains in the Homestake Shear Zone (HSZ), Colorado. Pseudotachylyte is a deformational product of frictional flash melting, yielding cm-thick, black glassy veins that cool in 10s of seconds along fault surfaces during earthquake slip. The melt matrix is chemically dominated by preferential melting of low-silica mafic minerals in the host rock; quartz (SiO₂) has a high melting point and survives as micron to

mm-scale, fractured clasts. Low silica and high FeO/ SiO₂ ratios are directly proportional to low melt viscosity, which could help lubricate faults and influence slip. To test this, we used handheld X-ray fluorescence (XRF) in the field with an analytical spot size of ~8 mm to collect FeO and SiO₂ content for host rock and pseudotachylyte in two contrasting domains (d1 & d2) with different host-rock structure. Since quartz clasts positively skew silica values relative to the more mafic matrix, we used WDS spectroscopy on an electron microprobe (EPMA) at Concord University to determine chemistry of 10-micron spots within the matrix in order to exclude unmelted quartz clasts to better reflect melt composition. The results of XRF vs. EPMA analyses normalized to 100% for SiO₂ and FeO show d1 pseudotachylyte has 92.1% vs. 89.9 SiO₂, (n= 55, 100), whereas d2 pseudotachylyte has 86.4% vs. 91.9% SiO₂, (n=53, 146). Pseudotachylyte XRF data showed d1 with an FeO/SiO₂ ratio of 0.086 and d2 with 0.157. EPMA results record d1 having a FeO/SiO₂ ratio of 0.112 and d2 with a ratio of 0.088. Within error, XRF and EPMA data are comparable, suggesting handheld XRF may have utility for obtaining field geochemical analyses from cm-scale pseudotachylyte. Ongoing work will further refine the model with additional EPMA analyses.

Abstract Name: LISA: The Design and Future of Collaborative Statistical Analysis

LISA: The Laboratory for Interdisciplinary Statistical Analysis is a worldwide network of statistical collaboration labs started by Dr. Eric Vance. Despite being such a widely used field in academia, statistics is often not taught to students and researchers in depth or specified well enough to be used with the precision it could be. Ignoring common errors or simple misconceptions, domain experts often don't have the bandwidth to have intimate knowledge of their domain as well as the best statistical processes that could be used in their research. By introducing a statistical collaborator, the research capacity for individual labs as well as the manpower required decreases, and the quality of the data science done skyrockets. It was this idea that sparked the initial LISA, then spread it across the world. The point of the labs is threefold: to provide research infrastructure to the local community, to improve community statistical literacy, and to teach the next generation of statisticians and data scientists as collaborators. To do this, the network of labs relies on community, student and staff engagement, donor and university funding, as well as the support and research from other labs. Getting this often is easier said than done: budget cuts, funding, staffing issues have all corroded the longevity and sustainability of LISA branches. The objective of the LISA project is to compile the findings and data of a variety of different LISA-centered projects into a cohesive report to support the sustainability of the existing labs, streamline the effectiveness of their pillars, and show how statistical collaboration is integral to the community at large.

Abstract Name: Investigating Missense Mutation Y189C of PSEN1 and Describing its Association with Acne Inversa

Acne inversa (also called hidradenitis suppurativa) is a chronic inflammatory condition that affects the skin. This disorder causes recurring abscesses to develop on the skin and will typically rupture, heal, and reform. Mutations in the PSEN1 gene have been linked to causing familial acne inversa. The PSEN1 gene encodes for the presenilin-1 protein, which is part of the gamma-secretase complex. If the Notch signaling pathway is disrupted due to a variant in PSEN1, acne inversa could occur. This study discusses a missense amino acid swap in the PSEN1 gene that could contribute to the development of acne inversa. A change in protein structure and function caused by pathogenic variants in PSEN1 is expected. A variant of unknown significance (VUS) was selected by analyzing genomic data from gnomAD. The VUS was found on amino acid position 189, with a swap from Tyrosine (polar) to Cysteine (nonpolar). This swap is also at the end of an alpha helix outside of the transmembrane region, which could cause a change in structure and function of PSEN1. In silico programs were used to predict the pathogenicity of variant Y189C. A Molecular Dynamics Simulation (MDS) was also conducted to compare the movement of the transmembrane protein for the native and variant.

Abstract Name: topological Feature Extraction on Clinical Images: Methods and Performance

Machine learning and deep learning methods have become standard options to apply for image processing applications to determine features from clinical images for classification algorithms. The black box nature of deep learning, however, presents obstacles in clinical use. Lacking clarity in the features being measured produces discomfort and uncertainty for medical professionals who utilize these processes and their findings. There is also a loss in information about the context of the features. Utilizing topological methods, we can observe the global structure of the data while producing features, preserving contextual information to aid clinicians in determining the formation or changes of the features. Through the technique of persistent homology, we observe the longevity of features, providing information on their stability and prevalence. These features and the information about them can then be worked with to perform feature analysis, both to describe the data for clinical understanding, and to be applied back to enhance deep learning techniques such as attention models. We analyze how meaningful the extracted features are, linking them to conceptual features and demonstrating their performance when used within classical machine learning models. Through presenting the extraction of salient features and displaying their performance when used in classification tasks on clinical images, we introduce a viable path for feature mapping other than deep learning methods. We explore methods and parameters in topological data analysis and their effects on feature performance. Additionally, we demonstrate the clarity preserved through these methods of feature extraction.

Abstract Name: Call Their Names: The Radical Activism of the Black Quilting Tradition and the AIDS Crisis

Socio-economic violence in the United States has left historically marginalized groups, particularly Black Americans living in inner cities, at an increased risk of infection and disease. From the violent overthrow of Reconstruction onward, social policy in the United States has continuously fought to undermine African

American communities by severely limiting resources not only for work and education but also for safe housing and medical services that include access to proper health care and disease prevention. This research project explores how the initial HIV/AIDS epidemic in the 1980s severely impacted inner-city Black communities due to socioeconomic issues created by historic anti-Black violence and oppression (employment, housing, medical discrimination) from the time of Reconstruction onward, and how this violence led large groups of Black Americans to be more vulnerable to infectious disease outbreaks. By deeply exploring the power of African American tradition and memory, specifically how Black Americans have utilized their knowledge of their history of triumph and tragedy and their talent for artistic expression to protest injustice in the present, this research aims to amplify the voices of African American allies and activists who used the art of quilting to claim as their own and humanize Black individuals who have died and/or are suffering from HIV/AIDS. By studying the art of quilting from exhibits around the country, the National AIDS archives in Washington D.C., numerous interviews with leading AIDS activists, and numerous oral history accounts of the Black quilting tradition, I hope to add to the scholarly discourse on HIV/AIDS awareness within Black communities and how quilting as an artistic form of expression and historical legacy of the Black experience has been a powerful form of activism, and continues to be used to create meaningful impact within the Black Lives Matter movement.

Abstract Name: Analyzing Kinematic Data with Machine Learning to Detect Injuries in Swimmers

Overuse shoulder injuries are among the most prominent injuries in collegiate-level swimmers. The high training volume, combined with the repetition and frequency of the overhead motion in a swim stroke puts the shoulder under an immense amount of biomechanical stress, degrading the joint over time. Some of the most common injuries include rotator cuff impingement, tendinitis, or labrum tears. These injuries are often rooted in issues of muscular imbalances, improper stroke technique, and excessive joint laxity. Tracking and identifying these tendencies can potentially reduce the number of injuries from swimming. Existing methods which track biomechanical movements in water struggle to obtain accurate data. They rely heavily on coach observation or above-water motion capture, both of which lack precision and real-time feedback underwater. Camera systems are expensive, difficult to calibrate, experience delayed data tracking, and are unable to track motions underwater due to glare and water distortion. To resolve these challenges, our system utilizes waterproof inertial measurement sensors, allowing for the ability to accurately and consistently capture underwater motion in real time. This study will incorporate machine learning techniques to transform raw motion data into accurate, predicative insights regarding athlete performance and injury risk. Machine learning is the use of artificial intelligence to create statistical algorithms by analyzing given data sets, with the ability to learn and adapt without following explicit instructions. Due to its ability to improve its own performance over time, its usage in different fields has risen exponentially over the past few years. It has shown high capabilities to analyze data and detect and classify outliers. By inputting high-quality IMU data from division 1 swimmers and water polo players into various ensemble models and neural networks, this study aims to discover hidden high-risk movement patterns to predict and prevent overuse injuries.

Abstract Name: College Student Success: Food Insecurity and Substance Abuse

Food insecurity plays a significant role in college success. Research has found that food-insecure students experience sleep deprivation, difficulty focusing, and higher rates of disenrollment, and lower GPAs. Substance abuse presents a related challenge, possibly contributing as a coping mechanism for stress and scarcity. Abuse of substances can lead to lower grades and cognitive deficits. Despite various campus interventions, knowledge remains limited regarding cultural factors, local food environments, and the long-term effectiveness of support programs at Hispanic-serving institutions. This mixed-methods study investigates food insecurity and substance abuse among Hispanic and first-generation students at Purdue University Northwest (PNW), exploring the challenges and what culturally responsive interventions institutions can implement. The first phase, a survey assessing food security status and alcohol misuse, is now complete. Approximately half of the respondents reported experiencing some degree of food insecurity. The most common reported challenges included the inability to afford balanced meals, followed by groceries not lasting. The second phase will involve semi-structured interviews and focus groups with students who reported food insecurity. In-depth exploration of local food environment barriers will be investigated in coordination with stakeholders, including the Food Bank of Northwest Indiana. The final phase will involve a survey assessing food security status, alcohol misuse, resource utilization, and cultural factors affecting food access. To enhance generalizability, this phase will incorporate a national sample of Hispanic students recruited through Prolific.ac, enabling comparison with the PNW findings. Results will contribute to understanding food insecurity at Hispanic-serving institutions while informing the development of evidence-based, culturally responsive support services for Hispanic and first-generation students at PNW and similar institutions.

Abstract Name: The Self-Concept of Neurodivergent Undergraduate Students in STEM

Students' academic self-concept in STEM includes their beliefs about themselves as learners, their learning behaviors, and their future success in STEM. Neurodivergent students in primary and secondary education, on average, have more negative views of their academic potential and feel less control over their academic success, but little is known about the self-concept of neurodivergent undergraduate STEM students. For this study, responses to open-ended survey questions on self-concept from 115 neurodivergent undergraduate STEM students were analyzed. Participants were enrolled at one of 8 U.S. institutions, majoring in a range of STEM disciplines. Institutions represented a range of institution types. All participants self-identified as neurodivergent (autism, ADHD, and/or specific learning disabilities). A codebook was developed through thematic coding, drawing from participant responses and existing theories about academic self-concept. Four overarching categories identified observed patterns: (1) self-image of how students viewed their neurodivergence, (2) self-knowledge of the ways they learn best in STEM, (3) sense of control or agency over their own success in STEM courses, and (4) perceptions of their future selves in STEM professions. In a second coding cycle, subthemes of each category were identified. For example, complex conceptualizations of how their neurodivergence related to their STEM learning led to a range of subthemes in self-image,

including strength, difference, non-differentiating, and challenge views, sometimes in combination for the participant. Study results suggest strategies for faculty, mentors, and departments to support neurodivergent students, including emphasizing the strengths that students associate with their neurodivergence, acknowledging and normalizing challenges, and providing opportunities for students to identify unique ways they learn and practice course content.

Abstract Name: Characterization of an Americium-Beryllium Tagged Neutron Source for a 30-Ton Water-Based Liquid Scintillator Detector

Understanding the detection capabilities of water-based liquid scintillator (WbLS) is critical for its deployment in next-generation neutrino detectors such as THEIA and Phase II of the Deep Underground Neutrino Experiment (DUNE). This study focuses on the characterization and alignment testing of an americium-beryllium (AmBe) radioactive neutron source. We plan to dope the 30-ton WbLS detector at Brookhaven National Laboratory (BNL) with gadolinium (Gd) to improve neutron detection capabilities. This will be tested by implementing an AmBe source as a calibration metric. The AmBe source emits neutrons coincident with a 4.4 MeV gamma ray, making it possible to perform tagged neutron studies in the 30-ton detector. With planned Gd doping, accurate source placement and response characterization are of high priority. This work involved testing spatial alignment, analyzing the AmBe energy spectrum to verify gamma ray tagging, and evaluating its suitability for future neutron detection benchmarking in large-scale neutrino detection experiments. Alignment analysis resulted in the design switch from a stainless steel housing to an acrylic housing for the calibration setup, which includes the AmBe source, 4 Lutetium-Yttrium Oxyorthosilicate (LYSO) crystals, and a small photomultiplier tube (PMT). The results of the energy spectrum analysis yield a clear 4.4 MeV gamma peak, suggesting that the use of an AmBe radiation source is suitable to calibrate neutron tagging in the 30-ton WbLS detector at BNL. These results contribute to the broader effort to validate WbLS as a scalable detector medium and inform the future implementation of metal-doped WbLS systems in high-precision neutrino experiments. This study aligns with BNL's mission to investigate the building blocks of matter through high-energy physics research. As a result of this study, I have developed an understanding of experimental particle detection and measurement, gained firsthand experience in detector development, and learned valuable programming/data analysis skills.

Abstract Name: United States Energy Policy Act of 2005: Investment and Incentivization of Nuclear Power in the United States and Unintended Stagnation of the Nuclear Energy Production Sector

Nuclear power has seen little development since the 1990s despite its potential to combat climate change by providing clean energy. The United States attempted to foster growth in the industry by introducing the Energy Policy Act of 2005 (EPAct 2005), which provided incentives and regulatory changes. This review

investigated the stagnation of nuclear power development, evaluated why the EAct 2005 was not as effective in stimulating the industry as intended by analyzing policy studies and cost analyses of energy production. The findings showed that nuclear power is competitive with other means of energy production in terms of operating costs, such as coal and gas, because of low and stable fuel costs. However, nuclear power requires the greatest initial capital of the major means of energy production. This capital requirement is what may have deterred investors from developing the industry. While the EAct 2005 attempted to offset initial capital costs, its incentives were insufficient to significantly alter corporate interest. Additionally, legislation permits only one form of financing, which requires substantial risk on developers, further discouraging developers from investment. Still, the lack of interest in nuclear energy can be attributed to more than just finance; public sentiment regarding waste, disaster, and weapons proliferation has strayed interest, and decommissioning requirements have become increasingly difficult. Based on these findings, this review proposes that the Federal Government should seek to incorporate larger tax benefits and heavily increased loan guarantees for nuclear power in their next energy bill to spark growth in the industry.

Abstract Name: Prosthetic Design For Everyone: 3d Printing For Accessible, Adaptable And Personalized Leg Prosthetics

Prosthetic devices are essential for restoring mobility and independence, yet traditional designs remain costly, difficult to customize, and inaccessible for many patients. Recent advances in 3D printing offer a promising alternative by enabling affordable, customizable, and rapidly produced prosthetic components. This study evaluated the feasibility of designing and fabricating below-the-knee prosthetic parts using additive manufacturing methods. Prototypes of foot and ankle components were created using Polylactic Acid (PLA) and Tough PLA with different infill densities and structural patterns. Fabrication was conducted on MakerBot and Ultimaker printers, allowing comparisons in strength, flexibility, and overall print efficiency. The design process emphasized modularity, durability, and adaptability to individual patient needs. Results showed that Tough PLA with a grid infill provided superior stiffness and durability for the foot component, while PLA with a diamond infill pattern was sufficient for the ankle joint. The prototypes demonstrated functional flexibility, secure connections to the pylon, and promising durability for everyday use. Cost analysis indicated that components could be produced at a significantly lower cost than traditional prosthetics, with print times ranging from several hours to a full day depending on printer type. These findings suggest that 3D printing can help improve accessibility in prosthetic care by allowing rapid replacement, customization, and affordability—benefits especially important for children and underserved communities. However, the research also revealed limitations, including restricted printing time, limited access to equipment, and the early-stage nature of the design. This study presents only the lower-leg portion of a prosthetic system, meaning the model is not yet complete. Future research should expand to above-the-knee components, conduct long-term durability testing, and include clinical trials to evaluate gait, joint performance, and full-system functionality. Continued development is needed to create a fully functional, patient-ready prosthetic device.

Abstract Name: Differential role of the ET-1/ETA axis in kidney inflammation during high oxygen supplementation

The mechanisms involved in hyperoxia-induced organ damage are not fully understood. Endothelin-1 (ET-1) plays an important role in kidney disease and inflammation. We reported elevated plasma ET-1 and kidney fibrosis after 72 h of hyperoxia; however, if ET-1 drives kidney inflammation under hyperoxic conditions is unclear. We hypothesized that high oxygen supplementation leads to increased inflammation in the kidney, and that pharmacological blockade of the ETA receptor ameliorates that inflammation. Male C57Bl/6 mice drank normal water or ABT-627 (ETA antagonist, 5 mg/Kg/day in water) for 1 week prior and while receiving hyperoxia (>95%O₂) for 72 hours. Kidneys were isolated and stained against T cells (CD3+) and macrophages (F4/80+). Kidney T cells and macrophages were quantified in whole kidney scans using Metamorph software, and specifically in the cortex by manually counting 20 40X microscope fields/cortex. Hyperoxia resulted in a significant decrease in whole kidney and cortical T cells (normal air vs. hyperoxia, whole kidney: 0.06 ± 0.01 vs. 0.03 ± 0.00 % threshold area, $p=0.0005$; cortex: 1.50 ± 0.16 vs. 1.07 ± 0.07 cells/field; $n=12$ /group, $p=0.03$), while macrophages tended to increase in the whole kidney and decrease in the cortex (27.6 ± 1.07 vs. 23.2 ± 0.84 cells/field, $p=0.01$). ABT-627 prevented the increase in macrophages with hyperoxia in whole kidney, while it did not change T cells. Our results demonstrate that the effects of high O₂ on kidney T cell infiltration are independent of ETA signaling, while macrophage infiltration in the cortex is ETA-dependent.

Abstract Name: Extracellular Vesicle Concentration as a Marker of Psychological and Physiological Stress in Early Life

Extracellular vesicles (EVs) are nanoscale, membrane-bound particles released by most cell types, including brain cells, immune cells, endothelial cells, and epithelial tissues, and carry molecular cargo that supports intercellular communication. Because EV release is responsive to cellular activation and stress, their circulating concentration may reflect aspects of physiological regulation. However, the relevance of total EV concentration to psychological symptoms or acute stress reactivity in adolescents remains unclear. This study examined associations between plasma EV concentration, mental health symptoms, cortisol responses to the Trier Social Stress Test (TSST), and neighborhood opportunity in adolescents. Participants included 30 females and 29 males (ages 15-20). Plasma EVs were isolated and quantified using ZetaView nanoparticle tracking analysis, which provides particle counts in the 50-200 nm range. Participants completed measures of lifetime major depressive disorder and current depression, anxiety, and stress symptoms using the DASS-21. A subset completed the TSST with baseline, pre-TSST, and four post-TSST salivary cortisol samples collected at 15-minute intervals. Neighborhood context was indexed using Child Opportunity Index domains. Across measures, EV concentration showed negative correlations with self-reported anxiety, stress, and physical symptom severity. This pattern indicates that adolescents with lower circulating EV counts tend to

exhibit higher psychological symptom burden, consistent with the interpretation that reduced EV concentration may reflect a less adaptive or more dysregulated physiological profile. Effects were strongest in females, with correlations in the small-to-moderate range ($r = -.22$ to $-.31$) for symptom measures. Females also showed modest inverse associations between EV concentration and TSST cortisol, including peak cortisol ($r = -.43$). Neighborhood opportunity demonstrated similar female-specific gradients ($r = -.24$ to $-.36$). Although exploratory, these findings suggest that lower bulk EV concentration may index heightened psychological symptoms and less regulated stress physiology, particularly among females. Larger samples are needed to clarify mechanisms and developmental implications.

Abstract Name: The Role of δ -Containing GABAA Receptors in Modulating Experimental Kainic Acid-Induced Seizures in Adult Mice

Epilepsy, a neurological disorder characterized by recurrent seizures, is often driven by hyperexcitable neural circuits that result from an imbalance between excitatory and inhibitory signaling. The dentate gyrus (DG) of the hippocampus is a brain region that plays a critical role as a gatekeeper, restricting excessive excitatory input to downstream hippocampal regions, and thereby preventing seizure spread. δ -subunit-containing γ -aminobutyric acid type A receptors (δ -GABAARs) help regulate the activity of neurons in the DG by providing steady background inhibition; dysregulation of δ -GABAARs is likely implicated in temporal lobe epilepsy (TLE), with prior studies suggesting that less inhibition is what leads to worsened seizure outcomes. This project will test the hypothesis that selective removal of δ -GABAARs from DG neurons exacerbates seizures by promoting overactivation of DG neurons. Two aims are proposed: (1) quantify seizure severity in DG- δ -GABAAR conditional knockout (cKO) mice versus controls after KA-induced seizures; and (2) assess neuronal activation using a marker of neural activity (c-Fos) visualized with fluorescence microscopy following immunostaining. The goal of this study is to uncover the potential role of δ -GABAARs in regulating seizures, providing mechanistic insights into tonic inhibition in epilepsy and identifying potential therapeutic targets for mitigating seizure progression and cognitive dysfunction.

Abstract Name: BEYOND THE FLESH: ASCETIC WOMEN, GENDER TRANSFORMATION, AND CHRISTIAN MONASTICISM IN EARLY CHRISTIANITY.

This project explores early Christian asceticism through a gendered lens, focusing on how fasting, celibacy, and withdrawal from traditional roles subverted gender in late antiquity. Roman society stressed marriage, domesticity, and familial lineage, but female ascetics undercut these norms by practicing celibacy, rejecting wealth, and pursuing holiness through bodily discipline. For women, asceticism offered escape from social constraints in gender roles. Hagiographical accounts described these women in terms that blurred gender norms, attributing masculine virtues as masculine or referring to them as male. While scholars have examined

women's roles in early Christian asceticism, female saints are often treated as peripheral to a male-centered ascetic tradition or focused primarily on themes of virginity. This project builds on that scholarship by emphasizing how women such as Macrina, Syncletica, and Mary of Egypt were portrayed as transcending gender categories. By highlighting the ways in which female ascetic practice destabilized cultural definitions of gender roles, the study reframes women not as exceptions but as central in the redefinition of holiness in late antiquity.

Abstract Name: Substack Speaks on Measles: Themes, Claims, and the Politicization of Vaccination

Misinformation about measles and the Measles, Mumps, Rubella (MMR) vaccine is spreading at a rapid rate throughout the United States. This has caused many to become hesitant about the vaccine leading to a resurgence in measles outbreaks. A substantial amount of this misinformation is spread on an app called Substack, a platform where anyone can publish articles, videos, and podcasts to subscribers. The issue with anyone being able to publish content is that Substack has now become a center for misinformation. The purpose of this research is to answer one question: What are the predominant themes in Substack posts about measles? To answer this question, 100 posts were coded in MAXQDA using reflexive thematic analysis, drawing initial codes from prior research and other codes from posts. Each post was classified into a pro, anti, or unclear stance on vaccination. Four common themes were identified in Substack posts addressing measles and the MMR vaccine: (1) Pro-vaccine Substack posts are primarily informational and emphasize case counts and provide details about the dangerous health effects of measles. (2) Anti-vaccine posts focus on the negative side effects of the MMR vaccine, including claims that the vaccine is linked to autism. These posts also portray pro-vaccine groups as withholding scientific truths about the MMR vaccine. (3) Both pro-vaccine and anti-vaccine posts accuse one another of putting lives at risk. (4) The pro-vaccine posts were more likely than the anti-vaccine posts to critique politics/political leaders. Anti-vaccine posts tend to be more detailed to debunk science proving that the MMR vaccine is effective and safe. Due to the anti-vaccine posts' investigative and detailed nature, they often appear to be more believable in comparison to the pro-vaccine posts.

Abstract Name: Dissemination of the implications of adopting Fourth Industrial Revolution technologies in organizations in Medellín

The Fourth Industrial Revolution (4IR), driven by the convergence of digital, physical, and biological technologies, has transformed social, economic, and technological domains globally. This revolution brings both opportunities and challenges for organizations, which must swiftly adapt to new business models and

operational processes. Medellín, recognized as an innovation district, is no exception. Therefore, this dissemination focuses on answering the question: How do organizations in Medellín contribute to sustainable development and social well-being through the adoption of 4IR technologies? This dissemination, a magazine with five sections, aims to share information with university students on the implications of adopting 4IR technologies. The material is based on research completed in 2024 regarding the contribution of these organizations in Medellín to sustainable and social development. The process behind its creation involved three phases: ideation and conceptualization, design and prototyping with user testing, and finally public presentation and dissemination, supported by experts to facilitate understanding. This work demonstrates that adopting 4IR technologies offers critical opportunities for strategic sectors in Medellín but also poses significant challenges in terms of socioeconomic equity. The material communicates these aspects in clear and accessible language, raising awareness and informing about the real impact of the 4IR on the city and its organizations. Thus, this scientific dissemination effectively promotes knowledge about local technological transformation, proposing strategies to optimize the responsible use of these technologies for the benefit of the community and organizational environment. The experience shows that communicating science in a practical and approachable way strengthens the readiness of future professionals to face the challenges of the Fourth Industrial Revolution.

Abstract Name: The Anxiety Gap: The Impact of Math Anxiety and Effort on Math Achievement by Sex

Introduction: Math achievement is a fundamental aspect of academic success for school children, setting the foundation for future STEM engagement and career pathways. However, psychological factors, such as Math Anxiety (MA), can be severely detrimental to a student's performance. Effort, meanwhile, is another critical motivational predictor that can positively or negatively impact Math Grades (MG). **Objectives:** This research aimed to clearly identify the relative influence of these key psychological and behavioral variables on math achievement and to test the critical role of sex as a moderator of these relationships. **Methods:** The study analyzed a cross-sectional sample of $N = 302$ students (4th and 8th grades). Validated scales were used to measure Math Anxiety (Math Anxiety Scale) and Effort (Intrinsic Motivation Inventory), while Math Grades were the most recent academic grades reported by the parents. The analysis included a multiple hierarchical regression, controlling for Family Income and Caregiver Education. **Results:** The full model confirmed that Math Anxiety was the most dominant, highly significant negative predictor of Math Grades ($p < 0.001$). We found that the negative impact of Math Anxiety was more pronounced for female students, demonstrating a greater psychological vulnerability to anxiety. Conversely, the positive academic return on Effort was significantly stronger for males. Although initially significant in bivariate models, the unique predictive power of Effort ($p = 0.0553$) and Family Income ($p = 0.0634$) became only marginally non-significant in the full model, suggesting their unique variance was largely absorbed by Math Anxiety's powerful effect. **Conclusion:** In conclusion, Math Anxiety remains the primary barrier to math achievement, operating with a sex-specific bias. The findings portray an anxiety gap and a differential return on effort, highlighting the necessity of targeted, sex-informed interventions that prioritize addressing underlying psychological barriers that may decrease math achievement for students.

Abstract Name: Determining Heparan Sulfate Levels on Glioblastoma Cells

Glioblastoma (GBM) is a devastating, fast-growing brain cancer that arises from glial cells and is the high grade IV glioma. After diagnosis, the five-year survival rate is only 5% for GBM patients. Despite multimodal treatment approaches, GBM remains a difficult disease to treat due to the aggressive nature of GBM. Therefore, further investigation into understanding the mechanisms involved in GBM tumor progression is necessary to enhance patient survival. Proteoglycans offer an attractive mechanism to study as they are found on the surface of GBM tumor cells. Proteoglycans are proteins with carbohydrate branches called heparan sulfate chains of which facilitates multiple GBM cellular processes: rapid growth, angiogenesis, invasion, and metastasis. Here, we learned mammalian cell culture techniques and maintained GBM tumor cells in culture. Experimentation with a competitive enzyme-linked immunosorbent assay (ELISA) kit was used to detect the level of heparan sulfate chains on the cultured GBM cells, as overabundance could contribute to increased proliferative mechanisms of this cancer. Therefore, we examined the abundance of heparan sulfate chains in multiple GBM cell lines to determine their potential influence in the aggressive nature of GBM.

Abstract Name: The Alabama Youth Relationship Education (AYRE) Project in Practice

Alabama has a history of family instability that can place youth at risk for developing unhealthy romantic relationships. Adolescents in the state experience higher rates of risky sexual behaviors and victimization, including physical dating violence. The Alabama Youth Relationship Education (AYRE) Project seeks to address these challenges by teaching youth about healthy relationship skills and, in the long term, strengthening marriage and parenting outcomes. AYRE does this by offering adolescents targeted relationship education and accessible support resources. During the spring and fall semesters of 2025, the author partnered with AYRE to complete a service-learning project. This presentation will share insights from that experience and illustrate how research can be effectively translated into community-based practice. The AYRE curriculum includes three core components. The first, Relationship Smarts Plus 4.0, is an evidence-based program designed to build communication, stress-management, and conflict-resolution skills while helping participants differentiate between healthy and unhealthy relationships. To incorporate emotional wellness practices, Mind Matters introduces strategies for emotion regulation, self-soothing, and resilience, offering practical tools such as breathing exercises and the 5-4-3-2-1 grounding technique. The curriculum concludes with Money Habitudes, which encourages participants to examine their personal habits and attitudes toward finances and to understand how financial decision-making can shape relationship dynamics. Working with AYRE highlighted the critical link between healthy relationships and overall well-being. Throughout the project, the author gained a deeper understanding of the role of parent-adolescent relationships during a pivotal developmental period. A central objective was to create meaningful learning experiences for youth by demonstrating how effective communication and relationship skills can improve their lives and positively influence those around them. This presentation will reflect on the author's work with AYRE and emphasize how evidence-based research can inform real-world programs that support youth and strengthen families across Alabama.

Abstract Name: Collecting Under Uncertainty: How Nostalgia and IP Familiarity Influence Consumer Motivation and Behavior in the U.S. Blind Box Market

Blind boxes are collectible products sold in opaque packaging that hides the specific character from a larger series inside. Buyers do not know which figure they will receive until unboxing, which creates a heightened sense of anticipation and surprise. This study will examine the connection between blind boxes and individuals' experiences, focusing on their emotions, memories, and forms of self-expression. Specifically, there is an emphasis on nostalgia and familiar intellectual property (IP) characters to determine whether they increase purchase motivations. Although existing literature has analyzed blind boxes extensively within the Chinese market, there is limited study in the American demographics. To address this gap, the research analyzes the behaviors and motivations of 157 participants (purchasers and non-purchasers) through an online survey to measure purchasing patterns, emotional responses, and the influence of personally meaningful IP characters. The preliminary results of the study found that the strongest purchasing motivators were surprise and excitement, closely followed by an interest in collecting specific IP characters. Participants also express greater confidence in their purchases when they recognize the brand, character, or series. Meanwhile, individuals who have never bought a blind box explained that they usually don't collect items, although they either enjoy looking at collectibles or own a few. However, several participants responded that if a blind box featured a brand or character they particularly liked, their tendency to purchase would increase significantly. The survey also investigates how different shopping environments, such as in-store or online platforms, shape impulse buying. In addition, the Big Five Factor Inventory was conducted to understand how personality traits influence consumer susceptibility towards surprise and probabilistic rewards. Ultimately, the research aims to uncover why American consumers are drawn to blind boxes and how nostalgia influences their interest and engagement.

Abstract Name: Where Mountains Meet Medicine: How Medical Syncretism Shapes Access and Care in the rural Cold Desert Cultural Landscape of India

Current efforts in the rural Cold Desert Cultural Landscape (CDCL) of India include both traditional healing practices and biomedical healthcare delivery. Therefore, the project will research how medical syncretism—the integration of these systems—shapes healthcare access and equity in the region. Prior literature, case studies and ethnographies demonstrate that indigenous and biomedical systems coexist in rural settings, establishing the CDCL's remote and resource-limited context valuable for investigating how integration influences access to care. Drawing on theories of medical pluralism and medical syncretism, the proposed research will explore how practitioners balance traditional healing values with biomedical protocols to deliver accessible and patient-centered care. The project will collect primary data through semi-structured interviews with both traditional healers and biomedical professionals in the CDCL. Using thematic coding, the study

will analyze patterns in perceptions of integration, access, and equity. It is expected that collaboration between systems and the cultural legitimacy fostered by medical syncretism will enhance healthcare access and satisfaction. Ultimately, the project situates the CDCL's experience within the broader challenge of ensuring that healthcare systems worldwide respect cultural diversity while promoting universal access and well-being

Abstract Name: Predicting Gas Solubility in Deep Eutectic Solvents Using Machine Learning

Industrial greenhouse gas emissions have accelerated global warming by 50% and contributed to worsening air and ecosystem conditions. Traditional capture technologies based on solvents face many challenges, as most solvents are volatile and corrosive, limiting their sustainability and large-scale applicability. Recently, deep eutectic solvents (DESSs), comprising an HBD (Hydrogen Bond Donor) and an HBA (Hydrogen Bond Acceptor), have been more sustainable alternatives with low toxicity and highly customizable physicochemical properties. However, the chemical design space for DESSs is large, and experimental evaluation of gas solubilities is slow and expensive. Machine learning (ML) offers a strategy for accelerating solvent discovery by ML models, trained on curated literature data and descriptors from density Functional Theory (DFT), to predict NH_3 , CH_4 , NO_x , SO_x , and CO_2 solubility across diverse DES systems, which enables fast screening of new solvent combinations. The following project uses a multi-descriptor framework originating from DFT to achieve a predictive power comparable to COSMO-RS while avoiding computational and financial overhead associated with it. Electrostatic Potential (ESP) maps are computed as 3D descriptors of the electronic environment of each DES component. In order to convert the 3D ESP maps into a format suitable for machine-learning models, those are discretized into eight bins to form a 2D histogram, then flattened into a 1D feature vector. Different ML algorithms will be trained using metrics including R^2 , Root Mean Square Error (RMSE), and Mean Absolute Error (MAE). The final optimized models will go through a virtual screening of unexplored compositions of DES for the discovery of new HBD-HBA combinations that are capable of enhanced gas capture. This research is expected to produce precise and generalizable ML models that can give insights into the driving forces behind the solubility of greenhouse gases in DES and minimize harmful industrial emissions.

Abstract Name: Visualizing the Invisible: Simulating Electromagnetic Field in 3D Space with MATLAB

Electromagnetic field behaviours in free space are defined by Maxwell's Equations, which couple the temporal and spatial variations of electric and magnetic fields through partial derivatives. These derivatives quantify the rate of change of each field's vector component with respect to position and time in a 3D lattice, forming the basis for numerical field analysis. This research will develop a mathematical and computational framework using multivariable calculus to model, simulate, and visualize electromagnetic wave propagation in free space using MATLAB. Gradient, divergence, and curl operations are implemented to compute local field variations and energy transfer. The resulting data are used to generate 3D plots that represent the propagation of electromagnetic waves and the coupling between electric and magnetic components. By integrating partial differentiation into simulation, this study demonstrates how calculus enables precise modelling and visualisation of dynamic field interactions, supporting validation of Maxwell's equations and providing insights applicable to spacecraft communication, sensor optimization, and electromagnetic system design.

Abstract Name: Before It's Too Late: Feminist Approaches to Sex Education and the Prevention of Violence in an Austrian Classroom

Globally, debates around sex education reveal deep tensions between tradition, religion, and an evolving understanding of gender equity and violence prevention. In Austria, while national guidelines promote a comprehensive sexual education curriculum, topics around healthy relationships, gender dynamics, and the influence of media on sexual norms are often overlooked. The delivery of these lessons frequently depends on individual teachers' interpretations, classroom management styles, and confidence in navigating sensitive topics within multicultural environments. This research explores how feminist-informed approaches to comprehensive sex education can help teachers both develop their pedagogic skills and help them deliver preventative methods against domestic and interpersonal violence, particularly within classrooms where students come from diverse cultural and religious backgrounds. Using a qualitative case study, semi-structured interviews with teachers and the school's headmaster and ethnographic journaling of classroom observations at a secondary school in Vienna over the span of three months were carried out. Findings suggest that younger students tend to engage with sex education topics playfully and with curiosity while older students exhibit greater discomfort and restraint, often hesitating to name body parts or use sexual terms even before explicit content is introduced. Teachers described navigating diverse cultural and religious attitudes, gendered differences in participation, and misinformation from social media or pornography. Across classrooms, engagement was highest when lessons connected biological content to personal meaning, emotional understanding, and real-world issues rather than abstract facts. This research could contribute to ongoing global discussions on the role of education in promoting equality and preventing violence. By highlighting classroom level experiences, it could offer an avenue for policymakers and educators to strengthen culturally responsive and feminist approaches to sexual education in adolescents.

Abstract Name: Navigating Changes: The Experiences of Nonprofit Leaders in Northwest Arkansas in the Current Social and Political Climate

Northwest Arkansas (NWA) is a rapidly growing region with an expanding network of nonprofits that play a vital role in meeting the needs of its increasing population. Many of these organizations are led by professionals committed to supporting minoritized, underrepresented, and under-resourced groups—terms frequently associated with diversity, equity, and inclusion (DEI) frameworks. In January 2025, the presidential administration requested a pause on payments for federal grants and other programs, generating widespread concern among nonprofits reliant on federal funding. Further, the federal government has intensified scrutiny of programs perceived as Diversity, Equity, and Inclusion (DEI) initiatives. A July 2025 Department of Justice memorandum instructed federally funded organizations to abandon practices interpreted as DEI-related, prompting uncertainty about compliance and sustainability. This study examines how funding-related legislative changes and shifting federal expectations impact NWA nonprofits and the leaders who guide them. The existing literature has not examined how federal, state, and local actions following anti-DEI decisions and funding rescissions have affected nonprofits in this region. Through semi-structured virtual interviews with nonprofit leaders and case studies of select organizations, this research investigates how leaders navigate a political and social climate increasingly resistant to DEI practices. Because interviewees serve diverse populations, they will likely report varied experiences within nonprofit leadership; however, common themes are expected to emerge regarding organizational responses to federal guidance, the influence of DEI perceptions on operational decisions, and the downstream effects on client services. By documenting these experiences, this study aims to contribute to scholarly and practical conversations on sustaining nonprofit organizations and supporting the human service professionals who lead them. It seeks to illuminate the challenges posed by legislative shifts, the strategies leaders employ to remain mission-driven, and the broader implications for equity-focused work in a changing national context.

Abstract Name: Design and Development of a Two-Axis Demonstration Gimbal for Engineering Education

This project focuses on the design and development of a compact two-axis demonstration gimbal intended to illustrate core mechanical engineering principles through an integrated electromechanical system. The system is required to achieve 90° of rotation in the cross-track axis and 120° in the in-track axis while maintaining smooth, controlled motion and a positional accuracy of 1.8°. To meet practical demonstration needs, the complete assembly must fit within a 1 ft³ envelope, mount to a standard aluminum base plate, and operate reliably from a 120 V outlet. The primary emphasis of the project is mechanical design, including structural and dynamic analysis, torque and bearing calculations, component sizing, and optimization under strict spatial constraints. The design integrates both machined aluminum components for strength and stiffness and custom 3D-printed parts to reduce weight, fabrication complexity, and cost. Following the design phase, we will move into prototyping, assembly, dimensional verification, and motion testing to evaluate the system against the defined performance criteria. Although the project includes electrical integration and motion-control programming, areas where we have less prior experience, we have embraced these challenges as an essential part of creating a fully functional system. We are learning to select and size stepper motors, determine feasible transmission methods, and implement basic motion-control strategies to achieve accurate multi-axis positioning. These additions broaden the scope of the project and strengthen its educational value. Overall, this work provides interdisciplinary, hands-on experience with realistic engineering constraints, multidisciplinary problem solving, and iterative design. The completed gimbal will serve as a

reliable and accessible platform for demonstrating mechanical motion, actuation, and system integration controls concept to engineering students

Abstract Name: A Tug-of-War Between NaCl and Phosphate: Environmental Effects on Calf Intestinal Alkaline Phosphatase

Alkaline phosphatase (ALP) is an essential enzyme involved in skeletal mineralization, liver function, and immune modulation, and serves as an important biomarker for bone and liver disease. ALP activity can be conveniently monitored by measuring the conversion of p-nitrophenyl phosphate (pNPP) to p-nitrophenol (pNP). Previous work showed that *E. coli* ALP is activated by high NaCl concentrations and inhibited by phosphate, with NaCl having little effect on phosphate inhibition. This study aimed to determine whether similar behavior occurs in calf intestinal ALP. Reaction rates were measured across different pNPP concentrations in the presence and absence of NaCl and phosphate, using both HEPES and bicarbonate buffer systems. From these data, K_M and k_{cat} were determined under each condition. Consistent with *E. coli* ALP, NaCl activated the enzyme and phosphate acted as an inhibitor. However, the nature of the activation by NaCl is dependent on the buffer. Moreover, unlike *E. coli* ALP, our results suggest that NaCl can impact the inhibitory effect of phosphate on calf intestinal ALP activity under some conditions.

Abstract Name: Assessing the Impact of Type 2 Diabetes on Cognitive Function in Middle Aged Hispanic/Latino Adults

Hispanic/Latinos experience a high rate of diabetes, which contributes to an increased risk of developing neurodegenerative diseases. Other factors, such as education have also been linked to cognitive functioning. Understanding the role between diabetes and neurodegenerative disease, while adjusting for education may be important for targeted prevention; however, there is limited literature examining the role of type 2 diabetes mellitus (T2DM) and cognitive function in the Hispanic/Latino population. Does T2DM and education level affect cognitive function among middle-aged Hispanic/Latino? We aim to expand our current knowledge by assessing cognitive function in 200 middle-aged participants (age 50-65) categorized as non-prediabetic, prediabetic, or diagnosed with T2DM using data from baseline and 2nd year. Data were collected as part of a study conducted at the University of Southern California examining both diabetes and cognitive function. Brain functionality was evaluated through MRI scans, clinical assessments, and cognitive testing to aid in the early identification of neurodegenerative diseases. The cognitive testing consists of the Montreal cognitive assessment-Basic (MOCA-B) and a neuropsychological testing battery. We conducted linear regression analyses with memory being the dependent variable and education and diabetes being the independent variable, adjusting for age and sex. We found a positive relationship between education and memory

(coefficient = 0.177, $p = 0.066$) and a small, non-significant effect on diabetes (coefficient = 0.211, $p = 0.845$). However, this difference was not statistically significant due to the small sample size. These data suggest that non-diabetic participants perform better than diabetic participants in memory due to differences in education level. Overall, participants with higher level of education scored higher than those with fewer years of education. This shows that education and diabetes both play a role in memory, which suggest early support to help lower the risk of cognitive problems in Hispanics with diabetes.

Abstract Name: ADVANCED CHEMICAL VAPOR DEPOSITION SYSTEM FOR SILICON NANOSTRUCTURE FABRICATION IN LITHIUM-ION BATTERY ANODES

Silicon's ten-fold higher theoretical capacity than graphite makes it a prime anode candidate, but significant lithiation-induced volume changes demand nanostructured architectures produced via deposition from silane synthesis. Unfortunately silane is very dangerous and an expensive precursor not suited for mass manufacturing of battery materials. In this work we demonstrate a prototype tool for silane-free (magnesiothermic) nanostructure synthesis for silicon anode fabrication. Our CVD-based tool enables the possibility of porous silicon and silicon-carbon composite bulk powder production eliminating need for SiH_4 . The tool is based on magnesium vapor reaction with porous silica particles. Optional carbon is added by pyrolysis of hydrocarbon precursors. Reactive gasses are added by remotely operated mass-flow controllers over various synthesis steps. Pressure and temperature, key factors in controlling Mg evaporation and matching its rate to Mg diffusion through silica particles, are tightly controlled with high accuracy by closed-loop controls and purposely designed hardware. Our custom CVD tool is fully automated using industry-standard programmable logic controller (PLC) and human-machine interface (HMI). Automation allows precise control of precursor gas flows, reaction zone temperature and pressure giving high level of reproducibility for nanosilicon synthesis. Automation also enabled integration of multiple safety interlocks, hazardous (hydrocarbon) gas sensors and self-leak check procedures for safe continuous operation. Real-time logging of temperature, pressure, and gas flow rates is implemented for better synthesis traceability. Resulting material produced in the tool were examined by X-ray diffraction (XRD): optimized runs display the expected Si ($\sim 28^\circ 2\theta$) and MgO ($\sim 42.5^\circ$) peaks with near stoichiometric ratio Si:MgO, confirming successful conversion of silica into silicon. To suppress unwanted byproduct, Mg_2Si formation, multiple powder preparation and synthesis recipe improvements were made demonstrating the ability of magnesiothermic reduction to produce anode material needed for the next generation of Li-ion batteries.

Abstract Name: Beyond the Data: Understanding Sociotechnical Bias and Gender Inequity in Algorithmic Credit Risk Models.

Credit scoring models promise efficiency in lending by predicting repayment based on financial and

demographic data, yet their reliance on historical records risks perpetuating the very biases and inequalities they aim to overcome. Through exploratory data analysis, we identify significant demographic disparities: although women demonstrate a lower actual default rate (7.0%) than men (10.1%), they face a higher average annuity-to-income ratio (18.9% vs. 16.5%), indicating greater financial strain. We employ linear regression to model default risk and uncover a critical fairness trade-off. A simple model using only the annuity-to-income ratio, while statistically significant, would systematically over-predict risk for women, penalizing them for their higher financial burden despite their superior repayment history. Refining the model by incorporating gender improves predictive power but creates a legal and ethical conflict, as using protected attributes for credit decisions constitutes disparate treatment. We demonstrate that simply removing gender does not resolve the bias, as it resurfaces indirectly through correlated indicators like the annuity-to-income ratio, leading to a disparate impact. Our analysis reveals the "formalism trap" in sociotechnical systems, where technically sound metrics can encode and perpetuate social inequities. We conclude that ensuring fairness in credit risk assessment requires moving beyond simple models and neutral-seeming financial ratios to proactively mitigate embedded biases, highlighting a fundamental tension between predictive accuracy and non-discrimination in algorithmic decision-making.

Abstract Name: When Does Simplicity Win? Comparing Classical and Deep Learning Methods for High-Dimensional Portfolio Risk Management

Despite the proliferation of deep learning in finance, it remains unclear whether neural networks provide meaningful advantages over classical methods for portfolio risk management. This study addresses the question: Under what conditions do classical dimensionality reduction techniques (PCA, SVD) remain competitive with modern deep learning approaches (autoencoders, variational autoencoders) for financial factor extraction? Principal Component Analysis (PCA), a classical technique dating back to 1901 and still frequently used in industry, is used to extract factors using eigendecomposition of the covariance matrix. Recent developments in deep learning, especially autoencoders and variational autoencoders, provide alternative methods that may be able to capture non-linear relationships and time-varying patterns. However, previous comparisons often analyze in-sample fit rather than real-world deployment factors such as computing cost, interpretability, and out-of-sample performance. Unlike previous research, this study evaluates techniques in three areas that are critical for industry practitioners: robustness under extreme market conditions, explainability, and speed. We implement and compare deep learning techniques (standard autoencoders, variational autoencoders) with classical techniques (PCA via eigendecomposition, truncated SVD) using S&P 500 stock return data from 2000 to 2024. We evaluate both approaches across multiple dimensions: (1) variance explained by extracted factors, (2) out-of-sample portfolio performance (Sharpe ratio, maximum drawdown), (3) computational efficiency (training time, inference speed), (4) interpretability (correlation with known economic factors), and (5) robustness during market stress periods (2008 financial crisis, 2020 COVID crash). This research will demonstrate that classical PCA-based approaches achieve around 85-95% of deep-learning's in-sample performance while offering major advantages in computational efficiency, interpretability, and stability during market stress. These findings matter for institutions that must balance explainability rules with the appeal of complex AI models. We contextualize these findings within the broader debate about when algorithmic complexity is justified vs when more straightforward, transparent approaches suffice, a topic with implications beyond finance.

Abstract Name: Tuning the photoluminescence of atomically precise Au nanoclusters with Pt and Rh dopants

Nanoclusters have the ability to conduct or be utilized for a range of applications, contributing to many research fields and findings. This research project specifically focuses on tuning the photoluminescence of nanoclusters using metal dopants and ligand engineering. Researchers have found that due to the small size of nanoclusters, this contributes to the distinct optical properties they withhold such as absorption and photoluminescence. These optical properties allow nanoclusters to be manipulated in such a way to be applied to various fields. This project utilizes a synthesis-based approach where the target metal nanocluster is produced using reagents, extraction procedures, phase transfer catalysts, etc. The final product is then verified using UV-vis and fluorescence spectroscopy to confirm the target cluster was successfully achieved. Depending on the size formed, the nanocluster will emit light at differing wavelengths. Objectively, the goal of this project is to increase the band gaps within a nanocluster and for it to exhibit quantum confinement. Band gaps are the minimum energy needed to excite an electron from the highest filled state to the next energy level available. Due to nanoclusters being small in size, they have minimal atoms, fewer electrons, and fewer energy levels. Fewer energy levels are associated with fewer band gaps. Increasing the band gaps also causes optical properties of the nanocluster to increase, the focus property being fluorescence. The importance of these optical properties lead to various applications such as biological imaging, catalysis, and light harvesting.

Abstract Name: Understanding Grief Support Needs in Rural Communities: a Mixed-Methods Study of Service Use, Access Barriers, and Perceived Gaps

Grief is a deeply personal process shaped by the availability and quality of support services. In rural areas, limited healthcare and mental health resources make accessing grief support especially difficult. Despite increasing recognition of grief's psychological and social impact, little research has explored how rural populations engage with or avoid these services. This study examines grief support use, perceived accessibility, and unmet needs in a rural Midwestern community after the loss of key providers. Through a large, cross-sectional survey, it addresses five questions: which demographic factors influence service use; what aspects are helpful or unhelpful; why some do not seek support; what barriers exist; and what unmet needs remain. By combining quantitative and qualitative data, the study offers a detailed view of service use and access. The findings provide practical guidance for healthcare providers, policymakers, and community groups to create more inclusive and sustainable grief support systems in rural communities.

Abstract Name: Lipid Emulsion-Dye Phantoms for Polarized Hyperspectral Imaging (PHSI) System Validation

Hyperspectral imaging (HSI) is a powerful optical technique that captures a continuous spectrum of light for each pixel, extending far beyond the limited red, green, and blue channels of traditional white light imaging. This enables precise characterization of biological tissues based on wavelength-dependent absorption and scattering. Meanwhile, polarized light imaging (PLI) detects structural and compositional variations in specimens via changes in the preservation and rotation (azimuth) of polarized illumination, often revealing subtle anisotropy. When combined, polarized hyperspectral imaging (PHSI) becomes a next-generation modality capable of detecting morphological and biochemical features that are invisible under standard imaging. Accurate PHSI calibration requires measuring how specimens absorb light and alter polarization state across a spectrum. This subsequently necessitates reproducible phantoms that mimic tissue-like scattering and absorption, often using commercial Intralipid and dyes. Intralipid is widely used because its optical properties resemble those of human tissue, but it can be costly and difficult to tailor to specific spectral ranges. In this study, we developed a tunable tissue-mimicking phantom composed of a homemade lipid emulsion, agar, and selected dyes. The lipid emulsion provides scattering, while the dyes act as absorbers, allowing for adjustment of optical properties across wavelengths. We examined emulsion concentrations of 0.1%, 1%, 10%, and 20%, along with methylene blue, crystal violet, safranin, and tartrazine at varying concentrations, to assess their usefulness for PHSI validation within the 460–600 nm range. Our results show that the lipid-dye phantoms reproduce the characteristic absorption spectra of each dye and that the homemade emulsion exhibits scattering behavior comparable to commercial Intralipid. Beyond validating PHSI performance, this low-cost, customizable phantom design supports broader imaging development, ultimately contributing to more accessible, reliable, and precise optical diagnostic tools for early disease detection and real-time intraoperative imaging.

Abstract Name: Ginkgo Biloba: an opponent of dementia?

We've all known at least one person who has suffered from some form of memory loss. With over 57 million people worldwide living with dementia, the search for tools that may preserve or improve memory has become more important than ever. Although there is no absolute cure, certain supplements have gained attention for their potential cognitive benefits. Among these, Ginkgo biloba sits at the top of the list. As a gymnosperm native to China, Ginkgo has been praised for centuries for its antioxidant and neuroprotective properties, leading it to become one of the most widely used herbal supplements in the world. The effectiveness of Ginkgo in supporting memory and slowing cognitive decline, however, remains a topic of debate. This project examines the impact of Ginkgo biloba and specifically the standardized extract EGb 761 in terms of memory performance, neurotransmitter levels, and long-term cognitive outcomes. By comparing evidence from clinical trials, neuropsychological assessments, and animal studies, we observed that the

results are varied. While some studies suggest that Ginkgo may influence neurotransmitter activity or support certain aspects of learning and motivation, many large-scale human trials report little to no improvement in memory or annual cognitive decline when compared to placebo groups. Despite its long history and promising theoretical properties, the current body of evidence suggests that Ginkgo biloba offers limited measurable benefit for dementia-related symptoms in most populations. Although, its safety profile, accessibility, and potential subtle effects make it a supplement still worth investigating. By integrating diverse findings, this project aims to provide a clearer understanding of Ginkgo biloba's true role in the ongoing fight against dementia.

Abstract Name: Impacts of the COVID-19 Pandemic on Caregivers and People with Down Syndrome

While it is widely accepted that some populations experienced disproportionate effects of the COVID-19 pandemic, there remains a paucity of research on the impact of the pandemic on people with intellectual and developmental disabilities. This study aims to document and describe the effects of the pandemic on people with Down Syndrome (DS) and their families across multiple domains of the Epidemic Pandemic Impacts Inventory, to identify latent risks and service needs posed to subpopulations within the DS community. Survey responses ($N = 214$) were collected across three waves, with a mean assessment at 16.1 months ($SD = 6.49$) into the pandemic, from caregivers reporting on behalf of themselves and the person with DS. Based on a series of Latent Profile Analysis (LPA), four-profile models were selected for their model fits and high entropies to identify subgroups within caregiver and DS survey endorsements. The four profiles for DS were moderate social and physical impacts (41.1%), high overall impact and infection (15.0%), low overall impact (33.6%), and severe economic stress, emotional, and educational impacts (10.3%). Pre-existing emotional dysregulation predicted membership across most subgroups, and older age predicted membership in the low-impact DS profile. The four profiles for caregivers were educational disruption (24.8%), low overall impact (57.9%), emotional and infection impact (5.6%), and economic impact (11.7%). A significantly strong association ($OR = 6.67$) was found between the emotional and infection impact caregiver profile and the high overall impact and infection DS profile. Conclusions will later be drawn based on future analysis of the results.

Abstract Name: Light Polarization Effects on Carbonaceous Meteorites by Raman Spectroscopy

Carbonaceous chondritic meteorites are considered some of the most primitive surviving materials of our solar system, and are mainly composed of micro/millimeter sized inclusions, surrounded by a matrix of microparticles. These constituents can provide valuable clues about planet formation, like the thermal, barometric and temporal conditions in which these meteorites formed. This information can be obtained through their physical properties, such as structure, composition, morphology and mechanical properties, which can be characterized by using microscopy and spectroscopy techniques. In particular, Raman spectroscopy has been used extensively on meteoritic samples since it is a nondestructive tool that provides information about their structure and mineralogical composition. One of the extensions of this technique is called polarized Raman spectroscopy in which the polarization of the laser excitation source and/or of the scattered light from a sample are taken into consideration. This method offers additional information about the orientation and symmetry of molecular bonds and vibrations within a sample. In this work, we characterize the original light polarization of our home-built Raman spectroscopy equipment and adjust this system by adding optical components for modified polarization experiments. We carry out Raman measurements on carbonaceous chondritic meteorites (e.g., Northwest Africa 3118). Our results show that the Raman peaks and bands of the analyzed materials found in the samples are affected to a lesser or greater extent due to the polarization of the light. For instance, the intensity of the peaks and bands increase or decrease when the polarization of the incident laser beam is modified with respect to the original polarization setup.

Abstract Name: Exploring Chinese Students' Preparedness, Expectations, and Motivation to Study Abroad in America in the 1+2+1 Program

There is little academic work on understanding intercultural communication and perceptions between China and the United States. In particular, there is little scholarship investigating the motivations, preparedness, and expectations of students studying abroad between the two countries. In this study, we conducted qualitative interviews with 19 students and a quantitative survey of 36 students at Suzhou University of Technology participating in the 1+2+1 study abroad program with University of Wisconsin - Eau Claire. Students reported high academic preparedness but low preparedness regarding social integration and safety, specifically in regards to the language barrier and a fear of gun violence while studying in the United States. The students also indicated that much of their perceptions of American culture are created or heavily influenced by Chinese social media. Considering the difference between social and academic preparedness, results indicate a greater need for support in social and cultural areas.

Abstract Name: Predicting Presence and Preventing Poaching: Saving the Spotted Turtle

Spotted Turtles (*Clemmys guttata*) are one of many freshwater turtles in the Eastern US whose population is declining from both habitat threats (like loss, urbanization, and climate change) and illegal wildlife trade and trafficking. In order to help investigate resolve these threats, I worked with the Smithsonian's Turtle Conservation and Ecology Lab (TCEL) on what factors might affect *C. guttata* capture rates in traps, and created material on spotted turtles for law enforcement. I used generalized linear mixed models (GLMMs) on TCEL data from VA and NC watersheds to evaluate 5 variables that might effect *C. guttata* captures rates, and found that bait type, emergent vegetation cover, and canopy cover have no effect on capture rates. Trapping site and wetland type were unable to have a GLMM properly fitted to them, so further evaluation in the future is needed. Overall, further study is needed into what environmental factors drive spotted turtle populations. Additionally, I created an “at a glance” guide for *C. guttata* for law enforcement for identification of spotted turtles and information about their trafficking. Both of these products are being used by the Smithsonian Turtle Conservation and Ecology Lab to help support their work on the Competitive State Wildlife Grant for *C. guttata*.

Abstract Name: Molecularly Active Donor-Specific Antibodies: Using Donor-Derived Cell-Free DNA to Separate Harmful from Harmless HLA Antibodies in Lung Transplantation

Lung transplant recipients face the highest burden of rejection and chronic lung allograft dysfunction (CLAD) among solid organ transplant patients, with median survival remaining approximately 6–7 years despite advances in surgical technique and immunosuppression. This project aims to synthesize emerging evidence on how DSA and dd-cfDNA can be integrated into a framework for diagnosing and managing antibody-mediated rejection (AMR). Donor-specific HLA antibodies (DSA) are widely used as biomarkers of alloimmune risk, but their predictive value is inconsistent. While persistence, complement-binding (C1q/C3d), and class II specificity (particularly HLA-DQ) sharpen risk stratification, many patients with detectable DSA never develop AMR or graft loss, highlighting the limitations of DSA as a stand-alone marker. Donor-derived cell-free DNA (dd-cfDNA) has matured into a practical, noninvasive measure of molecular allograft injury. A multicenter cohort demonstrated that dd-cfDNA discriminates acute rejection with high AUCs and a negative predictive value around ~1%, supporting its utility as an early injury signal missed by histology alone. Beyond detection, dd-cfDNA carries prognostic information; extreme elevations identify patients at sharply increased risk of severe CLAD or death, even when routine markers are quiet. dd-cfDNA also rises with primary graft dysfunction and respiratory viral infections, which portend worse outcomes. Recent data suggest that the combination of DSA and dd-cfDNA defines a subset of patients with “molecularly active alloimmunity,” correlating with AMR and adverse outcomes. Using a synthesis of

contemporary clinical and translational studies, this project will integrate these complementary signals into practical, lung-specific pathways. We expect to outline a risk-stratification matrix crossing dd-cfDNA levels with DSA characteristics, propose diagnostic workflows for when combined signals should prompt biopsy or intensified surveillance, and highlight therapeutic implications for targeting high-risk biomarker phenotypes. The review also identifies key evidence gaps where standardized thresholds and multicenter validation are needed, providing an implementable roadmap for biomarker-informed AMR care.

Abstract Name: The Impact of Functional Warm Ischemia Time on Long-Term Outcomes in Donation After Circulatory Death Heart Transplant

In donation after circulatory death heart transplantation (DCD HT), donor hearts undergo mandatory agonal hypoxia known as functional warm ischemia time (FWIT), traditionally considered safe when kept under 30 minutes. This study examined the impact of donor FWIT on long-term survival among DCD HT recipients. Using the UNOS database, adults (≥ 18 years old) undergoing DCD HT between 2019 and 2024 were stratified into nine FWIT subgroups: ≤ 15 , 15–20, 20–25, 25–30, 30–35, 35–40, 40–50, 50–60, and ≥ 60 minutes. Baseline characteristics, outcomes, and complications were compared across groups. Survival at 30 days, 1 year, and 3 years was assessed using the Kaplan–Meier method, and Cox regression models evaluated the effect of FWIT on overall survival. A total of 1,213 recipients were analyzed, including 409 (34%) who received NRP hearts and 804 (66%) who received DPP hearts. No significant differences in 30-day, 1-year, or 3-year survival were observed between FWIT groups ($p=0.68$). Notably, the ≥ 60 -minute FWIT cohort had survival rates of 93.3%, 85.7%, and 71.4%, compared to 96.6%, 92.7%, and 76.1% in the ≤ 15 -minute cohort at the same intervals. Rates of acute rejection ($p=0.7$), inotropic support ($p=0.8$), hospital stay ($p=0.7$), pacemaker implantation ($p=0.2$), stroke ($p=0.5$), and dialysis ($p=0.7$) were also similar across groups. FWIT ≥ 60 minutes was not associated with worse overall survival (HR 2.14, $p=0.119$). These findings suggest that prolonged FWIT ≥ 30 minutes does not significantly impact long-term outcomes in DCD HT. However, the role of NRP in donors with extended FWIT warrants further investigation. Centers may consider using donor hearts with prolonged FWIT in carefully selected patients.

Abstract Name: The Whey Forward: Successfully Advocating for the Galactosemia Community

Advocacy and public awareness are central to improving visibility and support for rare disease communities. This mixed-methods project examines how advocacy campaigns can increase awareness and engagement among Gen Z audiences through a case study on Galactosemia, a genetic condition similar to lactose intolerance, to explore how advocacy strategies can bring greater visibility to rare diseases. The study began with a literature review, which explored previous successful advocacy efforts such as the Ice Bucket

Challenge created by the Amyotrophic Lateral Sclerosis (ALS) community. An online survey was then conducted to gather Gen Z feedback on their willingness to engage in awareness efforts, and the findings were used to identify storytelling and design techniques that build long-term engagement. These insights informed the creation of the 'No Whey Challenge,' a campaign that invites audiences to reflect on dairy consumption and learn about the dietary restrictions faced by people with Galactosemia. My presentation at NCUR will begin with an overview of Galactosemia and its connection to the broader issue of rare disease awareness. I will then explain how existing campaigns inspired this project and present the survey's structure and findings. Next, I will show visuals from the "No Whey Challenge," including post prototypes and sticker designs, to demonstrate how audience feedback shaped the campaign's development. The presentation will conclude with strategies that attendees can use to design their own audience-centered digital advocacy efforts for underrepresented health communities. Attendees will better understand how audience-centered design and storytelling can strengthen digital advocacy for rare diseases and inspire new ways to bring visibility to underrepresented health communities.

Abstract Name: Structural Brain Correlates of Intrusive memories Following Exposure to Distressing Events and Experienced Childhood Trauma

Post-traumatic stress disorder (PTSD) is a prevalent mental health disorder, intrusive memories are a core symptom of PTSD and reflect disruptions in emotional memory and regulation. The first part of our study investigates gray matter correlates of intrusive thoughts following exposure to distressing visual stimuli. Using previously collected magnetic resonance imaging (MRI) data (Visser et al., 2021), participants viewed a series of 60-second aversive video clips during MRI scanning, completed self-report measures including the DASS-21 (Depression, Anxiety, and Stress Scale) (Lovibond & Lovibond, 1995), and tracked the frequency of intrusive thoughts through post-scan journaling. Previous studies have shown that anxiety symptoms were positively correlated with gray matter volume in the left amygdala and hippocampus, consistent with their roles in anxiogenesis and emotional memory encoding (Picci et al., 2022). Conversely, greater cortical thickness in the bilateral anterior cingulate cortex (ACC) was associated with reduced anxiety and fewer intrusive thoughts, suggesting a neuroprotective role (Frodl et al., 2008). These findings were in line with our own results, which suggests that structural variation in emotion- and memory-related brain regions may shape vulnerability to intrusive memories. The second part of our study aims to compare a larger population to examine whether these patterns of gray matter volume and cortical thickness remain significantly correlated with behavioral measures of trauma. The population is people who experienced trauma which comes from previously collected data (Chopra et al., 2025). Participants answered a Childhood trauma questionnaire to measure abuse and similarly to the other study a DASS-21 scale. One of the participants' tasks was to categorize shapes versus emotional faces, this test has been used to look at PTSD (Chopra et al., 2025). Understanding these neural markers may inform targeted interventions for individuals at risk of PTSD, with implications for prevention and treatment strategies.

Abstract Name: Characterizing the Cellular Landscape of the Pancreatic Cancer Tumor Microenvironment at Single-Cell Resolution

Pancreatic cancer is a particularly aggressive malignancy with a five-year survival rate of only 15%, underscoring the urgent need for improved understanding of disease mechanisms. Single-cell RNA sequencing (scRNAseq) offers a powerful approach for dissecting the complex tumor microenvironment and identifying potential therapeutic targets. We analyzed samples from cancer and non-cancer patients with pancreatic tissue with publicly available scRNAseq data (GSE140873, GSE205013, GSE231535) to compare tissue composition across non-cancer pancreatic tissue (n=3), primary tumor samples (n=11), and metastatic samples (n=3). Clustering and differential gene expression revealed distinct transcriptional phenotypes and enriched pathways between sample states. Upregulated genes were input to Enrichr to identify characteristic pathways, revealing immune system regulatory mechanisms enriched in cancer samples (p-val <0.001) and extracellular matrix remodeling pathways upregulated in primary tumors relative to metastasis (p-val <0.001). Marker-based cell type assignment revealed differences in composition between states. Primary tumors had a 21-fold increase in fibroblasts compared to normal tissue, consistent with cancer-associated fibroblast remodeling. Additionally, plasma cells (humoral immune response) and red blood cells (angiogenesis) were only observed in primary and not normal samples. Metastatic samples were dominated by immune infiltration with NK cells (33.8%), T cells (11.2%), and myeloid cells (10.7%) accounting for over half of the tumor composition, indicating active immune response compared to primary and normal samples. These findings delineate key cell phenotypes associated with pancreatic cancer progression, providing a framework for further investigation of transcriptional biomarkers and improving targeted therapeutic strategies.

Abstract Name: It's not what you eat, it's who you eat: Quantifying the isotopic shift of estuarine mud crabs infected by a castrating parasite

Species interactions, together with environmental conditions, regulate the structure and function of our natural world; yet, these interactions are both temporally and spatially context-dependent. Changes in the strength or direction of species interactions have the capability of fundamentally altering ecological communities and food webs. Within the Chesapeake Bay, Panopeid mud crabs occupy an important node in the Bay's food web, connecting low-level primary consumers and larger secondary and tertiary consumers. However, parasites can modulate host behavior and diets with the potential to form distinct trophic niches and significantly alter energy flow within a food web. The castrating barnacle, *Loxothylacus panopaei*, induces morphological and behavioral modifications of their host, likely altering the trophic niche of infected crabs.

Here, we quantified the impact of the crab-castrating parasite (*L. panopaei*) on the trophic niche of mud crabs (Panopeidae) within the Hampton River, a temperate, urban tributary of the Chesapeake Bay. We sampled from September through November 2025, using modified vexar cages filled with ~5L of sun-bleached disarticulated oyster shell. Cages were suspended from a pier, and mud crabs were collected weekly. We quantified the trophic niche of healthy and infected crabs using stable isotopes (δ^{13} Carbon, δ^{15} Nitrogen, and δ^{34} Sulfur). We hypothesized that healthy and infected mud crabs occupied distinct trophic niche space. While we are awaiting our results, we expect to find further evidence of how parasites can modify major nodes within food webs. Parasites, while often inconspicuous, may fundamentally alter energy flow within and between ecosystems.

Abstract Name: Engineering Bright Near-Infrared Fluorescent Proteins for Deep-Tissue Brain Imaging

Real-time imaging across the whole brain would allow in-depth study of the complex neural circuits underlying cognition and behavior in health and disease. A comprehensive view of distributed neural networks requires imaging techniques with both high spatial and temporal resolution, as well as cell-type specificity. Existing methods for brain imaging, such as functional MRI, have limited temporal resolution and cell type specificity, while conventional fluorescent proteins (FPs) in the visible spectrum suffer from limited tissue penetration and low signal-to-noise ratio in deep brain regions. To address these limitations, we are engineering near-infrared (NIR) FPs, which are genetically-encoded optical tools that will enable in vivo tissue imaging with greater depth and cell-type specificity. NIR FPs enable greater tissue imaging depth than visible spectrum FPs due to reduced light absorbance and scattering. However, currently available NIR FPs exhibit some limitations, particularly low brightness that limits their utility for deep-tissue in vivo applications. Previously we showed that NIR20, a novel NIR FP found through genome mining, has significant fluorescence and absorbance capabilities. In the present study, we assessed the biophysical properties of several NIR20 variants, testing photobleach, quantum yield, extinction coefficient, and potential as a protein fusion tag. We compared the properties of these NIR20 variants to that of their parent protein, mRhubarb713, as well as current best FP mRFP720, and found promising improvements. We anticipate that the NIR20 variants we have created, when tested in vivo, allow for deeper tissue brain imaging that goes beyond the capabilities of currently existing NIR FPs.

Abstract Name: Biochemistry of a two-enzyme pathway for short and branched-chain fatty acid metabolism among species of the gut microflora.

Numerous studies reveal the importance of gut microbiome-derived short chain fatty acids (SCFA), such as acetate, propionate and butyrate, in signaling, metabolic, and health outcomes for animal hosts. Colonic microbiomes in Western human populations are generally dominated by species belonging to two bacterial phyla, Firmicutes and Bacteroidetes, which engage in a complex metabolic network that adjusts SCFA levels within an individual. Bacteroidetes includes well-recognized commensal and mutualistic species that serve to break down complex polysaccharides in the gut and generate products such as carbohydrates, propionate, and acetate that can serve as nutrients for the host and other microbial community members. In turn, Firmicutes utilize available resources (carbohydrates, acetate, etc.) to produce metabolites including an array of short chain fatty acids (SCFA), primarily acetate, propionate and butyrate, through fermentation. One SCFA metabolic pathway recognized within these species involves two distinct enzymes: 1) an SCFA kinase and 2) an acyltransferase. Together, these enzymes can reversibly interconvert SCFA with their acyl-CoA derivatives. Heterologous expression and purification of histidine-tagged variants for SCFA kinases and acyltransferases of key gut microflora species *Bacteroides thetaiotaomicron* and *Phocaeicola vulgatus* has allowed biochemical characterization of these enzymes using an array of both commercially available and laboratory-synthesized substrates. Moreover, efforts to identify protein interactions between SCFA kinases and acyltransferases using crosslinking methods and biochemical assays have been explored. Context for results as well as potential promiscuous SCFA kinase activity has been generated through co-characterization of related SCFA kinases from *Bacteroides mediterraneensis*, *Roseburia intestinalis* and *Methanosarcina acetivorans*. Taken together, results from these experiments provide insights regarding potential physiological roles for these enzymes in short chain, branched-chain, and medium chain fatty acid metabolism that may influence gut community dynamics and human health.

Abstract Name: Fluconazole Treatment Patterns and Antifungal Switching in Patients With *Coccidioides* Infection Across a National EHR Network

Coccidioidomycosis (Valley fever), caused by *Coccidioides* spp., is increasing in incidence across the southwestern United States, yet real-world treatment patterns and outcomes remain poorly characterized. Fluconazole is the most widely prescribed antifungal, but little is known about how clinicians modify therapy in practice or whether treatment switching may reflect challenges in clinical response. This study aimed to evaluate fluconazole use and subsequent antifungal switching among adults diagnosed with coccidioidomycosis. Using de-identified electronic health records from the TriNetX Research Network, representing more than 73 million patients across 84 healthcare organizations, we identified 7,108 adults with a recorded diagnosis of coccidioidomycosis and analyzed antifungal prescribing histories. Patients were grouped as fluconazole-only, switched from fluconazole, other antifungals, or no antifungals. Among the 1,504 patients receiving any antifungal, 1,235 (82.1%) were treated with fluconazole, and 114 (9.2%) were switched to another antifungal, most commonly voriconazole or itraconazole. The average fluconazole treatment duration was 215.6 days, and 318 patients received fluconazole for over 90 days. Mortality analyses showed higher 90-day mortality among patients who were switched compared with those who remained on fluconazole or did not receive fluconazole. These findings indicate that while fluconazole remains the most commonly prescribed therapy nationwide, a subset of patients experiences delayed treatment changes accompanied by worse short-term outcomes. This work provides one of the largest real-world assessments of antifungal use in coccidioidomycosis and underscores the need for earlier evaluation of treatment response, improved diagnostics, and future studies examining clinical or biological factors that may contribute to antifungal switching and patient outcomes.

Abstract Name: Aphra Behn: Restoring Canonical Standing Through the Classroom

This project aims to examine the current state of Aphra Behn studies, with a particular focus on her standing within the British literary canon and how academic discourse can shape that standing. My interest in Behn emerged after taking an early British literature course in which no women authors were included on the syllabus. After taking that course, I was introduced to Behn by Dr. Philip Krummrich, my research mentor. As I immersed myself in Behn's prose, poetry, and dramatic literature, I was struck by the eloquence and sophistication of her writing, as well as her commercial success as a female Restoration playwright in a largely male-dominated field. This prompted me to question why such a significant historical figure in literature remains absent from many academic syllabi and broader canonical discussions. I have examined recent developments in Behn scholarship to gain an understanding of how scholars are working to recover and reassess her works. Through this examination of Behn studies, I will explore how these recent developments have made the case for Behn as a canonical author, as well as highlight what institutional barriers continue to limit her inclusion. Ultimately, I believe that integrating Behn's most accomplished and well-written plays into classroom syllabi is essential to securing her rightful place within the literary canon.

Abstract Name: The Tempo of Change: Queer Culture in Classical Music

Classical music, or music rooted in educated European tradition, including forms such as chamber music, opera, and symphonies, is deeply embedded with tradition, from recital rituals and ensemble formations to gendered roles as musicians. As such, queer (LGBTQ+) individuals have faced barriers of discrimination due to the indivisible relationship of religion and classical music throughout history. The discriminations faced due to the traditionality of classical music, such as the factioning of voice parts, make it difficult for queer and gender non-conforming musicians to participate in and rise within classical music. Despite the inhibiting and erasure of queer musicians from these barriers, earlier individuals such as composers Pyotr Ilyich Tchaikovsky and Ethyl Smyth were able to gain significance within classical music. In the 21st century, the presence of queer musicians within classical music has shown a substantial increase, such as in the work of vocalists Adrian Angelico, Davóne Tines, and Lucia Lucas, who work to mend the deeply ingrained gendered expectations of the opera industry. Efforts to break these binding traditions are also seen in the field of music education, with the advocacy for inclusive experiences for musicians in training as well as emerging pedagogy discussing the teaching of queer students. This research analyzes the history of queer musicians within classical music from the 19th century to the present, the barriers these individuals faced, and the efforts being taken to mitigate the barriers queer individuals face in becoming classical musicians. This research adds to the lacking queer historiography of classical music under an intersectional lens of gender, sexuality, and socioeconomic status by using qualitative comparative sourcework of primary and secondary sources.

Abstract Name: Mummy Brown and the Culture of Egyptomania

Mummy brown is an oil paint pigment which was used in Europe between the 1700s and 1900s which included ground Egyptian mummies and several types of tree resin to create a paint with translucent and often waxy qualities. This paint was especially useful as a wash but could be built up as well, which gave it flexibility as a medium. My research question deals with why this pigment was originally developed and used in Europe from an interdisciplinary perspective. What qualities did mummy brown have not only as a paint pigment but also as a symbol of status and trends, and how has this been studied? The interest and appropriation of Egyptian culture and history, often in an unethical and obsessive way in western civilizations is Egyptomania. This cultural phenomenon is the culprit for the fad of mummy brown which begun as early as ancient Rome, and later Napoleons' conquest in Egypt. Any humanity, especially art history, is extremely multifaceted. Reasons for historical questions always force us to look at many aspects including the cultural practices of the time, economics and trade patterns, colonization and appropriation which may not always be blatant, and the patterns of conquest. To understand why mummies were a preferred pigment, we must look at all these aspects. I also will use my own visual interpretations of multiple paintings, which are believed to include mummy brown from both the Virginia Museum of Fine Arts in Richmond, and the Louvre in Paris, and my own experience using and milling oil paints. I specifically want to focus on Eugene Delacroix's paintings as I found the brown paint used to have a unique quality in both The Virginia Museum of Fine Arts and the Louvre, which I expect contains mummy pigment.

Abstract Name: A SMAL Spark: Turning Student Curiosity into Research Impact

This session explores how undergraduate research labs can thrive even in environments with minimal infrastructure and limited funding if curiosity, mentorship, and collaboration are placed at the center. Drawing from firsthand experience building an interdisciplinary research lab focused on social media and consumer behavior, this talk demonstrates how faculty can design meaningful spaces where student-driven inquiry aligns with faculty research agendas, while fostering curiosity. The lab began as a response to a simple question from a student interested in how social media is changing the way we interact with each other and companies. With no funding, no lab space, and only a laptop, that discussion evolved into a research lab where students contribute to published research and conference presentations. Through accessible tools and a focus on real-world relevance, the lab has expanded to support multiple research streams with undergraduate students as co-creators—not just assistants. By following a model that provides structured guidance early on and gradually shifts responsibility to graduate student mentors as their skills and independence grow, the lab's success has been built from the organic energy of shared inquiry. Along the way, I've found ways to integrate more research into my teaching, collaborate with peers across institutions, and stay engaged in my own scholarship. This talk is for faculty who want to build undergraduate research ecosystems with what they already have: passion, curiosity, and students eager to explore. Even SMAL labs can make a big impact, demonstrating how research and teaching can merge to empower faculty at all levels to create inclusive spaces that ignite undergraduate innovation.

Abstract Name: From Classroom to Communities: Empowering Students' Data Analytical and Presentation Skills Through Project-Based Learning

Project-Based Learning (PBL) at the undergraduate level is a pedagogical paradigm that integrates content mastery, meaningful work, personal connection, and problem-solving to create powerful learning experiences. Students enrolled in introductory STEM courses at a two-year college in Georgia, United States, experience challenges with interpreting real-world numerical data representations, such as charts, graphs, and plot diagrams. This challenge created an opportunity to design a PBL intervention to improve data visualization literacy (DVL) for students. Specifically, the PBL project was designed to mimic the work of a scientist investigating infectious diseases within their community. This study aims to explore whether a semester-long PBL intervention in an undergraduate microbiology course improves students' ability to analyze real public health datasets and enhances knowledge and self-reported confidence in scientific inquiry through community engagement. We aim to bridge the gap in data interpretation and communication using pre- and post-content knowledge assessments, pre- and post-survey questionnaires, and individual reflections. Implementing this PBL will provide insights into addressing challenges of DVL in STEM-related fields and fostering a multi-faceted skill set, such as gathering datasets, analyzing data, constructing graphical information, delivering presentations, and creating public service announcements related to relevant health concerns within the communities of students enrolled in early college courses.

Abstract Name: Ulysses S. Grant: How an Author and a Memoir Saved a President

Ulysses S. Grant has had an upsurge in examinations by historians over recent decades, particularly regarding his controversial presidency. What many historians briefly mention about Grant is his own memoir and the reasons why Grant took up his pen to write it. After researching various primary and secondary sources, it becomes even more apparent that writing such a lengthy work was something Grant would never have done under normal circumstances. Given his own anxieties and disdain for writing about himself, it would take a financial scandal and a throat cancer diagnosis to make Grant step up to the writer's plate. As Grant worried about his wife inheriting his debt, he would be approached by Mark Twain, who was looking to avoid bankruptcy as well, to write his personal memoirs for Twain's publishing company. Grant attacked the project vigorously, working days on end to finish the book before his time ran out. Grant's memoir was published a few months after his death, with the royalties taking care of Julia for the rest of her life. The circumstances surrounding Grant's memoir serve as a testimony to not only his Civil War service, but also to his deep love and concern for his wife Julia. It is also a testimony to Grant's literary talent, one which Twain himself was impressed by. While never an individual to glorify his own actions in writing, Grant would put aside his own fears and self-criticism to spend his final year writing a thorough, balanced, and often critical reflection of his actions throughout the Civil War.

Abstract Name: Turning Agriculture Around Without Turning the Soil Over: The No-Till Revolution

Over the past century and a half, the increasingly mechanized approach to agriculture, particularly its reliance on conventional tillage, has severely compromised soil integrity and drastically increased erosion and loss of soil organic carbon (SOC) in the most fertile top horizon, known as the topsoil. As such, a more human-centered, less mechanized approach to no-till agriculture can help mitigate this concern. This study is a survey of several previous studies surrounding this method, especially concerning the preservation of the SOC and structure of the surface horizon. Keeping tillage to a bare minimum, utilization of cover crop, and consideration of the Three Sisters method were compared to the conventional methods common in agriculture today. Also, looking back at previous examples of high tillage and its consequences was considered. It has been found that no-till, despite its counterarguments regarding compaction in the top layer, yields notable benefits to the topsoil and, as a result, the agriculture that depends on it. The lack of disturbance in the topsoil allows it to not only maintain its structure, but also its composition, most notably that of organic matter. Annual die-off and decomposition of agricultural plants directly add carbon to the soil, allowing it to more readily hold onto essential nutrients that the following year's crops will depend on to grow and flourish. Further, the method conserves the soil's readiness to hold onto water as much as conventional tillage can. The usage of cover crops, especially in winter, has been shown to mitigate topsoil from being eroded by water and wind. Lastly, the Three Sisters method combines the benefits of cover crop on behalf of the squash and nitrogen fixation on behalf of the beans. Considering these factors, no-till agriculture should replace conventional tillage methods.

Abstract Name: Optimizing Pedestrian Routes Through an Integrated Walkability Cost Framework

Previous work on route generation, such as in Google Maps, primarily focused on shortest-distance optimization. Multi-objective optimization approaches, meanwhile, typically incorporated only two or three dimensions of walkability. Our system extends this by integrating four: accessibility, safety, appeal, and comfort, which together incorporate both perceptual and objective factors such as slope and elevation into a unified routing pipeline. Additionally, we introduced a series of cost transformation functions that normalize raw scores across these four categories to generate routes that balance walkability and effort without significantly compromising distance or detour length. These transformation functions are essential because the routing task is treated as a minimization problem for unwalkability, ensuring that higher costs correspond to less desirable walking conditions. After computing costs for each function, we mapped them onto a sidewalk-based graph for realistic pedestrian routing, combining categories using normalization constants to ensure comparability. An extended version of Dijkstra's algorithm was then applied, accounting for differing traversal costs between uphill and downhill segments. Finally, a weighted ranking process was used to evaluate transformation cost functions and distinguish between routes that appear equivalent under Pareto optimality but differ in practical trade-offs. We tested our routing system across 57 origin–destination pairs and observed reasonable trade-offs, such as one case achieving a 6.89% improvement in walkability and a 31.75% reduction in slope or elevation gain, with only a 12.07% increase in total distance. Future work could adapt the routing algorithm to dynamically minimize the highest encountered cost along a path to better handle outlier conditions. Overall, our novel transformation functions and detailed trade-off analysis contribute to a more robust, nuanced, and practical multi-objective routing framework.

Abstract Name: Collaborative Urban Walkability Assessment Using Large Language Models and Environmental Analytics Module

Current approaches to measuring urban walkability depend on costly audits or emphasize broad physical metrics, while newer AI methods are susceptible to bias and the loss of contextual nuance. This research addresses these challenges by developing a system that combines a Multimodal Large Language Model (LLM) with an Environmental Analytics Module (EAM). Together, these components provide a comprehensive walkability assessment across four dimensions: accessibility, safety, comfort, and aesthetic appeal. The Multimodal LLM, GPT-4o mini, scans street view images (SVIs) for key features related to each walkability dimension and scores them from a scale of 1 to 10. These scores aligned with survey responses on

the same SVIs, indicating that the Multimodal LLM can reliably mirror human perception. The EAM focuses on environmental data that enables precise scoring and captures the unique conditions of each street. We validated the framework through a case study in the Downtown Seattle area using more than 21,000 Google Street View images and multiple urban datasets. The system scores are combined with distance, slope, and elevation penalties through transformation functions into a single composite cost. A Dijkstra-based routing method is applied to the directed graph to minimize the overall cost, producing paths that balance efficiency, safety, and comfort. A weighted ranking process was used to evaluate transformation cost functions for minimization and to distinguish between paths that may appear equivalent under Pareto criteria but differ in practical trade-offs. Future work will refine the scoring process and weighting schemes to better balance competing factors in order to further improve walkability assessments and pedestrian path generation. This research proposes a way to combine multimodal perception with environmental analytics to support more inclusive pedestrian planning and provide safe, accessible, and comfortable routes.

Abstract Name: Why do elite leaders make costly decisions in the nuclear realm? Examining the influence of dispositional factors on elite leaders' decisions to acquire, use, and/or test nuclear weapons.

Why do some elite leaders acquire, test, or use nuclear weapons despite its costly effects, and why do others not despite having the capability to do so? Existing literature attributes leaders' decisions to external factors (e.g. in-group pressure, familial obligation, and public accountability), which explains materialistic motivations behind leaders' decision-making process. However, less is said about the psychological motivations of leaders—specifically how dispositional factors (narcissism, low self-esteem, paranoia, cautiousness, and recklessness) influence leaders to pursue or not pursue nuclear weapons. This paper studies whether dispositional factors significantly influence elite leaders' decision-making process and justification of their decisions. I conduct a comparative case study analysis of three leaders: Kim Jong-un (North Korea), Harry Truman (U.S.), and Eisaku Satō (Japan). Kim and Truman are positive cases (leaders who used or tested nuclear weapons); Satō is a negative case (leaders who did not develop nuclear weapons). I have collected archival materials (speeches, interviews, diaries, notes, and biographies) for each leader and will analyze them through discourse analysis on NVivo. I will generate relevant codes based on each disposition and measure the frequency of each one across all archival documents. I hypothesize that dispositional factors significantly influence leaders' decisions to either pursue or abstain from developing nuclear weapons. However, if these factors do not show significant influence, my alternative hypothesis is that rationality and strategic decision-making (e.g. security-driven motivations, cost-benefit analysis, and power-driven motivations) have a greater influence on leaders' decision-making process in the nuclear realm. Understanding dispositional factors is crucial for developing effective nonproliferation strategies. Leaders can better anticipate others' behaviors, which can ultimately foster deeper cross-national awareness of each other's actions.

Abstract Name: From Cartography to Cartomancy: An Iconographic Analysis of The World Tarot Card

This paper analyzes iconography of the World tarot card, tracing its origins from medieval cartography, specifically in relation to apocalyptic and paradise motifs that conflate geographic space and time, delineating Christian ideologies through normative mechanisms. Drawing from Asa Mittman's analysis of the Matthew Paris and Hereford maps, this paper asserts that cartographic depictions normalized and perpetuated Christian identity and ideology—specifically through utilizing mechanisms of organization, positioning and proximity—creating a distinct syntax of interpretation that continues into the World card through its original trump order, and later divinatory function. This continuity is presented through Tjamke Snijder's discussion of communities of practice that allows for an analysis of hermeneutics through space and time by defining communities through operations of mutual engagement, joint enterprise, and shared repertoire. Cartographic depictions were a salient feature of the medieval Christian shared repertoire whose iconography and syntax became a significant aspect of the globalized court visual language between the 10th and 14th centuries. Integrating Eva Hoffman and Alicia Walker's discussion of medieval globalization elucidates the afterlife of iconographic depictions through appropriation, its relationship to materiality, and semiotic reception as a portable object. Early World cards were used in elite gameplay, eventually disseminating into the wider cultural consciousness through the rise of printing technology. These early World trump cards depicted paradise scenes, continuing the tradition of conflating space and time under Christian ideologies. With the rise of occultism in the 18th century, tarot iconography was utilized in divinatory functions, its iconography appropriated to align with the interpretations necessary to fulfill this function. Early occultists such as Etteilla, Gebelin, and A. E. Waite continued to conflate space and time through conventionalizing evangelist tetramorph iconography, the World card depicting the end of times rather than the paradise beginnings. This paper asserts a continuation of Christian ideologies even within occultist iconographic appropriation.

Abstract Name: Tumor immune microenvironment features predict immunotherapy response in metastatic triple-negative breast cancer

Triple-negative breast cancer (TNBC) is an aggressive subtype with limited treatment options and poor outcomes. The central research question of this project is: How do specific features of the tumor immune microenvironment (TME) influence response to therapy in metastatic TNBC? To investigate this, we profiled immune phenotypes and transcriptional signatures in tumors from patients (n=14) treated with pembrolizumab monotherapy (C1) followed by pembrolizumab plus nab-paclitaxel (C2) in a Phase II clinical trial (NCT02752685). The patients showed a response rate of 47% after a median follow-up of 19.9 months. PD-L1 combined positive score (CPS) showed that 14% of tumors were PD-L1-positive (CPS ≥ 10), 64% had low CPS (1–9), and 22% were PD-L1-negative (CPS = 0). Formalin-fixed, paraffin-embedded tumor biopsies collected at baseline and after treatment cycles underwent gene-expression analysis using the NanoString Breast Cancer 360™ Panel and spatial immune mapping with OPAL Akoya imaging. Most tumors (n=11) displayed “hot” immune phenotypes - high cytotoxic T lymphocyte (CTL) infiltration and CTL-to-myeloid-derived suppressor cell (MDSC) ratios. In contrast, non-responders exhibited MDSC infiltration, indicating an immunosuppressive TME. Responding tumors showed enrichment of immune-related pathways (antigen presentation, interferon gamma signaling) and increased PD-L1 levels (higher CPS scores and gene expression). Pembrolizumab also induced broader immune activation, evidenced by increased expression of

effector genes (CXCL9, CD8A, NKG7, GZMA, IDO1) and reduced stromal-associated gene expression (FHL1, FLNC, LEP, SOX17, PDGFRA), consistent with enhanced immune cell recruitment and activity. Our findings demonstrate that a pre-existing, immunologically active TME strongly predicts therapeutic response to immune-chemotherapy in TNBC. This study highlights the value of integrating TME profiling to guide personalized treatment strategies and improve clinical outcomes.

Abstract Name: Neurovascular Remodeling in the Retina of 5xFAD Mice: A Structural Retinal Biomarker of Alzheimer's Disease

Alzheimer's disease (AD) is a progressive neurodegenerative disorder that currently lacks early diagnostic biomarkers. The retina shares embryological origin and structural similarities with the brain, making it a promising site for non-invasive detection of neurodegenerative changes. Our study investigates whether AD pathology causes structural remodeling of the retinal neurovascular unit (NVU), focusing on astrocyte and pericyte coverage in 5xFAD mice, a transgenic AD model. Retinas from 9-month-old 5xFAD mice were compared to 7-month-old controls using confocal microscopy with FIJI/ImageJ analysis. Astrocyte-vessel overlap was assessed in the ganglion cell layer (GCL), while pericyte coverage was analyzed across the GCL, inner nuclear layer (INL), and outer nuclear layer (ONL). We quantified area coverage by astrocytes, pericytes, and vessels, and categorized astrocytes by soma position and morphology. Since in vivo retinal imaging cannot resolve cellular-level changes, our analysis clarifies whether AD pathology alters astrocyte-vascular interactions in ways that link clinical imaging with underlying cellular changes, supporting the development of early biomarkers. Despite no change in the total number of astrocytes, 5xFAD retinas exhibited altered astrocyte characteristics, including reduced vascular coverage, fewer somas on vessels, increased somas off vessels, and fewer thickened or coiled processes. Findings suggest that AD pathology disrupts astrocyte-vascular interactions and morphology, contributing to retinal NVU remodeling. 5xFAD retinas also showed layer-specific pericyte remodeling. Pericyte coverage was significantly increased in the GCL despite capillary loss, while the INL and ONL showed preserved pericyte-vascular engagement. Findings suggest both pericytes and astrocytes undergo AD-related structural changes that contribute to retinal NVU disruption.

Abstract Name: Resilience and Representation: Reclaiming the Voices of White Child Laborers on North Carolina's Tobacco Farm

This project explores how working on tobacco farms shaped the lives, identities, and beliefs of white child laborers in North Carolina during the Great Depression. By reframing child labor not solely as exploitation but as a site of agency and survival, this project seeks to recover overlooked voices of white rural laborers through oral histories from the Federal Writers' Project. These life histories reveal how children often

understood their labor not as victimization but as a source of pride and responsibility. Living in overcrowded, poorly built homes, they balanced long hours of fieldwork with limited schooling, viewing their contributions as essential to family survival. I examine contributing factors of religion and political beliefs that frequently emerged as empowering forces that kept them motivated, while mothers were highlighted for the emotional and domestic weight they carried alongside their children. The project also considers how families navigated and occasionally escaped generational poverty caused by the depression through marriage, military service, higher education, or selling farm goods. Further analysis considers how the work ethic and sense of responsibility formed through tobacco labor continue to shape contemporary attitudes toward work and family obligations. Drawing connections to Joy Harjo's poem "Tobacco Origin Story, Because Tobacco Was a Gift Intended to Walk Alongside Us to the Stars," the project portrays tobacco as both an economic and spiritual force, symbolizing endurance and the link between labor and life itself.

Abstract Name: From Buchenwald to Montgomery: The Ripple Effects of Compassion in Social Justice Leadership

My research project investigates the profound moral and scholarly connection between Karl H. Hertz, a World War II veteran and professor at Capital University, and his former student, Reverend Robert Graetz, a white Lutheran reverend who became an active ally of Martin Luther King Jr. in the Montgomery Bus Boycott. My research asks, did Hertz's experience during World War II and in liberating the Buchenwald concentration camp shape his moral doctrine and scholarly work in ways that influenced Graetz's later civil rights activism? I believe that Hertz's confrontation with Nazi atrocities during the war deeply affected his worldview, compelling him to prioritize empathy, morality, and the importance in confronting injustices through both religion and action. Hertz charged this mentality into his teaching, influencing students like Graetz, who later risked his safety to support Montgomery's Black community in the struggle for racial equality during the Montgomery Bus Boycott. Using a mix of archival research, textual analysis, and historical context, my research draws from Hertz's *Everyman a Priest* and *Buchenwald and Beyond* alongside Graetz's memoirs *Montgomery: A White Preacher's Memoir* and *A White Preacher's Message on Race and Reconciliation*. Through close reading and comparison, I researched the moral and theological themes that connect the liberation of Buchenwald to the civil rights activism in Montgomery, Alabama. By highlighting this ripple of change, my research reveals how experiences of hardship and suffering can cause a ripple of intergenerational activism, shaping moral leadership across movements and locations. In the end, this project positions Capital University within a legacy of social justice education and action, highlighting how empathy constructed from a historical trauma can inspire lasting commitments to equity and compassion in American civil rights history.

Abstract Name: Increasing Out-of-Plane Stiffness in 3D Printed Pneumatic Soft Robotic Actuators Using a Print-in-Place Endoskeleton

In the field of soft robotic actuators, Pneumatic Networks (PneuNets) have shown promise for their ability to perform safe and adaptable robotic manipulation. Most PneuNets are manufactured by casting silicone into a mold. However, 3D printing is emerging as a compelling alternative, providing a more streamlined fabrication process and enabling finer control over actuator geometry. Nearly all PneuNets, both cast and 3D printed, are fabricated using a single soft material, which makes them prone to bending in undesired directions (out-of-plane) while they bend in the desired direction (in-plane). Previous research has tried to mitigate undesired compliance by inserting a strain limiting layer into a mold before the silicone is cast. While this design decreases the out-of-plane deformation, it also significantly reduces the desired in-plane compliance that makes the PneuNet effective. Our research aims to leverage the multi-material capabilities present in the Inkjet 3D-printing process to print-in-place a strain limiting layer that resists deformation in all but one degree of freedom (endoskeleton) into a PneuNet. Using this process allows us to reduce the out-of-plane compliance of the PneuNet while providing increased geometric complexity and a faster and more repeatable manufacturing process. The endoskeleton is printed simultaneously with the soft actuator body, then tested on a robotic-arm-based test rig that measures the applied force at different pressures. Data from a PneuNet with an endoskeleton indicate significant out-of-plane stiffness with a modest increase in in-plane stiffness, suggesting a promising trade-off between stability and compliance. Ongoing work focuses on optimizing endoskeletal geometry and material distribution to enhance further directional stiffness and force output relative to existing single-material and cast-in-skeleton actuators. Our project demonstrates that 3D-printed endoskeletal structures can outperform current designs in terms of rigidity and versatility, enabling soft robotic grippers to interact more effectively with high-force objects and tasks.

Abstract Name: Romanization in the Gallic Provinces as Supported by the Roman Army

This paper explores Romanization—the process through which indigenous populations become culturally Roman—in the provinces of Gaul (modern France) during the 1st to 2nd centuries CE. It argues that the process of cultural conversion, broadly defined as “Romanization”, is a topic that has been debated repeatedly within the history of Roman scholarship. My analysis focuses on inscriptions, specifically, for example, those containing Gallic names performing explicitly Roman functions. My research is built off the theoretical insights of historian Greg Woolf, who has been the foundation for much of my work. In this paper, I cover the history of the debate regarding Romanization and then go on to provide my own analysis of the subject based on the primary literary sources and archaeological evidence. I argue in favor of the current historiographical sources which interpret the evidence of Romanization in Gaul as a willing cultural conversion. I discuss how Gallic leaders would then go on to replace the Roman authorities and become the authorities of Roman rule over their very own people. I also discuss how the Romans viewed the process of Romanization as they spread their ideals and culture through the Gallic provinces. Rome controlled vast territories and for the Romans, Romanization was more than the spread of culture; it was essential to the very stability of the Imperial system.

Abstract Name: Sequential vs. Simultaneous Language Acquisition: Effects on Working Memory

This project investigates whether simultaneous bilinguals, individuals exposed to two languages from early childhood, demonstrate different working memory capacities compared to sequential bilinguals, those who begin learning a second language later in life. Prior research has suggested that managing two linguistic systems may shape cognitive processes such as attention, inhibition, and working memory, but findings remain mixed. This study aimed to clarify whether the age of bilingual exposure meaningfully influences working memory performance in young adults. Data collection was conducted in Morocco, where bilingualism is widespread, and individuals regularly navigate multiple languages in daily life. Participants completed two auditory working-memory tasks: a backward digit span task assessing the storage and manipulation of numerical information, and an auditory N-back task measuring the ability to update and monitor information in real time. Participants also reported their language histories, including age of acquisition and degree of proficiency, which allowed classification into simultaneous and sequential bilingual groups. Results indicated no significant differences in working memory performance between simultaneous and sequential bilinguals on either task. These null findings suggest that the age at which a second language is acquired may be less influential in contexts where multilingual exposure is deeply integrated into everyday cultural and social environments. The constant use of multiple languages in Morocco may lead to similar cognitive engagement across groups, minimizing differences often reported in populations with less frequent bilingual interaction. These findings will be discussed within the broader landscape of bilingual cognitive research, with emphasis on how cultural and linguistic environments may moderate or override effects typically attributed to bilingual experience. Ultimately, this project highlights the importance of considering sociolinguistic context when evaluating cognitive outcomes in multilingual populations.

Abstract Name: "Orders the Navy's Seal Team 6 to assassinate a political rival...Immune.": The Presence (or lack thereof) of Presidential Immunity in the U.S. Constitution, from Nixon's Justice Department to Trump v. U.S. (2024)

In the Constitution, only members of the legislative branch are granted any sort of legal immunity, yet in 2024 it was the president who received a sweeping immunity from prosecution from the Supreme Court. Is broad presidential immunity supported by any of the Founders or any constitutional law, or was the Court's decision a legal travesty as portrayed in the media? I answer this question through an extensive study of pamphlets and letters from prominent figures of the time, who helped shape the Constitution and advocate for (or against) its ratification. I supplement these sources with secondary writings from contemporary scholars of constitutional law. Finally, I track the growth of the idea that there was presidential immunity from Jefferson's attempt to avoid subpoena, to Lincoln's suspension of habeas corpus, to the 1973 OLC memo which gave presidents reprieve from Justice Department prosecution, and ending with the broad presidential immunity granted by the Supreme Court in Trump v. U.S. (2024). I find the Founders gave members of Congress clear immunity from arrest due to their adherence to British common law, yet presidential immunity was not explicitly included due to the Founders ignoring the common law concept of "the king can do no wrong." While presidential immunity has grown over the years, it is largely nonexistent in the Constitution, as the Founding Fathers broadly admit the president could be charged in a civil or criminal trial separate from

impeachment for private or nonpolitical actions, even ones related to their office, although they may be immune from arrest or prosecution during their time in office.

Abstract Name: How Should we Inquire Into Black Histories? A Critical Analysis of Inquiry Design Model Lesson Plans

Throughout our nation's history, African Americans have received inadequate attention in the curriculum and unfair treatment in schools. We see the irreducible need in teaching Black History because of the ample, more accurate understanding of history, and the ameliorated future that can be carved out because of which. The purpose of this research was to evaluate a multitude of African American History Inquiry Design Model (IDM) lesson plans. The IDM format claims to assist teachers in crafting lessons and units that engage students in investigating compelling questions, analyzing sources, and developing evidence-based arguments through its C3 framework. A framework that is innately incomplete and often poorly executed. Given the unique and complicated history of Black people in the United States, it is imperative that African American History is taught through a record of Black agency and advancement, as well as several other tenets. To that end, the 4 African American History IDM lessons qualitatively analyzed using both the Black Historical Consciousness (King, 2020) as a theoretical framing, as well as Fouche's. With this analysis, my professors and I have embarked on a series of presentations including the National Conference of Social Studies as well as CURC (Celebration of Undergraduate Research&Creativity) at Colorado State University where I was fortunate enough to be an awardee for the College of Liberal Arts.

Abstract Name: Characterizing and Identifying Human Brain Endothelial Cell Response to Encephalitic Orthobunyaviruses

The California serogroup orthobunyaviruses are mosquito-transmitted viruses that can cause neurological disease. La Crosse virus (LACV) is the primary cause of pediatric arboviral encephalitis in the United States, while Jamestown Canyon virus (JCV) is primarily associated with neurological disease in adults. LACV is both highly neurovirulent, it can cause damage and disease in the brain, and neuroinvasive, it can enter the brain by crossing the blood brain barrier (BBB). JCV is also neurovirulent but is not neuroinvasive. The viral M genome segment in LACV and JCV has been associated with differences in neuroinvasion. This segment codes for two virion surface glycoproteins (Gn and Gc) as well as a non-structural gene (Nsm). This study aims to identify whether it is the glycoproteins or the Nsm gene that allows LACV to cross the BBB while JCV cannot. Quantitative polymerase chain reaction (qPCR) was used to compare the host gene expression

response of LACV- and JCV-infected human brain endothelial cells (HBECs), the primary cell type in the BBB. Initially, HBECs were infected with LACV and JCV. Samples were collected at various timepoints post infection. From there, qPCR identified differences in host response by comparing messenger ribonucleic acid (mRNA) levels. HBEC host responses will identify how the infected cell responds to the different neuroinvasive phenotypes of LACV and JCV. Ongoing experiments are focused on developing viruses with swapped genes in the M segment (chimeric viruses). Infection of HBECs with these chimeric viruses will identify which M segment-encoded gene is responsible for eliciting different host responses between LACV and JCV. This presentation will focus on baseline differences in host responses to LACV and JCV as a first step in identifying the viral gene allowing for neuroinvasion.

Abstract Name: The Role of Political (Mis)fit in Workplace Experiences and Employee Turnover Intentions

The attraction-selection-attrition (ASA) model suggests that employees who perceive misalignment with their organization's beliefs and values experience an increased likelihood of attrition or a stronger desire to leave. Similarly, research on ideological migration shows that Americans often relocate away from politically incongruent communities and toward those that better align with their political beliefs, reflecting a drive for social belonging. Just as the need for belonging helps explain relocation patterns and political sorting at the community level, the ASA model points to a similar process in employees' workplace decisions. If political values guide residential choices, they may also influence whether individuals decide to stay or leave their place of work. The present pre-registered study tests whether political (mis)fit in the workplace predicts workplace experiences that facilitate or hinder employee attrition. Participants (N = 608) were part- or full-time employed American adults recruited through Prolific's online platform, all of whom reported frequent in-person interactions with coworkers. They provided information about their work background and completed measures of their left-right ideology, perceived political alignment and misalignment with coworkers, experiences of workplace ostracism and incivility, sense of belonging, job burnout, job satisfaction, organizational commitment, ease of finding a comparable job, and turnover intentions. Results underscored the central role of belonging in how political (mis)fit shapes workplace experiences and hence turnover risk. Employees who perceived political alignment reported more positive workplace experiences, including greater belonging, which in turn predicted higher job satisfaction and organizational commitment. Conversely, perceived misalignment was associated with negative workplace experiences, such as greater ostracism and incivility, which predicted less belonging, greater burnout, perceptions of better job alternatives, and higher turnover intentions. These findings integrate insights from the ASA model and ideological migration hypothesis, showing that political (mis)fit corresponds with distinct workplace experiences and underscoring the importance of environments that foster belonging.

Abstract Name: Neurological and Cognitive Impairments Following COVID-19: A Systematic Review

COVID-19 has been associated with persistent neurological and cognitive symptoms in many individuals, yet the extent of these impairments and the mechanisms behind them are not fully understood. This systematic review examines the current literature on the long-term neurological and cognitive effects in adults and adolescents following SARS-CoV-2 infection. Collected evidence includes peer-reviewed studies published between 2020 and 2025, drawn from scientific databases and informed by cohort studies, neuroimaging research, and longitudinal clinical surveys. We searched PubMed and Google Scholar databases and included 15 articles in our review. Across the evidence, long COVID patients frequently reported memory difficulties, reduced attention, executive functioning problems, headaches, sensory disturbances, and subjective “brain fog”. Reported prevalence for these symptoms varied, with 20% to more than 70% of individuals experiencing at least one neurological or cognitive symptom months after infection. Many studies found that symptoms persisted for several months to over a year, and recovery trajectories differed across age groups. Factors such as severity of the initial infection, older age, and preexisting medical or psychiatric conditions were consistently associated with worse long-term outcomes. Proposed biological explanations for these impairments included chronic neuroinflammation, microvascular injury, immune dysregulation, and hypoxic damage during acute illness. Neuroimaging findings supported several of these mechanisms by showing changes in gray matter volume, white matter integrity, and functional network efficiency in some post-COVID patients. By synthesizing these findings across study types, this review highlights converging evidence that COVID-19 can produce lasting effects on the brain and cognition. The results also identify gaps, such as limited adolescent-focused research and limited long-term follow-up, that remain barriers to understanding recovery trajectories. Overall, this project provides a comprehensive summary of what is currently known about neurological and cognitive impairment after COVID-19 and emphasizes the need for continued research to guide clinical support for long COVID patients.

Abstract Name: Weakening Bacterial Defenses: Competitive Inhibitors of the STP1 Phosphatase in *S. aureus*
NCUR Abstract

Antibiotic resistance in *Staphylococcus aureus* has made infections increasingly difficult to treat, with strains now exhibiting reduced susceptibility to drugs such as methicillin, vancomycin, and penicillin. A key contributor to this resilience is the serine/threonine phosphatase STP1, which coordinates essential cellular processes including cell wall integrity, biofilm development, and control of cell division and size. Targeting STP1 could therefore weaken bacterial defenses and improve the activity of existing antibiotics. To explore this, we expressed and purified STP1 and established a phosphatase assay to monitor its activity. Using this approach, we identified several small molecules that competitively inhibit STP1, demonstrating potential as antibiotic adjuvants. We have quantified the inhibition, modeled potential binding poses using SwissDock, and established initial structure-activity relationships.

Abstract Name: The Storytelling Involved in Marketing a Business/Club and the break down of proper Business Communication

This research examines how storytelling, personal branding, and business communication shape the development and marketing of a new student organization designed for Gen Z audiences. Although student organizations operate in academic environments, many adopt business-oriented strategies for branding, recruitment, and communication. This project uses the formation of The Business Strategy Room, a marketing-focused student organization, as a real-world case study to explore these dynamics. The study identifies a central problem: how can a new organization effectively attract members, communicate value, and establish credibility without an existing reputation? To address this, the project analyzes personal branding, digital communication, and marketing theory as they were applied throughout the organization's creation. Research on Gen Z consumer behavior, particularly their preference for digital engagement, informed the strategic use of Instagram as the primary communication channel. Design choices including dark color palettes and a bullhorn icon were selected to communicate professionalism and a focus on marketing, aligning with the organization's intended identity. Methodologically, the project combines practical application, demographic analysis, and business communication frameworks from Guffey & Loewy's Essentials of Business Communication. Key components include storytelling in logo development, message framing for recruitment, and the use of digital branding techniques in alignment with Gen Z marketing research (e.g., the Cafely case study on online purchasing behaviors). The study concludes by examining how setbacks, such as the required transition from a local club to a national chapter, provided opportunities to apply negative-news messaging strategies such as clarity, empathy, fairness, and professionalism. These experiences illustrate how business communication principles directly translate into student leadership and organizational development. The findings contribute to broader conversations on how undergraduate leaders can apply marketing and communication theory to build impactful, student-centered organizations.

Abstract Name: Pre-Flight GCP Planning for UAV Surveys Using Predictive GDOP Modeling

Accurate ground-based reference points, called Ground Control Points (GCPs), are essential for creating reliable 3D maps in ArcGIS. However, survey teams often design these GCP layouts based on experience or trial-and-error, which can lead to extra field visits, higher costs, and uncertain mapping accuracy. This work develops a predictive planning tool that helps surveyors determine how many GCPs are needed and where they should be placed before a drone mission begins. The method adapts a concept used in satellite navigation known as Geometric Dilution of Precision (GDOP), which describes how measurement geometry affects accuracy. By combining flight altitude, camera settings, image overlap, and a Digital Elevation Model describing terrain height, the system estimates areas where mapping accuracy may become weak. The system employs iterative optimization algorithms to identify GCP configurations that minimize predicted uncertainty

while reducing field survey requirements. Based on these predictions, the tool automatically generates suggested GCP placement maps and accuracy indicators, helping users see where additional control points might be required. All results are exported in ArcGIS-ready formats, such as KML, shapefiles, and feature layers, so that surveyors can load them directly into ArcGIS Pro or ArcGIS Field Maps. Validation testing across diverse terrain types—including flat agricultural areas, rolling hills, and mountainous regions—demonstrates the framework's ability to provide reliable placement guidance under varying topographic conditions. This predictive framework aims to reduce field trial-and-error, improve planning efficiency, and increase the likelihood of achieving mapping accuracy goals on the first attempt.

Abstract Name: Functional Characterization of a Novel Endogenous Retroviral Protein

Cells encode many mechanisms to fight off pathogens like viruses. The OAS-RNase L is an innate immune system pathway triggered by viral RNA; during infection oligoadenylate synthetases (OAS) synthesize 2'-5' oligoadenylates (2-5A), which bind and promote the dimerization of RNase L (Zhang et al., 2013). Active RNase L cleaves viral and cellular RNA, inhibiting viral replication and limiting the spread of infection. Mammals regulate this pathway with phosphodiesterase enzymes (PDEs), which cleave 2-5A to prevent RNase L overactivation. Some RNA and DNA viruses have acquired PDEs from their host's genomes, which inhibit the innate immune response by cleaving 2-5A (Zhang et al., 2013). A previously uncharacterized endogenous retroviral protein was found to share sequence and structural similarities to known viral PDEs (Basta et al., 2009); however, it is unknown whether it shares their inhibitory functions. We hypothesize that this protein functions as a viral PDE. To test this, we transfected human lung cancer cells with the zebrafish endogenous retrovirus (ZFERV) predicted PDE fused to a GFP gene and an empty GFP vector control. These cells were stimulated with a synthetic double-stranded RNA (poly(I:C)) to activate the OAS-RNase L pathway. GFP was visualized by fluorescence microscopy, and proteins were separated using a native gel and transferred to a western blot probed for RNase L. Cells stimulated with poly(I:C), but lacking the putative PDE, are expected to have an activated OAS/RNase L pathway, indicated by dimerization of RNase L. Stimulated cells with a functional PDE are expected to have a deactivated OAS/RNase L pathway, indicated by monomeric RNase L. Additional confirmation of RNase L activation provided by visualization of RNA fragmentation will support the protein's characterization as a viral PDE, representing the first observation of a PDE in a retrovirus.

Abstract Name: Gaming for Growth: Exploring the Impacts of Different Video Genres on Cognitive and Emotional Development in Adolescents and Young Adults

Video games are now a central part of adolescence and young adulthood, yet their effects on cognition and emotional development remain widely debated. This project examines whether broad genre labels (e.g., action, puzzle, sports simulators) or their underlying core game mechanics (e.g., task-switching, multi-object tracking, cooperative play) better predict cognitive and socio-emotional outcomes in adolescents and young adults, including those with cognitive dysfunctions. Clarifying this relationship matters because parents, educators, and players increasingly use games for learning and intervention but lack clear, mechanic-based guidance or harm-reduction advice. The research consists of four parts. Part 1 analyzes how core game mechanics place distinct cognitive demands on players in order to increase cognitive performance. Part 2 compares different genres of games to identify which combinations of mechanics are most associated with performance gains in cognition. Part 3 examines how cooperative versus competitive structures shape sociability, emotion recognition, and overall well-being to benefit the player's emotional development. Part 4 evaluates how commercial and purpose-built games are used with adolescents who have cognitive or social limitations, and reviews risks such as excessive play and extrinsically motivated gaming to minimize the negative effects of gaming. The synthesis suggests that specific mechanics and play context predict outcomes more reliably than genre labels alone. Action and strategy games tend to support executive cognitive functions; augmented-reality and collaborative games foster sociability; and targeted training games can benefit adolescents with conditions such as Sensory Processing Dysfunction. Parents, educators, and the player themselves should prioritize games with structured feedback and cooperative goals, keep play moderate and intrinsically motivated, and limit time in highly competitive stress-inducing environments.

Abstract Name: Efficient Pd-Catalyzed Amination of Benzodiazepine Scaffolds for GPCR Ligand Development

Palladium catalyzed reactions have become prominent reactions for creating C-N bonds and are widely used in the synthesis of pharmaceuticals. In this study, a palladium catalyzed Buchwald-Hartwig synthesis was used to introduce new amine substituents to a brominated benzodiazepine for the development of compounds with novel activity. We established an optimized protocol utilizing 5% Pd₂(dba)₃ in conjunction with 10% Xphos as the catalytic system. Conversions with substituted anilines, aliphatic amines and heterocyclic amines were observed with yields ranging from 23% to 89%. All products were analyzed and characterized using liquid chromatography-mass spectrometry and NMR spectroscopy. We identified that some of these compounds are having promising affinities for the Alpha 2B adrenergic receptor (AR α 2B) and the 5-Hydroxytryptamine 2B receptor (5-HT_{2B}). We are currently synthesising new molecules to identify ligands with high specificity and better affinity enabling us to evaluate their pharmacological effects in vivo.

Abstract Name: The Resurfacing Interest in Brutalism and Its Cultural Significance on Self-Expression: Analyzing the Intersection of Architecture and Graphic Design

After World War II, Europe entered the age of reconstruction and recovery for the millions of displaced victims of the war. The United Kingdom needed buildings, and concrete played a significant role in the creation of new buildings because the technological advances allowed for concrete to be widely accessible and became an extremely versatile medium for architects. The architectural movement of Brutalism—derived from *béton brut*, meaning raw concrete—becomes a global Architectural style, and the neutral materials used in Brutalism signified institutional power for many regions. Ultimately, European Brutalism is fundamentally intended to evoke truth and purity that would later be misconstrued into totalitarianism and apocalyptic dystopia in the United States. The graphic design movement of Brutalism holds the same fundamental ideas of truth and raw materials and has significant visual ties to 60's pop culture. The specific analysis of the promotional posters for the 60's "This is tomorrow" exhibition will be used to compare the possible influence this style of poster had on modern Brutalism. The modern resurgence of architectural and graphic design Brutalism in the United States is polarizing. Understanding the political response to Brutalist Architecture in government buildings is imperative to understanding the cultural removal of the fundamental ideas of Brutalism as a design. This paper analyzes the context behind Brutalism in graphic design, and the controversies surrounding the style are imperative in protecting the self-expression of design in the 21st century.

Abstract Name: Development of CRISPR/Cas9 Approach to Express and Visualize VAPA Protein in Astrocytes Using Endogenous HA-Tag

Astrocytes are the most abundant glial cell in the nervous system and play a critical role in the support and development of neurons. However, little is known about the mechanisms behind their morphology or intercellular cross-talk with neurons. Previously, we have shown that neuronal contact with astrocytes stimulates expression of the S1P receptor, which in turn regulates Vesicle-Associated Membrane Protein A (VAPA). This posits VAPA as a novel member of astrocyte-neuron communication pathways. VAPA is a specialized protein of the endoplasmic reticulum that facilitates the transport of lipids across organelles through the creation of membrane contact sites (MCSs). Loss of VAPA has been associated with Chorea Acanthocytosis (ChAc) along with other neurodegenerative disorders. Here we show our strategy of designing an astrocyte-specific adeno-associated virus (AAV) to tag VAPA in vivo using a CRISPR/Cas9 approach. We used multiple gRNA predicting webtools to identify potential sites of HA-tag insertion at the N-terminus of the VAPA gene. Interestingly, the 3rd ranked gRNA from GenScript targeting exon 1 of the VAPA gene was the only option for HA tagging. We designed the gRNA together with HA-tagIN primers, then cloned these into the appropriate plasmid vector with Cas9 and gRNA scaffolds. However, after transfecting this plasmid construct into HEK293T cell cultures, western blotting did not reveal HA-tagging of the VAPA gene. Therefore, we have and are exploring different options to observe VAPA's role in neuronal cross-talk using our AAV framework and immunohistochemistry.

Abstract Name: Evaluation of interfering substances in the novel D2HGlo assay for detection of D-2-Hydroxyglutarate (D-2-HG)

The 2021 World Health Organization (WHO) classification of Central Nervous System (CNS) tumors identified the mutational status of Isocitrate Dehydrogenase (IDH) as the most critical indicator for prognosis in glioma patients. IDH is a key component responsible for the energy generation of a cell. Mutations found in the active site of Isocitrate Dehydrogenase 1/2 confer a new function for the protein generating the oncometabolite, D-2-Hydroxyglutarate (D-2-HG). This oncometabolite is associated with disease progression in glioma and is found in other cancers such as AML (Acute Myeloid Leukemia). D2HGlo is a novel, fluorescence based, assay for detection of the oncometabolite, D-2-HG, and has the clinical potential to quantify D-2-HG concentrations in glioma preoperatively, intraoperatively, and postoperatively. D2HGlo quantifies D-2-HG in various body fluids including serum, plasma, and urine. Here, we investigate the efficacy of D2HGlo utilizing contrived samples containing interfering substances to determine the clinical utility of D2HGlo. Contrived clinical specimens including evaluation of anticoagulants found during a blood draw, hyperglycemia, hyperlipidemia, hyperbilirubinemia, and hyperproteinemia. The evaluation of D2HGlo in this interfering substances study is consistent with the guidelines of the CLIA 88 (Clinical Laboratory Improvement Amendments) federal standards.

Abstract Name: Wings of Change: The Audubon Society of Kentucky Amid Generational Shifts in Environmental Engagement

Recent studies show that Gen Z cares more greatly about the environment than previous Baby Boomer and Gen X generations, but spends far fewer time outside enjoying nature. This trend is reflected in the decline of environmental clubs at the University of Kentucky and the lack of engagement in nature. Locally, the Audubon Society of Kentucky, a branch of the national bird conservation organization, has undergone expansion and contraction as interest in environmentalism has waxed and waned over the past 100 years. In particular, the youth of the 1960s and 1970s ushered in the original catalyst for today's environmental movement. This transformation challenged conservation organizations such as the Audubon Society to stay relevant to new audiences. Activism groups like the Sierra Club and the Audubon Society were charged to

encourage the inclusivity of youth and women, change their specific messaging to a broader public-health centered narrative, and stimulate bipartisan policy for the sake of future-focused environmentalism. Today, the Audubon Society of Kentucky appears diminished in outreach and influence when compared to the Kentucky Sierra Club, which continues to expand. Using the meeting minutes, brochures, and bird counts of the Audubon Society of Kentucky Papers, 1940-1976, at the University of Kentucky Special Collections Research Center, the organization's success in aligning with and accomplishing these goals during the 1960s and 1970s will be analyzed in comparison to the local Lexington Sierra Club branch. Furthermore, this project will examine how the prior work of the Audubon Society can illuminate the organization's future growth in Gen Z environmental activism and interest. The project will produce an educational event proposal for the Audubon Society of Kentucky in collaboration with the University of Kentucky to establish how the organization can follow modern-day environmentalism trends to increase visibility and connection with a 21st century public.

Abstract Name: Determining the Retest-ability and Reliability of the Jamar Handgrip Dynamometer and the Vernier GoDirect Handgrip Dynamometer

Handgrip strength has been found to be a substantial predictor for overall muscle strength. A study that agrees with the previous statement states plainly that, “-handgrip strength can be an effective tool for predicting muscular strength and endurance.” (Vaidya and Nariya). Currently, the Jamar Hydraulic Dynamometer is considered to be the “Gold Standard” when it comes to total hand grip test. It is estimated that the Jamar will remain to be more accurate when it comes to the test-retest reliability in comparison to the Vernier GoDirect as well as the Jamar Hangrip Dynamometer. The purpose of this research is to identify the test-retest reliability between different handgrip dynamometers. Methodology includes testing participants on two different hand grip dynamometers over the course of three tests during an overall 4 month research project. Participants will be tested on the Jamar Hydraulic Dynamometer as well as the Vernier GoDirect Handgrip Dynamometer. Each participant will go through two trials on each dynamometer to ensure accurate results per test. The tests will be done on the dominant hand first followed by the non dominant hand second to provide ample rest time between tests. Significant literature regarding the Venier Handgrip Dynamometer has yet to be published, however this device has other capabilities that the other dynamometers don't have. These capabilities include testing for muscle fatigue as well as individual fingertip strength. For this study, we will not be testing for these two variables, and just using the devices function for overall handgrip strength.

Abstract Name: The Use and Effects of TMS Therapies on Restless Leg Syndrome and Chronic Pain

Both Restless Legs Syndrome (RLS) and chronic pain disorders show a shared pattern of cortical disinhibition measurable through transcranial magnetic stimulation (TMS). Prior research consistently reports reduced short-interval intracortical inhibition (SICI), reflecting impaired GABA-A-mediated inhibition, and shortened cortical silent period (CSP), associated with GABA-B dysfunction. These deficits indicate hyperexcitability in motor and sensorimotor circuits. Early therapeutic studies suggest that high-frequency excitatory stimulation over the primary motor cortex (M1) and low-frequency inhibitory stimulation over the somatosensory cortex (S1) may partially restore inhibitory function and reduce symptoms. Objective: This project investigates whether repetitive TMS (rTMS) can normalize cortical inhibition and improve symptoms in individuals with RLS and chronic pain. Building on current literature, we aim to compare expected outcomes with data from our dual-cohort study and evaluate whether changes in excitability measures (SICI, long-interval intracortical inhibition [LICI], intracortical facilitation [ICF], CSP, resting and active motor thresholds) predict symptom improvement. Methods: Participants with RLS or chronic pain, including a subgroup with spinal cord stimulators, will complete baseline assessments consisting of H-reflex testing, somatosensory evoked potentials (SSEPs), vibratory event-related potentials, and diagnostic TMS. After completing an rTMS treatment regimen, all assessments will be repeated to determine how changes in cortical inhibition relate to changes in symptom severity. Preliminary Evidence: Previous studies show that high-frequency M1 or supplementary motor area stimulation improves RLS symptoms by up to 50% and enhances sleep quality. In chronic pain, 10–20 Hz M1 rTMS reduces pain by 30–50% and increases SICI while prolonging CSP, suggesting restoration of inhibitory tone. These neurophysiological shifts often correlate with clinical improvement. Expected Results and Significance: We anticipate that increases in intracortical inhibition will predict symptom reduction across both cohorts. Findings will help refine individualized neuromodulation approaches and support the development of TMS-based biomarkers for sensorimotor hyperexcitability disorders.

Abstract Name: Navigating Changing Tides: Environmental Corporate Social Responsibility within the Cruising Industry

Royal Caribbean has been catering to guests for more than 50 years, having first set sail in 1970. As Royal Caribbean has grown, alongside the entirety of the cruise industry, the company has increased their commitment to environmental stewardship. Following the rapid rebound of the cruising industry after the COVID-19 pandemic, Royal Caribbean launched an environmental initiative, SEA the Future, in which they have prioritized Sustaining the planet, Energizing communities, and Accelerating innovation in order to make the corporation more sustainable. With this initiative, Royal Caribbean has committed to delivering vacations “responsibly.” But in an industry that is inherently damaging to the environment, what does “responsibly” actually mean? Using a case study approach examining the company’s website and social media, along with media coverage of the initiative, this research explored the SEA the Future campaign for the way in which Royal Caribbean has communicated its sustainability policies and practices to stakeholders, including consumers, investors, employees, the government, and port city communities. Additionally, this research considered how these different stakeholders responded to and interpreted Royal Caribbean’s environmental messaging. A separate, but complementary, journalistic article expanded on this work by comparing Royal Caribbean’s SEA the Future campaign with Carnival Cruise Line’s Sustainable from Ship to Shore plan and

Norwegian Cruise Line's Sail & Sustain initiative, using thematic coding to identify patterns across the three cruise lines. Ultimately, this research aimed to analyze how major cruise corporations define the idea of environmental responsibility and how these narratives influence public perception of sustainability within the cruising industry.

Abstract Name: Impact of Sound Propagation on Fish Behaviors Coordinated Through Sonic Communication

Animals frequently use sound to communicate with each other in a variety of different ways, such as using alarm calls to avoid predators, breeding calls to find mates, and foraging/predation calls to find food. In all of these cases, communication allows individual animals to behave as a collective entity. However, sonic communication is dependent on the medium of communication. For example, sound declines in intensity by distance much faster in air than it does in water. Little work has been examined for how underwater acoustic communication impacts prey strategies in fish. The project investigates two main sonic behaviors in fish. Fish can either effectuate the “shutting up” method where they decrease volume to flee and are classified as escapers versus “shouting loud” where fish increase volume to mob a predator and are the mobbers. We developed an agent-based model in NetLogo in which fish, predators, and sound propagation are simulated within an aquatic environment. The model evaluates how sound intensity, distance, and behavioral thresholds impact survival outcomes, with adjustable parameters including a baseline. Our results show that the shut up and flee tactic has higher survival rates across most conditions, especially when predator detection thresholds were low. The shout loud mobbing strategy was more efficient when sound traveled far and foraging exceeding thresholds, indicating mobbing is beneficial in environments where large groups can collectively pressure the predator.

Abstract Name: Economic Benefits of Insurance Coverage for Patient Care in Preventative Services

The economic implications of insurance coverage for preventative medicine not only affect individual health decisions but are much deeper and are seen to affect social outcomes. Variables such as externalities, price elasticity of demand, and consumer response support understanding of patient data. Externalities arise because preventative care physicians, such as doctors of osteopathic medicine, use a holistic and preventative approach, thus reducing health risks and overall healthcare costs. Third parties that are not directly involved in these transactions can gain benefits from lower risk of disease transmission and reduced public health expenditures. Price elasticity of demand for services is analyzed to explore how insurance coverage will affect access to patient care, particularly in marginalized populations. Medical expenditure Panel Surveys from IPUMS surveys were used with U.S. adults from 2020-2024 to assess insurance effects on preventative services. Dependent variables include prevention utilization and independent variables include U.S. insurance

states. RStudio, a coding software, was used by importing IPUMS to create regression models and evaluate factors. Insurance coverage of care not only includes individual health benefits but also promotes positive externalities with significant effects on economic variables through a reduction in public health expenditures and improved social health outcomes.

Abstract Name: Aesthetics and Accessibility: An exploration in incorporating accessorization into the creation of medical devices and mobility aids

The purpose of this study is to connect visual aesthetics to the creation and modification of medical devices, specifically allowing the wearer the choice of personalization according to their style. I have combined the traditional technique of lost-wax casting with CAD technology to create custom mobility aids and accessorize medical devices, making jewelry more accessible to individuals with physical disabilities. I want to continue to improve my skills in CAD, as it helps reduce the impact traditional metalsmithing techniques have on my body due to my disability. I was diagnosed with Sjogren's Disease at 18 years of age after several years of searching for a diagnosis, which significantly impacts my day-to-day functioning. Developing a disability after experiencing the majority of my childhood as a seemingly healthy individual left me with a sense of loss. To compensate for these feelings, I have gravitated towards creating functional work in my practice. I primarily focus on what it truly means for something to be functional and why creating something accessible matters. My knowledge as a maker, combined with my experience as a disabled individual, helps in navigating the challenges of adapting mobility aids for people to feel more comfortable to use them. I hope to emphasize that one's personal style does not have to be sacrificed at the cost of function. I desire for my practice to be a vessel for change.

Abstract Name: Cisplatin Induced Immunogenic Cell Death to Delay Tumor Onset in a Preclinical Model of Triple-Negative Breast Cancer

Chemotherapy remains the only systemic treatment for triple-negative breast cancer (TNBC), yet it achieves a pathological complete response in only 37% of patients. Patients with higher levels of tumor-infiltrating lymphocytes respond better (48%; Denkert, 2018), highlighting the immune system's importance in chemotherapeutic efficacy. Enhancing chemotherapy's immunogenicity is therefore crucial for both direct tumor killing and long-term immune surveillance. This occurs through immunogenic cell death (ICD), a regulated apoptotic process that releases damage-associated molecular patterns (DAMPs) to activate innate immune cells such as dendritic cells (DCs). We used a syngeneic orthotopic mouse model of TNBC to evaluate the immunogenicity of platin-based chemotherapies. TNBC cells were killed with oxaliplatin or cisplatin and injected into the right mammary gland of mice (n=10/group), while controls received saline.

One week later, mice were rechallenged with live cancer cells in the opposite mammary gland. If chemotherapy induced ICD, immune cells would eliminate the live cells, mimicking a vaccine-like effect. Over three weeks, cisplatin-treated cells significantly delayed tumor onset, whereas oxaliplatin-treated cells showed no effect. Gene expression analysis assessed immune infiltration. Cd45 was used as a pan-immune marker and Gzmb as a cytotoxic T-cell and NK-cell marker. Although neither differed significantly between groups, Ctla4 expression was significantly higher in tumors from mice injected with cisplatin-killed cells, suggesting increased immune infiltration accompanied by T-cell inhibition. Overall, these findings identify cisplatin as more immunogenic than oxaliplatin. Future studies will test whether this effect involves type I interferon signaling and DC activation, clarifying how chemotherapies stimulate innate immunity to improve TNBC outcomes.

Abstract Name: The Effect of Low Concentrations of Alcohol on Synaptic Transmission and Locomotion in *C. elegans*

Alcohol Use Disorder (AUD) is a chronic illness in which a person, despite detrimental health and social consequences, has an impaired ability to control or stop alcohol use. This research aims to enhance our understanding of the illness and identify how alcohol alters neuronal signaling. *C. elegans* are a useful model for the study of behavioral changes due to ethanol. Their simplified nervous system is strongly molecularly conserved with mammals, making them particularly advantageous for neuronal studies. In synaptic transmission, voltage-gated calcium channels are activated by an action potential, causing them to open. UNC-10, the *C. elegans* homolog of RIM (Rab3-interacting molecule), plays an essential role in organizing the presynaptic active zone and coordinating Ca^{2+} -triggered neurotransmitter release. It functions as a scaffold that anchors voltage-gated calcium channels near synaptic vesicle docking sites and recruits the vesicle-priming factor UNC-13 (Taru et al., 2019). UNC-10 ensures that calcium influx occurs precisely where primed vesicles are positioned, enabling rapid and efficient synaptic transmission. Loss of UNC-10 disrupts calcium channel localization and reduces synaptic efficacy, highlighting its central role in coupling active zone structure to neurotransmitter release (Taru et al., 2019). *unc-10* mutant animals are paralyzed, and surprisingly, low concentration ethanol can enhance the locomotion of these mutants. This project is designed to understand how ethanol causes this effect. To measure locomotion, we used a grid-crossing assay to determine how many grid squares each animal entered, allowing comparison of baseline versus ethanol-stimulated movement. Additionally, we used WormLab video analysis to quantify worm speed and total distance traveled under both basal and ethanol-exposed conditions. In this study, we are investigating how *unc-10* mutant animals' uncoordination can be rescued by low concentrations of ethanol, stabilizing intracellular Ca^{2+} stores and thereby bypassing the need for UNC-10.

Abstract Name: Reimagining Local History Through Interactive Technology

Traditional museum exhibits often struggle to capture the attention of diverse audiences, particularly younger generations accustomed to interactive and visual forms of learning. This project addresses that gap by introducing a technology-based approach to historical education through the creation of an interactive green screen exhibit. Designed to engage visitors with the rich history of Prescott, Arizona, the exhibit combines digital media and storytelling to let participants step into recreated scenes from historic local events, offering a vivid and engaging way to connect with the past. As a Simulation Science, Games, and Animation student, I drew on my background in 3D modeling, animation, and visual design to digitally reconstruct historical sites and bring still photographs to life. The department emphasizes cross-disciplinary collaboration, combining principles of 3D computer graphics, user experience design, and animation—skills that proved essential in developing this exhibit. The Western Heritage Center’s mission is to preserve and promote the Prescott area’s history through educational displays, art, and collaborative projects. Two major goals of the project were to digitally recreate the second Yavapai Courthouse and to feature Former President Theodore Roosevelt as a symbolic representation of the era, using tools such as Autodesk Maya, Adobe After Effects, and Adobe Substance 3D Painter. This was especially meaningful to the Western Heritage Center, as it provided a way to visualize important aspects of Prescott’s history that had previously existed only through text and static images. The development process incorporated green screen production, 3D modeling, video production, and digital compositing to create a functional and engaging exhibit. Through this hands-on collaboration, project members gained valuable professional experience while contributing to a meaningful community partnership. Ultimately, the project demonstrates how creative media technology and historical storytelling can deepen public understanding, inspire curiosity, and strengthen the connection between higher education and the broader community.

Abstract Name: Overturning Roe v. Wade and pre-medical students’ views and medical school choices

The overturning of Roe v. Wade in Dobbs v. Jackson Women’s Health Organization (2022) has led to varying abortion laws across states in the U.S., potentially influencing medical education choices. While some research has examined abortion policy changes and medical residencies and fellowship decisions, none has investigated abortion policy and medical school decisions. This study aims to determine whether pre-medical students’ personal views on abortion influence their willingness to attend medical schools in states where abortion is illegal at all stages EXCEPT to save the life of the mother. A cross-sectional survey was distributed to pre-medical organizations at the two largest four-year institutions in each U.S. state and the District of Columbia, except Wyoming, which has only one four-year institution. The survey collected demographic data, political affiliation, intended medical specialty, and personal stance on abortion. Participants indicated their willingness to attend medical school in states with different types of abortion policies. There were 182 completed surveys from participants in 20 different states. Analysis showed that students who believed abortion is acceptable and should be legal at all stages were significantly less willing to attend medical school in states where abortion is illegal EXCEPT to save the life of the mother. Abortion policy may influence medical school decisions among pre-medical students, which may have long-term implications for physician distribution, particularly in states with restrictive abortion laws. Future research should explore how these trends impact healthcare workforce shortages and access to reproductive care.

Abstract Name: Shielded by Power: U.S. Aid, Immunity, and the Palestinian Genocide

This research looks at how the United States is involved in the current conflict between Israel and Palestine, and whether U.S. support for Israel follows or violates international human rights standards. The main question is: Does U.S. aid to Israel contribute to human rights abuses in Gaza, and if so, why are those responsible not being held accountable? Many studies look at the Israeli Palestinian conflict, U.S. foreign policy, and human rights, but often discussed separately. My inspiration for this topic was brought to me by my mentor during class, along with growing discussion and footage online. This research shows how U.S. aid to Israel and certain laws protect both countries from being held accountable for actions in Gaza and the West Bank. Methods and sources used include books, articles, government documents, and news sources, applying literature review, content and thematic analysis, and both qualitative and some quantitative methods to understand connections between U.S. aid, international law, and human rights. A key finding is the United States Foreign Military Financing program (FMF), which gives Israel billions to buy American-made weapons often in the form of grants and stipends, some of which have harmed civilians in Gaza and the West Bank. Another important point is the Hague Invasion Act (2002), originally used to protect United State soldiers during the Iraq war, additionally the same act can protect allies like Israel from being prosecuted by the ICC or ICJ, blocking accountability for possible war crimes.

Abstract Name: Taxidermy and technology: A history of climate change exhibitions at 20th- and 21st-century American museums of natural history

My research is on the history of temporary and permanent climate change exhibitions at natural history museums in the United States. My primary research question is: How have natural history museums responded to human-caused environmental destruction through their exhibitions, and what, if anything, are natural history museums doing now to address our current environmental crisis? My research begins with a historiography of natural museums and examines how early 20th-century museums responded to a sense of environmental crisis and widespread threats of species extinction. In the early 20th century, museums shifted from Victorian-era glass cases to modern and artistic dioramas that presented beautiful and pristine wilderness. These new dioramas attempted to inspire audiences to care about the environment and preserve wilderness scenes that preservationists viewed as disappearing. 21st-century museums are again changing their displays to address climate change, environmental justice, and extinction, this time using different technologies. I explore four specific museums, their histories, and how they are addressing the threat of climate change: the Field Museum of Natural History, the Natural History Museum of Los Angeles County, the Harvard Museum of Natural History, and the American Museum of Natural History. My research brings into conversation museum history, climate communications, and environmental history, while fitting into the larger scholarly conversation of the cultural and political role of American natural history museums. My

approach to this topic is new because I am recognizing that the public presentation of natural history itself has a history, and climate change fits into what is considered a “difficult history.” My research is built upon primary sources, including museum multimedia archives, periodical archives, relevant secondary sources from historians, scientists, and museum practitioners, and visits to current climate change exhibitions at relevant museums.

Abstract Name: Analysis of Central Configurations and Bifurcations in the Planar Unequal Mass 4-Body Problem

The classification of central configurations plays a central role in the study of the Newtonian N-body problem, governing a variety of features such as the existence of relative equilibria and bifurcations of the integral manifolds. The N-body problem is fundamental to understanding the motion and stability of celestial systems, from planetary orbits and asteroid dynamics to star clusters and galaxies. Studying central configurations provides insight into these motions, and is approached in a stepwise manner. We present new study for the planar 4-body problem with three equal masses and one unequal mass. This mass distribution is a natural next step beyond the equal-mass case, bridging the connection between theory and physically observed models to study new behavior. We describe a systematic approach to identifying and categorizing central configurations—balanced geometric arrangements of bodies, as a function of the variable mass parameter μ and potential energy U . We combine numerical and computational methods, emphasizing GPU parallelization to address the problem's high computational cost. The combination of analytic reductions with computer-assisted techniques allows us to map out the bifurcation structure in (μ, U) -space and provides insight into classification of configuration families, as well as the behavior at critical mass ratios in more complicated systems. Our results describe the transition between symmetric and asymmetric families of central configurations, examine the bifurcation structure of the problem through the identification of pitchfork and saddle-node bifurcations, and point to the emergence of a unique single asymmetric family that bifurcates from symmetry.

Abstract Name: Psychosocial Pathways Linking Vicarious Discrimination to Academic Achievement via Stress, Ethnic Identity, Familism

Experiencing discrimination, whether directly or indirectly, has been linked to adverse academic and psychological outcomes among ethnic-racial minority students (Huynh et al., 2017; Stevens et al., 2018; Walsdorf et al., 2023). Existing research focuses on personal experiences of discrimination, while significantly less attention has been given to vicarious discrimination- instances in which individuals witness, hear about, or learn secondhand of discriminatory acts against someone close to them, such as a parent or

caregiver. Examining this gap is critical because caregivers play a central role in shaping students' emotional security, motivation, and sense of belonging within academic environments. (Koren-Karie et al., 2012). This study seeks to examine if vicarious discrimination witnessed towards a primary caregiver impacts among ethnic-racial minority college students' sense of academic self-efficacy. Additionally, this study will explore perceived stress, ethnic identity, and familism as moderators. Ethnic-racial minority college students from diverse ethnic and racial backgrounds completed a survey. Participants were given validated measures on stress, discrimination, familism, and ethnic identity. Data collection is underway and will be completed by the conference. Hierarchical linear regression analyses will be used to test hypotheses regarding (a) the direct effects of vicarious discrimination on academic outcomes and (b) the moderating effects of stress, ethnic identity, and familism. It is hypothesized that exposure to vicarious discrimination against a primary caregiver will negatively hinder ethnic-minority students' academic self-efficacy in higher education. Additionally, we hypothesize that the relationship between vicarious discrimination of a caregiver and academic achievement is exacerbated by general stress, lower ethnic identity, and lower familism. Understanding the effects of vicarious discrimination towards their caregiver provides information critical to developing programming to support ethnic-racial minority students, such as workshops on learning strategies for coping with ethno-racial discrimination and supporting caregivers through discrimination. Clinical implications will be discussed.

Abstract Name: Validating Environmental DNA (eDNA) Approaches to Assessing Soil Microeukaryotic Biodiversity

Microeukaryotic organisms, particularly nematodes, are highly abundant and diverse in soil ecosystems, where they fulfill critical ecological roles. Their spatial distribution is influenced by various environmental factors, including soil texture, nutrient levels, and vegetation. Despite their ubiquity, there is limited understanding of microeukaryotic biodiversity in soil habitats, especially within natural systems. Environmental DNA (eDNA) metabarcoding is a promising method to enhance our knowledge of soil microeukaryotic communities. Compared to traditional morphology-based taxonomy, eDNA metabarcoding can be more cost-effective, faster and may provide greater resolution, including the detection of rare species. In this study, we used eDNA metabarcoding (18S rRNA) to characterize microeukaryotic and nematode communities across various soil habitats in the Shipley-Skinner Reserve, Southern CA, USA. We also compared diversity patterns using two DNA extraction methods: raw soil and Baermann funnels, the latter is specifically designed to recover higher nematode abundance and diversity. Our analyses reveal that soil microeukaryotic diversity patterns are method-dependent, with the raw soil dataset exhibiting higher alpha-diversity across all metrics in habitats characterized by greater soil bulk density. When solely focusing on nematodes, the Baermann funnel dataset displayed the highest diversity, particularly in habitats with lower soil bulk density. Despite differences in alpha diversity and community composition, significant differences between soil types and among soil habitats were detected by beta-diversity analysis (nMDS and PERMANOVA) in both datasets, thus supporting their effects in structuring soil communities. As expected, nematodes were more abundant in the Baermann funnel samples, while fungi dominated the raw soil DNA sequences. Furthermore, our analysis revealed that nematode community composition varied considerably between DNA extraction methods, with cephalobids and dorylaimids more abundant in the Baermann funnel and soil datasets, respectively. These findings underscore the importance of understanding the nuances of different eDNA metabarcoding methods to accurately assess patterns of soil biodiversity.

Abstract Name: The Texture of a Threat: Machine Learning & Obfuscated Malware Detection

Accurately detecting malicious programs is an expanding field of research for machine learning, with a novel approach incorporating a bytecode-to-image pipeline that produces images representative of software. These images are provided to convolutional neural networks (CNNs) to be examined for malicious pattern indicators. In this research, three unique CNN architectures are trained with 15,000 benign and malicious software samples encoded into images for the three major operating systems (OSs) targeted by malware: Android, Windows, and Linux. After benchmarking their performance on these samples, these CNNs are tested with 15,000 obfuscated versions of the same software to test their resilience against adversarial malware. The roughly 25% drop in accuracy from this obfuscation is mitigated by retraining the CNNs with these adversarial examples. Although this step improves the accuracy of detection against the adversarial samples, the CNNs lose a significant amount of their ability to detect unobfuscated malware. The Deep Boosted Feature Space Malware Classifier, using a support vector machine with a dual resNet and denseNet voting classifier head, performs the best of the three with initial 98.9 and 61.1 F1-Scores on the original and obfuscated data respectively, changing to 77.4 and 95.0 after the retraining step. This research simultaneously reaffirms the benefits of adversarial training while emphasizing the need for better methods of modeling and detecting malicious patterns in cross-OS software, both ordinary and obfuscated.

Abstract Name: The Inherent Queerness of Horror: A New Perspective on Post-War Horror Literature

Horror as a genre has been relegated to the margins of literary studies, rarely considered a worthy object of analysis. Such marginalization, however, has allowed the genre to tackle societal issues in a way deemed too taboo for other media, which has attracted a particular set of people to horror media, including LGBTQ+ audiences. With its roots in the Gothic tradition, horror literature tends to conflate and purposefully confuse fear and desire, combining uncertainty and anxiety with excess and ornament. While such a breakdown of boundaries might elicit fear in a Western modern society predicated on efficient organization and discrete categories, it is also appealing to some. Drawing from scholarship in Gothic/horror studies and queer theory (including monstrosity and abjection), this paper examines the relationship between horror media and queer and transgender audiences, arguing that horror offers representation, catharsis, and weapons against societal marginalization. I examine four pivotal novels in horror literature which were published between 1950-1990, a period representing major sociopolitical shifts in British and American societies which had direct implications on normative understandings of gender and sexuality. This project engages with both close reading analysis and social context for each text: *The Haunting of Hill House* (1959), *Rosemary's Baby* (1967), *The Exorcist* (1971), and *The Hellbound Heart* (1986). Through my analysis of each literary text, I will explore an overlap of themes, including trauma, repression, domestic and family life, and liminality. These themes guide my reading of each novel, and thereby lead to uncovering the inherent queerness of horror.

Abstract Name: Astrocyte Association with a Surface-in Gradient Pathology in Multiple Sclerosis

Background: Multiple Sclerosis (MS) is one of the most prevalent inflammatory diseases in the central nervous system (CNS). Disability and progression have been linked to a surface-in gradient of neuronal loss, particularly in the outer layers of the cerebral cortex and the pial surface (Magliozzi et al., 2010). Objective: This project focuses on the pathology of intracortical astrocytes associated with vessels. We also look at the activation of pial surface-associated interlaminar astrocytes with apical processes extending to the pial surface and basal processes entering cortical layers II-IV (Verkhratsky and Nedergaard, 2018). Our preliminary data indicate a positive association between interlaminar astrocytes and vessels in MS brains. CSF components may induce interlaminar astrocyte activation, contributing to the surface-in gradient observed in MS. Methods: We conducted immunocytochemistry to investigate interlaminar astrocytes and vessel-associated cortical astrocytes using GFAP and CD44 antibodies. This analysis quantified vessel-associated CD44-positive cells in subpial and deep cortical regions. We used confocal and electron microscopy to examine morphology and associations/interactions of interlaminar astrocytes. Results: We found that compared to control brains, the MS cortex has a 40% increase in subpial CD44-positive cells and a significant increase in intracortical CD44-positive cells. Both GFAP and CD44 antibodies stained the pial surface. Some GFAP-positive astrocyte apical processes seemed to enter the pial surface and CSF space, and CD44-positive astrocyte basal processes appeared to descend into the cortex, often terminating on CD44-positive astrocytes associated with vessels in cortical layers II-IV and showing signs of pathology/degeneration. Descending processes from interlaminar astrocytes are often fragmented and associated with deep CD44-positive astrocytes. Conclusion: Our data suggest that CSF components at the pial surface may influence subpial CD44-positive cells as they interact with intracortical CD44-positive astrocytes and vessels in layers II-IV, influencing the surface-in gradient found in MS.

Abstract Name: The Model Minority on the Stand: Social Identity Theory's Effect on East Asian Mock Juror's Sentencing.

With growing East Asian immigrant generations, normative expectations for success remain strong. In line with the stereotyped image of the "model minority," East Asian Americans usually have higher socioeconomic success compared to other ethnic groups, and make up only 1.5% of federal inmates (Federal

Bureau of Prisons, 2019). Nonetheless, East Asian Americans can and do become defendants, and with population growth, they are more frequently serving on juries. This raises questions about whether East Asian Americans serving as mock jurors will demonstrate in-group favoritism toward East Asian American defendants or instead react punitively toward a norm-breaker (i.e., the “Black Sheep” effect). Commonly, scholars marshal Tajfel and Turner’s Social Identity Theory to examine when jurors are lenient to defendants in their in-group, finding in-group favoritism when case evidence is weak and a group composes the majority of the jury. However, this research has only been conducted on Hispanic, White, and Black mock jurors. This project aims to examine East Asian Americans as both defendants and jurors in a mock-jury study. East Asian Americans are important to study because, according to prior research, collectivist ideals will promote high normative expectations for success, which may undercut in-group favoritism and instead prompt in-group rejection. By investigating how East Asian mock juror sentencing varies based on factors like numerical jury composition or the type of criminal violation, this study can shed light on how East Asian people handle the impact of norm violations when they must sit in judgment of fellow group members.

Abstract Name: HIF1A Inhibition Reduces Radiation-Induced Profibrotic Signaling in Human Lung Fibroblasts

Radiation-induced pulmonary fibrosis (RIPF) is a severe and often irreversible complication of thoracic radiotherapy (commonly given for lung and breast cancers). RIPF is characterized by excessive extracellular matrix (ECM) deposition, which results in reduced lung function as it causes lung tissue to stiffen due to excess collagen production. A key driver of RIPF is the activation of fibroblasts into myofibroblasts – a process known as the fibroblast-to-myofibroblast transition (FMT). The FMT is associated with the upregulation of profibrotic markers such as COL1A1, FN1, and ACTA2, which indicate a state of fibrosis in tissues. Hypoxia-inducible factors (HIFs), particularly HIF1A, are transcription factors that regulate the cellular response to hypoxic conditions. HIFs have been implicated in both fibrosis in response to radiation. Radiation can induce pseudo-hypoxic signaling (hypoxic signaling even when sufficient oxygen may be present), which stabilizes HIF1A, even under normoxic conditions. This project investigates how X-ray irradiation influences HIF1A signaling and profibrotic gene expression in human lung fibroblasts (hLFs), and whether pharmacological inhibition of HIF1A can reduce the fibrogenic effects of radiation exposure. 10Gy of X-ray irradiation was given to hLF (human lung fibroblast) cells in an initial test to see the degree to which fibrotic markers were upregulated. In a second round of irradiation, the hLF cells were given a HIF1A pathway inhibitor, and a decrease in fibrotic markers was observed. This data supported our hypothesis that the HIF1A pathway is a mediator of radiation-induced fibrosis. Understanding this mechanism could inform strategies to mitigate RIPF and improve outcomes in patients undergoing thoracic radiotherapy.

Abstract Name: The Political Digital Age: Generational Influence On Congressional Social Media Usage

As younger generations who have grown up with social media become members of Congress, they arrive on Capitol Hill more digitally literate and potentially better able to use social media as a method of communication. This leads to the question of whether there are systematic differences in social media usage and content between members of Congress in different generations. While some representatives entered Congress before social media's rise, younger representatives are entering with existing familiarity with the power of social media. These generational differences potentially impact how highly representatives value and rely on social media as a communication tool for constituent education and raising their profile. This study looks specifically at a representative sample of median members of the House of Representatives in the 119th Congress. The study specifically focuses on social media usage during the 2025 government shutdown, beginning on October 1st, 2025. The shutdown presents a unique moment when it was particularly important for members to communicate with their constituents and shape public opinion. A content analysis will be performed on members' messages shared across social media platforms such as Facebook, Instagram, and Twitter, as well as a quantitative analysis of the frequency and reach of posts. Past congressional research suggests that incumbent members of Congress have significant advantages in their ability to communicate with constituents, and this study's findings will suggest whether younger members are able to more effectively use social media to meet their goals in office.

Abstract Name: Modeling the Projected Cross-sectional Area of Low Earth Orbit Satellites Using High-Fidelity Orbital Decay Analysis

Accurate modeling of atmospheric drag is critical for precise orbital propagation in Low Earth Orbit (LEO). However, the physical parameters required for drag modeling are often unknown or highly variable. This presents scientists with a challenging dilemma: attempt to isolate one physical parameter and find independent methods to solve for the others, or model a lumped aerodynamic parameter. This research lends itself to the former, presenting an open-source model for estimating the variable projected cross-sectional area of non-propulsive satellites by fitting high-fidelity numerical propagation models to historical Two-Line Element (TLE) satellite tracking data. The core of the numerical propagation model is a symplectic leapfrog integrator, which simulates equations of motion in an Earth-centered inertial reference frame. The integrator accounts for orbital perturbations due to Earth's oblateness, third-body gravitational influences from the Sun and Moon, and aerodynamic drag. The drag model incorporates a co-rotating atmosphere and utilizes the Jacchia-Bowman 2008 density model to precisely calculate atmospheric density at given epochs. Then, assuming that a value of 2.2 for any satellite's drag coefficient is scientifically defensible and that the mass of the satellite is known, the projected cross-sectional area of a satellite is calculated. The model is validated by using the known cross-sectional area of the spherical ANDE-2 Pollux and Starshine satellites, which the model successfully converged to. However, the idea that the only validation of this model was done with geometrically simple bodies indicates that there may be significantly greater error when it comes to modeling geometrically complex bodies. Therefore, further work seeking to resolve this hypothesized oversight would prove highly valuable.

Abstract Name: Exploring What College Seniors Prioritize in Their First Job

The purpose of this project is to explore what college seniors across different areas of study prioritize when searching for their first job after graduation. We will examine how students' sense of 'calling' impacts their expectations for meaningful work. This is relevant at a Catholic University, such as Duquesne, whose mission is to serve God by serving students through concern for moral and spiritual values. This creates an educational environment that encourages students to reflect on their ethical responsibility to others. Because college prepares students for the workforce, these messages shape how students think about what they value in a career. We will examine how the values of a Catholic university shape students' career priorities across different fields of study. Participants will be Duquesne seniors who complete a questionnaire asking them to identify their academic program (e.g., business, nursing). Then, there will be an open-ended question, "What makes a first job attractive?," which will allow students to explain what they prioritize. This will provide qualitative data on what participants value in a job. Next, participants will complete the Calling and Vocation Questionnaire (Dik et al., 2012), a standardized measure of how strongly they feel a sense of "calling" to their work. At the end, participants will have the option to enter a raffle to either win a \$30 gift card or donate \$30 to a non-profit. We will use this choice to see whether students' stated priorities in the previous questions align with their behavioral intentions. We expect students in service-oriented fields, like nursing, to value purposeful work. By contrast, business students may focus inward on their personal wants like higher compensation. These results will inform vocational psychology and showcase how higher education environments shape expectations formed prior to entering the workforce.

Abstract Name: How financial counterterrorism units can stop the flow of terrorist funds.

In order to stop terrorism, you have to stop the supply of funds enabling terrorist networks to operate and commit deadly attacks. Financial counterterrorism units are often the unsung heroes helping to keep the public safe. This project will explore how terrorist networks are funded and how these networks try and stay under the radar of law enforcement. These methods include, criminal activity, (robbery, drug and human trafficking) crypto, state-sponsored, Cash, and online transfer apps such as Hawla which is significantly used in the Middle East and Africa. I will focus my attention on the importance of ensuring that financial counterterrorism units have the resources required in order to combat the ever-changing complexities and challenges surrounding terror finance networks, and I will argue that one of the keys to stopping the flow of terrorist funds is spotting not only regular, but irregular funding patterns. For example, this could be a regular pattern of an individual repeatedly travelling from one country to another with large amounts of cash. Or an irregular pattern which could be a one-off large payment that rings alarm bells for counterterrorism. There are several methods which financial units use to crack down on terrorism. These include specialists trawling through the data, legislation to allow the seizure of funds, tracking the travel of individuals, and multi-agency cooperation including international cooperation. Breakthrough methods against drug cartels could be used in the fight against terror finance networks. These methods are international cooperation, asset seizure, and funding and training programs. Therefore, greater cooperation, stronger laws, and more funding would help combat terrorism. In my research, I will highlight why the funding of terrorist networks is so complicated and the various loopholes which provide safe haven for terrorists.

Abstract Name: Celebrate Gannon: Bringing the NCUR Model to an Annual Symposium at a Small Predominantly Undergraduate Institution

Celebrating research programs at predominantly undergraduate institutions presents challenges in creating sustainable, campus-wide structures that support and showcase student scholarship. These structures can also promote, and advance university initiatives related to enrollment, fundraising, and new community engagement. Celebrate Gannon is an annual student-centered symposium that brings together scholars from across the university to present their research, creative work, and scholarly accomplishments. In 2012 the Gannon Undergraduate Research Symposium, a primarily STEM-based traditional student-mentor scholarship program, was redesigned to encompass a more comprehensive celebration of undergraduate scholarship that aligns closely with the Boyer Model of Scholarship. Today, Celebrate Gannon showcases a wide range of contributions including course-based undergraduate research, community engagement initiatives, interdisciplinary contributions, and senior capstone projects. As long-standing members of the Celebrate Gannon planning committee, we will describe the event's growth, key successes, and lessons learned, including strategies for overcoming initial resistance from faculty and committee members as the symposium expanded in scope. We will also discuss approaches for coordinating effectively across university divisions including marketing, facilities, and upper administration to promote, support, and execute an institution-wide research celebration. Our experience offers a practical and adaptable model for small, predominantly undergraduate institutions seeking to build or enhance their own NCUR-inspired symposiums.

Abstract Name: Analyzing Differences in Weathered Products Between Icelandic Basalt Samples

Iceland is used as a terrestrial analog for Martian geology research because its weathered material is more dependent on protolith mineralogy and chemistry, similar to Martian regolith. One weathered product commonly observed on Mars, uncommon on Earth, is maghemite. It is known to affect soil magnetization on Mars and has also been observed by remote sensing. Therefore, weathered products from Iceland containing maghemite can be used as a proxy to study Martian surface process. The goal of this research is to identify factors potentially affecting maghemite formation on Earth. For this purpose, we analyzed weathered basalt samples from approximately 800-year-old lava collected from two locations in the Reykjanes Peninsula within southwest Iceland. We created powdered samples selected from seemingly less weathered and more weathered parts of the basalts to compare mineralogical and chemical differences. Preliminary mineralogical data from powdered X-Ray Diffraction (PXRD) analyses indicate evidence of magnetite to maghemite transitions in both locations. The presence of maghemite in these samples is intriguing because there is not yet

a consensus on the factors needed for its formation. This research aims to provide insight into the formation of maghemite in weathered basalts on Earth to potentially infer Martian surface processes. This poster will present preliminary data from mineralogical, chemical, and textural analyses of weathered and unweathered Icelandic basalts to understand how these findings can be applicable to Martian geology.

Abstract Name: Discovery of Scorpion Group 1 bacteria in the venom microbiome of the Eastern Swollenstinger Scorpion, *Anuroctonus phaidactylus*

Animal venoms are composed of a complex mixture of compounds with unique biological functions. Interestingly, protein components of venoms have shown potential clinical and pharmacological applications in a variety of areas, including the production of anti-cancer and antifungal medications. Despite the wealth of knowledge regarding venom proteins, scorpion venom has been presumed to be sterile and devoid of bacteria. Contrary to this belief, recent research in our lab found bacteria in scorpion venom, leading to a larger study characterizing the bacterial communities present in the venom of *Anuroctonus phaidactylus*, the swollenstinger scorpion. Using Nanopore sequencing, we analyzed venom DNA for amplicons from the 16S rRNA gene. Unexpectedly, we found four haplotypes of the Scorpion Group 1 (SG1) lineage in our venom samples. This finding indicates that SG1 is not unique to the family of Vaejovidae. Given that our four unique SG1 haplotypes are minimally divergent from those recovered in vaejovids, our discovery of them in a member of the Anuroctonidae family could represent a recent, successful host-switching event or a long-term pattern of frequent microbial exchange among scorpion hosts.

Abstract Name: Behavioral Olfactory Responses of Crickets to Essential Oils

The development of effective and safe repellents against arthropods is very important to prevent arthropod-borne diseases and is critical for human health and safety. The use of synthetic repellents (e.g., DEET) has been successful against pests, such as mosquitoes and ticks that cause diseases, e.g., malaria and Lyme disease. Other insects, such as crickets, cockroaches, and ants have omnivorous feeding preferences and can contaminate and destroy stored food products like sugar, flour, grains, etc. with their feces. Lately, DEET has raised environmental and human health risk concerns. Recently, selected aromatic plant-based essential oils have been used as alternatives to synthetic repellents against some arthropods. Essential oils work through the sense of smell of arthropods. In this study, the efficacy of 27 essential oils was measured in terms of their behavioral effects in an insect pest, namely house crickets, *Acheta domesticus*. We hypothesized that a selected panel of these essential oils would show strong levels of repellency against these crickets, while others would be weaker or ineffective. This hypothesis was tested in behavioral choice experiments where crickets were exposed to individual essential oils. Crickets were observed to either stay in an open-arena or

move toward the odor source located in a plastic bottle. In control experiments, where no odor source was present, crickets moved into the bottle. We observed 14 essential oils which exhibited the strongest levels of repellency (i.e., crickets avoided bottles containing these essential oils). The other 13 essential oils elicited weaker levels of repellency or no repellency at all. Some of the essential oils tested in this study may be considered green (environmentally friendly) repellents and have the potential to substitute harmful synthetic repellents. This work was funded by research grants from the Fisher College of Science and Mathematics (Towson University) and the NIH (Bridges grant 1T34GM150447-01).

Abstract Name: Sustainable Control of *Drosophila suzukii* Using Methyl Benzoate Analogs as Repellent Agents

Food security is increasingly threatened by invasive agricultural pests, such as the spotted wing drosophila (SWD), *Drosophila suzukii*. This fruit fly species poses a major risk to global soft fruit production, particularly berries, due to its unique ability to lay eggs in ripening fruits using a serrated ovipositor. Since its initial detection in Hawaii and California, SWD has rapidly expanded its range across the United States, leading to crop losses of up to 80% if unmanaged. This poses significant economic challenges for growers and directly impacts food availability. While synthetic insect repellents like DEET have shown efficacy in reducing infestations, their environmental impact and sustainability concerns have driven the search for greener alternatives. In this study, we investigated the repellency of methyl benzoate, a naturally occurring volatile organic compound, and several of its chemical analogs against SWD. Repellency assays using 24 female flies per treatment group were conducted across various concentrations and timepoints. Dose-response models were used to calculate RD50 values, enabling a comparative analysis of compound effectiveness. Promising results were observed with anthranilates and ether-substituted benzyl ester compounds, demonstrating a strong potential for the emergence of environmentally friendly repellents. This research contributes to sustainable pest management strategies essential for protecting fruit crops and ensuring long-term food security. This work was funded by research grants from the Fisher College of Science and Mathematics (Towson University) and the NIH (Bridges grant 1T34GM150447-01).

Abstract Name: Homeowner Well-Being and Community Livability: A Comprehensive Analysis in Lafayette, Indiana

Affordable housing is a cornerstone of any thriving community and is a critical priority for the Greater Lafayette region of Indiana. Through a collaborative partnership between the John Martinson Honors College, Habitat for Humanity of Lafayette, and the Quality of Life Foundation, our project focuses on

community revitalization by examining the quality of life of Habitat for Humanity homeowners. Habitat for Humanity is a nonprofit that works with volunteers and partner families to build new, affordable homes as well as complete critical home repairs. Our work integrates community engagement with a research-driven approach to create affordable neighborhood initiatives that enable residents to become connected. To guide our quality-of-life assessment, we developed a unified framework that combines Veenhoven's Four Qualities of Life and the Quality of Life Foundation's Framework 2.0. This model holistically evaluates both the livability of a neighborhood and the well-being of its residents. Using this framework, we created a homeowner survey that addresses five key dimensions: Safety and Transportation, Opportunities to Grow, Connectivity, Enjoyment of Life, and Accessibility. Preliminary findings from Habitat for Humanity homeowners reveal recurring themes, including limited neighborhood interaction, a lack of access to green spaces, and concerns about neighborhood safety. While some residents report opportunities for outdoor recreation, many experience barriers due to inaccessibility or lack of awareness. These findings underscore the need for initiatives that strengthen community connection and access to shared outdoor spaces. Based on these insights, our current phase focuses on conducting semi-structured interviews to gain a deeper understanding of homeowner experiences and aspirations. Guided by this feedback, we plan to implement a community gardening initiative in collaboration with local organizations to enhance neighborhood cohesion, promote access to healthy food, and foster long-term pride and self-sufficiency among Lafayette communities.

Abstract Name: Assessing the Role of Intracellular Progranulin in Restraining Inflammation and Supporting Lysosomal Function

Frontotemporal dementia (FTD) is the second most common cause of early-onset dementia after Alzheimer's. Roughly 20-25% of familial FTD cases are caused by GRN mutations, most of which cause haploinsufficiency of the protein progranulin. Progranulin is a glycoprotein responsible for restraining inflammation, exerting neurotrophic effects, and supporting lysosomal function. While it is known that progranulin undergoes both secretion to the extracellular space and direct trafficking to the lysosome, it remains unknown where progranulin exerts its critical functions. To address this topic, we created a novel knock-in mouse model (GrnL) that replaces endogenous mouse progranulin with L-PGRN, a modified version of human progranulin that is fused to the cytosolic tail and transmembrane domain of LAMP-1. This results in direct trafficking of progranulin to the lysosome with minimal secretion to the extracellular space. We sought to test whether this loss of extracellular progranulin would be associated with the development of FTD-like pathology including microgliosis, astrogliosis, and lysosomal dysfunction, thus helping to elucidate progranulin's critical site of action. Immunohistochemistry experiments were performed on mice expressing L-PGRN on a Grn knockout background. Both the heterozygous (Grn—/L) and homozygous (GrnL/L) knock-in mice displayed significantly lower levels of gliosis and lysosomal dysfunction markers than the progranulin knockout (Grn—/—) mice. To further assess lysosomal function, we asked whether mice expressing L-PGRN would display the dysregulation in enzymatic activity observed in Grn—/— mice. Lysosomal enzyme activity assays indicated that just one copy of the L-PGRN gene was generally sufficient to counteract dysregulation in enzyme activity. Together, these results suggest that extracellular progranulin is not necessary for preventing the onset of FTD-like pathology. Uncovering progranulin's cellular site of action is critical for informing the development of therapies to fight FTD and related disorders.

Abstract Name: Relating Microclimate Readings and Usage Patterns on the Mouse Creek Greenway in Cleveland, TN

Previous studies have suggested that a relationship exists between outdoor air temperature and the number of people using green spaces and trails. However, few studies have examined how trail usage relates to local microclimate conditions at specific locations. This study explores whether differences in the number of people present at different locations along the Mouse Creek Greenway in Cleveland, TN can be partially explained by differences in microclimate conditions during the summer at these locations. Microclimate and usage pattern data were collected on the Mouse Creek Greenway on June 4th and 5th, 2025. Spatial analysis was performed in ArcGIS Pro to calculate average temperature at each site, which was then normalized to NWS readings at Cleveland Regional Jetport. Ultimately, no relationship was found between temperature and usage pattern data. This is likely due to a limited amount of data and other variables influencing usage patterns.

Abstract Name: Identifying Academic and Non-academic Factors Associated with Undergraduate Mathematics, Mathematics Teaching, and Space Systems Engineering Programs

According to national reports and relevant scholarly literature, there are nearly nine million science, technology, engineering, and mathematics (STEM) jobs in the United States. Despite a booming job market, the U.S. is not graduating enough STEM graduates. Part of the problem is attrition, where STEM-interested students switch into non-STEM majors or drop out of college altogether. Mathematics, engineering, physical sciences, and other quantitative fields are disproportionately affected by STEM attrition. The purpose of this study is to identify to what extent academic factors (high school GPA, ACT scores, and grades in specific college classes) and non-academic factors (gender, first-generation college student, and socioeconomic status) explain why students who initially intended to complete an undergraduate degree in mathematics ($n = 94$), mathematics teaching ($n = 140$), and space systems engineering ($n = 256$) persist and graduate in their intended major, switch out of these majors but still graduate from college, or do not graduate. The study used a quantitative methodology, including descriptive and inferential parametric and nonparametric statistics, depending on the dataset's characteristics. Although the study is still in progress, preliminary findings suggest that students with lower high school GPAs, lower ACT scores in math and science, lower socioeconomic status, and those who are first-generation college students tend to leave their original major at significantly higher rates. Next steps include examining the role of grades in specific college classes and developing a multinomial regression model to identify the relative weight of the independent variables. This study is important because it could lead to establishing cost-effective academic and non-academic interventions that could help retain as many students as possible, resulting in better-qualified mathematics, mathematics teaching, and space systems engineering professionals in KY.

Abstract Name: Revolutionizing Veterinary Oncology: A Nanobody-Based Approach to Immune Checkpoint Therapy

Cancer is the leading cause of death in geriatric dogs (>10 years), yet current treatment options provide limited survival benefits and are frequently associated with significant toxicity. Tumor-mediated suppression of T-cell activity via the PD-1/PD-L1 immune checkpoint represents a major barrier to effective antitumor immunity, as many cancers exploit this pathway through PD-L1 overexpression to evade immune surveillance. To address this, we are developing a nanobody-based immunotherapy designed to restore T-cell function by blocking PD-1/PD-L1 signaling and thereby enhancing tumor clearance. We previously identified anti-PD-1 and anti-PD-L1 nanobodies that bind to canine PD-1 and PD-L1 receptors. From this panel, we have selected three cross-reactive anti-PD-1 nanobodies and one cross-reactive anti-PD-L1 nanobody that recognizes both canine and murine targets. These nanobodies were cloned into the SPB-015 vector and used to generate Expi293F-based stable cell lines for the production of recombinant proteins, followed by purification using affinity chromatography. ELISA and flow cytometry confirmed specific, high-affinity binding to both canine and mouse PD-1 and PD-L1. In functional assays, these nanobodies demonstrated inhibition of the PD-1 and PD-L1 interaction, demonstrating robust checkpoint blockade activity. These findings support advancement to in vivo efficacy studies in syngeneic murine tumor models and highlight the potential of nanobody-based PD-1/PD-L1 inhibitors as a translational immunotherapy platform for canine oncology.

Abstract Name: Early Risk, Lasting Impact: Adverse Childhood Experiences and Executive Functions in Older Adults

Adverse childhood experiences (ACEs) have been extensively linked to a range of negative health outcomes throughout the lifespan, with recent research suggesting enduring cognitive effects in older adulthood. Executive functions, a set of cognitive processes including planning, inhibition, and cognitive flexibility, may be particularly vulnerable to early-life stress. While previous studies have demonstrated associations between ACEs and poorer cognitive functioning, few have investigated this relationship within diverse U.S. aging

populations. This study aims to investigate whether exposure to ACEs predicts executive functions among older adults, with an exploratory investigation into whether this association differs among Hispanic/Latino and non-Hispanic White adults of similar ages and education characteristics. Seventy community-dwelling adults aged 50 to 79 years, including an equal number of Hispanic/Latino and Non-Hispanic White participants, completed cognitive testing and psychosocial assessments as part of a larger longitudinal aging study. Of the executive functions, working memory updating was assessed using the Keep Track Task, inhibitory control and selective attention were assessed using the Flanker Task, and cognitive flexibility was assessed using the Letter Number Task. ACEs were measured using a modified version of the Childhood Trauma Questionnaire (CTQ). Linear regression analyses will be used to examine the association between ACE scores and executive functions performance. Models including race/ethnicity will also be implemented to assess for racial/ethnic group differences. Based on prior evidence linking higher ACE exposure to long-term deficits in executive functions, we hypothesize that higher ACE scores will predict poorer executive functions performance overall. Additionally, given documented racial/ethnic disparities in ACE exposure, we expect exploratory analyses to reveal that Hispanic/Latino participants show higher ACE scores and lower executive functions performance when compared to demographically-matched non-Hispanic White adults.

Abstract Name: Sex hormones have differential effects in female and male rats on a reversal learning task.

It is often vital for organisms to visually discriminate between phenomena and to use that information to alter behavior in a process known as behavioral or cognitive flexibility. One aspect of behavioral flexibility is reversal learning, or reversing learned associations of the same stimuli modality. Areas of the frontal cortex are primarily responsible for these behaviors, including the medial prefrontal cortex (mPFC), implicated in learning associations with visual phenomena, and the orbitofrontal cortex (OFC), implicated in reversal learning. Many factors influence learning and reversal learning, including previous experience, stress, and hormones. To examine differential effects of the circulating gonadal hormones on each sex in rats, we conducted a touchscreen-based pairwise visual discrimination and reversal learning study on gonadectomized rats implanted with slow release capsules of testosterone, estrogen, and vehicle control. Rats had to select one of two visual stimuli with different frequencies. Once the rat learned an association (defined by 80+ correct trials in a 70 minute session), the conditioned stimulus switched in a subsequent session. Sessions until criterion were continued for both initial learning, and subsequent reversal(s). These data, and others, are still being collected and analyzed. Preliminary results suggest that gonadal hormones did not appear to have any effect on initial visual discrimination learning. However there it appears that estrogen and testosterone have differential effects on reversal learning in males and females. Estrogen treatment resulted in an increased number of sessions to reach the criterion for reversal learning in females compared to males, while testosterone appears to have increased the number of sessions the rats needed to reach criterion for reversals in males compared to females. These results may be attributed to the differential influence gonadal hormones have on the mPFC and OFC in each sex.

Abstract Name: Ensemble Modeling for H1N1

The H1N1 “swine flu” virus caused the first influenza pandemic of the 21st century in 2009, spreading rapidly across seventy-four countries and highlighting the urgent need for accurate disease forecasting tools. In time series forecasting, ensemble models have been proven to be superior to individually strong models and are widely used across various modeling problems. In this REU project, we sought to compare a variety of mathematical, statistical, and machine-learning models against a baseline Naïve Persistence Model (NPM) and employ an ensemble method to effectively predict future H1N1 surges. Using CDC H1N1 case data for the ten U.S. Health and Human Services regions, we implemented six forecasting models. These models were trained and tested using a sliding-window approach to simulate real-time deployment, and predictions were combined into a single ensemble model. When tested across all regions, we found that our ensemble outperformed the NPM at both 1-week and 4-week forecast horizons. Our results show that integrating diverse H1N1 forecasting models into a single ensemble produces superior predictions, validating existing ensemble research and providing valuable predictive power for H1N1 disease forecasting, which could better support public health decision-making. Furthermore, the region-dependent approach we employ supports localized disease management and can inform research of regional impacts on disease spread and model predictions.

Abstract Name: Sunscreens in the Sea: Quantifying Wash-Off to Protect Skin and Aquatic Ecosystems

This study investigates which sunscreen formulation, mineral, reef-safe mineral, or sport, remains on the skin most effectively during water exposure. The purpose of the research is to determine which type provides the strongest water resistance for human skin protection while minimizing chemical release into surrounding aquatic environments, a growing concern in marine ecosystem health research. Building on prior findings that sunscreen ingredients can accumulate in marine environments and harm coral reefs, this project contributes a comparative, laboratory-based analysis of wash-off rates under controlled conditions. Skin samples were rehydrated and treated with 0.1 g of each sunscreen type. Standard curves for each formulation were generated using serial dilutions and spectrophotometric analysis to enable precise quantification. Treated samples were then submerged in agitated water designed to simulate natural ocean wave motion, and water samples collected at timed intervals over 35 minutes were analyzed to measure sunscreen released. Preliminary results indicate clear differences in wash-off rates among formulations. The reef-safe mineral sunscreen adhered to the skin the longest and produced the lowest concentrations in the water, suggesting it may offer both superior water resistance and reduced environmental impact. These findings will be discussed in relation to consumer sunscreen choices, environmental protection, and the need for continued evaluation of sunscreen ingredients in aquatic systems.

Abstract Name: A Slimy Situation: Landscape effects on Slimy Sculpin (*Cottus cognatus*) morphology within West Branch Susquehanna River watersheds

Freshwater sculpin are a small-bodied, benthic fish species found in cool-to cold-water rocky streams. They can be a useful environmental indicator due to their partial tolerance to turbidity and siltation as well as intolerance to warmer temperatures, chemical pollution, and acidification. Slimy Sculpin *Cottus cognatus* (Richardson, 1836) is distributed within West Branch Susquehanna River watersheds. We vouchered specimens in the field within the Loyalsock Creek, Pine Creek, and Kettle Creek watersheds. Then we examined specimens for meristics such as fin ray counts, pore counts, and spine counts as well as morphological characters such as caudal peduncle length, palatine teeth presence, and the connection of the last two rays of the dorsal and anal fin rays. Previous research within these watersheds showed variability in traits among sites. We are investigating if landscape characteristics are influencing the variability of expressed traits. We hypothesize that there will be an increase in variability in traits depending on landscape characters like elevation and distance of the site from the main stem.

Abstract Name: The Impacts of COVID on Achievement Test Scores

This research will determine the extent to which state-level education spending per pupil affects SAT and ACT scores, controlling for other factors. By understanding the relationship between public education spending per pupil and how it affects achievement scores, we can see how effective funding is, determine whether there is a real need for public funding, and give policymakers insights. It also allows us to move in a direction that could lead to actual improvements in learning and programming, such as reduced class sizes, hiring higher-quality teachers, and providing tutoring support. In this research, we will determine the relationship between the yearly aggregated per-pupil spending and achievement scores on the SAT and ACT by running a multiple regression analysis. Two separate regression analyses, one for SAT scores and one for ACT scores, will be run (to conclude findings and compare results). The independent variables will be average per-pupil spending, exam participation percentage, teacher-to-student ratio, median household income, and state-level demographic percentages. The per-pupil expenditure data represents the total aggregate spending for that year within each state. All non-demographic variables are measured by state, spending and income are adjusted for inflation, and geographical and COVID dummy variables are also included. My data sources are composed of the Federal Reserve Bank of Minneapolis (for CPI), KIDS COUNT Data Center at the Annie E. Casey Foundation (for per-pupil expenditures data), and the National Center for Education Statistics (for mean SAT and ACT scores, and participation rates). Additionally, the research includes geographical dummies for the regions in the United States (Northeast, Southeast, Midwest, Southwest, and West as reference) and examines how this relationship is represented before and after COVID, because the pandemic caused major disruptions in both school funding and student performance. Preliminary results show a negative impact of COVID on achievement test scores

Abstract Name: The Role of Xyloglucan in Arabidopsis Root Growth

Arabidopsis thaliana is a fast-growing plant in the mustard weed family (Brassicaceae) that is widely used in plant research; its genome has been fully sequenced and is available online, making it a 'model' system for plant cell wall growth. Our focus for this study was to look at the genes that are involved in xyloglucan synthesis and study the mutants where one or more of these genes are deleted. Xyloglucan, a hemicellulose, is found in all vascular plants and is a polysaccharide (sugar) that has a glucose backbone with other sugars of xylose, galactose, and fucose forming side chains of varying lengths. Xyloglucan is involved in cell wall formation, wall integrity, and overall growth of the wall. Many studies have shown that xyloglucan directly interacts with the cellulose in the cell wall during growth. We used the wild-type seeds and measured seed germination rates, primary root lengths, root hair formation, and lateral root counts, and compared that to three *Arabidopsis* mutants that lack xyloglucan. Wild type and mutants (xxt1xxt2, xxt1xxt2xxt5, and cscl4,5,6,8,12) were surface sterilized and grown on media plates to score germination rates and root growth measurements. We used a stereo microscope to capture images of the seedlings at specific time points, used ImageJ to measure lengths, manually counted root hairs and lateral roots, and then used Excel to plot all graphs. We hypothesize that by deleting these specific xyloglucan genes (XXT and CSLC), we can reduce primary root growth and the number of root hairs in these mutants. This will tell us that xyloglucan is directly regulating cell wall growth in root tissue in *Arabidopsis*. By studying these gene deletions, we gain a better understanding of how a plant can be modified to affect function.

Abstract Name: Observing the Impact of Hamline University's Infrastructure on Bird Populations: Bird Strike Mitigation Project

Anthropological and environmental inquiry has sought to document the relationship between the built human environment and the other species that inhabit these spaces. Using this lens, the researcher examines the infrastructure of Hamline University's campus in Saint Paul, Minnesota, to observe its influence on the local bird populations by discovering potential solutions to decrease the number of bird deaths on campus, noting the influence birds and humans have on each other, and advocating for change in a meaningful way. In this study, an ethnographic approach is used to evaluate the health of the bird population by surveying bird species throughout Minnesota, conducting surveys on the Hamline University campus, and observing mitigation strategies in collaboration with institutional and community partnerships in Saint Paul, Minnesota. When considering mitigation solutions, a "do it yourself" approach can be extremely effective in reducing bird deaths on the Hamline University campus. It was recognized that this approach is accessible and inexpensive for institutions and individuals who are working towards decreasing bird collisions, and helps foster community engagement through creative expression of a significant issue. Additionally, administrative support of environmental and sustainability programs at local academic premises is crucial in protecting the well-being of bird species, showcasing the importance of students advocating for change on their campus. This research has worked in collaboration with another Hamline University undergraduate researcher who

focused on explaining the results of the surveys conducted, as well as investigating the types of birds that live on our campus, to increase general awareness of the waning bird population and broaden the scope of anthropological and environmental research. By utilizing a holistic approach, human influence on our environment can be examined in tandem with various mitigation strategies to decrease campus bird collisions and stress the importance of interdisciplinary work and collaboration within communities.

Abstract Name: Family Matters: Cultural Mismatch, Familial Support and Latine College Students

Literature on cultural mismatch highlights the negative impact on well-being for first-generation and Latine college students with collectivist backgrounds when universities primarily emphasize independence (Stephens et al., 2012; Vasquez-Salgado et al., 2015). Recent work also shows that cultural mismatch can be addressed. Latine first-generation (FG) students who experience a cultural connection to their college have a higher sense of belonging (Dueñas & Gloria, 2017). Separate literature highlights the importance of a supportive family for FG students for a higher sense of belonging in college (Roska et al., 2020). While experiencing a cultural match and family support are linked to belonging separately, research has yet to examine how they work together to predict belonging in the transition to college. This exploratory study examines this relationship for Latine FG students in their first year of college through secondary analysis of survey data of Latine FG college students (n=62) in their first year of college. The survey was part of a larger mixed-method longitudinal study focused on the college transition experiences of high school graduates. Using hierarchical linear regression analysis, we tested our two hypotheses. First, we hypothesized that a cultural match and family support would each positively predict belonging. Second, our main hypothesis was that family support would moderate the relationship between a cultural match and belonging, such that family support would buffer the negative effect of a low cultural match on belonging. Results showed that family support did not significantly predict belonging and did not moderate the relationship between cultural congruity and belonging. However, cultural congruity significantly predicted students' sense of belonging. This study highlights the need for further investigation of how universities can meet student needs culturally and emotionally. Insights show we can work toward creating ways to improve the college transition for both first-generation Latine students and their families.

Abstract Name: Mass Spectral Characterization of Blow Fly Pupae for Species Determination

Blow flies (Family: Calliphoridae) are often the first insects to colonize decomposing remains, making them

vital for estimating the postmortem interval (PMI) in forensic investigations. A back calculation method exists to enable forensic investigators to estimate the PMI by correlating species identity, environmental conditions, stage of decomposition, and species-specific life stages timelines. However, visual identification of the phenotypic features of the adults, which is the method most commonly used to identify species, is not suitable for the immature life stages most often encountered in forensic case work. Furthermore, insect species identification by DNA analysis is impractical for many crime labs and is time-consuming, limiting its use in casework. In this study, we explored the ambient ionization technique Direct Analysis in Real-Time High-Resolution Mass Spectrometry (DART-HRMS) as a means by which to identify species-specific metabolome profiles of blow fly pupae, one of the life stages encountered as forensic evidence. Pupae from several forensically-relevant were analyzed, and their distinct chemical fingerprints were compared using multivariate statistical tools. Application of Support Vector Machine (SVM) to the mass spectral data from 240 samples of 12 forensically relevant blow fly species revealed species level classifications with accuracies of 97.50% (leave one out cross validation) and 95.10 percent (external validation). Several key metabolome markers were also identified, including molecules whose presence or absence reliably distinguished species. Presence markers included nominal m/z 520, 536 and 546 which were specific for *Lucilia cuprina*, *Phormia regina* and *Calliphora livida*. Overall, these findings show that DART-HRMS offers a fast, non-destructive way to analyze insect evidence with the potential to improve PMI estimations, while overcoming some of the limitations of the traditional approaches to species identification.

Abstract Name: Libertatis Cunabula: Slavery in San Antonio Project

This research project discusses information that nobody else wants to discuss or acknowledge, whether that be important figures like Sam Maverick's role as an enslaver or the numerous monuments that don't represent the entirety of American history. This research project covered the Bexar County Tax Assessment Records from 1837 to 1862 and totaled around 1,200 pages. People have said that slavery wasn't a big deal since it wasn't as prominent within Bexar County/San Antonio, but these documents say otherwise. With the help of these documents, we can account for 11,096 enslaved people, 2,397 enslavers, and \$6,228,409 worth of taxable. Early scholars have consistently argued for independence, while later scholars claimed that Mexico was wronged by an illegitimate war initiated by the United States. However, no scholar has ever consulted any primary sources to see the impact that slavery had within San Antonio. These documents are an essential part of telling us the truth; slavery was not only here in Bexar County, Texas, but also prevalent within these specific years. Not only were men buying and selling enslaved people, but women were also participating in this. Another interesting fact that comes to light through these tax assessment records is that some of the famous historical figures in Texas were also enslavers, some even being those who enslaved the most people for specific years. Although this research topic is sensitive, it is imperative not to forget about this intensely realistic history. Another thing that became very common within these documents was that the majority of enslaved people were children under the age of 18.

Abstract Name: Integrating Flavin Cofactors into Peptide Amphiphiles for Electron Transport

Flavin is a redox cofactor found in many biological systems. Its ability to support electron transfer makes them a valuable tool to study this process in nature. In this project, I am synthesizing an Fmoc-protected flavin amino acid for use in peptide-based model systems that mimic redox-active proteins. This work is part of a broader effort to design an artificial system that isolates the biological properties underlying natural protein functions while being free from the complexity of evolutionarily affected systems. While working toward incorporating the flavin amino acid into peptide amphiphiles, I am learning techniques in organic synthesis, chemical purification, and NMR spectroscopy. These simplified systems will ultimately help us understand redox behavior in proteins and contribute to the development of next generation bioelectronic materials.

Abstract Name: Analysis of Space Dust Impact Waveforms on the Parker Solar Probe

Magnetic signatures measured by the Parker Solar Probe's (PSP) Fields search-coil magnetometers (SCM) are known to coincide with impacts of interplanetary dust, but the physical mechanism that links dust impacts to the observed waveforms remains poorly constrained. This project investigates whether a physics-based model of the expanding impact plasma plume can reproduce and interpret these magnetic signals, with the goal of using SCM data as a new diagnostic of dust populations near the sun. Building on recent electrostatic models that successfully explain dust-impact signals on spacecraft antennas, this work applies a similarly detailed description of the plasma plume geometry and ion kinematics to the PSP and SCM system. Using CST Studio, a simplified CAD model of the spacecraft and magnetometers is constructed to enable rapid electromagnetic simulations of the magnetic field perturbations generated by a moving, expanding cloud of charged particles. By varying key fitting parameters, such as impact location on the spacecraft, plume orientation, and effective dust charge and mass, the study will assess which physical configurations best reproduce the timing, amplitude, and multi-sensor structure of the measured signatures. The expected outcome is a validated modeling framework that links specific features of the SCM waveforms to properties of the impacting dust and its interaction with the spacecraft. Such a framework would establish PSP's search-coil magnetometers as a complementary dust-sensing instrument, provide new constraints on dust populations in the inner heliosphere, and contribute to a more complete understanding of how dust impacts shape the electromagnetic environment of spacecraft operating close to the sun.

Abstract Name: Determining the Binding Affinity of mAbs 17A5 and 24C10 to the GII.4 Norovirus P Domain

Norovirus is the leading cause of acute gastroenteritis worldwide. A major challenge in its control is the constant evolution of the virus, which enables it to escape existing population immunity. The protruding (P) domain of the norovirus capsid facilitates binding to host histo-blood group antigens (HBGAs), and antibodies that block this virus-host interaction generate immune pressure that drives viral evolution. Therefore, the quantitative investigation of antibody-P domain interactions is critical for understanding this evolutionary process and for developing effective vaccines. In this study, we expressed and purified the recombinant P domain from a 2012 Sydney GII.4 norovirus strain with an avitag in *E. coli*, then biotinylated the protein. The binding affinity of two monoclonal antibodies, 17A5 and 24C10, which target distinct immunodominant sites, will be characterized using Bio-Layer Interferometry (BLI). This technique allows us to quantitatively determine the association and dissociation rates, and calculate the equilibrium dissociation constants for both antibodies. We anticipate that this research, in combination with our structural studies of these antibody-P domain complexes, will contribute to a more detailed understanding of norovirus immunodominance and evolution, providing insights for next-generation norovirus vaccine development.

Abstract Name: Mycelium Conversations: Legal Protection of Funga in Colombia

The project "Mycelium Conversations: Legal Protection of Funga in Colombia" focuses on analyzing how the Colombian legal system protects the fungi inhabiting the country and regulates human interaction with these organisms for obtaining benefits. This research arises from the evident lack of recognition and specific studies on the legal protection of fungi, a fundamental component of biodiversity and ecosystems, which has been historically marginalized compared to traditional fauna and flora. The project's context is framed within a renewed international interest in incorporating fungi as an independent biological kingdom within global conservation agreements, reflected in initiatives such as the Convention on Biological Diversity (CDB) and the [Fungal Conservation Pledge]. Colombia, despite its biological wealth and leadership in biodiversity, lacks explicit regulations protecting fungi, limited to indirect inclusion within environmental regulations and general biodiversity legal instruments. The methodology employed in the study is mixed and predominantly qualitative. An exhaustive review of national and international legal sources, jurisprudence, and scientific literature was conducted, complemented by comparative law to identify successful cases of legal protection. Additionally, interdisciplinary collaboration with mycology experts, such as mycologist [Aida Vasco], was undertaken, along with field trips to Medellín ecosystems to observe fungal species and understand their ecological role, reinforcing the need for a legal-biological approach. The results show that fungi protection in Colombia is insufficient and mainly limited to commercial aspects, ignoring their crucial ecological role. It is concluded that it is essential to develop specific policies and regulations, including their incorporation into environmental licensing processes, and to promote public education to recognize their importance. This study proposes pathways to strengthen regulation, anticipating political and resource-related challenges.

Abstract Name: Effect of Acidic and Basic Treatments on the Adsorption Capacity of Avocado and Lemon Peels

Throughout the globe, lakes and rivers have been contaminated by synthetic dyes such as methylene blue that poses public health risk and environmental damage. While engineering-based water treatments exist, many are highly expensive and inaccessible for communities with limited resources. This study explores whether fruit biopeels can serve as an effective low cost bioadsorbent. Lemon and avocado peels were treated with a basic (sodium hydroxide) or an acidic (phosphoric acid) solution to evaluate their adsorption of methylene blue. Peels were washed, prepared, then soaked dilutions of sodium hydroxide or phosphoric acid. After treatment, samples were oven-dried at 60°C for two hours. Adsorption of methylene blue was monitored by a spectrophotometer. Sodium hydroxide treated peels showed the highest adsorption of methylene blue across both peels, on the contrary phosphoric acid treated peels performed lower than both the control and the sodium hydroxide group. Treated in dilute sodium hydroxide, avocado had an efficiency of 65.2% removal and 0.33mg/g maximum adsorption capacity. In comparison, lemon peels efficiency was 46.8%, and 0.311mg/g maximum adsorption capacity. These discoveries suggest that sodium hydroxide treated avocado and lemon peels, specifically avocado, are accessible, sustainable and promising bioadsorbents for removal of methylene blue from contaminated water. These waste materials may offer an affordable and efficient treatment option for communities lacking advanced water purification infrastructure.

Abstract Name: Seasonality of Nutrients in The Monterey Bay

Biological productivity is reliant on light, atmospheric carbon dioxide (CO₂), and nutrient availability. Nutrients are taken up in set amounts for a variety of phytoplankton- a plant-like single celled organism. Monterey Bay is home to many different functional groups and species, creating one of the world's most diverse locations. Nutrient availability in seawater is a key to the function of the marine food web, Earth's oxygen production, and climate regulation through CO₂ absorption. Previous research shows a link between phytoplankton's growth rate, and upwelling. In our study, we analyzed the nutrients concentrations in Monterey Bay. Monthly samples were collected at four different locations (Monterey Bay Harbor, Moss Landing, Santa Cruz Wharf, and Half-moon Bay). Seawater samples were filtered and frozen. Before analysis, samples are thawed and mixed. A SEAL nutrient analyzer is then used to measure levels of nitrate, nitrite, phosphate, and silicate. Our findings show variation in nutrient concentrations among the locations. Additionally, nutrients follow a seasonal cycle with higher concentrations during the upwelling season. As

such, we expect that phytoplankton productivity would also be high during upwelling since the nutrients stimulate their growth.

Abstract Name: Tailoring Social Activities In Memory Care Units For Urban Demographics: Using Art Therapy, Meditation, Exercise Programs, And Music Therapy To Decrease Cognitive Decline In Alzheimer's Patients

Alzheimer's disease is a progressive, degenerative brain disease that slowly reduces cognitive functions such as memory, thinking, and communication. Alzheimer's disease is the most common form of dementia and while it impacts the entire population, one of the main populations impacted by Alzheimer's disease are nursing home patients, specifically memory care patients, with Alzheimer's disease being one of the leading causes of death in these facilities. Though a cure has not been found for Alzheimer's disease, there are many treatments to slow the progression of this disease. Non-pharmacological treatments have been found to be increasingly more beneficial than medication in recent years. Implementing a plan that uses different social activities for each stage of Alzheimer's disease for patients in memory-care units may be beneficial to effectively reduce cognitive decline and may benefit patients from socializing with one another during planned activities. Memory care units in urban areas have specific barriers they have to overcome in patient treatment because factors such as city noise, limited space, and previous patient backgrounds have to be considered when creating a plan for patients. This literature review creates a plan with four social activities (exercise, meditation, art therapy, and music therapy) to be used in urban memory care units for Alzheimer's patients. This literature review aims to propose how promoting social activities such as exercise, meditation, art therapy, and music therapy may be able to reduce cognitive decline in Alzheimer's patients in urban memory care units by applying these activities to the specific stages of Alzheimer's disease (mild cognitive impairment, mild Alzheimer's disease, moderate Alzheimer's disease, and severe Alzheimer's disease).

Abstract Name: Quantitative Morphological Analysis of Collagen Networks in Alginate-Crowded Pastes

Alginate-based biomaterials are promising in regenerative medicine and tissue engineering applications given their biocompatibility, biodegradability, non-toxicity, and accessibility. These biomaterials have significant drawbacks as pure alginate-based gels demonstrate insufficient mechanical strength for surgical handling along with non-optimal biological activity, hindering their efficacy in clinical applications. We have explored alginate-composite gels to elucidate the full breadth and viability of the materials in the field. Prior work in the Lyon group (Neeraja Gajendran) has illustrated noticeable morphological changes in collagen fibrillogenesis induced by alginate in collagen: microgel composites. These observations have been largely qualitative to this point. Thus, quantitative collagen fibrillogenesis analysis techniques to quantify observed fiber growth differences in samples are needed. The morphological analysis technique utilized FIJI, an open-

source ImageJ software application for bioimaging applications. A custom data filtering and processing method was developed to permit differentiation of collagen fibers from background in differential interference contrast images. This technique was applied to 4 different compositions with the goal of understanding the behavior of collagen in the respective samples. The conditions studied were a pure collagen gel (control condition), alginate:collagen composite gel, collagen:microgel paste composite gel, and finally alginate:collagen:microgel paste composite gel. Thicker collagen fibers were observed in both the alginate:collagen systems, with the thickest observed in the alginate:collagen microgel paste gel. These qualitative observations were supported utilizing the FIJI-based analysis, and bolstered the hypothesis developed from previous projects in the Lyon Group of alginate:collagen composites polymerizing thicker collagen fibers due to molecular crowding effects. Future directions are applying this technique to understand the robustness of collagen in microgels to understand if alginate promotes self-healing, resistance to shear, etc of the collagen fibers, fostering a stronger understanding of the viability of alginate composites and their usage in clinical settings.

Abstract Name: As Indies Rise, Innovation Thrives

Since the 1990s, video games have been one of the most popular forms of entertainment in human history. The reason games have become so well-known is the monumental franchises they have spawned. The industry wouldn't be the same without games like Mario, Sonic, Kirby, and more. A lot of these well-known games are made by companies that fall under the Triple-A category. Triple-A companies are industry giants that have a ton of money to make bigger and greater games. Since the spawn of the industry, Triple-A companies have been known for their innovation and creativity, but recently, something changed. In 2025, Triple-A companies are losing money on their projects, and people want to support a different kind of company. Indie companies are the new talk of the town, but what exactly are they? An Indie company is small in size and doesn't have a massive budget to work with when developing games. If Indies are making games that are smaller and cheaper, then how are they even competing with the big Triple-A companies? The rise of Indies isn't just a coincidence; it's a direct result of layoffs, crunch, price, greed, and drive being problematic within Triple-A companies. Everything that Triple-A does is motivated by money, while Indies focus on innovation and creativity. The public is siding with Indies because they care about improving and building upon the industry to make it even greater. The gaming industry can only survive if people are willing to do the work, not because of money, but because they care.

Abstract Name: Health System and Payer-Level Decision-Making Factors in the Adoption, Integration, and Sustainability of Digital Health Tools

Alcohol Use Disorder (AUD) results in numerous health and economic burdens for millions across the United

States. Despite this, accessible treatment options remain limited due to barriers such as stigma and geographical constraints. Digital health tools have emerged as a promising option to overcome these barriers by expanding reach, supporting patient-driven self-care, and improving treatment outcomes. A recent study demonstrated that Tula, a smartphone-based intervention for individuals with mild-to-moderate AUD, reduced heavy drinking days across three support models in a hybrid effectiveness–implementation trial. Despite widespread interest in mHealth apps, their adoption and integration in health systems remains limited, and little is known about how health systems and payers decide whether and how to adopt and sustain tools like Tula. This qualitative study addressed this knowledge gap through ten semi-structured interviews with senior leaders across clinical, operational, behavioral health, and public and private payer roles within a large academic health center. Interview questions explored the organizational context in which digital health implementation occurs, including current AUD management, decision-making processes, perceived value and fit of digital interventions, barriers to adoption, and long-term sustainability. Data were analyzed using thematic analysis in Dedoose. Preliminary analysis highlighted several themes: requirement for robust evidence; importance of seamless workflow/electronic health record integration; payer emphasis on cost and return on investment; criticality of clinician champions; need for ongoing feedback loops; and recognition that stigma and accessibility challenges make implementation of digital tools particularly difficult for AUD. Results suggest the need for identifying core decision-making principles, considering barriers and facilitators to adoption, and creating conditions that promote long-term sustainability. Overall, this project provides insights into how digital tools like Tula can be integrated into complex healthcare systems to meet clinical, operational, and payer demands to improve the management of AUD and other chronic conditions.

Abstract Name: How does nutrient and trace metal availability in streams affect metal bioaccumulation in biofilms found on plastics?

Plastic pollution is a pronounced threat to aquatic ecosystems. Plastics physically degrade during transport and become microplastics (< 5mm in diameter), which can be easily ingested by marine life. These plastics can accumulate biofilms, communities of microorganisms, on their exterior that can bioaccumulate metals from the surrounding waters. These metals can then be released into the organisms that ingest these microplastics, with substantial impacts to aquatic food webs. Despite these environmental health risks, few studies have investigated the factors that control biofilm growth (nutrient availability) and their metal bioaccumulation potential (dissolved trace metals in streamwater). This research investigates the relationship between nutrient and trace metal availability in freshwater streams and the accumulation of metals in biofilms on plastics using incubation experiments conducted over 14 and 28 days. Water samples were collected from nine local streams in Pennsylvania exhibiting a range of nutrients and metal concentrations. Plastic incubations were performed by placing replicates of known plastic materials, polyethylene (PE) sheet and polyethylene terephthalate (PET) plastic water bottles, in stream water under artificial light for a total of 14 and 26 days. The plastic samples were then analyzed for their exchangeable trace metal concentrations using an acetic acid extraction. Study results highlight the risk of metal bioaccumulation in aquatic ecosystems resulting from improper waste disposal.

Abstract Name: Run From Water: Community vs. Household Level Flood-Preventive Infrastructure in Harris County, Texas

Rising sea levels from human-caused climate change have resulted in an increase in flooding that poses an immense risk to coastal communities. In Harris County, Texas, recent severe flooding events such as Tropical Storm Allison in 2001 and Hurricane Harvey in 2017 led to a reemphasis on flood-preventive infrastructure. Despite these investments by the city, county, and state, major flooding events continue to impact the Harris County area negatively approximately every two years. When faced with a hurricane or other extreme flooding event, “run from water” is the advice given to residents by the county; yet, population trends do not correlate with this advice. Despite an increase in the frequency and intensity of flooding events, the population in Harris County’s most flood-prone areas has remained fairly stable. While Harris County has invested in flood prevention technologies such as drainage infrastructure, bayou expansions, and wetland restoration, flooding continues to result in loss of life and property, prompting the development of household-level flood adaptation methods. These household-level investments include raising the elevation of the house above historic flood-levels, yet this investment is quite costly, raising the question: does income level greatly impact a community’s flood disaster resiliency in equally flood-vulnerable areas? This project uses Geographic Information Systems [GIS] mapping technology to map both population trends and housing design trends in response to flooding within Harris County’s Special Flood Hazard Areas. Research uses data from the American Community Survey, Harris County Appraisal District, and FEMA “Harvey Damage Assessments and Claims.” Surveying housing designs within specific neighborhood case studies provided additional data. This project argues that in Harris County, Texas, income level greatly impacts a community’s flood disaster resiliency in equally flood-vulnerable areas, with ineffective community-based adaptation methods prompting the development of individualized adaptation methods in the form of raised homes.

Abstract Name: ESTABLISHING THE DISCRIMINATIVE STIMULUS EFFECT OF NALTREXONE IN FEMALE AND MALE RATS WITH CHRONIC-INTERMITTENT ACCESS TO SUCROSE

We previously demonstrated that male Sprague Dawley rats maintained under chronic, intermittent sucrose learned to discriminate between subcutaneous (s.c.) injections of the opioid antagonist naltrexone (1 mg/kg) and saline. Sucrose produced a long-term change in opioid function. Substituting water for sucrose one hour before the session did not affect naltrexone’s discriminative stimulus effects. After two weeks of water consumption, naltrexone no longer served as a discriminative stimulus. In the present study, we sought to establish discrimination in both female and male rats. Rats were trained to lever press in an operant chamber. Rats then received 12-hour access to 25% sucrose solutions for two weeks. After, discrimination training began. One hour before sucrose access, female (n=11) and male (n=12) rats were trained to discriminate between naltrexone (0.32 or 1.0 mg/kg) or saline. After naltrexone administration, left lever responses were reinforced with a sucrose pellet and right lever presses were punished by eight seconds of darkness. The contingencies were reversed following saline administration. After the training session, rats received sucrose solutions in their home cages for 12 hours. Training continued until 80% or more condition-appropriate responses were emitted before the first consequence (and for the total session) for 8 of 10 daily sessions. Relatively few rats (2 females and 3 males) acquired the discrimination within 80 sessions. Both males and females learned the discrimination (M = 67 sessions for both). During generalization tests, responses toward

either lever were reinforced. Smaller doses of naltrexone produced discriminative stimulus effects in females. In sum, female rats acquired the naltrexone discrimination similarly to males. Naltrexone was more potent in producing discriminative stimulus effects in females. Although access to chronic, intermittent sucrose solutions produces long-lasting changes in opioid function, access to sucrose before the training session appears to be a necessary condition for training this discrimination.

Abstract Name: Seasonal and Diurnal Examination of Dissolved Oxygen in Bluff Creek, Wisconsin

Multiple water quality variables were examined within Bluff Creek, a spring-fed stream and a tributary to Whitewater Creek in southeast Wisconsin. The examination of how dissolved oxygen (DO) changed over a 12-month period (June 2024 to May 2025) was the central focus of this study. Bluff Creek is an exceptional water resource in southeast Wisconsin and serves as a Class 1 trout stream. Dissolved oxygen was measured once a month at a sampling site along Bluff Creek using a YSI meter. Monthly data indicate significant diurnal variation. July 2024 had the largest range (88.2%; 36.1% to 124.3%). Other monthly ranges were: June 72.4%, August 75.9%, September 67.3%, October 40.5%, November 30.5%, December 21%, January 16%, February 12.6%, March 29.9%, April 38.1%, May 64.5%. Seasonal averages revealed clear patterns; summer (June–August) showed the highest DO peaks (122.5%) and means (95%), followed by fall (109.9%, 93%), spring (108.8%, 94%), and winter (87.9%, 80%). Corresponding seasonal DO ranges were 78.8% in summer, 46.1% in fall, 44.2% in spring, and 17% in winter. Higher dissolved oxygen concentrations are typically associated with cooler water temperatures, but Bluff Creek does not consistently show this. In July, a minimum temperature of 17.7 °C corresponded to 36.1% DO, while its peak of 21.4 °C was related to 124.3% DO. Overall, the highest DO concentrations occurred when water temperature was also at its highest (e.g., June 20°C and 128.9%; August 17.5°C and 129.1%). This trend (seen in late spring through early fall) likely results from increased photosynthesis from submerged aquatic vegetation. These parameters will continue to be monitored and analyzed monthly through 2026.

Abstract Name: The Propaganda of China's Population Control Campaign

From 1979 to 2015, China's One Child Policy reshaped the nation's demographic structure and redefined the concept of family life. While most scholarship focuses on the policy's human cost — such as gender imbalance, forced sterilizations, and the psychological impact on the “only child” generation — this research examines how the Chinese government justified and enforced such a radical social experiment through propaganda. Using a collection of state-issued posters, slogans, and visual media from the 1980s to early 2000s, this project explores how the Chinese Communist Party employed moral, patriotic, and gendered messaging to persuade citizens to comply with population control measures. This research analyzes recurring symbols such as the idealized “model mother” and the family of three. Beyond printed media, propaganda was reinforced by local officials and family planning workers who promoted compliance through rewards,

public praise, and social pressure. By framing reproduction as an act of national duty, propaganda transformed obedience into virtue and sacrifice into honor. Ultimately, this project argues that propaganda surrounding the One Child Policy did more than inform, it redefined morality itself. By convincing citizens that compliance was patriotic and dissent was shameful, the state changed the way people valued life itself, persuading families to accept, or even justify, the abandonment or death of their own children. By examining these visual and rhetorical strategies, this study reveals how propaganda can alter human nature, molding personal belief into political obedience.

Abstract Name: The Page Act of 1875: Moral Panic and Racial Control

The Page Act of 1875, the first federal law to restrict immigration to the United States, used the language of morality to justify the targeted exclusion of Chinese women. Though framed as a measure to prevent prostitution and forced labor, the act primarily functioned as a racialized and gendered screening system that judged Chinese women as inherently suspicious. This project examines how the Page Act reshaped American understandings of Chinese womanhood and laid the groundwork for later exclusionary policies. Focusing on political rhetoric, interrogation practices, and immigration records, this study highlights how officials used very subjective moral judgments to control entry. Chinese women were routinely interrogated about their sexual histories, families, and intentions. These practices effectively halted female immigration, producing extreme gender imbalances, and hurting the formation of Chinese communities in America. This project argues that the Page Act operated less as a moral safeguard and more as an early instrument of racial exclusion. Its legacy is visible in later federal policy and in long-standing stereotypes surrounding Asian women. Understanding its impact offers insight into how gendered narratives have shaped American immigration systems from their earliest foundations.

Abstract Name: Purkinje Cell Mecp2 Loss Selectively Impairs Cerebellar Learning in a Female Mouse Model of Rett Syndrome

Rett syndrome (RTT) is a severe neurodevelopmental disorder caused by mutations in the X-linked gene MECP2. Because these mutations are typically lethal in males, female mice with mosaic X-chromosome inactivation were used to model the human condition. The purpose of this project was to determine how the loss of Mecp2 specifically in cerebellar Purkinje cells contributes to motor and learning impairments associated with RTT. Previous research implicates both cerebellar circuitry and altered neurotrophic signaling in RTT, yet the cell-type-specific role of Purkinje cells in behavioral outcomes remains unclear. To investigate this question, we compared behavioral performance in female heterozygous (Mecp2 Het) mice and Purkinje cell-specific Mecp2 conditional knockout (PC-KO) mice. A series of behavioral assays assessed locomotion, sociability, motor coordination, and cerebellar-dependent associative learning. These tests included open field exploration, the three-chamber social assay, grip strength, ladder walking, accelerating rotarod performance,

and delay or trace eyeblink conditioning. We also evaluated whether enhancing TrkB signaling with the small-molecule agonist 7,8-dihydroxyflavone (7,8-DHF) could improve learning-related behavioral outcomes. PC-KO mice displayed normal locomotion, social behavior, and basic motor coordination across multiple assays. However, they showed a pronounced deficit in eyeblink conditioning, indicating a selective impairment in cerebellar-dependent learning. In contrast, Mecp2 Het mice demonstrated broader behavioral deficits and reduced neurotrophic signaling. Treatment with 7,8-DHF partially improved learning in Het mice but did not rescue deficits in PC-KO mice, suggesting that Purkinje cell-specific loss of Mecp2 cannot be compensated by TrkB pathway enhancement. These findings identify a critical role for Purkinje cell Mecp2 in supporting cerebellar learning and provide insight into cell-type-specific mechanisms contributing to motor dysfunction in Rett syndrome.

Abstract Name: Thermal Degradation of Vitamin C in Freshly Squeezed Orange Juice

A single change in temperature can significantly reduce the amount of vitamin C contained in everyday foods. Vitamin C plays an important nutritional role, but its chemical structure makes it highly sensitive to heat, light, and oxygen. This experiment investigates how heating affects the concentration of vitamin C in freshly squeezed orange juice using iodometric titration with potassium iodate. Orange juice samples were heated within the range of 20-70°C and titrated with a standard potassium iodate solution to determine their ascorbic acid content. The titration result depicts an inverse relationship between temperature and the vitamin C concentration. As the temperature increases, there are less titrants needed which indicates greater degradation of vitamin C. This shows the vitamin C breaks down rapidly at higher temperature as a result of oxidation and structure instability. The findings emphasize the urgency of minimizing heat exposure to preserve the nutritional value in foods that contain vitamin C. Overall, this experiment shows that excessive heating significantly reduces the ascorbic acid content in orange juice which eventually lowers its nutritional value.

Abstract Name: Equivalence in Almost L-Space Knots

Mathematicians use knots (similar to those you tie in your shoelaces) to study and to understand the shape and structure of spaces. By looking at how knots interact with 3-dimensional spaces, we uncover surprising connections between geometry, algebra, and the way spaces can be organized. The L-space conjecture is a central open question in the field low-dimensional topology that connects three seemingly distinct properties

of irreducible rational homology 3-spheres: (not) being an L-space, admitting a taut foliation, and having a left-orderable fundamental group. This can be thought of as uniting the topological, analytic, and algebraic properties of these spaces. To study these mathematical objects, we focus on L-space knots. A mathematical knot is a (possibly) knotted up loop in three-dimensional space. A specific type of knot, L-space knots, play a key role in understanding the structure of L-spaces. In this project, we instead study almost L-space knots (knots related to objects called almost L-spaces) in order to test the boundaries of this conjecture. Using the Heegaard Floer knot complex, we compute the Upsilon function, a powerful knot invariant packaged as a piecewise linear function, for this infinite family of knots and compare the results to the Upsilon functions of L-space knots.

Abstract Name: The Development of Guiding Principles for Supplementary Instructional Videos

Supplementary instructional videos have proven beneficial in a wide range of disciplines, however, there are very few resources containing guiding principles for their creation. The goal of this research is to determine and communicate best practices on the production of these supplemental videos. Supplemental videos have proven particularly useful among audiences that require additional resources to succeed in the classes. We will discuss our video production methods, including media principles and equipment that facilitate student engagement in online instruction. For example, we target video lengths of five to six minutes, focusing on only one topic per video. This encourages students to watch a video on the exact topic they are struggling with instead of watching more generalized videos that may not be as specific to their needs. We will also discuss our utilization of special equipment such as a lightboard so students can see the presenter's face while watching written content delivery. We will use, as a case study, a general elective Physics of Music class, primarily composed of non-STEM majors taking the class to fulfill a requirement in natural sciences. This audience represents those that would tend to struggle with material in an introductory physics course and might benefit the most from supplementary resources. Our videos can provide extra time with the material to aid these students with no prior background in physics. They provide additional problem-solving practice and explanations of core concepts. We will present feedback from student focus groups to assess the impact that these videos have on students' understanding of core concepts and further inform future video creations.

Abstract Name: Doubling up on Healthy eating: Evaluation of a Healthy Incentive Program and Fruits and Vegetable Consumption.

Americans from low-income households often buy fewer fruits and vegetables than those from high-income households and face a higher risk of diet-related chronic diseases. To increase produce consumption among low-income households, the Double Up Food Bucks (DUFb) Alabama, a program supported by the United States Department of Agriculture-Gus Schumacher Nutrition Incentive Program (GusNIP) initiative, matches produce purchases for those participating in Supplemental Nutrition Assistance Program (SNAP)-- up to \$40 at farmers markets, and up to \$10 at grocery stores. This program operates by partnering with select Alabama grocery stores and farmers markets in seven counties. This study aims to examine how DUFb has helped low-income SNAP households access more fruit and vegetables. We focus on two questions: (i) how much of the available incentives participants have redeemed and (ii) how the program has influenced fruit and vegetable consumption. To answer the first question, we use four years of transaction-level data on fruit and vegetable purchases by SNAP households at grocery stores and farmers markets. Specifically, the incentives redeemed by SNAP households are summarized to measure the uptake of the program. Then, we compare incentives redeemed at farmers markets and grocery stores. For the second question, we use four waves of survey data collected as a part of a marketing campaign to SNAP households in the counties where DUFb operates. It provides information on the participation of SNAP households in the DUFb program, food security, and the frequency of fruit and vegetable consumption. We compare participants' product consumption with that of nonparticipants. We expect that participants' redemption of incentives has increased over the program years, and DUFb has improved the fruit and vegetable consumption of participating households.

Abstract Name: Designing for Retinitis Pigmentosa: An Accessible, Multisensory Residential Design

As visual function decreases, routine tasks and safe navigation within the home become increasingly challenging. Consequently, the housing design must respond to these evolving needs by creating a living environment that emphasizes safety, clarity, multisensory engagement, and long-term adaptability. This residential design aims to support the daily living needs of an individual with retinitis pigmentosa (RP), a progressive genetic condition characterized by night blindness, peripheral field loss, and eventual tunnel vision. Research informing the design, including precedent studies, literature on visual impairment, and insights from a professional working with individuals who are blind or have low vision, have helped establish key accessibility priorities. The resulting three-bedroom, two and a half bath layout is organized with simplicity and predictability, using defined walls, intuitive circulation paths, and a straightforward room sequence provide cognitive and visual stability, that reduces confusion and enhances orientation. Lensed can-lights minimize glare through soft, even illumination and task lighting helps to identify key areas for the user.

High-contrast wayfinding elements, like bold color differentiation at door frames, varied floor and wall textures, and subtle acoustic changes between areas support navigation using both residual vision and auditory cues. Smooth floor transitions further enhance safety, while acoustic treatments improve spatial awareness and aid in navigation. Integrated smart-home technologies, including voice-activated lighting, automated blinds, and climate control, promote independence for a resident who may also utilize tools such as canes, guide dogs, screen readers, and UV-blocking eyewear. The open layout ensures the home and furniture can evolve as RP progresses. Blending modern accessibility with the older colonial architecture, this project creates a balance of function, comfort, and dignity. This demonstrates how thoughtful residential design can meaningfully enhance quality of life for individuals with low vision.

Abstract Name: Optimizing Dye Removal from Water Using Exhausted Coffee Grounds: Effects of pH, Particle Size, and Adsorption-Desorption Cycles

Textile and dye industries discharge over 700,000 tons of dyes annually, contaminating waterways, blocking sunlight penetration, and disrupting aquatic ecosystems. Conventional treatment methods, like activated carbon adsorption, are effective but economically and environmentally unsustainable for large-scale use. This study explored exhausted coffee grounds (ECGs) as a sustainable, low-cost biosorbent for removing methylene blue, a common cationic dye, from water. This research investigated how pH and particle size (106-300 μm , 300-500 μm , 500-710 μm , and 710-1000 μm) influence adsorption efficiency and evaluated the reusability of ECGs through multiple adsorption-desorption cycles to assess performance over repeated use. It was hypothesized that higher pH levels and smaller particle sizes would enhance dye adsorption capacity. Batch experiments over 240 minutes supported these predictions. At pH 6, adsorption varied by particle size: the 106-300 μm ECGs showed the highest adsorption capacity (95 mg/g), while the 710-1000 μm particles exhibited the lowest (67 mg/g). When examining pH effects independently, both particle sizes performed substantially better under basic conditions, with the 106-300 μm ECGs reaching 163 mg/g at pH 12 and the 710-1000 μm particles reaching 167 mg/g. Under acidic conditions (pH 2), adsorption decreased for both sizes, dropping to 13 mg/g for the 106-300 μm particles and 9 mg/g for the 710-1000 μm particles, reflecting reduced electrostatic attraction between methylene blue and the biosorbent. Reusability trials over 60 minutes showed that the 106-300 μm ECGs consistently retained more methylene blue, increasing from an average of 98 mg/g initially to 113 mg/g by the third cycle. The larger 500-710 μm particles retained far less, averaging 19 mg/g initially and rising to 42 mg/g after the third cycle. These studies highlight the need to optimize pH and particle size to improve ECG use and reuse in dye-contaminated water treatment.

Abstract Name: The Impact of U.S. Migrant Returnees on Socioeconomic Conditions in Latin American Countries of Origin

While changes in U.S. deportation flows have remained a key component of scholarly discussion in the field of migration, the impact of these shifts on countries of origin has received significantly less attention. Latin American countries of origin are of particular interest as, in the last 15 years, Latin American migrants have accounted for over 90% of individuals deported from the U.S. Furthermore, the potential these individuals face of being deported has increased significantly within the past several decades; from 1997 to 2016, 5.7 million people were deported from the U.S., twice the total of all deportations from the U.S. before that point. As U.S. policies surrounding deportation and removal continue to shift, this study examines the challenges Latin American countries of origin face in receiving migrant returnees from the U.S. through the lens of observable impacts on socioeconomic indicators, such as employment, education, crime, and remittances, using a mixed methods approach. First, through quantitative analysis of U.S. Department of Homeland Security data on removals alongside key socioeconomic indicators within the University of Gothenburg's Quality of Governance dataset, the study examines possible correlations and notable fluctuations in U.S. deportations and socioeconomic indicators in Latin American countries of origin from 2003 to 2022. The qualitative portion will entail a week-long period of field study in Mexico in early 2026, interviewing reintegration professionals on their experiences and observations related to the challenges they may face in reintegrating returnees into education, employment, and other systems within Mexico— their country of origin. This mixed methodology, with potentially conflicting results, will contribute to a more accurate narrative on the experiences of returnees, reintegration professionals, and their countries of origin, lending additional nuance to scholarly discussion on U.S.-Latin American migration dynamics.

Abstract Name: Determining the Conductivity of Copper Experimentally using the Heat Diffusion Equation

The thermal conductivity of copper has been studied extensively, in part due to its many applications in thermal management and electronics. In this presentation, a method is described that first applies a brief heat pulse to one end of a copper rod and then measures the temperature as a function of time at discrete locations along the rod. The thermal conductivity and heat capacity can be extracted from the collected data by analyzing a solution to the one-dimensional heat diffusion equation. This project is a refinement of an undergraduate laboratory experiment on the use of computer instrumentation in the physics laboratory. One of the leading causes of error is heat loss from the rod to the ambient air. Such heat loss can be curtailed by hanging the rod within a vacuum chamber, thereby thermally isolating the specimen. Unfortunately, the thermal conductivity of copper determined by using this method differed by 56% from the accepted literature value. This deviation highlights the sensitivity of environmental factors, model assumptions, and data collection techniques. These systematic errors can be addressed by modifying the vacuum chamber design, rod length, and data acquisition electronics. With these modifications, we aim to improve accuracy and reproducibility, offering a valuable extension to this undergraduate laboratory experiment.

Abstract Name: Improving Capacity Retention in Anode-Free Aqueous Zinc-Bromide Batteries with Magnetic Fields

Zinc-ion batteries are an ideal alternative to lithium batteries, as zinc-based electrolytes are aqueous, non-volatile, and relatively earth abundant, promoting safety and reduced cost. However, the benefits of zinc-based batteries are constrained by limited reversibility, energy density, and capacity fading. In most batteries, metal foil is used as an anode with up to 90% of the active material not utilized during battery operation. The alternative—anode-free aqueous zinc battery configurations—are promising because a current collector made of copper or carbon can serve as the anode in which zinc can reversibly plate and strip on the surface. Pairing this current collector with carbon-based cathode materials will reduce expenses while maintaining a conductive and stable battery for durable cycling. Additionally, magnetic fields will be incorporated behind the electrodes to suppress growth of dendrites, which will improve the batteries reversibility through efficient plating and stripping of Zinc during battery operation. These disk magnets require zero energy input, are inexpensive and are infinitely reusable as they do not actively participate in the battery's chemical reactions. To explore the versatility of this configuration, a Zinc-Bromide battery will be investigated by mixing alkylated ammonium bromide complexing agents into the graphite cathode slurry and utilizing a Zinc-Bromide based electrolyte. Manipulating the chain-length of the complexing agent will provide tunable control over the viscosity of the electrolyte such that the diffusion of ions can be optimized to mitigate capacity fading over demanding cycling requirements. This anode-free Zn-Br battery configuration is an ideal candidate for grid scale applications, as the non-volatility of aqueous electrolytes and the use of carbon electrode materials results in a battery that is inherently safe. The incorporation of magnetic fields in the battery will extend cycle life without additional energy input, with the overall configuration boasting increased coulombic efficiency and reduced capacity fading.

Abstract Name: Anti-Predation Responses in Zebrafish (*Danio rerio*): Impact of Cold Storage Conditions on the Behavioral Potency and Chemical Stability of the Synthetic Alarm Substance, Hypoxanthine-3N-oxide ($C_5H_4N_4O_2$; H_3NO)

Zebrafish (*Danio rerio*) display complex social behaviors and social communication, making them a valuable model for behavioral neuroscience. Predation injuries cause zebrafish skin cells to release a chemical alarm substance known as “shreckstoff” that induces anti-predation responses in neighboring zebrafish (e.g.,

darting, freezing, and negative geotaxis). The synthetic version of the alarm substance, H3NO, triggers the same responses. Recent research has indicated that cold storage of naturally-derived alarm substances results in diminished behavioral potency, but the impact of storage conditions on the behavioral potency of H3NO has not been explored. The degradation pathways in H3NO are uncharacterized, raising additional concerns regarding the behavioral potency of H3NO after long-term cold storage. The existing literature suggests that storage conditions will not affect the potency of H3NO in evoking anti-predation responses in zebrafish, although no reported studies have directly investigated this effect. The present study investigates anti-predation responses in individual zebrafish exposed to 5.0nM concentrations of H3NO that had been stored in three different storage conditions: fresh, frozen overnight, and frozen for a month. Subjects' responses were recorded for 10 minutes pre-administration and 10 minutes post-administration, and video analysis will be conducted using DeepLabCut to provide positional data that will subsequently be analyzed with Python code. High-performance liquid chromatography is used to characterize stable H3NO as well as potential breakdown products to determine any chemical differences between fresh and frozen samples. Characterizing the potential impact of cold storage on behavioral potency, in addition to analysis of potential breakdown products of H3NO, will provide valuable information on the stability of this synthetic alarm substance. These findings will have useful implications for research on the chemosensory mechanisms for alarm signaling, anti-predation responses in social fish, as well as the utility of H3NO as an alternative to alarm substances derived from live animals.

Abstract Name: Navigating Empty Shelves: The Role of Financial Incentives in Medicine Availability and Patient Search Costs in Egypt

Access to essential medicines varies widely across global markets, with distribution channels ranging from traditional pharmacies to online platforms and in some areas of the world, major retail outlets. Ideally, pharmacists are expected to dispense available treatments, guide patients toward suitable alternatives when necessary, and provide reliable information during periods of shortage. In Egypt, however, weak regulatory oversight developed over several decades has contributed to persistent gaps in medicine availability and transparency, particularly during episodes of acute scarcity. This paper examines financial conflicts of interest within community pharmacies such as not dispensing certain medications due to profitability. It looks at patient access to medications under constrained supply conditions such as the manufacturing delays during 2016. Drawing on field observations, stakeholder interviews and a review of the current literature, the study explores how profit-driven incentives can shape dispensing behavior, limit the provision of truthful information about stock levels, and undermine patient trust. It further analyzes how price controls, currency instability, and distribution bottlenecks intensify pressures such as medication hoarding during price changes and lengthen patient search times. This research aims to identify practical mechanisms that can help customers locate essential medicines, obtain effective substitutes, or at least receive clear guidance during shortage events. This would maintain patient trust and ensure faithful dependence on community pharmacies during acute episodes of medication scarcity. By highlighting the tension between patient welfare and pharmacy profit motives, this paper underscores the public-health importance of ensuring transparent, patient-centered pharmaceutical care in Egypt's evolving healthcare landscape. This paper will explore the current assumption that pharmacists withhold medication for financial gain and prioritize profit over humane customer wellbeing.

Abstract Name: IRIS Performance in Coastal Blackwater Wetlands

Blackwater wetlands are important ecosystems along the Gulf Coast of the Southeastern US. Blackwater is characterized by an increased dissolved organic carbon (DOC) concentration in comparison to freshwater wetland systems. Increased DOC levels could affect the removal of iron or manganese oxides from IRIS films because the removal rate depends on anaerobic conditions, the microbial community, and a carbon source. We hypothesize that IRIS films deployed in blackwater systems have higher iron and manganese removal rates due to the elevated DOC levels. We deployed iron and manganese IRIS films in blackwater and non-blackwater wetlands along the Alabama Gulf Coast. Soils were sampled and characterized for soil texture, total and organic carbon, pH, and EC. Porewater was sampled at the time of deployment and retrieval of IRIS films and tested for pH, EC, turbidity, dissolved oxygen, dissolved nitrogen, and DOC. Porewater samples were further analyzed in UV-Vis and fluorescence spectroscopy.

Abstract Name: The Overrepresentation of Black Youth in Foster Care: How Structural and Implicit Bias Shape Child Welfare and Court Outcomes in the U.S.

Black youth in the U.S. foster care system experience disproportionately high involvement at every stage of child welfare and juvenile court processing. According to the American Bar Association, black children face higher rates of investigation, are removed from their families more frequently, receive fewer appropriate services, and are less likely to achieve permanent placement. More than half of Black children experience a child-welfare investigation before age eighteen, and youth of color remain consistently overrepresented in juvenile justice referrals. These disparities are rooted in structural inequality, discretionary decision-making, and implicit bias embedded within child welfare and court systems. This project examines how normal adolescent behaviors—such as conflict, defiance, or emotional expression—are more likely to be interpreted as criminal or problematic when exhibited by Black foster youth. Using a mixed-methods approach, the study combines: (1) a policy analysis of U.S. child welfare and juvenile justice reporting practices; (2) statistical analysis of publicly available datasets documenting racial and ethnic disparities; and (3) a qualitative review of literature capturing the lived experiences of system-involved youth. By identifying how structural and implicit biases influence professional decisions, surveillance practices, and pathways into the court system, this research seeks to explain why Black foster youth are disproportionately penalized. The findings aim to inform policy reforms that reduce racial disparities and promote a more equitable system of justice for all youth.

Abstract Name: The Relationship Between Illicit Stimulant Use, Perceived Interpersonal Connections, and Academic Performance in College Students

Illicit stimulant use is an epidemic throughout the United States in college-aged students. These students are the majority of illicit stimulant users due to high stress levels, pressure to succeed, perceived competition among peers, and normalization. While students believe illicit stimulants will boost focus and GPA, research has shown that use is correlated with a lower GPA. This study examines relationships between illicit stimulant use, academic performance/preparedness, and interpersonal connections. It is hypothesized that illicit stimulant use is correlated with lower academic performance and weakened interpersonal connections. This survey study was conducted anonymously on Google Forms, and distributed through campus outreach and social media. Our study collected 1409 responses, mostly ages 18-29 in North/Central America. The study included self-reported data on substance use, interpersonal connections and academic performance. Illicit ADHD medication use was evaluated through the Substances and Choices Scale (SACS). Strength of social ties was assessed using The Social Connectedness Scale. Academic performance was evaluated using the Academic Performance Scale. The data was analyzed in SPSS, Version 28.0, using Pearson's Correlation Coefficient. Illicit stimulant use is positively correlated with feeling distant from others ($p < 0.01$). Negative correlations were found between initiating projects when assigned and illicit stimulant use ($p < 0.01$) and between punctual assignment completion and illicit stimulant use ($p < 0.01$). Ensuring preparedness in all subjects is negatively correlated with perceived lack of togetherness with peers ($p < 0.01$). Results suggest that illicit stimulant users have worsened perception of their relationships with others and lower levels of academic preparedness. Those that feel less connected with their peers are less likely to have positive behaviors in academic performance. These results suggest a relationship between poor academic habits, weak interpersonal connections, and the illicit use of stimulants. This research has not received any funding.

Abstract Name: Evaluating the impact of an eight-week positive psychology intervention in improving the subjective well-being of Nigerian university students: A mixed-methods pilot study

The well-being of students in Nigerian universities is deteriorating, with many facing limited access to traditional mental health services due to financial barriers, low awareness, associated stigma, and concerns about service quality. There is an urgent need for accessible, non-stigmatizing mental health resources that go beyond clinical care. While positive psychology interventions (PPIs) can help individuals mobilize their psychological capacities to enhance their well-being, they remain largely underutilized among Nigerian university students. This study aimed to evaluate the effectiveness of an eight-week education + positive psychology intervention, compared to an education-only control, in enhancing the well-being of Nigerian university students. In this randomized controlled pilot study, 40 undergraduate students were randomly assigned to either an education-only control group ($n=20$) or an education + positive psychology intervention group ($n=20$). Mental well-being, positive affect, negative affect, and resilience were measured at baseline

(T1) and after the eight-week intervention (T2). Chi-square tests showed no significant baseline group differences in gender, age, level, or program of study. Post-intervention t-tests revealed that the intervention group scored significantly higher in mental well-being, positive affect, and resilience than the control group, while no significant differences were found in negative affect. ANOVA indicated significant main effects ($\eta^2p = 0.20-0.63$) for all outcomes and time-by-group interactions for positive affect ($\eta^2p = 0.18$) and resilience ($\eta^2p = 0.45$). Moderate effect sizes for mental well-being, positive affect, and resilience suggest the intervention had a meaningful impact, enhancing emotional well-being and the ability to cope with stress. Qualitative reflections from students further supported these findings, highlighting positive reframing as particularly effective for strengthening emotional resilience and shifting perspectives during adversity. The findings of this study highlight the need for mental health professionals and researchers to incorporate diverse, synergistic activities rather than relying on isolated techniques to improve university students' subjective well-being.

Abstract Name: Improving Distribution Records for Rare and Underreported Mayfly (Ephemeroptera) Species in Wisconsin

Mayflies (Ephemeroptera) are vital and diverse members of aquatic food chains. Sensitive to environmental fluctuations and pollutants, they are useful indicators of ecosystem health. Despite their importance, information on the ecology and distribution of mayflies in Wisconsin is limited. Our objective was to collect distributional data on Wisconsin mayfly species. Using existing Wisconsin mayfly records and various conservation reports, a list of 69 rare or underreported species was created to guide sampling efforts. To ensure a more complete survey of aquatic biodiversity, we targeted under-sampled microhabitats often missed by standard Department of Natural Resources (DNR) protocols, including root masses, woody debris, riffles, stones, and sand. Field sampling involved entering streams in waders and using D-framed and drift nets to sample such microhabitats for nymphs. Approximately 20 to 45 minutes was spent at each site. Samples were preserved in 70% ethanol in the field, then sorted by taxa in the lab. Species identifications were made by Dr. Tom Klubertanz under a microscope. We collected 93 species of mayflies across 54 sites in 16 counties. We also collected 23 of the 69 species on the target list. We tallied 104 first-ever state or county records, including *Caenis hilaris*, a squaregill mayfly found for the first time in Kenosha County. Among them was also the first Chippewa County record of *Hexagenia rigida*, a species classified as highly imperiled on the Midwest Regional Species of Greatest Conservation Need list. These results will be published in an upcoming paper. While more research is needed to document mayfly diversity in Wisconsin, our findings will aid conservation efforts and species ranking of the DNR and other agencies. They will also help improve assessments of current and future ecosystem health.

Abstract Name: Design and Simulation of TalonX: A Student-Developed Subsonic Fiberglass Launch Vehicle Optimized for 10,000-ft Flight Using OpenRocket and Computational Analysis

TalonX is a student-designed fiberglass rocket developed at the University of Texas Permian Basin for entry into the 2026 International Rocket Engineering Competition (IREC) 10,000-ft Commercial Off-The-Shelf (COTS) category. The project serves as a senior design capstone for the design team and applies the complete engineering design process from concept through simulation and preliminary testing to produce a competition-ready vehicle. TalonX is a subsonic, minimum-diameter launch vehicle with a 4.25 in outer diameter and 102 in total length powered by an AeroTech M1340W solid motor. Its airframe, composed of a symmetric five-ply G10 fiberglass layup, achieves high stiffness and low weight within IREC's nonmetallic-material restrictions. The design employs OpenRocket as the primary simulation platform to predict flight stability, apogee altitude, thrust-to-weight ratio, and aerodynamic performance under varying conditions. Iterative simulations allowed optimization of the nose-cone shape, fin geometry, and mass distribution to meet the 10,000-ft target altitude with a stable center-of-pressure-to-center-of-gravity relationship. Supporting analyses were conducted using SolidWorks Fluid Simulation and MATLAB for structural validation, fin-flutter modeling, aerodynamic refinement, and Monte Carlo landing spread simulations. The rocket uses NACA 0012 symmetric fins, a dual-deployment recovery system controlled by a Featherweight Raven 4 altimeter, and integrated avionics consisting of SparkFun GPS, barometric, and IMU sensors powered by a LiHV battery. Experimental data from low-speed wind-tunnel testing in UTPB's AeroLab Educational Wind Tunnel provide supplementary validation of simulated aerodynamic coefficients. Through this project, students gained direct experience in computational simulation, systems integration, and interdisciplinary teamwork. TalonX demonstrates how accessible, open-source modeling tools can guide practical design decisions and produce reliable results in collegiate rocketry.

Abstract Name: Using Contrast, Shape, and Tactile Wayfinding to Promote Safe and Independent Living for a Client with Glaucoma

With glaucoma affecting more than 80 million people globally, accessible housing is crucial for supporting independence and quality of life for those living with the condition. Glaucoma progressively narrows peripheral vision, creating challenges in depth perception, contrast recognition, spatial navigation, and hazard identification within the home. The goal of Canyon Vista is to design a single-family residence that promotes independent living for a 35-year-old adult with glaucoma. Drawing on case studies of visually accessible environments, expertise from a professional who works directly with individuals with visual impairments, and literature reviews on inclusive design, low-vision guidelines, and biophilic strategies to foster connection to nature. The home features an open layout with wide circulation paths to reduce unnecessary movement and lower the risk of disorientation. Matte and honed finishes, paired with an earth-toned, high-contrast color palette, enhance visibility, minimize glare, and contribute to a restorative atmosphere. Rounded corners improve safety by reducing the risk of injury, while layered ambient and task lighting provide consistent illumination and limit shadows that may confuse individuals with peripheral vision loss. Tactile wayfinding is supported through high-contrast wainscoting and textured wallcoverings to guide movement and enhance spatial orientation throughout the home. Daylighting controls, such as automated roller shades layered with window treatments, help maintain safe navigation and reduce visual strain as lighting conditions shift throughout the day. By integrating connections to nature, intuitive circulation, and low-vision design strategies, this residence promotes independence and restores confidence in daily living.

Abstract Name: Engineering Luciferase-Based Bioluminescent Reporters in *Pseudomonas aeruginosa* and *Escherichia coli* to Monitor Glucose Uptake

Bioluminescence is a natural phenomenon in which living organisms emit light through a chemiluminescent reaction. This occurs in organisms such as algae, marine vertebrates, fungi, bacteria, and several others. Although bioluminescence arises naturally in some species, it can also be engineered into non-bioluminescent organisms. When a luciferin-related gene system is introduced into bacteria, the resulting light emission can be used for various measurements, including gene expression, metabolism, responses to environmental changes, infection tracking, and other cellular processes. Coupling the luciferase–luciferin system with a promoter linked to a specific biological pathway enables luminescence to report changes in that pathway’s activity. The goal of this work is to introduce a luciferase-based bioluminescence system into *Pseudomonas aeruginosa* and *Escherichia coli* and to produce detectable light in these strains. The bioluminescent reporter will then be coupled with a glucose-transport promoter to measure glucose uptake. The *P. aeruginosa* and *E. coli* strains will be grown in appropriate media, and a transformation method will be used to introduce the target genes. After incubation, the presence and intensity of bioluminescence will be measured. The results of this experiment will be presented.

Abstract Name: Evolution of Antibiotic Resistance Demonstrated with *E. coli*

Escherichia coli, a common laboratory bacteria, is readily used in Adaptive Laboratory Evolution experiments. This makes performing genetic evolution experiments involving bacteria and antibiotics incredibly successful and time efficient. Sub-inhibitory doses of antibiotics select for beneficial mutations and allow genetic adaptation to occur. As time goes by, mutations accumulate and the bacteria become more adapted to antibiotics, requiring higher doses of antibiotics to inhibit them. In this experiment, we found the minimum inhibitory concentration of antibiotics for both wildtype and antibiotic-adapted *E. coli* populations using both broth and test strip methods. We observed that the minimum inhibitory concentration of antibiotic required to prevent bacterial growth was much higher (in both the broth and test strips) for the antibiotic-adapted *E. coli* than the wildtype *E. coli* (average 14.8-fold increase, range 4-to 32-fold). We also observed cross-resistance to other antibiotics in six of seven adapted populations, indicating evolution of broad mechanisms of resistance. Whole genome sequencing was used to analyze the developed mutations in each population. On average, each population had only 9.5 mutations. About half of these mutations were single nucleotide polymorphisms (SNPs; 45%) and half were insertions or deletions of one or more nucleotides (INDELs; 55%). Populations with evolved resistance to the same drug had few shared mutations and many

unique mutations, indicative of the randomness of genetic changes during evolution. Using two kanamycin-adapted populations as examples, mutations in expected genes arose (e.g., translation machinery) as well as mutations in many other proteins with currently unexplored connections to antibiotic resistance: porins and transporters, two-component systems, and metabolic pathways. By understanding how bacteria evolve antibiotic resistance in vitro, researchers can better combat the evolution of antibiotic resistance in natural environments.

Abstract Name: Mitigation of 2DHG Generation and Thermal Boundary Resistance at Diamond:H/GaN Interface Through Interlayer Development for GaN Based Devices

Diamond, with its exceptional thermal conductivity, is widely explored as a heat spreader to improve thermal management in GaN-based power and RF electronics. In this work, we use Sentaurus TCAD to model AlGaIn/GaN HEMTs with integrated diamond heat spreaders, incorporating advanced physical models such as thermal boundary resistance (TBR) and temperature-dependent band-gap narrowing. While diamond significantly enhances heat dissipation, our simulations reveal an important but often overlooked tradeoff: electrostatic modulation at the diamond and semiconductor interface. This modulation arises from Fermi-level pinning and the dielectric contrast at the bonded surface, which together generate strong local band bending. As a result, a two-dimensional hole gas (2DHG) forms at the GaN surface, altering hole transport, shifting the threshold voltage, and weakening gate control in short-channel devices. These results indicate that although diamond improves thermal performance, it can also actively influence the electrostatics of the transistor. To address both the elevated TBR and the undesired interfacial band bending, we propose the incorporation of an engineered interlayer. Building on our TCAD results, we outline an investigation of several material candidates including AlN, SiC, BN, and other wide-band-gap dielectrics to develop physical test structures that directly compare GaN and diamond interfaces with interlayer and diamond stacks. This approach aims to demonstrate interlayer effectiveness in simultaneously providing thermal efficiency and electrostatic isolation.

Abstract Name: Web Design As A Tool For Social Change

Many immigrants and refugees struggle to find jobs when they first arrive in the United States, often because of language barriers, limited computer experience, and confusion about how to search and apply for work. This project focuses on creating an easy-to-use, interactive website that helps newcomers served by the Refugee and Immigrant Support Services of Emmaus (RISSE). The website allows users to read job descriptions in their native language, explore job openings in the Capital Region, and follow clear instructions on how to apply for the jobs they are interested in. The goal is to help newcomers feel more confident and independent while also reducing the amount of time volunteers may spend going through every

step. To build the website, I spoke with RISSE employment volunteers, observed the challenges newcomers faced during job-search sessions, and used my knowledge in web design to make a simple and understandable website. I focused on making the layout clear, the wording easy to follow, and the instructions broken down into small steps. I also added visual guides and built-in translation so users could learn and move at their own pace. I expect that newcomers who use the website will feel more comfortable searching for jobs, better understand what employers are asking for, and be able to complete more applications on their own. This may also make volunteer work easier, since volunteers can spend their time offering support rather than repeating the same instructions. This project is important because it supports independence, confidence, and long-term success for newcomers to America. By offering a simple tool that helps people overcome language and technology challenges, the website can make the job search process more fair and accessible for everyone.

Abstract Name: Improving Wayfinding and Fostering Independence in a Home for Visually Impaired

Visual impairment affects 7 million people in the United States which directly interrupts their daily lives and routines. Among them, nearly 27,000 suffer from achromatopsia. Achromatopsia is a rare genetic disorder that ultimately causes total monochromatic colorblindness or seeing in shades of gray. With no treatments available to correct this disorder, individuals living with achromatopsia must use other senses for navigation, recognition, and daily tasks. For this reason, the purpose of this project is to design a single-family home that incorporates sensory-based wayfinding strategies to enhance the functionality for a user living with achromatopsia. Implementing a variety of materials, textures, and colors creates necessary contrast to aid in the user's ability to navigate the space they inhabit. Research shows that texture-based wayfinding can significantly improve functionality of spaces for the visually impaired, while also increasing the visual appeal for those with full vision. This approach aligns with the increasing implementation of universal design into the built environment. Design strategies that emphasize the intentional use of surface sensory details have the potential to change the environment of interiors, as they support user orientation. These components also create spaces that are subtly, but purposefully, balanced in accessibility and aesthetics. Through case studies, a specialist interview, and a review of accessibility codes, a programmatic design framework was developed and incorporated into the design process of this project. The primary design solution is to create a layout that promotes ease and independence as the user moves from one space to another. To achieve this, each individual room features a contrasting color, while having a consistent flooring color for circulation areas, to support clear wayfinding. Triangular tiles are used along all travel paths, with color variations that correspond to each room, guiding users. Overall, the design promotes navigation and independence throughout the home.

Abstract Name: How will PTAL Overexpression Affect Arabidopsis thaliana Phenylpropanoid Production

Phenylpropanoids are secondary metabolites produced by plants that are important for both plant and human

sustenance. Phenylalanine ammonia lyase (PAL) catalyzes the entry step of the phenylpropanoid pathway by converting phenylalanine to trans-cinnamic acid. PAL forms a metabolon with the next enzyme in the pathway, cinnamate-4-hydroxylase (C4H), which converts trans-cinnamic acid to p-coumaric acid. Phenylalanine tyrosine ammonia lyase (PTAL) enzymes have been found in grasses that are able to convert tyrosine to p-coumaric acid in one step, while retaining the ability to convert phenylalanine into trans-cinnamic acid... While this “metabolically flexible” PTAL has been shown to function in the *Nicotiana benthamiana* transient expression system, the effects of this enzyme when stably expressed in *Arabidopsis thaliana* are unknown. *Arabidopsis* typically does not accumulate high levels of tyrosine, but the Maeda Lab possesses unique tools to increase tyrosine in plants. We will be creating stable transgenic *Arabidopsis* plants expressing PTAL and analyzing the effects on the phenotype and metabolite profile. We hypothesize that expressing this enzyme in *Arabidopsis* in a background high in tyrosine will allow us to increase and direct phenylpropanoid production in these plants.

Abstract Name: Indirect Electrochemical Detection of Chlorophenols Using Hypervalent Iodine Reagents

Phenolic compounds are used in a variety of processes both industrial and academic, but are toxic if introduced into the environment. Compounds such as 2-chlorophenol are used in the manufacturing of pesticides, herbicides, and wood preservatives, which can easily be exposed to the environment. The possible presence of these compounds in the environment give need for rapid and continuous means of monitoring for exposure prevention and cleanup. Electrochemical monitoring is an attractive method due to the inherent sensitivity and cost effectiveness. However, this method of detection involves the oxidation of these compounds which often leads polymerization and subsequent electrode fouling thus inhibiting further use of the electrode surface. Previous work in our group has shown that hypervalent iodine reagents, such as hydroxy(tosyloxy)iodo benzene (HTIB), can initially oxidize simple phenolic compounds into a quinone that can then be electrochemically reduced. This project explores adapting these findings to more complex and environmentally relevant compounds such as chlorophenols. This presentation will focus on using HTIB to potentially detect 2-chlorophenol and 4-chlorophenol indirectly, via cyclic voltammetry and square wave voltammetry.

Abstract Name: Addressing Eco-Ableism in Richmond, Virginia's Urban Master Plan

As Richmond, Virginia, approaches its 300th anniversary in 2037 and continues implementing Richmond 300: A Guide for Growth, questions remain about whether individuals with disabilities are equitably represented in the city's future planning. Richmond 300 is the comprehensive plan guiding Richmond's policies, programs, zoning changes, and redevelopment. This master plan is a “living document” that will evolve as the city grows, meaning revisions and improvements are possible before its full implementation.

This study asks: Is eco-ableism present in Richmond 300: A Guide for Growth, and how could the City of Richmond address this issue? Ableism refers to discrimination against individuals with disabilities, whether explicit, such as denying equal employment, or implicit, such as the absence of ramps, sensory supports, or accessible pathways. The term eco-ableism expands this idea to environmental design and planning, highlighting how disabled individuals are marginalized through inaccessible infrastructure, exclusion from decision-making, and limiting narratives or beliefs. This builds on the planning concept of “spatializing disability,” or analyzing how people with physical or cognitive differences navigate spaces shaped by historical and structural forces. This study conducts a master-plan review of Richmond 300, focusing on disability inclusion with respect to vision, sensory, and ambulatory disabilities as defined by the U.S. Census Bureau. Using Critical Discourse Analysis (CDA), the plan will be examined for embedded power structures, whose voices are included or omitted, and whether accessibility is meaningfully prioritized. A Textual Analysis Approach (TAA) will guide coding for keywords, themes, and discourse patterns related to eco-ableism. The hypothesis is that Richmond 300: A Guide for Growth includes approved accessibility measures that equitably address the needs of disabled residents. This research aims to identify existing strengths and gaps to support more inclusive future planning.

Abstract Name: FOXI3 as a Molecular Switch Regulating BMP4 and TGF- β Responses in Prostate Cancer

FOXI3 has emerged as an important regulator of epithelial–mesenchymal dynamics in prostate cancer (PCa), a process closely linked to tumor invasion and metastasis. Previous work in our laboratory showed that knocking out FOXI3 in C42B prostate cancer cells reduces migration and promotes a more epithelial-like phenotype, especially in response to TGF- β , a major inducer of epithelial–mesenchymal transition (EMT). However, it is not known whether FOXI3’s role is limited to TGF- β –driven EMT or whether it also influences pathways that help maintain epithelial identity. This project examines how FOXI3-deficient C42B cells respond to BMP4, a growth factor associated with supporting epithelial characteristics and compares these responses to TGF- β treatment. Wild-type and FOXI3-knockout C42B cells were treated with TGF- β or BMP4, and differences in migratory behavior were assessed. qRT-PCR analysis revealed changes in the expression of key EMT-associated genes, including E-cadherin, N-cadherin, FOXI3, and CXCR4. Our results show that FOXI3^{+/-} prostate cancer cells behave differently when exposed to BMP4 compared to TGF- β , suggesting that FOXI3 interacts with both EMT-inducing and epithelial-reinforcing pathways. Notably, FOXI3-deficient cells exhibit a delayed transcriptional response to growth factor treatment relative to FOXI3-expressing cells. This delay indicates that FOXI3 may be required for rapid activation of pro-metastatic signaling programs. Overall, these findings suggest that FOXI3 participates in a broader signaling network that contributes to prostate cancer progression. Understanding FOXI3’s role in balancing epithelial and mesenchymal states may help identify new regulatory mechanisms involved in prostate cancer aggressiveness and future therapeutic strategies.

Abstract Name: A Sustainable & Universal Redesign of Hickory Hill Park in Richmond, Virginia

Urban green spaces provide essential environmental, psychological, and physical benefits, yet access to these resources is often inequitable. Cities are increasingly vulnerable to climate change, highlighting the need for adaptive design. This study focuses on the redesign of Hickory Hill Park in Southside Richmond, selected through a combination of site suitability analysis and qualitative survey. The guiding research question is: How can a park in Richmond be designed to optimize environmental resilience, accessibility, and community benefits? The selection of a research location and scope used a mixed-methods approach integrating spatial analysis, environmental assessment, and community engagement. A site suitability analysis was conducted using a combination of an Analytic Hierarchy Process, SVI scores, and accessibility factors on potential parcels. Equity criteria were incorporated through spatial and social equity modeling. A qualitative onsite tour identified Hickory Hill Park as the primary research location based on its open space, neighborhood characteristics, and potential for development. Community perspectives were collected through a combination of written surveys and interviews with residents and community center staff, both on-site and within the neighborhood. The resulting redesign integrates community-identified needs with universal design and climate-resilient features. Guided by the American Society of Landscape Architects, UCLA's Guidelines for Senior-Friendly Parks, and ADA regulations, the design supports people of all ages and abilities. Features include an amphitheater for public gatherings, an accessible main entrance, an intergenerational playground and quiet area, improved transit amenities, and inclusive recreation spaces. Green infrastructure, pervious surfaces, rain gardens, expanded vegetation, solar lighting, and heat-reducing materials strengthen stormwater management and mitigate urban heat island effects. Expected results suggest a redesigned Hickory Hill Park would improve environmental performance, increase accessibility, and address underrepresented community needs. This project provides a model for how community-driven, equity-centered park redesign can support long-term sustainability and public well-being in urban contexts.

Abstract Name: The Cognitive Consequences of Fatherlessness

Fatherlessness is a growing issue that is plaguing society as we know it, and the only thing that is examined is how it is correlated with behavioral challenges. However, there is little research on the very thing that is responsible for those behaviors to even occur, cognition. This presentation will address the question: What are the cognitive consequences of fatherlessness? This presentation will bring a psychological lens to the social issue of fatherlessness and examine how a father's absence may influence decision-making and concept formation in a child. All the information that will be gathered will be a byproduct of a literature review. This research will result in taking the necessary steps to take this question and create a framework that will in the end foster a dialogue on how family structures could shape cognitive outcomes and lessen the number of absent fathers.

Abstract Name: The Effectiveness of Natural Preservatives in Reducing the Growth of Microbes

Have you ever bought fresh fruits or vegetables, only to find them spoiled a few days later? You're not alone — food residuals are one of the most commonly wasted items in Georgia, contributing to approximately 12% of all solid waste and creating environmental and economic challenges. This study explores whether natural preservatives, lemon and vinegar, can effectively reduce the growth of microbes on produce, thereby extending freshness and preserving its quality. Both substances are known to inhibit microbial growth and reduce the risk of foodborne illnesses. To test antimicrobial properties, strawberries and cucumbers were soaked in three solutions: a commercial fruit preservative solution, a vinegar-and-water solution (3:1), or a lemon juice-and-water solution (3:1). The microbial characteristics from each solution were measured on TSA plates. The solution without any preservative contained the highest number of microbial growth. Overall, both vinegar and lemon juice reduced microbial growth on produce. The reduction of microbial growth from strawberries treated with vinegar or lemon juice was comparable. However, cucumbers treated with lemon juice showed a greater reduction in microbial growth and diversity compared to those treated with vinegar. Interestingly, the commercial fruit preservative was less effective than the natural options and showed the most diverse growth in color, form, elevation, and margin. Our findings suggest that simple, safe, and natural methods could help households reduce food waste and improve food safety. Future studies could explore a wider variety of produce or combinations of natural preservatives for household use.

Abstract Name: Robust 3D Cell Segmentation for Imbalanced Volumetric Electron Microscopy Using a Hybrid Loss

Over the past 20 years, machine learning has made significant progress and is now used in every sector of industry. Deep learning is a subset of the machine learning and is a foundation of large language models such as ChatGPT. However, deep learning is not limited to large language models. Due to its powerful ability to automatically learn features from images, audio, and video, it is widely used in biomedical fields. When applying deep learning, it is important to address imbalance in dataset as imbalanced datasets present a significant challenge in biomedical image segmentation. One common approach is to use specialized loss function and selecting an appropriate loss function is critical to enhance the performance of deep learning models. This study compares the performance of individual loss functions and their linear combinations using a 3D ResNet architecture on volumetric electron microscopy data from the Janelia Research Campus OpenOrganelle dataset. It then introduces a hybrid loss function, Focal Tversky++ loss, that is designed to improve model performance in imbalanced datasets. Experimental results show that the proposed method enhances segmentation performance by approximately 20% compared to simple linear combination of two different loss functions. This finding provides practical insights into selecting effective loss functions and developing techniques that improve upon basic linear combinations.

Abstract Name: INFRARED SIMULATION

BackgroundImage recognition for infrared images is more challenging than it is for visible spectrum, due to a lack of high quality infrared images to use for training. Also, the images used have lower resolution due to IR bands just having longer wavelengths than the visible spectrum. These constraints could be avoided by simulating infrared images with temperature simulation-driven rendering. Some applications of this include but are not limited to, monitoring health, heat detection within engines or buildings, thermal regulation, process control throughout engineering workflows and a ton more. Streamlining infrared simulations has plenty of valuable properties for a variety of different tasks

Abstract Name: Elevating Advocacy: Experiences of State APE Teachers of the Year

This study explored the underexamined experiences of state-level Adapted Physical Education (APE) Teachers of the Year (TOY) recipients through a mixed-methods investigation designed to highlight both quantitative and qualitative dimensions of professional recognition. Using a purposive sample of awardees, identified through publicly available data, participants completed a 44-item survey addressing key demographic, professional, and recognition-related variables. The survey provided a broad understanding of participant backgrounds and the structural context of state-level recognition programs. To add depth and perspective beyond numerical trends, semi-structured focus groups were conducted to capture the participants' personal reflections and experiences. Thematic analysis of the focus group data revealed three major findings: Professional isolation, the role of self-advocacy, and variability in recognition procedures across states. Professional isolation emerged as a recurring theme, with participants describing limited peer collaboration and few opportunities for connection within their districts. Many awardees emphasized that self-advocacy was a vital skill for promoting APE visibility and gaining access to resources that are often overlooked in traditional physical education programs. Additionally, participants discussed how recognition processes differed greatly from state to state, revealing inconsistencies in nomination procedures, evaluation criteria, and levels of institutional support. These findings illuminate systemic inequities that continue to affect APE professionals and highlight the importance of developing more consistent, transparent, and equitable recognition practices. By strengthening institutional backing, increasing mentorship opportunities, and promoting awareness of APE contributions, educational systems can better support the retention and

professional growth of these teachers. Ultimately, fostering consistent recognition practices across states is essential not only for sustaining excellence within the field but also for advancing inclusive physical education opportunities for students with disabilities nationwide

Abstract Name: The Development of the Conservation Movement Throughout the Victorian Era, as told by Children's Literature

My research paper explores how the shift in views on conservation and animal extinction that occurs throughout the Victorian era can be seen in Victorian children's literature. In the early Victorian period, collecting and displaying natural elements was a celebration of the environment, as Lynn L. Merrill explains in her book *The Romance of Victorian Natural History*. Early Victorian children's literature, such as Tom Brown's *Schooldays*—published in 1857—shows this. From the young boys stealing a kestrel's eggs, to the character of Martin, who is a naturalist and collects taxidermy, bird eggs, animals, etc., to the support and even participation in this interest by Arthur, the novel's moral example, this tradition was encouraged by Thomas Hughes, the author of the novel, and was not viewed as a negative pursuit during the time. However, as the Victorian era progressed, there was a growing concern for how such practices were negatively impacting the environment. According to Henry M. Cowles in "A Victorian Extinction: Alfred Newton and the Evolution of Animal Protection," Alfred Newton developed the modern understanding of extinction in the 1860s and 1870s. Later Victorian children's literature, such as *The Jungle Books*, published in 1894, shows this shift. Kotick's story explores this issue of human disruption of animal species in "The White Seal," where Kotick observes his friends being violently hunted by men. Kipling writing from the seal's perspective gives a more disapproving view of the practice, displaying the shift from the views displayed in Tom Brown's *Schooldays*. Through Victorian children's literature, a change in views of conservation, from an exploration of nature through the disruption of it, to the advocacy against animal exploitation, is evident.

Abstract Name: Portrayal of ADHD in Children's High-grossing TV and Movies and the Influence on Perceptions of ADHD: Percy Jackson and the Olympians, Shrek, and Finding Nemo

Attention-deficit/hyperactivity disorder (ADHD) is one of the most common neurological disorders that affects children, with about 11.4% of children aged three to 17 diagnosed in the US. ADHD has many negative stigmas, such as individuals are unruly, lazy, or intentionally choosing to be different or difficult, which are often enhanced by parents and educators; these perceptions can impact academic performance, social experiences, and psychosocial outcomes of children with this diagnosis. These negative narratives frequently emphasize behavioral conformity, focus on perceived deficits, and compare differences to peers and siblings, reinforcing the internalized stigma of children with ADHD. These experiences may shape children's self-concept and may lower self-esteem. On the contrary, increased representation of characters

with traits that align with ADHD in many movies and in popular media offers alternative narratives that challenge stereotypes. A literature review was conducted with peer-reviewed studies on childhood ADHD experiences, societal perceptions of ADHD, coping skills in children with ADHD, and social skills to determine whether the representation of ADHD in media can influence children's self-esteem and self-perceptions of ADHD. Percy Jackson and the Olympians, Shrek, and Finding Nemo demonstrated the positive attributes of ADHD represented by the children in these studies. The characters, Percy, Donkey, and Dory, are shown with behaviors that emphasize creativity, acceptance, and non-traditional problem-solving skills, reframing ADHD traits as strengths rather than deficits. The findings suggest that kids with a greater understanding of ADHD have a high acceptance level, better development of coping skills, and higher self-esteem. These findings suggest an association between representation and societal perceptions of ADHD, highlighting the potential value of increased, accurate representations of ADHD in children's media.

Abstract Name: The Potential Synergistic Effects of Low Paraben Concentration on Estrogen Receptor Positive Breast Cancer Proliferation In-Vitro

Estrogen-receptor positive (ER+) breast cancer is the most common subtype of breast cancer (BC) that grows through the binding of estrogen. As estrogen binds to the ER, metabolic pathways are activated such as those related to cell growth and regulation. The specific pathway being studied is the PI3K/AKT pathway. MCF-7, an ER+ breast cancer cell line, contains a PIK3CA mutation, primarily impacting the PI3K/AKT pathway. The purpose of this research is to analyze how parabens, an endocrine disruptor chemical that binds to ERs, stimulates the proliferation of the PI3K/AKT pathway when introduced at concentration found in personal care products (PCPs). The basis of the methodology to analyze the effects of parabens includes culturing and producing a stock of MCF-7 BC cell lines. Next, conduct an Apoptosis/Necrosis assay to analyze cell death when MCF-7s are exposed to parabens. After, Reverse Transcriptase-quantitative Polymerase Chain Reaction (RT-qPCR) will be run to quantify the upregulation of genes specific to PI3K/AKT pathway, followed by Immunofluorescence to visualize if any structural changes to the cell has occurred. Thus far, a stock of MCF-7s has been produced and an experiment no longer being conduct, AlamarBlue, was in attempt to optimize. It is expected to observe increases in overall cell growth, thus possibly seeing increase cell death due to higher turnover rates of the cells. Additionally, gene expression RT-qPCR experimentation should increase as exposed to parabens. Lastly, it is hypothesized that structural changes will occur as high cell turnover rate increases likelihood of mutations. This project works to understand the potential synergistic impacts parabens have on an in-vitro cell environment mimicking the real body.

Abstract Name: Determining the Role of BRINP2 for Formation or Migration in Neural Crest Cells

Neural crest cells (NCCs) are multipotent stem cells unique to vertebrate embryos. After forming in the dorsal

neural tube, they migrate and differentiate into many different cells such as melanocytes (skin pigment cells), cartilage and bone cells in your face, and neurons and glia in the peripheral nervous system. Proper development of NCCs are crucial to prevent birth defects such as cleft lip and palate, Treacher-Collins Syndrome and more. While it's known that certain genes play a specific role in NCC development, there is still a large knowledge gap. Previous work in our lab identified 674 genes that are candidate regulators of neural crest development, including Bone Morphogenic Protein/Retinoic Acid Inducible Neural-Specific Protein (BRINP2). BRINP2 is in the same superfamily as Astrotactin 1, which plays a role in cell motility, but there is no known function of BRINP2. Using early embryo electroporation to inject morpholino, a chemical inhibitor of protein expression, BRINP2 function was knocked down on one half of the embryo to compare development on the electroporated and unaffected side. Using in situ hybridization, Sox10 gene was stained to analyze NCC development differences within an embryo. More data is needed to determine the role of BRINP2 in NCCs. However, this pilot study established that the process of early embryo electroporation, in situ hybridization and analyzing imaged results can be conducted in one summer at Hamline University.

Abstract Name: The Ballad of Artist and Veterans Against the Vietnam War

The United States' involvement in the Vietnam War holds its place as one of the most controversial subjects in the history of the nation. The United States government was in a deep fear of communism after the McCarthyism era. If Vietnam fell to the communist forces of the Viet Minh, the United States government believed, then so would many others after it. However, many did not know in Vietnam that the United States military was killing and torturing innocent men, women, and children. The Ballad of Artists and Veterans against the Vietnam War tells the story of two groups who stood up and protested the United States government. The actions of the Artists' and Writers' Protest (AWP) from New York, and the Artists' Protest Committee (APC) from California, as well as artwork such as "Q: And Babies?" A: And Babies, Saigon, the Tattooed Dolls, and more, worked towards the protest efforts of the artist. On the side of the veterans, the organization known as the Vietnam Veterans against the War (VVAW) made significant efforts with the protest movements they did, such as Operation RAW, the Winter Soldier Investigation, and when they threw their medals at the capital. By looking at the efforts of both groups, one can see how veterans protested for similar reasons. The ballad of artists and veterans against the Vietnam War may have been different, but they sang the same song.

Abstract Name: Effect of Plant-Based vs. Standard American Diet on Cardiovascular Parameters in College Students

This study examines how adherence to different dietary patterns—specifically a plant-based diet compared to the standard American diet—can influence physiological indicators tied to cardiovascular health, including heart rate variability (HRV), blood pressure (BP), and heart rate (HR). Among these markers, HRV is

considered especially sensitive to autonomic nervous system (ANS) regulation and may offer earlier insight into physiological stress or dysfunction than HR or BP alone. Although nutritional habits are widely believed to impact heart health, few investigations have focused on how specific long-term diets affect autonomic and cardiovascular metrics in healthy, college-aged adults. This study aims to investigate if early, diet induced changes in heart health can be identified in college aged individuals, through non-invasive measures such as electrocardiography (ECG), seismocardiography (SCG), and galvanic skin response (GSR). Because this trend has been observed in older adults, where diet influences heart rate, blood pressure, and heart rate variability, it is likely that similar diet-related effects could be detected in young, asymptomatic, college aged individuals as well. By treating diet as the main variable of interest, and targeting a younger demographic, this study provides insight into the earliest physiological effects of diet on heart health, supporting the development of preventative strategies before clinical symptoms arise. The findings could reinforce the role of dietary habits in supporting or undermining cardiovascular health early in life. By identifying physiological differences linked to distinct eating behaviors, this study may highlight diet as a low-cost, widely accessible strategy to reduce long-term disease risk and promote autonomic balance.

Abstract Name: Evaluating the Effectiveness of the LISA Model in Training Interdisciplinary Data Scientists

Undergraduate and graduate students often learn statistics and data science in isolation from real stakeholders, yet most applied work requires collaborating with domain experts to define questions, analyze appropriate data, and translate results into action. This project evaluates the Laboratory for the Interdisciplinary Statistical Analysis (LISA) model at the University of Colorado Boulder, which pairs formal instruction with mentored practice on real projects. LISA's curriculum is grounded in the ASCCR framework - Attitude, Structure, Content, Communication, and Relationship - and uses structured practices such as the Q1-Q2-Q3 content flow and Video Coaching and Feedback Sessions to help students develop human-centered, impact-oriented data science skills. We assessed program effectiveness using multiple surveys administered from Fall 2020 through Spring 2023 to both student collaborators and domain experts. Student data included a beginning-of-semester baseline survey, project-level reflection surveys, and a long-term follow-up survey. Domain expert data included end-of-semester project feedback and multi-year follow-up surveys on longer-term outcomes such as publications, grants, and changes in practice. Quantitative items used 1-6 scales and were analyzed descriptively; open-ended responses were coded thematically to capture perceived growth and program impact. Findings indicate meaningful improvement across all ASCCR dimensions, with especially strong gains in Communication - shared understanding and the ability to explain results in plain language-and Relationship-trust, reliability, and team effectiveness. Domain experts reported clearer research questions, actionable results, and sustained collaborations. Long-term student reflections highlighted increased career readiness, leadership confidence, and skill in managing interdisciplinary teams. Overall, this evidence suggests that structured collaboration training, integrated with authentic projects, effectively bridges theory and practice. The LISA model offers a scalable framework for preparing interdisciplinary statisticians and data scientists who not only perform sound analyses but also co-create solutions that generate tangible benefits for society.

Abstract Name: That's Not Art! Artificial Intelligence in the Arts

Artificial intelligence (AI) has been deeply integrated into our modern lives: social media algorithms, email summaries, software to write essays, and tools to photoshop relatives out of family photos. This software is trained on countless data points sourced from our lives without permission, compensation, or accountability. This technology's rapid development coupled with its unknown limitations has prevented the implementation of effective regulations to address exploitation, copyright, and privacy rights. AI intersects many fields outside of its intended boundaries, the arts being this study's focus. The purpose of this project is to evaluate whether the products of AI can be classified as unique, independent works of art, and their creators, artists. AI art is a contentious topic, primarily due to the discourse over authorship and ownership of its creative works. AI's data gathering has scraped archives, artwork and art styles to develop generative software like ChatGPT or DALL-E. These allow people to create award winning art with a sentence, forcing artists to retroactively protect their works. Crucially, this devalues human-made art. Art is a reflection of society; it informs us of our history, our cultures, our desires and dreams. Art is innately human. If we claim the works of a machine as art, how do we define humanity? While I do not believe AI art should be considered equal to human-made art, I acknowledge its nuances, and the work of its emerging artists. With the pervasiveness of AI, we must work to integrate AI art in a regulated, open, and beneficial manner. Research for this study involved visits to collections and museums locally and regionally.

Abstract Name: (Dis)Respect in the School Context: Adolescent Perspectives

Research has found that respect is a central part of building healthy relationships within secondary schools. For example, scholarship has found that adolescents who reported feeling respected in the school environment had higher levels of belonging and engagement and better academic performance than peers who reported lower levels of respect. Despite current research that highlights the importance and value of respect in schools, there have been limited investigations of adolescents' thoughts and feelings regarding respect and disrespect. Additionally, there is limited conversation around how macro-level forces (e.g. racism, classism, sexism) inform adolescents' understanding of (dis)respect and the way they show (dis)respect to people around them. Therefore, this research project investigates the ways adolescents conceptualize (dis)respect in schools. This work is framed by a theoretical model that claims that (dis)respect is informed by macro-level processes (Harris et al., 2025). This is a qualitative study that uses focus groups to learn about students' perspectives. The research was collected at two Boys and Girls afterschool Clubs located in the Southeast region of the United States, with approximately 25 participants at each site (N=50). Participants are

between 6th and 12th grade. At this point of the research, 2 focus groups have been conducted. Preliminary data has been analyzed using the constant comparison method. Within this data, two preliminary themes have emerged. First, 8th and 9th grade participants talked about how stereotypes were the utmost form of disrespect, while 6th and 7th grade students focused more on interpersonal interactions. Second, male and female participants reported having different expectations on how they should or could respond to (dis)respect in schools. These findings will highlight the factors that can create a culture of mutual respect among teachers, students, and administrators to create safer and more inclusive school environments.

Abstract Name: Gun Violence & Data Science: Understanding the Gun Violence Death Rate Through Feature Importance and PCA

The United States is one of the wealthiest countries; however, it has a gun violence issue on par with some of the poorest nations. So, to understand this complex and multi-faceted issue, it seems useful to utilize machine learning techniques. In this study, I used feature importance scores and principal component analysis (PCA) to estimate if certain socioeconomic, demographic, and economic factors per state contribute to the knowledge of the gun violence death rate in America. To find feature importance scores, I assembled a database using information from the National Institute of Minority Health and Health Disparities, the Centers for Disease Control and Prevention, and U.S. Bureau of Economic Analysis and applied random forest regression, permutation feature importance, and gradient boosting regression. Across all machine learning models used, the percentage of people who have a bachelor's degree had the highest feature importance score by a large margin. This means that, out of the features I looked at, knowing the percentage of people who had a bachelor's degree per state was the most informative demographic feature to predict the gun violence death rate in that state. Additionally, PCA on the data revealed that the top two principal components are responsible for over 90% of the variance in the dataset, with the first principal component, representing socioeconomic conditions, having a 0.73 correlation with the gun violence death rate. Thus, a state's average level postsecondary educational attainment appears to capture the most information about the gun violence death rate, as well as socioeconomic conditions in general. Further, these findings demonstrate that viewing the issue of gun violence from different points of view may provide new paths towards reducing fatalities.

Abstract Name: Systematic Characterization of Ancestry-Associated miRNA Regulatory Pathways in Pancreatic Cancer

Pancreatic ductal adenocarcinoma (PDAC), the most common form of pancreatic cancer, has limited therapeutic options and a five-year survival rate between 10-13%. Previous literature suggests that post-

transcriptional regulation, particularly through microRNAs (miRNAs), can play a critical role in shaping tumor progression. MiRNAs regulate gene expression by binding to complementary sequences in the 3' untranslated regions (3'UTRs) of target transcripts (mRNAs). Therefore, disruptions to these interactions can alter the expression of oncogenic pathways. This study seeks to characterize miRNA variability and identify genomic variants that may influence miRNA–mRNA interactions by integrating whole-genome sequencing (WGS) and RNA sequencing data from a cohort of 21 patient-derived xenograft (PDX) models. We first performed presence–absence variability (PAV) analysis to identify miRNAs that have a variable presence across tumors, revealing 62 significantly variable miRNAs ($p < 1 \times 10^{-15}$). We will map predicted gene targets for each miRNA and assess the expression levels of these targets using our existing RNA-seq dataset, to better understand the miRNA regulatory pathways and functionality. In parallel, we will scan the WGS data for single-nucleotide polymorphisms (SNPs) located within miRNA seed sequences, as well as variants within the predicted 3'UTR binding sites that could disrupt or enhance miRNA–mRNA interactions. By integrating PAV results, gene expression profiles, and SNP variant data, we aim to uncover miRNA regulatory networks that highlight potential mechanisms driving PDAC heterogeneity and biology. Expected results include the identification of miRNAs and target genes whose altered regulatory pathways contribute to tumor signaling and progression. Overall, this work aims to uncover novel aspects of PDAC biology which may help inform future biomarker development or therapeutic strategies.

Abstract Name: Poultry Litter Beetle Insecticide Resistance in the Southeastern United States

The Poultry Litter Beetle (PLB) is a growing issue within the poultry industry. PLB causes significant economic loss by spreading disease, causing indigestion, and destroying poultry house infrastructure. The cheapest and easiest management strategy is to apply insecticide; however, the overapplication of insecticide has caused widespread resistance. This resistance is currently not well monitored, but doing so would provide vital information for a producer's ability to create successful Integrated Pest Management programs. To provide this information to producers, we sampled PLB across 6 major poultry-producing states and performed insecticide bioassays to quantify resistance. Through Probit analysis, we found extremely high resistance to Malathion and Permethrin in most populations. Additionally, we seek to elucidate the genetic mechanisms underlying this resistance by sequencing resistance genes. We have sequenced the acetylcholinesterase gene (Malathion's target) from our insecticide susceptible control population, and further work will sequence related genes from resistant populations to elucidate how mutations confer resistance. We expect genetic mutations to confirm our bioassay results, and these newly sequenced genes may be used to develop new resistance sampling methods and treatments.

Abstract Name: Revolutionizing Real Estate: The Impact of AI on Property Valuation, Marketing, and Sales

In this study, we examine the impact of artificial intelligence (AI) applications on real estate valuation, marketing, and sales performance. Specifically, we investigate whether the use of AI-enhanced or AI-staged listing images influences housing sale prices or time-on-market, after controlling for other established determinants of housing outcomes. Our empirical findings indicate that, overall, the adoption of AI-based image enhancement techniques does not exert a statistically significant effect on either sale price or selling speed. To further explore potential heterogeneity, we conduct subsample analyses by clustering properties according to geographic location and school district quality. The results remain consistent across these subsamples, with p-values generally exceeding 10%, suggesting that AI-driven visual enhancements have limited influence on transaction outcomes. A plausible explanation is that residential real estate purchases represent one of the most substantial financial commitments for households, and thus buyers' decisions are unlikely to be materially altered by aesthetically enhanced listing images alone.

Abstract Name: RamanSpec Safe Margin Pen

Incomplete tumor margin detection during cancer surgery increases the risk of recurrence and the need for additional surgical procedures. Current intraoperative margin assessment relies on biopsies that must be processed in a laboratory, delaying results by 20–30 minutes and limiting real-time surgical decision-making. To address this limitation, we are developing a disposable, handheld Raman spectroscopy pen for immediate detection of cancerous tissue during surgery. The device incorporates a 2.1 mm fiber optic cable housed within a stainless steel inner tube and a biocompatible resin outer shell, enabling safe optical signal transmission while maintaining sterility and disposability in the surgical environment. Key design objectives include optical lens compatibility, reduction of Raman signal interference, and mechanical protection of the fiber optic cable to ensure consistent signal performance. Multiple CAD-based design iterations were completed to optimize ergonomics, inner-tube geometry, and overall structural stability for surgical usability. Material comparison analyses evaluated fused silica, plastic, glass, and calcium fluoride lenses based on optical clarity, durability, signal transmission efficiency, and cost-effectiveness. Disposable body materials were also assessed to balance strength, safety, and manufacturability. These iterative design refinements improved both functional performance and clinical practicality. Experimental validation will be conducted using standardized chicken tissue and formalin-fixed biological samples to evaluate Raman signal strength, spectral precision, and repeatability. Testing will establish baseline performance thresholds for tissue differentiation under controlled conditions. The successful development of this Raman spectroscopy pen has the potential to improve real-time surgical margin assessment, reduce reoperation rates, and enhance patient outcomes through more precise tumor resection. This project integrates biological engineering, optical physics, and medical device design to address a critical unmet need in oncologic surgery.

Abstract Name: Affect Valuation and Beliefs about Emotion as Mechanisms Underlying Negative Symptoms in Schizophrenia

Introduction: Negative symptoms such as anhedonia, avolition, and asociality are core features of schizophrenia (SZ) and are characterized by disrupted processing of positive emotions and reduced reward-seeking behavior. Currently, negative symptoms remain an unmet treatment need. One theory that could advance the identification of novel treatment targets for negative symptoms is Affective Valuation Theory (AVT), which suggests that people act to reduce gaps between how they ideally want to feel versus how they actually feel. Initial research suggests that greater negative symptoms are associated with increased discrepancies between one's ideal and actual affective states. However, the exact processes underlying how affect discrepancies impact negative symptoms are unclear. This study examined whether dysfunctional beliefs that emotions are uncontrollable or useless mediate the association between affect discrepancies and negative symptoms. Methods: Forty-one individuals with SZ and thirty-five psychiatrically healthy controls completed the Brief Negative Symptom Scale (BNSS), Affect Valuation Index (AVI), and Emotion Beliefs Questionnaire (EBQ). Analyses included t-tests, bivariate correlations, and regression-based mediation. Results: Increased beliefs that emotions are uncontrollable and negative emotions are useless were associated with negative symptom severity; however, there was no significant relationship between affect discrepancies and negative symptoms. Affect discrepancies were not significantly associated with emotion beliefs in SZ. Mediation hypotheses were not supported. Conclusions: Results suggest that dysfunctional emotion beliefs, rather than discrepancies between how one wants to feel versus how they actually feel, may be stronger mechanisms of negative symptoms. Treatments targeting these beliefs via strategies such as emotion regulation could improve negative symptoms.

Abstract Name: Smart Speakers, Smart Ads: A Study of Voice Inputs and Advertising Algorithms

As voice assistants become ubiquitous in modern households, they raise significant privacy concerns about potential eavesdropping and targeted advertising. The study will help identify correlations between specific voice inputs on Google Home assistants and the appearance of related advertisements on Google services such as YouTube and Google Search engine. Three Google Home devices were used in the experimental design. One device served as a baseline of the experiment and did not receive any voice inputs. The other two devices were tested with specific voice commands towards travel and health to assess whether voice interactions influence targeted advertising. The data were manually collected on three computers for four weeks. The first advertisements shown were recorded, including dates and URLs, and compiled in an Excel database. These records were then analyzed using a custom Python-based tool to detect patterns and potential correlations between voice inputs and ad content. Preliminary results suggest that there is no strong evidence that there is a correlation between the specific voice inputs devices and targeted ads. Future research could further examine the conditions under which voice data may be used for advertising purposes and explore more advanced privacy protections for consumers.

Abstract Name: Validating Gene Targets and Increasing Stability of ω RNA to Enhance Gene Editing

Gene editing performance has been dependent on advancements of editing efficiency. The IscB- ω RNA system, an evolutionary precursor system of CRISPR/Cas, has a compact size and is mechanistically similar to Cas9 but limited by poor editing efficiency in mammalian cells. Existing research into IscB has been developing more efficient nucleases and stable ω RNA but these have only been experimentally used in plasmid form, not through transiently expressed systems, such as mRNA or RNPs, which would be more clinically relevant due to safety concerns. In the case of Cas9 sgRNA, researchers have used chemical modifications to improve sgRNA stability. These techniques can be applied to ω RNA to further probe the effects of chemical modifications to ω RNA for enhanced stability and possible effects to gene editing performance. Preliminary results have shown synthetic ω RNA incorporating chemically modified 2'-O-methyl-3'-phosphorothioate (MS) at the 5' and 3' ends has significantly increased expression levels and longer half-lives as seen in RT-qPCR. Preliminary sequencing data has shown promise for indel generation using the IscB- ω RNA system as an mRNA platform in validated guide locations. Furthermore, we screened for several different target sequences for potential therapeutic knockout of genes, which were selected from current targets of CRISPR therapeutics, PCSK9 and TTR, and atherosclerosis, TXNDC5. This system has been applied to the target sequences and shows long-term potential of IscB- ω RNA system in in vivo gene editing.

Abstract Name: Temporal Analysis of Defect Formation in Honeycomb Under Geometric Frustration

Honeybees are known to optimize their storage space and minimize the amount of wax material they need to produce by building hexagonal cells. However, prior research indicates that in sub-optimal conditions with geometric frustrations, such as those found in natural structures, they adapt their construction process to their immediate surroundings, resulting in the formation of merged and non-hexagonal cells. While these spatial adaptation patterns are increasingly well documented, the temporal dynamics of how such defects emerge and propagate during the construction process remain poorly understood. My work seeks to address that gap by investigating the effects of misalignment angles on honeycomb development over time. We implemented this experimental setup by placing 3D-printed experimental frames with controlled misalignment parameters in active hives and regularly photographing these frames throughout the construction period. Ongoing work involves processing this imaging dataset through an optimized image registration pipeline, enabling the creation of accurately aligned temporal sequences of honeycomb growth. The next phase of the study focuses on leveraging a range of neural network architectures to build a temporal machine learning model that effectively emulates how honeybees adjust their construction patterns under varying misalignment conditions. We expect the analysis to uncover quantitative and algorithmic rules governing the decisions honeybees make to modify structural components of honeycomb cells in response to geometric frustration. Altogether, the

conclusions of this study are expected to extend beyond characterizing honeycomb defects and into a broader understanding of how distributed biological systems achieve robust construction under uncertainty. Not only are these findings relevant to understanding the behavior of honeybee colonies, but also for informing theoretical models of collective organization and decision-making, which hold potential applications in bio-inspired engineering.

Abstract Name: Leading Causes of Mortality in Japanese Americans, National Vital Statistics System: 2005 - 2022

Background: Japanese Americans represent one of the most established Asian American subgroups in the United States, especially in the state of Hawai'i, where JAs represent a historically unique diaspora. This study characterizes mortality trends for JAs in Hawai'i and in the continental US. Methods: We analyzed mortality data from the National Center for Health Statistics (2005–2022) and population estimates from the 2000–2020 censuses. Age-standardized mortality rates were calculated for the leading causes of death among JAs, stratified by sex, geography, and nativity. Temporal trends were evaluated via joinpoint regression analyses. Non-Hispanic Whites and Asian Americans/Pacific Islanders (excluding JAs) served as comparison groups. Results: Heart disease (22.2%), malignant neoplasms (21.9%), and cerebrovascular disease (7.8%) were the leading causes of death among JAs. Overall JA mortality was lower than that of NHW (AMR 648 for JAs vs. 1191 for NHWs), with consistent female advantages (AMR 552 for JA females vs. 808 for JA males) across nearly all causes, with particularly large gaps in heart disease, cerebrovascular disease, and Alzheimer's disease. Hawai'i residents had higher all-cause mortality than counterparts in the continental US (AMR 694 for JAs in Hawai'i vs. 627 for JAs in the continental US). Cause-specific trends revealed mixed results, with lower heart disease and cancer but higher Alzheimer's and influenza/pneumonia rates. Foreign-born JAs exhibited the lowest mortality across all leading causes, while U.S.-born JAs showed increasing Alzheimer's, diabetes, hypertension, and accident mortality rates. Conclusion: Disaggregated analyses reveal distinct JA mortality trajectories shaped by sex, place of residence, and nativity. The elevated Alzheimer's and pneumonia mortality in Hawai'i, and the rising aging-related mortality among U.S.-born JAs, point to the influence of environmental exposures, lifestyle shifts, and differential access to care. These patterns underscore the importance of moving beyond aggregated Asian American categories to understand how cultural contexts contribute to longevity.

Abstract Name: Impact of Oxidized Polyunsaturated Acids on Macrophage Efferocytosis Capacity

Efferocytosis, the process by which macrophages engulf and digest apoptotic cells, is essential for maintaining tissue homeostasis and resolving inflammation. Impairments in efferocytosis are implicated in the progression of chronic inflammatory diseases, including inflammatory bowel disease (IBD) and

atherosclerosis. Oxidized polyunsaturated fatty acids (PUFAs), specifically hydroxyeicosatetraenoic acids (HETEs) and hydroxyoctadecadienoic acids (HODEs), accumulate at high levels in inflamed intestinal tissue, though their impact on macrophage efferocytosis remains largely unexplored. In this study, we investigated how exposure to oxidized PUFAs at varying concentrations alters efferocytosis capacity in human macrophages. Across a group of HETEs and HODEs, we found that several oxidized fatty acids including 12-HETE, 15-HETE, and 13-HODE significantly suppressed apoptotic cell binding and uptake by macrophages across a 1-hour timeframe. We further tested whether this effect was mediated by the leukotriene receptor BLT2. To investigate, we performed pharmacologic manipulation using BLT2 agonists and antagonists. Pharmacologic BLT2 agonism reproduced the inhibitory phenotype, while BLT2 antagonism rescued 12-HETE induced defects, supporting a BLT2-dependent mechanism. Efferocytosis capacity was quantified using a fluorescence-based assay in which macrophage–apoptotic cell interactions were imaged after 1 hour, and the ratio of bound/internalized apoptotic neutrophils to macrophages was determined. Together, these findings suggest that oxidized PUFAs impair early macrophage efferocytosis through BLT2 signaling, offering a potential mechanistic link between lipid oxidation and defective inflammation resolution in IBD. By clarifying how specific lipid mediators disrupt efferocytosis, this work contributes to identifying therapeutic targets aimed at restoring macrophage resolution programs in chronic inflammatory disease.

Abstract Name: Racial Disparities in Total Hospitalization Costs, Length of Stay, and Post Hospital Destinations, National Inpatient Sample: 2016 - 2021

Background: Non-Hispanic Black (NHB) and Hispanic patients experience inconsistent hospital stays, higher total costs, and fewer referrals to higher-level post-discharge services compared to Non-Hispanic White (NHW) patients. This study examines disparities in total costs, length of stay, and post-discharge destinations across racial groups over a six-year period. Methods: In this cross-sectional study using the National Inpatient Sample (HCUP-NIS), we included NHW, NHB, Hispanic, Asian American/Pacific Islander (AAPI), and Other adults hospitalized between 2016 and 2021 for the 10 leading non-elective hospitalization causes in the US. We determined median total costs, median length of stay, and non-home discharge rate by race. Using NHWs as a reference group, we calculated adjusted costs and odds ratios. Adjusted regression analysis stratified by insurance type was conducted. Generalized linear models with a log link and quasi-Poisson variance structure were used for total cost outcome variables. Multivariable logistic models were used for non-home discharge and length-of-stay variables. Results: Of 156,693,091 hospitalizations, 66.5% were NHW, 16.6% were NHB, 11.0% were Hispanic, 2.4% were AAPI, and 3.5% were Other. Among Medicare hospitalizations, cost ratios ranged from 1.044 (95% CI: 1.031, 1.058) to 1.297 (95% CI: 1.274, 1.319) for all race groups compared to NHW. Among Medicaid hospitalizations, cost ratios ranged from 0.894 (95% CI: 0.880, 0.909) to 1.190 (95% CI: 1.166, 1.217) for all race groups compared to NHW. Among privately insured hospitalizations, cost ratios ranged from 0.952 (95% CI: 0.936, 0.968) to 1.264 (95% CI: 1.238, 1.292) for all race groups compared to NHW. Discussion: Insurance status modifies the total hospitalization cost among racial minority groups. These findings offer opportunities to address insurance-driven hospitalization cost disparities for racial minority groups.

Abstract Name: Unintended Bistatic Signature Detection/Processing

The central purpose of this research is to validate the process of detecting, characterizing, and tracking high-interest items in Low Earth Orbit (LEO) using bistatic detection. The increasing density of objects in LEO necessitates developing capabilities to effectively geolocate and track objects of concern. Bistatic detection provides a unique contribution because it leverages existing systems without the requirement of building a new detector. For the project, we utilized the Northern California DX Foundation (NCDXF) International Beacon Network as the transmitter component of the bistatic system. This network comprises 18 beacons, distributed around the globe, with five beacons transmitting simultaneously at five unique frequencies every 10-second interval of the day. The core challenge was to reliably confirm the presence of these weak beacon signals within a noisy operational environment, forming the foundational step for subsequent geolocation efforts. The primary research focused on processing 3 TB of acquired data to isolate the transmitted beacon signals. Data processing was accomplished using a match filter technique, correlating the received signal with

a known reference signal, a replicated beacon emittance at the specific frequency and pattern of the transmitted message. The research successfully confirmed the existence of 13 out of the 18 NCDXF beacons within the collected dataset, confirming the reliable identification of the known transmitters in currently operational systems. It confirms that they have the sensitivity required to detect the beacon signals in a high-noise environment. The verified beacon identification established the necessary foundation for the subsequent phase of the project: finding and identifying the reflected beacon emissions. With the reflected and original transmissions, the time difference of arrival and frequency difference of arrival can be calculated to accurately establish the geolocation of the reflecting objects.

Abstract Name: The Role of MTHFR Gene Mutation in Neurodevelopmental Disorders

Diagnosis of Attention-Deficit/Hyperactivity Disorder (ADHD) is currently unstandardized. The variability of diagnostic methods and potential comorbidity with other psychopathologies present a challenge in securing an accurate diagnosis and appropriate treatment. Physiological measures could provide an objective way to corroborate ADHD diagnoses. Methylenetetrahydrofolate reductase (MTHFR) is an enzyme expressed by the MTHFR gene. It has a key role in regulating levels of folate and homocysteine. Imbalances of these molecules have been linked to adverse effects in the central nervous system, including schizophrenia and neural tube defects. A single point mutation (C677T) has been linked to reduced activity of the MTHFR enzyme, and in patients with myelomeningocele, a neural tube defect, this mutation has also been associated with attention-deficit/hyperactivity disorder (ADHD). We hypothesize that the presence of the C677T mutation would positively correlate with reported symptoms of ADHD. We also aim to examine possible associations between this specific mutation and symptoms of Generalized Anxiety Disorder (GAD) as well as Major Depressive Disorder (MDD). We tested 51 participants aged 18-68 years old for C677T using loop-mediated isothermal amplification (LAMP) and compared their genotypes to their scores on questionnaires used to screen for the aforementioned conditions: the Adult ADHD Self-Report Scale (ASRS V1.1), Generalized Anxiety Disorder-7 (GAD7), and the Personal Health Questionnaire-9 (PHQ9). The ASRS V1.1 was used to derive ADHD subtype scores: inattentive or hyperactive. Preliminary ANOVA results show a significant association between the high inattentive scores in homozygous mutant individuals when compared to homozygous wild-type individuals, but not when compared to the heterozygous group. Currently, there are no other significant differences between the groups, including the hyperactivity score. Our current sample size remains a limitation that we aim to mitigate by testing more samples.

Abstract Name: Crisis and Consequence: Sulla's March on Rome and the Institutional Decline of the Roman Republic

In 88 BC, Lucius Cornelius Sulla marched on Rome. While his seizure of Rome and the resultant laws were relatively successful in staying the deleterious effects of the Roman Revolution, their collective impact proved fleeting, as the Republic would ultimately collapse within a few brief and violent decades. I argue that, while a range of individuals and their collective actions contributed to the collapse of the Republic, it was Sulla's march on Rome and his role of Dictator that accelerated its dissolution perhaps more than any other, as it played a central role in (re-)directing the trajectory of the Roman Revolution and established a myriad of new precedents (e.g., politicizing the army; seizing the capital; declaring oneself dictator; enacting proscriptions; etc.) upon which others would thereafter model their own approaches. In this work, the root causes that led Sulla toward the decision to march on Rome are analyzed, with a particular attention on the marches effects on governmental systems and the extent to which his methods influenced other key actors contributing to the fall of the Republic. In short, this work builds upon and challenges present assessments regarding the extent of Sulla's role in the foundational change in the Roman Republic and its ultimate collapse into monarchy.

Abstract Name: Hoosier Horse Sense: An Examination Of The Effects Of Material Culture On Political Power Through Earl F. Landgrebe

Behind every political leader stands an array of material goods that act as vessels of symbolic authority. This paper examines one such object — a crystal water pitcher belonging to Earl F. Landgrebe, who represented Indiana's 2nd Congressional District during the 91st through 93rd sessions of Congress — as a case study in the material culture of political power. Born into a modest agricultural family, Earl F. Landgrebe rose through the ranks of local Valparaiso, Indiana, politics to become a staunch defender of Richard Nixon during the Watergate scandal. His crystal water pitcher, crafted from crystal and etched with a modified version of the U.S. House seal, embodies the illusion of political legitimacy through both its material composition and its aesthetic embellishments. By situating this object within the broader context of political material culture, this paper explores how the physical properties and visual qualities of political artifacts help to naturalize and reinforce authority within democratic systems. Comparative examples, including other congressional pitchers of the period and contemporary political symbols, reveal a recurring dynamic in which material objects both authenticate and amplify perceived power. Ultimately, this analysis points toward a larger, more troubling pattern: while objects like Landgrebe's pitcher help officials internalize their roles and connect with institutional authority, they also risk creating a feedback loop where perceived power eclipses genuine, constitutionally granted authority. In the current political climate, Landgrebe's pitcher — offering what he might have called a touch of "Hoosier horse sense" — serves as a reminder that political authority is as fragile as the materials used to represent it.

Abstract Name: Mobilizing the Next Generation: Social Media's Impact on Youth Political Engagement and Efficacy

This study seeks to answer the question: How do social media platforms influence political engagement and voter participation among young adults in the United States? The purpose of this project is to examine the ways in which social media sites, like TikTok or Instagram, shapes political behavior, decision-making, and civic participation within a generation that consumes much of its political information online. Existing research highlights social media's growing role in political communication and mobilization, yet few studies focus specifically on how these platforms affect the quality and form of participation among youth voters. This study contributes to that gap by analyzing how digital platforms both reinforce and transform traditional patterns of political engagement. Using the software Stata 13, a quantitative analysis is conducted of the 2024 American National Election Studies (ANES). The research focuses on respondents aged 18 to 29, historically the least likely to vote, but increasingly active in recent elections. Statistical correlations are used to assess the relationship between social media use and levels of political engagement. Preliminary findings suggest that social media exposure is associated with increased political awareness and participation among young voters, while also fostering new, non-institutionalized forms of activism that disrupt traditional political pathways. These results will be discussed within the broader context of democratic participation and generational change, offering insights for policymakers, educators, and advocacy organizations aiming to strengthen civic education and youth voter outreach.

Abstract Name: Earnings-Surprise Anomalies in U.S. Equity Markets (2000-2024)

Firms' earnings announcements are concentrated on bursts of information release that in theory should be fully incorporated into stock prices instantaneously when disclosed. Decades of empirical work, however, provide evidence that some equity prices continue to drift after earnings news. This study examines the behavior of stock returns following earnings surprises for U.S. common equities between January 1, 2000, to December 31, 2024, using daily stock data from the Center for Research in Security Prices (CRSP) merged with Bloomberg measures of expected and actual earnings metrics. The analysis will test if abnormal returns around earnings announcements are best explained by systematic risk exposure, behavioral attention constraints, or liquidity provision of frictions. "Abnormal" returns are measured by comparing realized returns around announcement dates to typical returns for each stock, after accounting for general market movements. I then study whether these abnormal returns can be explained by compensation for risk, by limits to investor attention, or by frictions in how liquidity is provided in the market. The study builds upon four foundational strands of prior research. The first has found a price "announcement-risk" factor connected to aggregate cash-flow news. The second strand presents evidence that investor inattention at low-attention times can generate underreaction to earnings. The third finds that context-dependent contrast effects shape how investors interpret sequences of earnings surprises. The fourth research shows that compensation for inventory risk can produce short-term return reversals around earnings events. Through using the various insights within a unified framework, this paper can reassess whether post-announcement return anomalies reflect rationally priced risk or persistent market inefficiency.

Abstract Name: Political Instability and Economic Growth: The Role of Foreign Aid

Political stability is generally viewed as a prerequisite for sustainable economic growth and development. At the same time, foreign aid is often promoted as a tool that supports economic growth, but its effectiveness may depend on institutional and policy environments. This raises an important question of whether aid can offset the negative effects of political instability on economic growth. I estimate the effect of political instability on economic growth in 148 low- and middle-income countries from 1996 to 2023, and test whether aid moderates this relationship. I use two-way fixed effects regressions to control for time-invariant unobservables and global shocks. I include an interaction term between political instability and aid flows to estimate how aid flows affect the association between instability and economic growth. Findings will indicate the effect of political instability on growth and whether this effect is conditional on the level of aid a country receives. Results will offer new evidence to inform development policy on how aid is allocated in different political stability conditions.

Abstract Name: Seismometer Analysis of Military Campus Activity

The seismograph created serves to measure nearby pedestrian activity in order to determine what movements are happening. Through future development this could be a tool for military application capable of detecting vehicles, troop movement, and other human activity through vibrations in the earth. Three sensors will be tested in order to determine the most effective in the given frequency range. The three different methods explored are a hall effect sensor, a geophone and a force sensor. With these methods the goal is to create a compact ground-vibration detection system capable of identifying and differentiating events across The Citadel's campus. Events include class changes, drill performances, and military parades. An accelerometer was used to determine the range of frequencies of different human movements. Initial testing showed human activity typically produces signals in the 1–10 Hz range, with walking generating relatively smooth patterns and actions like jumping producing more erratic data.

Abstract Name: Using the Theory of Planned Behavior to Design and Implement Emergency Winter Preparedness Among Unsheltered Populations

Purpose: This intervention utilized the Theory of Planned Behavior (TBP) to improve the preparedness and self-efficacy of unsheltered individuals during extreme cold weather events. We implemented a winter preparedness initiative leveraging a local nonprofit's existing outreach infrastructure to provide winter-safety

education, connect unsheltered individuals to local resources, and distribute emergency kits among unsheltered individuals. Nationally, unsheltered individuals have an all-cause mortality rate 5-10 times higher than the general population, largely due to exposure, chronic disease, and lack of medical care. In Northern Arizona, severe winters dramatically increase the risk of cold-related illness and death. This non-profit organization provides essential support for unsheltered individuals, including access through mobile outreach and shower bus, food and clothing distribution, employment assistance, and housing navigation. Despite their vital role, they face growing challenges due to rising demand, limited resources, and harsh winter conditions. Methods: We implemented an evidence-based intervention comprising three unique activities. First, to increase knowledge, we created and distributed pamphlets containing information on symptoms and prevention methods on hyperthermia and frostbite and 40 winter preparedness kits to unsheltered individuals in the Northern Arizona community. Second, to improve social norms, health education was provided to our partner organization's staff, including materials on frostbite, hypothermia, respiratory illnesses, and emergency contact cards to sustain the longevity of the intervention. Finally, to improve self-efficacy, winter kits were distributed. Results: Pre-test and post-test surveys were conducted among unsheltered individuals during the distribution of kits to determine the perceived level of preparedness for extreme weather events, knowledge gained on symptoms and prevention methods for frostbite and hypothermia, and the perceived self-efficacy around winter kit use. Surveys showed that individuals demonstrated a 100% increase in ability to correctly identify at least 2 signs and 2 symptoms of frostbite and hypothermia. Additionally, 90% of individuals demonstrated increased self-efficacy.

Abstract Name: PRL-3 and Rheb1: Novel Prenylated Proteins Controlling Mast Cell Function

Allergic diseases, including eczema, seasonal allergies, and food allergies, affect nearly 40% of Americans. These conditions often arise from a Type 2 inflammatory response, triggered when an allergen binds to IgE antibodies attached to the FcεRI receptor on mast cells. IL-33, an alarmin released during cellular stress or tissue damage, also contributes to this response by binding the ST2 receptor on mast cells. Activation of these pathways drives a pro-inflammatory intracellular signaling cascade marked by cytokine secretion and the release of inflammatory granule components. Isoprenylation, a protein modification that attaches a hydrophobic lipid tail, allows proteins to properly localize to membranes. This process is critical for cell signaling, but the proteins involved are only partly understood. To identify isoprenylated proteins potentially involved in FcεRI and ST2 signaling, we used the HumanPrenBase and RNA-sequencing data from bone marrow-derived mast cells (BMMC; in collaboration with Warren Leonard, NHLBI). We identified two prenylated protein candidates, PRL-3 and Rheb1. Neither have been studied in mast cells, but the literature links them to inflammation and to PI3K–Akt–mTORC1 signaling, a central axis in FcεRI- and ST2-mediated mast cell function. We treated BMMC with inhibitors of PRL-3 or Rheb1 prior to stimulation with IL-33 or IgE antigen crosslinking and observed significant reductions in IL-6 and IL-13 cytokine secretion as well as decreased degranulation. These findings support the hypothesis that PRL-3 and Rheb1 are key regulators of mast cell activation. These proteins may represent novel therapeutic targets for allergic inflammation.

Abstract Name: Examining the Impact of the SAIL Program and Occupational Therapy on Fitness and Balance Confidence

Background: Falls are one of the leading causes of injury in older adults, 20% of which result in serious injury. Stay Active and Independent for Life (SAIL) is a community-based fall prevention exercise and education program. Previous studies demonstrated that SAIL classes may improve strength, balance, and activities of daily living in older adults. The objective of this study was to examine the impact of SAIL program participation and individual occupational therapy (OT) sessions on balance confidence, occupational performance, satisfaction and fitness outcomes. Methods: Eight participants (average age 86) conducted an initial assessment using the Senior Fitness Test, Canadian Occupational Performance Measure (COPM), and the Activities-specific Balance Confidence (ABC) Scale. All participants completed two 60-minute SAIL exercise classes weekly for six weeks. Four participants received two 30-minute OT sessions during the study; four received OT sessions after the study. All participants completed at least 75% of the SAIL classes, with five participants attending 100% of classes. On-site classes and rapport between students and study participations may have attributed to greater compliance. Results: The results indicated that there were no statistically significant differences ($P > 0.05$) between pre- and post-test performance for either group. However, there were some positive trends towards clinical significance for COPM satisfaction (6.04 vs. 7.6) and 6-minute walk performance (483m vs. 528m). Conclusions: Despite the low sample sizes, a ceiling effect in the ABC scale, and a range of physical capabilities among participants, this study indicated that SAIL, coupled with OT sessions, can have a positive impact on fitness for older adults, showing promise as a program. Future studies should aim to increase the sample size and focus on alternative assessments that tease out discrete differences in balance confidence and the impact that pain and satisfaction have on activities of daily living.

Abstract Name: Spike Lee's Bamboozled & The Spectre of Minstrelsy

My research centers around a critical analysis of the film Bamboozled, directed by Spike Lee. Released in 2000, Lee's satire follows a struggling TV writer whose attempts to escape his contract backfire when the modern-day minstrel show he pitches to his boss gains unexpected success. The presentation will explore the film's themes of the legacy of minstrelsy in American entertainment and the psychic, dehumanizing toll of antiblackness on both an individual and community level. I will explore these concepts through Bamboozled's allegorical characters and discuss what they represent, while connecting the movie's themes to the writings of various black scholars. I will also discuss areas of today's media landscape where the messages of Bamboozled still resonate, and what we can take away from the film as writers, citizens, and academics alike.

Abstract Name: Identification of Reoviruses with Enhanced Oncolytic Potential Against Lung Adenocarcinoma

Lung adenocarcinoma is the most common form of non-small cell lung cancer, accounting for approximately 40% of cases. Despite existing treatments, new therapeutic approaches are needed, particularly for patients who do not respond to conventional chemotherapy. Oncolytic viruses, such as reoviruses, are a promising option because they can selectively infect and kill cancer cells. The well-studied T3D strain is currently in clinical trials against common cancers, yet the potential of other naturally occurring reovirus variants remains largely unexplored. Here, we investigated the ability of several reovirus strains to infect and kill human lung adenocarcinoma (A549) cells. Using metabolic assays to measure cell viability, we found several strains that significantly reduced cell viability relative to control at 4 days post-infection. Similarly, immunofluorescence analysis revealed that these same strains exhibited robust infectivity, with strain KC150 showing the highest infection rate. Together, these results suggest that multiple reovirus variants possess enhanced oncolytic potential against lung adenocarcinoma cells, with KC150 emerging as a particularly effective candidate for further studies. As the next step, we will test a panel of chemotherapeutic drugs and determine their optimal concentrations in A549 cells to eventually identify potential drug–virus combinations that may enhance therapeutic efficacy. This work shows the importance of expanding beyond the current T3D strain and exploiting the natural genetic diversity of reovirus.

Abstract Name: The Evolution of Visual Design in Video Games

The paper reviews the timeline of visual design in video games, from the early days of pixel-based games to the complex, AI-enhanced games of today. The study highlights the influence of technological advancements, graphic design principles, and innovations in both the functional and aesthetic aspects of games. In early arcade games, designers relied on pixel art and bitmaps, which taught them to convey emotion and gameplay through simple designs. During that period, game visuals were low-resolution and pixelated, as seen in games such as Pac-Man and Street Fighter. As technology progressed, more intricate layouts and typography enabled the development of more interactive gaming experiences. The latest innovation, artificial intelligence, has transformed the design process, allowing games to be produced faster, visuals to become more realistic, and prompting designers to explore their artistic identities. However, this also poses challenges: some artists worry that their visual styles could be replaced by AI, leading to job losses. The paper also highlights small, underrated developers who create stylized and experimental games, emphasizing lesser-known titles outside mainstream media. This underscores that even failures are part of the historical landscape, as not every game achieves mainstream success. Their research demonstrates how game visuals are shaped by a dynamic interplay of technology and creativity, influencing both player experience and the broader scope of interactive game design. Overall, the visual design of video games has evolved from simple pixel art to more sophisticated, AI-influenced creations that reflect the expanding relationship between technology and graphic design in enhancing player engagement.

Abstract Name: Investigating the Microbial Diversity and Alcohol Tolerance of College Hand Sanitizer Dispenser Organisms

This study aims to investigate the microbial diversity and potential alcohol tolerance of deposited bacteria colonizing hand sanitizer dispensers at Westminster College (New Wilmington, PA, U.S.), specifically within public spaces such as the Hoyt Science Center and Patterson Hall. Hand sanitizer dispensers, particularly manual ones, are frequently touched surfaces that may harbor diverse bacterial populations due to repeated contact from a plethora of users. The research seeks to survey the bacterial species present on dispenser fixtures and assess their alcohol tolerance. Given the exposure of bacteria to ethanol-based formulations near dispenser nozzles, there is the likelihood that some species may exhibit adaptation, raising concerns about sanitizer efficacy. To address these questions, dispensers will be swabbed, and bacterial samples will be cultured and isolated for further analysis. Then, DNA extraction, polymerase chain reaction (PCR) amplification, and Sanger sequencing will be used to identify bacterial species, while tolerance assays will be utilized to determine alcohol tolerance levels across varying ethanol concentrations. It is expected that a wide range of bacterial species will be recovered, and some may display reduced susceptibility to ethanol exposure due to contact with sanitizer formulations. The findings can inform institutional sanitation strategies, contribute to knowledge on bacterial colonization of high-touch surfaces, and provide insight into microbial adaptation to biocides. Additionally, the study may have broader implications for public health practices related to hand hygiene and the development of effective antimicrobial formulations. Ultimately, this research will aid in understanding microbial persistence in hygiene-focused environments and help provide insight into protocols for reducing bacterial transmission.

Abstract Name: The impact of gut health on brain and muscle decline

Previous research in fruit flies has discovered a relationship between increasing age and a deterioration in gut health, with developing intestinal barrier dysfunction tightly linked to mortality. Because of this tight association between organismal health and gut function, several markers of aging have been investigated in order to determine the role of barrier integrity on aging phenotypes. This study examines whether intestinal barrier deterioration can impact protein aggregation within the brain and muscles. Protein aggregates are a specific aging phenotype associated with several diseases of aging and neurodegeneration, such as Parkinson's Disease and Alzheimer's Disease, with an increase in age associated with elevated protein aggregate levels. This research utilizes the knockdown of the protein Snakeskin (Ssk) in the midgut of *Drosophila melanogaster*, with Ssk knockdown inducing intestinal barrier permeability and numerous

hallmarks of aging in young flies. Ssk is a septate junction protein, equivalent to mammalian tight junctions, important for maintaining the integrity of the connections between adjacent gut epithelial cells. Ssk mislocalizes in aging flies, perturbing these junctions and causing intestinal permeability. Knocking down its expression in the gut, using the GeneSwitch Gal4/UAS system in young flies, causes a decrease in barrier function and a severely reduced lifespan, in addition to other markers of aging such as gut microbiota dysbiosis, inflammation, stem cell overproliferation, and metabolic dysregulation. These experiments investigate whether manipulating Ssk expression in the gut can impact protein aggregate formation in tissues outside the gut in order to understand whether unhealthy or aging guts exhibiting barrier dysfunction may be associated with neurodegenerative diseases linked with protein aggregation in the brain and muscles. Behaviors associated with these aging phenotypes are also analyzed. Ideally, these insights will fuel a focus on intestinal health in the studies of several diseases with accompanying protein aggregation.

Abstract Name: Indigenous Blood Quantum and Its Demographic Impact: A Historical and Legislative Analysis

Repeatedly Native Americans are required by the United States government to prove their respective tribal affiliations through blood quantum in order to receive their entitlement to lands and resources. The measurement of Indigenous blood quantum is a strategy imposed by the United States Federal Government to limit Native citizenship and disempower Indigenous Americans. It dates back to the late 18th century as the official method for classifying “Indianness.” In the midst of the reservation period, legislative and federal regulations for legitimizing “Indian blood” were carried out by the Bureau of Indian Affairs. As the bureaucracy increased, so did the elimination of the “blood” status of Native Americans for federal benefits, protection, and recognition. This paper examines the continued use of this Indigenous blood quantum to assign citizenship in a Native American tribe and its dire consequences. In addition to tracing its historical use, this research evaluates the legislative structures that uphold blood quantum and explore proposed policy alternatives that might mitigate its destructive demographic impact. This matters because blood quantum operates as a stand-in device for Indigenous elimination, a genocidal tool of Native American culture, as characterized by the Native American activist and scholar, Ward Churchill. For Native Americans, blood quantum is part of the “colonial erasure tactics,” as Kylie Rice (Mohawk and Algonquin) argues. Take, for example, how Congress has estimated that by the year 2080, less than 8 percent of Native Americans will have less than one-half or more Native “blood.” Historically, in the 1950s and 1960s, certain tribes deemed too small were terminated by the federal government, and they also lost status and subsequent benefits. Thus, it is important to call attention to how blood quantum will lead to further erasure of Native American communities as sovereign nations.

Abstract Name: Understanding Autism in the Somali Community: Cultural Factors and Diagnostic Challenges in Minnesota

Autism diagnoses have increased over the past two decades, yet disparities in diagnosis and access to services remain, among immigrant communities. While prior studies have investigated disparities in autism care, few have focused on the unique intersection of culture, language, and healthcare access in the Somali community and how culturally responsive practices may improve outcomes for underserved populations. In Minnesota, Somali families have raised concerns about a relatively high autism prevalence and delays in diagnosis, emphasizing the need to examine; cultural and religious beliefs, linguistic barriers, stigma, systemic factors that shape autism understanding and access to care. This study builds upon a qualitative exploration of Somali community members' perceptions of cultural norms and beliefs about autism conducted in summer 2025. Themes from these qualitative data provided by parents and caregivers of children with autism and community leaders informed the development of the survey used in this study, a quantitative assessment of beliefs about autism and experiences in accessing related care. Participants will be recruited through community organizations and masjids with a target sample of approximately 60 respondents. Descriptive statistics will summarize beliefs and barriers, and chi square analyses will examine associations between individual characteristics and beliefs and experiences accessing care. The survey mirrors the key themes from the qualitative phase, and includes: (1) cultural beliefs, stigma, and misinformation; (2) autism being brought upon oneself; (3) personal, professional roles and lived experiences; (4) accessing the healthcare and support system; and (5) linguistic and communication barriers. It is expected that dual-role respondents will report greater familiarity with autism resources and fewer barriers, while single-role respondents (caregivers only) may report greater uncertainty and stigma. By integrating quantitative results with these themes, this research aims to support culturally grounded outreach and help inform equitable autism service access for Somali families in Minnesota.

Abstract Name: The “How Many” Routine: Visual Imagery as a Catalyst for Computational Fluency

It is not uncommon to hear adults claim they are bad at math or always disliked the subject. This negativity often stems from early mathematical experiences which ranged from boring to highly discouraging and embarrassing. Thus a new emphasis in mathematics education recommendations is to change the narrative and help students develop joy, wonder, and curiosity about mathematics (MAISA & GELN, 2023). This is reflected in defining computational fluency (skill in carrying out arithmetic procedures like addition or multiplication) as comprised of flexibility, accuracy, efficiency, and appropriate strategy use (NRC, 2001). The “How Many” routine, in which a carefully-designed image of a collection of dice, dominoes, or other real world objects is shown and the class shares a variety of viable solutions, is one way to provide meaningful, engaging computational practice that not only supports learner understanding but also builds mathematical confidence and interest. Yet this routine is considered a “black hole” in mathematics education research, as there has been a great deal of related research that indicates its potential, but a significant lack of research directly studying the routine (Matney, 2020). Our study attempts to address this research gap by examining an intervention consisting of nine “How Many” mini-lessons that were conducted in four elementary classrooms during May 2025. Data collection and analysis (in collaboration with researchers at Northwestern University) included pre- and post-interviews with participating children to look for growth in fluency as well as detailed video analysis of the lessons to identify teaching moves for promoting rich mathematical discussion and learning. Quantitative analysis of the interview responses suggest that “How Many” activities have the potential for increasing student fluency.

Abstract Name: The Lived Experience of Black Birthing People in Philadelphia

Background: Maternal Mortality refers to the death of a person while they are pregnant or within 42 days of the end of their pregnancy. Black birthing people are up to three times more likely to die during childbirth or have maternal complications compared to their White and non-Black counterparts. Concerning the Philadelphia area, as of the 2024 Severe Maternal Morbidity Report, Non-Hispanic Black birthing people, who accounted for 42% of all births during this time, had the highest rate of Severe Maternal Morbidity (118 cases per 10,000 deliveries) compared to other racial and ethnic groups. **Purpose:** This research project aims to investigate these disparities and explore ways in which health care professionals can better support Black birthing people throughout their pregnancy, childbirth, and postpartum care. **Methods:** This study analyzed articles regarding Maternal Mortality and Severe Maternal Morbidity in Philadelphia within the context of the United States. National statistics were referenced and compared in relation to the Philadelphia area. **Conclusions/Implications:** This research suggests that social determinants of health (i.e., neighborhood environment, access to stable housing, nutritious food, and quality health care), along with accessible perinatal care, resources during pregnancy, and maternal education, are essential to the overall well-being of those giving birth. It is imperative that health care professionals consider these factors when caring for Black birthing people. **Further Research:** The next phase of the research will involve a phenomenological study of qualitative interviews with Black birthing people in the Philadelphia area. This qualitative portion will help address the lived experiences of these individuals and where improvements should be made regarding maternal health for Black people.

Abstract Name: Circumnutation in *A. thaliana*: The Jasmonic Acid Pathway

Circumnutation is the helical movement of plant organs—leaves, stems, or roots—during its regular circadian (24 hour) growth period. It has been established that plants circumnutate for different reasons; each organ adapts this process for a different purpose (Stolarz 2009). The exact cause or reason for this action is yet to be fully understood as many hormones, stimuli, and pathways are involved. One of the hormones involved in plant-signalling is Jasmonic Acid ((1R,2R)-3-oxo-2-[(2Z)-pent-2-en-1-yl]cyclopentylacetic acid); JA. It is a lipid based phytohormone whose main constituent is Methyl Jasmonate or MeJA (methyl 2-[(1R,2R)-3-oxo-2-[(Z)-pent-2-enyl]cyclopentyl]acetate), and is the primary hormone involved in the repair of damaged plant tissues. Once there is damage to the plant, the site produces “defense molecules” constituting a pathway of jasmonates including JA. While these take effect, energy is consumed, particularly the energy that would normally be utilized for growth. Thus, growth is halted or slowed down and remains that way until much of the repair has been done. **Hypothesis:** Since circumnutation is a function of growth (mostly occurring as growth occurs) (Stolarz, 2009), a pause in the growth period will lead to shorter periods of circumnutation, characterized by narrower oscillations in the nutation wave. This means that the amplitude of each nutation (each helical movement) will be reduced or halted altogether. In short, I intend to discover whether JA directly pauses or halts the process of circumnutation in order to discern a specific pathway. **Results:** After data collection, I was able to establish that Jasmonic Acid may not have an immediate effect on

circumnutation in *A. thaliana*. In any case, it might promote it due to the hormone's ability to defend against stress responses. A positive control experiment, however confirms that it is able to inhibit root growth, and there may be possible interplay with other hormones.

Abstract Name: Rational Design and Evaluation of Quinoline Scaffolds as Next-Generation Tubulin Inhibitors

Microtubules are dynamic cytoplasmic proteins that play a crucial role in intracellular transport, cell division, and the formation of the cellular skeleton. They are made up of α - β heterodimers. Their ability to rapidly alternate between polymerized and depolymerized states is necessary for the development and function of the mitotic spindle during cell division. Disruptions in conventional microtubule regulation cause cancer cells to divide uncontrollably, making the microtubule network an important therapeutic target. Although various microtubule-targeting agents are often used in chemotherapy, many have severe limitations, including severe side effects such as neuro or cardiotoxicity, poor solubility or metabolic stability, and the rise of drug-resistant cancer types. These limitations underscore the need to develop novel tubulin inhibitors that can overcome some of these drawbacks. One such approach targets the colchicine-binding site (CBS) present at the interface of α - and β -tubulin, leading to the inhibition of tubulin polymerization and disrupting the proper functioning of microtubules. In this project, we have designed and synthesized a new class of phenyl(quinoline)methanone derivatives that can act as a CBSI or colchicine-binding site inhibitor. The core of these molecules allows for extensive structure-activity relationship studies, making it a suitable starting point for generating new tubulin-binding molecules. These analogs are designed to potentially enhance target engagement and exhibit improved toxicity and metabolic stability profiles. The synthesized compounds were tested for their capacity to reduce cancer cell survival using an MTT-based cell viability assay, and a few compounds proved to be bioactive. The future objective of this project is to perform iterative synthesis to obtain more potent analogs that can be further evaluated for their ability to directly inhibit tubulin polymerization and induce cancer cell death.

Abstract Name: High-Temperature Superconductors for Efficient Spacecraft Attitude Control

Spacecraft Attitude Determination and Control Systems (ADCS) depend on electromagnetic actuators that generate torque using limited electrical power, and this creates a constant tradeoff between performance and efficiency. Some of the tradeoffs include high resistive loss within its coils, frictional wear in the bearings, and limited torque capabilities. High-temperature superconductors (HTS) offer a possible way to improve these systems because they can carry electrical current with almost no resistive loss at cryogenic temperatures. This allows an HTS coil to produce a stronger magnetic field or higher torque for the same

power input. The potential improved efficiency is promising, but it also raises questions on the feasibility of HTS being used in the environment that attitude control systems require. REBCO tapes, which are a common form of HTS material, are thin multilayer structures with a brittle ceramic superconducting layer. When the tape is shaped into a coil, cooled to its operating temperature, or subjected to launch vibration, the layers deform in different ways and can develop strain in the superconducting film. If the strain exceeds certain limits, the material could crack or lose performance. In this project, we are examining both the efficiency implications and the physical feasibility of using HTS in spacecraft attitude control. We will use analytical equations to estimate the strain that develops during coil winding and cooldown, and we will compare those predictions with physics simulations to understand how the tape is expected to behave under realistic conditions. The overall aim is to evaluate whether HTS-based activators could improve spacecraft attitude control while remaining mechanically reliable under operating conditions.

Abstract Name: Evaluation of Microbial Antibiotic Resistance from Water Systems in Clarkston, Georgia

Antibiotic resistance continues to be a growing global health concern. Environmental reservoirs, particularly water systems, may contain antibiotic-resistant bacteria due to contamination from agricultural runoff, sewage discharge, and urban pollution. Understanding the resistance profiles of microbes in various water sources in a particular geographical region may help document resistant microbial genetic profiles, raise public health awareness, and lead to the development of environmental management strategies. This project aims to investigate the antibiotic resistance patterns of bacteria isolated from various water sources in Clarkston, Georgia. The sources will include residential water areas, including two local creeks and a lake site. Water samples will be collected and inoculated on nutrient agar to culture bacteria. Distinct colonies will be subcultured to obtain pure cultures of bacterial isolates. Antibiotic susceptibility will be tested using the Kirby–Bauer disk diffusion method on Mueller–Hinton agar with commonly used antibiotics—ampicillin, ciprofloxacin, tetracycline, erythromycin—followed by the measurement of the inhibition zones. The resistance profiles will be compared between the water sources to determine whether surrounding human behavior may influence antibiotic-resistant bacteria and public health concerns.

Abstract Name: Polyamine Depletion and Cytokine Production in the Ovarian Tumor Microenvironment

Within a tumor microenvironment (TME), cancer cell proliferation and survival are dependent on polyamines. Polyamines are small protonated alkylamines that are involved in growth, transcription, and survival. Some cancers respond well to immunotherapy treatments and usually have more pro-inflammatory cells in the TME even though the cells may not be active. Immunotherapy augments the activity of these pro-inflammatory cells allowing the immune system to help clear the tumor. This treatment is not beneficial for

tumor types that have predominately anti-inflammatory cells in their TME. There are ways to reprogram these “cold” tumors to have more immune-permissive cells by increasing macrophage and T-cells levels. In this project, we focus on the impact of polyamine depletion on cytokine production by immune cells. Ivospemin, when used as a treatment of ovarian cancer-bearing mice promotes the infiltration of traditionally pro-inflammatory cell types, however it has not yet been determined if these cells retain their pro-inflammatory function. We evaluated cytokine production from cells of ovarian tumor-bearing mice that have been treated with Ivospemin, a drug that depletes polyamine levels as well as another polyamine depleting drug Doxorubicin. We then test the production of different cytokines via ELISA to determine which pro-inflammatory cells are most active in this model. This will lay the groundwork for other projects in the future looking at the combination of Ivospemin and immunotherapies in ovarian cancer. There are multiple types of immunotherapies: some of which activate macrophages and some that activate T cells. The work proposed in this application will inform us as to which types of cells are most important in the ovarian TME. If macrophage cytokines are more noticeably changed with treatment, then we can consider immunotherapies targeting macrophages. If T-cell cytokines are changed the most, we would investigate Ivospemin and T-cell therapies such as CAR-T or anti-PDL1 therapies.

Abstract Name: Comparative Analysis of Language Impairment in Left versus Right Stroke Patients: A Preliminary Study

Stroke is a leading cause of long-term disability worldwide, yet the characterizations of stroke laterality on naturalistic language function remains incompletely understood. This study investigated whether left-hemisphere strokes produce more pronounced language deficits than right-hemisphere strokes using aphasia severity mannerisms such as repetition accuracy, and pausing behavior. Seventeen participants were drawn from the Aging of Brain and Cognition Post Stroke cohort to participate in this study. Aphasia severity was assessed using the Western Aphasia Battery–Bedside, a language function evaluation test to obtain naturalistic speech samples from a picture description task. Repetition accuracy and both unfilled-pause and retracing behaviors were quantified from digital recordings. No significant differences emerged for unfilled pauses or retracing behaviors, and aphasia severity scores did not differ markedly between left- and right-stroke participants. These null findings likely reflect limited statistical power and potential compensatory recruitment of contralateral networks following left-hemisphere injury. Future work with larger samples and linear mixed-effects modeling—including covariates such as age, gender, lesion volume, and stroke type—will probe the interaction of neurobiological profiles with discourse measures. Improved understanding of these relationships may ultimately inform tailored rehabilitation strategies to enhance communication outcomes in individuals with post-stroke aphasia.

Abstract Name: Screening of Potential Pathogens of *Trichostema dichotomum*

Trichostema dichotomum (aka. "blue curls") is a herbaceous plant in the mint family that is commonly planted in gardens as an ornamental. Regional *T. dichotomum* plants were found diseased, with initial work pointing to a fungal pathogen; however, it was unclear which fungus might be causing the disease. The goal of this study was to isolate and identify fungi from diseased *T. dichotomum* tissue to begin the steps of identifying the true causative agent. After obtaining isolates in pure culture, we used molecular approaches (PCR and sequence analysis of the ribosomal RNA gene spacer region) to identify and compare fungal isolates. A total of 18 fungal isolates were obtained from the diseased plant tissue. DNA sequencing analysis allowed more precise identification of 17 of the isolates. Further background analysis of those species revealed that nine of them are known plant pathogens and therefore could potentially be the pathogenic agent. To test this, healthy *Trichostema* plants were inoculated with these potential pathogens and their pathogenic effects evaluated. , and thereby see whether or not this is a unique pathogen-host relationship that was previously unknown. Two pathogens induced disease progression: the isolate most closely matching *Diaporthe gaultherii* produced a substantial major stem impact, and the isolate most closely matching *Diaporthe stewartii* produced leaf lesions. Investigation is currently being done to determine if either or both of these fungi represent new pathogens to *T. dichotomum*. These findings will provide a foundation for future pathogenicity studies and highlight the broader ecological significance of fungal interactions with regional *Trichostema* populations.

Abstract Name: Seminole War and Its Untold Impact on Seminole Culture and Social Dynamics in Florida

The focus of this study will be on examining the Seminole Wars and other contributing events on the Seminole Tribe of Florida over time in regards to internal social and cultural dynamics and traditions, whilst also observing external relations with other minorities in the state of Florida and the Federal, State, and various local governments. Despite the Seminole Wars being an important part of Florida history, it is not well discussed or taught in schools, leading to the erasure of knowledge about it, which impacts various communities' abilities to interact with the descendants of the military conflicts. Using mixed-methodology research practices, including library research, interviews with descendants of the Wars—since much of Seminole history is recorded orally within the tribe—and those involved with its research, and in-field excursions to physical sites that were large parts of the Seminole War. Making sure to gather information from a variety of sources serves as a counterbalance to what is in the written record in libraries to account for any bias in my sources. Afterwards, the collected data will be analysed and further discussed in order to take steps in the present to best navigate current-day social and cultural dynamics relating to the Seminole Tribe of Florida and its internal groups, as well as the dynamics it has with other descendant groups and Federal, State, and local governments in modern times.

Abstract Name: The Antimicrobial Efficacy of *Capsicum annuum* and *Capsicum chinense* on the growth of *E. coli* and *S. epidermidis*

The number of cases of foodborne gastroenteritis has increased in the United States. According to the CDC, consumption of foods and beverages contaminated with microbes has contributed to increased hospitalizations, causing up to 5,000 deaths every year among vulnerable populations, including the immunocompromised, young children, and the elderly. Bacterial pathogens such as *Salmonella*, *Campylobacter*, and *Staphylococcus* species are important agents of foodborne illnesses. Capsaicin, a chemical found in peppers, has been reported to have antimicrobial activity and may serve as a natural antimicrobial agent in food preparation to reduce illness. The pungency of capsaicin has a range of 0 – 16,000,000 Scoville Heat Units (SHU). This study explored the antimicrobial properties of bell pepper (*Capsicum annuum*, 0 SHU) and habanero pepper (*Capsicum chinense*, ~100,000 SHU) against *Staphylococcus epidermidis* and *Escherichia coli*. Sterile paper disks were soaked in pepper extracts and placed onto TSA plates containing *E. coli* and *S. epidermidis*. Ampicillin (10 µg) disks and TSB-soaked disks were included as positive and negative controls, respectively. After 48 hours, the zones of inhibition were measured to determine antimicrobial activity. While ampicillin-treated plates produced clear zones of inhibition for both bacterial species, none of the plates treated with pepper extracts produced measurable antimicrobial activity. Substantial widespread bacterial diversity was observed on all extract-treated plates, but not on ampicillin or TSB-control plates. These findings indicate that pepper extract solutions introduced additional bacterial species to the TSA plates. Furthermore, observation of differential microbial growth on plates with bell pepper and habanero extracts suggests differences in resistance and susceptibility to the antimicrobial properties in peppers. Further studies will explore alternative pepper extraction methods and testing of additional microbial species to evaluate antimicrobial activity. Findings could suggest using pepper extract as a natural preservative during food preparation to deter bacterial growth and reduce foodborne illness.

Abstract Name: The Effect of Jigsaw Puzzles on Cognitive Flexibility and Visuospatial Attention Processes

Jigsaw puzzling is a common everyday activity that requires careful coordination of visuospatial and attentional control processes. Jigsaw puzzling has been previously suggested to help preserve these processes, especially in aging adults (cognitive resilience), but the affected neural mechanisms is unclear. The strength of visuospatial and attentional control processes can be indexed by modulations in alpha-based oscillatory power (8-12 Hz). Specifically, alpha power is known to decrease when people open their eyes and increase when people close them. The difference in alpha power is referred to as alpha reactivity. Alpha reactivity is thought to reflect how well the brain can flexibly shift attention and the strength of neural connections across the brain's cortex (cortical connectivity). The current study tested whether alpha reactivity could reflect a mechanism by which jigsaw puzzling impacts visuospatial attentional control processes. Eight young-adult participants completed a classic eyes-open-eyes-closed paradigm while electroencephalography (EEG) was recorded. Participants then completed a jigsaw puzzle for twenty minutes followed by another eyes-open-eyes-closed paradigm. Alpha reactivity was measured as the average difference in alpha power between the eyes-open and eyes-closed segments. Results showed classic alpha reactivity, with alpha power being lower during eyes-open segments than during eyes-closed segments. This alpha reactivity, though, decreased after jigsaw puzzling. This implies that visuospatial attentional control processes indexed by alpha reactivity were

taxed by jigsaw puzzling. This suggests a possible mechanism by which jigsaw puzzling can challenge visuospatial attention processes toward long-term adaptive improvements and ultimate cognitive resilience. These results contribute to our understanding of visuospatial attention processes and how jigsaw puzzles can be used as a potential mechanism to increase cognitive resilience.

Abstract Name: Investigating Skate Population Dynamics and Feeding Ecology through Museum Specimens

This project is investigating the population dynamics and feeding ecology of skates through preserved museum specimens. Some recent studies have explored skate ecology, but more research is needed to investigate changes in skate populations and diet over time. Museum collections can be used to fill this knowledge gap. A total of 110 specimens of three skate species (*Amblyraja radiata*, *Leucoraja erinacea*, and *Rostroraja eglanteria*) collected between 1907 and 2001 were sampled from the American Museum of Natural History, the Yale Peabody Museum, and the Harvard Museum of Comparative Zoology. Population dynamics were explored through the collection date, collection location, length, width, and sex of each specimen. Micro-computed tomography was used to visualize the stomach contents of 12 of these specimens to analyze feeding ecology of historical skates. Preliminary results have shown a skewed distribution of sizes across the museums, but an even number of males and females. Additionally, the μ CT scans have successfully shown the presence or absence of stomach contents. Further analysis of the collected data is expected to reveal trends in populations aligning with the collection location, date, museum, and sea surface temperature. More detailed processing of the μ CT scans will likely validate this method as a new tool for stomach content analysis, providing insight into historical skate diets. With this additional data, I anticipate that the results of this project will reveal a decline in skate populations and habitat area aligned with increased pressure from fishing, habitat degradation, and climate change. I also expect to find a shift in skate diets between historical specimens and modern records, possibly due to corresponding declines in prey populations. Ultimately, the results of this study will provide a long-term analysis of skate communities along the east coast of the US, which is crucial for effective conservation efforts of these organisms.

Abstract Name: AI in Asset Management: A Performance Comparison Between AI-Powered Mutual Funds and Quantitative Hedge Funds

We examine the performance of artificial intelligence (AI)-managed mutual funds compared to quantitative and discretionary hedge funds from 2019 to 2024. We find that AI-managed mutual funds generate significantly higher cumulative returns than the overall hedge fund average, as well as quantitative and discretionary hedge funds specifically. Despite these superior returns, we observe a strong positive correlation

between the returns of AI-managed funds and both hedge fund strategies. Our risk-adjusted performance analysis indicates that none of the fund categories exhibit a statistically significant alpha. We attribute the superior gross returns of AI-managed mutual funds primarily to their higher factor loadings on systematic market risk, complemented by the relatively poor risk-adjusted performance of the hedge fund comparison groups. These findings suggest that the outperformance of AI-managed funds is likely attributable to their increased exposure to systematic risk rather than superior security selection or market timing capabilities.

Abstract Name: Understanding Food Security Strategies and Cultural Strengths Among NHPI Women in Hawai'i: A Hybrid Thematic Analysis Using the SOAR Framework

Native Hawaiian and Pacific Islander (NHPI) communities continue to face disproportionately high rates of food insecurity, shaped by Hawai'i's high cost of living, limited access to affordable groceries, and demands on working families. This qualitative study explores how NHPI women in Hawai'i experience and navigate food insecurity while drawing on cultural strengths, family networks, and shared community practices. Since women often serve as the primary grocery shoppers and meal planners in their households, their perspectives offer critical insight into daily decision-making around food. Using a hybrid thematic analysis that combines deductive coding from the SOAR (Strengths, Opportunities, Aspirations, Results) framework with inductive coding based on participant narratives, this study identifies how women balance cultural expectations, financial constraints, and time limitations. Many participants described struggling to prepare full meals because of long or irregular work schedules, leading them to rely on takeout even when it strained their budgets. Others highlighted the rising cost of staple foods in Hawai'i and expressed mixed experiences with the support and limitations of EBT benefits. Despite these challenges, participants emphasized resilience grounded in cultural values. Women discussed sharing food with extended family, preparing traditional meals when possible, and supporting one another during difficult periods. These practices provided emotional and practical support that helped families stretch limited resources. Participants also shared aspirations for greater access to affordable local foods, increased community gardens, and policy efforts that consider the lived experiences of NHPI households. By centering the voices of NHPI women, this study contributes to a deeper understanding of food insecurity in Hawai'i and highlights the importance of culturally informed solutions. The findings suggest that strengthening community-based support, expanding access to affordable groceries, and investing in culturally grounded food systems may improve food security and overall well-being for NHPI families.

Abstract Name: Religion, The Klan, and Socialism in Oklahoma in the Early 20th Century

Oklahoma offers a unique opportunity to research three seemingly separate key movements: Christianity, the Ku Klux Klan, and Socialism. The purpose of this study is to determine if there is a correlation between The Klan, Socialism, and Religion in Oklahoma in the early 1900s. The basis for this research is to show how

something like the Bible can be used to justify things that would otherwise be seen as contradictory to the Christian message. Searching through archives for primary sources and researching secondary source writings on the subject at the Western History Collection and the Oklahoma Historical Society were the main two ways of gathering primary and secondary sources. The summative findings were that one's theological beliefs often proved to be the pivotal reason why someone would either choose to be a Socialist or a member of the Klan. In most instances both the Klan and Socialists were targeting the same group of people and one's theological framework could be a reason that they pivoted one way or the other. The economic state of the state and country left farmers searching for political and religious movements that could be the answer for the struggles that they faced in everyday life. The popularity of Socialism and the Klan can also be attributed to various Christian movements in America during the time, primarily Christian fundamentalism. This research reveals that Christianity was often used as both a moral compass and a political tool for individuals to reconcile their own or others' conflicting ideologies under a shared religious framework.

Abstract Name: EPDS-US Initiative: Exploration of the psychometric properties of a culturally and linguistically adapted perinatal mental health screening tool within the community

Perinatal mental health (PMH) symptoms affect many pregnant and postpartum individuals, and early identification is important for supporting their well-being. However, commonly used PMH screening tools are often confusing, stigmatizing, or not culturally inclusive, especially for people from diverse backgrounds. Latina and Hispanic mothers often face additional language and cultural barriers that make it harder to accurately share their experiences or access appropriate care. To help address these issues, the EPDS-US was recently developed as an adaptation of the Edinburgh Postnatal Depression Scale that provides clearer and more culturally and linguistically appropriate screening questions using a respectful care and trauma-informed approach. The purpose of this project is to learn how pregnant and postpartum individuals, particularly Latina/Hispanic mothers, perceive the EPDS-US and to better understand their lived experiences with PMH symptoms and screening processes. This study uses an online survey hosted through an encrypted REDCap platform, along with optional semi-structured qualitative interviews conducted over Zoom. Through these methods, participants share their thoughts on how understandable the questions are, whether the screening feels supportive or comfortable, how well the questions reflect their cultural experiences, and how useful the adapted tool is overall. Recruitment relies on community-based outreach, including partnerships with local organizations, to encourage participation and prioritize engagement with diverse groups such as Latina/Hispanic mothers. Because data collection is still ongoing, my presentation will describe the types of quantitative information collected in the survey and share qualitative themes that emerge from the interviews. These may include feedback about EPDS-US wording, how participants interpret screening items, and what helps or makes it harder to talk about their PMH experiences. From these findings, I will highlight how accessible and useful the EPDS-US feels for participants and explore ways to improve and strengthen culturally sensitive, trauma-informed PMH screening in the future.

Abstract Name: A Morphological and Histological Comparison between Neoselachian Taxa

Tooth serrations present along the edge of the tooth crown in many modern sharks (neoselachians) are sharp projections adapted for cutting the flesh of prey. Each serration consists of an inner dentine core that is surrounded by an outer enameloid coat composed of layers of long fluorapatite crystallites orientated in different directions. Several ancient sharks have independently evolved serrations; however, much less is known about the morphology and histology of these dental structures from the fossil record. Using acid etching techniques, sectioning, and scanning electron microscopy, this study performs a systematic comparison of the morphology and tissue composition of serrations in carcharhiniformes, anacoracid, and Lamniformes, all neoselachians. Several genera in carcharhiniformes will be examined, including *Galeocerdo* (tiger sharks), *Carcharinus* (requiem sharks), *Physogaleus*, and *Hemipristis* (weasel sharks). From anacoracid, *Squalicorax* (crow sharks) will be examined and from the lamniformes, *Carcharodon* (white sharks) and *Otodus* (mackerel sharks). In the *Galeocerdo* genus, *Galeocerdo cuvier* (modern tiger shark) was compared with extinct tiger shark species *G. mayumbensis*, *G. aduncus*, *G. clarkensis* and *G. eaglesomei*. Although having subtle differences in overall serration morphology, overall findings suggest that recently extinct *Galeocerdo* species and the extant *G. cuvier* have a similar enameloid histological organization. Findings suggest that ancestral *Galeocerdo* species have more differences in enameloid structure in comparison to *G. cuvier*. Preliminary findings suggest that there will be more similarities between genera in carcharhiniformes and greater differences to more distantly related genera in anacoracid or lamniformes. The comparison between and within each genus will be used to aid in taxonomic grouping and phylogenetic analysis.

Abstract Name: Learning to Parent: How Dads Parent Following a Sex Change in *Lythrypnus dalli*

Parental care is crucial for the reproductive success of many organisms. The high level of variation in parenting strategies among fishes has made them ideal to broaden our understanding of parental care. *Lythrypnus dalli* is a harem and sexually plastic marine fish where only males exhibit parenting behaviors, while females are cannibalistic. These fish organize themselves into social groups comprised of one dominant male and multiple subordinate females: the absence of a male triggers the most dominant female to undergo a sex change. This process is accompanied by a physiological and behavioral shift across the reproductive axis. The sexual plasticity of *L. dalli* provides us with the unique opportunity to observe the initiation of parental behaviors following a sex change. Parental behaviors exhibited by male *L. dalli* include spending time in the nest by fanning and rubbing, termed as “wagging” on embryos to aid in their development. We formed all-female social groups of 3 fish ($n=8$) and 4 fish ($n=2$) to induce a protogynous sex change in the dominant female. We monitored the nest tube daily until embryos had reached late-stage development, after which we conducted live behavioral observations. The parenting behaviors of the new males were compared to the behaviors of stable males and females. New males spent significantly less time in the nest than stable males. This indicates a tradeoff of time for newly transitioned males as they balance their attention between parenting and establishing hierarchy. As expected, there was a significant difference in wagging between females and both male morph types. These data provide evidence that some parenting behaviors are innately known in *L. dalli*. In future, we will investigate how embryos development stages influence the onset of

parenting behaviors and expression of genes associated with male-typical phenotypes compares across morph types.

Abstract Name: Investigating Do-It-Yourself Antibiotic Resistance and Its Implications for Biosecurity

Antibiotic resistance is one of the most pressing threats to global health and safety. This research investigates how easily bacterial populations can acquire antibiotic resistance under do-it-yourself conditions and considers the broader implications for biosecurity. Using Gram-negative *Escherichia coli* as a model organism, multi-fold ampicillin resistance was developed by serial dilutions and selective plating to quantify bacterial survival and resistance frequency. Additionally, the antibiotic ciprofloxacin is used to assess whether similar adaptive patterns occur when different antibiotic mechanisms affect adaptation. Observations indicate that *E. coli* can acquire stable resistance with relatively few selective cycles, demonstrating how easily bacterial populations evolve under constant antibiotic stress. These methods will be extended to Gram-positive bacteria, such as *Bacillus globigius*, to evaluate whether similar resistance patterns emerge in organisms with different cell wall structures, thereby broadening our understanding of how easily resistance can develop across bacterial species. The rapid acquisition of DIY resistance highlights that antibiotic-resistant organisms could have serious consequences for the public if accidentally or deliberately released.

Abstract Name: A Comparative Study of Foxes in Art in the Edo Period and European Folktales

Animals have long been an important aspect of human culture and looking at the differences between how animals are represented by various cultures can shine a light on the ways that distinct cultures' views on the world differ. This comparative study examines the cultural significance of foxes in folktale from Japan and Russia by examining the woodblock New Year's Eve Foxfires at the Changing Tree, Ōji by Utagawa Hiroshige and the print Reynard the Fox by Vera Ermolaeva, from the late 19th to early 20th centuries respectively. In both artworks, foxes signify deception but also have distinct cultural meanings. In Hiroshige's artwork, foxes are mystical tricksters who predict the success or failure of the harvest. In the Russian artwork, however, foxes serve to represent morally corrupt humans. The discussion of the Edo period and Hiroshige will provide the context in which he created the artwork. Next, an analysis of symbolism behind the Japanese foxes and the Changing Tree will be provided. Following, I will provide a formal analysis of the print Reynard the Fox and its cultural significance within the framework of the folktale "Reynard the Fox." This study is based on art, historical resources, and a formal analysis of artworks.

Abstract Name: Experimental Design and Comparative Analysis of CubeSat-Based Reflector Concepts for Future Solar Energy Redirection on Mars

Previous research shows that redirecting sunlight with large orbital mirrors could support warming specific regions of Mars by targeting ice deposits and releasing greenhouse gases. Although the concept has strong theoretical support, deploying and adjusting massive rigid reflectors in orbit remains a major technical challenge. This study aims to investigate the impact of using a swarm of small, adjustable Cube Sats equipped with different reflector types on the effectiveness of solar energy redirection for Martian surface heating. Through comparison of multiple designs in controlled conditions, this work addresses whether smaller, flexible systems could offer a practical alternative to traditional large mirrors. This project follows an experimental approach. A detailed trade study evaluated six components: Fresnel concentrators, Scheffler concentrators, parabolic dish concentrators, aluminized PET film, Mylar aluminum membranes, and Kapton-aluminum membranes. Designs were ranked by absorption and reflectivity, focal precision, ease of assembly, cost, material availability, and fabrication feasibility. A custom metal test frame holds two trays with eight CubeSat simulators. Each unit mounts a reflector on a three-axis gimbal, adjusted by motors and Arduino boards. Data will be collected using thermocouples for heat measurement, with manual alignment. Software simulations will be run together with lab tests to check system behavior and reflector alignment. Initial research shows that all reflectors can focus sunlight effectively, with the Fresnel lens producing the sharpest focal point and highest heat output. The swarm setup keeps the beam stable with manual adjustments, supporting the idea that small adjustable reflectors can match the function of a single large mirror. This project demonstrates a flexible approach to adaptive solar energy redirection using CubeSat swarms. The findings will help identify the most effective solar reflector design, guide improvements to the control system, and support future work on scaling this concept for orbital use.

Abstract Name: Fangirl Culture, and Romantic Expectations and Acceptance of the Emotionally Neglectful and Unavailable Men in Young Women aged 15 to 25

Growing interest among young women in emotionally distant or brooding male characters reflects evolving cultural expectations around intimacy, identity formation, and media engagement. Fan communities offer social validation, a sense of belonging, and opportunities to reinterpret experiences of emotional neglect through shared storytelling and idealized engagement with fictional, media characters. As social media and online fan communities play central roles in adolescent and young adult life, fictional, parasocial relationships provide spaces for self-exploration. Despite this, fangirl culture, defined as a community of fans who express strong enthusiasm and emotional investment in a celebrity or media figure, often faces stigma, with practices dismissed as trivial or irrational, creating a tension between individual experience and cultural perception. This behavior is evident in fandoms centered around characters like Damon Salvatore from *The Vampire Diaries* and Conrad Fisher from *The Summer I Turned Pretty*, where emotionally distant male figures are idealized and defended by young female audiences. This paper examines how parasocial attachments, personal attachment history, peer influence, and repeated exposure to media shape young

women's attraction to emotionally neglectful romantic figures in media. Analysis of cognitive and emotional mechanisms revealed important factors, such as character identification, imagined interaction, and learned relational patterns, that sustain these one-sided bonds. Engagement with these fictional figures evokes emotional responses similar to those experienced in real interpersonal relationships, allowing young women to practice vulnerability and experiment with romantic expectations in a controlled environment. Individuals with insecure or anxious attachment patterns are drawn to distant fictional partners, while enthusiasm and reinforcement from peers within online fandoms increase the perceived desirability of these characters and normalize potentially dysfunctional relational expectations.

Abstract Name: Bias in research: Factors and mitigations

This study delves into the multifaceted issue of bias in research, aiming to understand perceptions, awareness, and attitudes toward this topic using a quantitative approach. Although bias can be a vast topic, bias in research encompasses errors that may occur in research which hinder getting transparent and correct findings. This bias can happen at any stage of the research from data collection and misinterpretation to using false arguments and imprecise deduction reasoning. The study tried to quantify how much the general public has awareness about research bias and how researchers deal with bias. Numerous factors were investigated and multiple solutions were proposed to determine both commonalities and disparities that exist inside the research community. The study also investigated how experience in research affects the responses and whether bias is dependent only on the researcher itself or whether there are other actors. Through these inquiries, the study aimed to contribute to a better understanding of bias in research and inform strategies for its mitigation.

Abstract Name: Metabolic Flexibility in Adipocytes

Metabolic flexibility is the capacity of cells to shift between lipid storage and lipid utilization in response to changing energetic demands, all while maintaining metabolic health. Adipocytes regulate this process by storing fatty acids as triglycerides and releasing them through catecholamine-stimulated lipolysis. Impaired metabolic flexibility, a hallmark of obesity, reflects the inability of adipocytes to appropriately modulate these transitions. This study focused on understanding whether adipocytes can return to a pre-lipolytic, basal metabolic state after lipolysis is halted. To do this, we monitored primary adipocytes before, during, and after inducing lipolysis (CL activation) using a Seahorse metabolic flux assay to assess oxygen consumption rate (OCR) and live-cell imaging to evaluate mitochondrial membrane potential. Our results showed that CL activation increased OCR and decreased membrane potential, confirming elevated mitochondrial activity during lipolysis. Furthermore, inhibition of ATGL (ATGLi) significantly reduced OCR, indicating recovery toward basal metabolism, while insulin showed no effect on OCR under these conditions. However, imaging

analyses demonstrated that insulin partially restored mitochondrial membrane potential following lipolytic activation. Together, these findings suggest that adipocytes possess measurable metabolic flexibility, to specific interventions. Particularly, ATGLi and insulin mitochondrial protection can help reestablish basal metabolic and mitochondrial states after lipolysis.

Abstract Name: The C-terminal Domain of Hmo1 Is Not Required for its Function in DNA Damage Tolerance in Yeast Deleted for Rad5

High mobility group box (HMGB) proteins are sequence-nonspecific DNA-binding proteins that can bind altered DNA structures, such as four-way junctions. They also bind linker DNA and destabilize nucleosome structure. The *S. cerevisiae* Hmo1 is an HMGB protein that contains two HMGB motifs referred to as domains A and B. Interestingly, Hmo1 differs from canonical HMGB proteins because it has a basic C-terminal domain (CTD) instead of an acidic CTD. This basic CTD resembles that of linker histone H1, indicating that Hmo1 exhibits linker histone-like functions. Thus, Hmo1 exhibits characteristics of both HMGB proteins and linker histone H1. One unresolved function of Hmo1 is its role in facilitating the "error-free" template switching (TS) pathway of DNA damage tolerance (DDT) when promoting sister chromatid junction formation. Rad5 is a key protein in the TS pathway that allows cells to tolerate DNA damage induced by methyl methanesulfonate (MMS) during DNA replication. Previous studies have shown that deleting Hmo1 suppresses the hypersensitivity of *rad5Δ* mutants to MMS. In this work, we examined if the CTD of Hmo1 is required for its function in DDT in *rad5Δ* cells. We introduced a plasmid carrying the *hmo1-AB* allele, coding for the Hmo1 protein lacking its CTD (*hmo1-AB*) into *rad5Δ hmo1Δ* mutants. We found that the presence of the plasmid reduced MMS-tolerance of *rad5Δ hmo1Δ* mutants to a level similar to *rad5Δ* mutants. Because *hmo1-AB* fails to suppress the hypersensitivity of *rad5Δ* mutants to MMS, this demonstrates that the CTD of Hmo1 is not required for its function in *rad5Δ* mutants. Given that the CTD of Hmo1 is required for its linker histone-like function, it is likely that Hmo1 acts in DDT through its HMGB-like activity.

Abstract Name: Factors influencing positive interactions between mammals and birds with camera traps in the Brazilian Amazon.

Camera traps are a globally and widely used tool for studying terrestrial mammal and bird ecology and conservation. However, some species are more likely than others to approach or shy away from cameras which could bias observations and scientific results. These biases would affect species diversity, community composition, and population estimates gathered from this method of field research. To investigate this issue, my research asks are certain species more likely to interact with cameras than other species and what aspects of the animals' behavior and life history might influence these interactions? My research uses data from

medium to large sized birds and mammals and a wide variety of behaviors both in social and dietary guilds. Cameras were placed in the central Amazon rainforest roughly 40 miles north of Manaus, Brazil. They were deployed for 3 weeks per location for a total of 60 locations during the dry seasons of 2022-24. After verifying species in photos, through Wildlife Insights AI and expert verification, observations of animal interactions with cameras were classified as no interest, possible interest, and definite interest based on a set group of behaviors for each. Only species with greater than 5 independent detections were used for analysis. This research is expected to show that foraging animals will have higher rates of interaction with the camera than hunting animals. Additionally, social species are anticipated to have higher interaction rates than solitary species. Results of this study will aid in the improvement of ecological and conservation field techniques with camera traps to improve monitoring schemes and statistical approaches that remove detection bias.

Abstract Name: A Novel 3D Imaging Approach to Study Evolutionary Innovations in Solanaceae Inflorescences

Understanding the relatedness of angiosperms and the evolution of their inflorescence remains challenging, as these structures are highly modified and prone to convergent evolution. The current research describing inflorescence architecture, whether genetically or morphologically focused, typically relies on text based explanations, 2D images, or 3D based models created with CAD modeling software. This creates a disparity in the reader's understanding of these models since descriptions rely heavily on the author's interpretation of the inflorescence. The goal of our study is to bridge this disconnection by producing anatomically and color-correct 3D inflorescence models using Solanaceae flowers that readers can explore directly, which will allow readers to view and rotate the inflorescence structure in real time. The Solanaceae clade serves as an excellent platform to demonstrate this concept, as it is an active area of floral research and exhibits high inflorescence diversity within the clade. Its ancestral scorpioid cyme-like morphology is presently thought to have been the result of convergent evolution from a currently unknown driving force. Developing 3D models of extant Solanaceae species could provide valuable insights into these evolutionary patterns and help clarify the mechanisms underlying inflorescence diversification. Here, we use a novel photogrammetry approach to create 3D renderings of the inflorescences of *Burgmansia* sp., *Juanulloa* sp., and *Nicotiana obtusifolia*, in the Solanaceae clade. This process will involve taking high-resolution 360° photos at various angles using a camera. Photos will be processed with SlicerMorph Photogrammetry software, donated by the developers, Thomas OO, Zhang C, and Maga AM, which generates 3D models using photographs. It is expected that the rendered 3D images will accurately reflect specimen dimensions with precise color. This will serve as a way to study and provide a larger 3D inflorescence library that can bridge the gap between authors and readers within the literature.

Abstract Name: KARE: A Community Partnership to Improve Kidney Health Through Awareness, Risk Screening, and Education

Chronic kidney disease (CKD) affects more than one in seven adults in the United States, yet most people do not know they are at risk. The KARE project, which stands for Kidney Awareness, Risk Screening, and Education, was created to improve early detection of kidney disease by bringing free, nurse-led screenings directly into the community. The study focuses on identifying both medical and social factors that contribute to kidney health in populations that experience high rates of hypertension, diabetes, and limited access to care. The research team conducts mobile health events where participants complete short surveys and clinical screenings. Each participant receives blood pressure, blood sugar (A1C), kidney function (eGFR), and urine albumin tests, as well as questions about housing, food, transportation, and stress. The study also offers optional genetic testing for the APOL1 gene to better understand hereditary risk in African American populations. The research question guiding this project asks: Can community-based kidney screenings increase awareness and improve early connection to care among individuals with medical or social risk factors for CKD? To date, more than 30 community members have completed screening events, with follow-up visits in progress. Preliminary findings show strong participation and positive feedback on personalized health education. Students involved in the project are learning how to apply public health and nursing research methods in real-world settings, including data collection, patient education, and interdisciplinary teamwork. Ultimately, this project seeks to develop a scalable, equitable model for community-based kidney health promotion that bridges the gap between awareness, early detection, and access to preventive care.

Abstract Name: Exploring the Role of Eugenics in United States Immigration Policy from 1924 to 2025

In the US, eugenic beliefs that white bloodlines should be protected from miscegenation quickly gained traction after the end of the Civil War, instilling fear and fueling support for White Replacement Theory rhetoric. The climax of this need to preserve America's ethnic composition occurred when the 1924 Johnson-Reed Act was signed into law, capping immigration quotas and restricting immigration from each nation to 2% of that nationality's population as recorded in the 1890 Census. This policy inflated European quotas by excluding descendants of enslaved Africans from the census count and people of Asian lineage entirely. Meanwhile, immigrants from the Western Hemisphere were exempted from the national origins quotas system to ensure American agricultural success. In stark contrast, 2025 immigration policies reflect different priorities, with limited accommodation for Latino refugees and a strong preference for white South Africans, reserving a majority of the 7,500 immigration quotas for Afrikaners. Amidst this, conversations of White Replacement Theory and religious superiority have returned to the discussions of political ideology. The explicit inclination to accept white, Christian South Africans amongst the travel ban of nineteen ethnically diverse countries raises questions of why it appears that the United States is adopting policies similar to another era of demographic engineering. Using the multiple streams framework, this research project will examine how modern immigration policies constructed to address public safety echo the objectives of the Johnson-Reed Act. The analysis will utilize primary sources from the Victor Howard Collection on Civil Rights and Church-State, 1907-1989, at the University of Kentucky Special Collections Research Center, contemporary news articles, and publications from academic databases and government agencies to explore how eugenic language of the 1920s compares to today's emphasis on national security. This research seeks to understand if demographic engineering has not disappeared, but merely evolved in its rhetoric.

Abstract Name: Integrating Experimental and Computational Techniques to Investigate Plant Immunity

Strengthening plant immunity depends on our ability to counteract the molecular mechanisms by which a wide spectrum of pathogens degrade the cell wall and initiate infection. Bacterial pathogens infect plants by emitting enzymes like xylanases and polygalacturonases that destroy cell walls. Plants can defend themselves in response with highly evolved inhibitors such as rice xylanase inhibitors (RIXI) which bind to xylanases and block their activity. Xylanase binding on RIXI also triggers a defense signaling cascade with immune gene activation (e.g. OsPR1a, OsPR1b, PR4), hormone-mediated signaling, and the buildup of reactive oxygen species. To predict the structure of the resulting protein complex, the protein pairs were docked using AlphaFold3 on MSU ICER's High Performance Computing Cluster. Using PyMol, several parameters such as close contact regions, buried surface area (BSA), Hydrogen Bonds, and Salt Bridges were visualized and analyzed to predict which factors were important for strong binding of the target proteins to their respective receptors. This structural information provides a foundation for future experimental work that will elucidate inhibitor-enzyme binding kinetics. To experimentally characterize these interactions, the proteins were expressed on the surface of yeast and analyzed using flow cytometry to assess target binding. This work contributes to ongoing efforts in our group to engineer plant immune receptors through machine learning and wet-lab screening. Together, these approaches aim to enhance plant defenses against cell wall-degrading pathogens.

Abstract Name: Understanding Widespread Pain in Rheumatoid Arthritis: The Role of the Trigeminal Ganglion

Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by inflammation of the synovial joints, leading to pain, swelling, stiffness, and progressive joint damage. While pain in patients is primarily localized to the affected joints, emerging evidence indicates the development of widespread pain that persists beyond joint pathology, suggesting mechanisms independent of local inflammation. Recent studies emphasize the role of neuroimmune interactions in driving persistent pain sensitization, particularly through IgG immune complexes, Fc gamma receptors (FcγRs), and macrophage activation. While the dorsal root ganglia (DRG) have been extensively studied in RA-related pain, the trigeminal ganglion (TG)—which processes orofacial sensory input—remains largely unexplored despite reports of facial pain and hypersensitivity in RA patients. This study aims to investigate the role of TG in RA-related widespread pain. We hypothesize that circulating IgG immune complexes bind to FcγRs on TG-resident immune cells, inducing neuronal hyperexcitability and immune cell infiltration. To test this hypothesis, we are using the K/BxN serum transfer mouse model of RA to assess the development of facial hyperalgesia in experimental and control groups. Facial mechanical sensitivity is assessed using the Von Frey test, a calibrated monofilament-based assay for measuring withdrawal thresholds. Using immunohistochemistry, we will also examine the activation of satellite glial cells, macrophage phenotypes, and the infiltration of immune cells such as neutrophils, T cells, and B cells as potential contributors to persistent orofacial pain. Identifying TG-mediated pain mechanisms provides novel insights into RA pain pathology beyond joint inflammation. This research offers a paradigm shift in pain management by highlighting FcγR-targeted and neuroimmune interactions as potential targets for RA-related widespread pain therapies. Understanding the TG's role in RA may lead to more effective pain interventions, improving patient outcomes where traditional anti-inflammatory treatments fall short.

Abstract Name: Human vs Machine Deception: Distinguishing AI-Generated and Human-Written Fake News Using Ensemble Learning

The rapid adoption of large language models has introduced a new class of AI-generated fake news that now coexists with traditional human-written misinformation, raising important questions about how these two forms of deceptive content differ and how reliably they can be distinguished. This study investigates the linguistic, structural, and emotional differences between human-written fake news and AI-generated fake news and evaluates machine learning and ensemble-based methods for separating these two content types. A comprehensive feature representation is constructed using document length measures, sentence structure, lexical diversity, punctuation and capitalization patterns, standard readability indices, and fine-grained

sentiment and emotion scores capturing affective dimensions such as fear, anger, joy, sadness, trust, and anticipation. Multiple classification models, including logistic regression, random forest, support vector machines, extreme gradient boosting, and a deep neural network, are trained to distinguish between human-written and AI-generated fake news. An ensemble framework combining these classifiers is further developed to improve classification stability and overall detection performance. Model performance is evaluated using accuracy, area under the receiver operating characteristic curve, and precision-recall analysis. The results indicate that human-written and AI-generated fake news exhibit systematic differences in readability structure, lexical regularity, and emotional expression, with AI-generated content showing more uniform stylistic patterns and compressed emotional variability. Across models, ensemble learning consistently improves discrimination between the two classes relative to individual classifiers. These findings provide insight into how machine-generated deception differs from human-authored misinformation and demonstrate the value of ensemble-based learning for distinguishing between these increasingly intertwined forms of fake news.

Abstract Name: Design and Computational Assessment of Novel JRM-28 Analogs Targeting HDAC2

Histone deacetylase 2 (HDAC2) remains an attractive therapeutic target in Alzheimer's disease due to its strong association with impaired memory formation and synaptic dysfunction. JRM-28, a thiadiazole-based inhibitor previously developed in our lab, demonstrated improved binding within the HDAC2 catalytic pocket. In this project, we aimed to design next-generation JRM-28 analogs with enhanced stability, binding affinity, and drug-like properties. A full library of analogs was first evaluated computationally using molecular docking and molecular dynamics (MD) simulations. RMSD analysis of the protein–ligand complex, ligand-only conformations, and protein backbone revealed stable trajectories for several analogs (<3 Å), indicating strong retention within the binding pocket. Among the designed structures, some of the analog produced the most favorable docking score and maintained a well-defined pose during MD, including strong coordination with the Zn²⁺ catalytic center. These results suggest improved binding performance relative to the parent scaffold. Experimentally, we synthesised and characterized several modified intermediates required for the synthesis of JRM-28 analogs based on the computational studies. Other intermediate analogs with the best computational results (Docking score) will be synthesized as well.

Abstract Name: Novel GEMMs to Investigate the Role of DREAM Complex in HPV-Driven Oral Tumorigenesis

Background: High-risk human papillomavirus 16 (HR-HPV16) is responsible for ~90% of HPV-induced oropharyngeal cancers. HPV16 induces tumor growth via HPV16 E7 oncoprotein, which promotes degradation of pRB, p107, and p130. While pRB is a known tumor suppressor, the roles of p107 and p130 are less well understood. In mammalian cells, p107 and p130 interact with LIN52 protein to form the DREAM complex that controls cell cycle progression by repressing E2F transcription. In HPV-infected cells, E7 binds to p130 and p107 and displaces LIN52, which disrupts the DREAM complex and promotes transcription of cell cycle genes and cell proliferation. LIN52-S20C mutation increases the DREAM formation in HPV-positive cancer cell lines, but the role of DREAM complex in HPV-driven tumorigenesis is not well known. **Aims:** The purpose of this study is to determine if stabilizing the DREAM complex leads to a decrease in tumor growth in HPV16-E7 oral carcinogenesis model. **Methods:** Mice with a knock-in Lin52-S20C mutation were generated and crossed with K14-E7 transgenic mice to establish K14-E7/Lin52-S20C or K14-E7/WT (wild type) animals. These mice were given 4-Nitroquinoline 1-oxide (4NQO) water for 16 weeks to induce oral tumor growth, and monitored for an additional 10 weeks by weighing and examining tumor formation in the oral cavity. **Results:** The results showed that K14-E7/WT mice had an increased tumor burden compared with the K14-E7/Lin52-S20C mutant mice. Lin52-S20C mutant mice had significantly longer survival. The majority of the WT mice also became moribund and were euthanized earlier than the mutant mice. WT mice had more aggressive tumor growth in the esophagus per H&E and KI67 staining. **Conclusion:** Reactivation of the E7-disrupted DREAM complex appears to reduce tumor growth and extend lifespan of the LIN52-S20C mutant mice. Restoring the DREAM complex could represent a therapeutic approach for preventing or treating HPV-induced cancers.

Abstract Name: Determining Genes Involved in Recovery From Chemotherapy in 4T1 and EO771 TNBC Cell Lines

Breast cancer is one of the most common types of cancer. Traditional treatments for breast cancer include . However, these treatments are not 100% effective, and patients might experience recurrence in their cancer months or years after achieving remission. Cancer cells can evade chemotherapy through five mechanisms: senescence, quiescence, cytoprotective autophagy, and apoptosis/necroptosis suppression. One of the ways these mechanisms can be targeted to make growth arrest permanent and make cancer treatment more definitive is through epigenetics, using gene silencing. In this study, a CRISPR screen was conducted to identify how silencing of different chromatin regulator genes would affect the growth of 4T1 and EO771 triple-negative breast cancer cells in mice. 4T1 and EO771 triple-negative breast cancer cells were transfected with a plasmid that would allow the cells to express Cas9 in a tetracycline-dependent manner. For in vivo experiments, the cells were implanted bilaterally in the mammary fat pad. A CRISPR screen will be conducted to determine the effects of silencing certain chromatin regulator genes, to determine the effects on the growth of these 4T1 and EO771 cells in mice. Finally an RNA-Seq analysis will be conducted to determine how the transcriptome of these cells were changed with administration of chemotherapy and subsequently after gene silencing, to determine genes involved in chemotherapy resistance. Genes that will be identified can present targets for epigenetic treatments and other gene-editing interventions, to help make chemotherapy a more effective treatment for breast cancer. These interventions administered in sequence or in conjunction with traditional chemotherapy can provide more targeted treatment for these cancers, that will reduce the recurrence of tumors in patients with cancer, and increase the likelihood of remission.

Abstract Name: Parsimonious Multinomial Model for Neural Decoding: Identifying Critical Neurons for Encoding Non-Spatial Memory

The hippocampus is crucial for encoding sequential memory in humans and animals, but the specific neurons that differentiate elements of those sequences remain relatively poorly understood. To investigate this, we analyzed neural activity data from rats in the UC Irvine Fortin Lab performing a sequential memory task where they were trained to recognize sequences of odors. We trained logistic regression models to distinguish a particular odor from others and predict if given odor sequences were in or out of order. To study more complex decision-making, we coded multinomial regression models and neural networks, using activity from all 46 neurons at precise millisecond times to identify specific odors. Our method identified neurons significantly associated with sequential memory processes. We then used a LASSO regression (dimensionality reduction technique) and a Random Forest model (ensemble method for prediction) to corroborate our findings based on our logistic and multinomial regression models to identify the neurons most critical for encoding each odor. We found that when the task was binary, i.e., using our logistic regression models, training with only the most critical subset of neurons preserved the predictive accuracy of using all neurons. Although baseline accuracy varied across the five odors, the accuracy gap between full and subset models was consistent for all the odors. This could permit the use of less resource-intensive methods for neural activity data collection. However, for more complex neural networks and multinomial models, using the same subset of neurons reduced accuracy significantly, suggesting that only in binary tasks, neurons encoding for non-target odors can be redundant. When distinguishing between all odors, the contribution of each neuron's unique information becomes more critical. These results have the potential to improve neural prosthetics and brain-computer interfaces by simplifying neural decoding applications in development or use.

Abstract Name: Investigating the Impact of 628 GFP + and 7aX DsRed + Transgene Combinations on Female Mosquito Mating and Egg Production with Wild-type Males

Anopheles gambiae is the most efficient malaria vector due to its abundance, preference for feeding on humans, long lifespan, and susceptibility to infection. In 2023, malaria caused 263 million cases and 597,000 deaths, highlighting the need for new vector-control strategies. Gene editing is a promising approach, but it's essential to understand how transgene insertions affect reproductive success. This study examined the effects of two insertions— 628 GFP+ and 7aX DsRed+ –individually and combined, on female mating with wild-type males, blood feeding, and egg laying. The 7aX line carries a piggyBac insertion on the X chromosome with a 3xP3-DsRed marker and a non-expressed hsp70-TEP1 construct. The 628 line is a CRISPR insertion disrupting TEP3 on chromosome 3 with a 3xP3-GFP marker. Earlier work suggested reduced blood feeding and egg laying in double-positive females, but it was unclear whether this phenotype came from the combined genotype or one insertion alone. This study tested whether 628 GFP+ females could produce eggs when crossed with wild-type males. Three trials were conducted using five groups: 628 GFP+, 7aX DsRed+, double positives, double negatives, and wild-type males. Crosses were set at the pupal stage, and mating

success was assessed via spermatheca dissection. Only double-negative females laid eggs. Neither 628 GFP+ nor 628 GFP+/7aX DsRed+ females produced eggs across trials. Both groups also showed lower blood-feeding rates. Spermatheca dissections revealed empty spermathecae, indicating failure to mate rather than defective oviposition. Thus, the 628 insertion is the main factor driving infertility. Possible explanations include altered mating behavior, disrupted timing of mating or feeding, or physiological effects of TEP3 disruption. Blood freshness or feeding conditions may also disproportionately affect 628+ females. Overall, the 628 GFP+ insertion severely impairs female reproductive success, highlighting the need to evaluate unintended fitness costs before advancing transgenic vector-control strategies.

Abstract Name: *Replaying the Past: How have films continued to perpetuate the memory of old conflicts? A Comparative Analysis of India-Pakistan & Japan-South Korea Relations.*

This paper examines how films have continued to perpetuate the memory of historical conflicts, focusing on two case studies: India-Pakistan relations and Japan-South Korea relations. While previous research has examined the political and social consequences of these conflicts, less attention has been given to the role of popular media, particularly cinema, in shaping collective memory and reinforcing narratives of historical animosity. By analyzing films from both regions, this study explores how films highlight and reinforce past conflicts in contemporary societies, influencing how societies remember and interpret these conflicts. This research employs a qualitative visual and media analysis methodology, examining narrative structures, visual symbols, characterizations, and themes within selected films. This approach enables a nuanced examination of how films represent conflict, grievances, national identities, and intergroup relations, as well as how they may influence audience interpretations of historical memory. A comparative historical analysis between the two case studies will assist in identifying shared historical patterns of conflict memory. Preliminary findings suggest that films often emphasize identity, nationalism, and cultural commonalities or divisions, thereby contributing to public perceptions of historical conflicts. In some cases, films reinforce existing grievances, while in others, they foster empathy or highlight opportunities for dialogue. This demonstrates the potential of cinema as both a medium for division and reconciliation. These results will be discussed in relation to interdisciplinary theories of collective memory, media influence, and post-conflict reconciliation, highlighting the complex role of film in societal understandings of historical conflict.

Abstract Name: *Interactive Analytics for Speed Compliance and Road Safety in Iowa*

Speeding is a leading contributor to traffic crashes and fatalities, yet current monitoring methods often rely on manual reporting or static summaries, limiting timely insights. This project develops an interactive dashboard to visualize speed non-compliance across Iowa, integrating daily traffic data, roadway segment maps, and county-to-law-enforcement district mappings. The dashboard allows users to filter by route type, county, district, and date, and provides visualizations including maps colored by non-compliance percentages and

trend charts over time. By bridging raw traffic data with actionable visual insights, this tool supports Iowa DOT and law enforcement agencies in identifying high-risk segments, targeting interventions, and making data-driven decisions to improve road safety. Beyond immediate applications, the dashboard establishes a framework for statewide monitoring, enabling planners and safety teams to track trends, compare districts, and allocate resources efficiently. Future enhancements include incorporating real-time speed data for live monitoring, predictive analytics to forecast high-risk areas, and integration with crash data for a combined safety analysis. By transforming complex traffic data into an accessible and interactive platform, this project contributes to safer and smarter transportation systems, demonstrating the potential of data-driven approaches in public safety and infrastructure planning.

Abstract Name: Silencing Ogoniland: Oil, Power, and the Politics of Neglect

Nigeria is Africa's largest crude oil producer. This resource is concentrated across nine states that constitute the Niger Delta. Despite the fact that oil is distributed across the Delta, since 1957, Ogoniland, Rivers state has been subjected to an unwarranted degree of exploitation and environmental degradation, and the Ogoni people have been subjected to uninhabitable conditions, inexistent economic opportunities, and what appears to be the intentional omission of basic human rights. To determine the primary causes for these discrepancies, I intend to compare another ethnic group which resides in an oil-rich territory in the Niger Delta against the Ogoni people. I will hold factors such as population size, geographic terrain, political power, and prevalence of a multinational oil company constant. Based on my current research, I hypothesize that the Ogoni people's history as a minority ethnic group-which was able to successfully organize a nonviolent resistance movement that gained international attention-has rendered the Nigerian government severely indifferent to their condition. There is currently no scholarship that focuses on understanding the differences between various communities before and after an extractive company enters them.

Abstract Name: AI's Impact on the Job Market: A Study Using Google Colab and IBM Watson

Artificial intelligence is rapidly reshaping the global workforce, changing which skills are in demand and how careers develop over time. With automation accelerating, understanding which jobs will survive or grow is critical for students and job-seekers. This project explores AI's impact on the labor market using two complementary datasets. The first dataset, Global AI Job Market & Salary Trends 2025 (15,000 listings), includes information such as salaries, job titles, experience levels, and skill requirements. The second dataset, AI Job Trends 2024-2030 (30,000 records), provides projections on job openings, automation-risk percentages, education requirements, gender diversity, and remote-work trends. This second dataset is especially useful for studying broader workforce changes, as it includes titles from non-AI roles. Study 1

focused on developing salary-prediction models and analyzing skill premiums using the first dataset. After extensive preprocessing, multiple regression models were built using IBM Watson and Google Colab. Among all ML algorithms (eg. Random Forest, Extra Trees, XGBoost), XGBoost performed the best, with MAE = \$13,586, RMSE = \$18,449, and $R^2 = 0.885$. The most influential factors on salary were experience level, job specialization, and geographic location. Study 1 concluded with a need for fresh datasets and a deeper understanding of global trends. Study 2 addresses these goals by utilizing the second dataset to shift the focus from salary prediction to measuring job vulnerability. Early results show that repetitive jobs face the highest automation risk, while technology and engineering roles are expected to grow significantly. By comparing outcomes from these two analyses, the study will evaluate whether changes in salary trends align with projected job growth or decline, offering insight into broader labor-market disruptions. The final presentation will explain new indices and a multi-model analytical framework used in this research, providing a scalable method for understanding future labor-market transitions in the AI era.

Abstract Name: Effects of Early-Life Stress on Ultrasonic Vocalization in Rats

Early-life stress (ELS) has been associated with long-term changes in emotional development, stress responsivity, and vulnerability to behavioral alterations, including those related to later drug exposure. The impact of early-life exposures on adult behaviors can be difficult to study in humans, and rat models provide opportunity to test early influences on adult outcomes in controlled settings. The overarching study examines the potential for early behavioral changes following ELS, in this study modeled through limited-bedding and nesting, to predict increased markers of drug-seeking behavior in adulthood. The work presented here will examine the hypothesis that ultrasonic vocalizations (USVs), a non-invasive indicator of affective-like communication, are altered by ELS both during exposure to ELS and at the end of stressor exposure later in adolescence. Rats produce ultrasonic vocalizations above 20 kHz that reflect emotional-like states. Infant distress calls occur around 40 kHz, 22 kHz calls in older rats are linked to aversive states, and 50 kHz calls are associated with positive, reward-related states. Because these calls emerge naturally in response to environmental and emotional conditions, changes in their patterns may help identify early alterations related to ELS. USVs in this study will be recorded using the Wildlife Acoustics system with acoustic foam used to reduce background noise. The calls will be analyzed using Kaleidoscope's Cluster Analysis to extract timing, duration, and frequency. USVs are measured twice during exposure to ELS and then during adolescent development at postnatal days 26, 36, 46, and 51. We will test the hypothesis that ELS disrupts call rate and acoustic features across adolescent development. Findings from the USV analysis will support the broader study's goal of determining how early-life environments may contribute to later behavioral outcomes. Given the importance of communication for social interactions, disruptions in communication patterns may lead to adverse social behaviors and increased risk.

Abstract Name: AN OPEN SUGGESTION TO THE UNITED STATES: TWIN TOLERATION IN MOROCCO

After the 2011 Arab Spring revolts within the MENA region, Morocco led in the inclusion of strengthened individual rights and governmental power, whilst retaining central authority within the monarch of the state. With the rise of religious nationalism in the United States, the research question considers whether Morocco, a constitutional monarchy, exhibits “Twin Toleration” through active legislation from 2011-2025 and within the state’s constitution. The proposed research question seeks to add to previous studies considering potential tolerance between state and religious institutions in democratic states. However, as opposed to the previous studies’ analysis of Western democracy, the current proposal considers tolerance between the religious state and secular institutions of a Muslim democracy, such as Morocco. The paper utilizes Alfred Stepan’s definition of Twin Toleration, defined as a state’s recognition and respect for a person or group’s beliefs, and a religious institution’s ability to respect the results of the democratic process. Through an analysis of the 2011 Moroccan constitution and active legislation, I thematically code legislation laws and titles from the constitution based on requirements for Twin Toleration to be visible in democratic states, and conduct interviews to gauge public opinion in Morocco about legislation performance. The data is collected from Titles One and Two of the Moroccan Constitution, which refer to the fundamental freedoms and rights of the people, as well as the rights of secularist groups in the nation. Additionally, it includes legislation passed through the House of Representatives after 2011, along with data presented in the interviews. The collected data aims to provide a concrete understanding of the tolerance between the state and secularist institutions within Morocco. The tolerance between state and secularist institutions will allow for recognition of potential tolerance between religion and secularism in other countries leaning towards religio-nationalistic political systems, such as the United States.

Abstract Name: Forward Deployed, Functionally (Ir)relevant? Assessing the Impact of Forward Deployed “Tactical” Nuclear Weapons on Nuclear Crisis Outcomes

This paper asks whether the presence of forward-deployed tactical nuclear weapons materially affects the outcomes of nuclear crises. The question sits at the intersection of long-standing scholarly debates over deterrence, nuclear superiority, and the credibility of escalation options. Proponents of “hard” deterrence argue that tactical nuclear capabilities enhance resolve by providing leaders with credible counterforce options within the brinkmanship processes described by Schelling and expanded upon by Kroenig. In contrast, scholars emphasizing the “nuclear revolution,” the nuclear taboo, or psychological uncertainty suggest that such deployments may have little practical influence on real crisis behavior. Against this contested backdrop, especially amid renewed policy interest in reintroducing U.S. nuclear weapons to the Indo-Pacific, this study evaluates whether forward-deployed tactical nuclear weapons have a tendency to improve a state’s likelihood of achieving its crisis objectives. To test this proposition, the paper combines the International Crisis Behavior (ICB) dataset of nuclear crises with a comprehensive dataset of foreign nuclear deployments compiled by Sechser and Fuhrmann. Using two alternative coding schemes for identifying forward deployments, it conducts chi-square and Fisher’s exact tests to assess statistical association between forward-deployed tactical weapons and crisis victory. A case study of the Cuban Missile Crisis supplements the quantitative analysis by probing whether tactical capabilities influenced decision-makers’ perceptions, options, and constraining factors. Across all tests, including those restricted solely to U.S. crisis dyads, this

study finds no statistically significant relationship between forward-deployed tactical nuclear weapons and crisis success. The Cuban case likewise reveals ambiguous effects. These findings suggest that tactical nuclear weapons do not function as meaningful levers of crisis bargaining. For contemporary policymakers, the results imply that redeploying U.S. tactical nuclear weapons to East Asia would provide limited crisis-level advantage and should not be assumed to enhance coercive leverage or crisis outcomes.

Abstract Name: Examining the Trajectory of Black Women's Health Through Policy Gaps and Clinical Training Frameworks

This study examines how the persistent and deeply-rooted health disparities experienced by Black women in the United States reflect long-standing gaps in health policy, clinical training, and structural discrimination. Studies from the past five years report that Black women face disproportionate burdens across a wide trajectory of health outcomes, including a 40% higher breast cancer mortality rate compared to White women, alongside increased risks for stroke, heart disease, type 2 diabetes, and uterine fibroids. While these studies may be recent, the patterns that create these health outcomes are nowhere near new. The health outcomes of Black women are shaped by discriminatory housing practices and historical laws that targeted both Black communities and women, contributing to pivotal differences in socioeconomic status and access to care. The maternal mortality crisis, for instance, is an urgent cause for intervention, with non-Hispanic Black women being three to four times more likely to die during pregnancy or within a year postpartum. Qualitative studies reveal that many Black women giving birth in low-performing hospitals continue to experience poor communication from providers, and barriers to receiving appropriate prenatal and postpartum care due to antiquated, racist protocols in fields like obstetrics and gynecology. Black women are also more likely to receive fewer or untimely interventions, contributing to preventable complications and poorer overall health outcomes. This history still influences present-day interactions, creating mistrust of healthcare providers, inconsistent adherence to treatment, and ineffective communication. This study relies on published data and autoethnographic research methods to analyze how policy structures and clinical training shape Black women's health experiences. This research is crucial to better understanding the need for policies and training frameworks that intentionally center and uplift the trajectory of Black women's health to create pathways toward equitable care for all.

Abstract Name: Engaging Minds, Empowering Students: Are You Ready for a Career in STEM?

A decade ago, the National Institutes of Health (2016) identified key "interventions to 'lift' [underrepresented] students' interests, commitment and ability to persist in STEM fields," including fostering organizational responsibility, developing impactful collaborations, optimizing curricula, addressing access gaps, and promoting creativity. Massey et al. (2022) highlighted the STEM hidden curriculum, advocating for the empowerment of students "to embrace their own distinct identities and scientific voices and explain how

students can overcome challenges unique to underrepresented students throughout their undergraduate career." The National Science Foundation (2024) reinforced that "a diverse workforce is vital for enhancing the nation's capacity for innovation" (Bell et al., 2019; Hsieh et al., 2019). This autoethnographic study explores educational dynamics in the transition from high school to college, emphasizing how the principles of discovery, innovation, collaboration, and excellence (DICE) promote student empowerment. Through personal experiences, self-reflection, and observation, I uncover overlooked perspectives within STEM and analyze the relationship between self-identity and pedagogical challenges. Using an autobiographical timeline and narrative analysis of essays, I investigate how DICE practices supported my transition and prepared me for a STEM career. The central question guiding this research is: Are You Ready for a Career in STEM? Findings suggest that when students actively shape their educational journeys, they strengthen critical thinking, cultivate a sense of belonging, and take ownership of their learning. This empowerment enables them to advocate for their needs and commit to academic excellence. This poster presentation invites educators and scholars to reflect on how underrepresented students develop STEM identities and challenges us to adopt innovative practices that prioritize engagement and learning for all. By sharing actionable strategies from my research, I aim to inspire educators to create environments where every student can thrive. Together, let's engage minds and empower all students to succeed in STEM careers.

Abstract Name: A Tool to Assess an Off-Target DYRK1A Inhibition by Clinically Used Anti-Cancer Drugs

Dual-specificity tyrosine-regulated kinase 1A (DYRK1A) has a significant role in cell cycle control via its regulation of the DREAM complex, and therefore could influence cancer progression. DYRK1A phosphorylation of LIN52 is critical for assembly of the DREAM repressor complex, which restrains cell proliferation. Thus, inhibition of DYRK1A may disrupt the LIN52/DREAM interaction and influence drug responses. Several approved anticancer agents, such as abemaciclib, silmitasertib, and olaparib, have been shown to inhibit DYRK1A in vitro, but the clinical significance of this off-target activity is unknown. DYRK1A's role in cancer is controversial since its inhibition has been associated with both tumor suppression and promotion. Here, we aim to develop a reporter system to quantify DYRK1A activity and assess drug effects at clinically relevant concentrations. The system uses a LIN52-turboGFP fusion (tGFP-rLIN52) and phospho-LIN52-specific antibodies to measure intracellular DYRK1A activity. Interaction of tGFP-rLIN52 with DREAM and related complexes is evaluated by immunoprecipitation and western blot. Drug effects are tested in SKOV3 and Kuramochi ovarian carcinoma cells and T98G glioblastoma cells, using cells with DYRK1A depletion by lentiviral shRNA or knockout via CRISPR-Cas9 to confirm the reporter specificity. Our data show that tGFP-rLIN52 phosphorylation is highly specific to DYRK1A and reproducible across the cancer cell lines. The reporter does not interact with DREAM and is unlikely to affect proliferation. This tool will enable quantification of in-cell DYRK1A inhibition by anticancer drugs and correlation with cytotoxic and cytostatic effects, providing insight into the therapeutic and biological significance of DYRK1A modulation.

Abstract Name: The Impact of Financial Distress on Airline Safety: A Regression Analysis of Economic Indicators

Financial stability plays a critical role in the airline industry, influencing both operational decisions and long-term safety outcomes. After deregulation in 1978, U.S. airlines experienced a sharp increase in competition, leading to significant overcapacity and frequent fare wars. As a result, profits declined for many carriers, which in turn raised the concern that short-term financial survival may come at the cost of investments in safety. Although scholars have debated the link between financial health and accident risk, prior studies have produced mixed results. Some suggest that profitability encourages risk-taking, while others argue that stronger finances enable greater investment in safety. Because findings remain inconsistent, there is a need for a clearer, data-driven approach to understanding how financial distress affects safety performance. This study examines 14 major U.S. airlines to evaluate whether financial indicators such as profitability, liquidity, debt ratio, etc., correlate with accident and incident rates recorded by the Federal Aviation Administration and National Transportation Safety Board. A fixed-effects regression model will be applied to control for airline-specific characteristics, with particular attention to the COVID-19 pandemic period, which created a natural experiment of financial decline and heightened safety concerns. The findings will provide practical insights for regulators, managers, and consumers. By clarifying the relationship between financial health and safety outcomes, this research aims to support proactive monitoring systems, inform regulatory policy, and encourage airlines to prioritize safety investments even under financial stress.

Abstract Name: The Effect of the Microbiome on Food Preference in *Drosophila Melanogaster*

Energy intake and feeding regulation are heavily impacted by interactions between the nervous system and microbiome. SINGLE-MINDED1 is a transcription factor needed for the development and function of neurons in the paraventricular nucleus, controlling such autonomic processes as metabolism and feeding. Loss or silencing of single-minded disrupts these processes and can lead to obesity-related issues. In *Drosophila melanogaster*, our previous experiments indicated that flies with silenced single-minded neurons extend their proboscis more than wild type flies when offered a sucrose solution. To further understand the mechanism of these responses, we considered the impact of the gut microbiome. The gut microbiome plays a critical role in influencing host development, physiology, behavior, and neural function. In flies, the microbiome decreases developmental time, increases adult weight, and increases hormone signaling, including insulin. To examine feeding regulation in flies, we compared food preference in wild type flies and flies with silenced single-minded neurons in both the presence and absence of the microbiome. To remove the microbiomes, we dechorionated the eggs and then grew the embryos on an autoclaved diet containing 50 µg/ml chlortetracycline. Proboscis extension reactions of the wild type flies and flies with silenced single-minded neurons was tested with two food sources: a 2 M sucrose and 50% live yeast solution. Both genotypes decreased their response to sucrose after microbiome removal, suggesting that the microbiome enhances sucrose preference. When tested with yeast, wild type flies lacking a microbiome extended their proboscis more often than flies with silenced single-minded neurons. The number of wild type flies that extended their proboscis for yeast increased after the microbiome was removed, whereas the number of flies

with silenced single-minded neurons decreased. These results suggest that both the microbiome and single-minded neurons shape feeding preference and may promote macronutrient preferences for sugar over protein.

Abstract Name: The Effects of Marijuana on Anxiety Levels.

Marijuana is a psychoactive drug that is considered the most commonly used federally illegal drug. In recent years, marijuana use has increased significantly, reaching historically high levels. In 2023, approximately 42% of adults 19-30 reported marijuana use in the past year. Current research on the subject has not drawn conclusive findings. Some studies report a significant relationship between anxiety and marijuana while others show no effects of marijuana on anxiety. The present study examines marijuana use in the past 12-months for non-medical purposes and compares the anxiety levels of individuals who have used marijuana to those who have not used marijuana. Data was gathered from college students who participated in cohorts 6 and 7 of the Spit for Science study (N=1022). Spit for Science is a longitudinal study that examines how genes and the environment work together to contribute to emotional health difficulties such as anxiety, depression, and substance use. Anxiety levels based on the SCL-90, as well as indication of marijuana use in the past 12 months, were examined among college sophomores. An independent sample t-test was conducted to explore the differences in anxiety levels between those who have used marijuana and those who have not. The findings indicate that individuals who used marijuana in the past 12 months reported significantly higher levels of anxiety ($M=4.63$, $SD=3.43$) than individuals who have not used marijuana in the past 12 months ($M=3.45$, $SD=3.32$) ($t=-3.746$, $p<0.001$). These findings add to previous research suggesting that there is a relationship between anxiety and marijuana. This may help increase education and awareness of marijuana and its effects on emotional health. However, more research is needed to determine whether anxiety is caused by marijuana use.

Abstract Name: Behind the Bars: The Injustices of Staff-Perpetrated Sexual Violence in US Women's Prisons

Behind the Bars is an analysis of the injustices that lie within staff-perpetrated sexual violence against U.S. women prisoners. Combining information from the few statistical reports on the matter with first-hand accounts from victims, this paper attempts to capture the true depth of the issue, despite the difficulties in measuring. In 2020, a Bureau of Justice Statistics report found that, though women only make up 7% of the incarcerated population, they are responsible for over 28% of reports of staff-perpetrated sexual violence. The

disproportion proves that this is an issue of gender, which has been recognized by scholars like Michelle VanNatta, Gina Fedock, and Barbara Owens. *Behind the Bars* builds on existing research by arguing that the problem exists at the intersection of gender and justice. First, staff-perpetrated sexual violence has an additive effect on prisoners' punishments. The loss of liberty inherent in incarceration is compounded by the loss of physical autonomy through sexual violence. When the attack is committed by a member of prison staff, the additional punishment (torture) is sanctioned directly by a representative of the state. Then, the various barriers that discourage victims from reporting and prevent effective investigations multiply these punishments by guaranteeing impunity to the staff perpetrators. This multiplicative nature is what makes staff-perpetrated sexual violence an issue of justice, while the disproportionate victimization of women makes it an issue of gender. This paper's dual perspective reveals that staff-perpetrated sexual violence is not merely a symptom of rape culture nor of the American prison system, but that it is an independent injustice that requires specific attention.

Abstract Name: Do Ethnic Groups Think Fast Differently? Nudging Diverse Consumers.

In consumer decision-making, nudges often guide choices by triggering well-established cognitive biases such as loss aversion, framing, affective heuristics, and processing fluency (Kahneman & Tversky, 1981; Slovic et al., 2007). Although these “fast thinking” mechanisms are typically assumed to be universal, surprisingly little empirical work has examined whether the magnitude, or even the direction, of these biases varies across cultural or ethnic groups (Henrich et al., 2010). This absence of comparative evidence represents a meaningful gap in both behavioral economics and consumer psychology. To address this gap, we conducted a mixed experimental survey ($N \approx 400$), using a between-subjects factor of self-identified ethnicity and a within-subjects factor that captured multiple behavioral nudges. Participants completed a fully randomized set of consumer scenarios probing established biases (e.g., framing, anchoring, social proof, affect heuristic, endowment valuation), enabling parallel effect-size estimation across four ethnic groups. Across all nudges, participants displayed classic bias patterns, yet the intensity of several effects, particularly affect-driven choices, fluency preferences, endowment gaps, and framing sensitivity under risk, varied systematically by ethnicity. These cross-group differences emerged reliably across both binary-choice and continuous-rating measures. At the same time, several biases typically treated as universal, including diminishing sensitivity and urgency-based scarcity cues, showed striking cross-cultural stability. Notably, we also observed unexpected pattern reversals, such as anchoring scenarios in which the absence of a reference price produced higher willingness-to-pay than either low or high anchors. Together, these results provide the first broad empirical comparison of multiple consumer-relevant biases across ethnic groups. The findings refine assumptions about the universality of behavioral biases and offer actionable guidance for cross-cultural marketing, communication strategy, and policy design in increasingly diverse consumer contexts.

Abstract Name: Sp7 is Required for Apoptosis of Hypertrophic Chondrocyte and Cartilage Turnover

Objective: Sp7 transcription factor is essential for skeletogenesis, as global deletion causes failure of bone formation. Sp7 gene mutations in humans cause osteogenesis imperfecta. Deletion of the Sp7 gene in developing chondrocyte blocks endochondral ossification. Sp7 role after chondrocyte hypertrophy and during postnatal chondrogenesis remains unknown. **Methods:** Sp7 gene was deleted in hypertrophic chondrocytes (HCs) by Col10a1-Cre. Endochondral ossification was analyzed in littermates from birth to 3 months, using molecular, biochemical, histological, and spatial transcriptomics. **Results:** We first confirmed Col10-Cre activity is restricted to HCs by using Td-reporter mice. Homozygous (Sp7^{HC/HC}) mice survive and exhibit comparable endochondral ossification to their WT littermates at birth. The length of the growth plate and hypertrophic zone is increased in the femurs of P3, 1- and 3-month-old Sp7^{HC/HC} mice. A decrease in caspase-3 and an increased Bcl2/Bax ratio revealed that Sp7 promotes apoptosis of HCs. Alcian blue/Saf-O staining showed a retention of cartilage in Sp7^{HC/HC} mice during postnatal development. Consistent with these observations, qPCR showed a significant decrease in the expression of collagenases (Mmp9, 13) and aggrecanases (Admts4, Admts5). Xenium in situ analysis established spatially decreased expression of these enzymes in Sp7-deficient HCs. Surprisingly, μ CT analyses revealed a 2-fold increase in trabecular bone mass at 1-month and 3-fold increase in adult Sp7^{HC/HC} mice. The increased bone mass is not linked to osteoblast activity, as histomorphometry, dynamic labeling, and qPCR showed that osteoblast numbers, bone formation/mineral apposition rates, and gene expression are comparable among littermates. Surprisingly, the number and surface area of Trap⁺ osteoclasts decreased in Sp7^{HC/HC} mice. The qPCR and Xenium analyses revealed a reduction in the expression of Rankl, Trap, Ctsk, and Car2, indicating impaired osteoclast differentiation. **Conclusion:** Sp7 regulates trabecular bone mass by controlling the expression of signaling factors and enzymes in hypertrophic chondrocytes.

Abstract Name: Investigating TP53 Codon 238 Mutations Through CRISPR Genome Editing and Computational Protein Analysis

Cancer remains one of the leading causes of mortality worldwide, and mutations in Tumor Protein 53 (TP53), the most frequently altered tumor suppressor gene, play a central role in its onset and progression. While hotspot mutations such as codon 248 are well characterized, codon 238 represents an understudied site with potential to reveal new insights into TP53 dysfunction. This project investigates the structural and functional consequences of missense substitutions at codon 238, determining how they disrupt protein stability and tumor suppressor activity. Using CRISPR-Cas9 genome editing, the codon ACA at position 238 is targeted in HEK293 cells to introduce pathogenic variants. The experimental workflow includes guide RNA design, single-stranded donor template construction, transfection, PCR amplification, and Sanger sequencing to confirm edits. Protein-level validation is optionally performed via western blot to assess expression and stability, providing empirical insight into the consequences of the mutation. Complementing wet-lab experimentation, this study employs web-based structural biology platforms such as AlphaFold, Ensembl Variant Effect Predictor, and SwissSidechain to model and compare wild-type versus mutant TP53 conformations. These tools visualize how single nucleotide substitutions alter protein folding and offer insights into disrupted tumor suppressor activity. By integrating CRISPR-based genome editing with computational modeling, this project provides a dual lens: empirical validation of cancer-associated variant and theoretical exploration of its structural impact. This project shows how combining lab experiments with computer-based modeling can give a fuller picture of how genetic changes drive cancer. By editing TP53 in cells and then predicting how the mutations reshape the protein, we connect genotype to function in a way

that is both practical and insightful. By connecting lab-based genome editing with structural modeling, the project deepens the understanding of genotype–phenotype relationships in cancer and highlights the value of integrative strategies.

Abstract Name: Healthcare Workplace Compassion Practices and their Associations with Patient – Care Provider Therapeutic Connections

Background: Patient-centered care is a defining element of healthcare delivery. Both healthcare organizations and providers are interested in ways they can improve patient experiences. Previous research has demonstrated that better patient health outcomes and satisfaction are associated with patients experiencing a therapeutic connection (TC) with their provider; yet there is little knowledge about factors that may strengthen TCs. However, related research has found positive associations between workplace compassion practices and outcomes for both patients and providers. Workplace compassion means that an individual notices someone in distress and acts to reduce their suffering. Compassion practices are ways of organizationally encouraging and normalizing expressions of compassion between coworkers. Purpose: We investigate the association between workplace compassion practices and healthcare clinicians' perceptions of TCs and two mechanisms through which workplace compassion practices may operate: psychological safety (PS) and perspective taking (PT). Workplace compassion practices are expected to be associated with PS because they likely elicit feelings that workers will not be penalized for expressing distress or supporting others who are suffering. In turn, feeling safe is likely positively associated with PT because other's perspectives are more likely to be heard and understood (i.e., empathy), which is an important component of TC. Method/Results: We conducted a cross-sectional survey of healthcare providers (n=341). Serial multiple mediation regression models were employed to test the association between compassion practices and TC directly and indirectly through the sequential mediators of PS and PT. Associations between compassion practices and TC were significantly mediated by PS and PT. Conclusion: Although we cannot infer causation from this study, it suggests that organizational compassion practices are associated with better patient-provider TCs through PS and PT. It provides preliminary evidence to incentivize organizations to adopt workplace compassion practices.

Abstract Name: Slain as an Italian, Revived as a "Turco": How One Diaspora Inspired a Global Literary Movement

I researched an unexamined mystery in Colombian author and Nobel Prize winner Gabriel Garcia Marquez's "Chronicle of a Death Foretold" (1981). This novel, reconstructing an honor killing that haunted the author for decades, catalyzed a global literary movement combining journalistic documentation with fictional

dramatization. When writing for the Sunday Times on October 24, 1982, Salman Rushdie praised Garcia Marquez's spectacular imagery. The biography of record by Gerald Martin from 2008 indicates the real-life victim was the son of Italian immigrants, but doesn't contemplate why the protagonist shifted from being Cayetano Gentile, to the son of an Arab immigrant, Santiago Nasar. To answer this question, I engaged in archival and secondary source research to cast light on the Middle Eastern immigrant community of early twentieth-century Colombia. I studied the author's papers held at the Harry Ransom Center at the University of Texas, examined census and immigration records from the Colombian government's official statistical collection agency (DANE), and read secondary sources on the Middle Eastern Diaspora. In the end, my analysis of Garcia Marquez's exploration of Arab identity in Colombia sheds light on broader questions of assimilation and cultural interactions around the world. Can immigrants ever fully be part of the societies they have sacrificed to call home?

Abstract Name: A Hybrid Classical and Quantum Side Channel Attack on Kyber 512

Kyber is a Module-Lattice based Encryption (Module-LWE) scheme recently standardized as MLKEM-512 for post-quantum security. In deployed systems it is wrapped in the Fujisaki Okamoto (FO) transform where decapsulation re-encrypts the recovered message to check ciphertext validity. In real hardware this FO decapsulation step leaks power or electromagnetic information which can be processed into a noisy "plaintext-checking" oracle, for a chosen ciphertext, it tells the attacker with some error probability whether the decrypted message equals a target value. This work asks how much such FO leakage can weaken Kyber512 and constructs a concrete hybrid classical-quantum key recovery pipeline. I first model each oracle response as a bit sent over a binary symmetric channel, design special ciphertexts such that each query reveals a sparse linear constraint on the secret key bits, and then collect many queries to get an LDPC system. I apply belief-propagation decoding, a standard iterative algorithm from coding theory, to recover most of the roughly 1,500 secret bits using only a few thousand oracle queries. The remaining uncertain bits are encoded as a QUBO problem, equivalent to an Ising spin model. We solve this residual problem using a quantum annealing style optimizer and a constraint aware multi-qubit correction step that explicitly enforces LDPC parity checks and encoding consistency. Finally, a blockwise phase uses a small number of additional oracle queries to detect and locally repair any remaining errors in blocks of the key. By comparing the total work of this leakage-assisted attack to standard primal lattice attacks on Module-LWE, We show that realistic FO leakage effectively reduces the underlying lattice dimension and lowers Kyber512's practical security level. This provides an end-to-end, quantitatively case study of how side-channel leakage and quantum inspired optimization can interact against post quantum cryptography.

Abstract Name: Low Concentration Locomotor Activation by Ethanol in *unc-13* Mutant *C. elegans*.

Alcohol Use Disorder (AUD) is a serious disease that affects millions worldwide and is the result of a combination of genetic and neuroadaptive causes. Our research aims to gain a deeper understanding of the molecular mechanisms underlying changes in synaptic transmission induced by ethanol. We are particularly interested in the effect of low concentration ethanol, because the low dose disinhibiting effects are thought to contribute to problematic drinking. The nematode *Caenorhabditis elegans* was used as our model because their nervous system is highly conserved with mammals, making them particularly useful for studying fundamental neuronal mechanisms. To explore the mechanisms involved in ethanol-induced changes in synaptic transmission, we analyzed behavioral responses to low concentration ethanol in wild-type and synaptic transmission-defective *C. elegans*. UNC-13 is required for the priming of synaptic vesicles, and *unc-13(e1091)* mutant animals are paralyzed. To better understand how locomotion in *unc-13* mutant animals changes with ethanol compared to basal conditions, we assessed locomotor activation using two approaches: a grid assay, to count the number of grid squares the animals entered based on their tracks, comparing ethanol-treated movement to baseline, and video-recording analysis (WormLab) to measure worm speed and distance travelled under basal and ethanol-treated conditions. We found that *unc-13* mutants display significantly increased locomotor activity in response to ethanol. This increase in locomotor activation was observed in both the grid assay analysis and in track maps generated from video recordings. Overall, these findings suggest that low doses of ethanol can bypass the UNC-13-dependent process in synaptic vesicle priming. We are now working to understand how ethanol is bypassing the function of UNC-13, and we will describe these results.

Abstract Name: 2025 SNAP Lapse, Stability or Collapse? An Analysis of Impacts on Tribal Communities and Grocery Decision-Making in Oklahoma

Recently, the lapse of funds for the Supplemental Nutrition Assistance Program (SNAP) during the most recent government shutdown caused unexpected turmoil for consumers. This was especially seen in states that have the highest levels of food insecurity, Oklahoma being one. In this research, we assess this unique policy occurrence to study how the change in food access affected food choices at grocery stores. We analyze items purchased across Oklahoma to determine the influence of the SNAP lapse on consumers using product-level data from NielsenIQ. Our purpose is to deduce how consumers' decisions change in response to the lapse, with some substituting to less expensive products while others substitute to no products at all. In our regression analysis, we measure how varying demographics change purchasing behaviors, for instance the difference between areas with large tribal presence, and differences in urban and rural areas, which may have many food pantries or other nonprofit organizations compared to areas facing food deserts. This work has important ramifications as it measures how the sudden and unexpected change in SNAP affects adequate food intake.

Abstract Name: Investigation of Biofilm Formation and Osmotic Stress Tolerance of Nonmotile *Escherichia coli* in Simulated Microgravity

Simulated microgravity presents multiple physiological stressors for astronauts, including bone demineralization, muscle loss, and weakening of the immune system. Bacteria serve as viable model organisms to study physiological changes because of their abundance in the human digestive system and skin. Motility in bacteria plays a significant role in cell survival, but few studies have been conducted on microgravity's effect on motility phenotypes. While motile strains like *Escherichia coli* K12 have been studied extensively under microgravity conditions, the effects of simulated microgravity on non-motile strains are largely unknown. To better understand this relationship, the nonmotile *E. coli* MG1655 strain was inoculated and exposed to simulated microgravity via a 2D clinostat to study growth, biofilm development, and behavior under osmotic stress conditions. Results from this experiment suggest significant changes in phenotypical expression occur in a microgravity environment, which presents potential implications for adverse effects to the human gut and skin microbiota like increased cell inhibition and virulence.

Abstract Name: Sex differences in the heritability of posttraumatic stress disorder, substance use disorders, and their comorbidity: a systematic review.

Background: Posttraumatic stress disorder (PTSD) and substance use disorders (SUD) frequently co-occur, are both moderately heritable, and have correlated genetic risk. Despite established sex differences in both PTSD and SUD prevalence, it remains unclear whether these sex differences are in part due to differences in genetic risk (i.e., if heritability estimates or genetic correlations differ between males and females). Clarifying these sex-specific patterns has important implications for understanding risk of PTSD and SUD co-occurrence, as well as informing prevention and treatment strategies. Objectives: This systematic review of the human literature examines whether existing behavioral genetic (twin/family-based) and molecular genetic (SNP-based) studies provide evidence for sex differences in the heritability of PTSD, SUD, or their genetic correlation. Methods: Searches were conducted through PubMed and PsycINFO, yielding 132 studies prior to screening. Studies were uploaded into Covidence for blinded review by the research team. Title and abstract screening applied hierarchical exclusion criteria, removing studies that were non-empirical, animal-based, did not assess our phenotypes of interest, concerned unrelated comorbid conditions, used single-sex samples, treated sex only as a covariate, did not report sex-specific heritability estimates, or did not estimate genetic variation. Full-text screening is currently in progress, and data will be extracted from eligible studies (expected $n = \sim 40$). Results: Although this study is still in progress, the review aims to synthesize existing evidence on sex-specific heritability to clarify the role of sex in the genetic influences on PTSD, SUD, and their co-occurrence. Conclusions: The completed work will identify current gaps in the literature, highlight areas where sex-specific data are limited, and provide direction for future research on the genetic and environmental pathways that shape risk across sexes.

Abstract Name: Restoring Balance in Lake Sagatagan: An Adaptive Management Plan for Improving Panfish Size, Predator Structure, and Angling Quality

This project investigates the central question of what ecological and management factors are driving long-term panfish stunting and predator imbalance in Lake Sagatagan, a 227-acre mesotrophic lake in central Minnesota, and how an adaptive management framework can restore a healthier, more sustainable fish community. Situated on the Saint John's Abbey and University property, the lake offers a unique case in which private governance, limited access, and shifting ecological conditions intersect. Existing research on bluegill stunting, predator-prey dynamics, and selective angler harvest provides essential context, yet few studies examine how these processes operate within privately managed lakes where institutional values, such as preservation and low intervention, shape management outcomes. This study aims to contribute to that gap by integrating ecological assessment with a historical and institutional analysis of local decision-making. Field methods included angling-based bluegill sampling, otolith crack-and-burn aging to evaluate growth rates, and comparison with regional benchmarks. Predator size structure and abundance were examined using catch-per-unit-effort data from previous surveys. Historical records and management narratives were analyzed to understand how past practices influenced present-day conditions. Results indicate slow early-life bluegill growth, high recruitment into intermediate size classes, limited representation of preferred-size fish, and an abundance of small northern pike, together reflecting a system characterized by density-dependent stunting and inefficient predation. These findings will be discussed in relation to institutional stewardship philosophies and the ecological mechanisms that reinforce imbalance. The project concludes by proposing an adaptive, multi-phase management strategy involving predator restructuring, modified harvest approaches, and long-term monitoring. This framework not only targets Sagatagan's specific challenges but also offers insights applicable to other small, low-access Minnesota lakes seeking data-driven, ecologically grounded management solutions.

Abstract Name: Therapeutic Use of Hydrocortisone in Neonates: Outcomes and Trends

Hydrocortisone (HC) is increasingly used off-label in neonatal intensive care units (NICUs) to prevent or treat bronchopulmonary dysplasia (BPD), a major cause of morbidity and mortality in extremely preterm infants. However, clinical practices surrounding HC administration remain variable, particularly regarding the

timing of treatment. This study aimed to characterize national trends in HC use from 2010–2022 and evaluate differences in infant characteristics and outcomes associated with early versus late HC administration. We conducted a retrospective cohort study of extremely preterm infants discharged from 323 NICUs across the United States. Deidentified data were extracted from the Pediatrix BabySteps Clinical Data Warehouse. Infants were categorized into three groups: no HC treatment, early HC (first dose ≤ 7 days of life), and late HC (first dose ≥ 8 days). Demographic variables, comorbidities, interventions, and clinical outcomes were compared using chi-square testing, and annual trends were assessed using a nonparametric trend analysis. Among 76,617 infants, 68,171 received no HC, 4,438 received early HC, and 4,008 received late HC. Infants treated with HC had substantially lower gestational age and birthweight than untreated infants. BPD occurred in 20% of the no-HC group, 34% of the early HC group, and 62% of the late HC group. Compared with untreated infants, those receiving HC exhibited higher rates of complications such as necrotizing enterocolitis, intraventricular hemorrhage, and spontaneous intestinal perforation. Early HC use rose significantly over the study period, while late HC use remained stable. Treatment duration was generally shorter in the early HC group. These findings suggest that increasing early HC use may reflect growing confidence in its role in reducing BPD among high-risk infants. However, substantial differences in baseline risk between groups highlight the need for prospective studies that control for gestational age and birthweight to more clearly evaluate the independent effects of HC treatment.

Abstract Name: The Loneliness Epidemic: Exploring the Relationship Between Social Connectedness and Misogynistic Attitudes

Limited research has explored how loneliness may contribute to more subtle or everyday forms of misogynistic attitudes within general, non-radicalized populations. Understanding how traditional gender ideologies structure experiences of loneliness and shape misogynistic beliefs is necessary to inform effective prevention efforts. This study addresses this critical research gap by investigating the early psychosocial mechanisms that may precede extremist radicalization. We further explore how gender identity might influence or moderate this relationship. To guide our research, we pose two central research questions: Does a correlation exist between self-reported levels of social connectedness, loneliness, and misogynistic attitudes? Are there demographic variables, such as gender and age, that moderate this relationship? Informed by the existing literature, we hypothesize that there will be a relatively strong, positive correlation between self-reported levels of social disconnection, loneliness, and misogynistic attitudes. We also predict this correlation will be stronger among men, due to gendered socialization and masculinity norms. This study will assess three main constructs using validated measures: loneliness, social connectedness, and misogyny, in addition to collecting demographic information. All participants will answer the same items in the same order. Descriptive statistics will be used to characterize the sample, and bivariate correlations will assess the relationship between social connectedness and misogynistic attitudes. Multiple and hierarchical linear regression analyses will be conducted to evaluate the potential predictive and moderating roles of demographic variables. Full analytic procedures, including planned regression and moderation analyses, will be conducted upon completion of the target sample and presented at NCUR if this submission is accepted.

Abstract Name: Development of a Doxorubicin derivative to Minimize Heart Failure Risk While Retaining Anticancer Efficacy

Doxorubicin is a widely used chemotherapy drug, but its use is limited due to its cardiotoxicity. This toxicity results from doxorubicin's strong affinity for the Ryanodine Receptor 2 (RYR2) calcium release channel. When doxorubicin binds to RYR2, it alters the channel's conformation, causing it to adopt a quasi-open, or leaky, state. This leads to calcium leakage, disrupting the heart's ability to maintain sinus rhythm and ultimately causing heart failure. Because of this, and because of its red color, doxorubicin is sometimes called "red death." The goal of this project is to develop a doxorubicin derivative that retains its anti-cancer properties while reducing its interaction with RYR2. To achieve this, I plan to use a ³H Ryanodine binding assay. The assay will help determine the activity of RYR2 while also being bound to Doxorubicin, to assess the effects the drug has on the protein. Once we have determined how the drug alters the protein's activity, I plan to use a combination of cryo-electron microscopy complemented with 3D modeling. Cryo-EM will help determine where the drug specifically binds to the protein. Then, I will use 3D modeling software such as Chimera and Pymol to analyze the structural features of the site of interaction between Doxorubicin and RYR2 and analyze any conformational changes derived from Doxorubicin binding. If time permits I hope to use the Surface Plasmon Resonance (SPR) to determine the binding affinity of a new drug derivative provided by a collaborator. This comprehensive approach will provide valuable insights into the drug's binding characteristics and the potential of its derivatives to reduce cardiotoxicity while preserving its anti-cancer efficacy.

Abstract Name: Charles Manson as a Prototype Psychopathic Offender: A Forensic Imperative to Identify Serial Homicide by Proxy

This project examines Charles Manson through a forensic-psychological lens to challenge the persistent cultural framing of him as merely a manipulative cult leader. The central research question asks: Can Charles Manson be understood as a prototype psychopathic offender whose behavior meets the forensic criteria for serial homicide even without direct physical participation? Grounded in forensic and criminological theory, the study situates Manson within contemporary research on psychopathy, coercive control, and organized serial violence. Methodologically, the project employs a qualitative forensic case analysis synthesizing archival evidence, psychological evaluations, court records, and secondary criminological sources. Manson's psychological assessments reveal traits of dominance, sadism, and manipulative charisma consistent with the Psychopathy Checklist-Revised (PCL-R). Comparative analysis with Ted Bundy highlights shared features of organized psychopathy—planning, control, and exploitation of systemic blind spots—demonstrating how Manson's orchestration of murder through subordinates constitutes as "serial homicide by proxy." Findings indicate that forensic and historical evidence—disappearances of associates, reports of desert graves, and patterns of symbolic violence—suggest additional uncharged homicides aligned with the dark-figure-of-crime framework. The research identifies systemic investigative failures, including fragmented jurisdiction, neglect of marginalized victims, and underestimation of psychopathy as a predictor of lethal violence. This study concludes that Charles Manson represents a critical forensic prototype: a charismatic psychopathic

orchestrator whose violence was psychological, organized, and premeditated. Recognizing such offenders requires expanding the definition of serial homicide to include those who kill through manipulation rather than direct action. By reframing Manson as a forensic warning rather than a cultural relic, this research contributes to improving early risk assessment, strengthening investigative collaboration, and preventing future manifestations of organized psychopathic violence.

Abstract Name: Discovering Multiple Anti-Lipopolysaccharide Factor Variants in the Atlantic Blue Crab

The Atlantic Blue Crab, *Callinectes sapidus*, is an ecological and economic marvel in the Chesapeake Bay, and their harvest here provides 50% of the commercial crabs sold across the United States. Despite this, recent reports show a steady decline in the natural population due to environmental causes that are further exacerbated by poor water quality and increased bacterial levels. This study focuses on anti-lipopolysaccharide factor (ALF) genes found in the blue crab genome responsible for innate immune defense. Anti-lipopolysaccharide factors are antimicrobial proteins that play a crucial role in identifying and neutralizing foreign bacteria. Initial phylogenetic analysis demonstrated that these genes in *C. sapidus* are closely associated with previously verified ALF genes in the related crab, *Portunus trituberculatus*. The 102 available sequences were analyzed to determine six novel gene loci in *C. sapidus*. Multiple sequence alignment further revealed conserved regions within the identified ALFs, including the conserved cysteine–cysteine disulfide bridge. This structural motif is widely recognized for its contribution to protein stability. Additionally, a protein structure prediction server representation shows conservation across all six sequences, highlighting its importance in maintaining ALF form and function. Overall, this study aims to establish a foundation for future research to improve the understanding of immune defense strategies in marine invertebrates for the development of disease management techniques in the aquaculture and fishing industry.

Abstract Name: Understanding the parasite Didymozoida within Atlantic Mackerel (*Scomber scombrus*)

Parasites play essential ecological roles in marine food webs and can serve as indicators of ecosystem health, yet their impacts on some commercially important fish species remain understudied. Atlantic mackerel (*Scomber scombrus*) in the western North Atlantic host trematode parasites resembling members of the Didymozoida, a group with complex multi-host life cycles. Published records of Didymozoida in western Atlantic mackerel are lacking despite high levels of infection proportions in local collections. This study aimed to characterize parasite communities in mackerel from two sites, Cape Cod and the Isles of Shoals, to identify factors influencing infection patterns and parasite development. Between June and August 2025, mackerel were collected from Massachusetts and Maine waters. Fish were measured, weighed, sexed, and

examined for didymozoid cysts in the mouth, operculum, and associated structures. Individual worms were extracted, measured, and scored for egg maturity, and subsets were massed to generate a length–mass index. High infection intensity (average 6.26 cysts per fish) was observed across all samples. Apparent differences between sites were attributed to fish size structure rather than location. A significant positive relationship was found between fork length, weight, and infection, while a negative relationship was found between condition factor and infection. Infection was more likely to be found on the opercula and pharyngeal teeth, though the pharyngeal teeth contained larger and more mature worms, suggesting this structure might be the primary infection site. No secondary or tertiary infections occurred without concurrent infection at these locations, indicating infection is likely occurring through digestive means. We are currently performing genetic analysis of the parasitic worms to determine species identification. This study is one of the first to provide data on the host-parasite interactions of a didymozoid in the western stock of Atlantic mackerel.

Abstract Name: The Choices Athletes Make, and the Regret They Face

Regret is a cognitive-based emotion arising when individuals compare real outcomes with better alternatives that could have occurred (Roese & Summerville, 2005; Zeelenberg, 2007). Regret research demonstrates a temporal pattern: actions tend to elicit greater short-term regret, whereas inactions often produce stronger prolonged regret—particularly when correction is no longer available (Gilovich & Medvec, 1995; Gilovich & Chen, 1995). Shaping this pattern is the perceived future opportunity principle. Beike and colleagues (2009) argue that lost opportunity predicts the strongest regret, whereas Roese and Summerville (2005) report that regret is often greatest in high future opportunity. The current study seeks to address conflicting results by examining both perceived future opportunity and the nature of the triggering decision (actions vs. inactions). The present study focuses on athletes, a unique contribution. Although regret has plenty of thorough studies, little research examines athletic decision-making. Athletes make rapid, high-stakes decisions under pressure and are continually evaluated for both their actions (e.g., taking a risky shot) and inactions (e.g., hesitating and missing an open opportunity). Yet little is known about when athletes experience more regret: during competition, when future opportunities remain, or after the game, when outcomes are fixed. Studying athletic decision-making, the current study can offer a potential resolution to the conflicting findings in the regret literature. We will use a vignette-based paradigm in which athletes rate the regret they would experience by imagining scenarios either at halftime or after the final whistle. The design adopts a 2 (Decision Type: Action vs. Inaction) $\times$ 2 (Perceived Future Opportunity: High vs. Low) between-subjects framework to assess regret intensity. Consistent with research, we predict (1) overall stronger regret after the game, given the loss of future opportunity (stronger inaction-based regret after the game); (2) action-based regret will be more intense during halftime (actions elicit greater immediate regret).

Abstract Name: Mindfulness: Learning to Accept the Past

Regret is a counterfactual emotion that arises when individuals compare an actual outcome to a more desirable alternative that “could have” occurred (Kahneman & Miller, 1986). Prior research demonstrates that regret is associated with anxiety, depression, and persistent rumination (Markman et al., 2009). Individuals high in evaluative-concerns perfectionism—characterized by heightened fear of mistakes and self-critical tendencies—may be particularly vulnerable to regret-related distress (Bergman et al., 2007; Stoeber et al., 2007). Mindfulness, defined as nonjudgmental present-moment awareness (Kabat-Zinn, 2003), has been shown to reduce rumination and promote emotional acceptance. This proposed project will examine whether brief mindfulness practices reduce regret and whether perfectionistic tendencies moderate this effect. All participants will first be asked to recall a regretful personal event. They will then complete pre-intervention measures, including emotional ratings (regret, sadness, responsibility) as well as the short 5-Facet Mindfulness Scale (Baer et al., 2006) and the Self-Compassion Scale (Neff, 2019). Participants will then be randomly assigned to either a mindfulness condition or a control condition. Those in the mindfulness condition will listen to a guided audio recording promoting present-moment awareness and nonjudgmental reflection; those in the control condition will complete a matched-duration neutral activity. Afterward, all participants will complete post-intervention measures, including the same mindfulness and emotional ratings to assess changes in regret. We expect that participants in the mindfulness condition will report reduced regret compared to those in the control condition. Additionally, we anticipate a moderation effect such that the benefits of mindfulness will be strongest among individuals high in evaluative-concerns perfectionism, who may struggle most with self-critical rumination. By integrating self-report measures with an experimental design, this study aims to clarify whether brief mindfulness practices can help individuals regulate emotional responses to regret—particularly those with perfectionistic tendencies.

Abstract Name: Counting Visually Distinct Placements of Possibly Overlapping Axis-Aligned Rectangles on Finite Grids

Much of the work on tiling with shapes requires that their placement avoid gaps or overlaps. This work investigates visually distinct ways axis-aligned shapes can be arranged on a finite grid that allows both. Although specific counting techniques exist for special cases, general methods for systematically characterizing all such arrangements remain limited. This study develops a structured hybrid approach that combines closed-form counting formulas with a geometric region-decomposition algorithm to enumerate all visually distinct placements of two shapes on a grid. Our approach begins with closed-form formulaic expressions for counting placements of each individual shape, including all distinct orientations. It then incorporates configurations in which the shapes overlap, including situations in which one shape becomes obscured by the other when viewed from above. Next, it considers arrangements where the shapes remain separate but produce identical visible patterns regardless of placement order. The core algorithm analyzes the free space surrounding a placed shape by partitioning the grid into a collection of sub-regions that capture all possible placements of the second shape. By combining these closed-form components with this geometric region decomposition, the method accounts for all cases that must be included or excluded to obtain the total number of top-down distinct arrangements. Our complete algorithmic approach operates in linear time with respect to the grid area, a substantial improvement over brute-force enumeration, which requires quadratic time by evaluating all ordered placement pairs. Complete brute-force generation of all arrangements was

implemented to verify correctness. This work provides a rigorous, efficient, hybrid formulaic–algorithmic technique for enumerating all top-down visually distinct shape placements on discrete grids.

Abstract Name: Detecting AI-Generated Text: An Interpretable Multi-Pipeline Analysis Across Stylometric, TF-IDF, and Transformer Representations

This study investigates differentiating human-written text from AI-generated text. The rise of AI-generated writing raises concerns for academic integrity, authorship attribution, and plagiarism detection. Our work addresses the growing need for detection methods that are accurate, interpretable, and grounded in measurable linguistic evidence by asking a central question: what linguistic and representational patterns most reliably distinguish AI-generated writing from human writing across different modeling approaches? We evaluate four supervised modeling pipelines: stylometric features with machine learning models (logistic regression, support vector machines, random forests, and gradient-boosted trees); word- and BPE-level TF-IDF representations with linear, kernel, and neural classifiers; fine-tuned transformer models; and a tokenizer-controlled TF-IDF pipeline using logistic regression and support vector machines to isolate vocabulary effects. A balanced dataset of 10,000 English texts was compiled from public sources, covering essays, creative writing, QA, paraphrasing, and summarization. The fine-tuned RoBERTa model performed best, achieving 0.925 accuracy. Stylometric models reached 0.77 to 0.85, while TF-IDF pipelines achieved 0.76 to 0.80. The tokenizer-controlled TF-IDF experiment improved model performance to 0.81, demonstrating the influence of representation. These pipelines allow us to ask whether detection accuracy is driven by model choice or the underlying feature representation used to encode text. Interpretability analyses, including SHAP, LIME, PDPs, TF-IDF contribution maps, and transformer attributions like attention and integrated gradients, showed that stylometric and TF-IDF features capture only broad linguistic tendencies without clearly separating human and AI texts, a pattern confirmed by unsupervised clustering. In contrast, t-SNE visualizations of RoBERTa embeddings revealed distinct separation driven by deeper semantic and structural signals. Moving beyond recent work that treats AI-text detection primarily as a classification problem, our study emphasizes the importance of understanding the representational signals behind predictions, underscoring the value of interpretability and evidence-based reasoning for developing more transparent and reliable detection systems.

Abstract Name: Intraday Capital Reallocation from Climate Disclosure: Evidence around CDP Score Releases

This article investigates how publicly released climate-related disclosure influences intraday capital allocation. It exploits the institutional design of a centralized, embargoed release of climate scores, ensuring simultaneous disclosure across firms and creating quasi-experimental variation in information arrival. The study constructs a high-frequency panel of U.S. large-cap equities, aligning intraday abnormal net order flow

and liquidity metrics to the release day, and partitions the trading session into fine-grained intervals (1-minute and 20-minute blocks) to identify when and where information is impounded. To isolate genuine disclosure effects from firm characteristics or recurring liquidity cycles, two placebo tests are employed. The “random-score” design permutes firms’ scores while preserving timing (breaking the firm–score link), and the “random-date” design preserves scores but randomizes disclosure dates (breaking timing synchronization). Together, these test whether any intraday pattern stems from synchronized, credible disclosure rather than background noise. Results show rapid capital reallocation within minutes: abnormal buying pressure is minimal or slightly negative at the open, flat through midday, then becomes economically and statistically significant in the final trading blocks before the close: consistent with investors delaying execution to the closing auction to exploit imbalance signals. The effect remains robust, controlling for liquidity and volatility, and disappears under both placebo designs; over multi-day horizons, little to no systematic drift emerges, aligning with semi-strong efficiency in which public signals are digested primarily through within-day order flow and depth rather than through prolonged post-event drift. By moving from day-level to trading-clock resolution, it isolates where within the session climate information is actually impounded and separates opening noise from pre-close rebalancing dynamics. By aligning minute-level flows with CDP’s strict embargo window and exploiting the closing-auction microstructure, the article closes a key empirical gap in understanding how, when, and through which microstructure channels climate transparency influences capital allocation within the day.

Abstract Name: Predictive Scour Analysis for Seasonal Flooding in the Sahel: Mitigating Climate and Humanitarian Risk

In response to the global rise in extreme weather driven by climate change, this study develops a predictive hydrological simulation framework for the Sudanese Nile Basin of the Sahel region. The region faces escalating threats from increasingly destructive seasonal flooding of the White and Blue Nile rivers, such as scouring endangering vital infrastructure. The primary objective is to obtain bridge scour results for the White Nile Bridge, Halfaya Bridge, and critically, the Al-Manshiya Bridge. The Al-Manshiya bridge had collapsed due to excessive scouring from the Blue Nile river and thus became a popular interest of study for scour analysis. With previous research from other studies to cross-referenced the scour analysis from HEC-RAS, the author develops a predictive simulation framework using HEC-HMS and HEC-RAS to model scouring for key local bridges such as Al-Manshiya’s neighboring White Nile Bridge, and the Halfaya Bridge downstream that takes both the White Nile river’s gradual flow and Blue Nile river’s rapid flow. The critical depths are also predicted by the software and confirmed with calculations to be considered for future hydraulic structure designs. The findings offer actionable data designed to enhance regional early warning systems for extreme hydrological events. This data will directly guide the necessary climate-resilient design for hydraulic structures within the vulnerable Nile Basin, thereby minimizing future infrastructure loss and improving regional resilience.

Abstract Name: Apical-Out Lung Organoids: A Platform for Spaceflight and CF Research

A genetic condition known as cystic fibrosis (CF) is brought on by mutations in the CFTR gene, which results in chronic lung inflammation and impaired chloride ion transport. CF bronchial epithelial cells enable direct comparison of disease pathology, while normal human bronchial epithelial (NHBE) cells offer an essential model for researching airway physiology. Realistic modeling of respiratory tissue and its reaction to environmental stressors like microgravity is made possible by the creation of 3D lung organoids from these cells. In this project, we developed apical-out organoids, which expose the apical surface of epithelial cells to the external environment. These organoids offer a powerful platform for studying host–pathogen interactions, mucociliary clearance, and drug response in a physiologically relevant orientation. This configuration closely mimics the in vivo airway environment and enables dynamic modeling of how external stimuli affect airway surfaces. The objective of this project is to identify the differences in structure, development, and function between NHBE and CF lung organoids, as well as how microgravity changes their shape, differentiation, and gene expression. NHBE and CF cells were cultured to primary human bronchial epithelial cells. Brightfield microscopy at 4X and 10X magnification was used to observe morphological changes at several time points during differentiation. To assess cellular organization, organoid types will be tested under altered gravitational conditions. Early organoid formation is successful by Day 4, and epithelial structures are more defined by Day 6, according to preliminary observations. We anticipate that CF lung organoids will exhibit more structural and functional abnormalities when exposed to microgravity. In addition to advancing our understanding of CF pathophysiology, understanding how bronchial epithelial cells react to microgravity is crucial to maintain astronauts' respiratory health during prolonged space travel.

Abstract Name: Consumers and the Machine: Effects of Human Input in AI-Personalized Recommendations

AI-powered recommenders now shape discovery and choice in streaming and e-commerce, yet consumers differ sharply in how they perceive and use them. Prior literature explores how AI-powered recommendations can be optimized for consumers, with some of the main factors being trust, transparency, and accuracy. Research also indicates that the product type heavily influences how consumers perceive and interact with AI-powered recommendations, with material goods AI recommendations perceived as more trustworthy compared to experiential product AI recommendations. We examine (1) how to improve AI recommendations with experiential products, (2) whether the addition of human input increases trust, perceived usefulness, purchase intention, and (3) the impact of individual preferences on consumer perceptions of AI-powered recommendations. We use a one-way factorial design in an A/B test with two AI-powered recommendation concept design variations. Participants will be randomly assigned to two levels: (1) a basic AI-powered recommendation for an experiential product or (2) a copy of the first design with the addition of human input, such as human reviews. Outcomes include trust, perceived usefulness, and purchase intention, with covariates including familiarity with AI, adoption, and product-related preferences. Findings from this experiment will explore how different types of recommendations can be further optimized for consumer decision-making and highlight the importance of adding human input to AI systems.

Abstract Name: Developing Classroom-Ready Cloud Chambers for Observing Charged Particle Tracks

This project investigates the feasibility of constructing cloud chambers of multiple scales, ranging from compact dry-ice diffusion systems to a larger 55-gallon demonstration chamber, to create stable supersaturated environments for visualizing ionizing radiation. Both designs use alcohol vapor saturation and controlled cooling to generate conditions in which charged particles form condensation trails. In the smaller chamber, a temperature of approximately -35°C produced a relative humidity near 200% within the bottom 1in–3in, enabling consistent cloud formation after about ten minutes of setup. Ionized particle tracks and curvature in a 0.5mT magnetic field were observable. The larger chamber focuses on improved temperature regulation, sustained vapor saturation, and optimized illumination to support repeatable classroom demonstrations. Limitations include the quality of environmental sealing and sensitivity to ambient temperature. Together, these designs demonstrate scalable methods for producing reliable, quantitative particle-track visualizations useful for physics and atmospheric science education in laboratory settings.

Abstract Name: Genomic Analysis of Cold-Adapted *Sulfitobacter pontiacus* from Antarctica

The Antarctic region is described as a frigid, oligotrophic environment. During a November 2009 expedition, phytoplankton were observed in the bottom 5 cm of the sea ice cores collected from Ross Sea, McMurdo Sound Station, Antarctica. This study focuses on understanding which type of heterotrophic bacteria are associated with these algae/phytoplankton and whether they have the genomic capacity to utilize these carbon sources. To test this, we used an enrichment culture approach using laminarin and cellobiose as the sole carbon source. The resulting microbial growth was serially diluted and plated on seawater-complete media (SWC), from which four well-isolated colonies (01DW25, 04NG25, 01KJ25, and 01JM25) were selected for pure culture. The 16S rRNA gene was amplified and sequenced. The phylogenomic analysis identified these isolates as *Sulfitobacter pontiacus*. Growth rate estimates on SWC and defined media showed that these isolates did not utilize beta-glucan, suggesting that other microbes had broken down algal polysaccharides into oligo- and monosaccharides (public goods) before isolation. Whole-genome shotgun sequencing and comparative genomic analysis with ANVIO confirmed that the Average Nucleotide Identity (ANI) between the *S. pontiacus* isolates and their closest relative, *S. pontiacus* (GCF_022788675.1), is 97.9%. CAZyme screening showed 22 glycoside hydrolase genes and 37 glycosyltransferase genes. These findings suggest that these psychrotrophic strains have the capacity to break down complex carbohydrates and adopted an energy-conserving strategy called carbon catabolite repression in the lab, which implies that these isolates represent a cheating strain of *S. pontiacus* that likely uses cross-feeding to sustain itself within Antarctic microbial communities, given the inherent costs of resource acquisition in a cold, oligotrophic environment. Future proteomic analyses will investigate specific proteins involved in carbon utilization and environmental responsiveness.

Abstract Name: The Influential Design Philosophy of Alan Fletcher

This paper offers a study of Alan Fletcher's design philosophy of using the world around him as inspiration for design, as well as his tendency to involve humor and playfulness into his work. It goes in depth on the art of observation and gives examples of various projects that he completed that embody that philosophy of his. It discusses the influence that Fletcher left that led to him being described by many as one of the most influential designers of his time, and even being called "The British Father of Graphic Design." This paper discusses his upbringing and education, both in the UK and the United States, as well as his major design partnerships such as Fletcher/Forbes/Gill and Pentagram. The paper uses his book, *The Art of Looking Sideways*, as a unique perspective for understanding Alan Fletcher's influential design philosophies. The book is wide mix of quotations, imagery, wordplay, and puzzles that all come together to portray the way that Fletcher approached projects in both his personal and his professional life. The paper gives an account of his accolades and awards in graphic design and discusses all the organizations that he participated in or founded/co-founded. The review suggests that the influence that Alan Fletcher holds over the graphic design community is not only due to his recognizable projects and logos, but also to his overall attitude towards design and the design process. It argues that his design and life philosophies of observation and humor set a standard for modern designers to follow, and to truly live a life of design.

Abstract Name: The Power of Patience: Delayed Gratification and Regret

Regret research highlights how individuals evaluate their decisions after negative outcomes occur, whether due to an action or inaction. Traditionally, the "action effect" suggested that failed actions elicit stronger regret than inactions (Kahneman & Tversky, 1982). Later findings challenged this view, showing that inaction regrets become more salient over time (Beike et al., 2009; Gilovich & Medvec, 1995). This shift suggests that the temporal dimension of regret—and the ability to manage emotions over time—plays a meaningful role in how people interpret their choices. Delayed gratification offers a useful lens for understanding this dynamic. Mischel's (1989) classic marshmallow paradigm demonstrated that individuals who can postpone immediate rewards in favor of later benefits tend to experience better long-term outcomes, including stronger emotional regulation and greater resilience. These findings point to the idea that difficulty delaying gratification may contribute to later regret: decisions made impulsively for immediate gain may lead to unfavorable outcomes that people come to regret more intensely. Decision-making involves navigating tension between short-term satisfaction and long-term consequences. Individuals who choose immediate pleasure may regret those actions when outcomes fail to meet expectations, while those who delay gratification may regret missed opportunities for enjoyment. This duality illustrates that both actions and

inactions can produce regret, depending on the perceived value of the alternative. Understanding how delayed gratification interacts with regret offers insight into everyday decision patterns. People routinely face situations that require balancing impulse and patience, and their choices shape both emotional experiences and long-term satisfaction. Examining these processes helps explain why individuals sometimes make choices that conflict with their future goals and how practicing self-regulation can reduce later rumination. Ultimately, exploring the connection between delayed gratification and regret deepens our understanding of motivation and decision-making. Recognizing these patterns may help individuals cultivate patience, emotional resilience, and make decisions aligned with long-term well-being.

Abstract Name: Two-Spirit Identity in a Colonized North America

This study examines the identity of Two-Spirit Indigenous people in contemporary North American society. The aim of this study is to show how the Western idea of binaries is not a set rule and highlight the ways in which Indigenous Americans previously had a fluid perception of gender and sexuality within their communities. Contemporary Indigenous Americans have labeled themselves Two-Spirit in order to reclaim the knowledge and culture of their ancestors. The history of Two-Spirit people in pre-colonial Indigenous communities will be a focus of the introduction in order to emphasize the roles these individuals held in their respective communities. In addition, the diminishment and erasure of their importance by European colonizers in their recordings of history will also be discussed. In order to show the importance that culture has in our perceptions of gender, the works of the Indigenous Canadian artist Kent Monkman and the historical American artist George Catlin will be examined to see the history and biases that influence our understandings of gender. The study of the intersectionality of queer people within different communities is important to challenge the ideas that are used to exclude and harm people in contemporary society.

Abstract Name: Madonna: A Representation of Gender Dysphoria

My painting "Madonna" is a visual culmination of the thoughts and feelings I experience about my gender when menstruating. As a nonbinary person, I often feel like my body is betraying me when going through this biological cycle. It can feel like my body is bared open to the world, my biology dictating who I am and how people view me. I wanted to explore the differences in the feelings I have about myself compared to my expectations of how other people view me. I looked at works and artists of the High Renaissance period to convey the sense of idealism present in this period of art. I used the iconographies present in historical paintings of the Madonna to show the idea of femininity that I am disconnected from. I referenced various paintings depicting angels from the Bible to express an androgynous appearance. The figure in my painting is displayed nude in a way that looks forced to contrast with the overall beauty of the image. The painting is done in oil on canvas to achieve the realism achieved in Renaissance paintings. The contrast between the beauty of the piece and the violent feeling of the figure menstruating works well together, and I hope to further the negative feelings by emphasizing the lack of autonomy through physically restraining the body. Gender is a central aspect of my life, and my art is a place for me to depict and talk about my experiences and who I am because of them.

Abstract Name: Systematic Review of Intervention Strategies Implemented for Developing Academic and Professional Writing Skills of Healthcare Students

Academic writing is a critical skill needed by all healthcare students. Healthcare professionals will share their research with their supervisors, other residents, and chair members of the department they're undertaking. Healthcare professionals will frequently uphold leadership roles, with a critical focus on contributing to the science of their professions. Being able to write advanced articles will help not only for their publications, but their professional career. This review was written to provide a summary of articles aimed to strengthen the overall skills of healthcare students, and identify knowledge gaps limiting student's access to academic guidance. The PubMed database was used to find three of the studies included. The VCU Cabel Library Web of Science database was used to find six of the studies. Google Scholar was used to identify one study. The last searched article was found on Nov. 6, 2025. The methods used to synthesize results included meta-analysis, descriptive statistics, thematic analysis, and conceptual models. The data was presented using tables, narrative summaries, interviews, and surveys. There are 10 studies included in this review and a total of 1,036 Participants. Participants were scouted by interviewing and identifying students at medical and nursing colleges who were deemed at-risk, by looking into their background, GPA, MCAT scores, NCLEX scores, publication rates of the university for specific groups (i.e., graduate, and nursing students), and undergraduate transcripts. The study with the most effective intervention was conducted with 159 participants who participated in a Publication Mentorship Program Curriculum. Of the 159 total participants, 84% reported being likely to write to publish in the future, and 96% reported improvements in their writing skills due to the program. The main limitations seen in most studies were delivering meaningful feedback in an adequate timeframe to all participants, given the substantial amount of writing to review.

Abstract Name: Exploring Cognition Through NYT Games

Prior research has shown that participating in cognitive games has the ability to improve cognition and delay one's cognitive decline. Solo games such as crosswords have long been played analogically, and can be played digitally. Murphy et al. (2016) suggest that short focused puzzle activities can improve specific types of verbal fluency. While there are articles released on New York Time's crosswords in the media, there is little academic research examining the actual impact on cognition. This correlational study aims to explore the relationship of someone who plays New York Time's games and their lexical fluency scores. Participants, between the ages of 30 to 60, will be asked to self-report their game playing habits in a series of questions and complete three short timed lexical fluency tasks. It is expected that results will be positively correlated with participants who report frequent game play having higher lexical fluency scores. The findings are anticipated to contribute to growing discussions of New York Time's games and cognition. Furthermore, while causal conclusions may not be drawn, the study highlights that word game play may have links to cognitive functioning worth exploring with larger longitudinal studies.

Abstract Name: The Price of Freedom: America's Privatization of Bodies and Mass Incarceration, a Historical Analysis

The climbing rates of incarceration of Black and low-income individuals are an issue in America. Labor is the backbone of any functioning society, and America has been through many forms of labor to sustain its economy. From using slaves to complete quotas to leasing convicts to develop an area, labor has been a tool used for capitalism to thrive. Labor and incarceration rates may seem like a hard line to connect; however, what if they are one in the same? Race and class find their way into many discussions, especially in politics and the social justice sphere; however, the main issue may stem from the need to supply cheap labor to keep the economy thriving. This project aims to explore the connection between the privatization of labor and how it has aided in the mass incarceration of minority communities. These communities may be disproportionately represented in prisons because of the 'War on Drugs' and minimum sentencing. Black Codes and the Anti-Drug Act may have more in common than originally thought. America demonized blackness and tried its best to wipe it from society; similarly, this can be seen now with drug users and traffickers. Demonizing a certain population can make it easier for people to justify the high rates of incarceration, allowing for private entities to continue to make money without scrutiny or pushback. Privatization in this project will refer to the capitalistic structure and how exploitative labor is the backbone of a capitalistic society. This project will dissect how this capitalistic structure is sustaining the modern Prison Industrial Complex. By finding the line between the privatization of labor/ bodies and the mass incarceration issue, we may be able to find a deeper systemic issue harming minority communities.

Abstract Name: Integrating Machine Learning for Improved Seasonal Forecasting of Coldwater Fish Habitat Stress

Freshwater lakes across the Upper Midwest are experiencing increasing summer warming, which creates stressful low-oxygen and high-temperature conditions for coldwater fish species such as cisco. Managers require reliable seasonal forecasts of this habitat stress, but existing models often rely on linear assumptions that fail to capture the complexity of climate-lake interactions. This study evaluates whether advanced machine learning techniques can significantly improve predictions of Cumulative Viable Habitat Thickness (CVHT), a key metric of coldwater habitat availability. Using a 42-year dataset (1981–2022) of climate teleconnections and in-lake spring conditions, I benchmarked two machine learning models, including Random Forest and Extreme Gradient Boosting (XGBoost), against the established Principal Component Regression (PCR) baseline. Models were trained using leave-one-year-out cross-validation and evaluated with deterministic metrics (R^2 , RMSE) and the probabilistic Ranked Probability Skill Score (RPSS), which measures model skill across the full distribution of Below-Normal, Normal, or Above-Normal habitat years. Across all five study lakes in Northern Wisconsin, XGBoost consistently produced the strongest predictions. In Big Muskee Lake, XGBoost nearly tripled the PCR baseline accuracy (R^2 increasing from ~ 0.28 to ~ 0.68) and achieved substantially higher probabilistic skill (RPSS ≈ 0.77). Similar predictive gains appeared across the other four lakes, demonstrating that the model generalizes well across different lake types. These findings show that climate-driven habitat stress contains non-linear patterns that modern

machine learning methods can capture more effectively than traditional approaches. This project demonstrates a clear path for advancing ecological forecasting by integrating machine learning with seasonal climate information. The results provide a foundation for developing a future decision-support tool that helps fisheries managers anticipate habitat stress, communicate uncertainty, and plan adaptive, climate-resilient management strategies.

Abstract Name: A Nuclear Crossroads: South Korea's Nuclear Stance and the Factors that Shape it

South Korea represents a standard case of latent nuclear power, where nuclear development is constrained by choice rather than capability. In the past, Seoul's rhetoric surrounding nuclear capabilities has ranged from endorsement of a domestic nuclear program to a staunch commitment to nonproliferation. These shifts are shaped by both foreign and domestic factors that reflect Seoul's broader strategic calculations. Through comparative case studies of three key periods in South Korea's nuclear rhetoric, this paper analyzes the main factors that influence the official stance on nuclear development. The first case covers early attempts at nuclear development in the 1970s with Project 890 after the Korean War. The second analyzes the transparency approach of the Roh administration (2003-2007), and its commitment to nonproliferation and the denuclearization of the Korean Peninsula. Finally, case three focuses on the transition from the Moon to the Yoon administrations (2016-2023), identifying the factors that contributed to the reemergence of nuclear discourse. This paper argues that no single factor consistently drives South Korea's nuclear stance. Instead, the nuclear rhetoric is shaped by the combination of global cooperation initiatives, regional tensions with North Korea, international conflicts, domestic politics, and the priorities of the ruling administration. This analysis moves beyond the predominantly US-centric narrative to highlight the broader range of influences affecting Seoul's nuclear discourse. The paper finds that nuclear rhetoric is used as a multi-faceted tool, reflecting both domestic political objectives and strategic responses to a shifting international order. By refining the factors that shape nuclear rhetoric into a trend, future shifts in this policy can be better understood.

Abstract Name: Knives and Normativity: The Self Repression of Peter Walsh in Virginia Woolf's Mrs. Dalloway

In Virginia Woolf's novel, *Mrs. Dalloway*, Peter Walsh can be read as a symbol of patriarchal norms. Feminist researcher and analyst Emel Zorluoglu, argued that, "it is obvious that [Peter] is proud to be a member of and acclaims patriarchy" (78). She, among other academics, suggests that Peter acts as a masculine, imperialist foil to the subversive opposition of Clarissa Dalloway. In this paper, I suggest that this analysis removes him from Woolf's broader conception of the novel and mischaracterizes the relationship between gender, empire, and identity in *Mrs. Dalloway*. I argue that Peter Walsh's insistence on a normative understanding of his own

gendered perspective is detrimental to himself and those around him, and that Peter's view of this perspective is far more ambivalent than Zorluoglu and others acknowledge. For Peter, this understanding can be understood as a set of rules which insist on adherence to the socially normative understanding of masculinity, sexuality, and adherence to values of the British Empire. Peter's insistence on fitting himself into this model is detrimental to his emotions and relationships, preventing him from questioning himself or making platonic friendships. Every time he confronts the incongruence between his internal self and the self he feels pressure to be by this insistence, he fidgets with his pocket knife. This knife is representative of his masculinity and his habit of fidgeting with it is representative of the moments in which he insists on clinging to it, whether this is helpful or harmful, despite his ambivalence. This research project concludes by examining the eventual genuine confrontation with his internal self provoked through his conversation with Sally Seton at Clarissa Dalloway's dinner party. There, through dialogical exchange, Peter's emotions are able to emerge free of the normative model and he is finally able to perceive Clarissa without social impediment.

Abstract Name: Psychophysiological and Self-Reported Reactions to Sensory Stimuli in Neurotypical vs. ASD Young Adults

Sensory processing difficulties affect up to 95% of individuals with autism and can significantly impact daily life. These challenges include hyper-reactivity—such as extreme sensitivity to noise, touch, or movement—and hyporeactivity, where individuals may be less aware of sensory input. Such issues can worsen social communication deficits, increase repetitive behaviors, and impair motor control. While the exact mechanisms are unclear, addressing sensory issues may lead to broad improvements in social, behavioral, and educational domains. The current study examines the question: "How do psychophysiological responses and self-reported reactions to sensory stimuli differ between individuals with autism spectrum disorder (ASD) and neurotypical controls?" This project uses a quasiexperimental design to examine these differences. Participants first completed a Sensory Hypersensitivity Survey and the Autism Spectrum Quotient (AQ, a scale of level of ASD traits) and those with scores in the neurotypical range and high levels of ASD traits on the AQ were invited to a laboratory session. During the session, physiological measures, including heart rate and skin conductance responses (SCR), were recorded using an electrocardiogram (ECG) and skin conductance sensors. Following a five-minute baseline, participants were exposed to visual (flashing strobe lights), tactile (makeup brush on the palm), and auditory (vacuum sound) stimuli, each presented for two minutes, with one-minute rest intervals. After each stimulus, participants self-reported their discomfort with each sensory experience on a 1-5 Likert scale. Data collection is ongoing and results of our MANOVA comparing the physiological responses and subjective discomfort ratings between groups will be presented. We hypothesize that participants with high ASD traits will demonstrate hyper-reactivity in physiological responses across sensory modalities relative to neurotypical controls. This research can be implemented into classrooms to aid the learning environment of both ASD and neurotypical individuals by providing them with a space that is low stress on the sensory processing system.

Abstract Name: Lost in the Letters: How Students with Dyslexia and ADD/ADHD Navigate College Challenges

Across higher education, many neurodivergent students continue to experience barriers related to academic engagement, retention, and performance, even when disability services are available. These challenges reflect broader national patterns in how colleges support students with learning differences such as dyslexia and ADD/ADHD. This study examines these issues within the context of a midsize public university, the University of Central Oklahoma (UCO), to better understand how neurodivergent students navigate academic demands and utilize available institutional resources. Using mixed-methods design, including surveys, interviews, and observational data, the study explores differences in academic challenges, executive-function demands, resource use, and perceived support across key neurodivergent groups. Rather than evaluating UCO as an institution, the research uses it as a case study to illuminate trends widely reported at colleges and universities nationwide. Preliminary findings indicate that students benefit from structured learning tools, peer support, and early academic intervention, yet many still report unmet needs related to sustained attention, processing demands, and communication about accommodations. These insights highlight areas where universities, broadly, may strengthen existing practices. The study's goal is not to criticize a single institution but to contribute evidence-based recommendations relevant across higher education. Ultimately, this work aims to inform campus policies, guide resource allocation, and promote inclusive learning environments that support persistence and equitable academic success for neurodivergent students. By identifying both strengths and gaps in current approaches, this research contributes to a growing national conversation on how to better meet the needs of students with diverse cognitive and learning profiles.

Abstract Name: Design Procedure for RF Spot-Focused Lenses with Low-Cost Materials

In this presentation, a design procedure for a low-cost spot-focusing lens at RF frequencies (K-band) is reported. The lens is fabricated from standard acrylic stock as opposed to more expensive RF materials such as Rexolite. The design is compatible with a measurement system to characterize anisotropic engineered materials (metamaterials). Such materials can be characterized by their response to electromagnetic (EM) beams at several angles. The measurement system requires a Gaussian beam profile with a spot size on the order of 10 wavelengths. Since most commercial Gaussian beam launchers are designed to create a small spot size (around one wavelength), a custom lens must be designed and fabricated. To maintain a low cost and short lead-time, this work explores a procedure for designing lenses with readily available acrylic. The reported procedure includes: (i) the electromagnetic characterization of readily available acrylic samples; (ii) an analytical initial lens design based on the material measurements and simple optical expressions; (iii) an optimization of the lens in a full-wave physical-optics solver; (iv) a g-code synthesis method compatible with a low-cost (\$600) hobbyist CNC machine; (v) a near-field measurement to validate the lens response. Key measured electromagnetic features such as the realized focal length and the spot radius will be reported. This work supports the hypothesis that an EM beam with a highly Gaussian profile can be produced with low-cost materials and fabrication technology. Starting with an optical design for a lens, further full-wave simulations can be done to account for the beam-spreading inherent to Gaussian beams. The reported procedure is straightforward, with all steps of the design and prototyping carried out in-house.

Abstract Name: Examining Nutrition and Physical Activity Behaviors Among Students at a Southern Urban HBCU

Overweight and obesity among college students represent a significant global health concern, with research indicating that students attending Historically Black Colleges and Universities (HBCUs) are disproportionately affected. Elevated rates of overweight and obesity in this population are often associated with insufficient fruit and vegetable consumption, high intake of energy-dense foods and sugar-sweetened beverages, and low levels of physical activity. This study examines findings from the American College Health Association (ACHA) survey administered in Spring 2025 at a southern, urban HBCU in North Carolina. Data were collected from over 400 undergraduate students, representing a 10% response rate, who completed an online questionnaire distributed via email. The survey included items related to eating habits, physical activity, lifestyle factors, dietary beliefs, nutritional behaviors, and other health-related practices. Responses were analyzed to identify patterns and trends in student nutrition and physical activity behaviors. The results offer valuable insight into health practices among HBCU students and highlight the need for targeted, culturally relevant interventions. Such strategies are essential to support student well-being, promote academic success, and reduce long-standing health disparities that disproportionately affect this population.

Abstract Name: Environmental Influence on the Spatial Distribution of Resources in Pavement Ant Colonies

The spatial placement of the queen and brood within an ant nest is critical to colony survival and reproductive success as typical social organization in ants involves one fertile queen and many sterile workers who care for the brood. Our experiment examines how sudden changes in humidity and lighting influence brood-placement decisions within the nest of *Tetramorium immigrans*. 3D printed modular hexagonal chambers were arranged into an interconnected artificial nest. Each chamber contains a lower reservoir separated from an upper living area via wire mesh. This reservoir held either a damp cotton ball or desiccant beads. Study colonies were provided access to two dry chambers and two wet chambers, which were assigned initial identities, and then were switched after a week to test whether the ants' preference for humidity levels would override scent-based environmental history. A camera and ring light were set up to take photographs of the colony every thirty minutes for one week. Interpretation of the photographic data from initial experiments aligned with our hypothesis that the pavement ants would actively exert a preference for a humid environment to store their brood. We further investigated the influence of light on brood-placement decisions by covering the clear acrylic lid of two of the chambers with red acetate sheets to simulate a dark environment, hypothesizing that the ants will prefer the dark chambers for queen and brood placement. Understanding the preferences that factor into collective decision-making for spatial usage within the ant colonies has the potential to inform policymakers and computer models that manage human disaster responses where vital resources must be rapidly and reliably protected.

Abstract Name: Coordinated Particle Transport During Development of a Soil-Dwelling Microbe

In response to food scarcity, the soil-dwelling social amoeba *Dictyostelium discoideum* undergoes a developmental transition from a unicellular organism to a multicellular organism, aggregating to form fruiting body structures that are crucial for survival. These cells possess a non-specific adhesive capacity that not only allows them to adhere to each other during aggregation, but also to particles in their environment, allowing for the manipulation of their physical environment. The ability of cells to selectively adhere to neighbors while potentially also remodeling surrounding materials represents a critical but understudied aspect of multicellular development. To investigate whether cells systematically remodel their microenvironment during the unicellular-to-multicellular transition, we designed experiments that allowed us to visualize coordinated motility and aggregation behavior in the presence of fluorescent microbeads simulating soil particles. Specifically, we performed time-lapse imaging using spinning disk confocal microscopy and transmitted light microscopy of starved cells undergoing the full developmental process. The key new result we observed is that beads become attached to cells transiently during early aggregation and are carried with groups of cells as they aggregate, but the beads are not included in the multicellular structure as it continues to develop. Our work has revealed a previously unknown way soil-dwelling organisms tune their interactions with the environment over time. We anticipate further experimental work and computational analysis will uncover differences in adhesion and coordination specific to each stage of development that control this phenomenon. Understanding how cells potentially tune adhesion to carry particles sheds light on the many ways organisms have evolved to interact with and survive in diverse environments.

Abstract Name: Exploring Depressive Rumination and Depressive Symptoms Among Adolescents from Three Countries

This study examined the association between depressive rumination (i.e., the repetition of negative thinking about oneself or one's circumstance) and depressive symptoms among adolescents from three culturally distinct countries: Colombia, Italy, and the United States. We also examined the relation of depressive symptoms and rumination with societal beliefs (i.e., individualism, uncertainty avoidance, and indulgence from Hofstede's Cultural Dimensions). Participants included 540 mother-child dyads (Youth Mage = 12.50 years; 50% females) representing six subgroups: Colombian, Napoletano, Roman, White, Black, and Latinx. Depressive rumination and depressive symptoms were significantly and positively correlated across all six subgroups ($r_s = 0.52$ to 0.69 , $p_s \leq 0.001$) and gender ($r_{boys} = 0.52$, $r_{girls} = 0.63$, $p_s \leq 0.001$). Depressive rumination was not significantly related to any of the three societal beliefs. Depressive symptoms were significantly and positively correlated with uncertainty avoidance ($r = 0.12$, $p \leq 0.01$) and significantly and negatively correlated with individualism ($r = -0.12$, $p \leq 0.01$). Indulgence was not significantly related to depressive symptoms. Our findings advance understanding of how depressive processes may be partially

shaped by culture and gender among adolescents from three distinct countries with different value orientation. Through this, future pathways of prevention could be considered to further benefit the development of youth.

Abstract Name: Shifting the Reading Experience to Engage Middle School Students

Over recent years, middle school literacy rates have declined, raising concerns about how traditional reading instruction fails to engage students who see reading as a chore. This research explores how to re-engage middle school students with reading in an authentic manner. By examining multimodal formats, including graphic novels, hybrid texts, and expressive writing, this study explores the cognitive, emotional, and behavioral benefits that different reading experiences provide. Drawing on neuroscience and Social-Emotional Learning (SEL), the research synthesizes findings from recent studies to identify which formats most engage adolescent readers. The goal is to highlight how these formats support the benefits of reading such as emotional regulation, identity development, and academic resilience, to point out the personal gains from reading. The study offers a framework for implementing innovative reading interventions in middle school settings to reshape reading environments to not only provide knowledge but also invite emotional development and cognitive growth. Ultimately, my study lays the groundwork for designing inclusive literacy interventions that help students see reading as personally meaningful, not just another assignment.

Abstract Name: Investigating Hypoxia-Induced Mitochondrial Gene Changes in Cultured Myotubes.

Mitochondria are dynamic organelles responsible for producing the energy needed by cells and are able to respond to physiological and pathological changes by fission, fusion, transport, and mitophagy. An imbalance of these processes leads to a range of diseases including diabetes and cardiovascular disease. Studying the pathways that target mitochondrial dynamics is crucial to identifying potential treatment opportunities like hypoxia. One pathway that has been identified as a negative regulator of mitochondrial function is hypoxia or low oxygen. Hypoxia induces the stability of the hypoxia-induced factor 1alpha (HIF-1a) transcription factor which controls a variety of genes. These targets when expressed, these target genes increase glucose transporters, glycolytic enzymes, and mitochondrial density via biogenesis in skeletal muscle. This increase in mitochondrial density generally causes fiber type switching in skeletal muscle from fast twitch to slow twitch fibers. Also, these hypoxia conditions cause a switch from OXPHOS to glycolysis to generate energy with a lack of oxygen. An increase in slow twitch fibers accompanied by an increase in GLUT 4 expression may improve insulin sensitivity. This increase in Glut4 expression can occur under hypoxic conditions due to the known subsequent increase of PGC1- α expression. Therefore, this project's goal is to determine if stabilizing HIF- α in skeletal muscle treats the mitochondrial dysfunction hallmarked by insulin resistance. We will utilize C2C12 myoblast differentiated them into myotubes treated with DMOG a hypoxia mimetic and test how mitochondrial function is affected by an increased accumulation of HIF1-a over a 10-hour period. We

will run a qPCR to figure out if the HIF1- α and glycolysis target genes expression has been altered. Then we will perform a Seahorse Mito stress test to measure mitochondrial function in the cells. We expect to see an increased expression of target genes and a higher rate of glycolysis in the cells.

Abstract Name: *Liberté, Antiquité, Publicité: How Jacques-Louis David's Neoclassical Approach to Painting Shaped History*

This thesis investigates how the art of Jacques-Louis David (1748–1825), the leading Neoclassical painter of Revolutionary and Napoleonic France, utilized classical ideals to document history and shape public perception. Primarily building on the scholarship of Dr. Dorothy Johnson, this study explores how David redefined history paintings - a genre of painting which depicts scenes from history, mythology, religion, or literature with a moral purpose. By incorporating Ancient Greek and Roman art conventions and beauty standards, David both elevated contemporary figures and events and made moral lessons from the past relevant to his time. His strategic use of straight lines, geometric shapes, and symmetry as well as archeologically accurate depictions of ancient settings and clothing not only cast events of his time in a heroic and monumental light but also shaped collective memory of Classical Greece and Rome. By applying a detailed visual analysis of his major works including *The Oath of the Horatii* (1784), *The Death of Socrates* (1787), *The Lictors Bring to Brutus the Bodies of His Sons* (1789), *The Death of Marat* (1793) and others, this research examines how David made use of classical topics and symbolism to connect the past with the contemporary man. Adding to Dr. Johnson's analysis of David's role in Revolutionary propaganda, his pedagogical approach, and his shifting political allegiances, this research positions Jacques-Louis David as both a recorder of history and an architect of its visual and ideological legacy. Ultimately, this thesis demonstrates how David's Neoclassical approach to painting helped define the way historical events and figures were remembered in Western art.

Abstract Name: *Never a Statue, Never a Story: The Unheard Tale of Kentucky's Black Civil War Soldiers*

In the spring of 2025, I carried out a research project for a history class that was based around creating a biographical account of the life of a single formerly enslaved member of the USCT (United States Colored Troops) during the American Civil War who was from Lexington, Kentucky. His name was Clifton Young, and based off of a few documents that had gone nearly forgotten by historians and archivists, I was able to bring his story back to the light. This research was primarily carried out by investigations done with wartime service records and soldier registration documents of Kentucky Civil War regiments acquired from the National Archives, as well as historical state and local government documents acquired from the Fayette County Clerk's Office and contemporary texts and personal narratives of the time like famous Kentucky USCT veteran and Baptist reverend Elijah T. Marrs' autobiography as well as Charles Kieker's 1866 historical account of the 116th regiment of the USCT, two documents that were actually the primary inspirations for this initial research. The intended goal of this research is to paint a fuller picture of Black military service in

Kentucky during the American Civil War, to tell a story about the Kentuckian veterans of the USCT and their families that has never been told before.

Abstract Name: The Threat Multiplier: How Climate Change Accelerates Radicalization in the Middle East

The MENA region, facing high climate vulnerability and chronic instability, creates a significant global security threat. This research models how climate change functions as a “threat multiplier,” not a direct cause of radicalization, by sequentially intensifying critical vulnerabilities. The proposed causal pathway is defined as: climate stress (drought) leading to livelihood collapse/forced migration, and ultimately the erosion of state legitimacy. Non-state actors (NSAs) strategically exploit this governance void by weaponizing resources like water infrastructure and offering economic incentives, which accelerates recruitment among climate-displaced populations. Using comparative case studies of Iraq and Yemen, this proposal will identify geographic “hotspots” where these risks converge, why the risk seems to be higher in the MENA region, and how climate change is increasing radicalization in this region. The key policy argument is that climate adaptation, resource security, and decentralized local governance are the most effective long-term counter-recruitment strategies, offering an empirical model for integrating climate resilience into global security policy.

Abstract Name: Optimizing a Novel In Vitro Model of Human Post-Traumatic TGFβ1-Induced Fibrosis

Post-traumatic tissue repair allows for the restoration of the architecture and function of the injured tissue. It involves two independent biological processes: regeneration, where the damaged tissue is partially or entirely restored to its steady state, and replacement, where tissue(s) are repaired by the layering down of connective tissue, a process known as fibrosis. However, a better understanding of the molecular mechanisms underlying post-traumatic fibrosis is still needed. The goal of this study was to optimize a novel in vitro model of human post-traumatic transforming growth factor beta 1 (TGFβ1)-induced fibrosis. Human bone marrow mesenchymal stem cells (BM-MSCs) were cultured in poly-L-lysine (PLL) treated plates, followed by TGFβ1 treatment. Several aspects of the protocol required optimization, including the TGFβ1 concentration [5 ng/mL to 20 ng/mL], PLL concentration [5 mg/mL to 20 mg/mL], and days in culture (1 or 4 days). Statistical analysis was performed using a two-tailed Student’s t-test. Higher concentrations of TGFβ1 treatment for 4 days increased the number of fibrotic nodules observed (Control: 2.4 ± 1.7 , TGFβ1 [5 ng/mL]: 11.1 ± 1.9 , $p=0.05$; TGFβ1 [10 ng/mL]: 17.7 ± 5.4 , $p=0.05$; TGFβ1 [12 ng/mL]: 17.3 ± 15.0 , $p=0.26$; TGFβ1 [15 ng/mL]: 17.6 ± 17.4 , $p=0.30$; TGFβ1 [18 ng/mL]: 25.4 ± 17.9 , $p=0.18$; TGFβ1 [20 ng/mL]: 27.2 ± 13.2 , $p=0.10$). Moreover, higher concentrations of PLL [15 mg/mL and 20 mg/mL] used to treat the cell culture plates before plating the cells, followed by BM-MSCs TGFβ1 treatment [10 ng/mL] for 1 day, showed a trend

towards an increased number of fibrotic nodules compared to the lower PLL-treatment concentrations [5 mg/mL and 10 mg/mL]. Altogether, our results support the notion that our in vitro model may be a useful system for future post-traumatic fibrosis studies. Supported by: NSF BRC-BIO (award # 2334535).

Abstract Name: Modeling the Impacts of COVID-19 and Climate Change on Eastern Thailand's Agricultural Sector by 2030

This study uses modeled scenarios to explore how Thailand's agricultural landscape may evolve due to the combined impacts of the COVID-19 pandemic and climate change on tropical farming. With a direct focus on provinces in Eastern Thailand, where rapid urbanization and climate variability have a direct impact on global food production cycles, the study examines whether the agricultural landscape can return to pre-pandemic conditions by 2030. Stakeholder interview data influenced the input into TerrSet's Land Change Modeler; from this, five land-cover scenarios informed by socio-economic and environmental variables were developed. Transition models developed with machine learning project consistent expansion of urban land into forest and farmland, with no scenario indicating a return to pre-pandemic agricultural extent. Instead, results show that climate change and increased megacity growth around Bangkok and the Eastern Economic Corridor will continue to fragment farmland and challenge the basis of agricultural resilience. The framework developed provides an adaptable quantitative approach for post-crisis land-change prediction and can be generalized across tropical South and Southeast Asia.

Abstract Name: Evaluation of the Correlation between Multimodal Cardiovascular Inflammation Imaging Biomarkers in Premenopausal Breast Cancer Patients

Background: As breast cancer survival rates improve, especially among premenopausal women, attention is shifting to long-term cardiovascular health. Cancer therapies can influence cardiovascular function through hormonal disruption, inflammation, and treatment-related vascular injury. Dysregulated epicardial adipose

tissue (EAT) and pericoronary adipose tissue (PCAT) promote an inflammatory environment around the heart and coronary arteries, linking both to coronary artery disease and impaired myocardial function, and may be measured with noninvasive imaging. Aims: To determine the relationship between EAT volume and PCAT volume in premenopausal breast cancer (BC) survivors. Methods: We performed an early interim analysis of premenopausal BC patients from the multisite CROWN study (n=90 to be enrolled) who underwent Cardiovascular Magnetic Resonance (CMR) imaging scans and Coronary Computed Tomography Angiography (CCTA) scans using standardized contrasted protocols. The EAT area was manually segmented, and mass was quantified from CMR scans using CVI42 software; volume was calculated using a fat density of 0.92 g/mL. PCAT volume was quantified from CCTA scans using QAngio CT software and normalized to coronary segment length to derive global length-adjusted PCAT volume. A Pearson correlation was conducted to evaluate the relationship between EAT and PCAT volumes. Results: Our interim analysis included a total of 16 premenopausal patients who recently completed treatment for BC. A positive, moderate correlation between EAT volume and length-adjusted global PCAT volume was observed ($r = 0.40$, $p = 0.12$). Conclusion: This preliminary correlation suggests that higher EAT volume measurements tend to be associated with greater PCAT burden. This interim data highlights the need for a larger sample size to allow adjustment for covariates (e.g., BMI and age) in our full cohort analysis and to validate these multimodality imaging biomarkers with cardiovascular outcomes in cancer survivorship.

Abstract Name: Examining the Impacts of Immersive Learning on Student's Math Anxiety

This study investigates how immersive learning activities influence students' confidence and levels of math anxiety in mathematics courses at a small, private university. The research is situated within ongoing institutional efforts to integrate immersive and active learning experiences across the curriculum, emphasizing applied understanding and reflective engagement during class time. Within the mathematics courses, immersive learning is defined as actively applying knowledge into practice and is implemented through collaborative group work, online learning platforms that offer immediate feedback, and the "Rough Draft Math" approach (Jansen, 2020), which normalizes unfinished solution attempts as part of the learning process. Research has shown that mathematics skill-oriented interventions, which aim to improve math ability through instruction and practice, increased mathematics performance and decreased participants' math anxiety (Liu et al., 2025). Math anxiety can manifest as feelings of tension, apprehension, or fear that interferes with students' mathematics performance (Ashcraft, 2002). Immersive learning can be classified as a mathematics skill-oriented intervention, and has the potential to impact student's math ability and their anxiety and confidence related to mathematics. Grounded in theories of growth mindset (Boaler, 2015) and math anxiety reduction (Liu et al., 2025), the study asks: How do immersive learning strategies, including rough draft math, affect students' confidence and math anxiety in College Algebra and Contemporary Mathematics courses? To address this question, students completed an anonymous survey measuring their math anxiety, confidence in solving mathematical problems, perceptions of immersive learning activities, and reflections on changes in these areas over the semester. Preliminary analysis suggests that immersive learning environments, particularly those emphasizing process over correctness, foster greater student confidence and reduce math anxiety by reframing errors as a natural and productive part of learning. The findings support immersive learning as a mathematics skill-oriented intervention that promotes growth mindset development and enhances students' emotional engagement with mathematics.

Abstract Name: A Comprehensive Study of Star Clusters in NGC 7320 Using the James Webb Space Telescope and Hubble Space Telescope

We present a study of star clusters in the galaxy NGC 7320, a nearby galaxy ($\sim 45 \times 10^9$ light years away), using archival images from the James Webb Space Telescope (JWST) and the Hubble Space Telescope (HST). Our goal is to find the ages and masses of star clusters within the galaxy. This study expands the knowledge of the formation of low mass clusters, possible due to this galaxy's proximity, the high quality of the archival images, and the wide span of wavelength coverage provided by these images. This was accomplished using photometry to create observational spectral-energy distributions that are compared to theoretical models of star clusters, from which we obtained their ages and masses. We also completed a search for star clusters that do not appear in the HST images by using the infrared capabilities of JWST. Such objects were previously undetected due to the extinction of optical light from gas and dust in the galaxy. We present our results on the ages and masses of these star clusters, shedding light on the low mass regime of star cluster formation.

Abstract Name: The Relationship Between Redirected Phage Packaging Protein and KIRK Phage Infection in *Francisella novicida*

Francisella tularensis (Ft) is a Gram-negative coccobacillus that causes Tularemia. It is a category A select agent, and as such it has a low infectious dose and high lethality rate. Currently, there is no approved vaccine in the U.S, increasing the necessity for alternative treatments. Phage therapy is an attractive option for treating diseases such as tularemia, but no bacteriophage able to infect Ft has been identified. We have identified two Phage-inducible chromosomal islands (PICIs) in *F. novicida* (Fn), a model organism for Ft. PICIs are mobile genetic elements that hijack helper phage machinery for their own dissemination. *F. hispaniense* (Fh) is another closely related *Francisella* species that contains a prophage in its genome (KIRK). To develop phage therapy for *Francisella*, we are attempting to understand the interplay between KIRK phage and the PICIs. Fn is unable to be transformed by the recircularized form of KIRK, but Fn lacking PICI-II can be transformed with KIRK. We hypothesize that the redirected phage packaging protein (Rpp) gene within PICI-II may be preventing KIRK infection. We are creating a Fn strain with a rpp knockout to test this hypothesis, as well as a Fn strain lacking PICI-II expressing Rpp from a plasmid. These strains will be tested for KIRK transformation, along with the wildtype and DPICI-II strains, to identify the factor(s) associated with phage hijacking. These studies may lead to novel PICI-based therapeutics against tularemia.

Abstract Name: Sex Hormone Effects on Weight Loss During Food Restriction in Male and Female Rats

Sex hormones are known to be involved in the regulation of appetite, metabolism, and patterns of weight change in mammals. Still, the nature of their relationship is complex and their specific contributions during caloric restriction are not completely understood. To further investigate the relationship between circulating hormones and weight fluctuation, we examined how hormone treatments may influence weight changes in male and female rats on a food-restricted diet. Twenty-four gonadectomized rats were surgically implanted with slow-release hormone capsules containing either estradiol, testosterone, or cholesterol (control). Following recovery, rats received unrestricted access to food to determine a baseline body weight and were subsequently placed on a restricted feeding schedule (one hour per day). Food intake and body weights were recorded daily, and the percent of weight change was calculated to assess the impact of hormone treatments on metabolic responses to food restriction. All rats showed reduced weight on the restricted food schedule. Weight reduction was calculated as the percent decrease from each rat's baseline weight. Preliminary findings indicate that percent weight loss in both male and female estradiol-treated rats was significantly greater than in their respective control groups. In contrast, percent weight loss in testosterone-treated male rats was lower than in control males, whereas testosterone-treated female rats showed a greater percent decrease compared to control females. Gonadectomized control rats appeared to lose weight at a similar rate. These results suggest that weight change is greatly influenced by estrogenic hormones. Overall, the effects of hormone treatments may play a role in the food intake and metabolic response of male and female rats. The implications of these patterns will be discussed in the context of hormonal regulation of metabolism and adaptive responses to dietary stress.

Abstract Name: From Ideas to Action: Interdisciplinary Student Leadership and Community Engagement in Practice through SWAP

Our leadership cohort participated in a structured community engagement process that guided us from exploratory problem identification to the implementation of student-led initiatives on our campus. Our goal was to gain experience in designing projects that respond to real community needs while learning how to collaborate across academic fields and lived experiences. Through a combination of workshops, guided reflection, and facilitated dialogue, we examined how community issues emerge, how they affect students in

different contexts, and how leadership can be practiced through targeted action. As we developed our initiatives, we learned how to articulate a clear purpose, analyze the environment in which our projects would operate, and evaluate the feasibility of our ideas. Several initiatives have already been implemented on campus, and these early projects have allowed us to observe how student-led interventions function within real institutional settings. We also discovered that our individual initiatives were connected in meaningful ways. By examining points of intersection across our projects, we identified shared challenges, complementary goals, and opportunities for collaborative impact. This experience demonstrated the value of interdisciplinary teamwork, particularly in understanding community issues that do not fall neatly within a single academic discipline. We gained practical leadership skills that include critical thinking, communication, and the ability to link personal motivation with broader community outcomes. Our work suggests that a collaborative initiative-building process can help students develop projects that stand independently while also contributing to a cohesive set of efforts that strengthen the campus community. We plan to continue refining our initiatives and to expand our partnerships as we deepen our understanding of community-engaged leadership.

Abstract Name: The Haven Partnered with Valdosta State University's Communications Arts Capstone Class

This project is designed to test our learning of communication theories and utilize this knowledge to real-world applications to help organizations meet their business needs. In this project we are teaming up with The Haven, a non-profit organization that provides 24-hour temporary shelter and services to victims of domestic violence, sexual assault, and human trafficking. We will design deliverables to promote The Haven's volunteering opportunities available to the local community. Volunteering participation is used toward helping to provide victims with the necessary supplies to lead a renewed, safe, and healthy life. The target audience of the "message" will be Lowndes County residents, Valdosta State University students and faculty between the ages of 20 to 55 that are available to donate their time and money/items to The Haven. The main goal of our project is to reach our targeted audience so that they are willing to volunteer with The Haven. We will not only promote the Haven, but also recruit more volunteers from Valdosta communities, more specifically to become more connected with the surrounding Latino community as this demographic was what the Haven desired to reach out to. Our secondary goal is to apply what we learned in school to solve a real-world problem for the client.

Abstract Name: Role of SPTLC3 in Mitochondrial ceramide composition and Cell Death During Acetaminophen-Induced Liver Injury

Sphingolipids are essential membrane components that regulate cell signaling and stress responses, initiated by the serine palmitoyltransferase (SPT) complex consisting of SPTLC1 and either SPTLC2 or SPTLC3. Dysregulation of sphingolipid metabolism has been linked to multiple diseases, including liver injury. Drug-induced liver injury (DILI) is the leading cause of acute liver failure, with acetaminophen (APAP) overdose being the most common trigger. This project aims to determine how SPTLC3 influences hepatocyte susceptibility to APAP-induced liver injury. We are focused on mitochondrial ceramide composition and cell death pathways, which may be either protective or deleterious, with early trends suggesting a protective response. To investigate this, we compare APAP-treated wild-type and SPTLC3 hepatocyte knockout (SPTLC3-hKO) mice. Mice are fasted overnight, dosed with 600 mg/kg APAP, and liver tissue is collected after 24 hours to assess injury. To evaluate regeneration, a separate cohort receives 300 mg/kg APAP and liver tissue is collected 3–4 days later. Complementary in vitro studies examine APAP exposure in normal hepatocyte cell lines versus SPTLC3-knockdown lines to assess viability and mitochondrial function. Preliminary data suggest that mitochondrial enzymes that degrade ceramides increase mitophagy. This suggests that loss of SPTLC3 triggers cell death that may help limit APAP-induced liver damage. We believe that mitochondrial effects may depend on the disease model, including high-fat diet, alcohol feeding, and drug-induced liver injury. Cells with compromised mitochondria may perform better under APAP stress because the injury environment resembles their normal state. These early findings support a model in which SPTLC3 regulates mitochondrial responses to injury, influencing hepatocyte survival after APAP exposure. Ongoing work will expand these findings through additional in vivo and in vitro analyses to clarify the role of SPTLC3 in DILI.

Abstract Name: Exploring Reentry and Recovery among Formerly Incarcerated African Americans with Co-occurring Mental Health and Substance Use Disorders.

The disproportionate incarceration rates of African Americans as reported by the Bureau of Justice Statistics (2024), highlight a critical area of concern within the criminal justice system. In 2021 African Americans were incarcerated at a rate six times higher than that of their White counterparts. Extensive research has explored reentry and recovery of formerly incarcerated African American populations. Yet, there remains a significant gap in the literature regarding the unique challenges faced by African Americans, particularly those with co-occurring issues of substance use and mental health disorders. The central research question for this study is “what insights does existing scholarly research provide on the intersection of mental health and substance use and reentry among formerly incarcerated African Americans in the United States?” This poster presentation aims to address this gap through a scoping literature review conducted using Covidence software, a specialized platform for synthesizing scientific research. This review seeks to illuminate the multiple barriers to successful reentry and recovery, thereby contributing to a greater understanding of the specific needs of this population. Preliminary findings from this study reveal four recurring themes: (1) the centrality of empowerment and social support in shaping recovery; (2) persistent racial discrimination that constrains access to mental health and substance use resources; (3) limited effectiveness and accessibility of prevailing substance use treatment models for this population; and (4) the influence of structural violence—including economic disadvantage, unstable housing, and community violence—on health trajectories and reintegration outcomes. Across studies, participants expressed strong motivation for recovery when engaged with culturally grounded, community-responsive behavioral health support.

Abstract Name: Developing Medical Countermeasures: Investigating the immune responses to a live attenuated vaccine for *Francisella tularensis*

Francisella tularensis (Ft), a facultative intracellular bacterium causing tularemia, poses a minimal risk of community spread in the United States but is a major bioterrorism threat due to its weaponization potential. A 1970 WHO study estimated that aerosolizing 50 kg of Ft over a city of 5 million people could kill 19,000 and incapacitate 250,000. A 1997 study also projected medical costs of \$5.5 billion (approximately \$11.1 in 2025) per 100,000 people infected. Ft is a Tier 1 Select Agent according to the CDC, and while it is treatable with antibiotics, the potential for antibiotic resistance and distribution challenges may limit their effectiveness. Various groups in the U.S. have tried to develop an Ft vaccine to remedy this deficiency, but none have achieved FDA approval. We are proposing Ft SCHU S4 Δ clpB (ATI-1701) as a live attenuated vaccine for tularemia. Animal studies to date have shown ATI-1701 to be safe and effective, with as few as six CFU protecting 100% of mice from subsequent lethal challenges. While most vaccines' effects are measured by humoral responses, Ft's intracellular nature implies that measurements of immune cell responses may be useful for development. This study explores immune responses of THP-1 macrophages and primary peripheral blood mononuclear cells (PBMCs) to ATI-1701. Specifically, these experiments investigate which immunity-related molecular pathways ATI-1701 activates in PBMCs. These results offer insights to help find potential mechanisms of immunity, which can be used to help bridge the gap between preclinical and clinical studies of ATI-1701 as a vaccine candidate. Abstract Name: The Birds and the Beehive: Exploring the Influence of Sexuality Information Seeking on Sexual Health and Well-Being in Utah Young Adults

Sexual health and well-being encompass three interconnected dimensions: sexual health, sexual pleasure, and sexual rights. Understanding how these dimensions impact young adulthood is important, as this developmental stage involves increased vulnerability to sexually transmitted infections, unplanned pregnancies, and formative relationships. Young adults learn about sexuality from diverse sources, including school-based sex education, parents, peers, and social media. However, limited research has explored how the specific sources from which young adults learn about sexuality contribute to their sexual health and well-being. This study addresses this research gap by asking the following questions: Which sources of sexuality information do Utah young adults access most frequently and perceive as most influential? How do sexual health and well-being outcomes differ across the sources of sexuality information that participants report as most frequent and influential? This project uses a cross-sectional online survey of young adults ages 18-25, recruited through convenience sampling on Utah college campuses. Measures include an established framework categorizing sexuality information sources, the Natsal Sexual Well-being Measure, and additional

demographic variables. Data analysis will involve descriptive statistics, one-way ANOVA, and Pearson correlations. Given the limited literature, analyses will use two-tailed hypotheses to detect effects in either direction. Findings will contribute to the field by examining multiple information sources within a restrictive sociocultural context, applying these sources to a holistic model of sexual health and well-being, and informing improved approaches to sexuality education. This project recently received grant funding to compensate participants. Data collection will begin shortly and is expected to be complete by March, after which analyses will begin. Preliminary findings will be presented at NCUR if accepted.

Abstract Name: 1 / 2 From Feelings of Belonging to Academic Success at GovState

Governors State University (GovState) is committed to enhancing students' academic engagement and overall success by fostering an inclusive and supportive environment. The university's strategic plan emphasizes its dedication to fostering a sense of belonging and community among its students, which is essential for both academic success and personal development (Governors State University, n.d.). In alignment with this mission, this study aims to explore the relationship between student success and a sense of belonging at GovState. A sense of belonging, or the feeling of being genuinely accepted, valued, and connected within a social environment, is a fundamental human need that influences a range of psychological and social outcomes, including emotional well-being and academic success (Allen et al., 2020). Research has consistently shown that students with a stronger sense of belonging tend to have higher GPAs, further emphasizes the important role that belonging plays in improving academic achievement and long-term educational outcomes, as well as further indicating how important belonging is for academic success (Kivlighan et al., 2018). Students who feel more connected to their school, peers, and academic environment are also more likely to succeed in various aspects of their college experience, including participation in classroom discussions, engaging in campus activities and clubs, and also collaboration with fellow students and faculty (Jorgenson et al., 2018). Therefore, understanding these variables in-depth are crucial for improving student retention and academic growth, as students who feel more connected to their academic and social environments tend to perform better and remain enrolled longer, further improving retention. Therefore, we will assess students' perceptions of belonging and its influence on academic engagement and GPA. We expect that students with a stronger sense of belonging will show a greater amount of academic success, further supporting the importance of fostering an inclusive and supportive campus environment to enhance student outcomes.

Abstract Name: Responsiveness and Mechanisms of TCR and IL-15 Stimulation by CD101+ and CD101-

CD57+ CD8 T cells

Terminally-differentiated CD8 T cells expressing the immunosenescence marker CD57 have been linked to cardiovascular disease risk. Our group has previously shown that the inflammatory cytokine interleukin-15 (IL-15) maintains CD57+ T cell viability and ability to proliferate, whereas T cell receptor (TCR) engagement drives CD57+ T cells toward activation-induced cell death. A substantial proportion of CD57+ CD8 T cells express the inhibitory glycoprotein CD101, but the function of CD101 expression remains unclear. Here, we evaluated the proliferative responses of human peripheral blood mononuclear cells (PBMCs) following antigen-specific (TCR) or antigen-nonspecific (IL-15) stimulation. Donor PBMCs were labeled with CellTraceViolet proliferation dye and cultured in vitro with either plate-bound anti-CD3 plus soluble anti-CD28 (TCR stimulation) or IL-15. The cells were harvested after 7 days, and proliferation and phenotypic markers were quantified using flow cytometry. In addition, we used the mTOR inhibitor rapamycin to assess the role of mTOR activity in these stimulations. We found that TCR engagement elicited significantly more proliferation from CD101+ CD57+ CD8 T cells than it did from CD101- CD57+ CD8 T cells. In contrast, IL-15 elicited similar levels of proliferation regardless of CD101 expression. Blocking mTOR signaling with rapamycin inhibited IL-15-induced proliferation but not TCR-induced proliferation. Interestingly, rapamycin exposure during TCR engagement resulted in a substantial reduction in the proportion of CD57+ T cells overall. This effect was driven not by TCR stimulation-induced death of CD57+ T cells, but is rather coupled with a trend that follows an increased proliferation of CD57- CD8 T cells in the presence of rapamycin. Our findings demonstrate differential responsiveness of CD101+ and CD101- T cells to TCR stimulation, and identify differential roles for mTOR signaling in antigen-specific and antigen-nonspecific responses of CD57+ and CD57- CD8 T cells. These results may have implications for the immunopathogenesis and treatment of cardiovascular disease.

Abstract Name: Enhancing Amino Acid Separation on TLC Using Silane Stationary Phase Gradients and Mobile Phase Gradients

Thin-layer chromatography (TLC) is widely used for rapid and low-cost analysis of molecules, but its ability to separate structurally similar molecules (such as amino acids) is limited by the uniformity of commercial TLC plates and fixed solvent conditions. This project aimed to improve amino-acid separations by introducing controlled gradients in both the stationary phase (the TLC plate surface) and the mobile phase (the developing solvent). Stationary-phase gradients were fabricated using a vapor-deposition method in which phenyldimethylchlorosilane and paraffin (7:3 v/v) react across the plate to create a smoothly changing surface chemistry. The plates were tested using mixtures of six DL-amino acids (histidine, arginine, proline, alanine, valine, methionine) under different solvent systems to identify conditions that maximized resolution. In parallel, I designed and built a dual-syringe-pump apparatus capable of producing dynamic mobile-phase gradients by dispensing and withdrawing solvent at controlled rates while keeping the total volume constant. Developed plates were visualized with ninhydrin to quantify separation performance. Results show that the vapor-deposited stationary-phase gradient consistently improved amino-acid separation relative to unmodified silica plates, producing clearer and more reproducible spot distinctions. The mechanical mobile-phase gradient system functioned as intended, but its early separation performance did not yet outperform the optimized isocratic (single-composition) solvent system. These findings indicate that stationary-phase gradients alone can significantly enhance TLC resolution and highlight the potential for combining both gradient strategies to develop a low-cost, higher-performance method for applications such as screening dietary supplement composition. Future work will focus on refining mobile-phase gradient control and integrating both gradient types into a unified analytical workflow.

Abstract Name: Assessing Barriers to Awareness of Social Services Available in Rural Communities

In rural communities, individuals and families face barriers to find proper assistance for their needs. Awareness of social service agencies plays a collaborative role in rural communities. The goal of the research is to explore the extent of community knowledge of rural social service organizations. The research type is descriptive. The questions being asked on the survey are a part of the mixed methods approach. The targeted sample size is 75 participants. The student researchers ran a bivariate correlation test to determine the relationship between the participants' ages and their likelihood to donate. Results indicated there is statistical significance and a moderately strong relationship between age and the likelihood to donate ($r = .31$; $p = .004$; $p < .05$). The student researchers ran an independent t-test to determine if there is a difference in awareness of social services on different social media platforms in relationship to the city they reside in. The results indicated that there is a statistically significant difference in awareness of social services on social media and the cities the participants reside in ($t(79) = 1.45$; $p = .003$; $p < .05$). Although the results are statistically significant, most participants are from one city in the county (73.5%; $n = 61$). The student researchers ran an independent-samples t-test grouping by those who have and have not received social services and their awareness of social services revealing a statistically significant difference ($t(81) = -2.40$; $p < .05$; $p = .019$). The student researchers ran a test of independence to determine the relationship between participants utilizing services and their position to utilize services. Results indicate that participants utilizing services and participants in the position to utilize services are dependent. The relationship is statistically significant ($\chi^2(1) = 10.9$; $p < .05$; $p = .002$). By bringing awareness to agencies in rural communities, this research provides citizens with more opportunities to obtain necessities.

Abstract Name: Association Between Neighborhood Deprivation and Neurological Mortality: A County-Level Analysis of Traumatic Brain Injury and Parkinson's Disease in the U.S.

Neighborhood socioeconomic deprivation is an important social determinant of health, yet its relationship with neurological mortality is not well defined. This study examines whether the Area Deprivation Index (ADI), a validated measure of neighborhood disadvantage, predicts county-level age-adjusted mortality rates for Traumatic Brain Injury (TBI) and Parkinson's Disease (PD) in the United States. TBI and PD mortality in the U.S. is a growing concern, with the age-adjusted death rate increasing significantly from 5.4 per 100,000 in 1999 to 9.8 per 100,000 in 2020 for PD and 69,473 TBI-related deaths reported in 2021. Mortality data from 2015 and 2020 CDC WONDER were merged with standardized ADI scores from the Neighborhood Atlas, with higher ADI scores indicating greater deprivation. Analyses were performed in STATA 18.5 using univariate, stratified, and multivariable linear regressions with interaction terms for sex, race, urbanization, and year. For TBI, higher ADI was strongly associated with increased mortality ($\beta = 0.47$, $p < 0.001$), with

stronger effects in males ($\beta = 0.52$, $p < 0.001$) and in micropolitan counties ($\beta = 1.09$, $p = 0.013$). ADI remained significant in adjusted models ($\beta = 0.32$, $p < 0.001$). For PD, higher ADI was associated with increased mortality ($\beta = 0.075$, $p = 0.011$), especially in women ($\beta = 0.040$, $p < 0.05$) and in White majority counties ($\beta = 0.080$, $p = 0.009$). The adjusted association showed a smaller effect ($\beta = 0.033$, $p = 0.105$) but a consistent direction. Interaction analyses showed stronger effects in micropolitan ($\beta = 0.89$, $p < 0.001$) and small metro counties ($\beta = 0.205$, $p = 0.025$). These findings show that neighborhood disadvantage, as measured by ADI, is a consistent predictor of neurological mortality for both TBI and PD.

Abstract Name: Tracing the Cost of Poverty: STEM Learning Pathways for Male Adolescents

This study investigates how the duration of household poverty shapes mathematics and science achievement trajectories for male high school students. Using data from the High School Longitudinal Study 2009-2016 (HSLS), the analysis reveals a clear socioeconomic gap in STEM performance. Male students living at or above the federal poverty threshold report a mean mathematics GPA of 2.10, compared with 1.81 for peers experiencing poverty, a statistically significant 0.29-point deficit indicating a moderate effect size. Although science grades are not sex disaggregated in HSLS, whole cohort patterns show even wider poverty-linked disparities across both disciplines. These findings align with prior research demonstrating that socioeconomic disadvantage restricts access to academic resources, increases exposure to stress, and limits engagement in technical subjects, collectively hindering STEM achievement for boys in low-income households. The results underscore the long-term consequences of persistent poverty, which can shift male performance from the low “B” to the mid “C” range and narrow readiness for advanced coursework. Targeted, school-based interventions, such as explicit instruction in foundational skills, strong STEM teacher support, and high-dosage small group tutoring, emerge as critical strategies for mitigating these effects and promoting equitable STEM pathways.

Abstract Name: Characterization of E-Paper for Temperature Regulation on a Cubesat

CubeSats are miniature satellites built in unit cubes with side lengths of 10cm to conduct academic research on components in space environments. The goal of this project is to build a 1U CubeSat for the purpose of conducting experiments on the thermal properties of e-paper at varying pixel densities. E-paper is a display device that contains charged pigments that can be attracted or repelled from the film to create monochrome patterns. It is of particular interest as it draws power only to change display patterns while being effectively powerless during static operating states. Identifying the thermal properties of e-paper as pixel densities vary, will confirm the potential use of e-papers as multi-use low-power passive thermal regulation tools on small sats. These properties will be determined through two experiments. First the e-paper will have half its surface covered in electric tape and then heated on a hotplate where it will be measured by an IR camera. The e-paper

and electric tape will be at the same temperature but have different measured temperatures due to differing emissivity. Then a solar simulator is used with an insulated brass tube placed underneath the e-paper to compare the temperature of the e-paper at steady to the tube which can be used to determine the absorptivity of e-paper. This project then targets several critical components for a functional satellite. Including structural manufacturing and the core computing aboard. This project selected a mounted side rail and end plate design for a relatively accessible CNC machining job, and to avoid significant stock waste born of a monocoque design. Additionally, building off an open, source, but outdated PCB design in the PyCubed framework, this project worked to replace obsolete and out of production components with commercially available parts, and manufacture the board to be fully integrable to external subsystems.

Abstract Name: Recovering Betsy Cole: Black Womanhood and Entrepreneurial Spirit of Jazz during the Age of Jim Crow

New Orleans in the late 19th and early 20th century is widely considered the birthplace of jazz culture. The life and legacy of Betsy Cole, a Black woman who emerged as a central figure in the early history of jazz, uncovers a gap in common understandings of the birth of this form of popular music. Though she is largely unknown today, famous jazz musicians like Kid Ory and Charles “Buddy” Bolden made frequent appearances at Cole’s residence, a well-known venue to the jazz community of New Orleans. Popular history and mythology of jazz centers on male musicians. However, as a case study, Betsy Cole will showcase a Black woman as a significant pillar of the social and cultural landscape of early jazz. Primary source research revealed not only Cole’s central role as a hostess within the burgeoning jazz community of New Orleans, but suggests the outlines of an entirely new class of Black women during Jim Crow. Neither working class, nor well-to-do, Betsy Cole made her way as a Black female property owner in a time and place where they were quite rare. As an impresario of lawn parties and litigant landlord, Betsy Cole embodied an underrepresented group of Black women entrepreneurs who were given an opportunity to gain economic independence through the unique development of jazz culture.

Abstract Name: Influence of Media Composition and Temperature on Microgel Paste Dissolution

Microgels are hydrogel microparticles that can respond to environmental stimuli such as temperature and pH. Due to their biocompatibility and sensitive responsiveness, they are widely used in regenerative medicine and drug delivery applications. We have developed a new class of biomaterials based upon microgels made from poly(N-isopropylacrylamide-co-acrylic acid), called microgel pastes, which have the potential to serve as foundational materials in tissue scaffold and drug delivery technologies. However, their swelling and dissolution behavior in different environments remains relatively unknown and poorly understood. Thus, this study investigated how microgel pastes behave when immersed in different solvents at physiological temperatures (37 °C). By observing the interface between the solid paste and liquids, we aimed to understand

the nature of the interface between these biomaterials and the solution environment. To conduct this, microgel pastes with different concentrations, prepared either in water or phosphate buffered saline (PBS) were used as samples. The sample was immersed in water or PBS. Then, the movement of microgel particles at the paste-solution interface during dissolution was captured via differential interference microscopy (DIC), which was analyzed with a particle tracking feature in FIJI. The microgel pastes displayed distinct temperature-dependent responses: In water, the microgel particles diffuse rapidly, forming a thick, swollen interface. In contrast, pastes in PBS maintained a thinner interface with slower particle movement and greater stability, even at high temperatures. These findings are significant as they provide insight into how biomaterials interact in physiological media, which can be applied in further technologies in the regenerative medicine and tissue engineering fields.

Abstract Name: Effects of Leptin Replacement on Metabolic Adaptations to Starvation

Historically, insulinopenia (low insulin levels) was the signaling event considered responsible for metabolic adaptations to starvation, including mild hypoglycemia, general sympathetic outflow, and increases in serum ketones, glucagon, and free fatty acid levels. Leptin, a hormone produced by adipose tissue, is known to decrease in response to caloric restriction. Recent work in the field suggested that leptin infusion following a 48-hour fast reversed all metabolic adaptations to starvation, thus raising questions about an unacknowledged role of leptin in the starvation response. We tested whether physiological leptin replacement during a 72-hour fast in rats is sufficient to reverse the physiological adaptations to starvation. Sprague-Dawley rats were subjected to a 72-hour fast with or without physiological leptin replacement (n=6 and n=6), or ad libitum feeding (control, n=7). Leptin replacement was achieved via iPrecio programmable mini-pumps. Metabolite and hormone levels (e.g. glucose, leptin, insulin, glucagon, corticosterone, catecholamines, and ketones) were measured at baseline and every 24 hours during the 72-hour fasting period. Data will be assessed for significant differences between the 72-hour fast and 72-hour fast+leptin or control groups at each time point during the fast, using 2-way ANOVA with Dunnett post-hoc test. Expected trends were observed in blood glucose and body weight in 72-h fasted group relative to fed controls ($p < 0.001$). Additionally, while leptin levels fell in 72-h fasted group relative to controls, there was no significant difference in leptin levels between ad libitum controls and the 72-h fast+leptin group (all $p > 0.17$), confirming the efficacy of our leptin treatment in replicating physiological leptin levels. Despite this, our data generally show that key changes in hormones and metabolites are unchanged by physiological leptin treatment during fasting. Leptin treatment had no effect on sympathetic tone, weight loss, or glucose homeostasis during the fast.

Abstract Name: Sexual dimorphism of the *Macaca mulatta* hamate: A trabecular bone analysis

The relationship between sexual dimorphism (when males and females have different shapes or masses) and trabecular bone structure (the sponge-like inner part of bone that houses bone marrow) is not well understood. This limits our ability to interpret the skeletal remains of fossil human ancestors. Though we know that macaque monkeys (*Macaca mulatta*), our close primate relatives, exhibit sexual dimorphism, there is a gap in the literature assessing their trabecular bone distribution in the wrist. We hypothesize that the trabecular structure of the hamate bone, located in the wrist, will show significantly different architecture between males and females. To test this hypothesis, we will examine the hamate bone of 15 adult male and 15 adult female macaque monkeys. The hamate will be manually segmented from existing microCT data using Volume Graphics StudioMax. A volume of interest will be isolated within the bone and analyzed. We will specifically test if males and females have statistically significant differences in BV/TV (bone volume fraction, a ratio of bone to empty space in the volume of interest that reflects loading forces). We predict males to have greater BV/TV than females because of their greater body mass and heavier loading. This study explores how sexual dimorphism may impact trabecular bone structure in our close primate relatives. Results will help fill a gap in the literature, with applications to the relationship between sexual dimorphism and trabecular bone, as well as human and hominin bone structure interpretation.

Abstract Name: An Empirical Study of Predictive Uncertainty Under the Right to Be Forgotten

Deep learning models have achieved remarkable success over the past decade, but still often fall short in providing accurate uncertainty estimates for their predictions. Quantifying uncertainty is particularly crucial in real-world applications, such as healthcare and autonomous driving. Motivated by this, numerous uncertainty quantification methods have been proposed to assess the reliability and confidence of model predictions. Meanwhile, machine unlearning has gained increasing importance due to growing demands for the right to be forgotten. Machine unlearning aims to remove sensitive data and its influence from a pre-trained model without requiring retraining from scratch. However, the impact of machine unlearning on predictive uncertainty remains largely unexplored. To bridge this gap, this research project conducts an empirical study of predictive uncertainty under the right to be forgotten. We investigate how different machine unlearning mechanisms, including the choice of unlearning method, the modality of unlearning data, and the fraction of data removed, affect a model's predictive uncertainty, providing a fundamental understanding of the impact of machine unlearning. Our evaluation uses a convolutional neural network as the backbone model and utilizes both the benchmark CIFAR-10 dataset and the real-world, medical-domain DERMAMNIST dataset. Results are evaluated using statistical tests across three independent runs to reduce analysis bias, and we report the mean and standard deviation. We use metrics such as the Brier Score (BS) and Expected Calibration Error (ECE) to quantify uncertainty errors before and after unlearning. Additionally, we report test accuracy and runtime to assess the efficiency of unlearning. By systematically examining the impact of unlearning on predictive uncertainty, this research contributes to the development of artificial intelligence systems that are both privacy-conscious and reliable in real-world scenarios.

Abstract Name: Social Media, Muscles, and Baggy Clothes

Social media content targeted towards men oftentimes revolves around fitness/athleticism, forming a rise in muscle dysmorphia among adolescent men. As a result, young males resort to baggy clothes to hide perceived flaws while participating in a rapidly increasing fashion trend. This research will showcase how social media fuels the correlation between muscle dysmorphia and trending baggy clothes among adolescent men. Previous scholars have identified how social media constructs the “ideal” male body, with influencers promoting unrealistic standards. Some studies have shown a connection between dysmorphic tendencies and harmful content, but debate remains on whether damaging media causes dysmorphia or dysmorphic individuals are drawn to unhealthy content. Research on masculine identity uncovered how men's low self-esteem and muscular dissatisfaction impact clothing choices, symbolizing how men's choice of loose-fitting apparel serves as concealment and emotional protection. Moreover, the researched psychological implications of men's clothing choices remains narrow, as well as leaving the female population unexplored. This research calls for a netnographic approach, an analysis on the online community surrounding the fitness/gym culture of the male population, as well as a study on individual men. Surveys will be distributed to young men of various body types and fitness habits/journeys, scaling qualitative data on how they feel about certain posts, their body image concerns, and their clothing choices. Quantitative data will calculate frequency of social media usage, percentage of muscle-related content, and clothing fit scales. The collected data is anticipated to illustrate a positive correlation between muscle-focused social media content to muscle dysmorphia among adolescent men, resulting in the popular choice of baggy clothes to hide flaws. The data collected and the conclusions formed from this research can stimulate psychologists, parents, and others to pinpoint early signs of dysmorphic individuals through their clothing habits and prevent harmful tendencies in the future.

Abstract Name: Hybrid Supervisory Control Architecture for Safe Student Driver Instruction: A Digital Co-Pilot

In 2021 drivers aged 15-20 made up only 5.1% of licensed drivers in the United States, yet they made up 8.5% of drivers in fatal crashes and 12.6% of drivers in all crashes. This highlights the need for a safety override system during student-driver instruction. A critical focus of autonomous driving systems is establishing a mechanism to assume control when a student driver makes a critical error. This research proposes and validates a novel Hybrid Supervisory Control Architecture (HSCA), implemented in a combined Simulink and Stateflow environment and designed to function as a digital driving instructor. The HSCA assists driving instructors by serving as a safety co-pilot, instantly overriding unsafe student commands such as excessive speed or unintended lane departure, while maintaining predictable vehicle actions. The system's intelligence is split in two: an Adaptive Model Predictive Controller that continuously generates optimal steering commands for trajectory tracking and a supervisory Stateflow chart that monitors unsafe behavior such as speeding or drifting out of the lane. The Stateflow chart triggers autonomous intervention when errors exceed safety thresholds and uses time-delayed criteria to ensure stability before returning control. Initial validation using a kinematic model and simulated student errors (lane drifting and

speeding) demonstrates successful intervention, reducing lateral error from 0.5 m to 0 m and velocity error from 2.0 m/s to 0 m/s within 2 seconds. This demonstrates that the HSCA can assume control and stabilize the vehicle quickly. The final stage of this project will validate the HSCA using high-fidelity human trajectory data from the highD dataset, a driving dataset recorded on German highways, as dynamic traffic. This will test the HSCA's ability to maintain safety during student deviations in realistic multi-vehicle traffic. The HSCA provides a predictable safety framework for driver education vehicles, allowing instructors to focus on teaching.

Abstract Name: Macrophage Reprogramming in the CML Bone Marrow Niche Determined by Lactate Assay

The bone marrow (BM) microenvironment is a dynamic network of cells, extracellular matrix components, and signaling molecules that regulates hematopoietic stem cell differentiation and immune cell development. When this microenvironment becomes dysfunctional, normal cell production is disrupted, and disease processes can be amplified. Cellular energy production is especially important as metabolism directly influences immune cell activation and function. Macrophages polarize into two main phenotypes: M1 and M2. M1 macrophages primarily rely on glycolysis for energy and promote inflammation, whereas M2 macrophages support immunosuppression and depend on oxidative phosphorylation. Immune cells can shift their metabolism based on available metabolites to support rapid energy generation, proliferation, and cytokine production. In chronic myeloid leukemia (CML), overactive immune cells promote inflammation, leukemic proliferation, angiogenesis, and suppression of anti-leukemic responses. Although tyrosine kinase inhibitors (TKIs) treat CML by blocking proliferative signaling pathways, metabolic alterations in macrophages remain poorly understood. We hypothesize that macrophages in the CML BM niche increasingly depend on glycolysis, contributing to inflammation and an overactive immune environment. To investigate this, we quantified lactate levels in bone marrow-derived macrophages (BMDMs) isolated from CML, TKI-treated CML, and normal C57/BL mice. Bone marrow was collected from long bones, and macrophage fractions were differentiated from vertebral marrow cultures and polarized using LPS or IL-4. Supernatants and cell lysates from BMDMs were processed to measure lactate using a fluorescent assay kit. Both intracellular and extracellular lactate displayed similar trends. Compared to controls, the CML group showed a significant increase in lactate, indicating heightened glycolytic activity and inflammation within the BM niche. In the TKI-treated CML group, lactate levels were reduced and approached those of the control group. Altogether, an increase in lactate levels suggests that macrophage reprogramming plays an important role in promoting glycolysis within the CML BM microenvironment, and targeting macrophages may improve CML treatment.

Abstract Name: GasderminD (GSDMD)-tagged Mitochondria Propagate Neuroinflammation in Parkinson's Disease

Parkinson's disease (PD) is a neurodegenerative disease characterized by progressively worsening motor deficits due to the death of dopaminergic neurons in the ventral midbrain. Neuron death, mitochondrial dysfunction, and increased brain inflammation are hallmarks of PD. In the brain, microglia exist as resident immune cells that initiate and regulate inflammation. It is known that neuron-released alpha synuclein (α -syn) aggregates contribute to the activation of the Nod-like Receptor Protein 3 (NLRP3) inflammasome, an innate immune pathway. However, the mechanisms by which it accelerates the disease course remain under-characterized. Though α -syn does not inherently cause inflammatory cell death of microglia, it provokes an inflammatory cascade that may contribute to the progressive nature of PD. Specifically, α -syn expedites mitochondrial dysfunction, serving as a damage-associated molecular pattern (DAMP) to activate the NLRP3 inflammasome. Subsequently, NLRP3 activation triggers the secretion of pro-inflammatory cytokines and the proteolytic activation of an enzyme known as caspase-1 (Casp1). Casp1 cleaves the pore-forming protein, gasdermin-D (GSDMD), which canonically induces inflammatory cell death by forming pores in the cell membranes. However, GSDMD activation does not cause inflammatory cell death in α -syn-treated microglia. Rather, our work aims to assess the method by which GSDMD translocates to other membrane-bound organelles and escalates the spread of neuroinflammation in PD models. We predict that GSDMD translocation and pore-formation at the mitochondria may result in the spillage of mitochondrial DNA into the cytosol, thus triggering the cGAS/STING pathway, another innate immune pathway that detects double-stranded DNA within the cytosol. Our hypothesis aims to elucidate the roles of GSDMD and mitochondrial dysfunction that increase neuroinflammation in PD models. Exploring the mitochondrial roles of GSDMD within the brain is an emerging field where limited research has been conducted. Overall, deducing these mitochondrial roles of GSDMD in microglia can establish therapies that target GSDMD-induced inflammation in PD patients.

Abstract Name: Rewiring Communication Pathways

Communication is central to human identity and participation in society. For individuals with aphasia, a language disorder affecting approximately two million Americans, expressing thoughts can be challenging, limiting engagement in families, communities, and social life. This presentation examines how creative and humanities-based approaches, including storytelling, writing, visual arts, and musical expression, as well as methods used in second-language learning, empower and innovate in supporting language recovery. This research was conducted while volunteering at the Russell Sage College Aphasia Center, where I observed and analyzed how creative communication methods are used in real therapeutic settings. In addition to my hands-on research, I compared how people learn a new language with how they relearn language after aphasia. Recovery is most effective when strategies focus on individual strengths rather than lost abilities. Creative activities offer alternative ways to communicate and express emotions, helping people regain confidence and a sense of self. These approaches support neuroplasticity, allowing the brain to form new pathways and helping individuals discover new ways to connect with their communities. Research shows that incorporating stories and arts-based activities can enhance motivation, communication skills, and social participation. Examining aphasia through a neurodiversity perspective demonstrates the importance of acknowledging and supporting diverse approaches to language use. Similar to how educators adjust methods to meet the needs of diverse students, creative interventions provide personalized support that encourages

engagement and community involvement. Based on observations from my research, individuals who participated in creative activities showed improved confidence, engagement, and willingness to communicate. This presentation demonstrates how students and educators can lead through creative and effective practices that promote inclusion and make a meaningful impact. Attendees will learn how to apply innovative and creative approaches in therapy and education, understand the role of neuroplasticity, and explore strategies to help individuals with diverse communication abilities succeed.

Abstract Name: Enhancing the Quality of Photonic Crystals using Nanoimprint Lithography

With the rise of radiation threats and nuclear energy demands, there is a growing need to have a method to detect radiation efficiently. Scintillators, materials capable of detecting ionizing radiation, are essential in order to improve our ability to detect radiation faster and more accurately. However, most scintillators being used today possess a high refractive index of 1.8 or greater. The high refractive index of a scintillator results in higher fractions of total internal reflection (TIR). Having TIR causes a major loss of photons reaching the photodetector, which reduces performance. This creates an inaccurate measurement of the ionizing radiation that the scintillator is absorbing. Inaccurate measurements can lead to less defined medical imaging pictures, inaccurate radiation exposure readings, and cause delays in mechanisms that need to detect ionizing radiation. Photonic crystals (PhCs) are an innovative way to not only reduce TIR but also be cost-effective with many different fabrication methods, such as nanoimprint lithography (NIL). PhCs are materials arranged in periodic patterns and geometries, e.g., spheres, pillars, and cones, to enhance the transport of light within the scintillator. This research aims to investigate different PhCs structures to study the correlation between the surface topography and the light yield of our scintillating crystals using the modeling software OptiFDTD to vary the PhC size parameters and observe the effects on scintillator light yield. Pairing this with a Lutetium–yttrium oxyorthosilicate (LYSO) scintillator and its refractive index of 1.82 provides a favorable ratio with Snell's law to enhance light output. Future work involving a cone-based PhC pattern based on peer-reviewed articles should result in a simulated light yield greater than 30%. In conclusion, this research aims to enhance scintillators' light yield and enhance performance by tailoring PhC geometries. This will assist warfighters in the field to more accurately detect ionizing radiation.

Abstract Name: “Prenatal Economic Stress and Emotional Dysregulation Among Young Black Mothers”

Prenatal economic stress is a significant risk factor for emotional dysregulation and poor mental health, particularly among young Black mothers who disproportionately face structural inequities and chronic stressors during pregnancy. Understanding how economic stress relates to emotional, psychological, and physiological functioning in this population is essential to developing culturally responsive, contextually grounded prenatal interventions. This study will examine associations between economic stress and emotion dysregulation, mental health, and physiological stress, as indexed by heart rate variability (HRV), among young pregnant Black mothers. Using a cross-sectional correlational design, data will be drawn from questionnaires and physiological assessments collected from N = 106 Black pregnant women (ages 18–41) in New York State between 2021 and 2025. Measures include the Difficulties in Emotion Regulation Scale–Short Form (DERS-SF), the MOS Mental Health Index (MOS-MHI), HRV, economic stress, income, age, social support, and parity. Economic stress will serve as the primary independent variable, and emotion dysregulation, mental health, and HRV will be examined as dependent variables. Planned analyses will include correlational analyses, comparisons across income brackets, and multiple regression models testing economic stress as a predictor of emotion dysregulation, mental health, and HRV while accounting for age,

social support, and parity. Analyses are currently underway and will be completed before presentation. Findings from this study have the potential to advance understanding of how economic stress shapes psychological and physiological functioning in pregnancy for Black women, inform prenatal mental health interventions that address both structural and emotional factors, and highlight the need for more equitable, culturally attuned prenatal care practices that effectively respond to the lived experiences of young Black mothers.

Abstract Name: Expanding Vision Care Access in Rural India: A Case Study of Mobile Ophthalmic Units

According to the World Health Organization (WHO), 2.2 billion people suffer from visual impairment worldwide. The prevalence of blindness is disproportionately high in developing nations. Mobile Ophthalmic Units (MOUs) have emerged as an innovative solution for delivering eye care to India's populations, where 25% of the world's blind reside, especially the most underserved population. MOUs are mobile eye clinics equipped to provide eye exams to individuals in remote areas. Patients are then taken back to the city for free surgeries on these buses. This study examines if the MOUs are a successful solution to providing eye care and reducing avoidable blindness in underserved parts of rural India through a case study of the Dr. Manohar Dole Foundation's MOU operations in Maharashtra, India. Research methodology includes seven years analysis of MOU operational data (2018-2024), in-person field observation of MOU operation in rural India, and questionnaire surveys with frontline healthcare workers. Findings show the MOU system to be an innovative and effective vehicle for providing eyecare and reducing avoidable blindness through cataract surgeries in rural Maharashtra. Various elements analyzed include design and operation of the MOU system, distances travelled from base hospital, community co-operation and symbiotic relationships with rural government health agencies, fee structures, hospital stays, etc. An interesting finding, however, was that a large percentage of people diagnosed with cataracts refuse to undergo eyesight-restoring surgeries even when free and brought to their doorstep. This highlights the need for further research and targeted interventions to address the barriers to surgery in order to reduce avoidable blindness in rural India.

Abstract Name: Rest and Results: The Relationship Between Sleep, Stress, and Grade Point Average (GPA) in Undergraduates

Background Sleep plays an important role in college students' overall academic success, making it a crucial area of study. However, the specific relationship between parameters of sleep and academic performance has not been well studied. College students have also reported increasing levels of stress over the past few years, and stress can affect both sleep and academic success. Therefore, the current investigation examined the associations between duration of sleep, sleep quality, and stress with academic success. Methods Data were collected by surveys completed by undergraduate students at a large, public university. Sleep duration and

sleep quality were assessed by the Pittsburgh Sleep Quality Index (PSQI), and stress was measured with the Perceived Stress Scale. Academic success was operationalized as a self-reported GPA. Pearson correlations determined association between the variables of interest with $p < 0.05$ set as the level of statistical significance. Results There were 196 undergraduate students that participated (70.1% female, 36% white/non-Hispanic, 27.6% Asian/Pacific Islander, age: 18.1 ± 0.5). Both sleep duration and sleep quality were statistically significantly related to GPA ($r = 0.17$, $p = 0.02$, $r = -0.13$; $p = 0.001$, respectively). Therefore, as the number of hours of sleep increased and as sleep quality increased (lower number on PSQI is indicative of better sleep), GPA increased. Elevated stress levels were related to both sleep duration ($r = -0.14$; $p = 0.01$) and sleep quality ($r = 0.40$; $p < 0.001$) but not significantly correlated to GPA ($r = -0.01$; $p = 0.92$). Conclusion This study found that sleep duration and sleep quality were positively associated with academic success. Although stress was not directly related to academic success, it was associated with both sleep duration and quality, suggesting that stress may influence academic success indirectly through its effects on sleep. Future research should explore how demographic, socioeconomic, and environmental factors influence sleep patterns and academic success to better inform strategies that support student success.

Abstract Name: The Rise of Napoleon: the Making of an Emperor

This project examines Napoleon Bonaparte's ascension to power by analyzing five key eras and events which transformed him from an obscure Corsican immigrant into First Consul of France. The central research question investigates how specific formative experiences and strategic decisions during critical moments enabled Napoleon's ascent during the chaos of the French Revolutionary period. This study surveys three categories of literature. Firstly, modern historiography and biography such as Andrew Roberts' critically acclaimed text, *Napoleon: A Life* and Norman Davies' expansive text, *Europe: A History*. Furthermore, Napoleon's influences through classical texts such as Plutarch's biographies of Caesar and Alexander to Enlightenment thinkers such as Jean-Jacques Rousseau and Thomas Hobbes. Lastly, writings from Napoleon's contemporaries such as Carl von Clausewitz's classic text, *On War* which provides a tactical view of Napoleon's strategies through the eyes of one of Napoleon's foes during the Battle of Borodino. These sources are interwoven within a chronological narrative giving context for Napoleon's actions during the French Revolution. This study traces five key eras, Napoleon's classical education in history and military theory, his victory at the Siege of Toulon, his pragmatism during the Sections uprising, his role in the Brumaire coup, and his reforms through the Napoleonic Code and Concordat of 1801. This methodology combines historical analysis with examination of political contexts that shaped each era, revealing how Napoleon's military genius and opportunism converged at critical moments with an emphasis on primary sources and reputable scholarship collated together to form a cohesive narrative. The analysis of these events demonstrates that Napoleon's success resulted from his ability to exploit key moments of instability to his advantage. This research contributes to the political science perspective of how individuals utilize political chaos to accumulate power, illustrating that Napoleon's rise was the product of several calculated decisions across a chaotic geopolitical climate.

Abstract Name: Comparing Percent Increase Of Energy Cost From Explosive Contractions In Upper Versus Lower Body Resistance Exercise

Our laboratory has demonstrated increased energy cost from including explosive repetitions, but it is unclear if this effect is greater in upper or lower body resistance exercises. PURPOSE: We compared the percent increase of energy cost in bench press versus squat as a result of performing varying amounts of explosive contractions. METHODS: 7 men (20 ± 0.9 yrs; 82 ± 12 kg; 181 ± 5 cm) performed 4 protocols of 4x8 reps of squat and bench press. Two of the protocols were work-matched using 50% of maximal strength (1-RM), with one of them using exclusively explosive reps (EXPL) and the other 3 explosive reps immediately followed by 5 recreational (Partial 3/5-50%). We also included an additional partial session using 3 explosive with 50% of 1-RM followed by 5 recreational with 61.2% (Partial 3/5-61%). This protocol was work-matched with a session of exclusively recreational reps using 57% of 1-RM (REC). Subjects' 1-RM was determined on a squat machine and barbell bench press, and peak power was determined using an accelerometer. Repetition speed, ROM, and rest intervals were standardized among protocols. Total work (reps·sets·load) among the protocols was: (REC=3/5-61%) > (EXPL=3/5-50%). Expired air was collected 15min before, during, and 30min after using a metabolic cart. Data were analyzed using a 2-way ANOVA with Fisher's LSD post hoc. We hypothesized that percent increase of energy cost due to explosive repetitions would be greater with squats compared to bench press. RESULTS: Percent increase of energy cost during EXPL and 3/5-61% was significantly greater than 3/5-50% for both squat and bench press (16.4 ± 6.3 ; 15.1 ± 5.4 ; 4.5 ± 5.7 and 24.6 ± 7.3 ; 18.9 ± 8.5 ; 8.2 ± 8.5 ; respectively). Percent increase during EXPL was greater than 3/5-61%, but only for bench press. CONCLUSION: Explosive repetitions had a greater effect to increase energy cost with an upper body resistance exercise, but only with exclusively explosive sets.

Abstract Name: Visual Evoked Potential Effects on Magnocellular and Parvocellular Pathways from Athletes After Mild Traumatic Brain Injuries

Background: The objective of this study is to examine magnocellular and parvocellular pathways differentiation based on checkerboard spatial frequency stimulation between normal and visually impaired individuals from athletes with mild traumatic brain injury. Purpose: Athletes who exhibited photophobia, and blurriness were subjected to 5 spatial frequency stimuli presented to the left and right eye, and both eyes simultaneously to determine the type of receptive field loss deprecation based on sports-related brain trauma. Methods: Checkerboard stimulation enables the measurement between 2 visual processing pathways and enables the determination of the integrity of visual processing through visual evoked potentials (VEPs). Conclusion: The principal results reflect P1 responses demonstrated distinct changes in amplitude from mTBI (>5 μ V) from normal cohorts concluding higher P1 amplitude of the VEP in mTBI cohorts had increased after injury. Latency in P1 was not as distinct as amplitude changes. Our major conclusion is that most of the mTBI cohort exhibited receptive field loss across all the patients appears to be magnocellular process

deprecation due to frequent instances of 8×8 and 16×16 spatial frequencies input as it relates to amplitude and latency output.

Abstract Name: Rule-Based Approaches to Atomic Sentence Extraction

Natural language often combines multiple ideas into complex sentences. Atomic sentence extraction, which is the task of decomposing complex sentences into simpler sentences that each express a single idea, improves performance in information retrieval, question answering, and automated reasoning systems. Previous work has formalized the "split-and-rephrase" task and established evaluation metrics. Additionally, while previous work has focused on machine learning approaches using large language models to improve extraction accuracy, these methods lack interpretability and provide limited insight into which linguistic structures cause extraction failures. There have been limited previous studies demonstrating how dependency-based methods can extract subject-verb-object triples and clauses, but no principled analysis has examined which specific clause structures and dependencies lead to extraction difficulties. This study addresses this gap by conducting an analysis of how complex sentence structures that include relative clauses, adverbial clauses, coordination patterns, and passive constructions affect rule-based atomic sentence extraction performance. Using the WikiSplit dataset, we implemented dependency-based extraction rules using spaCy's dependency parser. We manually generated 100 gold standard atomic sentence sets and evaluated performance using ROUGE and BERTScore. The system achieved ROUGE-1 F1 = 0.6714, ROUGE-2 F1 = 0.478, ROUGE-L F1 = 0.650, and BERTScore F1 = 0.5898, which indicates moderate to high lexical, structural, and semantic alignment. Challenging structures were relative clauses, appositions, coordinated predicates, adverbial clauses, and passive constructions. These forms often lead to truncated atomic sentences or missing predicates. In contrast, sentences with simple subject-verb-object structures are handled well. Overall, the findings show that rule-based extraction is reasonably accurate but sensitive to types of syntactic complexity, and that targeted improvements to clause boundary detection and coordination handling can improve rule-based systems.

Abstract Name: Maternal Microbial Transfer Methods for Infants Born Via C-Section: Using Vaginal Seeding and Fecal Transplants to Promote Neonatal Gut and Skin Microbiomes

In the context of an increase in C-Sections worldwide and the association between C-section births and adverse immunological outcomes, supplementing the microbial development of C-section delivered infants through maternal microbial transfer has gained traction. This comprehensive literature review aims to evaluate the effectiveness of different microbial transfer methods, such as vaginal seeding, fecal microbiota transfer, and oral vaginal microbial transfer in their ability to increase levels of beneficial bacteria and

decrease levels of pathogenic bacteria in C-Section delivered infants to more closely match the gut and skin microbiomes of vaginally delivered infants. This review explored the practicality and safety of these treatments in relation to their effectiveness. It was found that while the fecal microbiota transplantation methods greatly improved microbial development in C-section infants, they may introduce greater levels of pathobiont species. The vaginal seeding methods, while less effective, potentially introduced infants to microbes that overlap with microbiomes of the gut, mouth, and skin. If done with mothers who have been properly tested, the research suggests that vaginal seeding can partially reduce microbial diversity, and as a result reduce pathogenic bacterial exposure in infants. The vaginal seeding and fecal microbiota transplant methods of microbial transfer have inconsistent successes with the transfer of beneficial bacteria such as *Bacteroides*, *Bifidobacterium*, and *Lactobacillus* with notable differences between an external transfer and oral ingestion of vaginal microbes. Further research to directly compare these methods and investigate the compounded effects of infant exposures to vaginal and fecal microbes during labor, may highlight how microbes interact to aid in the development of infant gut and skin microbiomes. Additionally, it's important to consider the safety and practicality of microbial transfer methods to aid the microbial development of infants born via C-Section.

Abstract Name: Developing a method to separate contributors in Forensic touch mixtures

Touch samples in crime scenes are vital to the forensic evidence collected. Though, the presence of biological fluid from multiple individuals in the same evidence sample is a problem for forensic casework. This results in difficulty in DNA profiling interpretation, which decreases its value to the investigation. Currently, there are no methods that can separate biological material and/or DNA from multiple individuals before DNA profiling. The goal of this project is to develop a new method that can separate biological material from different individuals present in a mixture. For our experiment, we created a series of DNA mixtures samples where one person deposited blood onto a substrate and the other deposited biological material onto the same substrate through contact/handling. Each mixture sample was then fractionated into two biochemical components: one containing extracellular or cell-free DNA and the other containing intact cells. Each fraction underwent DNA extraction, quantification, and profiling. Using qPCR our preliminary findings will show whether the eDNA fraction was enriched in one individual who contributed material by touching the substrate, and the cell pellet fraction was enriched in DNA from the blood contributor. Overall, this can indicate that some types of DNA mixtures can be separated using this protocol. This method and these results can help casework by improving the accuracy of differentiating mixtures, which can lead to an increase of samples that can test and used.

Abstract Name: Empathy Avoidance Based on Perceived Cognitive Costs: A Replication of Cameron et al.'s (2019) Study

This research project aims to replicate Cameron et al.'s (2019) investigation into whether people choose not to empathize because they perceive empathy as effortful, aversive, or ineffective. This project seeks to clarify when, why, and how people experience empathy and to determine whether cognitive costs reliably inhibit empathic responding. Empathy, defined as the ability to share in and understand others' experiences vicariously (Cameron et al., 2019), has been shown across multiple studies to predict prosocial behavior, high-quality interpersonal relationships, and compassionate emotions (Beadle et al., 2012; Rabelo & Pilati, 2017; Pang, 2022). Empathy also plays a crucial role in reducing bias, systemic racism, and stigmatization toward disabled, homeless, and Black individuals, and those with AIDS (Batson et al., 1997; Okonofua & Eberhardt, 2015). Recent work suggests that empathy is a motivated phenomenon requiring meaningful effort, and that this effort may undermine people's motivation to engage empathically. Because cognitive costs—such as aversion and perceived ineffectiveness—have been identified as significant reasons why people might avoid empathy (Cameron et al., 2019), and given the broader replication crisis in psychology (Lilienfeld, 2017), a direct replication of this work is both timely and necessary. The present project attempts to contribute uniquely by examining these mechanisms in a contemporary context using child refugee images. To replicate Cameron et al. (2019), 300 participants will complete the empathy selection task, which involves choosing between an “objective” deck instructing detached observation and an “empathy” deck instructing them to infer internal feelings. After 40 trials, participants will complete post-task assessments measuring perceived effort costs. A one-sample t-test will determine whether the empathy-choice rate differs from 50%. It is expected that participants will show strong avoidance of the empathy deck. Results will be discussed in light of the current political and economic climates in which empathy has become increasingly difficult to sustain.

Abstract Name: Age-Related Changes in Infant Vowel Discrimination Under Reduced Spectral Cue Conditions

Spectral resolution, characterized by the number of frequency bands like the number of keys on a piano, affects speech perception. Researchers can reduce spectral resolution by manipulating the number of frequency bands to simulate a cochlear implant, a biomedical device to help individuals hear. Six-month-olds with typical hearing can discriminate vowels (/ti/-/ta/) with unprocessed speech and 32 spectral channels, but not 16 channels, showing infants need more detailed speech information than older children and adults to tell sounds apart. We have less information about how older infants process spectrally reduced speech. This study examined the effects of spectral resolution on vowel discrimination in 9- and 12-month-old infants with typical hearing to determine if older infants require the same amount of spectral detail to perceive differences in vowel sounds. Participants included 66 9- and 12-month-old infants plus 41 6-month-olds from a previously published study. Infants were randomly assigned to listen to speech stimuli (/ti/, /ta/) processed through a noiseband vocoder to reduce spectral information while preserving the temporal envelope cues. The noiseband vocoder simulated a cochlear implant with either 16 or 8 spectral channels. Using a visual habituation paradigm, we measured infants' looking times to familiar and novel stimuli as an index of speech discrimination. Results revealed a significant effect of age and spectral resolution on vowel discrimination. Although 6-month-olds could not discriminate vowel contrasts with 16 channels, 9- and 12-month-olds could, supporting a developmental effect. Additional testing revealed 12-month-olds also could discriminate /ti/-/ta/ with 8 channels, like patterns in older children. Findings indicate that increasing age and auditory experience enhance infant's ability to extract speech cues from spectrally degraded signals, with implications for understanding early perceptual development and optimizing cochlear implant processing for infants.

Abstract Name: Saudi Hesitation Toward BRICS: Alignments, Tensions, and Vision 2030

Saudi Arabia's delayed decision to fully join the expanded BRICS alliance has raised important questions about how states navigate shifting global power structures. On the surface, BRICS offers clear benefits that align with Vision 2030, the Kingdom's national plan for economic diversification, innovation, and reduced dependence on oil. The bloc emphasizes Global South collaboration, new development financing, and economic growth outside traditional Western-led institutions. These goals appear consistent with Saudi Arabia's long-term strategy. Yet the Kingdom has taken more than a year to finalize its BRICS membership, signaling that the decision is far more complex than it initially appears. This project explores why Saudi Arabia remains cautious despite the apparent alignment between Vision 2030 and the economic agenda of BRICS. Drawing on policy statements, regional scholarship, and comparative analysis of Gulf Cooperation Council (GCC) dynamics, the research examines several overlapping factors. These include Saudi Arabia's deep security and military ties with the United States, its desire to preserve strategic autonomy, and regional concerns, particularly regarding Iran's membership in BRICS. The project also considers the internal narratives promoted through Vision 2030, which position Saudi Arabia as a modern, globally engaged state that can work with all major powers without fully committing to any single bloc. By analyzing these political, economic, and regional layers together, this research offers a clearer explanation for why the Kingdom is balancing enthusiasm for multipolar cooperation with caution about the geopolitical consequences of joining BRICS. Understanding this hesitation matters because it reveals how middle powers in the Global South navigate pressure from both Western institutions and emerging coalitions. Ultimately, the project contributes to broader conversations about global governance, economic diversification, and the evolving role of Gulf states in an increasingly multipolar world.

Abstract Name: How are Values Represented in the EU Commission and Speeches by Leaders?

What defines a value compared to a principle? What leaders are taking initiative in supporting constituents and upholding their values? How can data be implemented in this process? In this oral/poster presentation, I will present the aims/missions of our current "PL2" lab project, which illuminate the ways that different leaders spotlight values different values over time. It showcases the lab's interdisciplinary approach, combining computational text analysis and public-facing data visualizations to promote deeper understanding of the European Union's power dynamics. We take bulky amounts of documents, excel, and archived word data that showcases speeches and mission letters, and parse them into sections and categories that highlight how many times a specific commission has mentioned and contributed to keeping the European Values of Human Dignity, Freedom, Democracy, Equality, Rule of Law, and Human Rights intact, using tools like R and Quanteda. Furthermore, through our research, we identify the distinguishing characteristics between principles and these values. Our lab achieves to create data visualizations & websites through this parsed data to showcase and highlight places of work and places of defined, supported values through actions.

Abstract Name: An Analysis of Misconceptions of the Economy

This research explores why Americans have pessimistic views about the economy even when economic indicators show growth, stability, and recovery. Even with the numbers of rising GDP, low unemployment, and moderating inflation, public sentiment remains shockingly negative. A large contributor to this is the widespread lack of economic literacy. Only half of Americans recall taking an economics course, leaving many without the conceptual tools to interpret data or distinguish between correlation and causation. So, because of this, people often fall into cognitive biases, such as assuming inflation is solely driven by government overspending or assuming inflation is caused mainly by corporations unfairly raising prices while overlooking factors like global supply chain disruptions, labor shortages, and post-pandemic recovery progress. Media coverage also further complicates public understanding. Economic reporting tends to track the experiences of wealthier households because aggregate indicators such as stock performance incorrectly reflect upper-income gains. In the meantime, stories about inequality or wage stagnation receive less recognition, which in total creates a skewed picture of overall conditions. Politics amplifies these misconceptions. Many voters believe the economy is improving only when their preferred party is in power, creating sharp divides in consumer confidence and expectations. These forces contribute to what economists call a “vibecession” or a recession in vibes rather than in a measure of economic data. Even when data shows stability, negative public feelings can slow consumer spending, reduce business investment, and influence decisions. This means people’s negative feelings can actually impact the economy. By analyzing education gaps, cognitive biases, media coverage, and political division, this research explains how misconceptions take place and why they continue to happen. In the end, the idea is that better economic education and clearer reporting can help shrink the gap between what the economy is actually doing and how people think it’s doing.

Abstract Name: The Pilkësh Woman: Indigenous Women’s Erasure in Manahatta’s Archival Record

On September 15, 1655, the former State’s Attorney of New Netherland, Hendrick van Dyck, murdered an Indigenous Lenape woman who was picking peaches from “his” Manahatta orchard, located somewhere between modern day Broadway and Morris Street. This incident would lead to the Peach War of 1655, a historically contentious day-long occupation of Manhattan, Staten Island, and local New Jersey by outraged Indigenous people. In the archival record this Indigenous woman is mostly erased and defamed with racist slurs – her name is at this point unknown, and her life and death questioned for historical relevance. In contrast, Dyck’s life and gilded legacy are well-documented beyond the archival record, despite his direct involvement in the genocide of Lenape natives. Even to Peter Stuyvesant and William Kieft, he was considered unlikable and incapable. I call this Indigenous woman the Pilkësh (Lenape for “peach”) woman,

as she has no historically supported name, and she was thought to have been picking peaches at the time of her death; her relative absence in the archival record is representative of a larger erasure of Indigenous women in academic and historical texts and tangible spaces, where they are most likely to be forgotten or intentionally excised from narratives due to political, racial, patriarchal colonial systems. In this project, I attempt to recover the Pilkēsh woman's story through archival records and maps, like the NYC Metropolitan Archives and New Netherlands digital archive. Given the paucity of material, I first identify Dyck and the location of his orchard and supplement the gaps with secondary historical sources. This research contributes to the acknowledgement of colonization and intervenes in the erasure of indigenous women in archival records, academic spaces, and historical texts, an erasure that I connect to modern day injustices against Indigenous women.

Abstract Name: Do neurodegeneration-associated actin mutations reduce neuronal survival?

Background and Hypothesis: Cofilin-actin rods and large actin inclusions are associated with neurodegenerative diseases, including Alzheimer's disease. Previous studies have shown that early cytoskeletal abnormalities, particularly involving actin inclusions, contribute to neuronal vulnerability. Understanding how different actin residues contribute to abnormal cytoskeletal structures is critical to understand neurodegeneration. In this study we investigated the effect of K18A and D154A actin mutations on neuronal survival. These mutations are located in the ATP-binding domain of actin and lead to inclusion formation in neurons. We hypothesized that these inclusion-forming mutants will increase neuronal vulnerability and reduce neuronal survival. **Methodology:** Cortical neurons were dissociated from E18 mouse embryos and plated on PDL/Laminin-coated 12-well plates (500,000 cells/well). On DIV5, neurons were transfected with GFP-labeled K18A and D154A actin constructs. Forty-eight to seventy-two hours post-transfection, neurons were fixed and immunostained for MAP2 and NucBlue™, and then imaged using confocal microscopy. Nuclear integrity and fragmentation were assessed in ≥ 50 transfected and ≥ 100 non-transfected neurons per coverslip. Cells were manually counted using FIJI/ImageJ by identifying GFP-positive neurons for the transfected population and NucBlue-labeled nuclei for the total population. Cytoskeletal inclusions and neuronal viability were quantified using FIJI/ImageJ. Basal neuronal death was low (12.7-11.3%) in the non-transfected population, indicative of healthy cultures. We found that neither of the two inclusion-forming constructs enhanced neuronal death. Basal neuronal death in the K18A-transfected neurons was 8.7%, while in the D154A-transfected neurons was slightly higher, at 17.6%. These preliminary studies from two independent experiments indicate that the K18A and D154A inclusion-forming actin mutants might not cause neuronal death. In ongoing studies, we will repeat these experiments and will also evaluate the effect of a rod-forming mutant (G158L) on neuronal survival.

Abstract Name: The Impact of Spatially Localized Feed Parameter Perturbations on Reaction-Diffusion Systems

The Gray-Scott Model is a prominent reaction-diffusion system that comprises two chemical species, u and v , which interact through complex reactions and transformations. By manipulating parameter values within the model, spatiotemporal patterns emerge that mirror essential biological, chemical, and physical processes, including DNA oligomer formation, skin pigmentation development, and oscillatory chemical reactions. While extensive studies have typically focused on fixed parameter values, this research innovatively introduces specially defined functional forms that spatially vary key parameters throughout the lattice. Specifically, by employing sinusoidal and other oscillatory functions to modulate parameter values, we can seamlessly integrate the dynamics and behaviors characteristic of diverse parameter settings within a single reaction framework. This novel approach not only reveals a spectrum of unique and intricate patterns but also enhances the model's applicability, extending its relevance to a broader range of natural phenomena. Through this exploration, we aim to deepen our understanding of reaction-diffusion systems and their potential implications in both theoretical research and practical applications.

Abstract Name: Investigating the Effect of Introspective Reports of Freedom on Volition Using Social Desirability

This project investigates the relationship between an individual's perception of their freedom and how free they actually are when making decisions. The central research question asks whether individuals recognize when subtle social factors are shaping their decisions or if they genuinely believe their choices are being made freely even when they clearly are not. Social desirability is the tendency to present oneself in a favorable light. It is commonly measured through scales such as the Marlowe-Crowne Social Desirability Scale (MCSDS) and the Balanced Inventory of Desirable Responding (BIDR). This study will test whether the presence of an onlooker influences the participants' responses in the social desirability scales, and whether they are aware of that influence. Participants completed the MCSDS and BIDR scales in two conditions: one where an onlooker was present and one where they were alone. Contrary to our expectations, we did not find an effect of the onlooker's presence on either the MCSDS and BIDR scores, nor the perceived influence reports. This finding is interesting, as it contradicts the intuition that when another person is present, our tendency to create favorable social impressions should increase. Additionally, we found that the participants reported feeling more influenced after answering questions from the BIDR scale than the MCSDS. This finding is surprising, as it indicates an important inequality between the two scales, which have otherwise been considered equivalent. The experimenter's presence didn't significantly impact the influence reports therefore future research should examine whether the lack of observable influence persists across different contexts, populations, and types of social presence.

Abstract Name: Predicting the Overall impact of using AI in education by employing multiple predictive Algorithms

The AI usage in education is increasing at a rapid rate but its impact on education is not fully comprehended. In this study we investigate three datasets which are directly related to students and their perception of AI usage in education. We developed AI models to predict students' involvement in AI, students intention to reuse AI, and impact of students' grades as they incorporated AI techniques in their day-to-day studies. An attempt is made to correlate three datasets which were modeled individually for the selected output parameters. The first dataset the AI Assistant Usage in Student Life was collected from Kaggle, which simulates 10,000 sessions across multiple disciplines and academic levels. The dataset captures behavioral and performance indicators, including session duration, number of prompts, task type, perceived AI helpfulness, and satisfaction ratings. Google CoLab was used to develop AI/Machine learning based predictive models by employing Random Forest algorithm to predict students' intention to resume AI techniques for their assignments and homework. The model achieved ~82% accuracy. The second dataset is Student AI Education Perception, which contains 5,000 student survey responses evaluating trust, ethical concerns, AI reusability intention. We achieved an RMSE of ≤ 2.3 for the predictive models that employed multiple algorithms. This study highlighted the AI usage in education and its impact on students' grades. The third dataset, Students' Perceptions of AI in Education, is incorporated to evaluate the model's ability to generalize across attitudinal signals and academic outcomes. In this phase, we investigate how the inclusion of students' perception-driven features enhances predictive performance. In the end three models are being integrated to predict the overall impact of AI techniques involvement in students education. Full results will be presented in the conference.

Abstract Name: Optimal Instrument Alignment Estimation and Attitude Filtering for the COSMO CubeSat Mission

The Compact Spaceborne Magnetic Observatory (COSMO) is a 6U CubeSat mission developed at the University of Colorado Boulder and designed to provide high-resolution measurements of the Earth's magnetic field from space. These measurements are made by a novel instrument called the vectorized rubidium magnetometer or VRuM. Measurements from COSMO will be used to contribute data to the World Magnetic Model (WMM), a global magnetic field model used widely for civilian and military applications including navigation, mapping, and in consumer electronics. In order for our measurements to be useful, knowledge of the precise attitude of the magnetometer is needed at the time of each measurement. For our magnetic field measurements to be highly accurate, we must know the magnetometer's attitude with very high accuracy, on the order of 10 arcseconds or better. COSMO measures its attitude using two star trackers, which capture an image of the sky to determine their own attitude. There are two components to this problem: first, we must accurately determine the geometric relationship between the star trackers and the magnetometer. For this purpose, we have developed an algorithm based on the optimal solution to Wahba's problem, which allows us to determine this geometric relationship from on-orbit data with arcsecond level

precision, without the need for expensive metrology. Next, we must apply a method for combining and refining our two star tracker measurements to provide the best estimate of the magnetometer attitude. We accomplish this task with a variation on a nonlinear Kalman filter, with some adaptation for our specific use case. This method allows us to leverage measurements of spacecraft body-fixed angular rates to achieve attitude estimates that are multiple times more accurate than that of a single star tracker. We have implemented these algorithms in numerical simulations on flight-like datasets to evaluate their performance.

Abstract Name: Bitcoin Mining Facilities, Air Quality, and Social Vulnerability in the United States

The recent explosion of artificial intelligence, cryptocurrency, and large-scale data mining has resulted in a rapid increase in the construction of data centers and Bitcoin mining facilities throughout the United States. These operations play an influential role in the digital economy, yet their environmental and social impacts are not fully understood. Based on current practices, these operations are resource-intensive, drawing large amounts of electricity from nonrenewable or unsustainable sources and contributing to CO₂ emissions, water consumption, e-waste, and noise pollution. Although their global effects are documented, the current literature provides little insight into impacts on the communities that host them or the processes surrounding their placement. This study explores whether there are discrepancies in population attributes, specifically economic status, race, and education level, between areas near Bitcoin mining facilities and areas farther away. Additionally, we examine air quality, focusing on PM_{2.5} levels near the facilities, compared with the same areas before and after the facilities were built and with tracts farther away. Facility locations were obtained from DataAxle, and socioeconomic and air quality data were collected at the tract level from the U.S. Census Bureau, U.S. Environmental Protection Agency, PurpleAir, and the Centers for Disease Control and Prevention. Using ArcGIS, these data were mapped, spatially joined, and analyzed with apportionment to compare conditions within 5 miles of each center to a surrounding 5 to 25 mile radius. We then ran comparison testing in R (v 4.5.0), which included two-sample comparison tests and spatial regression. We have found disproportionate placement of Bitcoin mining centers in low-income areas. The evidence provides policy-relevant insight that can catalyze environmental health research, urban planning approaches, and technology policy toward more sustainable digital infrastructure development.

Abstract Name: Effects of Histamine on Intestinal Epithelial Permeability

Stress has been closely linked with changes in the intestinal barrier function, resulting in elevated intestinal

permeability (“leaky gut”). Increased intestinal permeability is known to be an important factor for various gastrointestinal diseases, including irritable bowel syndrome (IBS) and inflammatory bowel diseases (IBD). Mast cells, activated in response to stress, are responsible for alterations in intestinal permeability induced by stress. Activation of these mast cells releases several chemical mediators such as histamine, which can potentially influence the integrity of the intestinal barrier. However, the exact role of histamine on intestinal permeability remains poorly studied. In the current research, we studied the direct effects of histamine on intestinal permeability by using isolated intestinal tissues of the ground squirrel. Intestinal permeability was measured by monitoring the transepithelial electrical resistance (TER), a reliable marker for paracellular permeability. Initial findings indicated that histamine treatment resulted in a significant decrease in TER. This showed increased paracellular permeability. To differentiate paracellular from transcellular routes, we used two different sized molecules. For paracellular, this study used FITC-inulin (4 kDa). Additionally, to test for transcellular pathway, horseradish peroxidase (HRP, 44 kDa) was used. FITC-inulin and HRP were added to the luminal chamber, with sample measurements of luminal-basolateral transfer for both molecules. Histamine significantly increased FITC-inulin flux in the large intestine reflecting an increase in paracellular transport. However, histamine did not significantly change HRP flux, indicating no increase in transcellular permeability. Additional research will investigate the role of histamine in paracellular permeability mechanisms and pathways to explain its role in intestinal barrier regulation. A comprehensive understanding of histamine's impact on intestinal permeability may yield valuable insights for developing novel therapeutic interventions for stress-induced gastrointestinal disorders.

Abstract Name: Examining the Role of Gut Microbiota in Chemotherapy-Associated Pain

Neuropathic pain and peripheral neuropathy are common and debilitating side effects experienced by patients receiving chemotherapy drugs, such as paclitaxel. While these drugs can directly destabilize axons and glia in peripheral nerves, thereby causing neuropathy, recent evidence suggests that the gut microbiome, microorganisms and metabolites in the gastrointestinal tract, may also contribute to chemotherapy-associated pain. However, it is not yet clear if and how alterations in the intestinal microbiota drive peripheral neuropathy following chemotherapy treatment. To test this hypothesis, we transplanted the fecal microbiota of animals treated with paclitaxel (8 mg/kg, IP every other day for 4 consecutive days) into naive C57BL/6 mice for 3 consecutive days. Compared to vehicle fecal microbiota transplant (FMT) recipients, paclitaxel FMT recipients developed persistent mechanical allodynia, cold allodynia, and ongoing pain that lasted for at least 28 days. To assess whether this behavioral phenotype was associated with anatomical and functional changes of peripheral nerves, we collected hind paw skin and dorsal root ganglia (DRG) neurons from an independent cohort of mice on day 14 post FMT. Histological analysis of nerve fibers (PGP9.5) in the hind paw skin revealed significantly reduced intraepidermal nerve fiber density ($p < 0.05$) in paclitaxel FMT mice compared to vehicle FMT skin. In addition, calcium imaging of cultured DRG neurons (T12-L2) from paclitaxel FMT mice showed a greater proportion of cells responding to application of lipopolysaccharide, a bacterial outer membrane component ($p < 0.01$). Lastly, data on sciatic nerve permeability using sodium fluorescein revealed reduced blood-sciatic nerve barrier integrity in paclitaxel FMT mice compared to vehicle controls. Understanding the gut microbiome's role in chemotherapy-associated pain and neuropathy is key to developing microbiome-targeted treatments, as chemotherapy-related microbiome changes can directly impact peripheral nerve anatomy and physiology. Future work will focus on identifying microbial and molecular drivers of these effects.

Abstract Name: Synergistic combination of immune-targeted photoactivable liposome (iTPALs) and nab-paclitaxel for inhibition of pancreatic cancer

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer and the third leading cause of all cancer-related deaths in the U.S., with an average 5-year survival rate of 13%. More than 50% of the patients are diagnosed upon metastasis. For metastatic PDAC, one of the standard of care regimens is nab-paclitaxel, which, even when combined with gemcitabine, only improves survival up to 8.2 months. In our previous studies, we identified that the clinically approved photosensitizer Benzoporphyrin derivative conjugated to lysophosphatidylcholine, or BPD-PC, is an effective agent for photodynamic therapy (PDT). PDT is a light-based anti-cancer treatment modality where photosensitizers are activated by a specific wavelength of light to generate reactive molecular species (RMS), capable of disrupting and modulating the tumor stromal and immune microenvironment. Recently, we harnessed BPD-PC and encapsulated it within a liposome and functionalized the liposomal surface with anti-PD-L1 antibodies to develop immune checkpoint targeted photoactivable liposomes (iTPALs). We found that iTPALs successfully modulate the PDAC tumor stromal and immune microenvironment, resulting in improved survival in mice bearing subcutaneous PDAC tumors by 42.9%. This study highlights the potential of combining iTPAL with nab-PTX to enhance treatment outcomes in patients with metastatic PDAC. In our current study, we investigated the synergy between iTPALs and nab-paclitaxel. We conducted a series of mechanistic studies on murine PDAC cell lines (CT1BA5, 6620c1, C419C5). Dose-response studies revealed a higher synergistic inhibition of the cells with the combination. Flow cytometry showed an increased expression of an immunogenic cell death marker, HSP70, with the combination in comparison to monotherapies. Additionally, we also found a significant increase in G1/S cell cycle arrest with the combination. Thus, these findings highlight the potential of iTPALs to improve the treatment response of nab-paclitaxel in metastatic PDAC.

Abstract Name: The Beneficial Effect of Ketogenic Diet to Reduce Mice Body Weight

As obesity rates continue to rise in the US, ketogenic diets (KDs), characterized as a high fat, and low carbohydrate dietary approach, have emerged as a promising strategy for managing obesity. KDs range widely in fat intake with pilot data from the Fu Lab indicating that diets exceeding 85% total caloric intake reliably induce ketogenesis, a metabolic process responsible for the production of ketone bodies. It remains unclear, however, what specific fat intake yields the best physiological and metabolic results. In this study, two ketogenic diets were investigated—80% KD and 90% KD—and its effects on mice body weight, blood

glucose, and ketone body production to mice previously made obese through a high fat-diet (HFD). Three groups of eleven mice were examined: HFD control (n=3), 80% KD (n=4), and 90% KD (n=4). Blood glucose along with β -hydroxybutyrate (BHB) levels were measured on Days 0 and 15, while body weight was measured twice a week throughout the study. The 90% KD produced the most physiological effects in obese mice, resulting in significant weight loss, in comparison to the minimal changes observed from the 80% KD mice group, while the HFD control mice group exhibited continued weight gain. Accordingly, mice in the 90% KD group also exhibited lower blood glucose, reaching 57 mg/dL, and BHB levels, suggesting strong metabolic responses, yet at potential risk of hypoglycemia. These findings confirm ketosis induction at 90% KD highlighting the effectiveness of a very high-fat KD. Due to the study's limited duration, long term sustainability and safety remain uncertain. Future work will incorporate molecular analyses techniques such as PCRs, and Western Blotting to clarify our understanding of KDs influence on metabolic pathways and its connection to the observed physiological changes.

Abstract Name: Exploring the Impact of Policy Changes on Sexual Violence Services for Marginalized Survivors

This project examines how recent federal policy changes and broader sociopolitical shifts in the United States are reshaping sexual violence services, with particular attention to impacts on marginalized communities. We analyzed 106 websites from national organizations and state sexual and domestic violence coalitions and compared versions from 2024 and 2025 to identify changes in publicly available resources. Using a structured survey tool, we evaluated each site for meaningful inclusion, limited mention, or absence of information related to trans and nonbinary people, LGBTQIA2S+ communities, BIPOC, Indigenous peoples, immigrants, non-English language resources, disability and accessibility, and reproductive health (e.g., abortion, Plan B, and contraception). In addition to this website analysis, we conducted interviews with over two dozen professionals working in sexual violence services and training and technical assistance who provided qualitative insight into how policy shifts are affecting resource delivery and survivor support. Together, these methods allow us to capture both the online presence of services and the lived realities of those navigating institutional changes. Early findings point to patterns of omission, where marginalized groups are not mentioned at all, and erasure, where previously available information has been removed. These changes raise important questions about accountability, transparency, and the politicization of survivor support. By highlighting how policy climates directly shape access to care, this project underscores the urgency of inclusive and equitable outreach. The findings contribute to broader conversations about justice, representation, and the responsibility of institutions to ensure that survivors from all communities can find the resources they need.

Abstract Name: AI-Driven Sensor Systems to Improve Yields in Smallholder Specialty Crops

We are proposing to develop an AI-sensor driven farm management system that continuously monitors several environmental variables (e.g., soil water potential, humidity, air temperature, sunlight, plant growth) at a specialty vegetable crops fields. The system will estimate four key vegetation growth and health metrics (VGHI), nutrient availability (NAI), light dose (DLI), and disease risk (DRI) then uses AI pattern recognition to automatically generate actionable alerts: critical RED alerts (sensor failure, immediate action) trigger SMS + emails within 2 minutes; ORANGE alerts (hidden stress like physiological drought or disease outbreak risk) send push notifications within 30 minutes with specific recommendations (e.g., "Increase irrigation to fix root zone salinity" or "Spray preventative fungicide now"); YELLOW alerts (preventative warnings) batch into hourly emails; and GREEN signals quietly confirm the system is optimized. The system learns from a knowledge base that we trained based on extensive records of University Agricultural Extension Service documents provide recommendations tailor-made for the local conditions, weather, types of crops and local and regional market prospects. In addition, our proposed system will also estimate plant water requirements, track available soil water, and automate an irrigation and fertigation schedule for optimal plant growth. The system will be designed such that it will be able to integrate multiple crops and variable planting schedules (lettuce, tomato, pepper, microgreens, etc.) by storing crop-specific targets (e.g., lettuce needs 12-16 mol/m²/day light, tomato needs 18-25). The system will be designed to learn from and provide improvements to the actual ground conditions as the growing season progresses. Our ultimate goal is to develop a system that can improve specialty crop productivity, minimize resource use and maximize net income for smallholder farmers.

Abstract Name: Smart Irrigation System for Specialty Crop Production at South Farm

Inefficient irrigation in specialty crop production leads to water waste, uneven crop hydration, and high labor demands. This project develops and field-tests a low-cost, scalable smart irrigation system for specialty crops at the University of Missouri's South Farm. The system integrates an ESP32-based controller that operates multiple solenoid valves and an electric pump with a METER ZL6 soil data logger and an ATMOS 41 weather station. Sensor and weather data are transmitted via cellular connection to ZENTRA Cloud and a Raspberry Pi running Home Assistant, which together provide a reliable control hub. An irrigation algorithm combines soil moisture thresholds with reference evapotranspiration (ET_o) from the Climate Engine API to decide when and how long to irrigate each zone. When thresholds are exceeded, the controller automatically starts the pump and opens the appropriate valves, logging each event and sending email notifications; a gas-powered pump provides a manual backup to ensure irrigation continuity. A Flask backend with a React-based web dashboard allows researchers to visualize soil moisture and weather conditions in real time, monitor pump and valve status, adjust scheduling parameters, and view zone locations on an interactive map. The system is currently deployed for field trials on specialty crops, where we are evaluating water-use efficiency, soil moisture stability, and labor savings compared to conventional manual irrigation. Preliminary observations indicate more stable soil moisture and reduced unnecessary irrigation events. At NCUR, we will present the system architecture, deployment experience, and quantitative results on water savings and management efficiency, highlighting how this approach can support climate-resilient, data-informed irrigation in specialty crop production.

Abstract Name: Plant Breeding: A Genetic Crisis

Plant breeding has become invaluable in the modern world as it improves crops by increasing yield and nutrition, enhancing flavor, and fortifying resistance to environmental stressors; yet, it also decreases genetic diversity among plant species, making them more susceptible to disease, and it makes plants more reliant on human interference to grow, exacerbating the negative environmental impacts associated with current industrial agriculture techniques. This shows a clear dilemma, as plant breeding is necessary to support crop production amid growing population and climate change, but it is also dangerous as it opens the possibility for a single disease to wipe out major staple crops. In order to fully explore the repercussions and possible solutions to this dilemma, scientific research regarding genetic diversity, manipulation, and climate change must be studied while also focusing on the humanitarian impact by looking at case studies of different communities' reliance (or non-reliance) on plant breeding around the world. While methods of addressing food insecurity and genetic diversity have been implemented in the past, the cultural impacts of changing agriculture in different communities across the world is rarely a central focus. Considering the necessity of plant breeding and industrialized agriculture, yet the deterioration of plant health and environmental damage associated, there is no clear solution to this issue. Despite this, there are undoubtedly three vital steps that must be taken in order to address issues associated with plant breeding: there must be encouragement of genetic diversity in agriculture, investment into research on plant genetics, and multinational agreement regarding how to increase crop genetic diversity. If nothing is done to address the issue of the continuous decline of plant genetic diversity, many of humanity's needed agricultural products could go extinct and bring with them massive environmental damage and food insecurity.

Abstract Name: Dose-Dependent Effects of Lead Exposure on Zebrafish: Implications for Survival, Development and Behavior

Lead (Pb) is an environmental toxin known to impair neurodevelopment. Understanding the molecular and developmental mechanisms underlying lead-induced toxicity is critical for designing risk assessment and developing protective measures for Zebrafish in their natural environment. This study aims to (1) determine the lethal and sublethal concentrations of lead exposure in zebrafish embryos and larvae, and (2) evaluate the impact of lead on zebrafish growth, morphological development, behavior, and gene expression. Embryos were exposed to increasing concentrations of lead nitrate (0, 25, 50, 100, 250 micrograms/liter) under standard conditions. Mortality and developmental abnormalities - such as delayed hatching, pericardial edema, impaired swim behavior, and spinal curvature - were assessed at multiple time points up to 7 days post fertilization. Growth metrics and behavioral changes were quantified using image analysis. Results from preliminary trials show a dose-dependent relationship between lead concentrations and growth abnormalities. The findings from this research can be used to enhance the current understanding of lead toxicity mechanisms, support environmental efforts, and contribute to the early identification of biomarkers for human health risk assessment. Zebrafish studies may also serve as a platform for screening potential therapeutic agents to mitigate lead induced damage.

Abstract Name: Hands to Plants: An Investigation Of The Effect Of Human Touch On The Lettuce Leaf Microbiome

Growing edible plants in public spaces has the potential to reduce carbon dioxide emissions from buildings and assist those frequenting the spaces who are experiencing food insecurity. However, growing plants in public settings puts them at risk of disease due to possible exposure to plant pathogens; additionally, publicly grown plants could present a health risk when consumed because of their possible contamination with food-borne pathogens by the people frequenting the space. To investigate these plant and human health risks, we used both our lab space and a Virginia Tech classroom to grow plants hydroponically with different levels of human interaction; occupants were instructed to touch some of the plants and stay away from others. For culture-independent study, plant leaf-associated bacterial communities were analyzed by 16S rRNA sequencing over multiple experimental periods of 3 months each. Nutrient solutions obtained from the tanks of the hydroponic systems were sampled simultaneously and also studied using 16S rRNA sequencing. For culture-dependent study, plant leaf-associated bacteria were cultured on Reasoner's 2A agar following the Spring 2025 semester trial and analyzed by whole genome sequencing. The plant microbiomes were expected to be minimally affected by humans in the absence of direct contact and strongly affected by touch. However, in our culture-independent study, we found no consistent differences in taxonomic composition between plants with differing exposures; alpha diversity values were similar, and no single operational taxonomic unit was enriched in any set of plants. Known opportunistic pathogens were identified across plants both touched and untouched by room occupants. In our culture-dependent study, bacterial abundance increased as much as 244% in plates cultured from plant leaves touched by room occupants as compared to those left untouched. While these preliminary results suggest minimal risk of transmission of human-associated bacteria to plants, more experiments are planned to confirm this conclusion.

Abstract Name: Access to Maternal Healthcare Devices in Rural Bihar: The Role of Ultrasound in Maternal Mortality Outcomes

Bihar accounts for one of the highest maternal mortality rates in India, nearly twice the national average, and despite national progress in antenatal care expansion, rural women continue to face preventable, life-threatening complications due to limited access to essential diagnostic devices. While maternal health inequities in rural India have been widely documented, the specific role that portable ultrasound plays in shaping survival

outcomes in low-resource settings has received far less focused attention. By integrating public health, biomedical engineering, and health-systems analysis, more operational insight becomes available regarding how diagnostic access, or the lack thereof, directly affects the timing of intervention. Existing research shows that inadequate infrastructure, uneven device availability, and high out-of-pocket costs delay the detection of complications such as malpresentation, preeclampsia, and fetal growth restriction, all of which contribute to preventable deaths. Additional determinants shaping maternal outcomes, including geographic disparities, cultural norms, and rural health-system fragmentation are also relevant, but none operated as strongly or consistently as diagnostic inequity. There were four major areas of focus in my study: (1) identifying how gaps between antenatal-care coverage and quality impact early screening, (2) analyzing the distribution barriers that limit access to portable ultrasound, (3) evaluating the financial burden imposed on low-income families seeking diagnostic services, and (4) assessing how insufficient provider training diminishes the clinical value of available devices. Collectively, the evidence shows that improving maternal survival in Bihar requires not only technological innovation, but also equitable distribution systems, sustainable financing, and comprehensive training frameworks to ensure that portable ultrasound fulfills its intended purpose.

Abstract Name: The Effects of Osteosarcoma on Whole Bone Properties

Osteosarcoma (OS) is the most common type of primary bone cancer, affecting mostly children and adolescents. OS typically develops in the long bones and disrupts normal bone formation, causing structurally abnormal and weakened tissue. The goal of this study is to evaluate the impact of OS on the structure and mechanical integrity of the whole bone to assist in treatment planning and patient recovery using an orthotopic OS murine model. Mice were injected with OS cells in the right tibia, with the contralateral limb serving as a control. After 21 days of tumor development, mice were sacrificed and both limbs were extracted. Each tibia was scanned using micro-computed tomography (micro-CT) at an 8.44um voxel resolution. Bone morphometric parameters such as total volume, bone volume fraction (BV/TV), trabecular thickness, cortical thickness, and cortical porosity were quantified using Dragonfly. BV/TV and trabecular thickness were analyzed in the trabecular region near the proximal head of the tibia and cortical parameters were analyzed 37% (closest to OS tumor cell injection site) and 75% distally from the growth plate. After scanning, uniaxial compression testing was performed on all tibiae until failure to evaluate mechanical properties such as stiffness and ultimate load. Preliminary data shows that tumor-bearing limbs have significantly higher cortical porosity and thinner cortical thickness than controls, effects typical of OS-induced bone weakening. Total volume generally trended higher in tumor-bearing specimens, but both cortical and trabecular regions showed a slightly lower total volume than normal regions, suggesting more bone destruction in these regions. There were no significant differences in cortical parameters at the 75 percent site suggesting the effects of osteosarcoma are more localized. Understanding how OS alters bone structure and integrity will support the development of improved treatment strategies and fracture risk prediction for clinical OS patients.

Abstract Name: Global Sustainable Stock Portfolios from an Investors Perspective

Sustainability is an increasingly important aspect of our world, yet many retail and institutional investors are unfamiliar with sustainable investments and do not consider them relevant. This research addresses the gap by empirically evaluating publicly traded sustainable stock investments and compares them to traditional investment alternatives. We propose using B Lab certification as a sustainability benchmark since B Lab certification is obtained by companies that strive to maintain stringent Environmental, Social, and Governance (ESG) scores. B Lab certification is challenging to attain and maintain, and therefore has become a significant standard for identifying sustainable investments. To demonstrate the potential outcomes of sustainable stock investments, our research constructs and compares multiple portfolio strategies composed of B Lab certified companies and relevant non-certified peers. We assess these strategies against traditional investments such as the S&P 500 to evaluate risk-adjusted returns, and long-term performance. Additionally, we conduct event analyses to measure the effects of sustainability-related social media events on the performance of sustainable portfolios. In particular, we quantify the impacts of sustainability-related social media posts from Elon Musk on the short-term performance of various sustainable investments, providing valuable insight into the effects of social media discourse and sentiment on sustainable investments. This research analysis on sustainable investments spans variations in company size, industry sector, and global region, offering a comprehensive evaluation of how sustainable investments perform in different market environments. Furthermore, by incorporating the effects of social media discourse on sustainable investments, this research contributes to a more nuanced and practical understanding of sustainable investments. We hope to equip investors with knowledge about sustainable investment alternatives and encourage informed participation in sustainable investing.

Abstract Name: Differential Elevation of IL-33, IL-6, and IL-4 in Bronchoalveolar Lavage Fluid following Micronanoplastic and Alternaria Exposure in a Murine Asthma Model

Asthma is a chronic inflammatory disease of the airways mediated by complex cytokine networks. Environmental exposures such as airborne micro- and nanoplastics (MNPs) may exacerbate airway inflammation when combined with common aeroallergens. In a prior study, intranasal exposure to 3D-printer-derived MNPs induced marked declines in lung mechanical function in mice. This was seen to exacerbate the asthmatic impact of allergen exposure alone and revealed a potential environmental risk factor for asthma severity. Building on those findings, the current study aims to characterize specific cytokine responses in bronchoalveolar lavage fluid (BALF) following exposure to MNPs coupled with the Alternaria allergen (MNPAAF) compared to the Alternaria allergen alone (AAF). C567BL/6 mice were assigned to three groups: saline, alternaria only, and combined alternaria + micronanoplastics. After an 8-day exposure regimen, BALF was collected, and levels of Interleukin-33 Th2 cytokine early alarmin, Interleukin-6, and Interleukin-4 Th2 cytokine were quantified by ELISA assay and analyzed using Gen5 software. These cytokines were selected due to their established roles in allergic airways inflammation and suspected elevation in both the AAF group and MNPAAF group. IL-33 acts as an epithelial “alarmin” molecule to promote type 2 immune activation while IL-4 acts in the immune cascade on downstream allergic responses. IL-6 is a pro-inflammatory cytokine which shows its effects as bronchial constriction, bronchospasms, and other asthma-induced complications. In previous research, exposures to micro/nanoparticles (MNPs) generated from 3D printing emissions led to a significant and progressive decline in lung mechanical function, characterized by reduced

dynamic compliance and elevated airway resistance, tissue damping, and elastance. These alterations in respiratory mechanics were more severe than those induced by *Alternaria*, a known biological allergen. Previous results suggested that inhaled MNPs contribute to airway hyperresponsiveness and structural remodeling of lung tissue, likely through inflammatory and biomechanical disruption of both airway and parenchymal components.

Abstract Name: Exploring Perceptions of Autism Spectrum Disorder Accommodations

This literature review explores the role of fairness, prejudice, and norms in how people perceive ASD accommodations. Approximately 3% of people in the U.S. have autism, highlighting the importance of understanding accommodations for neurodevelopmental disorders. Neurodevelopmental disorders are “developmental deficits or differences in brain processes that produce impairments of personal, social, academic, or occupational functioning” (DSM-5-TR, 2022, p. 36). Examples of these disorders include autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder, and dyslexia (Office of Minority Health, 2025). Many of these individuals identify as “neurodivergent” rather than “neurotypical” (Healy, 2024). In general, educational and workplace accommodations help individuals with physical and mental impairments to be successful. For example, educational accommodations may include longer verbal response time from the student, short breaks to leave class, and extra time for exams (Wheeler, 2014). Furthermore, workplace accommodations may include service or emotional support animals, flexible breaks, and workplace modifications for sensitivity to light and noise (JAN, 2025). This review found that although individuals with ASD are legally entitled to workplace and school accommodations, stigma persists. Common stereotypes include being viewed as incompetent, awkward, cold, unsociable, aggressive, unintelligent, frightening, and even dangerous (Patton, 2018). Additionally, studies have shown that when neurodivergent students are provided accommodations and outperform their classmates, neurotypical students may view these accommodations as unfair (Paetzold et al., 2008). Stigma can also occur when ASD individuals display behaviors that are different from typical norms within the workplace, as what is “normal” for neurotypicals may be challenging for neurodivergent individuals (e.g., neurotypical people may interpret an ASD individual's facial expression as rude; Vargas-Salas et al., 2025). This review shows that it is important to understand these perceptions to minimize the backlash associated with requesting and receiving ASD accommodations.

Abstract Name: The Price of Democracy: Foreign Direct Investment and Democracy in Latin America

Foreign direct investment (FDI) has long been theorized as both a catalyst for democratization and a potential source of democratic erosion, particularly in regions marked by political volatility and external economic

dependence. This research examines the role of U.S. and Chinese FDI in Latin America, analyzing how external capital flows contribute to the economic foundations of democratization while also posing risks of dependency and neocolonial influence. By employing a mixed-method approach, the study integrates quantitative data on FDI inflows and democracy indices with qualitative analysis of policy documents and country-specific case studies. By situating Latin America within the broader context of U.S.-China competition and regional democratic backsliding, the project interrogates the paradox of FDI as both a driver of political liberalization and a potential threat to democratic resilience. The findings aim to contribute to ongoing debates in international political economy and international relations, while offering insights into the complex relationship between global capital and democratic development.

Abstract Name: The Biological Evaluation of a Novel Set of Colchicine Binding Site Inhibitors Using A375 Melanoma Cancer Cells

Cancer is one of the leading causes of death throughout the world. This disease is treated using several different methods; however, chemotherapy is the most common. Chemotherapy consists of several different drugs that aim to halt cancer cell growth by targeting fundamental cell functions like DNA replication and cell division. One group of these drugs target tubulin, a fundamental protein involved in cell division. Currently, tubulin inhibitors like taxanes and vinca alkaloids face issues involving toxicity and drug resistance. Thus, new tubulin inhibitors have been synthesized that target the colchicine binding site on tubulin. These compounds known as colchicine binding site inhibitors (CBSIs) are promising future treatments as they are theorized to be less toxic and more likely to overcome drug resistance. In this study, we investigate a potential new set of CBSIs by examining the mechanism of action, functional consequence, and ability to overcome paclitaxel resistance using A375 melanoma cancer cells as a model system. As a result, we find that both CBSIs tested halt cells in mitosis, alter intracellular microtubule dynamics, and inhibit colony formation—an effect that was true in non-resistant and resistant A375 cells. In all, these compounds function in a manner consistent with tubulin inhibitors and should be considered for future studies aimed to characterize their potential as an effective anticancer therapy.

Abstract Name: An Historical Analysis of Collectiveness and Collegiality of the European Union

This paper uses data extracted from documents stored at the Historical Archives of the European Union in Florence to throw new light on the institutional development of the European Commission. The Commission is the European Union's executive/administrative engine, and interpersonal dynamics within the Commission have large effects on policy outcomes. Previous studies have examined collectiveness and collegiality in

national cabinets (Andeweg 1997; Ie 2024; Vercesi 2020) and the Commission itself (Patrin 2020; Scherpereel et al. 2025). These papers, however, focus heavily on conceptual matters and recent administrations. This paper will use a deeper historical approach. I will evaluate how the frequency, duration, and attendance rates at Commission meetings have changed over time (1958-2025), and I will defend these measures as indicators of collectiveness and collegiality. Throughout the EU's history, changes in the number of member-states and the number and organization of commissioners have dramatically affected the dynamics of Commission meetings. I statistically analyze information from thousands of pages of archived documents and attempt to understand how institutional changes have affected the power of individual commissioners, the strength of the collective Commission vs. individual commissioners, and the strength of the Commission president vs. vice-presidents and other commissioners.

Abstract Name: Welfare Hedonism and the Improved Experience Machine Objection

In this paper I analyze Roger Crisp and Jennifer Hawkins's reformulation of Robert Nozick's experience machine objection to welfare hedonism (Crisp 2006, Hawkins 2016, and Nozick 1974). The initial experience machine goes as follows: you have the opportunity to plug into a machine which will simulate all possible enjoyable experiences all while your body floats in a vat with nodes attached to your brain. While in the machine, you are not aware that what you are experiencing is fake, as it looks and feels real to you. If you would choose not to plug into a machine like this, then there must be more to life than only enjoyment and elimination of suffering, so welfare hedonism must be incorrect. I argue that there are problems with this reformulation that make it inadequate in its attempt to defeat welfare hedonism. First, I tackle arguments against Nozick's original thought experiment and explain why the reformulation is needed (De Brigard 2010, Kawall 1999, Sumner 1996). Then, I argue that Hawkins's reformulation does not retain the agency of the subject which is present in Nozick's original. Finally, I argue that the reformulation eliminates the spirit of the original by making the machine life indistinguishable from a real life from inside the machine. I conclude that because of these two reasons, Hawkins's reformulation of the experience machine objection fails to defeat welfare hedonism as a possible theory of well-being.

Abstract Name: Analysis of Human Plasma Cytokine/Chemokine Levels During EBV Infection

Epstein Barr Virus (EBV) is a lymphoproliferative oncogenic virus infecting over 90% of the global population. Primary infection is efficiently controlled in healthy individuals by the immune system and EBV establishes life-long latency in memory B cells. Immune-compromised individuals are at-risk for developing EBV-associated tumors. However, it is largely unknown what signals play a key role in orchestrating viral

latency and EBV-induced tumorigenesis. Here we used an in vivo human/mouse chimeric model of EBV to evaluate the profile of circulating human cytokines and chemokines during EBV infection. Following exposure of mice to EBV B-95.8, EBV-DNA levels were measured longitudinally in peripheral blood and in tissues at necropsy using real-time PCR. The presence of macroscopic tumors was also documented at necropsy. We also measured the levels of 38 human cytokines and chemokines in the plasma of mice collected pre-EBV exposure and at necropsy. In this study, 4 out of 11 mice had high levels of cell-free EBV-DNA in plasma at necropsy. A comparison of plasma cytokine/chemokine levels at the time of harvest between mice with high (VH) vs low (VL) viral loads revealed higher levels of several cytokines in mice with high plasma viral load: IFNA2 (188.09 in VH vs 146.59 in VL; pg/ml), IL-1 β (31.89 in VH vs 12.96 in VL; pg/ml), IL-6 (251.40 in VH vs 50.57 in VL; pg/ml), IL-10 (281.18 in VH vs 14.93 in VL; pg/ml), CXCL9 (33436.99 in VH vs 4515.27 in VL; pg/ml), MIP-1B (54.07 in VH vs 27.20 in VL; pg/ml) and PDGF-AA (168.21 in VH vs 107.67 in VL; pg/ml). Future work is needed to determine the role of these analytes in EBV persistence and tumorigenesis.

Abstract Name: Crushed or Not: The Effect of Shell Size on Adsorption

Increased population growth and a higher demand for industrial goods pose a threat to our limited supply of clean water. In an attempt to help eradicate this issue, bioadsorption exhibits promising results by removing contaminants such as dyes from water, offering a cost-effective and environmentally friendly approach. Our research question, "What is the optimal pH of crystal violet solution for pistachio shells in whole and crushed forms to achieve maximum adsorption efficiency?" investigates pistachio as a viable approach to this contamination. To optimize the adsorption of crystal violet, the pistachio shells were sonicated in isopropyl alcohol and dried for 20 hours after being rinsed in deionized water. Using a spectrophotometer, the absorption was monitored of whole and crushed shells in acidic, neutral, and basic conditions of crystal violet. The results indicate that both the whole and crushed pistachio shells exhibited the highest adsorption in basic crystal violet solution. Additionally, there was no difference in the whole shell adsorption compared to the crushed shells. Whole shells measured a percent removal of 84.34% while crushed had a percent removal of 83.57%. This further supports previous research where pistachio shells adsorb the most crystal violet in alkaline conditions and extends our understanding of pistachio shells as bioadsorbents, suggesting that surface area does not play a key role.

Abstract Name: Microfinance to Battle Poverty: Designing and Evaluating a Low-Interest, Crop-Insurance-Backed Microcredit Model for Agricultural Production in Ethiopia

This study designs and evaluates a low-interest, crop-insurance-backed microcredit model tailored to the needs of Ethiopian smallholder farmers. While traditional microcredit has long been promoted as a poverty-reduction tool, two decades of randomized evidence show only modest impacts on agricultural investment, income, and household welfare. In Ethiopia where climate shocks, liquidity constraints, and limited risk protection suppress productivity the standard high-interest, rigid-repayment model remains poorly suited for smallholder agriculture. Using existing literature, national reports, and household survey insights, this paper develops a policy-relevant experimental framework that integrates low-interest loans (0–5%), index-based crop insurance, and food-bank-linked repayment protection. A multi-arm randomized controlled trial is proposed to isolate the effects of interest reductions, insurance, and their interaction on yields, consumption smoothing, input use, and repayment behaviour. Complementary analysis using secondary data and light simulation illustrates the theoretical channels through which insurance-backed credit can stabilize income and reduce default risk. The study argues that an integrated microfinance model could substantially enhance resilience and productive investment among Ethiopian smallholders, providing a scalable blueprint for policymakers, Microfinance Institutions, and national food security programs.

Abstract Name: Examining Potential Differences in Aging Self-Efficacy Based on Disability Status in Adulthood

Age-related physical and mental health outcomes often differ between people in relation to factors like socioeconomic status, health care access, disability status, nutritional intake, socialization, environmental urbanization, etc. (e.g., Skoufalos et al., 2017). Additionally, as age increases, self-efficacy among people with disabilities decreases in comparison to peers of the same age (Schieman & Campbell, 2001). Our study aims to examine aging self-efficacy in a healthy manner among rural and urban populations. Our sampling relies on online self-report surveys, consisting of questions regarding how healthy the respondents will be or were at several points in their lives; the questions ask about social, physical, and mental health. A section of the demographic questions will ask if the individual has a disability, along with asking whether they have aged with a disability or whether they have aged into a disability. We expect to see that people who have aged with a disability will rate their own current abilities better than those who aged into a disability. We anticipate these results because those who aged with a disability may see the impact of their disability on aging self-efficacy as a normal part of their routine, whereas those who aged into a disability may view their aging self-efficacy worse after onset of disability due to self-comparison.

Abstract Name: Measuring and comparing signal feature variations under degrading temperature versus radiation conditions

Radio frequency (RF) devices in aerospace and other harsh environments experience both temperature extremes and ionizing radiation, each known to disturb signal features used in identification and performance monitoring. This work tests whether temperature-induced variations resemble total ionizing dose (TID) effects sufficiently to support lower-cost screening. We analyze 802.11a waveforms from four emitters under controlled thermal sweeps [-40, 20, & 80° C] and compare against prior TID data [0 4, 8, 12 krad]. Feature extraction targets carrier frequency offset (CFO) and Energy and is then analyzed through statistical metrics including mean, skewness, and kurtosis. Our findings suggest potential similarities in the behavior of CFO under both thermal and radiation stress. By scaling across multiple devices and different dose rates, we derive improved parameters for future experimentation. This research contributes to understanding whether temperature testing can serve as a proxy for certain aspects of radiation testing, to reduce testing costs.

Abstract Name: How the Far-Right Reads and Dreams: The Metapolitics of Fictional Words

While it is possible to understand all literature as inherently political (Politisches Schreiben: Klein Klärungsversuch, 2022; Das Politische in der Literatur der Gegenwart, 2019), the political novel is a specific genre that can be defined in two ways: (1) novels that depict fictionalized political processes or (2) novels that, through ideologically-tinted ‘metapolitical’ reading practices, are decoded for their political content. As part of a broader investigation into the state of the genre, I examine the original twenty-first century political novels of the latter category, published in English by right-wing publishers. To discern authorial intention and uncover far-right reading practices, I also explore interviews with right-wing fiction authors and commentaries on literature written by far-right activists. This theoretical methodology is inspired by Kølvræ and Forchtner in their study *Imagining Alternative Worlds: Far-Right Fiction and the Power of Cultural Imaginaries*, in which the scholars categorize right-wing fictional works by the ‘cultural imaginary’ they conjure up. I have found that far-right novelists, notably Tito Perdue, Lee Scrivner, Michael “Mike Ma” Mahoney, and Jef Costello variously deploy nonlinear and picaresque plot structures, highly antisocial protagonists, and references to distant historical figures, places, and events to detail their plots which are ultimately engaged in a metapolitical conflict over historical memory. Additionally, I note how the differences between literary criticism published in the White Nationalist outlet *Counter-Currents* and that by the more traditionally conservative author and critic Andrew Klavan underscore the gap that divides the Far-Right from the mainstream Right. This research argues that the deep battle that plays out in their fiction is one for control over historical narrative; these far-right authors strive to recapture a Western civilizational canon that they see as having been stolen and corrupted by the institutions captured by ‘radical leftists’ in the aftermath of the postwar settlement crises of 1968.

Abstract Name: #BookTok: Feminist or Feminized? Reimagining Online Literary Communities

This presentation explores the ways #BookTok, the online literary community based on TikTok, presents a unique opportunity to resist the Western heteronormative patterns reflected through the contemporary American publishing industry and literary culture. Through practices of taste-making such as book decoration, exclusive editions, and embodying the 'Bookish' aesthetic, #BookTok extends culture beyond the container of the novel to the self. This creates a tension that leaves the #BookTok community currently grappling with its purpose and platform: it simultaneously possesses the potential to disrupt the publishing industry, even as it reinscribes its exclusionary patterns grounded in Western heteronormative patriarchy through both the predominantly white female authors that make up its emerging canon, and their narratives' reliance on patriarchal tropes packaged and narrativized as "romance" and "fantasy." Consulting feminist digital humanities scholars, alongside traditional media and cultural studies thinkers, this presentation analyzes the influencer practices that have developed on #BookTok, considering how they contribute to critical taste-making of the novel. Through focused case studies of @thecalvinbooks and @illanaslibrary, I demonstrate how the #BookTok influencer functions similarly to a 'literary critic.' As well, I analyze a selection of #BookTok's "canonical" texts, comparing their narratives alongside the metadata across multiple reader-review platforms such as Goodreads, Amazon, and Barnes & Noble, and how they illustrate their popularity. This data reveals that #BookTok encompasses small pockets and windows for diverse stories to enter into the discourse, thereby posing a challenge for both the publishing industry and modern American literary culture to reevaluate how it may cultivate a literary community that includes a diverse array of creators, such as white women, women of color, and genderqueer individuals.

Abstract Name: The Impact of Graphic Design on Perception

Graphic design is a prominent factor of our everyday life that is often not given much thought by the average consumer. In an increasingly digital world, the application and importance of graphic design has become evident in society globally. This research will examine aspects of graphic design like color, shape, and typography to find out the psychological impacts of these elements on the human brain. This will help readers understand the effect of advertisements on people so that they might better recognize the impact of design on our visual perception of the world around us and, in turn, the effect of these elements on consumer behavior. Graphic design surrounds us daily in the form of advertisements, posters, billboards, product packaging, spatial design, web design, interior and exterior decoration and so much more. Designers and businesses use graphic design as a tool to influence the consumer in a certain way, direct a person to help them navigate through a space, or even guide a user's experience on an online interface. Through the exploration of various studies conducted by psychologists and design professionals that focus on each of the three elements stated earlier (color, shape, and typography) and an overview of the impact of each on consumer behavior, this research will highlight graphic design's profound psychological influence on the human brain and perception. Through the understanding of the importance of graphic design, it becomes evident how designs like the Obama "Hope" campaign posters can make such an impact on the public and the need to recognize the psychological effects of design.

Abstract Name: Sex-Specific Endothelial Actions of an Anti-Angiogenic miRNA in Diabetic Wound Healing

Diabetic wound healing exhibits sex-specific differences, but the molecular mechanisms remain poorly defined. MicroRNAs (miRNAs), small non-coding RNAs that act as key post-transcriptional regulators, are highly dysregulated in Type-2 diabetes (T2D). Increasing evidence suggests that miRNAs may also integrate sex as a biological variable in disease pathophysiology. Here, we investigated the role of endothelial cell (EC)-enriched anti-angiogenic miR-409-3p in sex-dependent regulation of wound healing. MiR-409-3p expression was significantly higher in non-healing human diabetic skin wounds and in the skin ECs of male miR-409 fl/fl mice compared with females. Using tamoxifen-inducible, EC-specific miR-409-3p knockout (miR-409 Ind-ECKO) and floxed (miR-409 fl/fl) littermates fed a high-fat-high-sucrose diet (HFHS) diet, we evaluated full-thickness cutaneous wound closure, perfusion, angiogenesis, and inflammation. Female miR-409 fl/fl mice displayed enhanced wound healing compared with males, with increased perfusion, granulation tissue, and angiogenesis. Interestingly, EC-specific deletion of miR-409-3p eliminated the wound healing advantage in females, resulting in decreased perfusion (31%), angiogenesis (47%) and proliferation reducing healing to male-equivalent levels. These outcomes correlated with increased pro-inflammatory M1 macrophage polarization and elevated expression of inflammatory and endothelial adhesion molecules; IL-1 β , MCP-1, COX-2, VCAM-1, ICAM-1, and E-selectin. Mechanistically, EC-specific neutralization of miR-409-3p increased the expression of zinc finger E-box binding homeobox 1 (ZEB1), a known target of miR-409 with a significantly stronger induction and simultaneously enhanced NF- κ B activation in female miR-409 Ind-ECKO mice (2.75- and 5-fold) compared to males. Collectively, these findings establish miR-409-3p/ZEB1 axis as a novel sex-specific regulator of endothelial angiogenesis and wound healing. Incorporating sex as a biological variable in miRNA-targeted approaches may enable more precise therapies for chronic diabetic wounds.

Abstract Name: Fungal Diversity on the Penn State Behrend Campus

Fungal Diversity on the Penn State Behrend Campus Elise Kelly (Presenter), Matthew Gruwell Penn State Behrend Biodiversity is an excellent marker of environmental conditions, as robust environments are able to support a diverse number of species. Fungal diversity, in particular, is indicative of multiple environmental factors such as nutrient composition, moisture levels, and air quality. Representations of biodiversity, like field guides and catalogs, simultaneously promote the beauty and importance of biodiversity, while providing information on environmental conditions. The goal of this research is to create a Fungal Diversity catalog of the Penn State Behrend campus, including Wintergreen Gorge, to describe the fungal community and its role in the environment. This will be executed by collecting fungal samples, extracting, amplifying, and sequencing the DNA, and classifying each fungal species. Upon its completion, the catalog will feature each fungus' morphology, location, possible ecological interactions, and phylogeny. This is an ongoing project that will continue until a confident representation of the fungal community has been reached. This research will provide insight into fungal diversity of the environment on the Penn State Behrend campus and encourage students to spend time outdoors identifying fungi and observing biodiversity in nature.

Abstract Name: Fungal Microbiome Analysis of Vineyard Soil Samples

Fungal Microbiome Analysis of Vineyard Soil Samples Elise Kelly (Presenter), Michael Campbell Penn State, Lake Erie Regional Grape Research and Extension Center, 662 Cemetery Rd, North East, PA 16428 Soil health is influenced by several factors including the soil microbiome. Soil microbiomes are defined by the biotic and abiotic factors that make up the soil on a microscopic level; i.e., bacteria, fungi, microorganisms, ions, and soil particles. Fungal composition is important for understanding moisture levels, nutrient composition, disease load, and potential mycorrhizal relationships. The goal of this research is to analyze the effect of cover crop and grape variety on fungal diversity/composition of the soil microbiome at Penn State's Lake Erie Regional Grape Research and Extension Center. Over the course of 11-week's, soil samples were collected every two weeks from three grape study groups: Vitis "Concord" with cover crop, Vitis "Concord" without cover crop, and Vitis "Chambourcin" without cover crop. Per grape study group, samples were taken at three different extraction sites in relation to a vine: under the rootstock, between neighboring vines, and between rows of vines. Three replicates of each extraction site were taken per variety. DNA was extracted from 162 soil samples, of which 160 samples were amplified at the Fungal ITS1 region, and sequenced using Illumina sequencing to survey the fungal composition of the soil. Bioinformatic technology will be used to classify and sort genomic data. This project will describe potential patterns and ecological interactions within the fungal community to support a greater understanding of the interactions

between both grape varieties and fungi, and cover crops and fungi. Preliminary data suggests there may be higher levels of diversity in soils with cover crop.

Abstract Name: An Abundance of Birds: An Exploration of the Relationship Between Poetic Text and Image

The experimental novel VAS: An Opera in Flatland (2002) by Steve Tomasula and Stephen Farrell is a creative venture into storytelling through both text and design. Photographer and writer Teju Cole synthesises words and images in *The Blind Spot* (2017) to explore the concept of sight. More recently, designer David Crow has written on elements of design that communicate like language in *Visible Signs* (2022). Yet the academic conversation about these types of relationships rarely extends to the relationship between poetry and designed image. The construction of poetry already relies on an artistic vision for line breaks, white space, and text density. The poet's creative decisions may be pushed further when transferred across disciplines to the design processes of typography, photography, and experimental layouts. This project began with writing a poetry collection inspired by Seamus Heaney, Mary Oliver, Wendell Berry, and other poets. These new poems explore themes of faith, grief, art, and the natural world in the context of Italian landscape and architecture. The second phase of the project reimagines the collection through experimental design, resulting in a non-traditional chapbook. Bringing together the two academic disciplines of poetry and visual design, the multimodal chapbook invites readers to encounter the themes of everyday devotion and lament in a more dynamic way.

Abstract Name: The Final Bureaucratic Frontier: Coordinating U.S. Orbital Debris Governance through the Office of Space Commerce

The United States faces an escalating orbital-debris challenge driven less by technological limitations than by fragmented governance. Responsibility for debris mitigation is dispersed across the FCC, FAA, DoD, NASA, and the Office of Space Commerce (OSC), producing duplicated reviews, inconsistent standards, and limited enforcement on orbit. Because debris threatens essential services—including broadband connectivity, weather forecasting, financial-timing infrastructure, and national security missions—this fragmentation elevates systemic risk long before a major collision draws public attention. Historical patterns in aviation, environmental regulation, and industrial safety show that institutional reform often occurs only after catastrophe, an outcome the United States can no longer risk in Low Earth Orbit. The rapid expansion of commercial megaconstellations and persistent gaps in tracking small debris further intensify these vulnerabilities. This project examines whether a unified, performance-based orbital-debris mitigation framework centered on OSC could reduce fragmentation while preserving commercial innovation. The proposed model integrates the Traffic Coordination System for Space (TraCSS) with an interagency code of

conduct and introduces a U.S. Space Sustainability Rating (U.S. SSR): a lifecycle-based metric applied consistently across licensing reviews. The methodology draws on regulatory docket analysis, international benchmarks, historical case studies, and interviews with government and industry stakeholders to evaluate the framework across five criteria: enforceability, transparency, interagency coordination, commercial viability, and political feasibility. The analysis suggests that standardizing debris-mitigation metrics through TraCSS, linking operator performance to regulatory incentives, and consolidating coordination under OSC could strengthen national space-sustainability governance. Preliminary findings indicate that this approach can reduce duplicative oversight, improve data consistency, and encourage responsible operational practices without stifling technological progress. Emerging bipartisan legislative efforts further support the feasibility of designating OSC as the lead civil authority for debris mitigation. This research concludes that proactive coordination offers a viable path for the United States to reinforce leadership in sustainable orbital governance.

Abstract Name: Automated Discovery of Predictive Structures in Financial Market Behavior Using AI

This research explores predictable structure within financial markets through a systematic integration of several AI techniques. The project begins with the robust collection and preparation of high-frequency market data from the S&P 500 Index. Genetic Programming is then used to randomly generate and aggressively optimize candidate control laws--composite functions built from simple atomic transformations of prices and volumes. These control laws are interpreted as sensor-like features and are evaluated as standalone market direction signals. High-performing control laws are assembled into voting groups (ensembles) that make binary decisions by majority or thresholded voting, providing robustness to noise and regime changes. Ensembles are further leveraged as structured feature inputs to neural-network models, allowing the networks to operate not on raw prices but on a curated layer of behaviorally meaningful, evolved features. To identify robust target parameters for model generation, the solution space is surveyed using risk-normalized Expected Value, realistic frequency constraints, and Monte Carlo permutation testing. Finally, candidate contributions to ensemble performance are quantified using Monte Carlo Shapley approximations, helping distinguish stable, generalizable patterns from artifacts of any single control law. The result of this research is a reusable framework for automated feature exploration, stacking, and evaluation in complex time-series systems, together with an ensemble-building approach that delivers robust, statistically significant gains on independent financial data. For the best-performing ensembles, Monte Carlo permutation tests yield p-values typically below 0.001 (median p appx.= 0.0005), indicating that the observed improvements are highly unlikely to arise by chance. Although this work focuses on S&P 500 index data, the methodology is designed to transfer directly to other symbols and domains where complex, noisy time-series information must be converted into reliable predictive structure.

Abstract Name: Playing for Passion, Not Pay: Economic Trade-Offs and NIL Awareness in Division III Women's Soccer

Playing a collegiate sport is the dream for many high school athletes, yet the decision to compete at the Division III (DIII) level brings unique challenges. Although DIII athletes commit similar weekly hours to their sport as Division I and II athletes, they are the only group ineligible for athletic scholarships. For women's soccer athletes, this can create hidden financial and personal pressures that shape their college experience. This study investigates how DIII women's soccer athletes experience and navigate out-of-pocket expenses, opportunity costs, and Name, Image, and Likeness (NIL) awareness. A mixed-methods design was used. We surveyed 23 athletes from a DIII women's soccer team and conducted follow-up interviews with a purposive sample to understand patterns in financial strain, career decisions, and NIL perceptions. Most athletes reported low direct financial stress, largely due to family support. However, many players noted that greater university coverage of gear and annual fees would improve their experience. Few athletes work during the season, citing time constraints, and most expressed that soccer commitments limit their ability to pursue academic or professional opportunities. Lastly, despite awareness of NIL, many do not participate due to limited time, low social media following, and uncertainty of how to begin. Overall, athletes acknowledged the financial and time costs associated with DIII athletics. However, most athletes conclude that the community and culture of their team outweigh these burdens. This research offers insight into how DIII women athletes weigh time, money, and future goals. Findings suggest that institutional policies, NIL education, and greater scheduling flexibility could enhance the experience and long-term outcomes for these student-athletes. Understanding the pressures DIII athletes face can help universities strengthen financial transparency, provide targeted support, and expand access to NIL education.

Abstract Name: Return on Investment of the Work of County Land and Water Conservation Departments in Wisconsin

As climate change continues to impact Wisconsin with warmer temperatures and increased precipitation, county conservation departments play a crucial role in protecting soil and water resources. However, it can be difficult to quantify their work. Current state reporting through the Department of Agriculture, Trade, and Consumer Protection (DATCP) Annual Survey captures information on each county's conservation practices, including nutrient management plans, water quality practices, and pollutant load reductions. However, there are concerns that this survey is not comprehensive enough. Thus, in collaboration with the Wisconsin Land and Water Conservation Association, this project aims to (1) assess how effectively the DATCP Annual Survey measures their work, (2) provide recommended revisions to the DATCP Annual Survey, and (3) estimate the return on investment (ROI) of county conservation activities using IMPLAN. We analyzed the 2024 DATCP survey data and conducted semi-structured interviews and a focus group with county conservation staff to identify data gaps and challenges in reporting. Based on our findings, we created and distributed a follow-up survey to conservation department directors to capture data not currently included in state reporting, including staff time allocation, experience, and community engagement. We found that county conservationists spend a significant amount of time building trust with landowners, collaborating with partner organizations, and responding to public complaints, activities that are essential for long-term conservation outcomes. Additionally, we heard concerns about the lack of standardization in how phosphorus reductions are calculated and reported. Overall, these data gaps might lead to staff work appearing less impactful than it is, which can have a negative impact on state funding decisions. By combining both direct and in-direct staff activities and suggesting improvements to measurements going forward, we hope to contribute to more accurate assessment of conservation programs to improve investment amidst a rapidly changing climate.

Abstract Name: Quantification of Microplastic Release From Bottled Water Under Simulated Daily Use Conditions

Microplastics (MPs) have been detected in human hearts, lungs, and even brain tissue, yet the pathways of exposure remain poorly understood. As college students routinely leave bottled water in hot cars, set bottles in sunlight, and repeatedly twist caps open and closed, we hypothesized that these everyday conditions may significantly increase MP release into drinking water. This study quantified MP release from three popular water bottle brands, each with different compositions including virgin and recycled PET plastic. Bottles were subjected to UV exposure for 3 hours in direct sunlight, heat exposure for 6 hours at 55°C, and a combined daily use simulation involving heat, UV, repeated cap twisting, and mechanical stress. MPs were tagged with ethanolic Nile Red dye and vacuum filtered through 1 µm glass microfiber filters, then quantified using a Nikon Ti-E A1R-Si confocal fluorescence microscope. Baseline contamination in untreated bottles ranged from 1,065 to 1,393 MPs per bottle. UV exposure alone increased particle counts by 55% to 132%, while heat treatment produced increases of 91% to 179%. The combined daily use simulation produced the most dramatic increase in MP counts, rising 3.5 to nearly 7 fold above baseline. Recycled PET bottles showed substantially greater vulnerability than virgin PET, with one brand reaching nearly 8,000 particles under daily use conditions. These findings reveal that everyday bottled water use, through the synergistic effects of routine handling, represents a significant and previously overlooked source of microplastic exposure.

Abstract Name: Overstuffed and Understuffed

This painting was inspired by internal turmoil caused by conflicting emotions. Originating from concept sketches of an overstuffed bear, the idea lingered before fully materializing on canvas. During the initial process, it was just the bear, but when observing the composition, it benefited more with the addition of the understuffed bunny. Before the bunny, the bear was alone to convey the emotional weight of feeling overwhelmed. By introducing the deflated bunny, it completed both the visual structure and the emotional dialogue of the work, with the bunny representing feeling underwhelmed. The contrast between the bear bursting at the seams and the deflated bunny symbolizes conflicting emotional states - everything being too much, while at the same time, everything being too little. Representing those opposing emotions, they lean against each other, left forgotten and abandoned in the corner of a room. Painted in acrylic on a 22 x 28-inch canvas, the piece emphasizes texture by using muted tones of brown, green, and blue to evoke a melancholic mood. Using the green as the wall color it accentuates the browns and greys used on the plushes. The layers of color and detailed brushwork recreate the softness of worn fabric, while brighter reds highlight exposed seams from previous attempts to sew the rift in the original stitching. Ultimately, this work acts as a psychological self-portrait through objects. The bear and bunny are metaphors for vulnerability and resilience, revealing how opposing emotions often inhabit the same space—where one can be both bursting and collapsing at the same time.

Abstract Name: Drone-deployed wireless Field Charging Station

This project presents the design and development of a Self Deployed Wireless Drone Charging Station, aimed at addressing the growing need for autonomous drone support infrastructure. As the drone industry rapidly expands, particularly in autonomous operations, there are current limitations in charging compatibility, human dependent setup, and limited flight range hinder scalability. Our design provides a portable, solar powered charging platform that can be deployed and retrieved by a drone without human intervention. The system utilizes wireless inductive charging to eliminate the need for physical connectors, supported by a 60-watt solar array, lithium-ion battery pack, and DC-AC inverter for autonomous energy conversion and delivery. The structure features a lightweight aluminum frame with ASA reinforcement for weather resistance, fiberglass over the charging coils for efficient power transfer, and TPU bumpers for impact protection. Initial prototypes will be 3D printed in PETG to validate design functionality and durability. Estimated prototype fabrication time is approximately 32 hours, with a projected cost between \$400–\$500. Potential applications span civilian, industrial, emergency, and military uses, particularly in remote or off grid environments requiring sustained drone operations. Future development will integrate AI based fleet coordination to optimize charging schedules and flight patterns, evolving the system into an intelligent, scalable infrastructure for autonomous aerial networks.

Abstract Name: Exploring the relationship between two parasites of American beech (*Fagus grandifolia*) in the Piedmont of North Carolina

Species-specific symbioses, such as parasitisms, are less common in temperate regions than they are in the tropics. American beech (*Fagus grandifolia*) is a native North American tree that is parasitized by two organisms, often simultaneously. One of the organisms is an annual flowering plant, beechdrops (*Epifagus virginiana*), and the other is a seasonal insect, the beech blight aphid (*Grylloprociphilus imbricator*). While there is literature on both organisms and their relationships to American beech, we found no studies on the interaction between them. Our study aims to collect data on the presence, abundance, and frequency of occurrence of both parasites on individual beech trees and to investigate the relationship between them. Specifically, we focused on how the presence of beech blight aphids affects the abundance of beechdrops parasitizing a host tree during the year of aphid infestation and the following year. We sampled beech trees in mature mixed-species forests in Shallow Ford Natural Area, Alamance County, North Carolina during late summer and fall of 2024 and 2025. At our study site, we found that 54.2% of beech trees had beechdrops present in both years, while insect infestation dropped from 8.3% of beech trees in 2024 to 0% in 2025. Compared to 2024, there was a statistically significant increase in the average abundance of beechdrops on

aphid-parasitized sample trees in 2025 (15.68, 35.55, respectively; $p=0.004$). Our data suggest that during the year in which the beech blight aphid is present, the tree does not support the same number of beechdrops as when the aphid is absent.

Abstract Name: Characterizing Individual Variability In Domestic Cat in Vitro Embryo Development

Studies of in vitro embryo development in felines contribute to improving assisted reproduction techniques (ART) for management of threatened wild cats. Unfortunately, success rates remain low and variable, especially for wild felines. To date, most feline studies have investigated the effect of season, stage of estrus cycle, or age on in vitro embryo development. The objective of this study is to investigate the variability of embryo development outcomes for individual female cats (queens) when season, cycle stage and age are controlled. A total of 40 ovaries from 20 follicular phase females were dissected and high-quality oocytes (grade 1 and 2) harvested, resulting in an average of 8.4 quality oocytes/individual. Oocytes were cultured in media supplemented with 1 IU/mL luteinizing hormone and 1 IU/mL follicle-stimulating hormone for 26 hours followed by in vitro fertilization (IVF). Presumptive zygotes were washed of sperm and incubated for an additional 5 days. All oocytes and embryos were fixed and imaged using DAPI, a DNA stain, no later than Day 8 of incubation. Even with age, season, and stage of cycle controlled, we found that 35% of individuals had low ($<20\%$) embryo development rates whereas 15% of individuals had high ($>50\%$) rates. These results suggest that the individuals themselves are a significant source of variation in IVM and IVF success rates. These preliminary data highlight the need for further inquiry of genetic or epigenetic factors involved in the success of in vitro techniques applied to genetically valuable felids. In future studies, we aim to identify gene expression patterns associated with high and low success rates with the goal of identifying biomarkers of success and/or informing improvements in culture conditions.

Abstract Name: The Newlands Reclamation Act and Its Role in the Genesis of the Dust Bowl: A Historical Analysis

This paper argues that the Newlands Reclamation Act of 1902 played a significant yet understudied role in creating the environmental vulnerabilities that produced the Dust Bowl. By promoting large-scale irrigation, encouraging settlement in arid regions, and enabling intensive monoculture farming, the Act disrupted native grasslands, depleted water resources, and fostered unsustainable agricultural expansion. These federal interventions created a false sense of land security that collapsed under 1930s drought conditions. Drawing on environmental history, policy analysis, and scientific research on soil and climate, this study reframes the Dust Bowl as a human-made disaster rooted in early federal land management.

Abstract Name: Shocking Into Consciousness: The Dismantling of the 'Just War' Narrative

In *The Sympathizer* by Viet Than Nguyen, the sexual assault scene of the film, the Hamlet, leaves the narrator and the Thai audience in a state of shock. This essay explores the audience's perception of the film and provides context to their reactions, which draw on the dehumanizing effects of Americanization. By implementing criticism from scholar Sylvia Shin Huey Chong's work, "Vietnam, the Movie: Part Deux," this essay expands and critiques her interpretation and the text, using theorists such as Walter Benjamin, Edward Said, and Hayden White. Through these theoretical frameworks, this essay interacts with the issue of political influence and submission through depictions of war in Vietnam films. By exposing the effects of American idealism on the audience, the film's influence on the unconscious mind continues to perpetuate war. This essay then contrasts the reception of violence with sexual assault as a method to compare the optical consciousness within extreme dehumanization of the Vietnamese. By exploring the contrast, this work discusses the importance of the sexual assault shock factor as a necessity in dehumanizing the "just war" narrative. Questioning Nguyen's inclusion of sexual assault within the narrative, this essay investigates the purpose of its inclusion while cautioning its methods. As a method of dehumanization, the sexual assault scene is argued to provide a clear path towards humanization, reclaiming the Vietnamese ability to control its own narrative. By aligning literary theories alongside this novel, this paper cautions against the complicity to the fabrication of the Eastern narrative in Western media. Calling on audiences to promote their individual narrative and counteract the idea that we cannot represent ourselves. I want to further thank the selection committee for taking the time to consider my application.

Abstract Name: Judith Slaying Holofernes and Goddess Kali Through The Gaze of Feminine Rage and Subverting Expectations of Seventeenth and Nineteenth-Century Women In Italy and India, Respectively

This study examines holy women's depiction in art in two different societies, West Bengal, in nineteenth-century India, and seventeenth-century Florence, Italy. While art history scholarship mostly focuses on the passive and submissive holy figures, I will study the violent holy women in art. This comparative research demonstrates that in both societies, the Holy Women were used to inspire resistance against social oppression of women, by reinterpreting existing religious narratives. First, I will discuss and compare the social and cultural aspects of West Bengal, in nineteenth-century India, and seventeenth-century Florence, to provide the historical context for the respective artworks. Second, I will provide a formal examination of artworks representing the respective societies, Judith Slaying Holofernes, and Goddess Kali. Third, I will compare how the composition and formal aspects of the artworks, within the framework of their social contexts, emphasize the women's resistance to social oppression. While Judith symbolizes woman taking control of her life and women's history, Kali frees herself from the social expectation of submission to male power. This research is based on scholarly art history and historical research. This study is important since it is relevant to the contemporary world, where prejudice and violence against women is very common.

Abstract Name: How Changeable is STEM Intelligence? Mindsets Towards Intelligence of Neurodivergent Undergraduate Students Majoring in STEM

Academic mindset is a pivotal motivator in a student's learning and academic persistence. Students may have a fixed mindset: they believe their intelligence cannot be changed, or a growth mindset: they believe their intelligence is malleable. A person's mindset is dependent on context and impacted by experience, which can lead to more complex views of intelligence that combine aspects of both mindsets. Prior research is inconclusive on whether neurodivergent students have different mindset profiles compared to the general population of students. However, some research indicates unique motivating factors and beliefs on control over success and failure for certain groups of neurodivergent students. The current exploratory study builds on prior studies of neurodivergent students' mindsets by investigating how neurodivergent STEM undergraduates view the malleability of their math/science intelligence. Open-ended survey responses from 115 STEM undergraduates were analyzed through thematic coding. Responses were categorized as representative of a fixed mindset, growth mindset, or a combination of both; and inductively coded to identify patterns in how students defined math and science intelligence and its malleability, as well as the origins of their beliefs. Themes under a growth mindset included: ability to learn more math/science concepts; building STEM intelligence through hard work/practice, the ability to grow intelligence from a foundational strength in math/science; and the ability to improve with patience. Themes under a fixed mindset included: math/science intelligence as an innate quality; negative treatment by others impacting views of intelligence; and prior experiences of effort not yielding success. These findings could help STEM instructors support their neurodivergent students to understand their mindsets, the reasoning for it, and ways to change it if desired. It can be used to educate university STEM faculty on growth and fixed mindsets of neurodivergent students, and use said knowledge to find alternative teaching methods.

Abstract Name: The Correlation Between The Covid-19 Vaccine and The Development of MEWDS

Multiple Evanescent White Dot Syndrome (MEWDS) is a rare, self-limited inflammatory chorioretinopathy that most commonly affects young myopic women. It is characterized by acute photopsias, visual disturbances, and punctate outer-retinal lesions on multimodal imaging. The condition typically resolves spontaneously within several weeks to a few months, with most patients recovering normal visual acuity without specific treatment. However, with the rollout of COVID-19 vaccines, several case reports have

described MEWDS occurring shortly after vaccination, raising questions about whether the temporal clustering reflects true risk or coincidence. This study synthesizes available reports documenting MEWDS onset following COVID-19 vaccination. Demographics data, vaccine platform, laterality, and symptom-onset intervals were extracted for analysis. Since case numbers were small and heterogenous, findings were synthesized descriptively. Across the published literature, most reported cases emerged within several days to four weeks after vaccination. They presented with unilateral involvement and classic clinical features consistent with MEWDS. Notably, the majority of lesions occurred following mRNA vaccination, a pattern potentially influenced by global usage but also biologically plausible. mRNA platforms may elicit robust type I interferon signaling and transient T-cell activation, mechanisms that have been previously implicated in MEWDS pathogenesis through disruption of the photoreceptor-retinal pigment epithelium interface. Conversely, far fewer reports followed adenoviral-vector or inactivated vaccines, suggesting that platform-specific immune profiles may differentially trigger MEWDS in susceptible individuals. Despite the consistent temporal clustering, current evidence remains insufficient to establish causality. Coincidental timing, publication bias, and underlying immune predispositions remain viable explanations. Nonetheless, the available data support a rare but observable temporal association between COVID-19 vaccination, especially through mRNA platforms, and MEWDS, while clinical outcomes remain uniformly favorable. Larger population-based studies and mechanistic investigations are needed to determine whether these events represent a true, platform-dependent risk or reflect background incidence detected through heightened post-vaccination surveillance.

Abstract Name: The Interactive Toy for Dogs

The purpose of this project is to develop an interactive solution for dog owners who are frequently away from home and concerned about their pets' emotional and physical well-being. Many dogs experience stress, boredom, and behavioral problems such as excessive barking or aggression when left alone for long periods of time. To address this issue, we designed and built an interactive smart toy that can respond to a dog's behavior, provide entertainment, and support basic training without the owner being physically present. The goal of this project is to reduce loneliness and anxiety in dogs while also giving owners peace of mind. In this experiment, we successfully created a working prototype of the interactive dog toy along with a connected mobile application. The smart toy uses basic behavior recognition to react to a dog's movements and sounds. The mobile app allows owners to observe their pets at home in real time and communicate with them by sending voice messages through the toy's built-in speaker. The toy also includes pre-set training commands and interactive responses to keep dogs mentally engaged. While the overall concept has many possible advanced features, our project focused on building a simplified but functional version that demonstrates the core idea. This project combines concepts from programming, electronics, and artificial intelligence and directly connects to our course by applying these technical skills to solve a real-world problem. Our results show that technology can be used not only for automation, but also to improve the quality of life for pets and their owners. This prototype serves as a foundation for future improvements, including more advanced behavior recognition, additional training features, and expanded app controls.

Abstract Name: Accessible Multi-View Computer Vision for Real-Time Tool Tracking and Feedback in High-Fidelity Medical Simulation Training.

Simulation-based procedural training is crucial for improving physician proficiency in high-risk medical procedures; however, most existing systems rely on expensive sensors and static setups that lack scalability. While high-end simulators can track subcutaneous tool motion using embedded electromagnetic or force sensors, their cost and complexity prevent widespread adoption. This research addresses that gap by developing an accessible, vision-based simulation framework capable of real-time 3D tool tracking and feedback generation using low-cost multi-camera networks. The system integrates geometric computer vision, embedded machine learning, and procedural analytics to deliver accurate, adaptive feedback during simulated procedures such as central venous catheter (CVC) insertion and colonoscopies. The goal of this work is to make high-fidelity simulation more accessible and ultimately improve procedural safety. We prototype a multi-camera imaging system using low-cost stereo Arducam modules positioned above and beneath synthetic tissue phantoms to capture external and subsurface tool motion. Modular aluminum camera rigs, OpenCV-based synchronization, and a calibration pipeline using ArUco and ChArUco boards provide sub-millimeter geometric accuracy across camera views. Pilot studies demonstrate stable tool-tip detection under variable lighting and confirm the feasibility of real-time 3D reconstruction. Building on this foundation, we propose a scalable, self-calibrating vision architecture with four technical components: (1) adaptive multi-view autocalibration using fiducials, feature matching, and bundle adjustment; (2) real-time 3D pose estimation through HSV segmentation, YOLO-based detection, and temporal smoothing via Kalman filtering; (3) automated feedback generation that compares kinematic metrics (e.g., insertion angle and motion smoothness) to expert baselines; and (4) clinical evaluation across multiple medical simulation centers. This work advances accessible, vision-based simulation by combining calibration and data-driven feedback in a modular, low-cost system. Broader impacts include improved training accessibility and patient safety, as well as generalization to robotic manipulation and human-computer interaction.

Abstract Name: How Differences in Social Structure and Resource Availability Relate to Androgen and Glucocorticoid Concentrations and to Parasite Burdens in Female Dominant (*Eulemur coronatus*) vs. Codominant (*E. sanfordi*) Lemurs

In most male mammals, testosterone promotes reproductive and competitive behavior, whereas cortisol governs energetic mobilization, including the stress response to social challenges; both physiological pathways can impose costs, including increased susceptibility to parasites. To meet energetic demands, males often face trade-offs between investing in reproduction versus investing in health. Because females typically have low androgen concentrations, we lack understanding about whether they face similar trade-offs. Lemurs offer a unique opportunity to address this gap because various species show androgen-mediated female dominance. We ask if female lemurs incur measurable physiological costs associated with testosterone and cortisol production by comparing endocrine variables and parasitism in two species that differ in social structure – *Eulemur coronatus* (a female-dominant or FD species) and *E. sanfordi* (co-dominant or CD species) – and co-occur in two ecologically distinct habitats – Montagne d'Ambre National Park (rich site)

and Ankarana Special Reserve (lean site) in northern Madagascar. We quantified concentrations of fecal androgen (fAM) and cortisol (fGCM) metabolites via enzyme immunoassay and assessed relative parasite burden via fecal egg counts. As predicted, preliminary results show greater fAM concentrations across sites in FD females than in CD females; however, both species and sexes show greater fAM concentrations at the lean site than at the rich site, indicating that resource scarcity may drive androgen-mediated competition. Contrary to prediction, CD females tend to have higher parasite egg counts than FD females, suggesting an unexpected benefit of female dominance or cost of co-dominance. Consistent with weather-associated patterns, parasitism was greater at the wetter, rich site than at the drier, lean site. Ongoing analyses will test for a relationship between parasitism and fGCM concentrations, as a possible marker of stress. Once all variables are integrated, this study should clarify the potential trade-offs faced by *Eulemur* and their variation across sexes, social systems, and habitats.

Abstract Name: Characterizing the structural and functional role of the β -hairpin2 motif in AAV genome packaging

Adeno-Associated Viruses (AAV) are considered the gold standard in viral vector gene therapy because of their non-pathogenic nature, tissue specificity, and ability to integrate at specific sites. There are 14 natural serotypes of AAV, which vary in their amino acid composition, influencing the properties of both the capsid and the non-structural Rep proteins responsible for the viral life cycle. Because the Rep-capsid coordination determines the efficiency of assembly, genome loading, and ssDNA delivery, understanding the AAV genome packaging is essential for vector designing and overall safety in gene therapy. In recent cryo-EM studies, we observed that complex formation between the empty AAV capsid and the Rep protein complex is produced by the β -hairpin2 motif within the Rep protein and the five-fold pore of the capsid. The goal of this project was to characterize the role of the β -hairpin2 in the ATPase and helicase activities of Rep68. To investigate this question, the enzymatic activity of three Rep68 mutants was measured: the Rep68 Δ h2 mutant had the complete hairpin (residues 427-434) removed; Rep68(427-429A) and Rep68(432-434A) had the residues mutated to alanine. ATPase assays were run to measure the effect of mutations on ATP hydrolysis. Results show that the removal of the β -hairpin2 had a drastic effect on the ATPase activity, while the two alanine mutants were less impacted. Results from the helicase assay show that the mutations have a similar detrimental effect on their ability to unwind DNA. Taken together, our results show that the β -hairpin2 motor allosterically regulates the motor activity and that interaction with the capsid may also affect Rep DNA translocation activity.

Abstract Name: Towards Trustworthy AI: Integrating Blockchain for Ethical Decision Oversight

Artificial intelligence (AI) continues to transform decision-making across healthcare, finance, and governance. While it offers major advantages in speed, accuracy, and scalability, it also introduces challenges such as bias, lack of transparency, and reduced human accountability. These issues highlight the urgent need for trustworthy AI systems that uphold fairness, explainability, and ethical integrity. This poster has two primary objectives. First, it presents a framework that leverages blockchain technology to enhance ethical oversight and transparency in AI. Blockchain's decentralized and tamper-resistant architecture enables verifiable, auditable decision processes while reducing reliance on centralized authorities, making it a strong foundation for ethical AI governance. Second, based on prior research in AI ethics and blockchain governance, this poster introduces an interdisciplinary framework demonstrating how decentralized, human-in-the-loop oversight can strengthen trust and accountability in AI systems. A central focus of this work is the development of a blockchain-based voting mechanism within the United States that enables verified human participants to influence AI decision rules. Using consensus models such as Proof of Personhood (PoP), the system prevents interference from automated agents and ensures equitable participation. This approach promotes fair, transparent, and accountable decision-making by validating each contribution through immutable blockchain records. By merging blockchain's transparency with ethical governance, this poster illustrates a practical pathway toward secure, value-aligned, and socially responsible AI. The framework contributes to ongoing efforts to connect technological innovation with human-centered ethics, reinforcing public trust in the next generation of intelligent systems.

Abstract Name: Prenatal Iron, Hypoxia, and Infant Brain Development in Pakistan: Understanding Risk Pathways for HIE and Neurodevelopmental Disability

Hypoxic-Ischemic Encephalopathy (HIE) continues to be a leading cause of premature death and lifelong neurodevelopmental disability globally, with a disproportionate impact in low-resource settings such as Pakistan. HIE has consequences beyond clinical pathology, reframing HIE not just as a severe birth complication, but also as an avoidable outcome of persistent dietary imbalance and inadequate maternal-fetal oxygen exchange. This comprehensive literature review examines whether maternal iron deficiency enhances fetal vulnerability to hypoxia and raises the risk and severity of HIE by analyzing clinical data, evaluating epidemiological patterns, and examining how maternal iron deficiencies may affect oxygen transport, disrupt mitochondrial energy production, and weaken antioxidant defenses. These abnormalities are evaluated in terms of their effect in affecting placental function and fetal oxygenation. Insufficient maternal iron stores limit fetal cerebral metabolic resilience throughout critical phases of neurodevelopment, increasing susceptibility to hypoxia damage and consequent cognitive, motor, and behavioral impairments. Maternal iron deficiency is a key mediating biological factor that increases fetal vulnerability to perinatal hypoxia and amplifies HIE severity. This research emphasizes the importance of broader, nutrition-centered maternal health strategies such as improved dietary diversity, enhanced food access, community-level micronutrient education, and targeted iron interventions, as practical, cost-effective approaches to improving fetal neuroprotection in Pakistan and other low-resource regions. Future research should focus on identifying appropriate dietary strategies, delivery systems, and timing approaches to alleviate the long-term neurological burden caused by perinatal hypoxia.

Abstract Name: Molecule Secretion From Glioma Cells in Relation to HSP27 Expression in Glioma-associated Reactive Astrocytes

Glioblastoma multiforme (GBM) is the most fatal CNS malignancy with a median survival rate of about 15 months. Regarding treatment, it has become evident that it is just as important to target cells in the tumor microenvironment (TME) as it is to target tumor cells purely. HSP27 is a heat shock protein involved with apoptosis, cancer metastasis, and other physiologic functions. HSP27 acts as a poor prognostic marker in not only GBM, but cancers involving the breast, ovaries, pancreas, and more. The purpose of this study is to determine which molecules secreted by glioma cells are involved with the upregulation of HSP27 in glioma-associated reactive astrocytes. Experiments were done in both spontaneous and syngeneic GBM models to determine where upregulation of HSP27 was the highest. To ensure observations were not due to injury by intracranial injections, sham surgeries alongside glioma implantation surgeries were performed. These findings were also tested in other cancers to determine if this was glioma specific. A variety of methods were then used to narrow down the class of molecules responsible for upregulation of HSP27. Subsequent to confirming that upregulation of HSP27 was not due to stress from injections, and the observation of increased expression of HSP27 in astrocytes was glioma-specific, further experiments suggested that the class of molecules responsible for this upregulation is a lipid that is less than 3 kilodaltons. Future directions include unbiased lipidomics to identify the lipid of interest.

Abstract Name: Bright Minds, Bold Ideas: A Look Inside the OneUSF Summer Research Symposium

Undergraduate research is one of 11 high impact practices. At the University of South Florida undergraduate research is key to student success namely through research experiences for undergraduates (REUs). USF's REU programs are strategically designed to enrich the academic trajectories of undergraduate students through meaningful research engagement. In 2025, the summer REU program addressed the critical demand for practical research experiences by involving 60 undergraduates from a variety of interdisciplinary backgrounds. This initiative plays a pivotal role in promoting both the academic growth and professional development of participants, immersing them in hands-on research activities within the vibrant and innovative USF research community. The program aims to enhance students' understanding of scientific inquiry while bolstering their preparedness for future endeavors. The primary objective of the program was to provide students with collaborative research experiences, coupled with academic enrichment and professional skill development, in order to adequately prepare them for advanced studies and careers in various research domains. Over a span of 12 weeks, students collaborated with faculty mentors and graduate researchers, contributing meaningfully to projects aligned with established research goals. Participants engaged in experimental design, data collection, and scientific communication, efficiently completing laboratory procedures, performing data analyses, and presenting their findings. The impact of the program was rigorously assessed through pre- and post-program surveys measuring advancements in research skill.

Analysis of pre- and post-program data revealed significant improvements in students' research competencies, evidenced by increases in areas such as experimental design (56%), data analysis (18%), and scientific communication (54%). Participants also reported heightened confidence in their capability to conduct independent research, along with a clearer understanding of potential STEM career pathways. The USF summer REU program offers a comprehensive, intellectually stimulating experience that fosters both technical and personal growth. This program serves as a model for cultivating future scholars and leaders.

Abstract Name: Green Chemistry Synthesis of Carbon Dots Using Natural Oils

Carbon dots (C-dots) are zero-dimensional, carbon-based fluorescent nanoparticles recognized for their unique optical, chemical, and physical properties, along with their excellent biocompatibility, simple synthesis, and low production cost. These characteristics make them promising for a wide range of applications, including biomedical research, food packaging, anti-counterfeiting, and semiconductor technologies. While various natural products have been utilized for C-dot synthesis, the use of oils remains underexplored. Coconut oil and olive oil, which are rich in fatty acids such as lauric acid and oleic acid, respectively, were used as carbon sources in this study. C-dots were synthesized from these oils via a bottom-up approach. Separate mixtures containing each oil, citric acid, and ethylenediamine were heated at 180 °C for 12 hours (coconut oil) and at 210°C 84 hours (olive oil). The synthesized C-dots were purified using liquid-liquid extraction and subsequently freeze-dried to obtain water-free, oily fluorescent nanoparticles. Characterization using UV-Vis, fluorescence, and FTIR spectroscopy confirmed the successful formation of fluorescent oil-derived C-dots. Furthermore, cytotoxicity assessment through the MTS assay revealed that these C-dots are non-toxic, indicating their potential for safe biomedical applications. Future studies will further investigate their biomedical capabilities, particularly their antioxidant and anti-inflammatory properties, as well as their use in bioimaging, biosensing, and drug delivery.

Abstract Name: Alzheimer's Plaque Pathology and Glial Environment Regulation by a Novel Variant of Aquaporin-4

Aquaporin-4 (AQP4) is the brain's most prevalent water channel protein. The Aqp4 transcript undergoes a non-canonical mode of translation called stop codon readthrough. This generates a C-terminally extended isoform, AQP4x, which localizes perivascularly. Previous studies have shown AQP4 to alter amyloid beta plaque morphology and peri-plaque glial environment in Alzheimer's Disease (AD). However, the specific

roles of AQP4x versus the normal-length AQP4 in amyloid beta plaque morphology remain unknown. Here, I hypothesize that AQP4x also affects the peri-plaque glial environment and neuropathology in AD. To test this idea, I crossed the AQP4x loss-of-function mouse (Aqp4_NoX, two extra stops added to prevent readthrough) and the gain-of-function mouse (Aqp4_AllX, stop mutated to sense to allow 100% readthrough) to the APP/PS1 AD mouse model. Age-matched APP/PS1 mice were used as a control. Using immunofluorescence staining, I quantified the colocalization of astrocytes (GFAP) and microglia (IBA1) with amyloid beta plaques (6E-10 for total, X-34 for compact). Our preliminary data show that in the Aqp4_NoX mice, colocalization between IBA1 and amyloid beta is reduced. Furthermore, in the Aqp4_AllX mice, we have observed significantly higher numbers of small dense plaques. Ongoing experiments are focused on expanding our findings to include astrocytes as well as determining if all plaques, or only those of specific densities, share the same glial environment across different age points. These preliminary insights suggest a critical role for AQP4x in Alzheimer's plaque pathology. Manipulating glial involvement could prove crucial to mitigating the detrimental effects of amyloid beta accumulation, thereby potentially shaping future Alzheimer's therapeutics.

Abstract Name: Tracing the Roots of Reproductive Inequity: How History, Discrimination, and Education Barriers Shape Care Today

Background: Reproductive health in the United States remains widely underserved, particularly for birthing individuals in Black and other marginalized communities. Structural racism, historical discrimination, and healthcare inequities contribute to disparities in access. Mental-health stigma further compounds these barriers, with over 80% of Black Americans reporting concern about stigma preventing them from seeking care. Pregnancy-related mortality rates for Black and American Indian/Alaska Native individuals are three times higher than those of white women. Foundational topics such as menstruation are also often under-discussed in adolescence, limiting reproductive health literacy and contributing to inequities in adulthood. Aim: This project explores systemic barriers to reproductive healthcare and seeks to understand how structural inequities shape access, outcomes, and health literacy. It also examines culturally responsive approaches to care, using the adaptation of the Edinburgh Postnatal Depression Scale (EPDS) to the EPDS-US as an entry point to study perinatal mental-health screening. Methods: I conducted a focused literature review and created annotated bibliographies to identify themes related to structural racism, stigma, and healthcare access. Results: Consistent themes emerged: systemic inequities, historical discrimination, limited healthcare access, and stigma around both reproductive and mental health reduce engagement with care. The EPDS-US represents a step toward culturally responsive screening, but broader structural and social factors continue to limit its impact. Conclusions: Through this work, I aim to translate these findings into real-world change as an advocate and future nurse. By improving menstrual education, supporting culturally responsive healthcare, and promoting policies that address structural inequities, I hope to help ensure reproductive health is accessible and equitable for all birthing individuals, regardless of background. This project informs not only my research but also my commitment to advancing justice and equity in reproductive healthcare.

Abstract Name: Investigating Hyperglycemia's Impact on Regeneration in Zebrafish Larvae

Zebrafish (*Danio rerio*) are well established as a model organism in biomedical research due to their genetic similarity to humans and their exceptional ability to regenerate complex tissues such as fins, cardiac muscle, and retinal neurons. In both zebrafish and humans, hyperglycemia, a hallmark of diabetes, is associated with delayed wound healing. However, the cellular processes linking high glucose levels to impaired regeneration remain poorly defined. This project examines the effect of hyperglycemia on fin regeneration in larval zebrafish. The central research question is whether elevated glucose conditions suppress caudal fin regrowth after amputation and whether this suppression is associated with changes in cell proliferation. To investigate how hyperglycemia affects fin regeneration, zebrafish larvae were treated with 120 mM D-glucose beginning at five days post-fertilization. At twelve days, caudal fins were amputated, and larvae were monitored for 20 hours using a microscope to capture a time-lapse video. Fin regeneration in glucose-treated larvae was compared to control larvae maintained in egg water and was assessed by analyzing the time-lapse video for changes in the fin length and blastema growth over time. Larvae exposed to glucose consistently showed slower regenerative progress compared to controls, with visible delays in blastema formation in the fin, and reduced overall growth in the injured area during the observation period. To better understand the cellular basis of this impaired regeneration, future experiments will use immunohistochemistry to examine proliferative activity in the regenerating fin tissue. While the zebrafish itself is not a therapeutic target, understanding how regeneration is disrupted under diabetic-like conditions can reveal signaling mechanisms relevant to human wound healing. By clarifying the relationship between systemic metabolic dysfunction and local tissue repair, this research contributes to the broader goal of improving regenerative outcomes in patients with diabetes and other metabolic disorders.

Abstract Name: Selective Humanitarianism in U.S. Foreign Policy: A Comparative Analysis of Responses to Uyghur and Palestinian Genocides

This research examines why the U.S. government responds inconsistently to mass atrocities, specifically investigating how strategic interests determine which humanitarian crises receive comprehensive policy attention. By comparing U.S. responses to China's treatment of Uyghurs versus Israel's actions against Palestinians, this study tests the hypothesis that humanitarian concern is deployed as a strategic instrument of great power politics rather than as a consistent moral principle. Since 2017, the Chinese government has detained over one million Uyghurs in what authorities call "re-education camps" in Xinjiang, where reports document forced labor, cultural suppression, and systematic human rights abuses. Since October 2023, Israeli military operations in Gaza have resulted in over 70,000 Palestinian deaths alongside widespread destruction of civilian infrastructure and displacement of the majority of Gaza's population. Despite similar allegations of human rights violations, the U.S. has imposed extensive sanctions and labeled China's actions "genocide" while framing Israeli actions as "self-defense." This study employs Critical Discourse Analysis (CDA) within a constructivist international relations framework to analyze U.S. political texts, including Congressional bills and presidential statements. Additionally, the research compares the framing of surveillance technologies when used by China versus Israel to demonstrate how discursive strategies reflect underlying strategic priorities. The analysis is expected to reveal systematic discursive differences in how the U.S. frames these two cases, with China positioned as an ideological threat to liberal democratic values while Israel is portrayed as a democratic ally exercising legitimate security measures. These findings will illustrate how narrative construction directly enables selective policy implementation based on strategic alliances rather than

consistent humanitarian principles. These results suggest that the concept of "human rights" functions as a flexible rhetorical tool in U.S. foreign policy, legitimizing containment of rivals while rationalizing abuses by allies.

Abstract Name: Oxygen-Dependent Regulation of Cardiac Metabolic Protein Expression During Postnatal Maturation

Congenital Heart Disease (CHD) affects approximately 1% of newborns, is the leading cause of congenital disabilities, and is a significant cause of childhood morbidity and mortality. Studies have shown that CHD is multifactorial and influenced by both genetic and environmental factors, yet one critical, understudied environmental factor is oxygen availability. Cardiac metabolic pathways are oxygen-sensitive, and disruptions in oxygen availability may perturb maturation programs essential for normal cardiac development. During normal postnatal maturation, cardiomyocyte metabolism transitions from a primarily glycolytic fetal state to one dominated by fatty acid oxidation. Perturbations in oxygen may disrupt these essential transitions. Chronic hypoxia activates oxygen-sensitive transcriptional regulators and shifts their reliance from fatty acid oxidation to carbohydrate metabolism, and has been shown to affect transcriptional proteins such as NF- κ B, activator protein-1, PPAR α , and RXR α . Conversely, transcriptomic profiling revealed that neonatal hyperoxia suppresses fatty acid synthesis pathways in the postnatal mouse heart. It remains unclear how oxygen abnormalities regulate protein expression and cardiac metabolism, as few studies have directly compared hypoxic, normoxic, and hyperoxic conditions. Our study aims to examine how oxygen environments regulate metabolic pathways involved in cardiomyocyte maturation. We will use top-down mass spectroscopy on sarcomeric proteins isolated from both ventricular and atrial tissue of mice to quantify proteoforms and modifications under normoxic and hyperoxic oxygen conditions. The results of this study are expected to identify key oxygen-related metabolic proteins that guide postnatal cardiac maturation. Understanding the mechanisms of oxygen-dependent metabolic remodeling is vital for CHD patients who may experience abnormal oxygen exposure either in utero or after birth.

Abstract Name: Recreating the Past Comparing Egyptian Faience to Western Faience Through Research and Experimentation

This project examines the key differences between Egyptian faience and Western faience, two materials that share a name but come from completely different traditions. As I begin this research, my goal is to understand how each type of faience was made, what it was used for, and why it held meaning in its cultural setting. I will also attempt to reproduce Egyptian faience to gain firsthand insight into its production techniques. Egyptian faience is a quartz-based material that develops a glossy blue-green surface when heated.

These colors were closely tied to ideas of rebirth, protection, and the divine, and the material was used for objects such as beads, amulets, and small sculptures. By experimenting with mixtures of quartz powder, salts, and copper, and by testing different firing conditions, I hope to better understand the challenges ancient craftsmen faced and how they achieved such vibrant surfaces. Western faience, which developed much later in Europe, is very different in both structure and purpose. It is a clay ceramic coated with a white glaze that artists painted on. This type of faience was used mainly for decorated tableware, tiles, and display pieces, and reflected the growing interest in colorful imagery and household decoration. By comparing these two materials, this project explores how different cultures used technology and artistic techniques to express their values. Through beginning research and hands-on reproduction of Egyptian faience, I hope to show how each tradition created its own identity through the materials it chose and the objects it produced.

Abstract Name: The Language of Sexual Violence in Social Media Discourse: A Jeffrey Epstein Case Study

Sexual violence is not only experienced but also constructed through hostile and harmful language, such as victim-blaming, minimization, and deflection. These words can have material effects on legal cases, survivors' mental health, and prevent people from speaking out. This violence is further reinforced in online spaces by anonymity and lack of accountability that normalize harm, shaping public perception of survivors and perpetrators. While studies on how language shapes public perception of survivors exist, few examine how social media shapes narratives of sexual violence and reinforces harmful stereotypes. Given the rapid evolution and influence of online platforms, understanding these dynamics is critical for recognizing how they contribute to broader patterns of sexism and harm. This project asks how language used in social media discussions of the Jeffrey Epstein case shapes public perceptions of sexual violence and survivors. Comments were thematically analyzed using new accounts to avoid algorithmic bias, three search terms ("jeffrey epstein," "epstein files," and "virginia giuffre") were used to identify the top videos across Instagram and TikTok, resulting in 18 videos and 677 comments. Interviews with a campus wellness counselor and a Sex Abuse Treatment Center outreach professional were conducted to gain insight into how everyday language affects survivors offline. Results show patterns in how language shapes how sexual violence is understood and addressed online. Comments frequently supported the perpetrator, denied the occurrence or minimized harm, while others validated survivors like Virginia Giuffre and called for accountability. Interview findings reinforced that everyday phrases like "why didn't she just..." minimize harm and shift attention away from perpetrators. In conclusion, survivor-centered framing and awareness of microaggressions are crucial in preventing minimization and victim-blaming. Further research includes examining how these linguistic patterns work across diverse contexts and platforms and the long-term impact of survivor-centered language on public perception, policy, and community support.

Abstract Name: On leading the Kentucky Ant Project, a Lab Run Entirely by Undergraduates Making Massive Scientific Impact.

Over the past 3 years I have had the wonderful opportunity to run a genetics and biology lab as an undergraduate student. In this time, I have taught over 10 students how to study ants, and we have worked on composing a document discussing the ants of Kentucky, which has never existed before the project started. Sensing needs for outreach and appreciation, I also designed an immersive public facing exhibit to help teach my lab about ants. Come and hear about this project and how it blew scientific expectations at the international ant meeting in Brazil. There will also be a brief discussion on the proper use of AI in these academic settings. (Subtítulos disponibles en Español e Português)

Abstract Name: “PRIVATE” WELFARE: THE UNSUSTAINABLE AMERICAN APPROACH TO FREE SPEECH

In the aftermath of World War II, the United States reshaped the Japanese constitution into a heavily westernized version of their previous constitution. One of the additions made by the United States Government was Article 21, which granted citizens the right to free speech. This article is modeled closely on the American Constitution’s First Amendment, and yet, the two nations have an entirely different legal approach towards free speech rights. Japan uses a “public welfare” method, placing the individual rights below the common good, whereas the American approach does the opposite, and values individual free speech rights above almost all else. This approach has been a key factor in the increased amount of hate speech in the United States, a phenomenon fueled by the unrestricted nature of the First Amendment. Unlike the current legal framework, which defends an American’s right to free speech above all else, this paper argues that Japan’s constitutional prioritization of public welfare offers a more sustainable balance for modern democratic societies. This paper will propose a statute, modeled on public employee free speech rights in America and on Japanese public welfare policy. If applied, the implementation of this statute would reduce polarization and restore a sense of community in the American public by minimizing the shortcomings of the marketplace of ideas approach.

Abstract Name: Assessing the Impact of Various Factors on Hypoxic Response

Hypoxia is a condition in which the body’s tissues are deprived of oxygen and has deleterious effects on cognition, perception, and performance. Hypoxia has a myriad of symptoms such as euphoria, difficulty concentrating, headache, fatigue, nausea, dizziness, tunnel vision, and more. Outward signs of hypoxia include cyanosis (blueing of the fingertips and lips), tremors, loss of coordination, pallor, and complexion change, and can be used to notice the onset of hypoxia in others. Many factors are known to contribute to the manifestation of hypoxia, namely altitude, exposure duration, and certain physiological conditions such as

heart problems and low blood flow or oxygen transport. However, there are many other factors that potentially relate to hypoxic response such as age, gender, acclimatization, physical fitness, fatigue levels, recent dietary intake, etc. This study aimed to examine the impact of various parameters on hypoxic outcomes, including symptom presentation, time of useful consciousness, and physiological responses. A normobaric high altitude laboratory was used to simulate oxygen levels of 6.2%, which translates to an altitude of 30,000 ft—only slightly lower than average commercial airline cruising altitude. Demographic and physiological data was collected from participants, who then experienced hypoxia and attempted to complete cognitive and physical tasks. After recovering, participants shared their personal symptoms of hypoxia, and researchers noted participants' outward signs of hypoxia. The outcomes of this study will help to inform training protocols and high-altitude impacts for aviators, ultimately contributing to safer aircraft operation and emergency response.

Abstract Name: Untargeted Metabolomics as a Platform for Identifying Gut Microbially Produced Metabolites

Gut microbes play an important role in host physiology. They interact with the host by producing a wide range of small molecules that can influence complex diseases such as cardiovascular disease, diabetes, and inflammatory bowel disease. However, the majority of gut-derived metabolites remain unidentified. To identify new disease-related, gut-microbially produced metabolites, we performed untargeted metabolomics on fecal extracts from mice treated with or without a broad-spectrum antibiotic (Abx) cocktail. Data analysis revealed that certain spectral features were upregulated, while others were downregulated following Abx treatment. Costunolide was among the annotated metabolites that was significantly reduced by the Abx-induced microbial suppression. Its structure was further validated through comparison of high-resolution collision-induced dissociation (CID) spectra and retention time alignment between a pure standard and the corresponding metabolite in the fecal extract. Additionally, an unknown feature (m/z 491.31345) was also significantly reduced by the Abx treatment. Using MicrobeMasst, a publicly available mass spectrometry repository of microbial cultures, this feature was matched to compounds produced by *Escherichia coli*, further validating its microbial origin. These findings highlight the ability of untargeted metabolomics to uncover both known and previously uncharacterized molecules that are microbially derived and sensitive to changes in microbial community structure. Expanding this approach may allow researchers to build a more complete map of the chemical interactions occurring between the gut microbiome and its host, especially for metabolites that have not been linked to canonical biosynthetic pathways. In future studies, we will quantify selected metabolites in human samples available in our lab, as well as in publicly available datasets, to establish their relevance to host health.

Abstract Name: Surfactant-Assisted Control of S-Nitroso-N-acetylpenicillamine Crystal Formation

Nitric Oxide (NO) releasing compounds such as S-Nitroso-N-acetylpenicillamine (SNAP) are being studied for their potential to improve the biocompatibility of medical devices such as catheters, cannulas, and sensors because of the antimicrobial, anti-inflammatory, wound repair, and anti-thrombosis properties of NO. Current methods of SNAP synthesis form crystals with rough surface texture and dimensions between 10 to 50 μm . The size and shape of crystals affect the chemical behavior and manufacturing-related properties of the compound. The size of SNAP crystals cannot be reduced by destructive means (milling, grinding) because the application of heat causes the decomposition of SNAP. Instead, constructive methods such as crystallization must be used to control SNAP morphology. This work utilizes surfactant-assisted recrystallization to produce uniform SNAP crystals of desired dimensions and form. SNAP was dissolved in a variety of surfactant solutions. The solubility of SNAP in solution was lowered, causing SNAP to form solid crystals. Surfactants form micelles around SNAP during crystal formation, affecting its ultimate crystal habit. A variety of surfactants are featured in this work, each of which produce unique crystal habits. Dipyramidal, cubic, and rectangular prismatic crystal morphologies are reported. SNAP crystals with widths $\leq 5 \mu\text{m}$ were achieved. Control of SNAP crystal habit may be useful in controlling the dissolution and decomposition rates of SNAP in medical devices. SNAP crystals with dimensions $\leq 5 \mu\text{m}$ may be particularly useful in the development of SNAP-incorporated microdevices.

Abstract Name: Assessing Seasonal Patterns in the Prevalence of Antibiotic-Resistant Bacteria in Chisholm Creek, Oklahoma.

The emergence of antibiotic resistant bacteria (ARB) is an urgent global public health concern. ARB enters the freshwater environments via agricultural runoffs, wastewater treatment plant discharge, and leaching from nearby farms. This poses a significant threat, especially when these freshwater ecosystems are used for recreation and as a source of drinking water. The objective of this study was to assess the presence of ARB in the water of Chisholm Creek in Oklahoma and to examine whether ARB levels vary across different seasons. It is hypothesized that amoxicillin resistance will be higher due to its frequent use in medicine, and there will be a seasonal difference in ARB due to the effect of temperature on bacterial growth. The Chisholm Creek sampling site was chosen for its proximity to residential areas and recreational spaces. Water samples were collected in Winter 2024, Spring 2025, Summer 2025 and Fall 2025. Reasoner's 2A agar with 4, 2 and 8 mg/L of amoxicillin, ciprofloxacin, and tetracycline, respectively, was used as the growth medium. Amoxicillin, ciprofloxacin, and tetracycline were selected for this study due to their widespread medical use and differing mechanisms of inhibiting bacterial growth. Amoxicillin targets bacterial cell wall synthesis, ciprofloxacin inhibits DNA gyrase activity, and tetracycline interferes with protein synthesis. Serial dilutions of water samples were plated on media containing individual antibiotics, and no antibiotics (control). The numbers and proportions of all ARB populations were significantly ($P < 0.05$) influenced by the seasons, location, and their interaction. In general, higher bacterial counts were observed in the Winter and Fall seasons. Besides, the highest level of antibiotic resistance was observed against amoxicillin, followed by ciprofloxacin and tetracycline. The results of this study provide insights into the presence of ARB in the freshwater ecosystem of Oklahoma and identify potential seasonal variations in ARB levels.

Abstract Name: A Novel AEP Inhibitor Selectively Suppresses Pathogenic Tau Species in a Neuronal Stress Model

Introduction: Alzheimer's disease (AD) is approaching epidemic levels and still lacks an effective disease-modifying therapy. Recent advances in clinically measurable biomarkers have improved the ability to evaluate emerging therapeutics. AD is characterized by the accumulation of hyperphosphorylated tau, which forms neurofibrillary tangles (NFTs), and amyloid- β plaques. The Amin Lab develops novel therapeutics targeting neurodegenerative processes, including compounds that inhibit asparagine endopeptidase (AEP), also known as legumain. AEP is a lysosomal cysteine protease that cleaves proteins at asparagine residues. Upon activation, AEP cleaves tau and contributes to downstream tau pathology. Prior studies have identified both tau and amyloid- β as physiological substrates of AEP, highlighting AEP as a promising therapeutic target in AD. In this study, we investigated the effects of Compound C, a novel AEP inhibitor developed in the Amin Lab, on AEP-mediated tau cleavage and phosphorylation. Methods: AEP activation was induced in HT22 neuronal cells using sodium arsenate (SA). Cells were treated with SA alone or with SA plus Compound C. Western blot analysis was used to quantify phospho-tau (~78 kDa) and total tau (~78 kDa) to determine whether Compound C selectively alters pathological tau species without affecting overall tau abundance. Results: SA exposure produced a robust band at ~78 kDa consistent with stress-induced tau hyperphosphorylation. Co-treatment with Compound C significantly reduced phospho-tau levels compared with SA-only controls, while total tau expression remained unchanged. These findings suggest that Compound C suppresses the formation of pathogenic phosphorylated tau species rather than altering global tau levels. Conclusion: Compound C attenuates stress-induced phospho-tau accumulation in HT22 cells without affecting total tau, supporting its potential role in modulating tau pathology. Future studies will include AEP knockdown using siRNA to determine whether the reduction in phospho-tau is specifically mediated through AEP inhibition.

Abstract Name: How Arousal Relates to Brain Network Functional Connectivity: A Within and Between Subjects Precision fMRI Study

Low levels of arousal often reduce performance in settings requiring attention, decision making, and reasoning. Because these tasks require coordinated activity across brain networks, changes in arousal likely influence these connections. Functional connectivity (FC) can capture this coordination, revealing how brain networks shift with arousal. Previous research has found a positive association between light sleep and resting-state FC for most brain networks. Generally, most studies average data across subjects, obscuring patterns only visible at the individual level. However, a precision approach collects substantial amounts of data per participant, ensuring highly reliable and individualized brain networks. Here, we explore the differences in FC between high and low arousal groups. We also use precision methods to investigate differences in FC within three participants with high and low arousal. For each resting-state run, participants self-reported arousal (1 = high arousal, 7 = low arousal). We classified these ratings into high, medium, and low arousal conditions. We only analyzed runs in the high and low arousal groups and subjects with more than five minutes of data (N = 53 subjects). Brain data were divided into 300 regions using the Seitzman atlas, then pairwise correlations were computed between averaged time series of those regions for each subject. Between subjects, FC matrices were averaged within each condition and compared. During low arousal, we expect between-subject FC to be stronger within somatomotor and visual networks, as well as greater connectivity between these networks. At the individual level, we expect similar yet idiosyncratic patterns, such as increased localized FC in specific brain regions. Connectivity patterns may fluctuate with low levels of arousal, which in turn disrupts the ability to complete daily tasks. Mapping FC at the individual level may reveal how previously masked patterns correspond with these disruptions, which would inform targeted therapies for populations struggling with diminished arousal.

Abstract Name: Cells having functional KLF4 enhances DNA damage repair through regulation of pChk1 and Rad54

Krüppel-like factor 4 (Klf4) is a zinc-finger transcription factor that has been implicated as a hallmark of colorectal cancers, one of the most common cancers worldwide. In addition, it has been found to play a role in activating cell cycle checkpoints following DNA damage. However, the molecular mechanism of Klf4 and its exact role in the DNA damage repair (DDR) pathway has yet to be fully understood. Thus, it is of interest to investigate the role of Klf4 in the DDR pathway, including the molecular mechanisms involved and its relationship with key DDR proteins. Previous work from our lab has shown that, compared to mouse embryonic fibroblasts (MEFs) null (-/-) for Klf4, MEFs that are wild-type (+/+) for Klf4 exhibit increased expression of DNA repair genes including ATR, Chk1, and Rad51 and decreased expression of γ H2AX, a biomarker for DNA damage, after a chemotherapy drug treatment, etoposide. In this study, a protein assay using western blot analyses indicate that while Klf4^{-/-} MEFs treated with doxorubicin, a topoisomerase II poison, continue to express higher levels of γ H2AX, they also exhibit higher expression of phosphorylated Chk1 (pChk1) and Rad54 as compared with Klf4^{+/+} MEFs. In addition, after a 24-hour recovery period, pChk1 levels decreased and Rad54 levels increased, yet still with higher expression in Klf4^{-/-} MEFs. Furthermore, we used the comet assay to detect double stranded DNA breaks (DSBs) and found that cells lacking Klf4 exhibited more DSBs. Taken together with previous findings, the results from this study strongly suggest that Klf4 plays a role in detecting DSBs. These results support a model in which KLF4 promotes proper coordination of DDR signaling, providing a molecular basis for potential therapeutic strategies targeting KLF4-mediated genomic stability in colorectal cancer.

Abstract Name: From Click to Guilt: The Emotional and Algorithmic Forces Shaping Gen Z's Online Buying Sprees

Online shopping is deeply embedded in Gen Z's routines, supported by seamless mobile access, fast payment systems, and highly personalized recommendation algorithms. These environments expose young consumers to emotionally engaging cues that may increase impulsive purchasing, especially when individuals experience stress, boredom, or negative emotions. Emotional vulnerability has been linked to reduced self-control and stronger reactions to persuasive stimuli, while algorithmic recommendations may heighten exposure to tempting products. The purpose of this study is to explore how algorithm exposure, impulsive buying tendencies, emotional vulnerability, and post-purchase regret relate to one another among Gen Z consumers. Participants were 49 individuals aged 18–29 recruited through convenience sampling. An online survey assessed four 5-point Likert constructs: algorithm exposure, impulsive buying, emotional vulnerability, and post-purchase regret. These composite variables were used to compute Pearson correlation coefficients, examining their interrelationships. Impulsive buying was moderately related to emotional vulnerability ($r = .66$). It also showed a smaller moderate relationship with algorithm exposure ($r = .29$). Other correlations were small. Post-purchase regret demonstrated a moderate positive association with algorithm exposure ($r = .50$). In contrast, its association with impulsive buying was negligible ($r = .03$). Likewise, its association with emotional vulnerability was effectively near zero ($r = .01$). This pattern suggests that regret in Gen Z is more influenced by algorithmic factors than by their internal emotional tendencies. This study provides insights into reducing algorithm-driven impulses and regret by targeting emotional vulnerability in Gen Z but is constrained by a small sample, which precluded regression, mediation, or moderation analyses. Future research should employ larger, more diverse samples to test predictive pathways and assess whether emotional vulnerability amplifies the effects of algorithm exposure. Incorporating behavioral data, such as browsing logs or recommendation interactions, could validate self-reported tendencies and deepen understanding of how algorithms shape decision-making.

Abstract Name: Weight Change and Health Awareness Among College Students Through the Social Ecological Model

Obesity is widely regarded as a major risk factor for numerous diseases, so obesity and overweight remain key areas of global public health attention. Research has shown that the risk of obesity and overweight in adulthood is higher for those who were overweight or obese as young adults. The underlying cause of this weight gain is not easy to determine; therefore, further observation is required. The Social Ecological Model (SEM) supports the examination and promotion of sustainable health behavior change among college students through a holistic lens. According to the SEM, health behaviors are determined by the dynamic interaction of five interrelated levels of influence: individual, interpersonal, organizational, community, and

structural support. This perspective emphasizes the need for multi-level interventions that address not only personal awareness and behavior but also the environmental and policy contexts that influence students' overall well-being. This study was designed using the SEM to examine college students' self-awareness of their health status in relation to weight changes during their college years. Thus, data from surveys based on the perspectives of SEM will be used to investigate weight changes, weight management strategies, and barriers to maintain health habits. Descriptive statistics will summarize weight changes and behaviors in different academic years, while thematic analysis will identify effective strategies for maintaining a healthy weight and assess students' understanding of the risks associated with weight gain. The findings from this study are expected to highlight how weight gain is primarily driven by lifestyle and environmental factors among college students. Furthermore, these findings provide guidance on the important role universities play in shaping student health outcomes through improved dining options, wellness education, accessible fitness opportunities, and mental health support. These changes at universities could foster a healthier campus culture and lower long-term health risks among the student population.

Abstract Name: Using non-linear narratives and visual design to guide aspiring divers to make safe decisions before and after emergency situations.

Scuba diving is a thrilling experience, but the sport isn't without risk. Scuba-related accidents usually occur as a result of a diver's actions. It comes down to the decisions scuba divers make leading up to and in those stressful environments, which dictate the severity of the outcome. With decision-making in mind, I began my research, questioning how one person can teach another to make the right choices. Cautionary tales are a popular format shared between individuals as a means of forewarning. I desired readers to interact with these stories which led me to select a pick-your-own-adventure book for my subject. These books utilize non-linear narratives, allowing the reader to pick and choose which path they'll take. In my book, readers are guided through a series of seemingly harmless scenarios leading up to the main conflict. Their character can live, survive, or die as a result of their choices. The visual design of the book replicates a divers' needed level of awareness. For instance, when the main character enters a dive, icons will appear at the bottom of the page indicating ascent, depth, time, deco-limits, and air consumption. The reader must remain attentive to these icons as their values will increase or decrease throughout the story. The condition of the character is represented through type treatment. As words become faded and illegible their character has passed out or become light-headed. If the type becomes distorted the character is disorientated or sick. The paper is also used to indicate environmental conditions such as depth and temperature. The deeper their character goes the darker the page. The colder the water and the more prominent 'frost' will appear on the pages edges. All of these elements work together to develop the observational skills and critical thinking needed to survive a real world emergency situation.

Abstract Name: Military Culture: An Examination of Military Culture's Effect on African American Intimate Relationships

This study explores how the norms, values, and stressors of military culture affect the emotional and intimate relationships of African American service members. While previous research has examined the general impact of military life on relationships, few studies have focused on the intersection of race, identity, and intimacy—particularly among both heterosexual and same-sex African American military couples. The purpose of this project is to understand how the structure and demands of military service shape emotional expression, communication, and connection within these relationships. Using qualitative research methods, three focus groups of ten participants each will be conducted. Participants will include African American military personnel who have been in committed relationships for at least five years. Each group will meet multiple times to discuss shared experiences related to discipline, stress, identity, and intimacy. These conversations will be analyzed to identify recurring themes and unique insights into how military expectations influence relationship satisfaction and emotional closeness. Preliminary findings are expected to highlight the dual impact of military culture—its potential to strengthen commitment through shared discipline, yet also to strain relationships through emotional restraint and stress. This study aims to inform the creation of culturally responsive workshops and support programs designed to strengthen intimacy and communication among military couples. Attendees will learn about the intersection of race, service, and emotional well-being, as well as potential strategies for improving relationship support within the military community.

Abstract Name: Characterization of the Deuterated Cyclohexadienyl Radical (C6D7) Using Matrix Isolation Infrared Spectroscopy

Matrix isolation infrared spectroscopy was used to characterize the deuterated cyclohexadienyl radical (C6D7), which was generated by adding a D atom to deuterated benzene (C6D6) in an argon matrix at 12-15 K. Deuterium atoms were produced using a microwave discharge plasma source with D2S and SiD4. Comparing the two D atom precursors, the SiD4 produces a higher yield of C6D7 than D2S. The D atoms reacted with co-deposited C6D6 to form the C6D7 radical, which was trapped and stabilized in the argon matrix. Multiple infrared absorptions for C6D7 were observed at 420.4, 459.0, 746.1, 751.7, 765.0, 1038.8, 1214.5, 2032.6, 2045.0, 2048.8, and 2052.9 cm⁻¹. The peak at 459.0 cm⁻¹ is the most intense C6D7 radical band. Annealing the argon matrix to 20 K resulted in increased intensities for several C6D7 features. A mercury-xenon lamp was used to photolyze the matrix with filtered (visible) and unfiltered (ultra-violet and visible) light to confirm the C6D7 peak assignments by monitoring the changes in infrared spectra. Theoretical calculations at the B3PW91/aug-cc-pVTZ level were performed to obtain an optimized geometry and harmonic vibrational frequencies for the C6D7 radical. The computational results were used to help assign the observed infrared bands and distinguish the radical features.

Abstract Name: 2D Metamaterial Fourier Analyzer

A lattice test bench to gather the isofrequency contours and wavenumbers of a selection of engineered materials (metamaterials) was designed. The reported material test platform is made to launch a cylindrical wave into a parallel plate waveguide and supported metamaterial lattice. The upper plate is replaced by a semitransparent boundary (metallic chicken wire) in order to leak a fraction of the fields propagating within the waveguide. A near-field scanner equipped with a coaxial probe is used to detect the leaked fields just outside the chicken wire. These detected fields are then used to reconstruct the propagation behavior of the lattice. Specifically, the speed of the wave as a function of propagation angle is deduced from the spatial Fourier transform of the detected fields. For a given propagation angle, it is expected that the 2D Fourier transform of the leaked fields will produce a peak corresponding to the wavenumber in the ideal metamaterial lattice. The agreement between the measured and simulated wavenumbers will be reported. The presentation will provide an overview of the proposed methodology and its accuracy. This will include a numerical study on optimal probe orientation for the near-field scanner such that the signal-to-noise ratio is maximized. Further, these results will be compared to an ideal simulation of the metamaterial in a perfectly periodic environment. This will serve as the ground truth when validating the measurement procedure. The presentation will also detail the construction of a test-platform fabricated using low-cost materials and fabrication methods. Such a design will enable the characterization of a broad class of metamaterial lattices in a 2D setting.

Abstract Name: Opposing Views of the Indigenous People During Colonization

European colonists in the Americas competed for the region's resources through political influence, exploitation, deception, and forced conversion. During their conquests, Spanish, English, French, and Dutch colonizers shaped distinct perceptions of Native peoples, as reflected in their art. These portrayals, in turn, influenced how Europeans in their homelands viewed indigenous Americans. The Spanish artwork of José de Páez, such as *Destruction of the Mission of San Saba in Texas* and *Martyrdom of Fray José de Santiesteban* and Fray Alonso Giraldo de Terreros, depicted Native tribes as violent, barbaric, or savage to justify colonization, exploitation, and conversion. When the English arrived, they saw traits of sin among the people based on their Christian beliefs and standards. The English artist, John White, showed the indigenous community attacking Christianity while dancing and acting like wild animals in his painting *Festive Dance*. Jacques Le Moyne de Morgues, René Goulaine de Laudonnière, and the Native people in Florida portrayed the indigenous as savages; the French shared similar views as the English, considering them sinners. The Dutch, meanwhile, depicted the natives as potential business partners, recognizing themselves as outsiders and the natives as the original inhabitants. Gilbert Stuart's *A Portrait of Thayendanegea* portrayed natives according to European standards. This study highlights the contrasting perspectives of Spanish, English, French, and Dutch colonists toward Native Americans through eight depictions of Native peoples and various library and government resources.

Abstract Name: Nectar of Ambrosia? Have palm plantations increased bark beetle densities in primary and secondary Bornean forests

Ambrosia beetles (Scolytinae, Coleoptera) attack and consume the phloem, wood, fruit, and seeds of a variety of tree species and often transmit pathogenic fungi. Damaging pathogens transmitted by introduced Scolytinae have caused economic losses in timber plantations, crop plants, and natural systems elsewhere. Recent studies found >150 species of Scolytinae in Sabah, Borneo and reported distinct species assemblages within rubber (*Hevea brasiliensis*, Euphorbiaceae) plantations compared to intact forests. Currently 39% of Borneo has been deforested to cultivate African Oil Palm (*Elaeis guineensis*, Arecaceae). The diversity of palm feeding Scolytinae is unknown, as only a few species in the subfamily have been documented feeding on palm wood or fruits globally. However, open forest structure, like that which occurs in both palm and rubber plantations, can increase trap captures of these beetles. Borneo is a biodiversity hotspot for palms, containing over 300 different species. Thus, increases in ambrosia beetles that lead to tree death could result in loss of food, shelter, or pollination services. To estimate ambrosia beetle diversity, we placed pan traps at three distances from the forest edge in each habitat type in two nature reserves - Maliau Basin and INIKEA – and one palm plantation in central Sabah, Borneo. We asked 1) does an open forest structure, such as that in plantations and secondary forests, increase trap captures of Scolytinae, 2) do *E. guineensis* plantations show similar patterns in ambrosia beetle diversity and density as rubber plantations in previous studies.

Abstract Name: Impactful Art Pieces Depicting the American Revolution

Art played a vital role in the American Revolution, serving as a powerful way to express and energize colonial resistance against British rule. From early protests against the Stamp Act and the depiction of Paul Revere's The Bloody Massacre in 1770, to the symbolic images of Emanuel Leutze's Washington Crossing the Delaware in 1815, visual art captured the spirit and struggles of the revolution. Although these paintings and other representations of the American Revolution were made in various eras and settings, they reflect the people who fought for what they believed in to gain freedom. Artistic works from both the United States and Great Britain vividly depict the key moments and ideas related to the fight for independence from monarchical rule. These pieces, rich in imagery and symbolism, stand as lasting testaments to the colonists' unwavering resolve and to art's power to shape national identity. This study focuses on the American Revolution and its conflicts with Britain through artworks and objects created during and after the Revolution.

Abstract Name: The Impacts of Covid on Labor Force Participation

Labor force participation is an important measure of productivity and growth in the economy. Covid-19 was unique as a recession because it had immediate and drastic impacts on our economy due to lockdowns and mass lay offs, disrupting labor markets greatly. My thesis is that Covid-19 negatively impacted labor force participation in the United States. Many states saw a dip in labor force participation, followed by a slight increase over the following years. Different states had different impacts on the changes in labor force participation due to covid. This paper examines the effects of covid on labor force participation state by state. It uses state CPS data to examine the differences before and after covid of labor force participation. I use OLS regression to estimate the impact using a difference in difference approach. I include labor force participation data from 2019-2025, excluding the year 2020, in my data set. I include a dummy variable for before and after covid. I include a dummy variable for states that had strict school closings during the shutdown. I am including control variables for percentage population female per state and percentage population college graduate per state. I am including a region variable to view the different impact in different regions of the country. Preliminary results suggest that along with our dummy variable for pre vs. post covid, the percentage female and percentage college graduate both help to explain the variation in difference in labor force participation per state before vs. after covid.

Abstract Name: Using DeepLabCut to Quantify Anxiety-Like Responding in Zebrafish Shoals Synthetically Alarmed with Hypoxanthine-3N-Oxide

Zebrafish (*Danio rerio*) are a common model organism for behavioral neuroscience research due, in part, to their elaborate social repertoire. A common behavioral characteristic of zebrafish includes shoaling, the loose aggregation of individuals without synchronized movement within the group of zebrafish. Like most other fish, zebrafish also have an antipredation chemical alarm system. When predatory attack results in skin damage to one of the members of the shoal, epithelial club cells release a substance known as “schreckstoff” that serves as an alarm signal for surrounding fish. As a result, this “schreckstoff” activates a variety of anti-predation responses, including darting, freezing, and negative geotaxis (bottom-dwelling). A synthetic version of this alarm substance has been identified as Hypoxanthine-3N-Oxide (H3NO), and exposure to H3NO is known to activate the same anti-predation responses. However, the complexity of such responding has yet to be investigated in mixed-sex zebrafish shoals. For the current study, mixed-sex shoals (n = 4, 2 males & 2 females each) were exposed to varying H3NO concentrations (1.5nM, 3nM, or 5nM). Digital video recording obtained the shoals’ behaviors for 10-minutes after administration. Videos were subsequently tracked via DeepLabCut, an open-source markless position-estimation tool for characterizing spatial movement. Positional data were subsequently analyzed with Python to quantify freezing, darting, and twirling. Results indicate dose-dependent effects across darting and freezing, indicating that different dosages elicit different patterns of behavior. Future research will investigate additional behavioral patterns such as inter-individual distance in grouping responses as well negative geotaxis by shoal members. Furthermore, this study illustrates the necessity of quantifying behaviors in multiple ways, identifying additional opportunities for future research. Understanding these responses in detail provides implications of anxiety, fear responding, and anti-predation behaviors. Better understanding these mechanisms could contribute to animal models investigating social development or disorders of social functioning.

Abstract Name: Effects of Phytoremediation on Horizontal Gene Transfer

The widespread use of antibiotics in medical, veterinary, and agricultural practices has resulted in the accumulation of antibiotic residues within aquatic systems. This environmental contamination fosters the development and dissemination of antibiotic-resistant bacteria and antibiotic resistance genes, posing significant ecological and public health challenges. This study investigates the potential role of aquatic plants, specifically *Vesicularia montagnei* and members of the Lemnoideae family, in influencing horizontal gene

transfer (HGT) among bacterial populations. Two *Escherichia coli* strains were employed: an F⁺ tetracycline-resistant donor capable of HGT and an F⁻ ampicillin-resistant recipient. We examined whether co-cultivation with aquatic plants promoted the emergence of dual-resistant strains, signifying HGT. Preliminary data revealed an initial increase in HGT activity within plant-containing systems during the first 24 hours, followed by a progressive decline in total bacterial populations over a 10-day observation period. These trends were not observed in control systems lacking aquatic plants, where bacterial populations and HGT activity remained relatively stable. Collectively, these findings suggest that aquatic plants may influence microbial community dynamics by initially facilitating gene exchange before contributing to the suppression of bacterial abundance and a potential reduction in antibiotic resistance gene prevalence over time. Ongoing research seeks to determine how plants influence HGT, with the goal of informing phytoremediation strategies to reduce antibiotic resistance in aquatic ecosystems and protect public health.

Abstract Name: Youth Access to Health Education in Sri Lanka: A Nationwide Needs Assessment

This independent research project investigates disparities in health education access among Sri Lankan youth aged 12–25. After the civil war in Sri Lanka from 1983 to 2009, the quality of healthcare and health education has decreased, leaving the citizens with a lack of an effective healthcare system and knowledge on important health topics. Through a digital survey distributed across urban and rural provinces, the study is being conducted to gather data on knowledge of key health topics such as hygiene, nutrition, reproductive health, and mental wellness. Through these surveys, the goal is to understand how much access to health topics students in Sri Lanka have, while also understanding the topics which they wish to learn more about and to identify regional gaps and cultural barriers to health knowledge, within and out of Sri Lanka. Not only that, as part of the study virtual workshops in Sri Lanka to go over various health topics, listed on the survey, will be conducted starting October 2025. After these workshops, the students will fill out another survey with similar questions, and the data will be used to compare how health education can be implemented in Sri Lanka for the youth. The data will inform the creation of virtual workshops and future interventions. Findings will be shared with Sri Lankan youth organizations, such as PEARL, CMU clubs, and global health research mentors.

Abstract Name: Reimagining Wellness: Transforming Space into a Holistic Healing Haven

The Wellness Center on a college campus does not provide sufficient resources for wellness beyond physical movement. With many college students struggling with wellness in multiple areas of their lives, including mental, nutritional, and therapeutic, there is a growing need to provide holistic wellness resources on campus. The goal of the Wellness Center redesign is to create a space that addresses this need for holistic wellness resources on campus by providing a facility for physical, mental, and nutritional wellness. Survey findings

identified key wellness priorities, with students expressing a strong interest in a nutritional restaurant. Research also has shown that malnutrition increases health risks and diminishes students' ability to focus and perform academically. The redesign includes the addition of a restaurant, which will serve wholesome meals using ingredients from the community garden on the patio of the wellness center. The facility provides the community access to quick, nutritious meals and the opportunity to enrich their knowledge of preparing nourishing food. The facility addresses the growing concern for student mental wellness by incorporating a clinic staffed with trained healthcare professionals, offering both nutritional support and mental health resources. The clinic offers spaces for therapy, health exams, and sensory support, providing students with accessible mental and physical wellness care on campus. The redesign also provides a fitness space to support students' overall physical health. The project will create a campus wellness resource that supports holistic well-being by addressing the major areas of students' physical, mental, and nutritional health.

Abstract Name: Investigating the Potential for Distributed Solar Energy Production on Commercial Properties in the Greater Duluth, Minnesota Area

This project investigates the conditions necessary to incentivize commercial property owners in the Greater Duluth, Minnesota area to install distributed rooftop solar. Although the price of solar photovoltaics (PV) has been declining and numerous incentive programs are available for businesses, commercial solar installations remain a small share of Minnesota's total solar capacity. At the same time, commercial buildings are the largest source of greenhouse gas emissions in Duluth, and local utilities such as Minnesota Power must increase solar generation to meet the state's 100% clean energy by 2040 legislation. Existing research identifies financial, informational, and organizational barriers as the most common obstacles to solar adoption, with enablers including subsidies, environmental concerns, and the opportunity to reduce expenses. Few studies estimate property owners' willingness to pay for solar, the return on investment required to make adoption compelling, or renters' preferences, and this project addresses gaps by examining these factors and other considerations affecting commercial rooftop solar feasibility in Duluth. Personal contributions focused on supporting survey development, testing, and analysis of incentive structures. I worked to translate feedback from interviews with solar stakeholders and local experts into survey questions designed to capture commercial property owners' views on solar adoption and inform the research team's ability to assess the financial performance required for adoption. Additionally, I assisted in facilitating focus groups with local commercial property owners to test the survey, collecting feedback and incorporating revisions. Additional contributions include researching federal solar incentive changes introduced through the "Big Beautiful Bill," including updates to tax credits, sourcing requirements, and accelerated depreciation, and applying these provisions in evaluating a solar financial calculator to understand how different incentive structures affect owners' return on investment. Findings from the study will help provide guidance to local policymakers and utilities seeking to expand distributed rooftop solar across the Duluth area.

Abstract Name: The Continued Influence of Health-Related Misinformation

Misinformation is not a new phenomenon, but the advent of artificial intelligence and social media has allowed bad actors to create misinformation that can be designed to be spread widely or can be specifically tailored to specific audiences. Health misinformation is especially dangerous because it is often unaccompanied with corrections, or as was the case with the COVID-19 pandemic, the corrections are often delayed. Misinformation is especially dangerous because it is difficult to eliminate their influence or revise the information after it has been learned to be false. Indeed, misinformation often influences our reasoning despite it being known as false (i.e., the Continued Influence effect). The purpose of this study is to examine the effectiveness of the type of correction in a health misinformation setting. Participants are exposed to multiple (false) causal claims related to how something affects health. For some of these stories, a correction follows that is either simple or elaborative. A control condition is also included in which the stories are not corrected. Participants are told that the study is an experiment about learning. After reading the stories and corrections (if appropriate), participants answer a questionnaire about the story and their beliefs. We hypothesize that participants will rely on the misinformation less often when the correction is more elaborative than when it is a simple negation. This study has the potential to inform policymakers and researchers alike on methods that can be used to effectively combat health misinformation. Even with the large amount of research examining health misinformation, there has been less examining how corrections influence reasoning when the state of knowledge is tentative, and subject to revision.

Abstract Name: Political Polarization in the Christian Church

How can Christians who claim the same scripture hold opposing positions on politically charged topics? Rather than seeking to determine the definitive biblical position on certain topics or explain why different Christian groups hold certain views, this study examines which politically charged topics Christian pastors believe the Bible addresses clearly and how they perceive Christians who hold opposing views. Based in Tucson, Arizona, this research draws on a series of semi-structured interviews with Christian pastors across the political spectrum, classified as conservative, progressive, or mixed based on their descriptions of their congregations' political leaning. A grounded theory analysis reveals that both conservative and progressive pastors view faith as the center of their worldview and see their political beliefs as emerging directly from scripture, yet they disagree on which issues have clear scriptural mandates. Each group perceives the other as imposing political beliefs onto scripture rather than allowing scripture to guide their politics. In communities where certain issues are considered "biblical," disagreement becomes difficult, as challenging these positions is seen as challenging scripture itself. Pastors of mixed and moderate congregations adopt more varied strategies for navigating the relationship between faith and politics. These findings contribute to a more nuanced understanding of political fault lines in the American Christian community by highlighting differing assumptions about the clarity of scripture on various issues.

Abstract Name: The Effects of Carbon Labeling Techniques on Consumer Purchasing Behavior

Agriculture accounts for approximately 21% of global greenhouse gas emissions, necessitating a dramatic reduction in agricultural emissions to prevent worsening climatic conditions. One strategy to facilitate this shift is through carbon labels—a label added to food products to notify consumers of the environmental impact of a product. Traditional carbon labels present quantitative emissions information, an ordinal rating (color-coding or star rating), a certificate, or combine quantitative emissions information with color-coding. This study experimentally examines consumer choices in relation to four different carbon label designs with the goal of understanding which label design most effectively steers consumers toward environmentally-friendly products. Our study expands upon previous work by examining the effects of carbon labels on U.S. consumers, an understudied population in carbon label research, and employing a comprehensive carbon label design (presenting color-coding, a star rating, and quantitative emissions information). Nearly 400 participants completed a survey assessing participant product choices when presented with different carbon label designs, alongside participant concern for the environment and shopping priorities. The results suggest the comprehensive carbon label design most effectively steers consumers toward environmentally-friendly products, indicating this novel labeling strategy may be more effective than previous carbon label designs. However, individuals who express low levels of environmental concern prefer no label. Accordingly, labels may not encourage sustainable purchasing behavior for individuals with low levels of environmental concern. Overall, this study indicates label design impacts consumer choice, and the comprehensive label design has strong potential for directing consumers toward environmentally-friendly products and opens up new avenues for researchers to explore expanded label designs in other contexts.

Abstract Name: Severe Traumatic Brain Injury Induced Chronic Motor and Sensorimotor Deficits in Sprague Dawley Rats

Introduction: Traumatic brain injuries (TBIs) affect 2 million Americans annually, causing an economic and healthcare burden. Patients with severe TBIs (sTBIs) suffer from sustained volumetric brain tissue (~1.5%) loss each year, and functional impairments. Therefore, we assessed the impact of sTBIs on the overall motor and sensorimotor function, over time, in a rat model. Hypothesis: We hypothesize that sTBI causes chronic motor and sensorimotor impairments. Methods: We performed functional assessments for 16 weeks post-sTBI using tests such as the vertical cylinder test and modified neurological severity score (mNSS), on Naive (uninjured, n=4), Sham (craniotomy only, n=4), and controlled cortical impact (CCI sTBI, craniotomy with injury, n=4) animals, that received unilateral injuries to the right brain hemisphere (rostral forelimb area or RFA, ML: +2.5 mm, AP: +3.0 mm, DV: +2.0 mm). Results: Our mNSS data demonstrates significantly higher motor and sensorimotor deficits through an overall higher mNSS score in the CCI animals over 16 weeks, compared to Naive ($p < 0.0001$) and Sham controls ($p < 0.0001$). Our vertical cylinder test showed that the CCI sTBI animals had significant functional deficits through fewer unsupported rearings, compared to Naive ($p < 0.0001$) and Sham controls ($p < 0.001$). We also observed a significantly lesser number of left forepaw touches in the CCI group, compared to Naive ($p < 0.0001$) and Sham controls ($p < 0.01$). Conclusion & Future Directions: Together, these findings indicate that sTBI induces

sustained and progressive functional deficits that impair chronic recovery. This study opens avenues for circuit-level assessments of motor and sensorimotor function after severe TBI.

Abstract Name: Comparing Cortical Responses to Mechanically and Electrically Evoked Somatosensations

Phantom limb pain (PLP) is characterized by pain and discomfort in an amputated extremity. Our overall goal is to develop an at-home therapy to reduce PLP by restoring sensation in the amputated extremity through electrical stimulation. Our hypothesis is that there will be changes in the cortical activity related to this decrease in phantom limb pain. This project aims to find similarities between brain responses due to mechanically and electrically-evoked tapping sensations in able-bodied participants in preparation for working with participants who have PLP. A 96-electrode electroencephalogram (EEG) cap was used to measure cortical activity in response to two types of stimuli: i) Using transcutaneous stimulation of the common peroneal nerve behind the knee (stim condition 1), and on the top of the foot (stim condition 2) to electrically evoke sensations on the top of the foot, and ii) Mechanically-evoked sensations with and without vision by tapping on the foot at the match location corresponding to the perceived area of the stimulated sensation on the top of the foot. The EEG data were analyzed using EEGLAB and the ERPLAB plugin. After preprocessing, evoked responses were compared across conditions in both timing and amplitude. Preprocessing steps included filtering, artifact rejection, and epoching the data around each stimulus onset to isolate neural responses. Evoked responses were then compared across conditions by examining both the timing (latency) and size (amplitude) of key somatosensory ERP components. It is anticipated that some participants will show similarities in cortical responses at common peak latencies, although the exact nature of these relationships will be determined through further analysis.

Abstract Name: Simplified Multimodal Imitation Learning for Day–Night Autonomous Driving

Traditional approaches to autonomous driving in structured environments, such as cities, heavily rely on path-planning algorithms and kinematic models for low-level vehicle control. These approaches are complex, requiring detailed system modeling and parameter optimization. While such systems are generally intended for use in unconstrained urban environments, this raises the question of whether a simpler model could be effective in more constrained settings, such as a university campus. This study investigates a simplified, conditioned Imitation Learning (IL) model for day–night autonomous driving on a university campus. An initial proof of concept was tested using an end-to-end CNN model, inspired by NVIDIA's approach, which controlled only steering and throttle to perform low-level commands. The model used RGB cameras for daytime driving and a thermal camera for nighttime operation. The test involved a 0.3-mile route from the

College of Engineering to the College of Business. Although the trained model for daytime driving achieved 99% accuracy, it performed worse than its counterpart trained on thermal imagery, which achieved only 94–97% accuracy. A total of three interventions were required during nighttime testing. The daytime model failed to operate autonomously, as the go-kart consistently oversteered toward bright patches of grass or sidewalks. This failure is likely explained by an imbalance in the training data, as the go-kart was tested later in the day under lighting conditions that differed from those in the dataset. Future work will incorporate high-level commands, enabling the model to execute specific turns based on input from a path-planning algorithm.

Abstract Name: Monocular Visual-Inertial Depth Estimation in Off-Road Environments Using Uncertainty-Aware Neural Networks

Autonomous navigation in off-road environments remains challenging due to unstructured terrain, unreliable GPS signals, and the inaccuracy of wheel odometry caused by frequent slippage. Localization in autonomous and manually operated vehicles enables the system to determine its position within the immediate environment, and, when combined with global path planning, supports optimal navigation and obstacle avoidance. Conventional LiDAR-based localization, currently used in the industry, while accurate, is costly, computationally intensive, and susceptible to degradation under vibration. To address these limitations, we present a monocular visual–inertial depth estimation framework designed specifically for off-road conditions using uncertainty-aware deep learning. Our method employs a U-Net–based architecture with dual outputs for dense depth prediction and pixel-wise uncertainty estimation. The model is trained on a custom RGB dataset collected on a modified electric go-kart platform, using stereo-derived pseudo-ground-truth depth and synchronized inertial measurements from a CAN-based IMU. Unlike tightly coupled visual–inertial odometry systems that fuse IMU data during the estimation process, our approach maintains modularity by predicting depth independently, with uncertainty intended for integration into downstream back-end fusion modules. This separation allows for more flexible integration into existing system architectures and enables targeted improvements to the perception module. The proposed architecture provides the accurate depth perception needed to overcome key challenges for localization in unstructured off-road environments and provides a foundation for robust depth-aware navigation. Preliminary qualitative results on held-out off-road sequences demonstrate the model's ability to generate consistent depth maps in rough dirt terrains. Future work will focus on incorporating the predicted depth and uncertainty into dense mapping frameworks such as TSDF fusion, with the goal of achieving full integration into an MVS-VIO pipeline for off-road autonomous navigation.

Abstract Name: The Relationship Between Alcohol Use, Dietary Habits, and Academic Productivity in College Students

Alcohol use is a prevalent concern among college students and may influence nutrition and academic engagement. Stress, social pressure, and irregular schedules can increase the disposition to alcohol consumption and contribute to unhealthy lifestyle patterns. Understanding how alcohol consumption relates to nutrient intake and academic functioning is essential for identifying factors that hinder student productivity. This study examined the relationship between alcohol use, dietary habits, and academic productivity among college-aged individuals. It was hypothesized that higher alcohol use is associated with less nutrient-dense diets and reduced academic engagement. A total of 1,409 participants aged 18 to 29, primarily from North and Central America, completed the AUDIT-C, Food Mood Questionnaire, and Academic Performance Scale through an anonymous Google Forms survey. Pearson's Correlation Coefficient in SPSS Version 28.0 was used for statistical analysis. Significant relationships were found between alcohol use and dietary habits. Students who drank alcohol in the past year consumed sugary foods more frequently ($r = 0.063$, $p < 0.05$). Among those who drink, greater alcohol intake was associated with lower consumption of green leafy vegetables ($r = -0.078$, $p < 0.05$), fruits ($r = -0.073$, $p < 0.05$), fish or shellfish ($r = -0.098$, $p < 0.01$), and whole grains ($r = -0.116$, $p < 0.01$). Academic productivity also showed meaningful associations with alcohol use. Higher alcohol consumption was linked to reduced classroom attention ($r = -0.120$, $p < 0.01$), a lower likelihood of initiating long-term projects early ($r = -0.120$, $p < 0.01$), and to engaging in social activities rather than studying ($r = 0.138$, $p < 0.01$). Overall, these findings suggest that frequent alcohol use coincides with poorer nutrition and reduced academic engagement, emphasizing the need for campus strategies promoting healthier eating, reduced alcohol use, and academic motivation. This research has not received any funding.

Abstract Name: EEG Signal Analysis System for Detection of Epileptic Seizure

Electroencephalography (EEG) provides a detailed representation of neural activity and contains physiological indicators—including alpha, beta, theta, and delta rhythms. These rhythms often shift dramatically prior to neurological events such as epileptic seizures. Sudden amplitude jumps, oscillatory abnormalities, and instability across brain regions like FP1 (left frontal pole), FP2 (right frontal pole), C3 (left central cortex), C4 (right central cortex), F7 (left frontal region), and O1 (left occipital cortex) can indicate the early onset of pathological neural behavior. These EEG changes are subtle to the human eye but detectable through computational modeling, making EEG-based epileptic seizure forecasting an essential direction for improving safety and clinical response. This project develops a machine-learning EEG epileptic seizure prediction system using the widely adopted CHB-MIT scalp EEG dataset from IEEE DataPort. The dataset includes multi-channel recordings sampled at 256 Hz from pediatric patients with intractable epilepsy, allowing the model to learn pre-seizure patterns. After preprocessing the signals, the system extracts both statistical and neurophysiological features, such as band-power ratios, spectral entropy, peak-to-peak amplitude variation, and short-time frequency shifts. These features form the input to a learning pipeline combining Support Vector Machines, Random Forests, and XGBoost classifiers. The final seizure probability is determined through majority voting across the models, where probability values approaching 1.0 indicate increased seizure likelihood. An interactive Streamlit dashboard was developed that displays raw EEG traces, extracted features, probability curves, and prediction outcomes. Users can upload EEG clips and receive immediate assessments indicating whether a seizure is likely to occur. The system can reliably demonstrate

strong potential for clinical decision support and early warning tools for individuals with epilepsy. Full details will be presented in the conference.

Abstract Name: Glypican-3 abundance within the microenvironment of Glioblastoma Tumor Cells

Glioblastoma multiforme (GBM) is an aggressive and highly invasive brain tumor with a poor prognosis, known for its rapid growth and resistance to standard treatments. GBM's complex tumor microenvironment further drives disease progression and limits clinical effectiveness. Proteoglycans, major components of the tumor microenvironment, play crucial roles in regulating cell signaling, adhesion, and proliferation. A type of proteoglycan, glypican 3 (GPC-3), is especially important because it shapes growth factor pathways in GBM, making it a promising biomarker and potential therapeutic target. In this study, we learned mammalian cell culture techniques and performed sandwich enzyme-linked immunosorbent assays (ELISA) to detect the level of GPC-3 on the cell surface and in the tumor microenvironment across multiple GBM tumor cell lines. The abundance of particular proteoglycans such as GPC-3 on GBM tumor cells and in its microenvironment will provide more clues on the mechanisms involved in driving GBM tumor progression.

Abstract Name: Assessing the Effects of Race on NFL Head Coaching Tenures

Much commentary and discussion by professional football media pundits has centered around the issue of race in National Football League (NFL) head coach hiring and firing decisions. Motivated by this long-standing public debate and media portrayals suggesting unequal treatment of Black coaches, this study investigated whether measurable disparities existed in the lengths of employment between White and Black NFL head coaches. Prior research has documented the underrepresentation of coaches across many professional sports, including in the NFL. This study aims to contribute to that discussion by providing an empirical analysis of head coach employment data. Data was collected for all Black and White NFL head coaches hired between 1989, the year of the first Black head coach hire in the modern era, and 2024. Active coaches were excluded to ensure complete employment data. A between-subjects ANCOVA test was used to compare employment lengths of Black and White head coaches, controlling for prior NFL head-coaching experience, win-loss records, and team performance before each coach's hiring. Results revealed no statistically significant differences between racial groups in their coaching tenure lengths. These findings suggest that race did not predict head coach longevity in the NFL.

Abstract Name: New Electron-Rich Polycyclic 1,2-BN-Heteroarenes with Phenyl Spacer: Synthesis and Photophysical Properties

Incorporating a B–N bond into polycyclic aromatic hydrocarbons generates planar azaborine scaffolds with unique optoelectronic features, including high photochemical stability, strong absorption, high fluorescence quantum yields, large Stokes shifts, and tunable emission. These attributes make BN-substituted heteroarenes promising candidates for applications such as organic light-emitting diodes (OLEDs) and related optoelectronic devices. However, enhancing electron density and controlling conjugation without compromising stability remain significant challenges. To address this, we designed and synthesized new electron-rich polycyclic 1,2-BN-heteroarenes incorporating strong electron-donating groups, including carbazole and dimethylaminodiphenyl, attached through a phenyl spacer. This design improves conjugation, introduces steric modulation, and enables control over charge-transfer interactions while mitigating aggregation-caused quenching (ACQ) of emission. Using palladium-catalyzed cross-coupling method, we successfully synthesized two target compounds featuring extended π -systems and enhanced donor–acceptor character. We propose that the phenyl spacer and bulky substituents reduce ACQ, improve photophysical stability, and yield tunable optical responses with potential multi-stimuli responsiveness. These structural modifications highlight a versatile strategy for tailoring BN-based heteroarenes. Beyond OLEDs, such multifunctional chromophores hold promise for chemical and biological sensors, adaptive optoelectronic systems, and security applications, expanding the utility of BN-embedded materials in next-generation technologies.

Abstract Name: Investigating Effects of rmTBI on BDNF, PGC-1 α , and ICAM-1 to Evaluate BBB Disruption, Oxidative Stress, and Neuroinflammation in Wild-type Mice

Roughly 10 million people experience a traumatic brain injury (TBI) every year and in the US alone, roughly 5.3 million people live with a TBI related injury. Previous studies have shown that TBIs can induce neuronal death and contribute to neurodegeneration. Repetitive mild traumatic brain injuries (rmTBIs) influence this process because they have also been shown contribute to neurodegenerative disease and cognitive decline, often times leading to cumulative effects and worsening damage. Proteins such as Brain derived neurotrophic Factor (BDNF), peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1 α), and intercellular adhesion molecule 1 (ICAM-1) act as biochemical markers that can be detected in brain tissue to observe neuroinflammation, oxidative stress, and blood-brain barrier (BBB) disruption. BDNF plays an important role in facilitating cell growth and survival and decreased concentrations can be seen in those suffering from neurodegenerative disease. PGC-1 α has been shown to impact mitochondrial functions,

influence mitochondrial biogenesis, reduce oxidative stress, and modulate neuroinflammation in cells. This is important because TBI has been shown to increase oxidative stress, worsening neuronal injury. Neuroinflammation is also a key factor that contributes to neurodegeneration. ICAM-1 helps facilitate cell adhesion, specifically in the context of blood cells in response to inflammation. This process is vital for the BBB to function properly, as variations of ICAM-1 concentrations can impact BBB permeability and have been noted in neurodegenerative disorders such as Parkinson's Disease.

Abstract Name: Exploring the Effects of Pay-for-Performance Contracts in Community Corrections Facilities

In the United States, approximately two-thirds of those released from prison are rearrested within three years. One common approach to reduce recidivism in the US has been the implementation of halfway houses, often administered by contracts with private entities. Using a policy change in Pennsylvania's halfway housing contracts, we study the impact of pay-for-performance contracts resident recidivism rates. Our research adds to the scant literature on the impact of pay-for-performance contracts in the provision of social services. We analyzed administrative data from the Pennsylvania Department of Corrections which allowed us to see the impact of the implementation of pay-for-performance contracts using a difference-in-difference model. Results provided little evidence to suggest that those released from halfway houses impacted by the change in contracting differed in parole violations compared to individuals in a facility without the contracting change. However, there is evidence that facilities impacted by the contract change were less likely to house inmates with drug history. This suggests evidence of "cream-skimming" as drug programs are expensive making rates of recidivism for drug offenders difficult to improve. Overall, evidence suggests that pay-for-performance contracts with halfway house facilities did not reduce rates of recidivism, but led to a potential "cream-skimming" effect.

Abstract Name: The Flower Child vs The War Hero: How Media in the 1960s Divided a Nation

The topic of this paper addresses the legacy of divisive media in the United States during the Vietnam War, and the media's exploitation of conflict between returning veterans and their families against the counterculture movement and the protesters involved. Historians and sociologists, such as Jerry Lembcke in his book *The Spitting Image: Myth, Memory, and the Legacy of Vietnam*, argue that news outlets purposely used inflammatory language and cherry picked stories to push unsubstantiated narratives about counterculture protesters. However, there is still a large debate surrounding certain events that took place during this time. Many people can imagine the stereotype of spat upon veterans and protesters screaming at returning soldiers, but historical reports have failed to confirm the accuracy of these eyewitness accounts. By exploring how protesters and Vietnam veterans were portrayed in the media during the Vietnam War, this paper will argue that news outlets fueled an ideological war at home to discourage citizens from realizing that soldiers were fighting a losing war overseas. It will also argue that protestors and pro-veteran citizens were not as different

as portrayed, and instead both just wanted their friends and family to stop being sent to Vietnam. This study examines newspapers, footage from protests, and historical accounts in texts to convey how media sources' depiction of the counterculture movement in the 1960s is why the average American and those who were involved with these counterculture groups were so heavily divided. This legacy of divisive media has only continued to exploit and misinterpret Americans' differences instead of celebrating them.

Abstract Name: Europeanization or Colonization: Immigration Policies in Albania

This study investigates how Albanian television constructs public narratives about emigration and the refugee situation, situating these representations within the country's broader social and political landscape. Albania continues to grapple with the dual realities of sustained outward migration and the arrival of refugees from regional conflicts, making televised discourse a key arena for negotiating ideas of national identity, belonging, and moral responsibility. Using critical discourse analysis, this study examines a purposive sample of political talk shows, current affairs programs, and news commentary segments broadcast. The analysis focuses on the language, tone, and visual framing used to represent emigrants, asylum seekers, and state policies. Findings reveal that television hosts and commentators often frame emigration as a symptom of national loss and frustration, while refugees are alternately portrayed through humanitarian and securitized lenses. These representations expose underlying tensions between empathy, fear, and national pride. This research highlights how Albanian television both reflects and reinforces public sentiment toward migration. Ultimately, this project contributes to ongoing debates about media responsibility, identity politics, and migration communication in Southeastern Europe, emphasizing how small-state media systems mediate complex global narratives within a localized cultural context. This research also incorporates a comparative analysis of immigration debates in the United States and Albania.

Abstract Name: Blue Dog Bark: "God Talk" and Religious Cues by Centrist Democrats

Despite extensive research on "God talk" among conservative Republicans, the use of religious language by moderate Democratic politicians remains understudied. This gap is particularly significant for members of the Blue Dog Coalition, who represent constituencies with many "split ticket" voters; those who elected Democrats locally while voting Republican in the national election. Previous research has focused on coded religious cues in conservative political communication, primarily relying on media appearances and campaign rhetoric, while largely leaving House floor speeches unexamined. This study analyzes all 2,059 congressional floor speeches offered by the ten current Blue Dog Coalition members from the 116th through the 119th Congresses (2019-2025). It employs comparative content analysis alongside thematic analysis to capture both the frequency of religious language and the contexts in which it appears. Preliminary findings reveal that Blue Dog Democrats explicitly appeal to faith during commemorations of retiring or deceased

constituents and colleagues, as well as when honoring mass casualty events. "God talk" - implicit, coded religious language - was found in references to community stewardship, heritage, and the value of "neighbors" in civic life. Blue Dog Democrats primarily deploy religious rhetoric during moments of change and loss, rather than in policy debates, suggesting a "Blue Dog Bark" focused on the virtue of associational life rather than partisan identity.

Abstract Name: Reproducing Glioblastoma Architecture: A Miniaturized Organotypic Slice Model for Studying Tumor Microenvironment Interactions

Glioblastoma is the most common and aggressive primary brain tumor, marked by rapid growth, invasion, and poor survival of 12–18 months. Many current laboratory models fail to capture the native spatial organization of glioblastoma, including its cellular diversity, extracellular matrix structure, and specialized niches such as vascular and perivascular regions. These limitations restrict their usefulness for studying the tumor microenvironment and for developing effective, patient-specific treatments. To address this gap, we created a rapid and versatile 3D Miniaturized Glioma Organotypic Slices (MiGOS) model using freshly resected human glioblastoma tissue. The goal of MiGOS is to preserve the native architecture and cellular complexity of patient tumors while enabling real-time biological studies and therapeutic testing. Fresh GBM tissue was collected within 30 minutes of surgery, embedded in low-melt agarose, sectioned into 300 μm slices, and punched into 1.5 mm miniaturized tissue units. These were cultured at an air-liquid interface for up to 15 days in serum-free, defined media. MiGOS samples were analyzed by hematoxylin and eosin staining, immunofluorescence, and confocal microscopy to assess overall structure, cellular composition, vascular features, immune cells, and extracellular matrix proteins. We also developed an ex vivo invasion assay by transplanting fluorescently labeled MiGOS onto normal mouse brain slices. MiGOS preserved hallmark features of the original tumor, including cellularity, pleomorphism, necrosis, microvascular proliferation, and extracellular matrix organization. They also maintained perivascular niches and spatial heterogeneity of the tumor microenvironment. The invasion model showed robust tumor cell infiltration into healthy brain tissue within 72 hours. Overall, the MiGOS platform provides a physiologically relevant and rapid preclinical model that maintains native tumor structure and supports studies of tumor biology, cell interactions, invasion, and therapeutic response, offering strong potential for advancing personalized glioblastoma research.

Abstract Name: Synthetically Available Vittatalactone Analogues for Improvement of Pheromone-Based Control for *Acalymma vittatum* (Striped Cucumber Beetle) and Other Cucurbit Pests

Current methods of biological control for *Acalymma vittatum* (striped cucumber beetle) in the United States are limited to pesticides that bring up significant environmental and health concerns. Adult beetles lay eggs and overwinter alongside them—a single infestation requiring long-term attention. The use of traps offers an ecological alternative, in which lures attract these invasive beetles to draw them away from possible host plants. *A. vittatum* prefer to feed on the Cucurbitaceae family, including squash, zucchini, and other agriculturally important crops. Vittatalactone is an aggregation pheromone released by male *A. vittatum* when actively feeding. Previous studies identify this compound as an efficient lure for cucurbit pests, but synthesis methods are difficult due to the many chiral centres on the aliphatic chain. We hypothesize that the rigid β -lactone core of vittatalactone is essential for molecular recognition, mediating specific hydrogen bonds with the insect receptor that demand precise spatial arrangement. In contrast, the sidechain, which mediates hydrophobic interactions with the receptor, is expected to be more permissive of structural variation because hydrophobic interactions rely primarily on surface complementarity and desolvation rather than strict geometric constraints. As such, we are synthesizing vittatalactone analogues with simplified sidechains. With aldehyde and imide starting material, we optimized an initial aldol addition reaction for the purpose of maintaining sufficient yield. The addition product then undergoes cleavage and cyclization to mimic the vittatalactone headgroup while keeping the hydrocarbon chain achiral. Structurally simplified analogs of vittatalactone are expected to facilitate the development of new pheromone-based behavioral control strategies for *A. vittatum* and other cucurbit pests. This presentation will outline the synthesis of the promising vittatalactone analogues and their further analyses of stability and volatility, laying out the groundwork for subsequent behavioral assays aimed at identifying compounds with the most promising bioactivity.

Abstract Name: Mentoring Research Writing Success: Cross-Campus Collaborations in Student Research and Campus Writing Centers

Collaborations between campus research institutions and writing centers can be a fruitful means by which undergraduate researchers develop their research writing skills beyond a relationship with their research mentor. Writing centers are sometimes pigeonholed as a remedial resource for student essays or grammar and punctuation help, which undervalues the depth of research writing expertise offered by peer mentorship. We present a model for collaboration between undergraduate research offices and programs and university writing centers at multiple stages of the research development process. The Undergraduate Research Institute at Embry-Riddle Aeronautical University, Prescott requires student researchers to acquire feedback from peer writing center tutors on their research proposal prior to the initial funding request submission each semester. The writing center and Undergraduate Research Institute also host a poster design session in the lead up to the campus research showcase to provide student researchers with visual design and writing feedback before submitting finalized posters for approval. The writing center director will describe the administrative set up and coordination for these interactions, the benefits to both the campus writing center and the undergraduate research offices and programs and some of the unique constraints and opportunities offered by the quirks of a small STEM university. An experienced undergraduate peer tutor from the writing center will describe these peer mentoring interactions and how they differ from the conversations about research writing that often happen between student researchers and mentors. Through these collaborations, student researchers gain clarity on their research design process, outside perspective on how best to communicate their research to others, and feedback from peer writing tutors that can benefit the student researcher and mentor relationships. We will provide a framework and possible avenues for developing similar peer tutor collaborations at other institutions.

Abstract Name: Targeting TDP-43 Aggregation with Novel Small RNA Chaperones Using the FIT System

Protein aggregation of TAR DNA-binding protein 43 (TDP-43) is a hallmark in many neurodegenerative diseases, particularly in Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal Dementia (FTD). Recent findings have proven that short RNA chaperones consisting of 34 nucleotides are able to bind to TDP-43 to prevent aggregation. To enhance the therapeutic potential of these RNA chaperones, my project is focused on finding reduced-size RNAs consisting of only 20 nucleotides that prevent TDP-43 aggregation in both wild-type and disease-associated mutant variants. To identify potentially potent 20-nucleotide RNAs, 105 randomized RNA sequences were screened using a feedback inhibition of translation (FIT) system in yeast, yielding promising candidates. To validate the most promising RNA candidates, RNA-1, RNA-K, and RNA-Q, the RNAs were then cloned into the yeast FIT system and assessed using yeast viability spotting tests. Secondly, in vitro TDP-43 aggregation assays were performed against wild-type, Q331K, and K181E variants to test the candidate RNAs at various concentrations. Preliminary tests show that small RNA-1, RNA-K, and RNA-Q prevent TDP-43 aggregation at 5 μ M concentrations and delay aggregation at 1.25 μ M concentrations. Additionally, yeast spotting assays suggest that RNA-1 and RNA Q inhibit toxic wild-type TDP-43 aggregation. Our findings suggest that 20-nucleotide RNAs may be a viable therapeutic approach for treating TDP-43 proteinopathy. Furthermore, future directions include concentration gradient tests to determine 50% inhibitory concentration (IC-50) values, as well as testing in human cells.

Abstract Name: Expanding Cultural Heritage Digital Curation and Dissemination Using Kintsugi 3D Viewer

Kintsugi 3D is a software platform that uses a photographic technique called photogrammetry to create 3D models of cultural heritage objects. Kintsugi 3D includes two software applications: Kintsugi 3D Builder and Kintsugi 3D Viewer. Viewer is intended to be a free, open-source software directly targeted to cultural heritage institutions and their needs for disseminating models and intended to be an alternative to SketchFab, a popular web-based 3D model viewing website. The goal of this research was to implement an improved workflow experience to ease the transition between building and refining models in other software and then setting up models to be viewed by the public in Viewer. The solution we've created is to have a desktop version of Viewer act as a configuration menu, providing tools to prepare model data to be sent to a server, which the web version of Viewer will be able to read to create a curated viewing experience for the public. This research is supported by multiple cultural heritage institutions including the Minneapolis Institute of Art (MIA), Cultural Heritage Imaging (CHI), and the National Gallery of Art (NGA). I worked closely with individuals responsible for digital imaging and preservation of items at their respective institutions, this

application's primary users, to find solutions to their wants, needs, and pain points through regular meetings and user testing. When discussing needs with stakeholders, we found that top priorities included model viewing configurations such as camera constraints, environment selection, artifact placement, and lighting settings. These settings are essential, allowing models to be viewed in intentional and culturally appropriate ways over a generic western gallery display. Other tasks related to the functionality of this workflow include developing a local save system with read/write functionality to allow for seamless use between different instances of the application on different machines.

Abstract Name: One Candidate, Under God? How Gender, Partisanship, and Religiosity Shape Voting Behavior

This study investigates how intersecting identity traits—gender, partisanship, and religiosity—shape political impression formation among American voters. While existing research typically examines dyadic interactions (e.g., gender $\times$ partisanship), few studies explore how multiple identity dimensions jointly influence voter evaluations. Given the increasing conceptualization of partisanship as a social identity, it is essential to consider how demographic traits interact to produce intersectional effects on candidate perception (see, e.g., Gershon & Lavariega Monforti, 2019). This inquiry is especially timely amid rising support among some voter segments for traditional gender roles and recent upticks in Christian identification (e.g., Smith, et al. 2025). Using a nationally representative sample, I will conduct a survey experiment in which participants evaluate political candidates described in vignettes that systematically vary gender, party affiliation, and religious identity, all while holding policy positions constant (e.g., support for quality schools and a strong economy). This design enables a rigorous test of hypotheses concerning the interactive effects of identity cues on impression formation, offering new insights into the psychological underpinnings of voter decision-making in contemporary political life.

Abstract Name: 3D Corneal Phantoms: An Accessible Simulation for Penetrating Keratoplasties

The rising cost and limited availability of surgical training models for ophthalmology have restricted access to critical education in corneal transplantation techniques. Traditional training relies on cadaveric tissue, animal eyes, or commercial kits, all of which present ethical, logistical, and financial barriers. This study presents a novel, affordable, and globally accessible corneal model designed to simulate penetrating keratoplasties (PK). Using modified bio-inks composed of sodium alginate and pectin, combined with 3D-printed molds, we developed a corneal phantom. This phantom is part of a greater PK Simulation kit costing approximately \$11 per unit. The model, and greater kit, eliminates reliance on animal products, cadaver tissue, improves inclusivity in surgical education, and expands accessibility for students worldwide, particularly in low-resource geographic locations. The novel bio-ink that is the basis of these corneal phantom

demonstrated suitability as a tool for surgical training and for wider applications in corneal transplant research. This innovation provides a scalable path toward democratizing ophthalmic surgical education while potentially improving patient outcomes in regions with high burdens of corneal disease.

Abstract Name: Analyzing the Effects of Vaccination and Sanitation on the Viral Spread of Hepatitis B

SIR Models (Susceptible, Infected, and Recovered) are popular epidemic models that are used to better explain disease spread in specific populations. While previous research has focused on disease transmission and even the rate of spread with vaccination, there is a lack of studies that consider the effects of proper sanitation measures on reducing the spread of Hepatitis B. My research aims to mathematically show the effects of sanitation and argue for its funding in certain sub-Saharan African countries, specifically Nigeria, that would greatly benefit from these preventative measures. I recognize that vaccines are extremely expensive to create, manufacture, and distribute and understand that low-income countries rarely receive an adequate amount of doses to effectively handle an epidemic. Therefore, this model is important not only to understand the spread of Hepatitis B in sub-Saharan countries but also to emphasize the implementation of lower-cost sanitation strategies to mitigate the effects of the disease while waiting for vaccines. Through a series of math models in Maple, I studied the general equilibrium and stability of the disease-free and endemic state under four conditions: (1) No Vaccination or Sanitation, (2) Vaccination, (3) Effective Sanitation, and (4) Vaccination and Sanitation. In evaluating each of these conditions in the disease-free state where there are no infections and the endemic state where there are a certain number of existing cases, the combination of effective sanitation in hospitals and current vaccination success leads to Hepatitis B in Nigeria becoming stable in the disease-free state.

Abstract Name: A Deep dive into surface chemistry and binding dynamics in biosensor stack formation

In order to create highly efficient biosensors with high stability and sensitivity, it is important to characterize and optimize the binding interactions between the sensor surfaces, crosslinkers, and antibodies, as well as the binding interactions between the sensor surface and aptamers, especially in the field of biosensors. This research study takes a deep dive into the concepts of surface functionalization and characterizations of antibody binding to the crosslinker (3,3'-dithiobis(sulfosuccinimidyl propionate) also known as DTSSP, which will bind to the surface of the sensor. Many characterization techniques were used to understand the different aspects of surface chemistry and the efficiency of binding. Fourier Transformation Infrared Spectroscopy (FTIR) was used to directly confirm the creation of thiol and amide linkages between the antibody and crosslinkers, which shows the high binding efficiencies. Zeta Potential (Zeta) measurements provided insight into each surface charge modulation, which demonstrated the charge stabilization of binding

interactions, and the hydrodynamic size informed about the change in size upon binding. Cyclic Voltammetry (CV) and Electrochemical Impedance Spectroscopy (EIS) showed us the changes in the charge transfer resistance and double-layer capacitance, which show the biomolecular binding and the degree of crosslinker and the antibody coverage over the surface of the sensor. By using all these different methods, we are able to establish an extensive, multifaceted approach towards characterizing and optimizing biosensor surfaces, making it easier to create a noninvasive health monitoring program that uses sweat in real-time, which will help with disease diagnosis in future biosensor applications.

Abstract Name: Bulletproofing the Heart: Investigating GLP-1 Pathway-Mediated Protection Against Alcohol-Related Cardiomyocyte Injuries

Alcoholic cardiomyopathy (ACM) is a chronic, progressive form of cardiac dysfunction driven by long-term alcohol exposure and associated cellular damage. Despite its prevalence, there are currently no therapies that directly protect cardiomyocytes from alcohol-related injury. Semaglutide, a GLP-1 receptor agonist with known metabolic and cardiovascular benefits, has been suggested to enhance nitric oxide signaling and promote protective intracellular pathways; however, its potential role in reducing cardiomyocyte injury in ACM is not well understood. In this project, AC16 human ventricular cardiomyocytes were exposed to alcohol-related stress and examined in the presence or absence of semaglutide to evaluate whether semaglutide could mitigate cell damage. Initial experiments were conducted using ethanol as the injury source, and cell viability was measured using an MTS-based assay, while changes in apoptosis and fibrosis markers were assessed through immunohistochemistry and Western blotting. These early results showed only minimal reductions in viability and limited activation of apoptosis pathways following ethanol exposure, making it difficult to assess the protective effects of semaglutide. Based on these findings, the experimental model has been refined to use acetaldehyde, a more reactive and physiologically relevant metabolite of ethanol known to induce stronger cellular stress responses. The ongoing phase of the study will evaluate whether acetaldehyde produces clearer injury phenotypes and whether semaglutide can meaningfully reduce this damage. Through this work, we aim to clarify the potential of semaglutide as a protective agent in ACM and contribute to the development of therapies that directly address cardiomyocyte loss in alcohol-related heart disease.

Abstract Name: Nostalgia Marketing: Using Disney's Model to Revitalize Nickelodeon Subscriptions and Revenue on Paramount+

The role of nostalgia marketing on consumer behavior has been a growing topic of discussion within the field of marketing. Peer-reviewed studies discussing nostalgia marketing's effect on Purchase Intention, Ad-attitude, Brand attitude, Brand Loyalty, and Self-Continuity, worldwide, were examined and analyzed to determine the effects of nostalgia and nostalgia marketing on a consumer. A comprehensive literature review

was conducted to determine how the use of nostalgia marketing by childhood brands in the US is, their differences between marketing styles, and the levels of success that have been found with each style. Instagram posts from Disney, Disney+, Nickelodeon, and Paramount+ were analyzed to ascertain the differences between nostalgic and non-nostalgic advertising. The findings suggest that the application of nostalgia marketing on Instagram may have positive effects on generating revenue through subscription growth stemming from interactions on the platform's posts. This paper aims to discuss how the use of nostalgia marketing from childhood brands such as Disney can promote the utilization of their model of marketing to generate revenue for similar brands like Nickelodeon and Paramount+. More research focusing on how much of the nostalgic content encompasses the revenue generated from the streaming platforms should be conducted.

Abstract Name: Impact of ALCAM Impairment on Mitochondrial Function in Idiopathic Pulmonary Fibrosis

Idiopathic Pulmonary Fibrosis (IPF) is a chronic and irreversible disease that causes scar tissue formation in the lungs and changes their architecture, thereby restricting movement necessary for respiration. IPF primarily limits the function of Alveolar Type II Epithelial (ATII) cells, which enable alveolar regeneration and produce the surfactant protein needed for lung tissue to glide against itself during breathing. Those diagnosed with IPF have a prognosis of 3-5 years. The cause of the disease remains unknown. The Activated Leukocyte Cell Adhesion Molecule (ALCAM), which is a membrane protein that plays a protective role in cell adhesion, is downregulated in IPF. Similarly, mitochondrial function, including biogenesis and mitophagy, is also downregulated, meaning that the removal and replacement of damaged mitochondria is reduced. Altogether, this means that ATP production is lowered and reactive oxygen species (ROS) increases, leading to oxidative stress, DNA damage, and cell death. We were interested in exploring a potential relationship between mitochondrial dysfunction and ALCAM impairment in IPF. We hypothesized that ALCAM impairment impacts antioxidants, inflammatory proteins, and DNA repair proteins, which leads to mitochondrial dysfunction, ATII cell injury, and IPF development. To test this, we used human lung tissue, including IPF tissue from transplant patients and healthy tissue from post-mortem organ donation. We also looked at ALCAM knockout in A549 cells, which are a model for ATII cells. We found that some antioxidants and products of ROS are significantly upregulated in IPF and that, unexpectedly, markers of DNA damage and repair are downregulated, which we suspect is to combat the ROS increase. We concluded that cells are likely trying to rescue ROS balance, or redox homeostasis. In the future, we hope to directly analyze ROS levels in ALCAM knockout cells and definitively link IPF to ALCAM to determine if antioxidants can be a therapeutic target.

Abstract Name: Behavioral Complexity in Joint Territorial Defense of a Tropical Understory Bird

Many species use vocalizations to distinguish between familiar territorial neighbors and unfamiliar strangers, a phenomenon known as neighbor-stranger discrimination. The Chestnut-backed Antbird (*Poliocrania exsul*, CBAN), a tropical understory bird, vocalizes in response to territorial intrusions, yet it is unclear whether males and females differ in their territorial responses. This study aimed to provide insights into the behavioral ecology of CBAN to determine whether CBAN portrays neighbor-stranger discrimination in joint territory defense and whether responses are influenced by sex. I tested two hypotheses describing potential territorial responses: the “dear enemy” hypothesis (stronger reaction to strangers versus neighbors) and the “nasty neighbor” hypothesis (stronger reaction to neighbors versus strangers). To test these hypotheses, I conducted 56 playback trials of different intruding neighbor, stranger, and sex combinations in Soberanía National Park in Panama in summer 2025. I found that CBAN display neighbor-stranger discrimination, supporting the “dear enemy” hypothesis. CBAN pairs duet more to any stranger intrusion, regardless of sex. The sex of the intruder and the territorial bird plays a role: females approach intruders faster and closer than males. This research provides a deeper understanding of communication networks, challenging the assumption that females are passive followers of males in joint territorial defense. Future studies should consider the complexity of pair responses in year-round joint territory defense strategies.

Abstract Name: Tumor Control after Gamma Knife Radiosurgery for Meningiomas

Meningiomas account for approximately 36% of all primary brain tumors. Leksell Gamma Knife provides an effective treatment for patients with intracranial meningiomas by targeting tumors and minimizing peripheral cell damage. We evaluate the connection between radiologic dosing and post-surgery outcomes. We reviewed outcomes of 56 patients (41 female, 73.2%) who underwent stereotactic radiosurgery (SRS) treatment from 2022-2024. Median age of patients was 68 years (32-85 years). Median follow-up time was 16.4 months (0-40 months). Median WHO grade was 1 (range 1-3), Ki-67 was 7% (range 2-46%). The median Karnofsky Performance Score (KPS) score before SRS was 80 (range 60-90). Presenting symptoms included headaches (22 patients, 39.3%), seizure (11 patients, 19.6%), gait dysfunction (17 patients, 30.4%), motor deficits (2 patients, 3.6%), sensory dysfunction (32 patients, 57.1%), and cranial nerve palsies (5 patients, 8.9%). Thirty-one (55.4%) patients underwent pre-SRS surgical resection. Median prescribed margin dose was 13 Gy (range: 11-40). The median cumulative tumor volume was 1.75 cc (range: 0.02-13.35) while the median 12Gy volume was 2.96 cc (range: 0.04-31.0 cc). Overall, 8 patients (14.3%) experienced local tumor progression at their last follow-up with the median timespan between SRS and local tumor progression of 14 months (range: 5-44). None of the patients had any distant tumor progression. Three patients (5.5%) required repeat-SRS treatment due to local tumor progression. Adverse radiation effects (ARE) were seen in 1 patient (1.8%) as an edema, which was treated with surgery and steroids. Three patients (7.1%) had improved neurological function, and 9 patients (92.9%) had no change in neurological function. Median KPS at last follow up was 80 (range: 50-100). Overall, SRS demonstrated favorable outcomes with low associated morbidity, low rate of progression, and minimal toxicity, suggesting that current dosing strategies remain effective and well-tolerated in meningioma management.

Abstract Name: The Reality of the Reality: Dating Shows on Dating Experience

This research focuses on the question of: How do dating shows influence their viewers' dating expectations and dating actions? This includes seeing what people believe the social norms of dating are, as well as communication styles and social scripts used in a romantic setting. The research area of this project is Television Production and the importance of how television production decisions have a social influence on audiences. The theoretical framework of the research is based on the idea of Social Scripting and Social Cognitive Theory. The methodology behind the research was a qualitative Google Form Survey with over 20 responses. The survey asked a multitude of questions, such as asking the participants for their dating background and television watching habits, as well as asking the participants social and behavioral questions. The results found that there were no major/conscious influences that reality dating television shows have on their audiences. Still, there is some correlation between social scripting and how watching reality dating shows is then reflected on a person's dating experiences and behaviors. In addition, if not for guiding scripts and expectations, reality dating shows instill some type of confidence and self-worth in their viewers. Limitations of this research include a lack of exploration on the effects of gender identity and gender roles in dating, the survey was only attained via the researchers' socials (which made the results not generalizable), and there was not enough time to perform a study of super-fans via social media (for example, Reddit and X).

Abstract Name: Effects of Light Pollution on the Activity of Bat Populations within the Schlitz Audubon Nature Center

Bat populations have been in rapid decline in recent years, with 4 out of the 8 native bat populations in Wisconsin listed as endangered. There are many reasons for this decline, but despite the findings on light pollution in other species, including humans, there is very little data on the effects of light pollution on different species of bats. Within the bounds of the Schlitz Audubon Nature Center, the parking lot's lights serve as direct light pollution. From June 1st to July 31st, 2025, 4 different areas within the grounds were surveyed using Audiomoth bioacoustic recorders, all at variable distances from the parking lot lights. Data collected during the summer was analyzed and coded depending on whether the lights were on, off, or if there was a wedding, into the averages for each area. Each Audiomoth bioacoustic recorder filters and converts noise to a spectrogram in order to look at the frequency and duration of each echolocation call. This data can then be used to determine which species of bat made the call. The data also shows how many pulses per instance, which is used to get the average of how active the bats were during each randomly selected lighting setting. With the data collected, there is already an emerging trend that the most bat activity is on nights with lights off, while nights with weddings on the grounds had the least bat activity. Moving forward, further analysis will be done into the presence of certain species of bats and their frequency, as well as how distance from the light affects each area's bat sightings.

Abstract Name: An Empirical Study of Waste Generation and Disposal at NMU

This study examines patterns of waste generation and disposal across Northern Michigan University's (NMU) campus to evaluate the effectiveness of current sustainability efforts and identify areas for improvement. The project involved conducting weekly waste audits over 1.5 months at 13 key academic and residential sites, covering 20 dumpsters. Each audit consisted of collecting the full contents of selected dumpsters, sorting the materials on a tarp, and categorizing them into food waste, recyclables, compostables, e-waste, and general waste. The sorted data were recorded and analyzed to assess recycling accuracy and determine the volume of recoverable materials being sent to landfills. The results revealed widespread contamination in recycling bins, along with a significant amount of compostable and recyclable materials misclassified as general waste. Food waste was particularly prevalent in residential areas, highlighting the need for improved composting infrastructure and enhanced education on proper waste separation among students. These findings highlight the importance of integrating sustainability practices into NMU's daily operations and student culture. By comparing academic and residential waste streams, the project offers valuable insight into campus waste behaviors and identifies opportunities to expand recycling and composting programs. Ultimately, this research supports NMU's broader goals of reducing landfill dependency and promoting environmental stewardship within the university community.

Abstract Name: Analyzing Impactful Methods of Supporting Migrant and Refugee Integration in Mexico City, Mexico

In Mexico City (CDMX), migrants and refugees experience disadvantages and discrimination in the process of resettlement, particularly in labor and social integration. The integration of these groups has been highly studied in the United States and Canada, however, this issue remains understudied in Latin America, specifically in Mexico, where the focus has been on migrants in transit. To investigate this issue, I conducted a qualitative case study on Programa Casa Refugiados (PCR), a non-profit migrant and refugee support organization in Mexico City. Over the course of my three month internship with PCR, I conducted six semi-structured interviews with employees and clients of PCR. The interview questions focused on the functions of the organization, and the perceptions and experiences of participants relating to Programa Casa Refugiados. Participant observation was conducted at two PCR offices, the CeahPaz shelter, and several PCR events. Critical race theory informed both the interview questions and the analysis of my observations. My investigation finds that Programa Casa Refugiados offers a holistic approach to migrant and refugee integration that values the unique experiences, skills, and needs of clients. The findings demonstrate the importance of the workplace environment in employee productivity, performance, and satisfaction. This research fills a gap in the current scholarly literature by revealing the strategies employed by Programa Casa Refugiados that are effective in addressing the social and economic challenges faced by migrants and refugees in CDMX. Finally, the findings identify the challenges facing PCR and the methods they have

developed to withstand these pressures and strengthen their services. These findings offer valuable insight for other non-profit organizations in the Americas with similar goals and financial restrictions. The implementation of PCR strategies could be beneficial for these organizations and strengthen migrant and refugee support systems throughout the Americas.

Abstract Name: Labor Supply Behavior: A Study on the Role of Culture

In this paper, we study the role of peoples' attitudes on their labor market behavior. Focusing within a household, we estimate how one's labor market decisions are dependent on their partner's labor market outcomes, and how these decisions are driven by their culture component. Historically, man has been associated as the primary earner in a family. We argue that culture might play a role in determining a person's labor market outcomes as it induces an aversion to the situation of when the wife earns more than the husband. We find that husbands increase their participation as well as hours worked in the labor market if their wives earn more and this effect is even more prominent if they are from a country where people have the traditional view that man should be the primary bread-winner for the family. However, wives do not exhibit any such behavior. We argue that this irregularity is explained by the role that culture plays on forming labor market decisions. This result is important as it might contribute to the explanation of the slowdown in the convergence of the gender gap in the recent past.

Abstract Name: Language Learning in Childhood: Impacts on Brain Development and Academic Success

This research continues my previous work from Fall 2025 and deepens the understanding of why learning a second language in childhood is so important. Learning another language in early childhood is recognized as a powerful tool that enhances both cognitive and social development. This study explores the benefits of early second language acquisition through findings in neuroscience, education, and psychology. Children who grow up in bilingual or multilingual environments show greater cognitive flexibility, stronger memory, and improved problem-solving skills. They also demonstrate higher academic performance and increased success in areas such as music. Beyond cognitive and academic advantages, children who learn another language gain exposure to cultural diversity and develop stronger cultural awareness. In a world where diversity remains a pressing issue, language learning offers children meaningful tools for understanding and engaging with the environment around them. Despite these advantages, access to second-language instruction remains limited, especially in underserved regions. This research identifies practical steps that expand opportunities for language learning. The study focuses on three key factors: how the brain receives and retains language depending on developmental stage; the current benefits of learning a language in childhood; and ways parents

can use available resources to support language learning at home. Although the emphasis centers on childhood, the research also explains that it is never too late to learn another language. Studies, including those involving individuals with dementia, show that bilingualism helps slow cognitive decline associated with Alzheimer's and related conditions. Overall, this research affirms that early language learning provides meaningful developmental, academic, and social benefits in a multilingual world.

Abstract Name: Evaluating Sense of Purpose as a Protective Factor in the Link Between Sleep Disturbance and Depressive Symptoms

Sleep disturbances are correlated with various outcomes, such as an increased risk for depression. However, few studies have focused on understanding how this risk can be minimized. According to the Stress-Buffering Model, the effects of negative stressors can be reduced with coping mechanisms known as buffers. One understudied buffer is the sense of purpose, which supports psychological resiliency. When navigating sleep concerns, a sense of purpose could reduce stress reactivity and promote emotional regulation, which could buffer the effects of poor sleep on depressive symptoms. The goal of this study is to assess whether sense of purpose functions as a protective factor when analyzing the association between sleep outcomes and depressive symptoms. Participants will be recruited from Project 2 of the Midlife in the United States (MIDUS) study, which includes a nationally representative American population aged 34 to 84 (N = 3,487). Using moderated hierarchical regression analyses, we will evaluate if the association between sleep and depressive symptoms varies as a function of purpose in life. Sleep will be operationalized as the PSQI (Model 1) or sleep onset latency (SOL), wake after sleep onset (WASO), total sleep time (TST), and sleep efficiency (SE) from sleep diaries (Model 2) and actigraphy (Model 3), and these will serve as primary predictors of depressive symptoms. Depressive symptoms will be studied through a questionnaire measuring depressive affect with Purpose in Life being introduced as a moderator of this relationship. By demonstrating that purpose in life can moderate sleep and depression, the findings could strengthen theoretical frameworks that emphasize psychological resilience. Because purpose in life is a modifiable factor, these findings could offer a meaningful target for prevention and intervention efforts. Future research can test purpose building interventions as a tool to reduce depressive symptoms among individuals with sleep disturbances.

Abstract Name: Mitigating Bias in Heart Disease Prediction Models Using Machine Learning on IBM Watson Platform

Heart disease is a top cause of death globally, but traditionally has been underdiagnosed in marginalized populations due to clinical bias in prediction models. This study is based on the hypothesis that machine learning models trained on clinical heart disease datasets may reflect demographic biases, particularly across sex and age. IBM Watson was used to select an ML algorithm, and Google Colab was used to perform subgroup fairness analyses. The dataset was a consolidated heart disease dataset from the Cleveland and Hungarian heart disease records. It contains 1,190 instances and 12 different demographic and clinical features. The target parameter was the presence or absence of heart disease in the patient. IBM Watson determined Logistic Regression as the top model (87.2% in Watson, 83.8% in Colab). Subgroup analyses showed accuracy differences (female 91.5% versus male 81.5%; <55 years 83.8% versus ≥55 years 83.7%), but selection rates differed. Males were classified as having heart disease more frequently at 61.5% versus females at 22%, and older patients at 72.7% versus younger patients at 33.5%. In the data, male participation was about ~76.4%, whereas the corresponding participation of women was about ~23.6%. Similarly, the population 55 and older was ~49.24% as compared to the younger population ~50.76%. These disparities reflect both underlying dataset imbalances and the model's difficulty accounting for sex-based differences in clinical presentation. To address this bias, efforts are being made to mitigate bias using sample reweighting, which is a bias-mitigation technique that increases the influence of underrepresented demographic groups during model training. This approach is being evaluated for its potential to reduce subgroup prediction disparities while preserving overall diagnostic performance. The preliminary results are meaningful and will be presented with full details in the conference.

Abstract Name: Building Generative AI Applications - GANs, RAG and Agents

This project integrates three distinct generative AI applications into CSC 590 to provide undergraduate data science students with practical, real-world development experience. We deployed a Generative Adversarial Network (GAN), a Retrieval-Augmented Generation (RAG) system, and an agentic AI application via a JupyterHub-based science gateway on Jetstream 2. The instructor pre-developed each application and made them accessible as individual web links within the JupyterHub environment, allowing students to access the applications through their web browser without requiring SSH, tunneling, or direct JupyterLab access. Through instructor-guided tutorials, students explore the development process and underlying architecture of each application, gaining hands-on experience in building generative AI systems while developing industry-relevant skills. This pedagogical framework prepares undergraduate students for AI careers through accessible, cloud-based learning environments that lower technical barriers to entry.

Abstract Name: Suicide Prevention: Understanding the Factors that Influence Intervention

In 2023, 1.5 million Americans attempted suicide (CDC, 2025). Studies have investigated how personality and situational variables interact to impact bystander intervention in emergency situations. However, these factors are often studied in isolation or within contexts that are not directly applicable to the domain of suicidality. The purpose of this research is to examine how one's personality perception of a person disclosing suicidal ideations as well as their relationship with that person interact with situational factors such as group size to predict likelihood of intervention. Approximately 300 undergraduate students are participating in in-person laboratory sessions (175 students have completed the study thus far). A 2 (Number of Bystanders: Self Only vs. Group) x 2 (Relationship to Person Expressing Suicidal Ideation: Friend vs. Stranger) x 2 (Extraversion of Person Expressing Suicidal Ideation: Low vs. High) between-subjects design is being used with likelihood of intervention as the dependent variable. Participants first complete measures of empathy (Davis, 1996) and personality (Soto & John, 2017). Then, participants read a vignette about a character who is described as an introverted or extraverted friend or stranger who expresses suicidal ideation when they are alone or with a group. Next, participants complete a measure of likelihood to intervene (Aldrich & Cerel, 2024) and three manipulation check questions. I will conduct a between-subjects factorial ANOVA with likelihood of intervention as the dependent variable and extraversion of person expressing suicidal ideation, relationship to person expressing suicidal ideation, and number of bystanders entered as independent variables. I expect an interaction to emerge such that likelihood of intervention is highest when the person expressing suicidal ideation is described as a friend low in extraversion disclosing to the participant only. This research will give insight into interactions between factors that influence suicide intervention and guide subsequent research on facilitating intervention.

Abstract Name: Characterizing Meteorites with Atomic Force Microscopy

Atomic force microscopy (AFM) is a technique that can be used to analyze different properties of the surface of a sample (e.g., topographical, magnetic, chemical, electrical, optical and mechanical properties) through accurate and non-destructive measurements with very high resolution at the nano- and micro-scales. In particular, it can be used to characterize carbonaceous chondritic meteorites, which are mainly composed of micro/millimeter sized inclusions, surrounded by a matrix of microparticles, that date from around the time of the formation of our solar system. The study of the physical properties of these relics by carrying out AFM experiments can help to understand how planets formed since they can give evidence of the conditions (e.g., thermal, temporal and barometric) in which the materials found in the meteoritic samples developed in our solar system. In this work, we use an AFM system in contact mode to characterize carbonaceous chondritic meteorites (e.g., Northwest Africa, NWA, 6603) in different regions of the sample (inclusions, matrix and inclusion-matrix interface) at the nano- and micro-scales. From our measurements, we observed that these regions present distinctive physical characteristics. For instance, considering the topography of NWA 6603, the matrix reveals a relatively homogenous distribution of circular/elliptical-shaped particles of 0.5-1 micrometers in diameter, while the inclusions exhibit more irregular structures. In addition, the AFM findings are correlated with the results obtained with other experimental techniques (e.g., optical microscopy and Raman spectroscopy) applied to the same regions to look for signatures of the physical processes that drove the formation of these meteorites.

Abstract Name: Playing with Mystery: Understanding Catalan Identity Through Medieval Performance

Within medieval European society existed a world surrounded by the inexplicable and mysterious. To unite people, language, and traditions, medieval societies practiced the Christian religion within the realm of the outside world, incorporating the tangible in the intangible and creating a presence in absence. Many took part in processions and in cyclic dramatic reenactments of biblical scenes, called Mystery plays. While a universal catholic practice in Europe, even if the “scripts” had the same content—starting from the creation of the universe and ending in the final judgement—each society depicted the events distinctly. This project analyzes the “Misteris” (or Mystery plays) and other performances that took place in medieval Catalonia, when the region was independent of Spain. My focus is not solely on the performances themselves, but on their effect in creating Catalan communities. The project analyzes the impact of performances recited in Catalan and performed in the open streets as a socio-political motive. It studies the aspect of drama, or play, as medieval folk would perceive it, before theatre etiquette, with open space to ad lib, as a device to explain the divine. To better embody how the Catalan people would have felt, the paper stresses medieval scholar Lauren Mancia’s methodology of reperformance to understand a time when so little was documented. The project expands on these Mystery plays as well as other performances, like the Dansa de la Mort (Dance of Death), as something inherently Catalan, as mentioned in the notable works of scholars Francisc Massip and Lenke Kovács, and demonstrates that this remains embedded in traditions that persist and comprise part of modern Catalan identity. Alongside studying archives in Catalonia, it captures my personal experience in the fall of 2025 in the ecclesiastical and urban spaces where these performances took place, and where some still do.

Abstract Name: The Hidden Cost of Helping Others: Understanding Compassion Fatigue, Burnout, and Paths to Prevention

Compassion fatigue and burnout are present in a variety of different careers, but they're especially prevalent in helping professions. Helping professions include, but are not limited to nursing, social work, teaching, and child life specialists. Although these careers can be rewarding, they can often cause negative psychological, physical and emotional impacts to one's life. The specialized knowledge and advanced skills that are needed in these fields are often emphasized, but the emotional aspects are equally crucial to these careers. These professions require a set of personal values and qualities along with a deep desire to devote their lives to helping others. A few of these needed individual characteristics include empathy, patience, and resilience, but the persistent compassion that is shown by these helping professionals is a factor associated with the increased fatigue and burnout. For example, research has shown that on average 68% of nurses experience burnout, which is considered part of compassion fatigue. Recognizing the widespread presence of these harmful effects- such as depression, anger, sadness, negative relationships- that result from the continuous act of helping others, contributing factors and evidence-based strategies to mitigate this issue, have been explored by researchers. This presentation provides an in-depth examination of the concept of compassion fatigue, specifically burnout, in helping professions, and how the underlying cause is rooted in the demands of their professional responsibilities. Attendees will gain a better understanding of this complex and abstract concept, and they will learn about several promising studies that highlight effective strategies for reducing both compassion fatigue and burnout. It will provide pre-service and in-service professionals in these related fields with key knowledge that should assist in mitigating these issues in their practice.

Abstract Name: Stability of Neuron-Derived Extracellular Vesicle microRNAs in Adolescents and Young Adults

Neuron-derived extracellular vesicles (nEVs) enriched using L1CAM antibodies provide a minimally invasive approach to measure microRNAs (miRNAs) originating from the central nervous system (CNS). Although nEV miRNAs are increasingly studied as candidate biomarkers, their stability across individuals has not been systematically characterized. This study used a twin design to quantify the stability of nEV miRNAs and to identify miRNAs that show relatively consistent versus variable expression across twin pairs. Plasma samples were collected from 174 adolescent and young adult twins (76 monozygotic and 98

dizygotic). nEV miRNA expression was quantified using the Affymetrix GeneChip miRNA 4.0 Array, and 138 miRNAs passed detection and quality-control thresholds. We computed within-pair stability metrics for each miRNA across the full sample. Metrics included mean absolute twin difference, percent difference, coefficient of variation (CV), and twin–twin correlation. Stability varied widely across the nEV miRNA transcriptome. The most stable miRNAs, such as miR-4505, miR-4743-5p, miR-607, miR-3185, and miR-4801, showed very low mean absolute twin differences (<0.25) and relatively low CVs, indicating high within-pair similarity. In contrast, the least stable miRNAs, including miR-3613-5p, miR-5787, miR-638, and miR-1469, exhibited large mean twin differences (>0.85) and higher CVs, reflecting greater variability across twin pairs. Ongoing bioinformatic analyses will evaluate whether these stable and unstable miRNA subsets differ in their predicted gene targets and pathway enrichment profiles. These findings provide the first characterization of expression stability for L1CAM-enriched nEV miRNAs. We used twin pairs which are uniquely informative because they naturally control for many background factors, including shared genetics, in utero environment, early-life experiences, and family-level exposures, allowing within-pair comparisons to highlight miRNAs that remain consistent under highly similar conditions. Our design strengthens inferences about which nEV miRNAs are stable or unstable, providing insight into how reliably different miRNAs reflect underlying biological processes.

Abstract Name: Celestium: Invariant-Manifold and Perturbation-Driven Orbit Propagation for Next-Generation Mission Architectures

The proliferation of satellite constellations and the emergence of autonomous deep-space mission architectures demand orbital modeling tools that extend beyond classical two-body formulations while retaining computational tractability. In response, this work presents Celestium, a mathematically rigorous astrodynamics framework that synthesizes higher-order perturbation theory, invariant manifold dynamics, and optimized boundary-value algorithms into a unified propagator capable of modeling trajectories from Low Earth Orbits (LEO) to multi-body regimes. We begin with the canonical two-body Hamiltonian expressed in Keplerian orbital elements and introduce a time-transformed numerical integrator that admits the inclusion of perturbative forces - atmospheric drag, Solar Radiation Pressure (SRP), oblateness effects, tidal forces, third-body gravitational potentials, and more - treated as non-autonomous perturbations to the baseline Hamiltonian flow. Building upon this structure, we formulate a novel representation of the Circular Restricted Three-Body Problem, deriving Lagrange-point dynamics and associated variational equations in a form suitable for efficient computation of multi-body orbits and stable/unstable manifolds. Trajectory design is further enhanced through an optimized solver for Lambert's Problem, constructed as a modified boundary-value method with accelerated convergence properties, enabling rapid generation of transfer arcs within the perturbed dynamical field. Interplanetary capability is achieved via a patched-conic maneuver architecture employing Variable-Impulse Leveraging Maneuvers (VILM), allowing the synthesis of gravity-assist trajectories and complex mission profiles such as Mars transfers. Validation against empirical ephemerides from Space-Track and CelesTrak demonstrates centimeter-scale agreement when assimilating measurements through a Kalman-filter pipeline coupled to the full perturbation set. The resulting framework provides a high-fidelity, mathematically grounded, and fully extensible system for modern orbital mechanics, uniting analytical structure with practical mission design in an open-source tool.

Abstract Name: Development of a Novel Point-of-Care Differential Scanning Calorimeter for Early Detection Across Diverse Cancer Types

Early-stage cancer detection remains constrained by the limitations of contemporary diagnostic modalities, which are often invasive, cost-prohibitive, and insufficiently sensitive to proteomic perturbations preceding clinical symptoms. Differential Scanning Calorimetry (DSC), however, has demonstrated that the thermal denaturation profiles of blood plasma encode robust signatures of disease state, reflecting global changes in protein composition, stability, and intermolecular interactions. Yet traditional DSC instruments are inherently incompatible with point-of-care deployment due to their scale, thermal inertia, and operational complexity. In this work, we present the foundational development of a miniature, sensor-driven micro-DSC platform engineered for clinical translation. Central to this effort is the reformulation of the DSC's thermal feedback architecture at the microscale, achieved through the fabrication and comparative evaluation of two custom sensor geometries: a radial "spiderweb" trace layout and a redesigned rectangular trace configuration. By systematically analyzing their resistance-temperature response curves under controlled thermal ramps, we establish that sensor stability, governed by material selection, heat distribution symmetry, and trace topology, is the critical determinant of accurate calorimetric measurement. The rectangular architecture exhibits a predictable monotonic response, resolving the nonlinearities and discontinuities inherent to the spiderweb design, and thereby establishing a viable microscale foundation for reproducing diagnostic thermograms. These findings constitute a necessary first step toward the realization of a portable DSC capable of generating clinically meaningful thermal fingerprints directly from undiluted patient plasma. We conclude by discussing the implications of integrating machine-learning frameworks for automated thermogram classification, and the broader potential of micro-calorimetric proteome profiling as a diagnostic modality scalable to low-resource clinical environments.

Abstract Name: The Influence of Health Literacy on Adherence to Prescribed Eye Drop Medications and Attendance at Follow-up Visits Among African Americans with Glaucoma

Glaucoma is currently one of the leading causes of irreversible blindness around the world, characterized by damage to the optic nerve due to an increase in intraocular pressure. African Americans disproportionately face the burden of this disease, with higher prevalence rates, earlier onset, and faster progression compared to white populations. Despite vision loss being largely preventable through consistent adherence to prescribed eye drop medications and regular attendance at follow-up ophthalmology appointments, these outcomes are significantly poorer among African Americans. This inequity suggests that sociobehavioral factors, particularly health literacy, may play a central role in shaping glaucoma management. Health literacy influences a patient's ability to understand glaucoma's initially asymptomatic yet progressive nature, the purpose of lowering intraocular pressure, and the long-term consequences of uncontrolled disease. Prior studies have shown that African Americans are more likely to score within the poor health literacy range, which has been associated with reduced comprehension of glaucoma, lower perceived severity, and

diminished motivation to adhere to treatment. Furthermore, systemic barriers such as inconsistent patient-provider communication and intricate glaucoma education material further complicate glaucoma management. This review synthesized over 20 peer-reviewed studies to assess how health literacy relates to medication adherence and follow-up attendance among African Americans with glaucoma. The findings reveal that the low health literacy is strongly associated with missed eye drop doses, inconsistent follow-up attendance, and limited understanding of disease severity. Culturally tailored interventions, however, have shown promise in improving such outcomes.

Abstract Name: Identification of Host Cell Receptor Involved in *Candida auris* Adhesion

Candida auris is an emerging multidrug-resistant fungal pathogen that has been designated a top-priority threat by both the World Health Organization (WHO) and Centers for Disease Control and Prevention (CDC). *C. auris* can colonize a wide range of abiotic and biotic surfaces, including human tissues and medical devices, allowing it to spread rapidly in healthcare environments. A key determinant of this colonization is adhesion to host cells; however, the molecular basis of this process remains poorly understood, including the identity of the host and pathogen receptors involved. In this study, we compared nine clinical *C. auris* isolates belonging to different geographic clades for their ability to adhere to human embryonic kidney (HEK) cells and human keratinocyte (TERT) cells in vitro. Adhesion assays revealed striking strain-dependent variability. Notably, the clade I isolate T033 consistently exhibited significantly enhanced adhesion across both cell types compared to the other isolates. This hyper-adherent phenotype suggests that T033 may possess unique molecular interactions that strengthen its ability to colonize host tissues. To identify host factors that may mediate this interaction, we biotinylated surface proteins from HEK and TERT cells to generate enriched membrane-protein fractions that could be used as "bait" against the T033 strain. Early findings reveal a distinct protein interaction pattern associated specifically with T033, indicating the presence of host receptors that may facilitate its heightened adhesion. These interaction patterns are currently under further proteomic and biochemical investigation to validate receptor candidates. Identifying the host-cell receptors exploited by *C. auris* during the earliest stages of infection contributes to the broader goal of understanding its colonization biology. Ultimately, defining these interactions may support the development of targeted strategies to prevent *C. auris* adherence and limit its spread within healthcare environments.

Abstract Name: Blow the Whistle, Get a Dismissal: Expose Government Secrets, Then Vanish Like You Were Never Official

This research examines disclosure of institutional wrongdoing as a moral act situated at the intersection of ethics, law, culture, and identity. Acts of revealing concealed harm can expose abuses of power and reorient public judgment, yet individuals who disclose often face retaliation, criminal charges, and social exclusion. Existing scholarship typically approaches whistleblowing through organizational procedure, democratic

accountability, or compliance frameworks, but these perspectives frequently overlook the deeper moral and cultural structures that shape how such actions are interpreted. This project addresses that gap by integrating Kantian ethics with comparative cultural analysis and case studies of Edward Snowden and Chelsea Manning. Kant's account of duty and the good will provides a framework for understanding disclosure as a principled act grounded in universal moral law rather than personal advantage. The categorical imperative clarifies why truth-telling retains moral authority even when it conflicts with institutional preservation. The cases of Snowden and Manning illustrate how duty-based action collides with political narratives that frame dissent as disloyalty. Their experiences show how states deploy national-security rhetoric, media strategies, and appeals to identity to control public interpretation and suppress accountability. The research also analyzes how cultural expectations structure the reception of disclosure. Comparative studies of individualist and collectivist contexts demonstrate that loyalty, harmony, and dissent are morally coded in divergent ways, shaping whether truth-telling is seen as civic obligation or betrayal. Legal frameworks further complicate this terrain, as vague standards and inconsistent protections create uncertainty for individuals acting from conscience. By synthesizing Kantian moral theory with cultural and legal analysis, this project develops an integrated account of disclosure as a form of public reasoning. It argues that democratic legitimacy requires protecting duty-based truth-telling, and that societies must recognize disclosure not as defiance but as an affirmation of moral autonomy.

Abstract Name: Metabolic Targeting of Breast Cancer Brain Metastasis Using ACSS2 Inhibitor Analogues

Breast cancer brain metastasis (BCBM) is a severe and often fatal progression of breast cancer, affecting nearly one-third of patients, with an 80% mortality within one year of diagnosis. Current studies indicate that BCBM tumors are highly dependent on ACSS2, an enzyme that converts acetate into acetyl-CoA to sustain tumor growth through altered metabolic programming. Inhibiting ACSS2 presents a promising therapeutic strategy, particularly for brain-metastatic tumors. In this study, I screened and evaluated a group of small-molecule ACSS2 inhibitor analogues derived from lead compounds AD-8007 and AD-5584, previously shown to induce BCBM tumor cell death. Compounds were first assessed using a GFP-based viability assay, where lower GFP fluorescence following treatment indicated reduced tumor cell survival. This initial screen identified 17 high potency candidates. To determine brain accessibility, compounds underwent Parallel Artificial Membrane Permeability Assay (PAMPA) testing to model passive blood-brain barrier (BBB) penetration. Top-performing molecules were then evaluated in an ex-vivo murine brain metastasis model, tracking tumor reduction over nine days in tumor-injected brain tissue. Results revealed multiple analogues with both strong cytotoxic potency and favorable BBB permeability. These findings supported advancement into Phase 2, where isomers of lead candidates are now being tested through additional ex-vivo, in-vivo, clonogenic, and SPR binding affinity assays to further assess therapeutic durability and molecular interaction strength. The most effective compounds will serve as promising candidates for the creation of the final drug. Our ongoing work contributes to the development of a metabolically targeted treatment for BCBM by disrupting acetate utilization through ACSS2 inhibition.

Abstract Name: Digital Media Literacy: Do American Romantics Dream of Electric Screens?

Contemporary Americans rely on digital media for information, socialization, and expression of our identities – yet we rarely question how this information is broadcast to us. Today, we can plug an idea into a large language model program and receive a seemingly well-thought out response. Yet, recommender systems and machine learning technologies are algorithms one can imagine would have Ralph Waldo Emerson rolling in his grave. Due to its focus on philosophy and questions surrounding man and spirit, Transcendentalism is still relevant for the 21st century American reader. Transcendentalists questioned nearly everything, from logic and institutions to nature and the divine. Transcendentalism pits the true self against universal truths, but a question remains for the modern consumer of online media: How do we trust our spirits, intuitions, imaginations, and individual experiences when we are relying on a digital landscape? Understanding how machine learning technologies are intended to interact with the interface user (to handle complex tasks and large data pools using prediction regimes) is the first step towards digital media literacy. When misinformation and its malevolent counterpart, disinformation, are predatory and rely on user engagement, critical thinking becomes a crucial skill in navigating the digital world. Today, sharing false information can have real-world consequences. Interface users must learn how to identify, evaluate, and fact-check information; a difficult task when personal and demographic data is brokered without the explicit knowledge of the user. If they were alive today, the American Romantics would direct us to think for ourselves, to live our online lives deliberately and with the responsibility of a free and fair thinker.

Abstract Name: Media-Dependent Changes in Candida Morphology and Biophysical Properties

Dielectrophoresis (DEP) is an important technique for cell sorting, as different cells exhibit characteristic DEP signatures based on their size and morphology. DEP assays usually require the resuspension of cells in media that is optimized to facilitate the characterization of such DEP signature. However, resuspension alters the physical properties of the cell. The objective of this study is to evaluate how different culture and resuspension media affect cell characteristics, specifically size and morphology. To this end, the characteristics of multiple *Candida* strains were quantified using Logphase 600 and hemocytometer counts across Yeast Mold Broth (YMB) culture conditions and both a DEP media and a mannitol solution. The study of *Candida* cells is important because of the clinical impact candidiasis has on immunocompromised people. Data was collected on cell size and shape in YMB media, and after washes in DEP, and mannitol medias. Results suggest that the composition of the resuspension media and number of washes can alter *Candida* cell morphology. These findings contribute to the field by helping assess the impact of the media on cell morphology and likely its DEP signature. The most notable size and shape comparison across *Candida* in resuspension medias are as follows. B) Average and deviation in diameter of *Candida* after one wash in DEP media. *C. dubliniensis* and *C. krusei* show an increase in size, while *C. parapsilosis*, *C. albicans*, and *C. tropicalis* all showed a decrease in diameter. E) Average and deviation in diameter of *Candida* spp after 3

washes in mannitol. *C. dubliniensis* remained the largest in size. *C. krusei* showed a size increase, while *C. tropicalis* showed a decrease. The others consistently showed a decrease in size throughout the three washes. F) Average and deviation in diameter of *Candida* spp after 3 washes in DEP media. *C. dubliniensis* showed an increase, while the other strains showed a decrease.

Abstract Name: Investigating Plasma-Induced Changes in Red Blood Cells under Varying Ionic Conditions

Cold atmospheric plasma is increasingly explored for biomedical applications, but its direct effects on blood cells are not fully understood. This project investigates how plasma exposure influences red blood cell (RBC) morphology in saline solutions with varying ion concentrations. The hypothesis is that plasma exposure increases the effective ion concentration in the surrounding solution, creating a hypertonic effect that causes RBC membrane shrinkage and produces additional structural changes related to wound coagulation. RBCs were suspended in saline solutions of differing ionic strength to examine how external ion concentration affects osmotic balance and cell morphology. Under hypertonic conditions, where the ion concentration outside the cell exceeds that inside, RBCs demonstrate predictable shrinkage as water exits the cytoplasm. These responses served as controls for distinguishing normal osmotic behavior from plasma-induced effects. Identical saline environments were then treated with cold atmospheric plasma, and RBCs exposed to these plasma-modified solutions displayed additional changes beyond normal osmotic shrinkage, including changes in membrane texture. The experimental setup allowed imaging of RBCs under control conditions (hypertonic, isotonic, hypotonic) as well as plasma-treated RBCs. The changes in the RBC's membrane may be attributed to the interaction of plasma-generated reactive species and their interaction with the lipid bilayer. By comparing plasma-treated and untreated samples under matched salinity conditions, clear morphological signs are shown. These findings contribute to a broader understanding of how plasma interacts with blood components and highlight potential implications for medical treatments involving plasma, including wound healing and coagulation support. Ongoing work will examine plasma dosage, exposure duration, and reactive species composition to further characterize the viability of plasma-based biomedical technologies.

Abstract Name: Healing through Music: Tracing Rochester's Local Music Scene from Street Events to Hospital Halls since 1858

Background: Since the mid-19th century, there has been a vibrant music community in Rochester, Minnesota, even before the founding of the Mayo Clinic in 1889. Some of the early musical groups, like the Rochester Music Union (1869) and the Rochester Philharmonic (1920), have shaped the city's musical and cultural identities. As the Mayo Clinic became a global name in medicine, the intersection between music and

healthcare has increased, from volunteer singers in the hospital atriums to the Harmony for Mayo concert series. This research project investigates the evolution of Rochester's music community alongside the establishment of Mayo Clinic as a medical center and whether the city's musical roots contributed to the development of a "healing" community within the clinical scenes. Methods: Using an archival historical approach, digitized newspapers from the Rochester Post Bulletin (1858–2023) were reviewed. Keywords such as "music performance," "concert," "healing," "Mayo Clinic," and "patient entertainment" were used to identify articles. A qualitative content analysis compared two periods: (1) Pre-Mayo (1858–1889) and (2) Post-Mayo (1889–present). Results: Findings indicated a strong foundation of community-led music activity before the establishment of Mayo Clinic, including orchestras, school programs, and public concerts. After Mayo Clinic grew, music became more connected to therapy and community health. Articles highlighted healing-focused programs like Harmony for Mayo, music volunteering programs, and research-supported activities that demonstrate how music reduces pain and anxiety. Music became more meaningful for both members of the Mayo Clinic and the broader Rochester community. Conclusion: The strong preexisting music scene in Rochester seemed to have shaped how Mayo Clinic incorporated music into patient care. Over time, the presence of the clinic has strengthened the community's identity towards music and healing. This demonstrates how Rochester's local culture and the healthcare mission of Mayo Clinic mutually reinforced a city's social and emotional well-being.

Abstract Name: Liver Fibrosis-Induced Interorgan Crosstalk: Investigating Fiber Morphology, Muscle Vascularization, and Lipid Accumulation

Background: Liver cirrhosis is the scarring of the liver caused by excessive alcohol consumption, high-fat diet, and hepatitis virus infection. It is one of the leading causes of mortality worldwide, affecting an estimated 1.5 billion people with the rates of prevalence and mortality increasing in the United States in recent years. Sarcopenia (muscle wasting), which leads to a decrease in muscle mass, is commonly observed in patients with cirrhosis and in 50% of patients considered for liver transplantation. Mechanisms on why sarcopenia seems to prefer liver-disease complications, either due to metabolic consequences of transplantations or other confounding factors, remain unknown. Methods: The mice model for liver injury includes mice injected with Carbon Tetrachloride (CCl₄) to induce liver fibrosis (1 µL/g) for 6 weeks and olive oil as a vehicle. Skeletal muscles were sectioned using a cryostat for Hematoxylin and Eosin (H&E), immunohistochemistry (IHC), and immunofluorescence (IF) staining. Images were taken under a histology microscope and live-cell immunofluorescence microscope. Images were analyzed using Fiji (ImageJ). Results: The diameter of the muscle fibers decreased for mice exposed to CCl₄ conditions compared to olive oil. CD31 immunofluorescence staining indicated reduced muscle vascularization in CCl₄-treated mice compared to olive oil. BODIPY 494/503 analysis revealed that there is no differential lipid accumulation in myofibrils exposed to olive oil or CCl₄. Conclusion: Our results suggested that skeletal muscle fiber diameter was reduced in CCl₄-treated mice compared to olive oil controls. A non-significant decrease in muscle vascularization was observed in CCl₄-treated mice vs olive oil. Lipid accumulation appeared lower in CCl₄-treated tissue but without statistical significance. CCl₄-treated mice (fibrotic mice) exhibited reduced muscle fiber diameter, with trends toward decreased vascularization and lipid accumulation. These findings highlight key muscle alterations relevant to understanding the relationship between liver cirrhosis and sarcopenia.

Abstract Name: “We do research too!”: Empowering Students in Humanities Research Through Mentorship

The science-centric branding of undergraduate research—typically seen in images of laboratories, test tubes, and beakers—can obscure the vibrant research opportunities for undergraduates within the humanities. This misperception creates a barrier to student engagement, particularly among students who might be eager to contribute to knowledge but cannot picture themselves as researchers outside of STEM. This presentation explores how intentional mentorship practices can counter these narratives and spark a Research Renaissance among undergraduate humanities scholars. Drawing from the presenter’s 10+ years of mentoring undergraduate researchers in the humanities, this presentation shows how to demystify humanities research via mentorship. Mentors must articulate what inquiry looks like in the humanities—including archival exploration, textual analysis, ethnographic interviews, and collaborative coding—while showcasing how these methods make meaning and teach skills transferable to the real world. Students can serve as co-investigators, archivists, coders, theory translators, project designers, and even community liaisons. This mentoring approach centers on treating students as paid collaborators and training them in rigorous scholarly practices. Through these collaborations, students learn interviewing techniques, grounded theory, and interpretive reading, empowering students to identify patterns, ask meaningful questions, and see themselves as emerging scholars. With the right mentorship, students don’t just learn that humanities scholars do research—they learn that they can do it as well.

Abstract Name: Abiotic drivers of ecological resilience and stability of plant communities across the United States

Climate change is predicted to have extensive impacts on species persistence and the dynamics of ecological communities. Therefore, this study aims to assess temporal beta diversity of plant communities across the United States and Puerto Rico, between 2013 and 2023 surveys. We used long-term field surveys of plant presence and percent cover collected by the National Ecological Observatory Network (NEON) from one site each in the 20 eco-climatic domains, resulting in 1105 1 m² individual plots. We ran separate generalized linear mixed models (GLMMs) to investigate the effects of soil and climatic variables on three temporal turnover metrics – temporal beta Sorensen (beta.sor), temporal beta index (TBI), and stability, accounting for NEON site and plot nestedness, as random effects. We also used variance partitioning to quantify the relative contribution of these predictor groups on temporal beta diversity. Analyses were conducted both at 1 m² plot and aggregated for each NEON site. Results show species loss in seven of the 20 NEON sites, while the stability metric varied between 1.62 and 234.3. We also observed that temporal beta diversity was higher for NEON sites in lower latitudes and longitudes. Our GLMM results show that soil pH, silt content, and fine organic carbon, as well as standard deviation of minimum and maximum temperatures, and coefficient of variation of actual evapotranspiration have significant effects on beta.sor and TBI. Variance partitioning show

that soil and climatic variables explain 6% and 8% of the temporal beta diversity, respectively, while both predictor groups jointly explain another 20-22% variance in the response variable. These findings highlight varying degrees of resilience in plant communities across ecological regions in the United States; furthermore, both soil and climatic variables contribute to floristic changes in these sites. These results can be used to inform conservation policies and climate adaptation management.

Abstract Name: AN EXPLORATION INTO INVESTOR RESPONSES TO FINANCIAL INNOVATION IN GHANA: THE CASE OF OPEN BANKING.

The study aims to explore how the perceptions of retail investors in Ghana, following multiple adverse financial shocks, influence their response to and adoption of open banking. Evidence from existing studies suggests that trust is a key factor in the adoption of these financial innovations, particularly for open banking, where individuals consent to sharing their bank data with other financial service providers such as fintech companies. Ghana has announced plans to implement open banking. While promising, it remains unclear how retail investors will respond to this innovation, given that they have experienced multiple adverse financial shocks over the last decade. Retail investors are the primary focus of this study because they are the key stakeholders affected by negative financial shocks, and their trust is more challenging to repair. This study aims to address the existing knowledge gap in the literature through a qualitative research design guided by the interpretivist research philosophy. Data will be collected through interviews and analysed through thematic analysis. A sample of 25–30 investors will be selected using purposive sampling from Accra, Ghana's economic hub. The findings will be interpreted within the context of how negative financial shocks affect investor trust and adoption of open banking. The study's findings are expected to reveal the experiences of each of these investors following the negative financial shocks, how retail investors in Ghana felt after those shocks and how likely they are to adopt open banking. Finally, variations in the responses of investors from different demographics should be evident. If these findings are obtained, the study will be relevant for informing policymakers and financial service providers on how to design and implement a consumer-centred open banking system.

Abstract Name: Future of Fuel – Unleaded Fuel Initiative

The aviation industry has shown a rapidly growing desire to transition from leaded fuel to unleaded fuel. Since the establishment of the Eliminate Aviation Gasoline Lead Emissions initiative on February 23, 2022, stakeholders in aviation have worked to accelerate this shift. This urgency soon increased after the Environmental Protection Agency's acknowledgement on October 18, 2023, regarding the health risks associated with lead exposure from aviation emissions. These findings clearly indicate that the industry must therefore transition to unleaded fuel quickly, efficiently and safely. Over the past year, research has examined

multiple categories related to this transition. This includes certification, maintenance, infrastructure and supply chain logistics. While many methods of certification for unleaded fuel have been evaluated, maintenance stands out as the primary safety concern for this transition. The University of North Dakota experienced valve seat recession in 2023, similar to the automobile industry's own transition away from leaded fuel. Despite this issue, airports like Centennial Airport in Denver have found success in their distribution of unleaded fuel to consumers. This project not only provides justification for Embry Riddle Prescott's Cessna 172 fleet to adopt unleaded fuel but also plans to be a framework for other airports and flight schools around the country to apply. Ultimately, this research aims to support the aviation community in its transition to unleaded fuel as well as promote public education and awareness on aviation's role towards achieving a cleaner and more sustainable future.

Abstract Name: Permissible Deception Vs. Impermissible Coercion

Courts have long tolerated limited police deception in custodial interrogations, reasoning that tactics like fabricated witness statements or false forensic reports do not necessarily render confessions involuntary. Artificial intelligence, however, destabilizes the already wavering "gray line" between permissible deception and impermissible coercion. AI interrogation tools can fabricate hyper-realistic deepfakes, generate adaptive feedback through behavioral analytics, and manipulate rapport by mimicking race, culture, or emotion. The use of AI in this way heavily influences a suspect's likelihood of confessing, while simultaneously shaping interrogator tactics based on AI-provided information. Unlike traditional deception, these tools operate in an opaque way that neither suspects nor courts can meaningfully scrutinize. The result is twofold: AI deception both magnifies the risk of false confessions and undermines constitutional doctrines that rely on the voluntariness and reliability of confessions under the Fifth and Fourteenth Amendments. Some scholars defend AI's beneficial uses and advantages in the realm of interrogation, but such optimism often overlooks how AI can subtly manipulate suspects' choices in real time, which makes confessions less voluntary and undermines constitutional protections. Current jurisprudence, from *Frazier v. Cupp* onward, has failed to articulate a defined limit to deception. Thus, courts lack the tools to evaluate whether AI-enhanced deception is fundamentally coercive. This article argues that AI-enhanced deception should be treated as a per se category of unconstitutional structural coercion. It proposes categorical bans on AI-generated false evidence, mandates statutory disclosures, and requires independent validation of any algorithmic tools used in interrogations. By reframing AI-enhanced deception as coercion rather than mere trickery, the paper offers a normative framework to ensure that technological innovation does not erode guarantees of fairness, voluntariness, and evidentiary reliability in the criminal justice system.

Abstract Name: From Laundry Waste To Material Resource: Lint-Reinforced Nylon Composites

Lint microfibers are a byproduct of the clothes making and laundering industries and are one of the most commonly produced waste products. Making up as much as 35% of all marine microplastic pollution, lint microfibers augment the global saturation of microplastics and contribute to degradation of the environment and human health. However, recent interest has emerged in finding practical uses for lint, saving resources that would otherwise be spent on disposal and containment. One such use case lies in upcycling lint into useful plastic composites. This research aims to assess the feasibility of such plastic composites through production and examination of their mechanical properties. Through the facilities of the NIU bioplastics lab composites of nylon with 20% lint were, prepared, cryogenically ground, successfully compression molded, conditioned and mechanically tested for their ultimate tensile strength per ASTM standard. Through parametric study, consistent results were demonstrated for UTS in the range of 20 to 25 MPa. A chemical treatment process tailored to the characterization of lint was also incorporated resulting in a further UTS increase of ~90% compared to the best past average. Ultimately, the research shows that lint can be converted into plastic composites with useful mechanical properties, with and without intensive processing, while also demonstrating the benefits of any further processes. These composites have broad implications in the areas of textile processing and environmental protection, presenting completely new avenues for repurposing a largely unexplored form of waste.

Abstract Name: Making Room for Morality: Kant's Third Antinomy

The Resolution to the Third Antinomy of the Critique of Pure Reason presents Immanuel Kant's attempt to reconcile freedom of the will with the deterministic structure of nature. The Resolution is thus crucial for Kant's philosophical system, since Kant's practical philosophy in the Critique of Practical Reason is entirely grounded in freedom. However, there is no interpretative consensus on precisely what Kant proves in the Resolution. The standard interpretation in the literature holds that Kant merely shows that freedom and natural causation do not logically contradict each other. I argue that this interpretation is too thin and does not provide Kant with the necessary preconditions to ground his practical philosophy on freedom. By contrast, Bernd Ludwig's strong interpretation, which sees Kant as proving that freedom of the will could really exist, also faces significant problems as it oversteps the boundaries of what Kant claims theoretical reason can prove. Through a constructive engagement with these interpretations, I formulate an alternative "middle ground" interpretation that argues that the Resolution to the Third Antinomy demonstrates how both freedom and the laws of nature can determine one and the same action. It is uniquely positioned to be stronger than the standard interpretation without going as far as the strong interpretation, thereby providing practical philosophy with the theoretical ground it needs to place freedom at its core without overstepping the boundaries of theoretical reason.

Abstract Name: Analyzing Correlations Among Biological and Behavioral Stress Markers in College Students

Pursuing a college degree is often accompanied by emotional distress; occupational, financial, and social concerns can trigger an emotional response. As students perceive distress, biological stress pathways are initiated signaling release of substances such as cortisol to prepare the body for a stressful event. Unfortunately, prolonged stress can result in immune dysfunction. The purpose of this study is to evaluate the association between behavioral markers of emotional distress and levels of cortisol in the hair of students at a four-year university. A convenience sample of 19 students completed measures of perceived stress, somatic symptom burden, and interoceptive bodily states and underwent collection of ~100 hair strands cut from the posterior vertex of the head. The majority of the sample are white (68%, N=13) women (84%, N=16) with a mean age of 26.59 (SD=14.41) who are pursuing Psychology (26%, N=5) or medicine/nursing degrees (21%, N=4). Cortisol levels from hair samples are currently being processed through a validated protocol developed by the Biomolecular Analysis Core using liquid chromatography tandem mass spectrometry. Pearson/Spearman analyses will be performed in SPSS to evaluate 1) the degree of association between cortisol and measures of behavioral stress, and 2) the impact of academic factors on biological measures of stress. I anticipate a strong correlation between behavioral and biological markers of stress, particularly in students majoring in Psychology or medicine/nursing degrees. Within these majors, there is pressure to perform well academically, gain acceptance into graduate programs, and obtain clinical experience. Understanding the presence of biological markers of stress and their association with behavioral stress measures is vital as college students are prone to mental health concerns due to lifestyle changes following enrollment into college.

Abstract Name: Computational Modeling of Amorphous Silicon Nitride as Optical Coatings for Future Gravitational-wave Detectors

The sensitivity of current gravitational-wave (GW) observatories, such as Advanced LIGO, is limited in their most sensitive frequency band (around 100 Hz) by Brownian thermal noise originating from the mirror coatings. To enhance the sensitivity of current and future detectors, coatings made from materials with reduced thermal noise are essential. Research stemming from a more advanced GW observatory would provide invaluable data for testing major astrophysical theories. One of the promising candidates for such coatings is amorphous silicon nitride (SiN_x), particularly for cryogenic detectors. A detailed understanding of the origins of SiN_x coatings' mechanical loss and optical absorption, in terms of their atomic and electronic structure, could be useful in guiding experimentalists toward optimal GW coating design. However, such understanding is currently lacking. My work in this project aims to fill this knowledge gap. To do so, I generate atomic models of SiN_x by using state-of-the-art Molecular Dynamics (MD) simulations with varying values of x . It has been empirically observed that Nitrogen-to-Silicon ratio, denoted to x , is critically important parameter scientists can tune to influence coating behavior. I then use quantum calculations, specifically Density Functional Theory (DFT), to compute electronic structure based on the resulting atomic

structure. Using this data, we predict key properties like bond angles, geometric defects, optical band gap, and defect states. By varying x above and below the stoichiometric level ($x=1.33$), I will predict its effects on mechanical loss, optical absorption, and refractive index—the key performance metrics for high-performance GW detector coatings.

Abstract Name: The Relationships Among Anti-immigrant Attitudes and Behaviors, Moral Foundations, and Distributive Justice Beliefs

The current research investigates moral foundations and distributive and procedural just world beliefs as foundational in forming anti-immigrant attitudes and behavior in an undergraduate population. This study aimed to show a causal relationship between distributive justice beliefs for others (DJO) and prejudice, based on previous research demonstrating that increasing one's DJO belief increased one's likelihood to support anti-immigrant policy. I also aimed to find positive correlations between binding moral foundations, prejudice, and justice beliefs. A population of 85 students participated in a DJO scenario- response manipulation, where they read situations in which they witnessed another student or outgroup members receiving the benefits of a resource distribution. Those in the control condition read scenarios pertaining to Distributive Justice to the Self (DJS), where the participant was said to benefit from resource distribution. Following the scenarios, participants completed measures of anti-immigrant attitudes and behavior. There was no significant difference found between the DJO and DJS conditions, despite a measured change in pre/post DJO scores for both conditions. Moral Foundations of authority and ingroup/loyalty were shown to have a significant impact on how much a participant was affected by the scenarios. As predicted, binding moral foundations were positively correlated with both DJO and prejudice; DJO was positively correlated with prejudice. Contrary to predictions, Procedural Justice Beliefs for Others (PJO) were positively correlated with binding moral foundations and prejudice. Binding foundations, DJO beliefs, and PJO beliefs were negatively correlated with pro-immigrant behavior. This research confirms previous findings, where binding foundations and justice were shown to influence anti-immigrant prejudice, but expand understanding to consider the unique features of undergraduate belief systems, including the connected nature of binding foundations and justice beliefs. Findings indicate further research is necessary to understand how undergraduates use moral foundations and justice beliefs in conjunction to develop prejudiced beliefs.

Abstract Name: Broadside Ballads and Warrior Women: A Look at Eighteenth Century England Through an Unofficial Lens

The everyday lives of people from the past are often shrouded in mystery for modern day historians. While official documents from the past preserve information from legal trials, military conflicts, and political institutions, they often overlook the more nuanced aspects of society at the time. My aim is to use less substantiated primary sources to look into underrepresented aspects of history. Specifically, this research will

take an in-depth look at broadside ballads from eighteenth century England in order to gain a deeper understanding of the role women played in society. I will be doing a close analysis of several different ballads in order to identify patterns that emerge in the writing, which will then signify common themes and knowledge from the time. I will also be referencing the work of experts like Dianne Dugaw to gain a more well-rounded understanding of ballads and their purpose in early modern English society. I will in no way be arguing that broadside ballads provide a foolproof and accurate depiction of history, but their limitations don't take away from the stark societal implications that seem to be accepted as common knowledge during the time they were originally published. Through the course of my research, I have found that broadside ballads have a wealth of information to reveal about how women were perceived in eighteenth century England. The common themes that stood out the most were the descriptions of the physical strength of women in the eighteenth century, the role of women within the military during the constant upheaval of turn of the century England, and the common use of cross-dressing and disguise as a way for women to gain independence and power over their own lives.

Abstract Name: How Horror, and Subsequently an Obsession with said Horror Can Influence the Human Psyche

The horror genre is very popular among avid viewers and is responsible for inducing fear and excitement in individuals, while also aiming to make them uncomfortable. The genre of horror in the context of films may not seem important in the study of human psychology, but it is. The paper has a focus on the sub-genres: extreme horror and hardcore horror, that will guide an exploration of an individual's psychology. Psychological studies emphasize that empathy and fear shape individuals' reactions to frightening content. Repeated exposure to fear can reduce an individual's flight or fight reaction, which may be why horror veterans are more desensitized to the genre. Fear can also be viewed as positive in the context of control. Furthermore, psychological studies on obsessive compulsive disorder (OCD) conclude that OCD obsessions can arise from a misinterpretation from "self-as-is" and "self-as-could-be". Obsessions can be triggered by film for some. It is important to note that obsessions, a lack of empathy, and little fear does not necessarily imply a person is dangerous. Ultimately this paper argues that a person's reaction to horror can imply a baseline of their ability to handle and process empathy and fear, along with their relationship of an obsession with horror. Although, there are various ways that empathy, obsession, and fear can play into the experience of watching and thinking about horror that differ from person to person. It is also important to note the relationship between the dangerousness of a person and an obsession with horror through the content of those films can interfere with the "self-as-is" and "self-as-could-be" relationship in OCD. In conclusion, the relation of horror and psychology can reveal a lot about a human's psyche.

Abstract Name: Exploring Cobalt-Based Heterogeneous Catalysts for Suzuki-Miyaura Cross-Coupling Reactions

Palladium, a costly precious metal, is the standard catalyst for the extremely common Suzuki-Miyaura Cross-Coupling Reaction (SMCCR). The SMCCR creates carbon-carbon bonds by coupling organic groups on an organohalide and a boronic acid. Using a different metal to catalyze the SMCCR is a way to reduce spending and lower drug prices. This experiment aimed to investigate cobalt as a heterogeneous SMCCR catalyst. Cobalt catalysts were prepared and then tested in SMCCRs, and results were produced via GC-MS and TEM imaging. Catalytic nanoparticles were agglomerated on multi-walled carbon nanotubes by ball-milling, and reactions were run at 50°C in a 2:2:1 ethanol:water:tetrahydrofuran solvent system. Of the nine cobalt precursors tested in 96 SMCCRs, only cobalt acetate and cobalt stearate yielded catalytically active species. Cobalt was successful in catalyzing the SMCCR in high yield, showing its viability as an eventual palladium replacement. More research is needed to reliably predict cobalt catalyst behavior, but it is hypothesized that varying oxidation states in the precursors (confirmed by XPS) could influence subsequent catalytic activity, as could the number of active sites created by the ball mill.

Abstract Name: Consequences of Alkane Chain Length to Structure, Dynamics, and Frequencies in Imidazolium Chloride Ionic Liquids: A Molecular Dynamics Study

The alkyl chains attached to the cation in ionic liquids play a significant role in stabilizing the cation-anion ion pair. We performed classical molecular dynamics (MD) simulations to analyze the effect of alkane chain length on the local structure in imidazolium chloride ionic liquids. The local structure and hydrogen bonding between the cation and anion were studied using radial distribution functions and vibrational frequency analysis. The mean square displacement of the cation and anion increases with alkyl chain length, possibly due to a weakening of the cation-anion interaction. The presence of intra- and intermolecular interactions in the system is reflected in vibrational frequency shifts. Local mode analysis revealed the effect of the alkane chain on the hydrogen bonding between the ring CH bonds and the Cl anion. The weakening of the cation-anion interaction is evident in the stretching and bending regions of the vibrational spectrum. These molecular-level insights provided a clearer understanding of how structure-property relationships are important for designing ionic liquids for catalysis, electrochemistry, and other applications where hydrogen-bonding networks are essential.

Abstract Name: Voxel Reconstruction as a Tool for Building Geometry Correction

Urban-scale 3D geometric models have enabled a new capability to run city-scale wind field simulations at

higher resolutions. However, currently available models often contain distorted or incomplete building geometry due to the photogrammetry errors. These geometric errors render the models unsuitable for scientific simulations, necessitating hours of manual repair to correct surfaces, fill gaps, or smooth irregular shapes. This project aims to automate the model reconstruction step by developing a method to clean and correct building geometry using voxelization techniques. Voxelization converts a 3D model into a grid of small cubes (voxels) that represent the structure's volume. By reconstructing a building from a voxel grid, we can remove noise, enforce solid walls, and generate more uniform surfaces without altering the overall shape of the building. This process helps standardize buildings that originally contain messy triangulated meshes, floating geometry, or holes. After voxel reconstruction, the resulting model is suitable for simulation tasks. This project demonstrates a workflow that transforms publicly available models into simulation-ready models with minimal manual editing. The goal is to provide researchers, urban planners, and engineers with a faster and more reliable method for preparing city-scale datasets. By automating geometry correction, this approach saves time, reduces human error, and makes large-scale environmental simulations more accessible and efficient. However, the current method has a few limitations, such as over-voxelization, which creates a blockier model, and distortion in model images and models with severely poor geometry.

Abstract Name: Designing a Novel and Effective Childproof Gun Lock for Gun-Ownning Families

In Virginia, nearly 50% of adults own a firearm. Glock 17 and 19 models are the most common handgun models owned. Both handguns also cause the most self-inflicted youth and adult gun injuries, with a majority of unintentional children's injury deaths being from handguns. Gun locks are the most common solution, but the majority of gun owners do not use locks, especially with handguns. Current gun lock limitations are high cost and not user-friendly for adults. Simple childproof locking mechanisms are already prevalent in the medical field. Pharmaceutical companies developed multiple successful systems like push-and-turn and squeeze-and-turn locks that prevent children from accessing dangerous products. These locks significantly reduced youth poisoning rates. Similar techniques can be applied and transformed into a mass producible gun lock that can reduce firearm injury rates for children. We propose a lock that is made of plastic/polymer that can both protect the firearm from damage and the user from unintentional injury. This holster-inspired lock can be easily and quickly removed by an adult user, featuring a locking mechanism which can be disengaged via a squeezable tab similar to those found in standard childproof pill bottle designs. This gun lock aims to successfully disincentivize firearm usage by children while also providing a user-friendly design for adults.

Abstract Name: The Impact of Chemotherapy-Induced Peripheral Neuropathy on Quality of Life in Pediatric Cancer Survivors Background

Chemotherapy-Induced Peripheral Neuropathy (CIPN) is a dysfunction of the peripheral nerves caused by chemotherapy. Occurrence is unknown, but estimated at >90% in pediatric cancer populations. CIPN can reduce children's ability to perform physical activities, play, and engage in activities of daily living, potentially affecting quality of life (QoL). The purpose of this study is to analyze how CIPN affects the QoL of pediatric cancer survivors and how they compare to their peers. Age and sex-matched controls and cancer survivors between ages 12-22 completed the validated and standardized measure, the PROMIS Physical Function Pediatric Short Form, to measure physical QoL, such as the ability to keep up with peers and perform certain activities. The Pediatric Modified Total Neuropathy Score (Peds-mTNS), a validated CIPN measure, defines sensory or motor neuropathy as a score >1 in a relevant subtest, and general neuropathy >4. Subjects included 17 cancer survivors (mean age 16.7±3.83 years, 58.8% female) and 45 controls (mean age 17.3±3.1 years, 60% female). Statistically different values between cancer survivors and controls were found on the PROMIS (Mann-Whitney 602, p<0.001, median=2 (95% CI 1-3)) and the Peds-mTNS (Mann-Whitney 2568, p<0.001, median=-4 (95% CI -5--3)). When comparing PROMIS scores in those with and without neuropathy, cancer survivors had a significant difference (Mann-Whitney 304, p=0.003, 95% CI 2 (0-4)). PROMIS scores were not significant in those with sensory-only neuropathy (p=.056) but were in motor-only neuropathy (Mann-Whitney 58.5, p<0.001, 5 (95% CI 3-6)). A measurable difference in the physical QoL of pediatric cancer survivors was found for those with motor and general neuropathy. This indicates assessing QoL in pediatric cancer survivors with motor and general neuropathy may be fundamental to ensuring overall well-being 6 or more months following cancer treatment.

Abstract Name: Effects of Sleep Deprivation on Cardiac Health determined by Heart Rate Variability (HRV)

Sleep deprivation is a major issue in human health. Studies (Hollis et al. 2025) have shown that adequate sleep is necessary for many cellular and neural functions. Despite this, it remains that 1/3 of Americans report less than the recommended 7-9 hours nightly, with 70 million of them reporting chronic sleep deprivation (Barber et al. 2025). An individual's cardiac health is an essential system affected by sleep deprivation. This study measures Heart Rate Variability (HRV), using a noninvasive, relatively inexpensive method to collect data through electrocardiograms (ECGs). Increased or decreased cardiac health due to sleep deprivation will be reflected as an increase or decrease in HRV. Previous research has identified positive correlations between sleep and HRV (Gouin et al. 2015), but the effects of chronic versus acute sleep deprivation on HRV are further explored in this study (Elon IRB 23-160). This study utilized surveys and HRV data from ECGs to examine differences in chronic (n = 40, avg age = 25.75) and acute (n = 36, avg age = 26.36) sleep deprivation. Chronic sleep deprivation vs average R-R time was more strongly correlated (R = 0.363) than acute sleep deprivation vs average R-R time (R = 0.156). Paired ANCOVA analysis demonstrated significant differences between chronic and acute RR average data (p = 0.0470) as well as chronic vs acute pRR50 data (0.0469). These results show that chronic sleep deprivation has a significantly greater impact on HRV, and thus cardiac health, than acute sleep deprivation. The hypothesis that an increase in chronic sleep deprivation will lead to a decrease in HRV is supported by these results. Future research that uncovers direct links between sleep deprivation and HRV could be used to advance public awareness of chronic sleep deprivation. Funded by Elon University's Undergraduate Research Program and Biology Department.

Abstract Name: The Social Media Marketing of Formula One: Using Parasocial Relationships to Increase American Fanbase in Individuals Aged 18-25

Formula One, the highest class of single-seater, open-class racing, is often regarded as the pinnacle of motorsport. However, by 2017 the sport was facing a decline in both profit and popularity, with its worldwide viewership decreasing from 600 million people in 2008 to 352 million people in 2017. A major factor in this decline was Formula One's failure to effectively engage younger audiences. For years, the sport's leadership dismissed the appeal of younger viewers, assuming that they lacked the financial resources to contribute meaningfully to the sport, focusing instead on traditional broadcasting and corporate sponsorships while neglecting digital and social media engagement. The turning point for the sport came in 2017 when Liberty Media bought the rights to Formula One, Liberty Media shifted the focus toward leveraging the power of social media to engage fans in new and innovative ways. Recognizing the influence of platforms like Twitter, Instagram, Facebook, and YouTube, Liberty Media launched targeted campaigns that built parasocial relationships, one-sided connections between fans and media figures, between audiences and drivers. This approach particularly resonated with Generation Z, who are highly active on social media and inclined toward forming emotional connections with online personalities. This strategy was particularly effective in the United States, where Formula One had historically struggled to gain a foothold. By fostering these parasocial relationships, Liberty Media cultivated a more loyal and engaged fan base, creating a sense of community and excitement that significantly boosted fan involvement and profitability. This literature review examines how increased social media engagement contributed to the rise of parasocial relationships among Formula One fans and how Liberty Media strategically used this phenomenon to revitalize the sport. The findings highlight the growing importance of social media marketing, demonstrating how digital engagement can strengthen consumer loyalty and drive financial success across industries.

Abstract Name: Unraveling Political Discourse: A Stand for Missing and Murdered Indigenous Persons

This project explores the intersection of Native American identity, legal jurisdiction, and Missing and Murdered Indigenous Persons (MMIP) initiatives, using the veto of Oklahoma House Bill 1137 (2025) as a key case study. We ask: Should Native American identity in U.S. law be treated primarily as a function of race/ethnicity or of political identity? This distinction has serious implications for criminal jurisdiction and tribal sovereignty as viewed in historical, legal, and political contexts. The investigation will focus on how the legal framing upholds and undermines political identity in recent policy decisions. We specifically examine the rationale and apparent motivations behind Governor Stitt's veto of HB 1137, a bill which aimed to improve MMIP reporting and inter-agency coordination through the removal of federal funding limitations and grant requirements. Given Oklahoma's complex tribal landscape and past jurisdictional disputes (McGirt, Castro-Huerta), this veto raises questions about state-tribal cooperation and the willingness to prioritize Indigenous persons' safety. With Oklahoma ranking second in the US for MMIP cases, the urgency of such an investigation is clear. We then explore how current political trends and legal definitions may shape the future of MMIP initiatives. By bridging legal theory and political analysis, this project aims to illuminate the systemic barriers that persist in protecting Indigenous communities and propose pathways for reform.

Abstract Name: The Power of Language: Harriet Beecher Stowe's Construction of Empathy and Moral Authority in "Uncle Tom's Cabin"

This project examines Harriet Beecher Stowe's sentimental novel, *Uncle Tom's Cabin*, and analyzes how it transforms language into a moral tool to advocate for abolitionist persuasion. This study explores how Stowe uses sentimental diction and stylized dialect to construct empathy for enslaved characters while positioning herself as a moral and religious authority for her nineteenth-century readers. The paper argues that Stowe utilizes the domestic sphere and a Christian ideology to appeal specifically to her white, Christian audience, whose moral values she wanted to activate against slavery. Her use of both Black and Southern white characters with accent-filled dialogue challenges the assumptions about the relationship between race, speech, and intelligence, further humanizing the enslaved by portraying them as linguistically and emotionally familiar to white readers. The methodology involves close textual analysis of Stowe's narrative strategies as well as secondary scholarship in literary studies, nineteenth-century cultural history, and rhetoric. Through her sentimental diction and direct address to the audience, Stowe pushes the readers toward seeing emotional identification with enslaved characters as a moral responsibility. She frames slavery as a spiritual and religious issue rather than merely a political or economic one. By invoking religious language and presenting herself as a translator of God's will, Stowe elevates her narrative voice to a position of moral authority. The results indicate that *Uncle Tom's Cabin* functions both as a literary text and a form of moral persuasion capable of influencing public sentiment. It positions Stowe's novel as a linguistic and cultural artifact that highlights how rhetoric, sentimentality, and moral authority can shift politics. This research contributes to the discussion of rhetoric, racial representation, and nineteenth-century American literature by showing how Stowe's methods combined emotional appeal with moral authority to shape public morals.

Abstract Name: Are *Daphnia* Naive to Chemical Cues From the Invasive Predator *Bythotrephes longimanus* (Spiny Waterflea)?

In aquatic ecosystems, prey use chemical cues released from predators (kairomones) and/or chemical alarm cues from injured conspecifics to gauge predation risk. In response to those cues, prey may adjust their behavior or development to minimize their vulnerability to predation. Laboratory experiments have shown that *Daphnia* (a common zooplankton prey species) from lakes with established populations of the invasive zooplankton predator *Bythotrephes longimanus* (spiny waterflea) display light-avoidance behavior (negative phototaxis) in response to *Bythotrephes* kairomones. In situ, negative phototaxis behavior is presumed to equate to *Daphnia* migrating into deeper, darker waters during the daytime to minimize predation risk from the visually-oriented *Bythotrephes*. However, little is known about the vertical migration behavior of *Daphnia* from populations of uninvaded lakes. Our research compared the phototactic responses of *Daphnia pulicaria* from two Minnesota lakes where *Bythotrephes* has been present for several decades, to *D. pulicaria* from populations of three uninvaded lakes. In our phototactic assay experiment, *Daphnia* from five lakes were exposed to different media: control media (no chemical cues), *Bythotrephes* kairomones, and *Bythotrephes* kairomone/*Daphnia* alarm cue combination media. We hypothesized that, compared to kairomone-free

controls, *Bythotrephes kairomones* would elicit a more negative phototactic response in *Daphnia* from invaded lakes, while the behavior of “naive” *Daphnia* from uninvaded lakes would not differ from the control. Consistent with our hypothesis, we found that *Daphnia* from invaded lakes showed a significantly more negatively phototactic response ($p < 0.001$) to *Bythotrephes* media compared to *Daphnia* from uninvaded lakes. These findings imply that 1) *Daphnia* from the invaded lakes have evolved to respond to this non-native predator, and 2) the lack of a response by the “naive” *Daphnia* from the uninvaded lakes may contribute to successful early establishment of *Bythotrephes* populations in ecosystems where they have not previously existed.

Abstract Name: Malleable Ideologies and Opposition to Welfare

As egalitarian values have become more widespread, prejudice has shifted from overt expressions to more subtle and socially acceptable forms. One expression of this phenomenon is malleable ideologies, where individuals alter minor details of egalitarian principles to maintain social hierarchies. The purpose of this study was to examine whether opposition to welfare can operate as a malleable ideology. We conducted a nationally representative survey experiment ($n = 298$) using a pretest–posttest design. For the experiment portion of our design, we presented participants with an article to induce perceived symbolic threat, perceived realistic threat, perceived benefit, or no stimulus (control). We found that among individuals low in hierarchical orientation, exposure to different article conditions significantly influenced welfare attitudes and shifted the justifications they provided for their positions. In contrast, individuals high in hierarchical orientation showed more stability across conditions. These findings suggest that those lower in hierarchy attitudes are more responsive to messaging, while those higher in hierarchy attitudes maintain consistent rationales. This indicates that messaging interacts with hierarchy orientation in shaping welfare justifications. The malleability of welfare justifications based on hierarchy orientation contributes to the broader literature of how social attitudes shape the way people respond to political messaging.

Abstract Name: Creating Spaces for All: A Study on Accessibility in Theatre Experiences

The present study is exploring the lack of accessibility measures in the performing arts across the United States, with a major focus on how to combat these barriers. The researchers at UWM are committed to working with and for the community of disabled artists that surround them. Local accessibility-based companies and theaters are involved in achieving this goal by working closely with the UWM researchers to achieve their goal of accessibility in the arts. To do this, the researchers are working towards what has been coined “UWM’s Most Accessible Show Ever”, which would involve a wide range of inclusive measures, including, but not limited to, in-ear audio description, braille playbills, a presentation on invisible disabilities, ASL interpretation, and much more. A show like this has never been performed on the UWM stage, nor in

theaters in the area. This research will lead to better accommodation and understanding of accessibility and inclusivity at not only the university, but for all the patrons and artists as well. Beyond that, the researchers hope to induce these changes on a much larger scale and inspire others to do the same.

Abstract Name: Mother Tree Resilience: Tracking Plant Stress

Stable carbon isotopes provide a powerful tool for evaluating plant physiological stress and tracing carbon exchange between trees and their associated fungal networks. In this study, we analyze $\delta^{13}\text{C}$ values from southern live oaks (*Quercus virginiana*) across five distinct regions of the University of Louisiana at Lafayette campus to assess spatial patterns of water stress and intrinsic water-use efficiency. We further test the hypothesis that these oaks function as “Mother Trees,” distributing carbon resources through shared mycorrhizal fungal communities. Carbon isotopes from leaves, bark, soil, and associated fungi allow us to identify environmental drivers of stress and determine whether fungi are sourcing carbon primarily from C_3 or C_4 plants. By correlating isotopic variation with site-specific factors, we aim to map zones of heightened stress across campus and evaluate the extent of carbon transfer within tree–fungus networks. Previous work has demonstrated that $\delta^{13}\text{C}$ signatures effectively track changes in water availability and fungal resource acquisition, providing a framework for interpreting our results. This research contributes to a broader understanding of how live oaks respond to environmental pressures and how belowground symbioses may enhance their resilience. Future directions include modeling the effects of rising atmospheric CO_2 on photorespiration and intrinsic water-use efficiency, with the goal of better predicting how long-lived canopy trees may adapt to ongoing climate change.

Abstract Name: Comparison of Two Instruments to Measure Optical Imperfections in Eyes Before and After Dilation

Purpose: Optical distortions of the eye are described by Zernicke polynomials, the values of which can be combined to provide a single value of distortion termed higher order root mean square (HoRMS). In this study, we compared measures of HoRMS using the single capture COAS wavefront aberrometer to the newly developed video capture Wavedyn in both dilated and undilated eyes. **Methods:** 34 young adults were measured using the COAS and the Wavedyn in random order both pre and post dilation (three repeated captures with each). Eyes were dilated using 1% tropicamide and 2.5% phenylephrine. The instruments measured to the 10th Zernicke order. Images were analyzed over a 4mm pupil diameter, and the root mean

square of the individual Zernicke polynomials was calculated to determine the HoRMS for each condition. Comparison of the instruments was completed using an ANOVA with instrument, condition, and eye as repeated factors. Findings are reported as adjusted means (from ANOVA) with 95% CI. Results: 33 participants completed all testing, while 1 participant only had nondilated measurements. For COAS, the HoRMS pre and post dilation adjusted means were 0.16 (0.13, 0.19) and 0.17 (0.14, 0.19), respectively. For the Wavedyn, the HoRMS changed significantly pre and post dilation ($p=0.025$) with adjusted means of 0.17 (0.14, 0.19) and 0.19 (0.17, 0.22), respectively. While HoRMS did not differ between instruments at pre-dilation ($p = .80$), there was a significant difference when comparing post-dilation values of the COAS and Wavedyn ($p=0.031$). Conclusions: Although the Wavedyn provided statistically significantly higher values of HoRMS after dilation, the differences were small and unlikely to be considered clinically relevant. Additional analysis of individual Zernike polynomials can be performed to identify which term(s) may be contributing to the differences after dilation.

Abstract Name: The Effects of VR Nature on Stress and Anxiety

The question being pondered here is regarding whether Virtual Reality (VR) nature environments effectively reduce stress among individuals with limited access to real-world nature situations? The purpose of this research is to explore whether VR nature can replicate the effects typically associated with spending time in nature. In today's fast-paced and urban world, many people face barriers such as limited access to green spaces, busy schedules, or mobility restrictions that prevent them from engaging with tangible nature. Therefore, it is important to identify accessible alternatives, like VR nature, that might have meaningful implications for wellness and mental wellbeing. Research by Rapuano et al. (2022) stresses the importance of green spaces and their stress-reducing qualities, emphasizing how nature exposure supports mental health and emotional regulation. Ultimately, this study aims to understand whether VR nature can provide similar psychological benefits. The research methodology includes gathering participants via Towson University's research pool. Participants must be at minimum 18 years old. Participants answer questions relating to sleep quantity, substance use, etc. Upon completion, participants have five electrodes placed on them to gauge Electrodermal Activity and Heart Rate Variability. Participants then answer math questions, provided by the Trier Mental Challenge Test. Participants then answer the first ten questions of the State-Trait Anxiety Inventory, which serves as a manipulation check and pre-test. Participants then watch the virtual reality nature video, either on the desktop or VR headset. Participants are then given a two-minute reacclimation period. Finally, the participants take the subsequent ten questions of the State-Trait Anxiety Inventory and answer post-qualitative questions to gauge post-formal thought. Researchers expect and predict that viewing the virtual nature video will decrease stress and anxiety within participants.

Abstract Name: Do you feel the burn? Exploring lightweight haptic feedback and how it can improve exercise performance.

Automated, computerized exercise feedback systems have become favored proposals to monitor and provide live feedback to users while completing unsupervised exercise training at home. Positive impacts such as reducing errors in motor learning, detecting missed repetitions, and enhancing exercise performance have been observed. Haptic feedback has shown to be an effective method of feedback for these systems and has been explored via various metaphors. Forceful haptic feedback is effective in guiding motion, but has also been reported to be difficult to interpret. In contrast, tapping haptic feedback has shown to be more distinguishable than forceful, while remaining effective in motion trajectory correction. However, there is another feedback method used in practice that has not yet been explored. In addition to forcefully guiding a patient through an exercise, and gently tapping their arms or legs to move into a certain position, they'll also tap on certain muscle regions of the body where a patient should be feeling activation in certain muscles. We propose a new haptic feedback metaphor, MyoTap, that utilizes vibrotactile cues similar to that of the tapping metaphor, but instead of placing an actuator on an end effector that is being instructed to move, the actuator is placed on a muscle region that is supposed to feel. We propose this feedback method will result in a more positive user experience in terms of usability while remaining comparable in motion trajectory correctness.

Abstract Name: Genetic and Functional Diversity of Plant-Pathogenic Oomycetes Isolated from Industrial Hemp Soils in Southeastern Pennsylvania

Oomycetes are common aquatic and soilborne microbial eukaryotes that have the capacity to infect a broad range of plant and animal hosts. Understanding the relationship between genetic diversity and virulence is crucial for developing effective management strategies to control disease. In this study, we focus on two oomycete species, *Globisporangium irregulare* and *G. ultimum*, which vary in their reproductive mode (sexual versus clonal) and pathogenicity on agricultural crops. Multiple isolates from both species were collected in a recent biodiversity survey of industrial hemp soils in 2022. We have assessed both genetic diversity (nuclear microsatellite, nuclear and mitochondrial gene sequencing) and functional traits (pathogenicity assays, fungicide resistance) across isolates to explore variation in virulence levels within these two species. For *G. irregulare*, molecular data suggest a complex pattern of sexual recombination among genetically diverse lineages and the possible occurrence of a cryptic species, *G. cryptoirregulare*, within some of the sampled locations; isolates of *G. ultimum* showed low levels of genetic diversity consistent with clonal reproduction. Both species showed pathogenic phenotypes on two strains of industrial hemp (Bialobrzeskie, Henola) and soy, but neither were pathogenic on a cover crop control (hairy vetch). Despite high genetic diversity, isolates of *G. irregulare* showed significant variation in virulence against soy but not hemp or vetch. Only one isolate of *G. ultimum* showed significantly lower virulence on all hosts compared to other isolates. Fungicide sensitivity assays showed higher levels of mefenoxam resistance for *G. irregulare* compared to *G. ultimum*, although variation among isolates was observed for both species at different exposure levels. Our results suggest that despite different modes of reproduction, both species exhibit low levels of variation for the functional traits measured here. Future research will characterize additional morphological and physiological attributes related to host-pathogen interactions.

Abstract Name: Development of a specific primer to detect the PRSV gene in GMO papayas

Genetically modified organisms (GMOs) are a key agent in modern agriculture, as they improve the quality of crops by providing resistance to pests and diseases. A concrete example is the transgenic papaya, designed to resist papaya ringspot virus (PRSV), which is transmitted through aphids and can devastate entire plantations. To verify such traits in practice, modern biotechnology, supported by bioinformatics tools, makes it possible to design precise diagnostic methods, such as specific primers used in PCR, which facilitate the identification of genetic modifications in plants of agricultural importance. In this study, specific primers were developed to detect the coat-protein (cp) region of the PRSV gene in papaya using PCR. Thirty-five primer candidates were designed in Primer-BLAST and evaluated with OligoEvaluator; three primer pairs met all selection criteria (hairpin: pass; self-annealing: pass; dimers: very weak/none). Genomic DNA from known transgenic and organic papaya samples was extracted and tested by PCR, and primer performance was assessed by agarose gel electrophoresis. Papain and CPA-1 amplification were included as experimental controls and endogenous markers for papaya DNA. The cp-targeted primers yielded amplification rates of CP4 F/R: 6/8 (75%; 3 organic, 3 transgenic), CP6 F/R: 1/8 (12.5%; transgenic only), and CP7 F/R: 1/8 (12.5%; transgenic only); CP4 F/R showed the highest detection rate across both organic and transgenic samples and was prioritized as the lead primer. This project aims to establish a rapid, reproducible, and economically accessible PCR assay for detecting the PRSV transgene in papayas produced in Puerto Rico, thereby supporting quality control, agriculture, and labeling transparency.

Abstract Name: Investigating Correlates of Parental Well-Being: A Focus on Daily Hassles/Uplifts and Child-Centric Parenting

Previous research has found that daily hassles and uplifts are both associated with parental well-being (DeLongis et al., 1988). Among parents, child centric parenting (i.e., a mindset in which parents are motivated to maximize their child's well-being) is also positively related to well-being (Ashton-James et al., 2013). The goal of the current research was to replicate and extend previous research in parents specifically. More specifically, our aim was to investigate how each of these variables relate to one another, particularly child-centrism and the extent to which parents view their children as hassles/uplifts. To do so, parents (N = 1576) completed an online survey via the platform Prolific. They indicated the extent to which several life

domains (including their children) are hassles and uplifts, as well as their well-being (on a wide range of measures) and level of child-centrism. A series of Pearson correlations was used to test three categories of hypotheses, all of which were supported. First, daily hassles/uplifts were associated with well-being. For example, overall daily hassles was positively associated with overall happiness, $r(1586) = .60, p < .001$. Second, viewing children as hassles/uplifts was associated with well-being. For example, viewing children as uplifts was positively associated with overall happiness, $r(1586) = .34, p < .001$. Finally, child-centric parenting was positively associated with viewing children as uplifts, $r(1586) = .34, p < .001$, and negatively associated with viewing children as hassles, $r(1586) = -.06, p < .05$. These data are important, representing one of the first investigations into hassles/uplifts in parents and how viewing children as hassles/uplifts may relate to well-being and parenting styles (e.g., child-centrism). Future work may focus on whether a child-centric mindset impacts perception of daily hassles/uplifts in a causal manner.

Abstract Name: Impact of Stress on Evaluating Ambiguous Cues in Dominique Chickens

Complex decision making abilities such as the ability to weigh sensory evidence differently based on past memories or current context or be more or less confident have been traditionally restricted to humans. Such abilities are considered non-declarative metacognition: the top-down mediation of how sensory information is interpreted. While there have been some studies on non-declarative metacognition in intelligent species such as chimpanzees and dolphins, our study explores whether chickens are more cognitively complex than we give them credit for. We investigated cognition and decision-making in Dominique chickens (*Gallus gallus*), specifically assessing the extent to which chickens display non-declarative metacognition. We hypothesized that stress changes how chickens assess ambiguous cues. We measured ‘ambiguous cue interpretation’ through judgment bias tests, which capture optimism and pessimism through behavioral responses to ambiguous stimuli. We trained chicks to associate two visual cues with either a food reward or an aversive sound. After the training period, chicks evaluated an ambiguous cue in a “go/go” binary speed accuracy tradeoff task. These tasks were repeated under stressful conditions; stress was induced by playing the sound of wolves howling prior to the task, a known auditory stressor for chickens. Chicks were deemed pessimistic if they treated the ambiguous cue more like the “aversive” cue or optimistic if they treated it more like the “reward” cue. We extracted the latency, accuracy, and pathways of each chick using an AI video tracking software. Preliminary data suggests that chickens evaluate ambiguous cues optimistically under stress-free conditions and pessimistically under stressful conditions. In human psychology and neuroscience studies, that effect is considered meta-cognition. Our findings can also be applied to biomedical research in understanding stress effects on non-human and human cognition, as well as improving current animal welfare by creating stress-free environments and husbandry practices.

Abstract Name: Assessing the Accuracy of Commercially Available Sensor Derived Running Gait Impact Measurement

Running is one of the most common forms of exercise; however, the rates of running related injury are high. Biomechanical analysis of running gait mechanics provides vital data for quantitatively understanding musculoskeletal loading and preventing running related injuries. It is known that high impact loading is related to running related injury risk. Peak positive acceleration (PPA) is a frequently used estimator of joint loading and ground reaction forces during running. Leg and foot mounted inertial measurement units (IMUs) containing accelerometers represent a low-cost option for measuring acceleration. However, the validity of specific commercially available IMUs remains underexamined. This study aims to determine whether lace-mounted commercial grade RunScribe sensors accurately measure acceleration data when compared to research grade running accelerometers. Participants aged 18 – 80 years old with no medical concerns that may impair their ability to comfortably run for 10 – 15 minutes were recruited from the community and screened for pain or injury at the beginning of each data collection session. Sensors for RunScribe (commercial grade) and MyoMotion (research grade) systems were affixed to the lower extremities bilaterally and calibrated while the participant was introduced to the Borg RPE (Rate of Perceived Exertion) scale and asked to maintain an RPE of 10 – 14. Participants ran on a treadmill with their natural foot strike pattern; sensor recording began after several minutes of warm up. 1 minute of data was recorded per indoor trial, with RunScribe and MyoMotion sensors recording simultaneously. The PPA was calculated as the resultant vector of x, y, and z acceleration from both RunScribe and MyoMotion sensor data, and average RunScribe and average MyoMotion PPA was calculated for a 20 second window for each trial. Pearson product moment correlations will be calculated to evaluate a relationship between MyoMotion and RunScribe measured PPA ($p < 0.05$).

Abstract Name: Musical rhythm discrimination and speech-in-noise recognition in older adults: exploring the role of lexical stress sensitivity

INTRODUCTION Speech-in-noise (SIN) recognition, critical for functional independence, is commonly impaired in older adults, often coinciding with age-related hearing loss (ARHL). Although behavioral, epidemiological, and genetic evidence link musicality to hearing and speech outcomes, little is known about how individual differences in music perception abilities relate to SIN recognition in aging. Musical and speech rhythm (i.e. lexical stress) perception are both implicated in auditory processing, yet their relative contributions to SIN recognition remain underexplored. This study examines the role of lexical stress sensitivity as a mediator of the relationship between musical rhythm discrimination and SIN recognition. **METHODS** Adults ≥ 65 years with self-reported normal hearing ($N = 42$ completed) were recruited through the MyHearinG study at Vanderbilt University Medical Center. Assessments included SIN recognition (PRESTO; Tamati et al., 2014), musical rhythm discrimination (Swedish Musical Rhythm Discrimination Test; Ullén et al., 2014), lexical stress sensitivity (TOPsy; Nayak et al., 2022) and questionnaires on demographics and musical experience. Hearing sensitivity was measured using audiometry. Bivariate correlation and linear regression analyses were conducted for variables of musical rhythm discrimination, lexical stress sensitivity, and speech-in-noise (SIN) recognition, while controlling for age, sex, and hearing sensitivity in the better ear. **RESULTS** Musical rhythm and lexical stress, as well as musical rhythm and SIN recognition were found to be correlated and significantly associated, controlling for age, sex, and hearing

sensitivity in the better ear. Lexical stress sensitivity and SIN measures were not found to be associated. Subsequently, mediation did not reveal any indirect or direct effect of lexical stress on SIN recognition. SIGNIFICANCE This research can inform future approaches seeking to disentangle relationships between sensitivity to speech characteristics (e.g., lexical stress) and SIN recognition, contributing to strategies that reduce communication difficulties and social isolation in older adults.

Abstract Name: Examining the Relationship Between Health Behaviors and Academic Performance Among College Students: Exploring the Role of Social Determinants of Health Influencing this Relationship

(Background) College students navigate a critical developmental period characterized by increased autonomy and the establishment of lifelong health behaviors. During this transition, students experience substantial changes in sleep patterns, nutritional habits, physical activity, substance use, and mental health practices, influenced by new environments, social determinants, and academic pressures. Research demonstrates that health behaviors significantly impact cognitive function and academic performance. Inadequate sleep diminishes cognitive abilities, while regular physical activity enhances concentration and memory retention. Despite these established connections, few studies have comprehensively assessed multiple health behaviors simultaneously or explored how social determinants moderate relationships between health behaviors and academic outcomes. This study addresses this gap by examining multiple behaviors concurrently while investigating how social factors influence their relationship with academic success. (Aim/Purpose) This study examines the complex relationships between health behaviors, social determinants of health, and academic performance among college students, and how social factors moderate these relationships. (Approach) This study employs secondary analysis of cross-sectional data from the National College Health Assessment, a nationally representative survey conducted by the American College Health Association. Key variables include health behaviors (physical activity, nutrition, sleep, substance use including alcohol and cannabis, and mental health indicators), academic performance measures (self-reported GPA, perceived performance, class attendance, and academic difficulties), and social determinants. Statistical analyses will be conducted using IBM SPSS Statistics v28.0, analyses including descriptive statistics, correlation and regression analyses to assess behavior-performance relationships, and moderation analyses to examine how social determinants influence these relationships. (Expected Results) Expected findings will identify health behaviors most strongly associated with academic success and reveal how social factors moderate these relationships. Results will inform evidence-based approaches enhancing both academic achievement and lifelong health trajectories. supporting diverse student populations in a college.

Abstract Name: The Effect of Place Attachment Predicting Coffee Shop Purchases and Store Loyalty in Oklahoma City

The purpose of this study was to determine a relationship between place attachment and brand loyalty, and how they collaborate to influence consumer expenditure at coffee shops in Oklahoma City, Oklahoma. Place attachment can be defined as a bond with a particular place or location. There are three commonly recognized aspects of place attachment: 1. place dependence, the functions or qualities of a particular place; 2. place identity, an individual's sense of self that is developed over time because of psychological investment into a setting; and 3. place affect, an individual's emotional connection with a particular place. A sampling frame of coffee shops in Oklahoma City was created using information from the VisitOKC website and a Google search based on City and State. Six coffee shops were randomly sampled with replacement, and QR codes leading to an online survey were posted at tables in participating shops. The survey included 25 questions that evaluated place attachment, brand loyalty, consumer expenditure, and participant demographics. Likert response (1 – strongly disagree to 5 - strongly agree) was used for participant response to place attachment and brand loyalty questions. An example expenditure question: "On average, approximately how much do you spend at this coffee shop per visit (nearest whole number)?" The planned data collection is from mid-December 2025 to mid-February 2026. The study is ongoing, and data will be analyzed once the survey response collection concludes in mid-February 2026. Understanding the effects of place attachment and brand loyalty on consumer expenditure may help local small businesses stay afloat by acknowledging and enhancing characteristics that encourage the development of place attachment.

Abstract Name: Boundless Debt; Rolling Apocalypse: Eschatology and Capitalist Money

A putative break occurred during the age of the Enlightenment, one where the west substituted reason and rationality for religion and the sacred. This is the heart of the "modernization thesis," popularly attributed to Max Weber and his analysis that saw modernity as being centrally about the disenchantment of the world. Following Jason Josephson-Storm, I utilize humanistic analysis informed by critical theory and historical research to problematize this thesis, setting sight on one of the most rational discourses bequeathed by this break: economics, specifically the study of money and finance. Employing a political theological lens, I ask if there exists an eschatology that is immanent in capitalist money. Critical finance theorists such as Hyman Minsky posit an inherent instability and tendency toward crisis within the system, but make no allusions to an end or existential threat. Others, such as Amin Samman and Stefano Sgambati focus on those subordinated by the demands of a debt-oriented system, seeing their plight as a "rolling apocalypse" that appears interminable. My analysis by contrast finds that there exists at least two forms of eschatology immanent in capitalist money. I posit that these emanate from the existence of two distinct categories of debt-derived money— long and short horizon monies. An end is only possible in the collapsing of these two spheres, or the extermination of difference, through either the settlement of all debts or radical redistribution by the state. I identify modern money's birth with the formation of the Bank of England in 1694, arguing that it coterminously forged these idiosyncratic types for the purposes of social reproduction. My intervention elucidates that our monetary system is suffused with notions of the sacred, against ascriptions of positivistic rationality. Further, identifying an immanent eschatology enables a realization of an end and thus potentially a reconfiguring of social reproduction.

Abstract Name: Morag Myerscough: The Secrets to Blending Design and Community

This research explores the work of London-based designer Morag Myerscough, focusing on how her innovative use of color, geometric patterns and community collaboration transforms public spaces into the environments that foster belonging and social connection. Drawing on her up-bringing in a multigenerational household, Myerscough developed an appreciation for creativity, collaboration and inclusivity, which informed her design philosophy. This study analyzes her educational background at Saint Martins School of Art and her career trajectory emphasizing key projects such as The Power at Battersea Power Station and Flock of Seagulls Bag of Stolen Chips at the Folkestone Triennial. The methodology combines qualitative analysis of her public installations with a review of primary sources, including Myerscough's own statements, exhibition records, and media coverage, as well as secondary sources that contextualize her work within contemporary graphic and architectural design. Special attention is given to how community participation is integrated to her projects, including workshops, collaborative painting sessions, and local consultation, highlighting the social impact of her designs on urban environments. Findings indicate that Myerscough's work not only enhances the aesthetic value of public spaces but also strengthens social cohesion and promotes emotional well-being among community members. Her installations exemplify the interplay between individual creativity and collective experience, demonstrating how design can be a catalyst for connection, engagement, and joy. The research concludes that Myerscough's approach provides a model for socially engaged design, offering insights from the future designers seeking to balance artistic expression with community involvement. The study contributes to the understanding of contemporary graphic design as a tool for social impact and underscores the importance of designing public spaces that are both visually stimulating and socially inclusive.

Abstract Name: Constructing Meaning in Campus Protest Coverage: Role Conceptions and Framing in Student Journalism

As the Israel–Palestine conflict has become one of the most visible and divisive movements over the past several years, college newsrooms have emerged as critical sites for negotiating meaning, expression, and power. This study examines how college newspapers frame campus protests and explores potential explanations for those framings. Previous research has found that professional role conception affects how journalists approach their work, the resources they use, and their reporting goals. My study aims to investigate how frames reflect broader journalistic norms while revealing the unique pressures and responsibilities of reporting within educational institutions. This research draws on two sets of data to investigate undergraduate college newspaper coverage of Israel-Palestine in their communities. My first set of data will consist of semi-structured interviews with undergraduate college newspaper editors and reporters at liberal arts colleges across the U.S. I will use these data to explore their overall knowledge of the Israel-Palestine conflict and identify other factors influencing coverage. My second set of data will include

approximately 20 undergraduate student newspaper publications (e.g., articles and op-eds) on Israeli-Palestinian protests. I will conduct a content analysis to identify relevant frames in protest coverage. My coding schema will draw on prevalent frames within the protest paradigm and literature on media representations of the Israel-Palestine conflict more broadly. I anticipate that perceived state and campus environments will contribute to reporters' and editors' self-censorship, even if governments and colleges do not directly regulate college newspapers. I also expect that newspaper actors and publications will position campus administration as the voice of authority, but activist voices will still remain in coverage due to the influence of student networks. My multi-methods approach will allow me to detail connections between journalistic role conception and the use of frames.

Abstract Name: Cryptocurrency: A Legal and Tax Analysis

AbstractWhen it comes to taxing currency, it has been quite complex. Digital assets like Bitcoin and Ethereum are becoming more common assets to own and invest in. However, many taxpayers cannot comprehend how to report their cryptocurrency accounts and transactions to the Internal Revenue Service (IRS). There are other challenges as well with investing in cryptocurrency, such as staking, mining, and airdrops. The IRS has to rigorously update its regulations to keep up with this digital environment. This paper looks over various cases, such as the Jarrett case, where a taxpayer couple filed against the Internal Service Revenue for their disagreement on how it taxes on stakeholder rewards. Although it is now resolved, it exemplifies how legal proceeds can impact how future digital assets can be taxed. Moreover, the paper demonstrates struggles from the taxpayers' side with filing those taxes and the efforts from lawmakers to make more comprehensive and accommodating guidelines in this financial world.

Abstract Name: Effects of Fast Mimicking Diet on Behavior and Alzheimer-Pathology in EFAD Mice with APOE3 versus APOE4 Genotypes

Alzheimer's disease (AD) is the most common type of dementia with age being the main primary risk factor. In addition, there are several other factors that contribute to the development of late-onset AD. For instance, biological sex is linked with women having higher prevalence and genetic variations in apolipoprotein E (APOE) gene is linked with allele 4 (APOE4) being at a higher risk than allele 3 (APOE3). Given these relationships and the potential effectiveness of dietary interventions against aging outcomes, we investigated whether fast mimicking diet (FMD) influences the AD-related behavioral and pathological features in young adult EFAD mice. Upon comparing AD-related pathology, we observe a statistically nonsignificant trend in female EFAD mice of higher plaque number with APOE4 being higher than APOE3 ($p = 0.06$). However, we observe no significant differences in the total number of thioflavin-identified plaques in the cortex between

FMD and control diet in males ($p = 0.58$) or females ($p = 0.92$). When assessing the size of plaque deposits, there is a nonsignificant trend for FMD groups to have a lower percentage of large plaques ($>100\ \mu\text{m}$ diameter) compared to the control, across both male ($p = 0.14$) and female ($p = 0.22$) mice. Next, we assessed the overall motor, exploratory and anxiety in open field maze and found a nonsignificant trend in the time spent in the center zone of the maze between APOE3 and APOE4 in male ($p = 0.07$) but not female mice. Overall, these initial results suggest that FMD has modest effects on AD-related pathology and behavior in young adult EFAD across biological sex and APOE genotype. These preliminary findings contrast with our recently observed protective effects of FMD in aged male EFAD mice, suggesting that FMD may be most effective in the context of aging and or late-stage of disease.

Abstract Name: A Myoelectric Prosthesis Utilizing A Convolutional Neural Network and Signal Processing

Commercially available myoelectric prostheses available to transradial amputees utilize electromyography (EMG) sensors to observe electrical signals from superficial muscle contractions and control robotic fingers; yet they often have several flaws, including adaptability and dexterity. The current devices require users to learn awkward muscle patterns, as the EMG placement and gesture recognition has not considered how humans would normally think about moving their hand. Additionally, the number of available gestures are more limited, as the devices are threshold-based and do not sample enough muscles. This work seeks to address these issues by creating a low-cost myoelectric prosthetic device, utilizing a 1-D ResNet Convolutional Neural Network (CNN). This is a machine learning model which can learn to recognize patterns in the electrical signals generated naturally by the user and translate them into 3-4 hand gestures, thus the device adapts to the user's muscles rather than vice versa. The CNN has been trained offline on labeled segments of EMG signals, which have been captured from the forearm as gestures such as open, close, and pinch are repeated, thus building a reference from which the network learns. The work has also included designing hardware which captures the desired signals and filters unwanted interference, utilizing a smoothing function to preprocess the signals, and preliminary results with the CNN have reached a classification accuracy of 97%. Future work includes ultimately embedding the neural network on a microcontroller and completion of the signal processing hardware designs, thereby completing the goal to create a system which will sense and recognize the user's intention and control an adaptable, multi-gesture robotic hand while maintaining user safety.

Abstract Name: Molecular characterization of Pepino mosaic virus and species identification of tomato fruits sold at local and international grocery stores in Maryland

Tomatoes (*Solanum lycopersicum* L.) are widely consumed in the United States and globally due to their nutritional and health benefits. U.S. tomato supply comes from both domestic production and imports—mainly from Mexico and Canada—resulting in diverse varieties that require molecular identification and characterization. Tomato crops, however, face significant abiotic and biotic threats. Among biotic stressors, pathogenic infections by Pepino mosaic virus (PepMV) and Tomato brown rugose fruit virus (ToBRFV) pose major challenges. PepMV, a member of the family *Alphaflexiviridae* and genus *Potexvirus*, causes fruit discoloration, cracking, and scarring, and frequently co-infects with ToBRFV, compounding damage and economic loss. Early detection, mutational analysis, and identification of highly susceptible tomato species are essential for developing effective management strategies. This study investigates the molecular characterization of PepMV co-infecting with ToBRFV in tomato fruits sold in Maryland. Symptomatic tomato fruits were collected from various grocery stores for RNA and DNA extraction using QIAGEN RLT buffer. Extracted RNA was converted to complementary DNA and subjected to reverse transcription polymerase chain reaction (RT-PCR) and Sanger sequencing for viral confirmation. DNA extracted from the same samples was quantified and amplified using the *rbcL* marker to accurately identify tomato species. RT-PCR detection revealed PepMV in 16 of 47 samples (34.04%) and ToBRFV in 46 of 47 samples (97.87%). Co-infection of both viruses occurred in 16 samples (34.04%). BLAST analysis showed PepMV isolates closely related to strains from Spain, France, Germany, and Florida, with identities ranging from 98.48–100%. Mutational analysis identified nucleotide variation at position 434 (A/G) and an amino acid change at position 130 (S/N). *rbcL* sequencing produced matches with 100% identity to multiple *Solanum* species, including *S. lycopersicum*, *S. sitiens*, *S. pennellii*, *S. arcanum*, *S. habrochaites*, *S. cheesmaniae*, *S. huaylasense*, *S. neorickii*, *S. pimpinellifolium*, and *S. corneliomuelleri*. Additional analyses are ongoing and final conclusions will be provided upon completion.

Abstract Name: Deployment of *rbcL* and *matK* barcodes for phylogeny and genetic diversity of *Capsicum* spp. in Maryland

Pepper (*Capsicum* spp.) of the family *Solanaceae* is cultivated worldwide for its nutritional, medicinal, culinary, and ornamental value. More than 38 species have been documented globally, yet limited information exists on the DNA barcoding and genetic diversity of peppers sold in grocery stores in Maryland. DNA barcoding, which relies on short standardized DNA regions, provides a powerful tool for species identification and diversity assessment, particularly when morphological traits are inadequate due to similarities among species. This study employs two markers—ribulose-1,5-bisphosphate carboxylase/oxygenase large subunit (*rbcL*) and maturase K (*matK*)—to barcode and evaluate genetic diversity within grocery-sourced *Capsicum* accessions. Using multiple markers is widely regarded as the most robust approach for phylogenetic analysis, genetic diversity assessment, and species discrimination. Thirty-six pepper accessions were collected from various stores, and DNA was extracted from seeds and fruit tissues. Extracted DNA was quantified via spectrophotometry, diluted, and amplified using PCR with *rbcL* and *matK* markers. Amplicons were Sanger sequenced and analyzed for mutations (insertions, deletions, transitions, and transversions), intra- and inter-species variation, BLAST matches, and phylogenetic relationships. Maximum Parsimony phylogeny grouped the accessions into eight clusters using *rbcL* and four using *matK*. Some peppers sold under the same commercial name clustered differently, indicating species-level discrepancies. For example, samples labeled as Sweet Snaps (AH-3, AH-4, AH-5) were distributed across groups A, B, and D, while Jalapeño samples AH-15 and VM-3F clustered separately. Anaheim samples

VM-1 and EP-4 grouped together but differed at the sub-group level. A point mutation at position 378 (A/G) in *rbcL* distinguished several accessions, while *matK* revealed transversions (A/T) and insertion–deletion events across the 36 samples. Although further analyses are ongoing, *rbcL* appears more effective than *matK* for species identification, phylogenetic resolution, and detecting genetic variability in grocery-sourced *C. annuum* accessions. Both markers revealed multiple pepper species marketed under single names.

Abstract Name: Climate-Induced Flooding and Healthcare Utilization in Nebraska: A Retrospective Analysis of Inpatient and Outpatient Encounters (2020-2023)

The purpose of this study was to examine the relationship between climate-induced flooding events and healthcare utilization in Nebraska. By analyzing inpatient and outpatient hospital encounter data alongside flood records, the study aimed to identify patterns in healthcare demand during and after flooding incidents. Flooding is among the most frequent and damaging natural disasters, with evidence linking climate change to increased flood severity. Flood events disrupt access to healthcare, intensify chronic illnesses, and increase infectious disease incidence. Vulnerable populations, including older adults and individuals with comorbidities, face disproportionate risks. Severe floods in Nebraska, including the March 2019 event, have had lasting impacts, highlighting the importance of examining healthcare utilization changes to guide resilience strategies. Healthcare utilization data (89,000 inpatient and 750,000 outpatient encounters) were obtained from the Nebraska Hospital Association (2020–2023). These were linked with county-level flood records from the National Oceanic and Atmospheric Administration (NOAA). Descriptive analytics, including PivotTables and PivotCharts, were used to identify demographic trends, leading diagnoses, and alignment between flooding events and emergency department visits. Diagnoses were grouped by clinical category, and facility-level utilization patterns were assessed statewide. Findings indicated alignment between flood events and increased healthcare utilization, particularly for conditions such as type 2 diabetes, respiratory infections, and gastrointestinal illnesses. Older adults and patients with chronic conditions accounted for a disproportionate share of admissions. Urban medical centers had the highest volumes, raising concerns about rural access disparities. While causation could not be definitively established due to limitations, results suggest a meaningful association between flooding and healthcare demand. These findings underscore the importance of equity-focused disaster planning, improved data granularity, and integration of social determinants of health metrics to enhance resilience against climate-driven health challenges.

Abstract Name: Capturing dialectal and hierarchical representations for the evaluation of English developmental speech

Research on children's speech patterns during language development informs clinical and educational practices. Mainstream American English speech developmental norms used for clinical/research purposes in the country (Smit et al. 1990; 1993a, b) are outdated and do not reflect social and regional dialectal variation. Similarly, previous cross-linguistic works do not account for the effects of variant language input on children's speech acquisition. To address this gap, Babatsouli et al. (2025) first introduced methodological procedures that include a phonological assessment tool, a demographic survey, and a language input assessment procedure to investigate children's English speech production in the Louisiana family context. The phonological development test comprises 120 child and culturally appropriate words and is representative of English phonotactics. The linguistic input assessment comprised a reading and retelling task. The present work examines the phonotactic content of the speech elicitation test from a non-linear theoretical perspective (Bernhardt & Stemberger, 1998; Mohanan, 1992; Rice & Avery, 1995). Nonlinearity relies on the view that autonomous phonological units—segments, syllables, and prosodic words—have underlying hierarchical representations that are not directly observable but interact across multiple tiers, from features to the phrase level. Our results inform the frequency distributions of singleton segments, consonant clusters, as well as syllable and whole-word structures represented in the test materials. We report and compare our findings with previously used assessment tests in the literature and identify those features of the assessment test that uniquely capture segmental and structural complexity in the English-speaking children's developmental speech in the sociolinguistic context of Louisiana. Keywords: child; nonlinearity; phonological development; English; dialects; Louisiana

Abstract Name: An Examination of Retirement Plans Across Universities in the United States

This research examines faculty retirement plans across U.S. university systems in all 50 states. The study evaluates defined benefit (DB) and defined contribution (DC) plans, focusing on key data points such as contribution rates, vesting schedules, benefit formulas, and plan flexibility. By analyzing data collected from a diverse set of institutions, the research identifies trends in retirement offerings, including the prevalence of stable DB plans versus adaptable DC plans, and it assesses their implications for employee and employer obligations. Preliminary findings highlight a spectrum of retirement models, with some universities prioritizing predictable benefits through DB plans and others emphasizing flexibility via DC plans. The study explores how these variations impact faculty retention and satisfaction, offering insights into the strengths and limitations of different retirement structures. The goal is to provide a comprehensive comparison of retirement benefits across U.S. universities located in all 50 states, contributing to discussions on enhancing faculty retirement security and for policy recommendations for higher education.

Abstract Name: Developing a Simplified Predictive Model to Estimate Embodied Carbon of Steel Moment-Resisting Frame Building at Early Design Stage

Early stages of building design significantly influence a building's environmental impact, leading to more environmentally sustainable construction. Life cycle assessment (LCA) is a quantitative approach to evaluate the environmental impacts of a building through its production, construction, operation, and demolition. Despite LCA's potential for evaluating post-construction environmental impacts, it is not a common component of early design of buildings due to the fast nature of this stage and the challenges of performing a large number of LCAs for different design variations. Therefore, this study develops a predictive model connecting building design and geometry parameters to embodied carbon. The predictive model was derived from a database of 60 steel moment-resisting frame buildings of varying geometries and designs. The building's embodied carbon was estimated using Athena Impact Estimator software in terms of global warming potential (GWP). A statistical analysis was then performed to identify the building parameters associated with GWP. To address the possible limitations of Athena Impact Estimator, a subsequent sensitivity analysis was conducted among five of the buildings in the database by replacing a portion of the software's GWP data. These five buildings instead use GWP data from an environmental product declaration released by the Nucor corporation. Results suggest a strong correlation between embodied GWP and gross floor area and frame weight, with a coefficient of determination (R^2) of 97.8% over the entire building database. The results of the sensitivity analysis show an overall decrease in carbon when utilizing the data from Nucor. The predictive model can serve as a design aid for minimizing environmental impacts of steel-framed buildings, and support similar approaches for other structural systems.

Abstract Name: Triggering Stringent Response in *Microcystis aeruginosa* by Nutrient Limitation with Implications for Oyster Filter Feeding

The Mississippi-Atchafalaya River system (MARS) transports enriched freshwater and cyanobacterium *Microcystis aeruginosa* to Louisiana estuaries during flooding events. Cyanobacterial blooms have become increasingly common in estuaries and represent a changing food supply for filter feeders like oysters. As *M. aeruginosa* blooms travel downstream, they are exposed to higher salinities and reduced nutrient concentrations. These stressful conditions may induce osmotic stress, trigger cell lysis, and release microcystins (MC). Nitrogen limitation and low salinity may trigger stringent response (SR), a stress-induced mechanism that upregulates production of extracellular polymeric substances (EPS) containing carbohydrates and proteins that protect the cell membrane, help form colonies, improve photosynthetic efficiency, reduce oxidative stress, and increase cell MC quotas. Previous studies have examined the effects of elevated salinity on MC production and failed to account for nutrient stressors. This pilot study tested whether nitrogen limitation and increased salinities stimulate SR in a toxic culture of *M. aeruginosa* with implications to observe the effects of colony size and EPS on *Crassostrea virginica* feeding. We measured particle size (μm), whole MC concentrations (particulate and dissolved), and photosynthetic efficiency (F_v/F_m) over 48 hours across varying nitrogen availability (100–0.01%), and salinity (0, 5, 10). Preliminary results indicated no significant differences ($p \geq 0.05$) in particle size between the control treatment (100% nitrate at salinity 0), the most nitrogen-limited (0.01% nitrogen) and salt-stressed (salinity of 5 and 10) treatments throughout the experiment (48 hours). Optical densities – a proxy for whole water MC concentrations – were slightly highest for cultures in the lowest nitrate (0.01%) and salinity (0) treatment (Mean $\pm$ SE = 0.326 ± 0.005 ; $H(6) = 11.7$, $p = 0.07$). These results suggest that the lack of SR in *M. aeruginosa* is potentially caused by low starting cell concentrations, and may represent density dependence for initiating SR in *M. aeruginosa*.

Abstract Name: Period Pieces: Challenging Taboos Surrounding Menstruation in Contemporary Art

This research is a discussion of my virtual exhibition that challenges the shame and stigmatization surrounding menstruation by showing menstruation as a beautiful natural bodily cycle. The exhibition includes seventeen different contemporary artworks on the topic. These artworks do not hide the bloody side of menstruation, but blatantly confronts it, to show menstruation as a bold and empowering experience. The layout of my virtual exhibit in the shape of a uterus and ovaries creates an immersive space that leads the visitor into the realities of menstruation. Inside the exhibit there are vivid red walls, with deep burgundy floors, and a white ceiling. These colors, which are reminiscent of the interior of the human body and period blood, bring to life the shape of the museum, placing the visitors in the reality of menstruation, not purely as an abstract shameful fact, but as a daily lived experience. In the canal, central uterine space, and ovaries there are contemporary artworks that depict the physicality and realities of menstruation. Every piece I chose in this exhibit defies the negative rhetoric surrounding menstruation, showing that the hidden should be seen, the private should be public, and the shamed should be sacred. The exhibit as a whole emphasizes that menstruation is not this uncomplicated sanitized subject, but messy, painful, beautiful, and transformative.

Abstract Name: Resilience and Adaptability: Hybridity of New Orleans Voodoo

This paper examines the hybridity of Voodoo in New Orleans, Louisiana in the contemporary period. By analyzing Voodoo, I will demonstrate the adaptability and resilience of the people who practice this religion under societal oppression, by appropriating local cultural practices. The introduction will examine the origins of Vodou in West Africa, as well as how enslaved Africans brought Vodou to Haiti, through the African transatlantic slave trade. Section two will analyse how Vodou practices were introduced by enslaved Africans and Haitian refugees in New Orleans. Where Voodoo was transformed by the Native Americans costumes and religious practices, in addition to being forcibly adapted to both the local Creole cultural traditions, and Catholicism, brought by French and Spanish colonizers. The third section will examine Voodoo in New Orleans in the contemporary time period, with an emphasis on its resilience and adaptability. The final section of the paper will provide formal and historical examination of three Voodoo inspired artworks that serve to demonstrate the rich multicultural significance of Voodoo in New Orleans. Therefore, this study will demonstrate the importance of Voodoo in New Orleans as a way for enslaved people and refugees to preserve their religious and cultural identity under strict colonial oppression and cruelty. This research into the cross-cultural resilience of New Orleans Voodoo ultimately aims to demonstrate how despite the forced cultural blending, adaptation, and resilience Voodoo has persisted as a huge part of New Orleans' artistic, spiritual, and communal culture.

Abstract Name: Forest Restoration Proves Critical for Animal Biodiversity Recovery in The Amazon

The Amazon is the most biodiverse terrestrial landscapes on earth but is experiencing widespread degradation which threatens biodiversity and ecosystem function. Forest restoration is a great way to restore forests, biodiversity, ecological functions, and sequester carbon. While forest growth and restoration are quantified through remote sensing, fauna detection and responses are harder to quantify. We assessed the recovery of wildlife at the BDFFP in the Amazon after forest restoration almost 50 years ago. We deployed camera traps across the recovering BDFFP landscape in continuous forest, secondary forest, and forest fragments (100ha, 10ha, 1ha) to understand terrestrial bird and mammal recovery across the landscape. Camera images were processed using AI-assisted classification and expert verification to identify all birds and mammals. We compared the number of species and foraging guilds present in each recovering forest type to continuous forest sites. We detected 50 species of terrestrial birds and mammals, 36 in continuous forest, 33 in Secondary Forest, 36 in 100ha, 29 in 10ha, 20 in 1ha forest. Secondary forests 100ha and 10ha forests had relatively similar faunal communities to continuous forests, indicating greater recovery. For six species we have historical and modern abundance data and assessed how they changed in 40 years. Most species populations increased, indicating recovery with forest growth. Results capitalize on new and emerging technologies, such as AI, to assess and demonstrate biodiversity recovery from tropical forest restoration which could be critical to averting population declines in tropical animals. Thus, technology-informed management is essential for effective ecosystem and biodiversity recovery.

Abstract Name: Beyond the Surface: A Neurobiological Comparison of Human and Orca Brain

This study investigates the neural foundations of intelligence and social behavior in humans and orcas, two species known for complex cognition and advanced social structures. Drawing on previously published anatomical, behavioral, and neurological research, this systematic review compares how brain structure and function shape cognitive abilities and social dynamics across both species. Background literature shows that humans and orcas each possess specialized brain regions supporting communication, emotion, memory, and problem-solving, though their neural systems reflect distinct ecological and evolutionary pathways. Data for this review were taken from peer-reviewed studies examining major neural structures—including the cerebral cortex, paralimbic lobe, limbic system, and sensory-processing regions—along with documented examples of communication, cultural learning, and cooperative behavior. Special attention was given to neural features associated with high-level cognition, such as spindle neurons and regions involved in language, auditory processing, and social-emotional integration. Synthesized findings indicate that humans exhibit strong

cortical specialization for language, abstract reasoning, and symbolic thought, supported by an extensively developed prefrontal and association cortex. Orcas, by contrast, display an enlarged paralimbic lobe, advanced auditory networks, and neural adaptations enabling echolocation, complex social bonding, and culturally transmitted behaviors. Despite these differences, both species share neural markers of social complexity, including spindle neurons linked to empathy and sophisticated social cognition. Overall, the review demonstrates how distinct neural architectures can yield convergent forms of intelligence, offering insight into broader patterns of brain evolution. It concludes that integrating neuroscientific research with conservation strategies is essential for developing ethical, evidence-based approaches to protect cognitively advanced species such as orcas and to preserve the social and ecological systems that sustain them.

Abstract Name: Exploring Male College Students Perceptions on Sexual Health and Decision-Making

Sexual health is a critical aspect of college students' well-being as young adults encounter new independence, relationships, and risk-taking opportunities. Yet male students remain underrepresented in sexual health research and programming, limiting understanding of their experiences and needs. This study explored how male undergraduates perceive and navigate sexual health while in college. Semi-structured interviews were conducted via Zoom with 12 male college students ages 19–22, all of whom identified as African American, though this was not a recruitment criterion. As such, the findings may reflect the unique perspectives of this demographic group. Interviews addressed sexual health knowledge, influences, prevention practices, and access to care. Audio recordings were transcribed and analyzed using thematic analysis to identify shared patterns in perceptions and decision-making. Four interconnected themes emerged. (1) Learning from Everywhere Except Experts: Most participants learned about sex through media, peers, and early exposure online, with formal education described as inconsistent or incomplete—especially regarding STI symptoms and partner communication. (2) Risk as a Negotiation: Condom use was often viewed as necessary only at the beginning of sexual relationships, with some participants admitting they relaxed precautions based on trust, routine, or pleasure. Encounters with STIs heightened awareness but also introduced shame and selective disclosure. (3) Social Pressures, Private Choices: Peer expectations around masculinity and sexual activity were influential, yet participants expressed personal responsibility and emotional self-regulation in deciding when and with whom to have sex. (4) Resources Exist, but Engagement Lags: Although campus reproductive health services were considered accessible and judgment-free, participants reported that not all men actively seek or use these supports unless they are already facing a problem. Together, these findings reveal a complex balance of confidence and uncertainty among male students navigating sexual health. Enhancing proactive, stigma-free education tailored to men may strengthen their ability to make informed, safer decisions.

Abstract Name: Hydrogen Gas-Infused Bandage Device for Treating Bedsores Wounds and Heart Complications

Decubitus ulcers (bedsores) affect 2.5 million Americans annually, costing the US healthcare system upwards of \$11 billion. Current treatments like negative pressure therapy and oxygen gas therapy are bulky, hard to use, and demonstrate inconsistent clinical results. Recently, scientists have been investigating molecular hydrogen as a therapeutic agent that nullifies reactive oxygen species generation in ischemia-reperfusion (I/R) injury, the biochemical process behind conditions like bedsores and heart attacks. While the results are promising, current methods of hydrogen delivery, namely the consumption of hydrogenated water and the inhalation of hydrogen gas, target the entire body and experience leakage during administration, limiting their clinical feasibility. Our central research question is whether a hydrogel-integrated electrochemical device can generate, trap, and locally deliver hydrogen gas to effectively treat these injuries. To address this, we embed an electrochemical hydrogen gas generation device within a thin gel bandage, using the gellified water (hydrogel) within the bandage as a source for hydrogen. The hydrogel traps the generated gas, creating hydrogen bubbles that diffuse directly into the desired organ, treating these wounds and heart injuries in a precise and cost-effective way. We rigorously explore the biophysics of the hydrogen gas hydrogel, measuring its diffusion kinetics, gas storage, and generation capabilities. Furthermore, we validate the therapy across scales. Firstly, on a cellular level by defining its protective biochemical pathway in mouse heart cells, and later macroscopically by demonstrating reduced injury and accelerated healing in live rat hearts and mouse ulcer models. All in all, our work provides a novel approach in drug delivery and gas-based therapies to precisely and effectively treat I/R injury-derived illnesses, unlocking the potential for hydrogen-based therapies to be used for unexplored I/R injury illnesses such as frostbite, organ preservation, and stroke.

Abstract Name: Algorithmic Isomorphism: Agentic AI and the Structural Decay of Strategic Variance in a Homogeneous Optimization Regime

Neo-institutional theory posits that organizations in uncertain environments tend to copy one another to survive—a phenomenon DiMaggio and Powell (1983) termed the “iron cage.” This study argues that the widespread deployment of standardized Agentic AI (e.g., enterprise agents built on shared foundational models) accelerates this process into a hyper-efficient “Algorithmic Isomorphism.” We posit that as firms delegate strategic micro-decisions to identical third-party models, they inadvertently import a shared “global optimization logic” that erodes idiosyncratic advantage, creating a “Strategic Monoculture.” Methodologically, the paper develops a comparative theoretical framework to characterize the industry-level impact of shared AI adoption. It contrasts two regimes: (1) a Human Regime, characterized by diverse decision-making driven by bounded rationality and local culture, and (2) an Algorithmic Regime, in which agents optimize a common objective function using overlapping training corpora. The analysis demonstrates that as dependence on standardized AI scales, the variance of strategic choices collapses toward uniformity, effectively commoditizing management at the margin. Theoretically, the paper formalizes a “Convergence Paradox,” predicting that while AI adoption increases firm-level operational efficiency, it compresses industry-level profit margins by eliminating the differentiation required to sustain competitive advantage. The findings imply that in an AI-driven economy, lasting success will not come from adopting

intelligence per se, but from designing and customizing the unique objective functions that intelligent systems are asked to optimize.

Abstract Name: Title: The Coasean Collapse: Agentic AI and the Re-Optimization of Firm Boundaries in a Low-Transaction-Cost Economy

The Theory of the Firm rests on Coase's (1937) insight that organizations arise to economize on transaction costs: when the cost of coordinating production internally is lower than transacting in the market, firms expand; when the reverse holds, they contract. Building on Coasean and Williamsonian economics, this paper argues that the deployment of Agentic AI—autonomous contracting, monitoring, and coordination algorithms—is pushing core transaction costs toward a structurally lower regime, triggering a “Coasean Collapse” in the efficient scale and scope of the firm. We posit that the vertically integrated, managerially intensive corporation becomes progressively dominated by “AI-orchestrated swarms”: decentralized networks of specialist talent coordinated by algorithmic protocols rather than hierarchical authority. Methodologically, the paper develops a comparative economic framework that evaluates the total cost of executing a project under two organizational forms: (1) a traditional managerial hierarchy, subject to bureaucratic delay and supervision limits, and (2) an AI-mediated “flash organization,” modeled as a low-friction talent market with automated search, matching, and enforcement. By decomposing transaction costs into search, bargaining, and enforcement components, the analysis demonstrates how Agentic AI shifts the optimal boundary of the firm, drastically shrinking the region of activities for which internal employment contracts are cost-minimizing. Theoretically, the paper formalizes a “Dissolution Hypothesis,” predicting the rise of “headless brands”: entities with substantial output, brand presence, and asset control but negligible permanent staff. The results recast the corporation not as a timeless unit of analysis, but as a historically contingent solution to high transaction costs, now under structural pressure. The findings generate testable implications for employment, unionization, and antitrust policy, suggesting that regulatory frameworks built for a high-friction economy may be systematically misaligned with the emerging Coasean landscape.

Abstract Name: Capacity-Constrained Attention: How Algorithmic Feeds Reshape Viral Marketing and Brand Equity

This paper develops a formal model of attention contagion on digital platforms where user attention is treated as a scarce, capacity-constrained resource. Departing from classical epidemiological models (SIR) often applied to marketing, we define the state of the system not at the user level, but at the level of limited "attention slots" over time. In our model, a user has a finite number of slots per period that can be empty, occupied by a focal meme, or filled by competing content. A platform ranking function—incorporating watch time, click-through rates, and diversity constraints—governs the probabilistic transition of content into these slots. Within this framework, we introduce the Attention Reproduction Number R_A : the expected number of additional attention slots generated by a single occupied slot. We derive how R_A and equilibrium outcomes shift depending on feed saturation and algorithmic policies. Our analysis yields three key findings for marketing strategy: (i) highly contagious but rapidly fatiguing "viral" content is often outperformed in cumulative attention by slower-burn narratives under diversity-oriented ranking algorithms; (ii) in saturated environments, increasing contagiousness yields sharply diminishing returns due to slot cannibalization; and (iii) algorithms maximizing short-term watch time systematically underprice long-term brand equity. We conclude by discussing implications for designing healthier attention ecosystems and robust brand strategies in algorithm-driven markets.

Abstract Name: The Valuation Paradox: Structural Insolvency Signals in AI-Centric Firms Under GAAP Intangible Asset Recognition

The rapid proliferation of Generative Artificial Intelligence (GenAI) has exacerbated a fundamental disconnect between economic reality and statutory financial reporting. Under standard U.S. accounting rules (GAAP), internally generated intangible assets—such as the massive computing and development costs required to build Large Language Models (LLMs)—must be recorded as immediate costs rather than capitalized as long-term assets. This paper argues that this industrial-era reporting regime precipitates a “Valuation Paradox”: firms that rely heavily on proprietary AI models appear systematically asset-poor on their balance sheets, generating artificial distortions in standard performance and solvency indicators. Methodologically, the paper develops a comparative valuation model to capture the mechanical divergence between reported book value and true economic capital. By deriving a modified accounting identity that incorporates a measurable “Hidden Capital” factor, the study isolates the specific mechanisms that cause AI-heavy firms to exhibit symptoms of technical insolvency despite robust operating performance. The analysis demonstrates that as a firm’s investment in AI scales, the likelihood of false signals of financial distress approaches certainty under current constraints. Theoretically, the paper interrogates the viability of the accounting “Conservatism Principle” in the digital age. It posits that the systematic exclusion of AI training costs creates a massive informational blind spot, compelling investors to infer the value of hidden capital from noisy, incomplete disclosures. The findings suggest that traditional financial metrics are materially biased when applied to AI business models, calling for a recalibrated “Probabilistic Asset Recognition” framework that better aligns financial statements with the dynamic risk profile of the GenAI economy.

Abstract Name: The Double-Edged Sword of AI: Its Impact on College Students' Mental and Physical Health

The rapid integration of artificial intelligence (AI) tools into college life has created both opportunities and challenges for student well-being. Academic AI platforms like ChatGPT can reduce workload and ease academic pressure, while AI-based fitness and wellness applications can promote healthier physical and emotional habits. This study aimed to explore impacts of AI on university students by evaluating its academic influences and its effects on general health. Mixed-methods research was administered to 48 college students in The United States, with 59% male, 41% female, and mostly sophomores, consisting of 12 questions and two open-ended prompts. The questionnaire included two distinct domains: (1) students' use of AI for physical activity support, motivation, and mental health management, and (2) academic reliance on AI and its association with stress reduction and academic confidence. Quantitative data were analyzed for correlations, and qualitative responses explored students' perceptions of benefits and concerns. Correlation analysis revealed a prominent result. Students who felt that AI fitness apps made exercise goals more manageable also showed stronger motivation to pursue those goals ($r = .79$). A moderate correlation emerged between relying on AI for homework and feeling anxious about completing assignments independently ($r = .50$), suggesting that greater dependence may relate to lower academic confidence. Students also reported increased awareness of their physical activity through AI apps were moderately more likely to feel that AI helps break fitness goals into achievable steps ($r = .58$). Qualitative comments reflected this tension, portraying AI as both helpful and a source of reliance. Overall, findings highlight AI's dual role: it can enhance students' health-related motivation while simultaneously contributing to academic overdependence. Future research should investigate how patterns of AI engagement evolve over time and develop evidence-based recommendations for fostering balanced, intentional, and developmentally supportive uses of AI within higher education contexts.

Abstract Name: In situ hybridization of zebrafish embryos to study ER stress on neuronal development

In cells, the accumulation of misfolded or unfolded proteins activates the unfolded protein response (UPR), a stress pathway triggered by conditions such as heat shock or nutrient imbalance. UPR activation is implicated in human diseases, including several neurodegenerative disorders such as Alzheimer's and Parkinson's disease. Although the UPR protects cells by preventing excessive buildup of unfolded proteins in the endoplasmic reticulum, prolonged activation can trigger apoptosis, leading to neuronal loss. Because ER stress can induce cell death, it is considered a potential driver of neurodegeneration. The timing of translation re-initiation is critical, restarting too early can lead to apoptosis and waiting too long prevents the production of essential proteins. The proteins GADD34 and CReP are central to restarting translation. Studies show that inhibiting this process can protect neurons after stroke and prevent degeneration in models of Parkinson's Disease and Charcot-Marie-Tooth disease, showing this pathway plays important roles in both the central and peripheral nervous systems. The goal of this project is to use zebrafish to examine how mutations in GADD34

and CReP affect neuronal development or survival. Zebrafish embryos are ideal because they are transparent and share similarities with humans. We chose in situ hybridization to visualize the nervous system and detect changes in neuronal gene expression. Three zebrafish genes were cloned to target different neurons; *elavl3* (pan-neuronal), *isl1* (peripheral nervous system), and *neuroD* (developing neurons). We will stain wild-type, GADD34, and CReP mutants in parallel and increase sample numbers for statistical significance. We will then repeat the experiments with *isl1* and *neuroD* probes and later expose embryos to stress-inducing drugs to assess how stress influences neuronal development in these mutants.

Abstract Name: Water Soluble Binders in Lithium Ion Batteries

The current standard of binding agents in lithium-ion batteries is a mixture of polyvinylidene fluoride (PVDF) dissolved in N-methyl-2-pyrrolidone (NMP) which is thermally and chemically resistant and is highly adept at adhering electrode material together. However, NMP is highly toxic and a known teratogen, which poses severe health risks as the disposal and general handling of batteries is uncontrollable to a certain extent. Therefore, it is pertinent to identify and test alternatives, ideally ones that are water soluble, to this industry standard to mitigate the health risk while preventing cycling performance loss of the batteries. To achieve this, several ratios of water-soluble polymers were created and used in place of the industry standard. Water was chosen as the solvent due to its abundance and cost effectiveness. The primary polymers explored are: Carboxymethyl Cellulose (CMC), Styrene-Butadiene Rubber (SBR), and Polyacrylic Acid (PAA). Graphite anode powder was used as the standard electrode largely due to cost, with various ratios and mixtures of the aforementioned polymers being applied in the standard binding process to ascertain both general malleability and adhering properties as well as electrochemical prowess. For each test group, at least two batteries were created, and cycled 100 times in a manner that would simulate real world uses. These were then plotted with a clear goal of at least 90% retention. Standalone PAA was the best performer, and increased attention will be given in the future as research continues, however some literature also points to a combination of CMC/SBR being highly adept at maintaining the volumetric expansion of silicon electrodes as it undergoes lithiation. Therefore, both should be explored in more detail.

Abstract Name: Impact of Dynamic Stretching on Functional Movement and Range of Motion

Stretching prior to activity is known to increase flexibility and range of motion, and an insufficient warm-up elevates the risk of injury (Opatowicz et al., 2022). Much of the existing research on stretching has focused on static stretching, which over the past 25 years has been shown to decrease performance, prompting a shift

toward emphasizing dynamic stretching (Konrad et al., 2023). Current literature primarily supports dynamic stretching for enhancing athletic performance; however, far less attention has been given to its effects on essential functional movement patterns used in everyday life. The purpose of this study is to examine whether dynamic stretching influences range of motion and functional movement. Functional training and the Functional Movement Screen (FMS) were used to assess movement quality and participants' ability to perform tasks without pain. Middle-aged male and female adults volunteered for the study, which used a one-sample experimental design. Participants completed both a structured ten-minute dynamic stretching warm-up, and during a separate trial remained static before undergoing FMS testing and range-of-motion (ROM) measurements which served as the dependent variables. The order of trials performed was randomized. A paired-sample t-test will be used to determine whether ROM measurements differed significantly between pre- and post-dynamic stretching, with alpha set at $p \leq 0.05$. A Chi-squared analysis will be used to determine whether FMS scores differed significantly. We anticipate the results will indicate whether there is a significant improvement in both ROM and FMS scores. These findings may contribute to the growing evidence supporting dynamic stretching and clarify whether it should be incorporated into adults' daily routines to enhance mobility and reduce injury risk. Overall, FMS served as a valuable tool for identifying changes in mobility and movement quality following dynamic stretching, reinforcing its potential role in effective warm-up practices. Data collection is in progress. IRB #544498

Abstract Name: BallotBot: Designing AI Systems to Support Informed and Justified Voter Decisions

Background: Ballot measures often contain technical legal language that limits public understanding and participation. This study asks whether large language models (LLMs) can enhance voter comprehension and reasoning when evaluating complex measures, contributing to research on AI-assisted civic engagement. Methods: A randomized online experiment was conducted with 149 Arizona voters reviewing Proposition 310, a real 2022 ballot measure. Participants were assigned to one of three conditions: (1) a static LLM-generated summary, (2) a structured civic information source modeled on Ballotpedia, or (3) an interactive chatbot ("BallotBot") using retrieval-augmented generation to answer voter questions. After reading, participants voted (Yes/No/Abstain), rated their confidence and understanding, and completed comprehension and open-ended reasoning tasks. Analyses measured factual accuracy, reasoning depth, engagement time, and vote distributions. Results: Participants using BallotBot spent the most time engaging with the materials (median = 9.8 min), significantly more than Ballotpedia (7.6 min) or the LLM Summary (5.3 min; $p \leq 0.001$). Chatbot users generated longer and more detailed responses (median = 88 words vs. 47; $p = 0.011$) and identified a greater proportion of factual drawbacks (0.46 vs. 0.31; $p = 0.043$). Voting patterns differed by condition: 58% of LLM Summary participants voted Yes, compared with 40% for Ballotpedia and 36% for Chatbot users ($\chi^2(2) = 6.08$, $p = 0.048$). Confidence and comprehension quiz scores did not vary significantly across groups. Conclusions: Interactive AI systems can deepen civic reasoning and engagement without altering confidence levels. BallotBot encouraged participants to consider more nuanced pros and cons and produced greater awareness of potential drawbacks. These results demonstrate how AI-driven dialogue tools can support informed, reflective democratic participation and contribute to the broader effort to design trustworthy civic technologies.

Abstract Name: The Effects on Selected Motor, Cognition Behavior, and Brain Pathology in Mice with Gulf War Illness Treated with the Immunotherapeutic LNFPIII and an Inulin Diet

During the 1990-1991 Gulf War, United States veterans were exposed to harmful toxicants that are believed to cause Gulf War Illness (GWI), a chronic multi-symptom illness, in about 30% of the veterans. This study looked at the effects of GWI chemical exposure on male and female mice in two preclinical models, when treated with Lacto-N-Fucopentaose III (LNFPIII) and an inulin diet, as potential GWI therapeutics. In one of the models (DFP model), mice were treated over 15 days as follows: pyridostigmine bromide (PB) and DEET were administered for 14 days, corticosterone (CORT) was added to the drinking water from days 7–14, and on day 15, diisopropylfluorophosphate (DFP) was given to complete the GWI induction. In the PB/PM model, mice received daily injections of PB and permethrin (PM) for 10 days. Control mice from both models received appropriate vehicle treatments. Eight months later, delayed intervention with the immunoprophylactic LNFPIII or dextran control and/or inulin diet or isocaloric control began. Behavioral testing started 1 month after intervention initiation. 3 months following the start of intervention, the mice were sacrificed for histological analyses of the brain. Up to date, data from three behavioral tests were analyzed: the gait test which analyzes motor function, nest building test which analyzes a natural behavior perturbed in models of psychiatric illness, and the novel object recognition test (NORT) which analyzes recognition memory. Additionally, glial activity was analyzed through immunohistochemistry using antibodies against IBA-1 and GFAP, for microglia and astrocytes, respectively. The NORT was analyzed in the DFP males, while the gait was assessed in the DFP males and females. Both models and sexes were analyzed for the nesting test. Results suggest LNFPIII with an inulin diet may restore recognition memory and moderate nesting hyperactivity in GWI, while glial activity is still being analyzed.

Abstract Name: Nested Pediatric Ethicality in Medical Decision Making

Children depend on others to exercise their rights, which can create an ethical conflict between the parent and adolescent when it comes to medical decision making. This tension, when the adolescent and parent come to opposing decisions, can be defined as Adolescent Consent Dissonance (ACD). This relates back to childism—the prejudice where it's assumed that adults are superior—which can manifest in various ways including dismissing an adolescent's values and needs, and ignoring their capability as an autonomous, ethical agent. Supporting ethical agency and autonomy is a key part of acknowledging adolescence as a developmental stage from childhood to adulthood, and it needs to be promoted by healthcare professionals in coordination with the adolescents' family. My novel contribution is to offer a structured way to approach this responsibility by adapting the Patient Activation Measure (PAM) to pediatric medical care. Previously utilized for adult chronic disease management, PAM provides guidelines—recognizing one's role in health, understanding

individual needs, taking action and maintaining it—parallel to how adolescents learn to navigate their own ethical agency. In applying this tool as a framework to pediatric medical care, PAM can help practically assess an adolescent’s readiness, capability, and confidence to participate in medical decision making on an individualized basis. This assessment can then help us guide and support how the adolescent moves through their development as they gain the ability to express their ethical agency. Through acknowledgement of this issue, and by bringing PAM into this context, we gain a clearer way to recognize and support adolescents’ ethical agency in cases of ACD, and fulfill our moral obligation to support them as they transition into champions of their own informed decision making.

Abstract Name: Art and Ownership: Cultural Claims in Museum Display

Does an artwork’s display reveal various claims about its purpose, who it belongs to, where it came from, and how it is valued? An examination of three displays within the British Museum, the Parthenon Sculptures, Benin Bronzes, and Lamassu from outside the throne room of Ashurnasirpal II, will explore this question while considering arguments regarding national versus universal museums, modes of acquisition, the classification of an object as art, and decontextualization. These three cases were selected due to their varying places of origin, treatment, methods of acquisition, and perceived connections to British culture. Utilizing comparative formal analysis of the three museum installations, this paper will examine how museums react to criteria that work to determine the validity of cultural claims discussed by scholars such as Carolyn Dean, Karin Edvardsson Björnberg, and Salam Al Quntar. Drawing more attention towards the broader effects these issues have on the governments, people, and cultures to which the works belong will allow for better policies and international agreements to be created regarding the display, protection, and return of stolen art.

Abstract Name: Tangible Memories: Ishiuchi Miyako’s Methods for Documenting Objects

Ishiuchi Miyako’s series *Mother’s*, *Hiroshima*, and *Frida* demonstrate her poetic way of illustrating personal history by invoking visceral memory through the tactility of objects. She purposefully selects items that have a connection to the body, creating an intimate viewing experience. *Mother’s* contains items that belong to her deceased mother, and each photograph shows Ishiuchi’s careful aesthetic decision process, especially regarding color and compositional setting. Grief, motherhood, and femininity are central themes throughout the series. In *Hiroshima*, the use of color contextualizes the objecthood of the personal items worn when the atomic bomb was dropped in Hiroshima, intensifying themes of loss and grief. *Frida* reflects an object’s transition from private to public through never-before-seen items that belonged to Frida Kahlo and conveys themes of loss and womanhood. Ishiuchi connects personal and collective histories by engaging with these archival collections. This paper examines these three series by Ishiuchi, considering her methods for capturing memory and expressing empathy through the photo documentation of personal belongings.

Abstract Name: Aughrim, Out of Reach: A Cultural Linguistic Analysis of James Joyce's "The Dead"

In the early twentieth century, Irish cultural identity was in crisis. After hundreds of years of oppression under English colonization and the devastating famine of the previous century, Irish cultural identity had been reduced significantly. However, there was a political push to reclaim this identity through independence from England. James Joyce, famed Irish author, lived through this era and personally struggled with his Irish identity. His short story "The Dead" follows Gabriel Conroy as he attends his family's holiday party and draws upon this cultural and political shift, as well as his own experiences, to explore the conflict existing in Irish cultural expression during this era. This research will address the contrast between literacy and orality which resulted in themes of cultural alienation and disillusionment found in "The Dead." Gabriel Conroy represents the qualities of literate culture: internalized, subordinative, and liberal in his thought. He is contrasted with his distinctly Irish community that has the qualities of oral culture: externalised, additive, and conservative in theirs. Conroy appeals to his surroundings by mimicking orality, but he internally condescends and belittles such actions. His self-conscious conflict mirrors the issues of Irish Independence. Gabriel Conroy, in his literacy, appears as an English colonizer and oppressor, yet he is Irish, so he is also a betrayer. His internal cultural expression contrasts with his external cultural expression to comment on the conflict in Irish identity. The narrative of "The Dead" is driven by cultural historical themes that are conveyed in the linguistic contrast between the literate and oral expression of the characters.

Abstract Name: Navigating Identity and Belonging. A Comparative Study of Domestic Latina/o/e and International Latin American Students at a Predominantly White Institution

This study explores the experiences of undergraduate international students from Latin America compared to domestic Latina/o/e students at a predominantly white institution (PWI), examining issues of colorism, racism, and belonging. Using qualitative interviews with 55 students over three years, participants were categorized into three groups based on their skin tone identification and international status (white identifying, non-white identifying, and international). Each participant completed demographic information and participated in 1-2 hour interviews focusing on their experiences with race, racism, colorism, mestizaje, and perceptions of belonging at a PWI. Interview data was transcribed and analyzed using Dedoose Qualitative Research Software, followed by the creation of analytical snapshots for each participant group to provide a comprehensive view of the dataset. Our findings revealed that while international Latinx students initially feel more welcomed at PWIs than their domestic counterparts, both groups report similar challenges with inclusion overall. International students experienced higher rates of microaggressions and developed different but effective support systems to navigate campus life. The recurring negative experiences of international students in the classroom stemmed from a lack of cultural awareness within the student body and limited opportunities for meaningful cross-cultural interaction on campus. This research addresses critical

gaps in current literature on international Latinx students' experiences at PWIs and provides insights into how different Latinx student populations navigate belonging.

Abstract Name: Investigating the Role of ASTN1 in Neural Crest Cell Specification and Migration

Neural crest cells are multipotent stem cells that originate from the dorsal neural tube, the precursor to the vertebrate brain and spinal cord. These cells migrate extensively during embryonic development and differentiate into a wide variety of tissues, including craniofacial cartilage and bones, the cardiac outflow tract, and much of the peripheral nervous system. While several genes that regulate the processes of neural crest cell specification and migration have been identified, many remain unknown. Astrotactin-1 (ASTN1), a cell adhesion protein encoded by the ASTN1 gene, is commonly found in rapidly migrating cell types in the central nervous system. Previous research has identified ASTN1 expression in early embryonic stages, but whether it plays an active role in neural crest development has not previously been determined. This study investigates whether ASTN1 is required for the proper specification and/or migration of neural crest cells. To test this, chick embryos in early developmental stages were unilaterally electroporated with a morpholino – an antisense nucleotide sequence that binds to mRNA and blocks translation – to prevent ASTN1 expression in one half of each embryo. In situ hybridization was subsequently used to stain neural crest cells for visualization, and light microscopy was utilized to analyze any differences in specification or migration patterns between the electroporated and non-electroporated sides of each embryo. Preliminary results indicate that ASTN1 likely plays a role in neural crest cell specification. However, its involvement in migration remains unclear, primarily due to a limited number of replicates. Additional studies are needed to provide further evidence for the role of ASTN1 in neural crest cell specification and to determine its role in migration. Understanding the molecular mechanisms that govern neural crest cell specification and migration will help create new therapeutic targets to treat a variety of congenital neural crest birth defects and disorders.

Abstract Name: THE EFFECT OF POSITIVE AFFIRMATIONS ON COLLEGE ATHLETE'S 40 YARD DASH TIME

A self affirmation was defined by Steel (1988) as an act that manifests one's adequacy and affirms one's sense of global self-integrity (Howell, 2016). These statements are a method of lowering distress and restoring self integrity (Shin et al., 2021). Affirmations have become a widely used psychological tool, yet little research has been conducted to see if they correlate to significant differences in athletic populations (Howell, 2016). This study aims to explore whether the use of self affirmation has an effect on 40 yard sprint times among collegiate athletes. Participants with sprint experience who are free from injury will be recruited for this study. Participants will undergo an experimental and control trial on different days and the order of trials will be randomized. Each participant will complete a baseline 40 yard dash and completion time will be measured

using handheld timers. During the experimental trial, participants will say three self affirmations out loud to themselves, and repeat them for 60 seconds prior to the sprint. The control trial will follow the same procedures without the self affirmations task. Once all data has been collected, a repeated measures ANOVA analysis ($p < 0.05$) will be conducted using the sprinting times from each of the trials. We expect to see that the trial where participants engage in affirmative behavior will have a faster sprint time than the trial without affirmations. We hope that the results of this study will produce evidence to support the claim that self affirmation is a psychological tool that can be used by athletes to improve their sprinting performance. Future research may ask questions about how self affirmations may impact different types of performance, such as strength. IRB: 542865

Abstract Name: Wearable Piezoelectric Bone-Conduction Systems for Spatial Directionality and Awareness

Workers in occupational environments such as construction sites must remain continuously aware of nearby hazards while increasingly relying on connected devices for real-time safety information. Conventional technologies—phones, smartwatches, and in-ear headphones—can visually distract users or occlude environmental sound, undermining situational awareness. Bone-conduction headphones provide an attractive alternative by delivering audio through the skull while leaving the ear canal open. However, realizing effective spatialized audio over bone conduction is challenging due to limited low-frequency response and inter-channel crosstalk, and current systems remain far less developed than in-ear solutions. To address these limitations, we developed a wearable bone-conduction headset based on piezoelectric actuators that delivers spatialized safety and navigation cues while preserving environmental audibility. The system integrates with standard occupational PPE, including safety helmets, to minimize interference with existing workflows. Worker position and head orientation are tracked in real time and mapped to a spatial audio engine, which renders directional alerts and guidance. We systematically investigated strategies to mitigate bone-conduction constraints, including actuator placement, frequency-dependent signal filtering, and spatial sound design techniques tailored to bone-conducted cues. We evaluated the system in a virtual reality industrial fire scenario implemented in Unreal Engine, where participants navigated evacuation routes under time pressure. Performance metrics included evacuation time, path efficiency, hazard avoidance, and subjective measures of comfort, distraction, and perceived situational awareness. Results showed that spatialized bone-conduction guidance improved evacuation performance and hazard localization relative to non-spatial or no-audio conditions, while maintaining access to ambient environmental sounds. These findings demonstrate the potential of piezoelectric bone-conduction systems as a wearable, low-intrusion platform for spatial directionality, safety awareness, and emergency navigation in high-risk occupational settings.

Abstract Name: Examining Job Training Programs for Neurodivergent Young Adults: A Community-Engaged

Approach

The unemployment rate for neurodivergent individuals is estimated to be 30 to 40%, roughly eight times the rate of individuals without disabilities. Little is known about how school- and community-based job training programs designed to address this gap translate into real employment opportunities or whether the skills that are taught align with the types of jobs neurodivergent young adults ultimately obtain. To address this issue, an interdisciplinary team of undergraduate students from Siena University's Nonprofit Excellence and Transformation (NExT) Fellowship partnered with Bring on the Spectrum (BOTS), an organization that supports neurodivergent individuals with opportunities to reach their best quality of life. We have already gathered insights from 6 program professionals in job training programs in the Capital Region of New York to identify funding limitations for enrollment, age restrictions, and the skills-based trainings that the programs provide. In the next stage of this research, we will reach out to three distinct groups of caretakers, including parents who are looking for transition programs, people currently in these programs, and people whose children who have recently completed a transition program to understand the challenges that parents face throughout this process. Participants will share their perspectives on whether the training reflects market needs, whether families feel supported in identifying these programs, and what factors contribute to successful or unsuccessful employment outcomes for their children. This approach allows us to gather firsthand insight into the structure, effectiveness, and the perceived value of existing programs and will help our partner, BOTS, to advance their current support efforts. By centering a community engaged approach, this research will also provide evidence-based insights that will support BOTS and these transition programs in the Capital Region to collaborate more effectively or provide suggestions to them as they develop new programs that offer more robust pathways to employment.

Abstract Name: The Effect of Volunteers and Brain Games in Preventing Cognitive Decline

This study sought to understand the effects of non-pharmaceutical interventions, specifically mental exercises and engagement with art, on the cognitive function of nursing home residents with early stages of dementia or mild cognitive decline. Nursing home residents were recruited by distribution of information regarding the Brain Exercise Initiative's activities within nursing homes in Richmond, after which residents could choose to participate in monthly activities with mentally stimulating tasks. Residents were guided through packets each containing three sections: a trivia section where residents were tasked with re-writing the question and coming up with an answer to general trivia, a timed math section with simple arithmetic problems, and a reading section where residents were tasked to read a non-fiction passage out loud. Tasks were designed by the national Brain Exercise Initiative organization and inspired by research from neuroscientist Dr. Ryuta Kawashima, which demonstrated that consistent reading and math exercises could result in significant improvement on cognitive function tests for individuals with Alzheimer's. Data has thus far been collected from participants for over a year to measure their performance on each section of the activity tests as a way to measure cognitive function overall. Results will be measured by comparing each participant's task scores over the course of each month to determine whether or not there was significant improvement in performance. Future research will seek to determine the significance of intervention strategies on cognitive function in participants and understand how additional mentally stimulating activities, such as art activities, can impact cognitive decline.

Abstract Name: Barbie: An Analysis of Diversity in the World Icon

This study examines the growth of diversity in the Barbie Fashionista Line due to increased media attention towards representation and how these developments have affected Barbie's main audience, young girls. Dolls play a crucial role in developmental psychology as children can explore relationships and dreams through active role-play. By incorporating more diversity into Mattel's most budget-friendly Barbie line, more children are able to feel represented, and all children can be exposed to and respond to diversity as they will in school and throughout life. There are three main areas of diversity that were implemented starting in 2015: racial, body, and disability. While there are many statistics on doll sales, few studies have previously investigated how children are responding to the increased diversity. Using correlation to the increased diversity in media and the role of dolls in development, an analysis of the importance of diversity in dolls was carried out. The results show positive benefits of doll diversity in allowing more children to feel represented by the world beauty icon and her slogan of empowerment. It also showed a unique role in allowing all children to learn to develop relationships of diversity using their dolls. Children can model relationships based on what they see in media or in life, but they are also able to incite imagination and create their own ending, which helps stimulate the brain areas of learning, memory, and executive functioning. These skills can then be brought to real life when children interact with those who have different physical characteristics. Overall, with Barbies in the hands of more than 90% of young girls, it is vital that diversity be displayed to increase knowledge and communication among children of all races, bodies, and disabilities and to foster a population of empathy and empowerment.

Abstract Name: Modeling Ligand Hardness to Predict Binding Affinity in Protein Kinases

Protein kinases are essential regulators of cellular signaling pathways and are major therapeutic targets due to their central roles in cell growth, survival, angiogenesis, and stress response. They are high-priority drug targets in oncology, inflammatory conditions, and other diseases driven by dysregulated kinase signaling. These enzymes share a common adenosine triphosphate-binding pocket but differ in surrounding motifs. Thus, the challenge in designing selective inhibitors of these enzymes lies in the identification of key residues both in the pocket that binds adenosine triphosphate and its surrounding. One way to study the active site is to probe its interactions with known ligand molecules and rationalize the binding using the molecular hardness of the ligands. Thus, the present study has examined five clinically relevant kinases: cyclin dependent kinase 2, epidermal growth factor receptor kinase, mitogen-activated protein kinase 14, Src kinase, and vascular

endothelial growth factor receptor 2. The study utilized an informatics database to analyze over 50 ligands per enzyme, calculating molecular hardness and predicting binding affinities. The relationships between the molecular hardness and binding affinities were studied in detail. Together, these computational docking studies highlight the interplay of hardness in ligand–kinase interactions and provide insight that may aid rational design of selective kinase inhibitors for immense therapeutic potential

Abstract Name: SignGPT: Real-Time ASL Keyword Spotting with CTC and Lightweight LLM Contextual Completion

We present SignGPT, a real-time American Sign Language (ASL) keyword-to-English rendering pipeline designed for CPU-only laptops. A holistic tracker extracts hand and upper-body landmarks and hand crops at 30 fps. Crops are encoded by a compact visual backbone and fused with landmarks, then decoded by a BiLSTM/GRU temporal head trained with Connectionist Temporal Classification (CTC) to recognize a 15-keyword vocabulary without frame-level alignments. The recognized 2–5 keyword sequence conditions a lightweight language model that performs constrained contextual completion and returns the top 3 English candidates consistent with the tokens and an optional task prompt (domain, style, register). We outlined an evaluation protocol combining per-keyword precision/recall/F1, sequence accuracy after CTC collapse, and sentence-level quality with human preference judgments. On a held-out set, SignGPT attains 97.0% sentence-level accuracy with LLM guidance versus 73.5% without underscoring the value of contextual completion. Ongoing work extends SignGPT with a cross-LLM evaluation, comparing small on-device and hosted models under identical prompts for accuracy, keyword coverage, style control, and latency. We will report interim results from this student-led study in the final poster/paper.

Abstract Name: Quantifying the Amount of Sodium Chloride and Water Hardness Found in Parks on Milwaukee's Kinnickinnic River

The purpose of this investigation was to determine the amount of salinity and water hardness found in the Milwaukee rivers. River samples were collected and analyzed from the Kinnickinnic River from the following three locations: Zablocki, Wilson, and Jackson Park. Data collected demonstrated a change in the amount of sodium chloride (231-561 ppm) and water hardness (305-441 ppm) found in the rivers over the 4-week period (6/3-24/2025).

Abstract Name: Testing the Bioremediation Potential of Oyster Mushrooms on Cigarette Butts

Discarded cigarette filters remain one of the most ubiquitous forms of plastic waste in our world today, with an estimated 1.2 million tonnes of filters ending up as litter in the environment each year. These filters are designed to trap toxic compounds like tar, nicotine, heavy metals, and more before they reach the lungs of the smoker. Once these filters find their way into water and soil systems, these toxins leach into the environment while the filter itself resists biodegradation and contributes to microplastic pollution. Multiple studies have shown macrofungi, especially white rot fungi in the genus *Pleurotus*, to be effective at remediating a variety of such pollutants. A 2014 study by Updyke demonstrated the ability of *Pleurotus* to grow on a substrate of used cigarette filters. While this study focused on the financial feasibility of this process, it did not address concerns of the edibility of mushrooms produced in this way. This study aims to determine whether *Pleurotus* mushrooms grown on a substrate of used cigarette filters are suitable for human consumption. A baseline chemical content of used cigarette filters will be determined via High Performance Liquid Chromatography (HPLC). After the fruiting stage is complete and mushrooms are harvested, the spent substrates will be analyzed via HPLC and the results will be compared to the baseline to determine if any degradation of the chemicals within has taken place as the fungus fed on the filters. Mushrooms grown on test substrates will be compared to those of the used filter baseline as well as mushrooms grown on a traditional substrate to compare the presence of toxins in each. A graphical representation of the data will be created.

Abstract Name: Atomic Priests, Glowing Cats, and Cursed Monoliths: The Story of Nuclear Semiotics

Humans have harnessed the power of myth and symbolism to transmit information through generations and cultural changes. Specifically, a concentrated effort has been made to mark dangerous nuclear waste sites to prevent future generations from digging them up, an action that would be deadly for humans and the environment. How can we avoid dumping responsibility on future societies? The Human Interference Task Force was assembled in 1984 to bring cultural studies, psychology, politics, agriculture, economics, and other fields together to engineer a solution to this problem. The glue that would connect the different fields was semiotics, an interdisciplinary field of research under linguistics, which deals with how to convey messages successfully. This solution would need to last at least 10,000 years - a, quite literally, monumental task. I will cover notable processes, symbols, signs, and conventions that were agreed upon in past efforts (the "nuclear priesthood" recommended by the task force), current solutions that are being applied, and solutions that were not seen as viable, such as "Ray Cats" – genetically engineering cats to glow in a radioactive environment, thus creating a myth that may be passed on (Trauth, Hora, & Guzowski, 1993). I will reference literary works by Frank Herbert ("Dune") to explore the question of "What makes a good myth that lasts millennia?", as well as other sci-fi works ("Foundation" by Isaac Asimov, and "Aspic's Mystery" by Arsen Darnay) that directly depict "atomic priesthoods" and their downfall. Stories, symbols, and myths are some of the more

resilient methods of cultural transmission; it is worth exploring their influence on culture as it adapts and advances, their role, and their potential as a solution - or hindrance - to long-term cultural transmission.

Abstract Name: Claiming Space in Dance Through Creative Autonomy

This paper presentation discusses how incorporating more autonomy and creative freedom in dance training can create an entirely new sense of individual identity and artistic confidence that change the way dancers approach their training and their own lives in general. This can be especially beneficial for dancers that plan to take their careers into a professional space. I will start by exploring how autonomy and the idea of “taking up space” is a much bigger and essential part of the culture when dance is formed from a place of survival and embedded in community. Contrasting that, I will then examine classical ballet culture in studio settings and the ways young girls and boys are trained to conform to specific ideals of dance in order to pose the question: is this training hurting these dancers’ chance at a professional career just as much as it may be helping them? To expand on this the idea of taking up space as a dancer is then investigated. What does taking up space mean, and how can having creative autonomy expand dancers’ ideas of what performance looks like and feels like? Several examples across different dance cultures will be compared to make a point that dance styles that include more autonomy, such as Jazz Funk and Krump, lead to dancers being able to take up more space in their careers. A variety of multi-media sources from case studies to a documentary film will be analyzed, qualitatively comparing findings across different dance cultures, in an attempt to prove my point that creative freedom in dance training leads to not only successful careers, but a stronger sense of self that dancers can take into their own personal lives.

Abstract Name: Unpacking Modern Day Lynching: Engaging in Understanding Racial Trauma

With historical context in mind, researching modern-day lynching is essential because it reveals how past racial violence continues to shape present-day ambiguities and psychological realities for Black Americans. As systemic racism and racial division persist into the 21st century, the study of Post Traumatic Slave Syndrome (PTSS) creates a critical bridge between historical acts of terror such as lynching and contemporary mental and physical health disparities. PTSS offers a theoretical lens through which I can examine how the psychological wounds of slavery, segregation, and racial terror continue to surface in measurable ways, such as increased rates of depression, hypertension, anxiety disorders, and internalized stress responses. By observing behavioral patterns and distinct psychological characteristics, I gain an objective framework for understanding how history remains embedded in the present. Through analyzing case files and patient records from individuals who identify as living with PTSS, I can identify recurring patterns that guide the psychological dimensions of this study. Additionally, community discussions and student-led workshops deepen this work by fostering collaborative learning and allowing participants to confront the ongoing implications of historical trauma. Data consistently reveals themes of anxiety, social distrust, and cognitive dissonance powerful indicators of how deeply historical wounds continue to echo

across generations. Together, these findings underscore the urgent need to confront historical injustices, not only to promote awareness but also to foster healing and cultivate a community capable of advocating for justice, resilience, and meaningful social change. Incorporating measurable mental-health outcomes such as stress indicators, coping mechanisms, and community support networks will strengthen the empirical foundation of this work. Building sustainable pathways for education, dialogue, and advocacy, this research can serve as a long-term model for addressing racial trauma and promoting collective healing across generations. These efforts will inspire continued community growth and deepen understanding and resilience for future generations.

Abstract Name: Investigation of the Impact of HPLC Mobile Phase pH on the Quantification of Nicotine in E-Liquids Containing Freebase Nicotine versus Those Containing Nicotine Salts

It is becoming common practice for smokers to utilize e-cigarettes as an aid for smoking cessation, and this practice is also widely encouraged by medical practitioners. This is concerning because many studies show significant inconsistencies in the amount of nicotine reported on e-liquid product labels and the amount of nicotine detected in the e-liquids. If users rely on the labeled nicotine content to help control their nicotine intake, they can be misled and potentially unintentionally increase their exposure to nicotine when that is not desired. Often the nicotine content in e-liquids is quantified using high-performance liquid chromatography (HPLC), but when utilizing HPLC to analyze an ionizable compound such as nicotine it is important to note that the ionized and unionized forms will have different retention times. Thus, without careful control of experimental parameters the quantification of nicotine could be incorrectly determined if it is assumed to be only in one form. This project aims to investigate differences in the quantification of nicotine using HPLC in samples containing freebase nicotine versus ones containing monoprotonated nicotine to determine optimal conditions to study the nicotine content in e-liquids with different forms of nicotine.

Abstract Name: "Can I Live" Black Woman in Urgency Culture, Mattering and Self Medicating

Black women's patterns of self-medicating have received little scholarly attention, despite growing evidence that their lived experiences and coping strategies are often shaped by urgency culture and limited opportunities to reflect on one's sense of mattering or self-value. The reinforcement of stereotypes such as the strong Black woman stereotype combined with a culture of urgency create conditions in which Black women are expected to suppress their own needs to quickly respond to the demands of others, leaving little time for rest, emotional processing, or self-care. Russell (2024) seeks to extend the conceptualization by framing mattering as a mindset rooted in self-compassion and awareness of the human labor infrastructures. Yet, no

research has examined how Black women's sense of mattering is shaped or hindered by urgency culture that results in the chronic feelings of being overwhelmed can lead to self medicating. Although data collection is ongoing, emerging themes from both the future IRB process and data collected observations, this heavily reflects the core of my academic interest. This study examines the emotional, cultural, and structural barriers that limit Black women's access to healthier and more sustainable coping strategies. We will tackle how factors such as internalized expectations, lack of accessible resources, and cultural stigmas surrounding mental health influence in these coping behaviors. Through hands-on qualitative research, including interviews and reflective analysis, the study will gain insights into personal lived experiences of Black woman who navigate these pressures daily. This study looks to contribute to a broader discussions on mental health and sociocultural being that highlights how urgency culture influences Black women's coping strategies and their evolving sense of mattering.

Abstract Name: Accuracy Validation of a Consumer-Grade Structured-Light 3D Scanner

This project examines the applicability of a consumer-grade structured-light 3D Scanner (i.e., Shining 3D EinStar) in the automotive reverse engineering of a 1984 Dodge D150 Truck frame to accept the subframe suspension off a 2022 Dodge Challenger SRT. Precise models of all frames were necessary to design a set of adaptation brackets that permanently connect the suspension to the main frame, while preserving proper suspension and drivetrain geometry. All procedures were performed in a standard workshop environment with basic scanning aids like infrared dots and scanning spray. Each component was scanned three times. Afterward, each scan was aligned, cleaned, and converted into a mesh file using ExStar. The digital geometry was then replaced in ExModel, and the components were assembled in SolidWorks using STEP files. The average of three scans for each component was used to ensure measurement repeatability and accuracy. The digital models were aligned in SolidWorks to ensure proper centering of the subframe, ride height, and drivetrain geometry before designing brackets. A series of fitment brackets was designed based on measurements from the aligned assembly, then 3D printed using standard PLA filament. In three separate experiments, involving a total of ten brackets, each 3D-printed bracket fit precisely, securely bolted into position without interference or visible deformation, thereby confirming geometric accuracy prior to load-bearing designs. Physical measurements indicated an average deviation of 0.41 mm across 69 trials. Employing two verification methods ensured both redundancy and confidence in the results. This study demonstrates that a consumer-grade 3D scanner can achieve sub-millimeter accuracy suitable for structural automotive reverse engineering, providing an affordable, repeatable solution for engineers. These critically assessed findings confirm that this workflow can deliver fabrication-ready dimensions under typical shop conditions, enabling a streamlined process for complete retrofits at a fraction of the cost of traditional reverse engineering.

Abstract Name: *Agrobacterium*-Mediated Transformation with Chitinase and Glucanase genes against *Aspergillus flavus* in Georgia Peanuts

The State of Georgia is known to produce approximately 50% of the national peanut supply, contributing to making the United States the third-largest peanut producer in the world, after India and China. *Aspergillus flavus* produces aflatoxin (AFB1), which is among the most carcinogenic naturally occurring compounds known to pose significant health risks to humans. This study aims to develop genetically modified (GM) peanut lines through *Agrobacterium tumefaciens*-mediated transformation, introducing pathogenesis-related (PR) protein genes that encode β -1,3-glucanase and chitinase enzymes, which are known to degrade fungal cell walls and enhance resistance to AFB1. Embryogenesis was performed by culturing sterilized peanut embryos on Murashige and Skoog (MS) medium. For callus formation, embryos were co-cultivated with *A. tumefaciens*. Transformed embryos were cultured on MS media containing 3 mg/L of 2,4-D for callus induction, followed by shoot and root regeneration on media supplemented with 1 mg/L Benzyladenine (BA) and 1 mg/L Indole-3-Butyric Acid (IBA), respectively. Untreated samples served as the control, and experiments were conducted in replicates. Transgenic peanuts were used in a colorimetric assay to confirm chitinase gene expression, and a GUS assay was performed to detect glucanase. Embryogenesis was successful at a rate of 98%. Successful callus induction and regeneration of shoots and roots that survived antibiotic selection indicated potential transgene integration. Data from the colorimetric assay revealed the presence of chitinase, while the GUS assay was positive for glucanase expression in the GM peanut seedlings. Our results to date indicate that transformed peanuts expressing PR proteins may reduce infection by *A. flavus* and the production of AFB1. Our findings could contribute to developing peanut varieties with improved resistance against *A. flavus*, improve crop safety, and lessen economic losses for peanut growers in Georgia.

Abstract Name: Conflicting Functions: The USSR Impact on the Provenance, Conservation, and Display of Two Orthodox Russian Icons

Numerous Western institutions acquired Russian icons following the 1917 Russian Revolution through a deliberate dissemination of Orthodox devotional objects staged by the newly-formed Soviet Union. The practices of the Antikvariat and the Central State Restoration Workshops to fund the newly established government through the sale of seized Russian icons warped their initial role and audience. The process of monetizing these objects obscured the provenance of Russian icons beyond the boundaries of the country. The University of Kentucky acquired two Russian icons within the twentieth-century, both of which feature clear signs of retouching prior to their entry into the University's collection. This paper poses the two icons to explore contemporary conservation ethics and modes of display when applied to previously restored Russian icons. It examines how the two objects at the University of Kentucky compare to similarly attributed objects in their native country and setting in the restored legitimacy of the Orthodox Church to further existing discourse on what level of structural and visual impairment warrants additional conservation work despite previous, likely historically significant, interventions. It also seeks to address the dichotomy between the religious past of the icon and the secular contemporary application of the Russian icon as art.

Abstract Name: Comparison of Traditional and Modern Mordanting in Natural Dyeing: Quantitative analysis of metal ion incorporation and contribution to resulting color

Many traditional practices in fiber folklore call for iron, tin, or copper pots in the natural dyeing process. The purpose of the following investigation is to determine the impact of the folk tradition of various metal cooking vessels in comparison to modern mordants through X-Ray Fluorescence Spectroscopy (XRF) and CMYK values of dye samples. A total of 13 silk samples were cleaned, treated with the prescribed mordants, and dyed with Osage wood chips. Four silk samples were treated with no mordant, iron mordant (Ferrous Ammonium Sulfate), and alum mordant (Potassium Aluminum Disulfate). Then, the samples were divided into individual dye pots of glass, iron, aluminum, and copper with dye. Finally, the rinsed samples were scanned with XRF to determine the quantity of metallic ions present in relation to the visible distinctions. The results of the XRF provided significant evidence of iron in non-mordanted and alum-mordanted silk samples, however, the iron mordant contributed significantly more than the iron pot when compared. The CMYK values and visual evidence support the spectra observed. The impact of the copper pot was largely insignificant, with only small quantities of the element found in silk samples exposed to copper. Similarly, the samples and CMYK values reflect the insignificant impact of copper on the intensity of the Osage dye. The XRF did not effectively capture the impact of the aluminum from the mordant or pot due to the low atomic number and corresponding low energy fluoresced (~1.5 keV). There is a visible distinction between the aluminum pot and mordant contribution, but there are no quantitative spectra to support such findings.

Therefore, it can be concluded that the iron cooking vessel did impact the natural dyeing process, whereas the copper vessel did not. To determine the impact of aluminum through spectra, a different quantitative process is necessary.

Abstract Name: Understanding Appalachian Dialect Through Visual Identity and Editorial Design

When thinking about connections and divisions within Appalachia, I began researching how regional colloquialisms could be used to ease cultural gaps. The topic of understanding Appalachian dialect was inspired by my childhood in West Virginia. Growing up in the area, you hear a unique dialect that is completely foreign to outsiders. Appalachian culture is rich with unique language, and not all people today understand it. This led to the question, how can a book teach non-Appalachians how to understand and incorporate Appalachian colloquialisms into their daily lives? Using primary sources from documentaries, websites, and direct quotes from my own family members, the contents of the book began to take form. Presenting the phrase with its definition, possible origins, and a quote helps educate and inform readers on how to use it. Keeping rhythm and pacing in mind, additional quotes were included from primary sources alongside images of Appalachian people. The book's design mirrors the tradition and style of family photo albums serving to connect generations of people. Helping people understand one another and appreciate culture can help bridge the separation created by cultural differences. I learned how excited people get over sharing their culture through information gathering. Non-natives who viewed the book gained an understanding of the colloquialisms, and those already familiar found appreciation in the celebration of their culture.

Abstract Name: Marred Existence: Race, Gender, and Law in the Afterlives of Billie Holiday and Whitney Houston

This project is a preliminary examination to determine how the intersection of race and gender mediates the politics of public existence within the philosophical and legal domains of twentieth-century American society. The lives and afterlives of entertainers Billie Holiday and Whitney Houston make plain a convergence of ontology and law, as it stands subject to the complexities of intersectional politics. Supplementing existing scholarship on these women, this study will make use of archival materials, philosophical theory, and court records to articulate the relationship between the two figures and the complex politics of public existence. The results seek to restore their humanity in the broader historical narrative by situating it within, and beyond, the discourses of race, gender, and law. Their individual beings are made more whole by an ontological vantage point. Inevitably, the politics of existence assert themselves in any inquiry into the implications and applications of American laws, particularly those concerning figures such as Holiday and Houston.

Abstract Name: Impact of Light Exposure on 5-6 Year Olds' Circadian Rhythms and Sleep Health

Sleep is a critical component of children's health, influencing their emotional and behavioral development. Both sleep quality and duration are shaped in part by circadian timing, which is regulated by the body's internal clock. Light exposure plays a pivotal role in regulating the circadian clock. Evening light exposure and disruptions to sleep can lead to negative effects on children's health. Despite this, there is a gap in research regarding interventions that could promote early bedtimes and healthy sleep behaviors in younger children. The object of this study is to examine sleep timing, light exposure, and sleep quality in a community sample of children aged 5-6 years old before and after an intervention aimed at reducing evening light exposure. We hypothesize that adjustment to home lighting environment and blue light-blocking glasses will result in earlier dim light melatonin onset (DLMO), earlier sleep onset, and that the interventions will be perceived as feasible and acceptable by the parents and children. Data will be analyzed from the children's actigraphy watches, sleep journals, and salivary melatonin. Parents will complete post-intervention assessments and qualitative interviews to assess the feasibility and acceptability of each intervention. Results from the analyses will indicate whether the two intervention strategies can improve children's sleep health by advancing children's sleep and circadian timing. This study will contribute to further research in understanding how light can affect sleep and circadian timing in younger children. It will highlight the importance of developing effective circadian interventions to support healthy sleep patterns in children.

Abstract Name: Diet Quality, Mental Health, and Chronic Disease Risk Among College Students

College students experience significant mental health challenges, with rising rates of depression, anxiety, and loneliness across U.S. campuses. Diet quality, particularly fruit and vegetable intake, has been linked to emotional well-being, yet few large-scale studies examine these relationships using nationally representative college samples. This study investigates whether daily fruit and vegetable consumption is associated with mental health outcomes among U.S. college students. Data were drawn from the Healthy Minds Study (HMS) 2023–2024 cycle, a nationwide survey of college students. After filtering for complete cases, the analytic sample included N= 3,092 students. The primary predictor was fruit and vegetable intake (1–4 servings/day). Outcomes included depression symptoms, anxiety symptoms, and loneliness. Covariates included age, race/ethnicity (SOC), gender identity, first-generation status, and parent education level. To address the research question: Is higher fruit and vegetable intake associated with lower depression, anxiety, and loneliness among college students? we conducted unweighted linear regression models for each mental health outcome. Across all models, higher fruit and vegetable intake was significantly associated with better mental health. Fruit/vegetable intake predicted students that eat more fruits and vegetables tended to feel less

depressed, less anxious, and less lonely. Lower depression scores ($\beta = -0.96$, $p < .001$), lower anxiety scores ($\beta = -0.60$, $p < .001$), and lower loneliness scores ($\beta = -0.31$, $p < .001$). Effect sizes were small but consistent across outcomes, demonstrating a clear pattern: students who consumed more fruits and vegetables reported fewer mental health symptoms. These associations remained significant after adjusting for demographic and socioeconomic covariates. Findings highlight fruit and vegetable intake as a meaningful correlate of mental well-being during emerging adulthood. Integrating accessible, culturally relevant fruit and vegetable options on college campuses may support student mental health and inform future intervention development.

Abstract Name: Perceived vs. Objective Social Connection as Predictors of Alcohol-Related Problems in Heavy-Drinking Young Adults: A Prospective Investigation

Alcohol use disorder (AUD) is a leading cause of preventable harm in the United States, and young adults who drink heavily are particularly vulnerable to these harms. Social (dis)connection is a key risk factor for problematic alcohol use, but prior studies have relied on small, nonclinical samples; examined only one facet of social connection; and rarely employed prospective designs that assess change in alcohol problems over time. The present study addresses these gaps by testing whether deficits in perceived social support and actual social connections prospectively predict alcohol-related problems in heavy-drinking young adults. This project leverages data from 393 heavy-drinking young adults (aged 21–29) who participated in an NIH-funded longitudinal study and completed assessments at baseline and 12-month follow-up (90% retention). Perceived social support and objective social network characteristics were measured using the Interpersonal Support Evaluation List-12 (ISEL-12) and the Support Network Inventory (SNI), respectively. Alcohol-related problems were assessed with the Alcohol Use Disorders Identification Test (AUDIT). Multiple regression models will test cross-sectional and prospective associations, controlling for baseline alcohol problems and demographic factors, and will compare the unique contribution of perceived versus objective social connection in predicting later alcohol-related problems. We expect that both lower perceived support and smaller, less diverse networks will predict worsening alcohol-related problems over time, with perceived support emerging as the stronger predictor. Findings will clarify the nature and strength of interpersonal risk factors for alcohol misuse in young adults and inform the development of more targeted and effective AUD prevention and intervention strategies.

Abstract Name: Structural Integration of a New Eukaryotic Organelle (Nitroplast) and its Remodeling During the Day

Biological nitrogen (N₂) fixation, the reduction of atmospheric N₂ gas to biologically available ammonia, is a key source of N₂ for terrestrial and aquatic ecosystems, and was long considered restricted to prokaryotes. However, this dogma was changed with the recent discovery of the N₂-fixing organelle, the nitroplast, in the marine alga *Braarudosphaera bigelowii*. The nitroplast was originated as a cyanobacterium that underwent endosymbiosis, and while its cellular location and dynamics in cell fission were described by soft x-ray tomography, the structural features of the nitroplast and its relationship to other organelles remain unknown. The function of the nitroplast is dependent on multiple exchanges between the nitroplast itself and the cell, including proteins and metabolites. Here, we use focused ion beam scanning electron microscopy (FIB-SEM) and cryo-electron tomography (Cryo-ET) at various magnification scales to decipher the nitroplast ultrastructure at macromolecular resolution within the cellular milieu. Unlike other known organelles, the nitroplast envelope consists of four distinct membrane layers and is surrounded by two additional layers derived from the host that presumably mediate exchanges with the cytoplasm. During the period of nitrogen fixation in the day, the nitroplast undergoes major structural remodeling including the loss of the host-derived membrane and the influx of “spiky” membrane vesicles into the cellular cytoplasm. Additionally, unique membrane-bound features that we describe as “hat-like structures” proliferate on the nitroplast lamellae during the night cycle. These results provide an unprecedented insight into the fascinating cellular and structural biology of the nitroplast, facilitating its harnessing for various applications in the future as well as allowing a deeper understanding of the process of endosymbiosis evolution.

Abstract Name: Challenging Asian Caricature: Anti-Yellowface Activism and Representational Politics in 1970s Hollywood

The research investigates the radical evolution of anti-yellowface activism in Hollywood, tracing its transformation from the 1970s to the 1980s amidst the film industry's persistent use of yellowface. Following a rising demand for Asian imagery, filmmakers reinforced established racial sentiment by relying on yellowface to portray Asian characters while simultaneously restricting opportunities for Asian American performers. Yellowface also reinforced racial hierarchies and controlled Asian American visibility. I argue that anti-yellowface protests initially emerged in the 1970s as a reactionary response to offensive racial caricature. Public demonstrations, court injunctions, and scathing reviews developed against films that had already been created, with the objective to simply reject and demonstrate disapproval for pre-existing yellowface. In turn, 1970s activism can be categorized as defensive and reactive. However, by the 1980s, I contend that the anti-yellowface movement evolved to center around proactive efforts. In response to failed reactionary activism, a recentered focus emphasized identity formation, cultural reinforcement, and Asian-led representation in media spaces. It underscored the prevention of yellowface's inaccurate portrayals by first establishing a more “authentic” Asia. Instead of rejecting Hollywood and treating yellowface and its stereotypes as a symptom, the 1980s sought to confront the roots of misrepresentation and reshape Hollywood, constructing an accurate depiction before any false ones from yellowface could be made. This study draws on photographs, protest statements, internal documents of Asian organizations, Asian activist publications, newspapers, and film analysis to trace how Asian American activists navigated both public protests and internal community discourse. By reconstructing these campaigns, this research documents a pivotal moment in Asian American cultural history and situates Hollywood within larger debates over race and representation. Ultimately, I assert that this transformation highlights a broader commentary on Asian adaptation to cultural portrayals.

Abstract Name: Identifying Genes that Instruct Wiring Specificity for Functional Channels of the Vestibulo-Ocular Reflex

Behavioral dysfunction in neurodevelopmental disorders can arise from improper circuit assembly. Understanding how neural circuits are classically organized and assembled can provide insight into aberrant mechanisms of disease, but these processes remain unresolved for vestibular reflex circuits. The gaze stabilization reflex uses a simple and highly conserved 3-neuron circuit to maintain a stable visual percept after head/body destabilization. In the vertical axis, nose-up/nose-down destabilization is transformed into compensatory eye rotations (eyes-down/eyes-up). Previous work identified common spatial and temporal topography to nose-up and nose-down channels that span the sensory periphery inputs to ocular motor neuron outputs, suggesting that a common spatial and/or temporal factor could organize a complete oligosynaptic circuit. To test this hypothesis, we performed transcriptomic profiling of the central relay node: the central vestibular projection neurons. We used fluorescent in situ hybridization to investigate candidate genes that may be commonly restricted to nose-up (dorsal, early-born) or nose-down (ventral, late-born) central and motor neurons. Two axon guidance molecules, *sema3aa* and *sema3ab*, were restricted to ventral nose-down central and motor neurons. To test whether *sema3aa/ab* may shape nose-down circuit formation, we measured eye tilt behavior in mutant lines and indeed found selective deficits in nose-down/eyes-up behavior. We are now screening additional spatially restricted genes, such as *nav2a* and *nrp1b*, for behavioral changes. In the future, we will work to establish where (i.e., specific circuit node) and how *sema3aa/ab* act to disrupt nose-down circuit formation. Our findings speak to molecular mechanisms that could coordinate functional oligosynaptic circuit assembly and, by extension, how specific molecule disruptions may contribute to behavioral dysfunction in vestibular diseases.

Abstract Name: Optimizing Pricing and Trade-In Compensation in High-Tech Industry Under Strategic Consumer Behavior

This study develops an analytical model to examine how firms in the high-tech sector should optimize product pricing and trade-in compensation simultaneously when designing device take-back programs. High-tech products depreciate rapidly, and consumers often behave strategically. They tend to delay purchases or trade-ins until discounts, new model releases, or improved incentives appear. These behaviors influence both demand timing and the return quality of used devices, complicating firms' pricing and recycling decisions. By embedding consumers' purchasing and recycling valuations (i.e., the valuation gap), depreciation dynamics, salvage value of product, and strategic consumer behavior into the decision model, we analyzed the firm's optimal pricing strategy and trade-in programs. A survey was distributed to Elon University students to

collect data on their purchasing and recycling behaviors and support empirical calibration. We also compare the firm's optimal decisions and profit when facing strategic versus myopic consumers. Results show that when the consumer's valuation gap narrows, a portion of consumers participates in recycling, and higher recycling compensation increases return volume. This is profitable only when the salvage value of product is sufficiently high or depreciation is slow. Under these conditions, the optimal strategy shifts toward higher recycling incentives paired with moderate product pricing. With strategic consumers, depreciation creates uncertainty about future valuations, causing more buyers to delay purchases. This reduces optimal stocking quantities and pushes the firm toward lower prices and carefully calibrated recycling incentives. Across all conditions, coordinated decisions on pricing, recycling compensation, and stocking outperform optimizing each variable independently. The results highlight how firms can design profitable take-back programs while supporting circularity in high-tech supply chains.

Abstract Name: A Network Analysis of Pedagogy in 177 International Conference of the Learning Sciences Papers 1996–2025

The learning Sciences (LS) has continuously redefined how teaching and learning are understood, yet the evolution of its core pedagogical and theoretical foundations has not been systematically documented. This study analyzes 177 papers from the International Conference of the Learning Sciences (ICLS), spanning the early years (1996–2008), middle years (2010–2018), and recent years (2020–2025), to see how pedagogical theories and practices have evolved. After qualitative coding across 52 categories and 631 coded segments, network analysis of correlations at $p < .05$ was applied to identify patterns and clusters within each era. Understanding these thematic shifts is crucial for identifying contemporary research priorities and addressing intellectual gaps concerning the field's dominant paradigms. Findings show that the early years established foundational paradigms centered on cognitive and constructivist theories such as conceptual change, model-based reasoning, and collaborative learning alongside constructionist and apprenticeship-based practices. The middle years demonstrated diversification, introducing critical, identity-oriented, and social-cultural perspectives while maintaining constructivist and experiential pedagogies. In the most recent years, network mapping revealed an integration phase, characterized by a strong socio-collaborative core linking social constructivism, critical pedagogy, and learner agency. Supporting clusters emphasized structured teacher guidance, systemic and ecological models of learning, and renewed attention to hands-on, project-based engagement. This study investigated a maturing discipline that increasingly views learning as social, contextual, and transformative. By mapping this intellectual evolution, the project provides a clearer understanding of how the Learning Sciences have shifted from studying individual cognition toward building collective, inclusive, and agency-driven educational models.

Abstract Name: Influence of Size and Shape Selectivity of Silver Nanoparticles Embedded in Functionalized Clays for Determining Antimicrobial Efficacy and Biocompatibility

The global economic impact of wound care is growing rapidly, with a significant thrust on microbial infections. As a result, substantial efforts are underway to develop cost-effective antimicrobial wound dressings that can limit microbial penetration and reduce the risk of life-threatening infections. Clays are among the most promising candidates for biomedical applications due to their non-toxicity, porosity, low cost, and biocompatibility. Our effort adopts an innovative approach to developing organo-functionalized, infection-resistant, biocompatible membranes embedded with silver nanoparticles that offer antimicrobial efficacy. While clay serves as the host material, betaine acts as a binder to facilitate membrane formation, and the shape-selective silver nanoparticles provide sustained antibacterial activity. The effects of silver nanoparticle shape and size selectivity on the antimicrobial activity of membranes reveal structure-property relationships that influence the development of silver nanoparticle-clay systems, including mechanical durability, flexibility, fluid permeability, and pathogen activity, across different shapes, including spherical, cubic, and rod-shaped structures. We are evaluating WST-1 cell viability assays on clay membranes, which can be used as wearable, implantable devices where direct or indirect contact with cells or biological fluids may occur. The WST-1 biocompatibility results are significant because they: (1) verify that these membranes can be integrated into biorelevant applications, (2) help rule out potential toxicity arising from the fabrication steps and betaine, and (3) strengthen the broader case for clay materials as safe, sustainable, and multifunctional components in emerging biomedical applications. The overarching goal of unique membrane systems is to treat various burns, skin conditions, and complex open wounds.

Abstract Name: Annotation of the Pten and Foxo Genes in Drosophila Species

We investigated evolutionary change in two genes involved in the Drosophila insulin signaling pathway: Pten, a tumor suppressor that counteracts PI3K as a negative regulator of insulin signaling, and foxo, a transcription factor linking insulin signaling to the regulation of metabolic processes. To do this, we annotated Pten in *D. rhopaloa*, a species closely related to *D. melanogaster*, as well as the more distantly related species, *D. albomicans*. We also annotated the foxo gene in *D. guanche*. Orthologous regions to *D. melanogaster*'s Pten and foxo genes in the genomes of *D. rhopaloa* and *D. albomicans* (Pten) and *D. guanche* (foxo), provided by the GEP, were identified using NCBI BLAST. We then used the GEP Genome Browser's gene prediction models and RNA-Seq data, particularly splice junctions, to identify the coordinates of each Pten and foxo coding exon in our target species. We found that Pten isoforms in *D. rhopaloa* showed higher similarity to those of *D. melanogaster*, differing only by minor insertions or deletions, than did the isoforms in *D. albomicans*, which exhibited larger structural differences. The higher similarity between the more closely related species suggests that Pten evolution was not influenced by selection. We also found that the foxo-PH isoform present in *D. melanogaster* was absent in *D. guanche*, while the other isoforms showed high similarity across the first half of the gene. Collectively, our annotations will be used in the GEP Pathways Project, a nationwide collaborative research program to develop accurate gene models for genes in the insulin

signaling pathway across the *Drosophila* genus to compare evolutionary changes across these genes to their role within a signaling pathway.

Abstract Name: Welcoming the Dear Neighbor?: The Legacies of Desegregation and Integration Efforts in St. Paul Public Schools

In 1971, the St. Paul Human Rights Commission filed a lawsuit against St. Paul Public Schools (SPPS), the school district serving Minnesota's capital city, for failing to provide equal educational opportunities for all children. SPPS ultimately negotiated the dismissal of the suit by developing a desegregation-integration plan. My research sought to understand how SPPS researched and developed their plan, its implementation across already existing schools and newly established learning centers, and the overall effectiveness of their desegregation and integration efforts before and after being sued. The SPPS desegregation-integration plan was spearheaded by the St. Paul Superintendent George P. Young, who was white. Close reading and analysis of his statements, speeches, and letters in the SPPS archives, held at the Gale Family Library at the Minnesota History Center, reveal that Young was the St. Paul Superintendent from 1969 to 1985. Young demonstrated a commitment to desegregating and integrating SPPS, but in creating a system that allowed for voluntary integration, he also allowed for voluntary resegregation. Before this lawsuit, SPPS had already begun open enrollment in 1965, but this measure eventually exacerbated segregation through "White flight" as White parents began to move their families away, and with that move came the gradual loss of funding for desegregation and integration programs. In 1971, St. Paul voted against a 32 million dollar bond to finance school facility improvement, specifically the building of specialized educational centers; a serious blow to Young's desegregation and integration efforts. Analysis of historical records from the time reveals that efforts in desegregation and integration, such as the learning system model, open enrollment, and magnet schools, required continued attention and funding, resources that SPPS was slowly losing or failing to attain in the first place.

Abstract Name: An Unflinching Step to the End: An Analysis of Virginia Governor James L. Kemper's Veto of the 1874 Petersburg Charter

This research seeks to address the question regarding Virginia Governor James Lawson Kemper's controversial veto of Senate Bill 5 in 1874. The story begins with the Virginia Conservatives of the 1870s, who represented a group of individuals, mostly Confederate veterans, who fought the Radical Republicans for control of Virginia's government. Their impact has been rather understated, and their leaders have been rebranded as hopeless "Lost Cause" advocates. Among this group was James Lawson Kemper, who served as Governor from 1874-78. During the third month of his administration, he faced a crisis. The white citizens of Petersburg had rewritten their city charter to effectively neutralize the black vote. Governor Kemper chose to strike the bill down, showing his commitment to all Virginians and his denial to give in to pressure. His act

proved that the Virginia Conservatives were not as racist or suppressive as they may have seemed. This research investigates the context of Kemper's decision, placing it within the larger period of Virginia Conservatism. It was conducted using a collection of primary and secondary sources, which were synthesized to create the full picture of Kemper's veto decision. The research concludes that Kemper's veto was prompted by his commitment to be "every inch the Governor" of all Virginians, black and white. This work is significant because the historical body of knowledge has yet to have a study focusing exclusively on this topic and its impact on Virginia Conservatism in the late 19th century.

Abstract Name: Quiet In the Library: The U.S. Information Service and Korean Student Resistance

Student activism has long been a driving force in South Korean political movements. This project explores the intersection between Korean student protests, American foreign policy, and media framing, specifically examining how Korean perceptions of U.S. involvement in the Gwangju Uprising led to the occupation of the U.S. Information Services (USIS) library in Seoul in 1985. While the United States positioned itself as a global advocate for democracy, its "quiet diplomacy" approach toward South Korea's military regime contradicted that narrative, fostering resentment among the most politically active demographic: university students. Drawing on archival materials, U.S. and Korean media coverage, and secondary analyses, this research investigates two central questions: How did South Korean student activism challenge American political influence and public diplomacy in Korea? And how did media framing shape public understanding of these events in the U.S.? This thesis aims to fill a gap in scholarship by integrating Korean domestic activism with American media and diplomatic responses. By examining competing narratives surrounding USIS, it seeks to reveal how information politics and student protest intersected during a pivotal decade of democratization, with implications for understanding international perceptions, media power, and grassroots mobilization.

Abstract Name: Clock In, Burn Out: The Heart Risks of Job Stress

Burnout, a state of emotional, physical, and mental exhaustion from occupational stress, is linked to cardiovascular disease (CVD) and related risk factors. In the U.S. Virgin Islands (USVI), diabetes, hypertension, and hypercholesterolemia are prevalent and are a leading cause of death in the territory, yet the connection between burnout and these conditions remains unclear. The aims of the study were to examine rates of occupational burnout amongst residents in the island of St. Thomas, USVI and examine whether occupational burnout is related to CVD risk factors among St. Thomas residents. A cross-sectional survey of 120, St. Thomas residents in July 2025 was conducted. Participants completed a modified Maslach Burnout Inventory and reported on demographics and CVD risk factors. The median age was 39, with 51% female, 80% Black, and 19% Hispanic, representing a range of occupations. It was identified that 64% of participants met criteria for burnout, especially young adults (78%) and women (70%). Burnout was not significantly

associated with diabetes, hypertension, or hypercholesterolemia. These findings highlight a high prevalence of burnout in St. Thomas and the need for workplace and community-based interventions.

Abstract Name: “Advancing Men’s Mental, Physical Health, and Wellbeing Through Supportive Environments.”

Since the 1960s, historical and contemporary research has consistently shown disproportionately high rates of violent suicide among men, particularly those who are Latino, Native, or from low-income communities. These outcomes are closely tied to rigid cultural expectations surrounding masculinity, which often discourage vulnerability, emotional expression, and help-seeking behaviors. As a result, many men internalize psychological distress, delay or avoid accessing mental health resources, and experience compounded physical and emotional challenges. This project investigates how intentional architectural design can address these disparities by creating a wellness environment tailored to men’s physical, mental, and social needs. The proposed facility integrates inclusive fitness, rehabilitation, and recovery zones that strengthen the body while supporting discipline, confidence, and resilience. Although accessible to all genders, the layout incorporates private and semi-private spaces that respond to men’s comfort levels, reducing fear of judgment and encouraging consistent engagement. Beyond physical wellness, the design promotes mental and social health through educational spaces where men can develop everyday life skills, such as communication, cooking, sewing, and emotional literacy, which are rarely emphasized in male-centered environments. Group rooms and communal lounges foster peer support, allowing men to share experiences, normalize vulnerability, and cultivate healthier coping strategies within a connected community. By bridging physical activity, mental health education, and community-building elements, this project demonstrates how the built environment can actively reduce stigma, empower men to seek support, and reshape cultural narratives surrounding masculinity. The study highlights architecture’s potential to serve not only as a backdrop for healing but as a direct contributor to long-term well-being for at-risk male populations.

Abstract Name: 2-Neighbor Bootstrap Percolation in Graphs

The r -Neighbor Bootstrap Percolation process is defined on a graph. The process begins with an initial set of infected vertices. In each subsequent round, an uninfected vertex becomes infected if it is adjacent to at least r previously infected vertices. We refer to r as the percolation threshold. If an initially infected set of vertices begins a process in which every vertex of the graph eventually becomes infected, then we say that this set of vertices percolates. A graph is r -bootstrap good, or r -BG if it contains a percolating set of size r . We will explore sufficient and necessary conditions for a graph to be 2-BG. That is, we will show that certain structural qualities force a graph to be 2-BG, and we will show that 2-BG graphs must have certain characteristics.

Abstract Name: Two Thresholds, One Deal: How Post-Brexit Merger Control Shapes UK–EU M&A Financing

In less than a decade, UK–EU mergers and acquisitions (M&A) have shifted from a straightforward, single-review system to a more complex and uncertain one. Before Brexit, the European Commission alone reviewed large UK–EU deals. After Brexit, both the UK’s Competition and Markets Authority (CMA) and the European Commission (EC) can review the same cross-border agreement, often with different rules, timelines, and information requirements. Over this shift to dual review, UK-related foreign direct investment projects fell from 2,265 in 2016–17 to 1,555 in 2023–24, suggesting that Brexit may be reshaping how firms plan and structure cross-border deals (European Central Bank 2021, p. 60). This raises a central question for scholars and policymakers: What explains firms’ choice between cash, shares, or hybrid consideration in UK–EU M&A after Brexit? To answer this, the project uses descriptive statistics and a short-window event study on deal-level data from Orbis M&A and Bloomberg Terminal, combined with CMA and EC merger decisions for UK–EU technology deals. This approach links different types of regulatory exposure to firms’ financing choices, whether deals are completed or collapse, and short-run share price volatility. Building on Chung et al. (2023), who find that stricter competition rules tend to lower acquirers’ share prices around merger announcements, the project examines short-term share price changes around deal and regulatory announcements as a simple signal of investor uncertainty. Key independent variables are regulatory exposure (no review, single EU or CMA review, or dual review) and timing relative to Brexit. Outcomes are financing structure, deal completion, and short-window volatility. The project tests whether dual-review deals, which face greater uncertainty, rely more on cash or cash-heavy hybrids, even though internal rules and misjudgments limit firms’ ability to adapt, and whether post-Brexit oversight encourages more conservative deal structures and dampens investor confidence in UK–EU capital markets over the medium term.

Abstract Name: Relationship Between Body Composition, Grip Strength, and Countermovement Jump Ground Reaction Forces to Hitting Metrics in Division I Collegiate Baseball Players

Strength, power, and body composition (BC) underpin high-velocity movements and are integral to success in baseball. In hitting, the ability to generate bat and ball exit velocities are believed to relate to these physical attributes. Performance assessments, such as bioelectrical impedance analysis (BIA), grip dynamometry, and countermovement jump (CMJ) force-plate testing provide quantitative insight into qualities that influence baseball performance and are foundational across anaerobic power sports. This study examined the relationships between BC, grip strength, and CMJ ground reaction forces (GRFs) with key hitting metrics (bat velocity and ball exit velocity) measured both in the laboratory and field settings. Twenty-four Division I (DI) collegiate baseball hitters volunteered during the offseason. BIA, using the InBody 770, assessed BC; a

Jamar hand dynamometer assessed dominant and non-dominant grip strength; and akimbo CMJs performed from Hawk Dynamics force plates assessed GRFs from the highest jump. Bat and ball exit velocities were measured on the field using a Blast Motion sensor and Trackman system, and in the laboratory using Qualisys motion capture system and Jugs radar gun. Pearson product-moment correlations ($p < 0.05$) were computed to evaluate relationships among BC, grip strength, CMJ GRFs, and hitting velocities. Results indicated multiple statistically significant relationships between BC, grip strength, CMJ GRF measures, and both mean and best bat and ball exit velocities in DI baseball players. These data support the relevance of measuring these performance variables to determine a player's baseline strengths and weaknesses, potential return-to-play if injured, or a player's training program. Strength and conditioning coaches may use these results to help design offseason training programs attempting to improve BC, such as lean body mass; grip strength; and CMJ GRFs including jump momentum, braking forces, propulsive forces, net impulses, and peak power to improve bat and ball exit velocities in collegiate DI hitters.

Abstract Name: The Effects of Music on Time Perception and Rate of Perceived Exertion during Exercise

Many individuals believe that listening to music while exercising increases enjoyment and makes the perception of time seem faster. Wu et al, (2022) found that listening to high-tempo music helped participants' performance increase both physically and mentally. Current literature has focused on music tempo and fatigue perception, while much less is known about music and time perception during physical activity. The purpose of this study was to determine whether music affects perception of time and Rate of Perceived Exertion (RPE) while exercising on a stationary bike. College-age students from a small liberal arts college were recruited and a one-sample experimental design was used. Participants will be asked to provide a sample of music they consider positively and negatively stimulating before the commencement of the study. Participants will be free to pedal at an RPM of their choice during each trial. During each trial, heart rate (HR), Revolutions per Minute (RPM), and RPE will be measured at various intervals. Music conditions included positively stimulating music, negatively stimulating music, and no music. Immediately following each trial, participants will report how long they think they were on the stationary bike. The independent variable is music type and the dependent variables include HR, RPM, RPE, and perceived time during the exercise trial. Repeated Measures ANOVA ($p < .05$) will be used to determine significant differences between trials. Results may indicate that when individuals are listening to music they consider stimulating, they will perceive a bout of exercise to be shorter and less difficult. Future research might look at how music impacts time perception during daily living tasks. Data collection is in progress. IRB #546675.

Abstract Name: Progress Towards the Synthesis of Hyrtinadines C and D

Hyrtinadines C and D are bisindole alkaloids isolated from the marine sponge genus *Hyrtios* that, despite showing some antimicrobial and antifungal properties, have little reported biological activity. Additionally, no practical means or published synthetic pathways exist for acquiring hyrtinadines C and D. The goal of our research is to develop a novel synthetic pathway for producing the molecules to allow further investigation of biological activities. We hypothesize that the structures should serve well as acetylcholinesterase and butyrylcholinesterase inhibitors, as recent literature reports indole-containing compounds bind favorably to the active sites of the enzymes. Preliminary molecular docking calculations support this, with results indicating favorable hydrogen-bonding and pi-pi stacking interactions between the indoles of the hyrtinadines and the aromatic amino acids located in the enzymes' active sites. Development of a synthetic pathway began with retrosynthetic analysis of the hyrtinadines' structures. We believe the most viable route requires formation of a stereospecific linkage between benzyloxycarbonylglycine-oxazolidinone, a protected glycine with an oxazolidinone chiral auxiliary, and an N-protected bisindole derivative. Recent work has focused on synthesizing the bisindole derivative, beginning with the reaction of 5-benzyloxyindole with oxalyl chloride and methanol to add methyl 2-oxoacetate to the indole's 3 position. Subsequent protection of the indole nitrogen with tosyl, triisopropylsilyl, carboxybenzyl, and benzyl groups has been attempted; only the carboxybenzyl group failed to afford the desired product. Hydrolysis of the methyl ester substituent was attempted via reflux with NaOH, and only the benzyl protecting group withstood the reaction conditions and afforded the desired indolyl-2-oxoacetic acid. Current work to complete the formation of the bisindole is investigating a Pd-coupling reaction between N-protected 5-benzyloxyindole-3-carboxaldehyde and the aforementioned indolyl-2-oxoacetic acid. The full results of these synthetic studies will be presented.

Abstract Name: Exploring Access to Services Among Individuals with Substance Misuse in the Bear River Region

In 2024, over 97,000 people in the United States died from a drug overdose. Although this represents a continued decline from the record-high rates of 2021, progress has not been felt equally across the U.S. The Centers for Disease Control and Prevention anticipate that Utah's overdose death rates will increase by five percent from 2023, making it one of only five states that see an increase between 2023 and 2024. The disease model of addiction acknowledges that addiction is a chronic but treatable medical condition. Functional brain imaging demonstrates that substance use disorders [SUDs] have the potential to change the brain, reinforcing the need to treat addiction similarly to other chronic medical conditions like hypertension or diabetes. This scientific reframing has helped to reduce some stigma within healthcare and mental health settings by shifting perceptions of addiction away from a moral failing toward a medical condition. Despite this progress, stigma remains widespread in the broader community, impacting the availability and access to treatment options. One study found that 79% of respondents view people with SUD as untrustworthy, 74% perceive them as dangerous, and 64% believe that these individuals are deserving of blame. When people face greater marginalization and stigma, they are less likely to seek treatment and rely on their social networks for support. Given Utah's rising overdose rates, it is vital to better understand the lives and needs of people with substance misuse in the Bear River region. This qualitative study conducted interviews with individuals currently experiencing substance misuse or participating in recovery to explore their experiences meeting basic needs, accessing services, and navigating stigma. Findings will inform service providers and policymakers in developing more responsive interventions tailored to the unique needs of this community.

Abstract Name: Accuracy of the information in Instagram video posts about food product reviewing at point-of-purchase settings.

Social media has become a significant source of health and nutrition information. Food product reviews at the point-of-purchase are commonly depicted. However, the content quality of these posts are difficult to discern by the lay user. This can lead to exposure to misinformation that can negatively impact food-related attitudes, choices, and behavior. The purpose of the study is to determine the accuracy of the claims in food product review video posts from Instagram accounts using content analysis and social media assessment guidelines. A content analysis of food product review videos was conducted. A list of Instagram accounts with 25,000 or more followers was identified via FeedSpot. Accounts were included if they had one post reviewing a food product in a point-of-purchase location (e.g., grocery store) within 6 months. Hashtags and keywords (e.g., #groceryhaul, #grocerytips, #budgetshopping) were used to identify video posts that met the inclusion criteria. Preliminary coding was done independently by two trained analysts to create a codebook. Concepts and ideas represented through visuals, dialogue, and captions were identified. Codebook refinement was done through reflective discussion. Full videos were analyzed for code contextualization and to identify components from the Assessment Flowchart for Credibility of Health Information in Social Media (Kington et al, 2021) and the Social Media Evaluation Checklist (Squires et al, 2023). Fifty videos, one from each Instagram account, that met the inclusion criteria were preliminarily coded. The resulting codebook consists of 329 total codes. An analytical sample of videos will be obtained through Meta Content Library API. Video content will undergo content analysis and be assessed for credibility. Social media platforms are highly accessible sources of information. Characterizing the extent to which nutrition information is accurate in these settings can help identify interventions to improve the information environment in these platforms to foster health-promoting food-related attitudes and behaviors.

Abstract Name: Partisan Divides in Environmental Spending Attitudes: A Two-Level Hierarchical Linear Analysis, 1973-2022

Public attitudes toward environmental spending have become increasingly divided along party lines, with sharp shifts over the past five decades. This thesis updates and expands on Johnson and Schwadel's 2019 study by applying a two-level hierarchical linear model to General Social Survey data updated to include data from 2015-2022, capturing how political affiliation, education, race, and economic context interact with broader political and economic contexts to shape environmental attitudes over time. The results show that political affiliation remains the strongest and most reactive predictor of environmental spending attitudes. Republican respondents are significantly more likely to oppose environmental spending, especially under Democratic presidencies. In contrast, Democratic support remains relatively stable across changing political contexts. Education and Age also emerged as significant factors: individuals with more education and younger respondents are more likely to support environmental spending. Race had mixed statistical

significance. Income, sex, and unemployment are not significant predictors on their own, but interactions indicate that attitudes may shift based on context. This study reinforces the central role of partisan identity in shaping environmental views and demonstrates how political and economic context can activate or dampen that divide. By incorporating new interaction terms and updated data, the model offers a clearer understanding of how these dynamics have evolved over time. The findings underscore the challenges of building bipartisan support for environmental policy and point to the importance of messaging that considers political context and reactive partisan patterns.

Abstract Name: Threads of History: Textiles in Pre- and Post-Colonial Peru

This research focuses on textile production as an art form in Wari and Inca societies, examining the textile-making process and its cultural significance. The study contributes to academic research on the role of both genders in textile creation and the use of textiles in rituals to reinforce social status. This examination demonstrates that, although aesthetically different and used in various rituals, the Wari and the Inca Unku tunics served as symbols of political power, social status, religious beliefs, and imperial control. This study begins with a brief discussion of the Wari and Inca's political, social, and cultural systems and gender roles to provide a historical context for textile production. Following, the discussion of textile materials, dying techniques, the weaving process, and social purposes in the lives of the respective societies will be presented. The examination of the use of textiles in burial practices further demonstrates their role in reinforcing social status and gender roles. This comparative study is based on art-historical and historical studies, as well as on iconographical examination of the Wari tunic and the Inca Unku tunics.

Abstract Name: Shaping Inclusive Cities: Exploring Cultural Equity in Urban Planning

City plans guide the development of infrastructure and public services in an area, but there is a growing emphasis on cultural planning. According to scholars like Kovacs (2011) and Ashley et al. (2021), cultural plans are a framework for improving community and economic development by integrating the arts and a neighborhood's values in the planning system. This shift reflects a broader understanding of how culture plays a vital role in the growth of an environment through building place identity, fostering social cohesion and supporting financial revitalization. This project examines about 90 cultural plans from cities nationwide to gain insight into how they engage with social justice themes such as equity and diversity in the planning process to shape more inclusive and representative landscapes. We began by analyzing existing plans, searching for terms indicative of cultural consideration such as gentrification and traditions, to explore how existing cultural development plans address questions surrounding crime, race and belonging. We aim to assess how municipalities define and prioritize communities in order to uncover the benefits and limitations of using cultural planning as a tool for equity and inclusion. By identifying what is emphasized and what is overlooked, this study highlights opportunities to strengthen cultural plans so they better reflect the diverse needs and voices of communities.

Abstract Name: Elongation Factor-P mediated translation of AmpG is required for meropenem resistance in *E. Coli*.

Antibiotic resistance occurs when bacteria survive in the presence of antibiotics. Two classes of antibiotic-resistant pathogens have been on high alert for the CDC: carbapenem-resistant Enterobacterales (CRE) and extended-spectrum beta-lactamase-producing Enterobacterales (ESBL-E). These pathogens are resistant to beta-lactam drugs that target bacterial cell wall biosynthesis. Elongation Factor-P (EF-P) is a translation factor that facilitates polyproline synthesis. When EF-P is absent, many bacteria become hypersensitive to antibiotics. While it is established that EF-P plays a role in resistance in many bacterial species, it's unclear if EF-P plays a similar role in resistant pathogens such as CRE and ESBL-E. Here, we aimed to characterize the role of EF-P in antibiotic resistant *Escherichia coli*. Loss of EF-P resulted in hypersensitivity to carbapenem and penicillin antibiotics. Carbapenem hypersensitivity in Δefp cells was maintained when the bacteria expressed carbapenem resistance gene NDM1. To better understand the mechanism behind EF-P dependent resistance, EF-P dependent genes involved in cell wall biosynthesis were identified from previous ribosomal profiling studies. AmpG is an EF-P dependent gene utilized by bacteria to synthesize the cell wall. In this study, WT ampG and ampG without the encoded polyproline motif (ampGPAF) were cloned and expressed in Wild Type and Δefp *E. coli*. When the polyproline motif was abolished, WT and Δefp displayed comparable meropenem resistance, indicating the Δefp antibiotic hypersensitivity phenotype originates from the inability to synthesize AmpG. The hypersensitivity phenotype observed in the absence of EF-P is caused by the bacteria's inability to synthesize AmpG, a necessity for cell wall biosynthesis.

Abstract Name: Identity at Work--Help or Hindrance?: How Disability Identification Shapes Cognitive Interference in the Workplace

Historically, neurodivergence has been stigmatized as a deficit, with accommodations being seen as a setback rather than being beneficial. (Solovieva & Walls, 2013). This deficit view has created difficulties for neurodivergent employees. Challenges have been created from this stigmatized view. Some examples include stigma, disclosure concerns, as well as reduced work performance (Moloney et al., 2019; Kulkarni, 2022). Researchers have begun reaching for a shift toward viewing neurodivergence as a difference rather than a weakness/deficit, emphasizing its strengths and its flexibility in workplace design (Sheppard-Jones et al., 2021; Petty et al., 2023). However, few studies have proven whether positive stigma reframing actually improves work outcomes. The study examines whether reframing neurodivergence in the workplace affects

productivity. I hypothesize that positively reframing the stigma of neurodivergence will lead to increased workplace productivity. Participants will complete an online survey where they choose one of three options describing neurodivergence: positive, negative, or neutral. After reading the question, participants will answer questions that measure the perceived advantage of neurodivergence, anticipated stigma, and affected productivity while doing a task in the workplace. T-tests will be used to compare productivity between participants who were shown a positive stigma reframing compared to those that were negative, and those who had no effect. Correlations between anticipated stigma and affected productivity will also be examined. The study will give evidence as to whether positive descriptions of neurodivergence can improve workplace productivity.

Abstract Name: Synthesis of Polyimine Covalent Adaptable Networks Through Imine Metathesis Chemistry

Polymers, commonly known as plastics or resins, are classified as thermosets, thermoplastics, or elastomers. Thermosets possess excellent mechanical strength and thermal stability but cannot be reprocessed or recycled once cured. Thermoplastics, by contrast, can be reshaped and recycled but lack the durability required for many high-performance applications. In recent years, Covalent Adaptable Networks (CANs) have emerged as a promising class of materials that combine the strengths of both systems. CANs behave like thermosets under service conditions yet undergo reversible bond exchange, enabling reprocessing and repair. However, many reported synthesis routes rely on hazardous, expensive, moisture-sensitive chemicals or complex procedures, limiting their practicality and broader adoption. Our project aims to develop a more accessible and versatile method for synthesizing polyimine CANs by leveraging formamide-functionalized methacrylate (FEMA) as a monomer platform. This approach has not been explored previously and offers a safer, more cost-effective route that broadens monomer compatibility and simplifies fabrication. We successfully synthesized FEMA-based CANs through a straightforward free-radical polymerization and crosslinking process and are now investigating how different monomer combinations influence network formation and dynamic behavior. To characterize the materials, we use analytical techniques including nuclear magnetic resonance (NMR) spectroscopy to confirm chemical structure, Fourier-transform infrared (FTIR) spectroscopy to monitor imine bond formation, and differential scanning calorimetry (DSC) to assess thermal transitions. Mechanical performance and reprocessability are evaluated using a Carver press and subsequent mechanical testing, such as indentation and sonication. These analyses allow us to determine how formulation choices affect recyclability, thermal stability, and mechanical properties. This work contributes to the development of next-generation reprocessable thermosets by demonstrating a practical, scalable pathway for synthesizing polyimine CANs. By lowering cost and safety barriers, this method may expand the accessibility of CAN research and enable broader industrial and academic exploration of dynamic polymer networks.

Abstract Name: Cultural Adaptation of CBT for Hwabyung versus GAD

Culturally-bound syndromes, such as hwabyung—, a Korean syndrome that includes symptoms like heat sensations, heart palpitations, and fatigue that come from a sense of social injustice—pose a particular problem for clinicians applying evidence-based treatments like Cognitive Behavioral Therapy (CBT), which are often standardized for DSM-5 disorders such as Generalized Anxiety Disorder (GAD). Although the symptoms of anxiety and distress may overlap between conditions such as GAD and hwabyung, their individual conceptualizations and core features are very different. This raises uncertainty in how treatments are selected and applied. There is also a factor of cultural differences and cultural heuristics that play into the understanding and ability to appropriately diagnose psychological disorders. Clinicians may change how they treat uncommon disorders such as Hwabyung in comparison to western mental disorders due to unfamiliarity. This study examines clinician treatment decisions in response to symptom profiles for GAD and hwabyung. The central goal is to ascertain whether and how clinicians apply CBT for a culturally-bound syndrome compared with a similar DSM-5 disorder. In order to investigate this, 98 clinicians were recruited from state licensing boards (psychologists, licensed professional counselors, marriage and family therapists and licensed clinical social workers) via email and given two case vignettes of clients meeting criteria for GAD and hwabyung, respectively. Thirty-eight (38.78%) clinicians used CBT as part of their treatment plan for Hwabyung, and 56 (57.14%) clinicians used CBT as part of their treatment plan for GAD. It is hypothesized that clinicians are more likely to culturally adapt their approach for Hwabyung than GAD in their application of CBT. This hypothesis will be evaluated by qualitative analysis of the content of clinicians' treatment plans. Implications of these findings for training and best practice will be discussed.

Abstract Name: Effects of Agricultural Land-Use on Amphibian Immune Defenses Against the Skin Pathogen *Batrachochytrium dendrobatidis*

Chytridiomycosis, an infectious skin disease caused by the fungal pathogen *Batrachochytrium dendrobatidis* (Bd), has driven catastrophic amphibian population declines across the globe. More than 500 species have been affected, and even in habitats lacking other obvious environmental stressors, Bd can still cause severe mortality and local extinction. Amphibians rely on a vital innate immune defense—antimicrobial peptides (AMPs)—secreted to their skin to inhibit the growth of pathogens such as Bd. Yet, with the expansion of agricultural activities, the chemical composition of freshwater habitats has been profoundly altered by fertilizer and pesticide runoff, which introduces nitrogen, phosphorus, and heavy metals and changes water pH, conductivity, and total dissolved solids. These shifts may impose chronic physiological stress that can potentially suppress immune function, including AMP production. This study investigates how agricultural land use affects the quantity and antifungal effectiveness of AMPs in green frogs (*Lithobates clamitans*) across a 0–60% agricultural land-use gradient in northwestern Pennsylvania. During field sampling at sixteen ponds, approximately 220 frogs were collected, and environmental parameters and individual morphometrics were recorded. Skin secretions were induced using norepinephrine injections and collected through water baths. In the laboratory, peptides are enriched via Sep-Pak C18 solid-phase extraction and quantified using the Pierce Micro BCA Protein Assay. Future analyses will include growth inhibition assays to assess AMP effectiveness against Bd and Matrix-Assisted Laser Desorption/Ionization (MALDI) mass spectrometry to compare molecular profiles across agricultural sites. We hypothesize that agricultural land use reduces AMP secretion and weakens Bd inhibition capacity. By integrating biochemical, ecological, and pathogen-level

analyses, this research will clarify how anthropogenic stress influences amphibian immune defenses and inform habitat management strategies to mitigate disease risk in human-altered landscapes.

Abstract Name: The Impact of Generative AI on Student Learning in College-Level Mathematics: How AI Can Be Effectively Incorporated into the Learning Process

This research investigates the impact of generative artificial intelligence (AI) tools on student engagement, perceived learning, and math anxiety in college-level mathematics courses. The study addresses the question: How can generative AI be effectively incorporated into the mathematical learning process to enhance student learning experience? Building upon existing literature on math anxiety, AI-assisted learning, student engagement, and prompt engineering, this project contributes to the growing body of research exploring how emerging technologies, such as artificial intelligence, reshape traditional mathematics education. The study hypothesizes that thoughtful integration of generative AI can support student confidence and conceptual understanding, provided that its use is guided by structured learning frameworks. Employing a mixed-methods, survey-based approach, data will be collected from undergraduate students who have experience in college math courses. Surveys will be conducted to assess participants' engagement, anxiety levels, and attitudes toward AI use. Responses will then be qualitatively coded and statistically analyzed to identify patterns, correlations, and predictors of AI reliance and perceived academic outcomes. The anticipated findings are expected to provide insight into how AI may have long-term learning benefits when used collaboratively, supported by a foundational understanding of prompt engineering. The research aims to produce a structured study guide that empowers students and educators to incorporate AI thoughtfully into mathematics instruction. Ultimately, this project seeks to balance innovation with pedagogical integrity, offering evidence-based recommendations for the responsible adoption of AI in mathematics education learning environments.

Abstract Name: To compare environmental pattern of nursing care to patient activity patterns over a 24-hour period in a critically ill patient in intensive care unit

Delirium is an acute brain dysfunction occurring in 50% of intensive care units (ICU) patients. Delirium survivors are twice as likely to develop dementia. The parent study prospectively recruited aging adults (≥ 50 yo) admitted to the ICU for ≥ 24 -hour. The study team collected continuous video data and delirium assessments four times daily. This secondary analysis analyzed the type, timing, and duration of documented

patient activities. Each nursing and patient activity was coded minute by minute in two-hour increments across three time periods: morning, afternoon, and night. We summarized observed activities using descriptive statistics and examined the relationship between type of activity (nurse, patient) and time of day. The 53-year-old white, non-Hispanic, female was a high school graduate and admitted with diabetic ketoacidosis. The patient had severe, hyperactive delirium. The nurse spent time conducting each activity: assessment (214 minutes), medication administration (82 minutes), and non-patient related tasks (74 minutes). The patient spent time engaged in these activities: speaking with visitors (12 minutes), restlessness and agitation (71 minutes), and resting (178 minutes). These activities did not vary greatly between the afternoon, night, and morning time periods. From the data, we see that the nursing workload is high, and most activities are tasks that do not directly involve the patient. The patient activities highlight the characteristics of delirium, restlessness and agitation, and how they may limit the ability to meaningfully interact with others. Future research can further examine these time periods in additional patients to expand on these findings.

Abstract Name: DetermiLogic: A Reliable Pipeline for Translating Natural Language into Formal Logic

DetermiLogic is a natural-language-to-logic translation pipeline designed to make formal reasoning more reliable and reproducible. Many large language models (LLMs) can convert written requirements into logical formulas, but their outputs are often inconsistent and difficult to verify. Our project addresses this challenge by developing a structured pipeline that combines LLM-based translation with symbolic verification tools, allowing each step to be checked, replayed, and validated for accuracy. As undergraduate researchers, we contributed to the design and implementation of all three stages of the DetermiLogic system: (1) translating natural-language requirements into propositional logic ($NL \rightarrow PL$), (2) validating the translation by converting the logic back into natural language ($PL \rightarrow NL$), and (3) compiling the formulas into conjunctive normal form ($PL \rightarrow CNF$) for automated reasoning. We fine-tuned the models used in these stages, built the logging components, and implemented deterministic decoding settings to ensure that the system produces identical outputs for identical inputs—an essential property for reproducible formal reasoning. To evaluate the pipeline, we tested it on the SatBench dataset of 2,100 natural-language specifications. The final system achieved 94.46% correctness on SAT/UNSAT solver judgments, meaning that the logical formulas generated by the pipeline align with the ground-truth solver outcomes. The median similarity score between the original requirement and its round-trip translation (87.73%) indicates that the logic also preserves the text's meaning. Together, these results demonstrate that combining deterministic LLM behavior with automated validation steps can make natural-language interfaces significantly more transparent and trustworthy. This work highlights a promising direction for building reliable AI tools that support software verification, safety-critical reasoning, and educational applications that require accurate logical translation.

Abstract Name: The Gut Brain Connection: Exploring how microbiome diversity influences anxiety and health in young adults

The rate of anxiety and depression have nearly doubled among young adults compared to teenagers, making it increasingly important to understand the factors that contribute to this growing mental health problem. One factor that has emerged as a crucial factor in influencing the development of physical and mental health is microbiome diversity through the gut-brain axis. This study explores the relationship between the gut microbiome and mental health (specifically anxiety) in young adults. We aim to answer the question how gut microbiome diversity affects the anxiety level in young adults, a population increasingly affected by stress challenges. Previous research suggests that certain bacteria groups help decrease risk and severity of anxiety. Data were compiled from a study examining the HAMA 14 (Hamilton Anxiety Rating Scale) score across three different treatment groups, and comparing the relative abundance of various beneficial gut bacteria in these groups to determine the correlation between differences in microbial diversity and anxiety levels. This research hypothesizes that higher gut microbiome diversity is associated with lower anxiety levels in young adults. The one-way ANOVA test revealed a P value (< 0.001) with the significant level of 0.01, there was a statistically significant change in anxiety scores attributable to the treatment. But due to the limitation of a one way ANOVA test, the analysis does not directly associate the change in anxiety level with the microbiome diversity. This highlights the need for further research to explore the biological influences on mental health to better understand the gut-brain axis and solve the ongoing issue.

Abstract Name: Death or Liberty: A Legacy Stretched Through Time

While attending my second African American Studies class at Virginia Commonwealth, I was introduced to the story of Gabriel's Rebellion, a story about a slave rebellion that took place in Henrico County in the year 1800. This rebellion, however, was prevented due to a thunderstorm that made their plans near impossible to carry out and it was resolved that it would be carried out the next day. However, was all it took for betrayal to spread through the air. Two slaves cracked out of fear and informed their masters of the plan. And so, after so much time and effort, the plot died with twenty-six of its conspirators, including Gabriel. After hearing about this story, I knew I needed to expand my knowledge on it. The original plan for this project was to make a standard forty minute documentary but I realized how many times this story had been told in every format. This new film is not meant to serve as a retelling of the events of the rebellion or its immediate aftermath. It instead focuses on the ripples sent over time that can still be felt by people two-hundred and twenty-five years later. Gabriel's final act stretches out through all of Virginia and leaves a mark from the punitive laws his conspiracy triggered, to the memorials held to honor his tenacity and bravery in the face of insurmountable adversity. The second piece is what this film is about, the legacy Gabriel left behind through his actions, and how it continues to affect the African diaspora of Virginia. After spending weeks researching, attending a memorial service and a play, Gabriel's legacy and the strength he left behind. That is the story I plan to tell.

Abstract Name: The Role of Income Inequality and Personal Characteristics in Charitable Donations

Charitable giving remains a major component of civic life in the United States; however, it is still unclear which variables might turn out to be deciding factor in the donation behavior. This study examines how regional income inequality and individual-level factors such as income, educational level, age, happiness, church attendance, and ideology affect charitable donations. The model uses 2014 data from the General Social Survey combined with the state-level U.S. Gini coefficients from the Census Bureau. A log-linear regression model estimated using Ordinary Least Squares was used to test three hypotheses: (1) individuals who live in more unequal neighborhoods contribute a larger part of their income; (2) charitable giving has a nonlinear relationship with income; and (3) conservatives contribute more than liberals. The empirical analysis supports the last two hypotheses; however, the relationship between income inequality and charitable donations is found to be negative. An increase in the Gini coefficient of 0.01 is associated with a 6.82% decrease in expected share of income donated to charity. The results are promising in terms of shaping nonprofit fundraising strategies and policy action meant to encourage charitable contributions across various demographic segments.

Abstract Name: Fine-Tuning Foundation Models for Cell Type Annotation of Mus Musculus Cancer Data

With the wealth of scRNA-seq data that has been produced, it is necessary to create methods to label the types of cells in these datasets to understand their functions. Foundation models are an important tool in analyzing biological datasets, as they are trained on large amounts of data for a variety of analytical tasks. One such task is annotating the cell types of a given dataset. Foundation models trained on diseased single-cell data can play a key role in identifying healthy and malignant cell types. Through the identification of these biomarkers, we can better understand the influence a drug may have had, or what impacts a disease can cause. However, applying general foundation models to disease datasets can lead to imperfect classification due to the heterogeneity of the data. Mus musculus cancer datasets are abundant, but the labeling and clustering may not be fully processed, and there is a lack of foundation models trained on mouse cancer data. This complicates the analysis for researchers who may not have the computational knowledge required to train or fine-tune a model accurate enough to glean statistically valid insights. This project has two central aims: (1) train foundation models and evaluate their cell type annotation performance on Mus musculus cancer data, and (2) construct a consensus cell type annotation package. Fine-tuning will be done by taking the last-layer embeddings, averaging them, and using methods such as k-nearest neighbors or logistic regression to map them to annotations. We will then create a ranked-choice voting system, as seen in CHAI (Lodi et al. Brief Bioinform. 2024), and compare it to popV (Ergen et al. Nat Genet. 2024). By combining fine-tuned models, we expect improved annotation accuracy and reduced burden on researchers analyzing mouse cancer scRNA-seq data.

Abstract Name: PVPA-30 Coated Titanium Substrates as a Means of Bone Marrow Protein Deposition and Stability

Titanium (Ti) is widely utilized in implantation technology due to its strength, biocompatibility, and anti-corrosive properties. Our research involves covalently attaching human recombinant bone marrow protein (hBMP-2) to the surface of polymer-coated Ti discs with the potential for use in the context of bone marrow transplantation in spinal surgeries. We synthesized a co-polymer named PVPA-30 which consists of thirty percent vinylphosphonic acid and seventy percent acrylic acid. PVPA-30 is reported to be biocompatible, biodegradable, and a good model for calcium chelation. Ti discs were dip-coated with PVPA-30 and baked to stabilize the polymer on the surface of the titanium before being exposed to PBS buffer over varying amounts of time. Covalent attachment of hBMP-2 to the polymer-coated Ti discs was performed via 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide and N-hydroxysuccinimide (EDC-NHS) coupling. Surface activation and hBMP-2 attachment were analyzed via video contact angle (VCA) measurement, Fourier Transformed Infrared Spectroscopy (FTIR), and X-ray Photoelectron Spectroscopy. Currently, we are developing different chemical environments of the polymer-coated Titanium surface in order to maximize hBMP-2 protein deposition to further support cell attachment. Moving forward, we plan to perform immunohistochemistry (IHC) assays to quantify the amount of protein attached to the surface. Assessment of hBMP-2 activity by cellular study is actively being pursued in collaboration with UPMC with the goal of extending the study to animal surgical replacement models.

Abstract Name: Upregulation of TMEM45B in a Rat Model of Stress-Exacerbated Orofacial Pain

Orofacial pain is a type of pain originating from the face, neck, and head, and is 2-4x higher in females. The reason behind the sex differences is not completely understood yet. Previously, our lab performed RNA sequencing and identified pain-related genes that are differentially expressed in males and females in stress-exacerbated orofacial pain. Transmembrane protein 45B (Tmem45b) is a pain gene that was found to be upregulated in stressed females compared to males. We also confirmed higher expression of Tmem45b cDNA in females compared to males in the Sal+FST (stress only) group. Transient Receptor Potential Vanilloid 1 (TRPV1) is expressed in a subpopulation of nociceptive sensory neurons of TG. To understand the role of the TMEM45B protein in pain nociception, we investigated the expression of TMEM45B and TRPV1 in the trigeminal ganglia (TG) of male and female rats using immunohistochemistry (IHC). Our preliminary data showed that there was less co-expression of TMEM45B and TRPV1, and TMEM45B was found to be expressed in larger ($>40\mu\text{m}$) neurons. To investigate the expression of TMEM45B in larger neuron cells, we will perform IHC with TMEM45B and NF200 (a marker for large, myelinated A- β fiber neurons). We hypothesized that the expression of TMEM45B is higher in females than in males. We created stressed rat

mode by subjecting the male and female rats to the forced swim test (FST) for three consecutive days. We fixed the rats by perfusion fixation and extracted the TG. TGs were sectioned into 30µm sections using a Leica cryostat, mounted onto glass slides. IHC will be performed on sectioned tissue using rabbit anti-P2rx3, guinea pig anti-TRPV1, or chicken anti-NF200 primary antibodies, and goat anti-guinea pig 568, goat anti-rabbit 488, and goat anti-chicken 568 secondary antibodies.

Abstract Name: Shared Parental Leave Accelerates Women's Reintegration into the Labor Market

Maternity leave has been widely studied regarding its negative effects on women's labor market participation and the wage penalizations they face around it. Then, paternity leave has been proposed as an alternative to promote shared responsibility. However, little is known about its effect on women's labor market participation. Therefore, this paper estimates the impact of extending paternity leave and implementing shared parental leave on women's reintegration into the labor market. Using administrative records from the Social Security system in Colombia, we analyze data on the number of women and men reporting parental leave before and after the 2021 policy change. We estimate difference-in-difference models with time and place-specific effects for months and cities. We find that after the shared parental leave policy was implemented, men increased in 40 percent the number of months on parental leave taken compared to women, accelerating women's reintegration into the labor market.

Abstract Name: From Classroom to Research Lab: Reimagining Teacher Education

Undergraduate research experiences (UREs) have increasingly been recognized as a high-impact educational practice that deepens students' disciplinary understanding, professional identity, and academic engagement. Within teacher education, UREs offer distinctive opportunities for pre-service teachers (PSTs) to bridge theory and practice, develop critical inquiry skills, and position themselves as producers of knowledge rather than mere consumers. A growing body of research highlights how participation in undergraduate research enhances pre-service teachers' research identities, pedagogical capacities, and reflective practices. Engagement in research helps students reconceptualize research as accessible, valuable, and directly relevant to K–12 teaching. Rather than viewing research as laboratory-based or detached from classroom life, PSTs who engage in inquiry-based projects learn to interpret data, communicate findings effectively, and see

themselves as contributors to educational improvement. Despite the established benefits of undergraduate research participation, few studies have systematically examined how research engagement influences pre-service teachers' development within HBCU contexts, particularly within colleges of education. In this presentation, we will present our preliminary data from a study comparing the experiences of pre-service teachers with and without undergraduate research experience. Using the Larrivee tool (2008) for assessing reflective practice, we surveyed ~100 pre-service teachers and then subsequently conducted two focus group interviews (UREs and non-UREs) to determine the impact of undergraduate research experiences on reflective practice. By examining differences in their confidence, teaching orientation, research identity, and professional self-concept, our research seeks to clarify the role that undergraduate research plays in preparing critically reflective teachers. The comparative design helps illuminate whether and how undergraduate research serves as a pathway to deeper reflective practice among HBCU pre-service teachers.

Abstract Name: Comparative Analysis of Histone Modifications and Chromatin Accessibility Across Leukemia Subtypes

Leukemia is the most common form of cancer in children, though it affects individuals across all age groups. As a blood-based cancer, malignant cells circulate throughout the body, instead of being confined to a localized tumor site. This increases the likelihood of metastasis and frequent relapse, making it particularly challenging to understand or treat. Acute leukemias are characterized by the rapid proliferation of different types of immature blood cells within the bone marrow. These immature cells lack many of the essential structures and functions of mature blood cells, resulting in a more aggressive, faster disease progression compared to chronic leukemias. This project will focus on acute leukemia subtypes, including T-cell acute lymphoblastic leukemia (T-ALL), acute myeloid leukemia (AML), and acute megakaryoblastic leukemia (AMKL). A computational analysis will be performed using publicly available chromatin profiling sequencing (ATAC-seq) data to compare the chromatin features of patients across different leukemia subtypes and healthy hematopoietic stem cells. Incorporating both cell line and patient-derived data in the analysis will provide a more accurate understanding of whether differences are consistent and may be attributed to disease-specific changes rather than natural genetic variation. ChIP-seq data will be used to analyze differential histone modifications, including H3K27ac, associated with the activation of genes and H3K27me3, linked to gene repression. Analysis of ATAC-seq data will be used to identify differential regions of chromatin accessibility, providing insight into which areas are more transcriptionally active or inactive. By integrating ChIP-seq and ATAC-seq data, this project aims to conduct an analysis of chromatin features to understand how genes are regulated differently in disease states compared to healthy individuals. Additionally, improving the understanding of the epigenetic landscape specific to each acute subtype will support future research efforts in identifying and expanding subtype-specific therapeutic targets.

Abstract Name: The Latino Virginia Oral History Project: Documenting Migration Experiences and their Integration in Virginia Among Colombians and Venezuelans in Virginia

The United States has witnessed a significant expansion of the Latino population throughout the country. Virginia has become a key location for understanding Latino migration and integration, given the rapid growth of this population and the diversity of national origins represented across the state. Despite this growth, the experiences of Latinos in emerging destinations, especially Colombians and Venezuelans, remain understudied. Given this gap in scholarly research, the present study seeks to answer the following questions: How have Colombians and Venezuelans in Virginia experienced migration and integration? How can documenting their stories contribute to a more accurate representation of Latino communities in the state? This study is part of a larger project that seeks to enrich Virginia's archival history by documenting and preserving the migration journeys and integration processes of Latinos across the state. The Latino Virginia Project collects oral histories with Latino adults aged 18 or older who have lived in Virginia for at least one year. Interviews include questions about migration experiences, identity formation, community integration, and social or economic challenges. Oral histories are audio-recorded and transcribed in their original language, and all materials are being archived in the Latino Virginia Digital Archive to support future research, preservation, and community engagement. For the purpose of this study, we will focus on 15 participants from Colombia and Venezuela, or whose parents immigrated from those countries. Possible findings from these interviews may include common patterns of cultural adaptation, challenges related to language or employment, and the role of community networks in supporting integration while building new lives in Virginia. These insights will help illustrate the diverse realities of Colombians' and Venezuelans' integration and contribute to a more inclusive historical record.

Abstract Name: Soy de aquí, como el coquí: The re-indigenization movement within the Caribbean diaspora

Over the last two decades, claims of Indigeneity among the Caribbean diaspora have sparked academic discussions on authenticity and who can rightfully claim Indigenous identity. However, scholars are reluctant to specify the criteria that constitute Indigeneity, leaving the elements of Indigenous Taíno identity unexplored. While previous research recognizes the importance of questioning dominant non-Indigenous pedagogy and centering marginalized perspectives within academia, limited attention has been paid to challenging conventional historical narratives regarding the Taínos. Researchers have overly focused on blood quantum among self-identified Taínos, despite Indigenous communities valuing other criteria such as family history, cultural differences from the majority population, previous experiences of colonization, and connections to ancestral lands to justify their Indigeneity. Interviews with Caribbean-Americans who self-identify as Taíno focus on reclaiming Indigenous identity and the revival of Taíno culture. Thematic analysis of these interviews will identify common metrics used to justify claims of Indigeneity among the participants' responses. This research may reveal collective historical memory and spiritual ties to the ancestral islands as key criteria of Neo-Taíno identity. Ultimately, the findings aim to amplify Taíno voices in academic conversations and dispel the myth of Taíno extinction.

Abstract Name: Narratives of Fear: Xenophobia, Media, and Immigration Anxiety

The United States is not just shaped by its history, but by the strong influence of immigrants who helped it grow. Yet today, immigration has curiously evolved into one of America's prominent fears. What was once a matter of policy has advanced into a growing societal tension. With the rise of politicized media and xenophobic themes in our political climate, the fear of illegal immigration continues to surge among the American population. Prior research demonstrates that race significantly influences how individuals interpret immigration policy and form attitudes toward immigrant communities. Building on this work, I will analyze the effect that partisan media has on xenophobic rhetoric to help explain the intensified fear of illegal immigration. Using the dataset from the Chapman Survey of American Fears, I employ a design of quantitative research to examine how politically fueled media sources reinforce negative perceptions of immigrants and thus contribute to the growing fear of illegal immigration. The findings aim to highlight the overall role of the media in our nation's anxiety about immigration and ultimately reveal how distorted patterns of representation continue to perpetuate inequality in American society. To uphold ethical impartiality, we must address the disparities that affect immigrants in order to truly achieve equality in our state.

Abstract Name: Let the Students Design: Building an AI Critical Literacy Course with and For Students

Note: The lead faculty mentor is proposing these presentations before students conduct research (Jan-May), due to the loss of funding in July 2026. Four student presenters and three faculty members in an English Department plan to attend NCUR. We propose a round-table or two presentations with two student presenters each. The students will show how collaborative, student-centered research and design can foster critical thinking, technological fluency, and equitable access to AI education while offering a model for integrating AI critical literacy into general education writing programs. The rapid spread of AI across communication and composing technologies has made it harder for faculty and students to maintain integrity and autonomy as writers. In response, faculty mentors and undergraduate researchers are collaborating to develop AI critical literacy. Student researchers will help formalize a relevant, accessible, evidence-based course and address our guiding question: How can collaboration between student research assistants and faculty mentors inform the design of an ethical AI critical literacy course that engages students while addressing evolving debates about machine learning and authorship? This project is grounded in work on digital ethics, critical information literacy, and student-centered curriculum design, particularly in HSIs where first-generation and Hispanic students often lack equitable access to emerging technologies. Students will present selections from their mixed-methods approach that incorporate the following: surveys and focus groups, analysis of existing AI literacy curricula, experimental piloting of assignments, and their evaluation of AI outputs for bias, accuracy, and rhetorical appropriateness. The presentations will demonstrate how student-centered design can foster critical thinking, technological fluency, and equitable access to AI education. Expected results include a modular course proposal with units on ethics, authorship, and algorithmic bias; a digital portfolio of adaptable materials; and recommendations for inclusive pedagogies that foreground student voices in course design.

Abstract Name: Microbes vs. Explosives: Bacterial Degradation of Nitroguanidine

Insensitive munitions (IM), such as nitroguanidine (NQ), NTO, and DNAN, are modern explosives designed to be safer for military personnel, but they still pose significant environmental hazards. These compounds can leach into surrounding soil and water, threatening ecosystems and public health. This project explores how microbes found in wastewater sludge might offer a sustainable bioremediation strategy to help clean up explosive contamination. The central question guiding this research is: Can sludge-derived microbial communities degrade nitroguanidine, an IMX-101 component? While previous studies have explored microbial degradation of traditional explosives, much less is known about microbial metabolism of newer insensitive munitions. This work aims to fill this gap by identifying and characterizing environmental microbes capable of degrading these emerging pollutants. To investigate this, we performed enrichment cultures with municipal sludge samples and NQ-based media, followed by microbial isolation, HPLC analyses, Gram staining, DNA extraction, and 16S rRNA gene sequencing for bacterial identification. We also monitored bacterial growth through OD600 measurements and visualized microbial DNA using agarose gel electrophoresis. Preliminary results suggest that certain isolates, including *Pseudomonas putida* and other unclassified strains, may possess the ability to break down NQ. Ongoing analysis is focused on genomic annotation using RAST and assessing whether these microbes express enzymes relevant to nitro-compound degradation pathways. Our findings suggest that native microbial communities could play a role in mitigating contamination from military sites, highlighting the potential for low-cost, community-informed bioremediation approaches. This work not only contributes to the scientific understanding of bacterial degradation of insensitive munitions but also addresses broader questions of environmental justice and the long-term impact of military-industrial activities on marginalized communities.

Abstract Name: 3D-Printed Freestanding PEDOT:PSS for Soft, Stretchable Electrochemical Sensors

Semiconducting Poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT:PSS) has been widely employed in flexible electrodes and organic electrochemical transistors for biomedical sensing due to its high electrical conductivity, favorable electrochemical behavior, optical transparency, and biocompatibility. However, conventional fabrication methods—such as spray coating, spin coating, and dip coating—offer limited design flexibility, complicate device integration, and often yield short operational lifetimes. Direct ink writing (DIW) 3D printing provides a compelling alternative, enabling microscale patterning, complex 3D geometries, and integration with other printable materials to form heterogeneous soft-electronic architectures. These 3D microstructures allow precise control over surface area, alignment-induced anisotropic conductivity, and mechanically reconfigurable device geometries that retain performance under deformation. Despite these advantages, most PEDOT:PSS structures remain limited to simple 2D layouts, and few studies

explore DIW printing of PEDOT:PSS as the 3D active electrochemical sensing material. In this work, we introduce 3D freestanding, highly flexible PEDOT:PSS structures for soft, multifunctional electro-chemical platforms. By pre-repolymerizing sorbitol before blending with PEDOT:PSS and employing a rapid solvent-drying process, we achieved freestanding printed structures with exceptional mechanical compliance—100–150% stretchability—without additional thermal curing. Using an AC electrochemical measurement approach, we induce shallow, reversible ionic diffusion and continuous regeneration of oxidized PEDOT, substantially extending device lifetime and suppressing irreversible hysteresis. The tissue-like mechanical properties of these printed structures enable tactile sensing in which electrical conductivity, ionic transport, and viscoelastic behavior are tightly coupled. This platform provides a data-driven framework for the systematic design and optimization of soft electrochemical sensors, opening new pathways for wearable technologies, lab-on-a-chip systems, and implantable medical sensing platforms.

Abstract Name: The Complexity of a Mother's Life: An analysis of Claudia Llosa's film, *Distancia de Rescate*.

This research will examine the theme of a mother's fear and desires and the techniques of sound and use of nature in Claudia Llosa's film *Distancia de Rescate*, 2021. Located in a rural town of Argentina, Llosa includes the country's personal attributes that play a part in the story's narrative, expanding on the themes of fear and desire. In my presentation, I talk about the complexities that come with being a mother. Examining specific scenes of the two mothers, Amanda and Carola, I explore the growing relationship that begins to develop between them and their two children, Nina and David. Llosa highlights this new riveting relationship between Amanda and Carola, and it becomes known to the audience that something deeper is happening beyond the surface. I build upon prior analysis of this film, from scholar Andrea Meador Smith's "Monstrous Desire in Samanta Schweblin's and Claudia Llosa's *Distancia de rescate*". In the analysis by Smith, she writes, "Amanda's memories, however, repeatedly return to her fascination with Carla and her constant preoccupation with Nina's safety" (Smith 110). I identify the monstrous desires and unprecedented dangers that follow this mother's children, and I identify how a mother's own personal desires play a role in the safety of her children. Furthermore, I seek to analyze how the mothers in the film are in a constant state of measuring their children's rescue distance to be there to save them from death. This will be a PowerPoint presentation presented in Spanish.

Abstract Name: Familism is not always protective: Family Weight Stigma, Familism, and Body

Dissatisfaction for Latine Youth

Body dissatisfaction is a rising cause of concern as bodies become larger and culturally, we continue to wage war on obesity. Although Latine youth suffer from the higher rates of obesity, previous work demonstrates that Latine youth are protected from body dissatisfaction by higher rates of familism. Specifically, values of family connectedness increase the likelihood of that Latine youth do not internalize thin ideals and feel encouraged about their bodies. However, what happens if families are the source of body dissatisfaction for Latine youth? For example, when Latine youth receive body related messages from siblings, they were more likely to internalize thin ideals and report more depressive symptoms. Although Latine intervention studies show positive effects of family support on weight loss, these studies do not examine the negative effects of familism on weight stigma and body dissatisfaction. The current study examines the effect of family-based weight stigma on body dissatisfaction and identifies if familism is a moderator. Using a mixed-method approach, this study will examine family sources of weight stigma, familism, and body dissatisfaction, controlling for obesity and gender. Latine adults aged 18-25 will be recruited from a regional university and Latine community programs to participate in a laboratory visit, which will include adiposity measurements, and self-reported surveys of body dissatisfaction, family sources of weight stigma (open- and closed- ended responses), and familism. We hypothesize that if Latine youth have high rates of familism, increasing family related weight stigma will predict increased body dissatisfaction. Understanding the role of familism and increased risk of family-based weight stigma for Latine youth will help inform interventions tailored to reduce obesity while not increasing body dissatisfaction.

Abstract Name: Targeting Metabolic Reprogramming in Drug-Resistant Breast Cancer Using Shikonin

Drug resistance in breast cancer (BC) remains a major challenge, and many resistant cancer cells rely on the Warburg effect—where glycolysis is favored over oxidative phosphorylation (OXPHOS) even when oxygen is available. This metabolic pattern supports rapid cell growth but also creates weaknesses that can be exploited therapeutically. In this study, we examined whether shikonin can disrupt this glycolytic dependence and push drug-resistant BC cells toward mitochondrial respiration. We tested their effects in MCF-7 (ER+/PR+), MDA-MB-231 (triple-negative, highly drug-resistant), and non-cancerous MCF-10A epithelial cells by measuring cell viability, oxidative stress, oxygen consumption, and metastatic potential. Shikonin significantly reduced viability in both MCF-7 and MDA-MB-231 cells, while having minimal effects on MCF-10A cells. Treated cancer cells also showed increased oxygen consumption, indicating a shift toward OXPHOS. This metabolic change was strongest in the MDA-MB-231 line, making them more sensitive to disruptions in mitochondrial function. Increased mitochondrial activity led to higher levels of oxidative stress, pushing these cells beyond their survival limits and triggering apoptosis. ROS levels remained lower in MCF-7 cells, likely due to their naturally higher dependence on OXPHOS. To better understand the metabolic changes driving these outcomes, we propose using real-time reverse transcription PCR to measure transcriptional changes across major categories of metabolism-related genes. These include genes that regulate mitochondrial biogenesis and electron transport chain function, key enzymes that control glycolysis, transporters that influence glucose uptake and lactate handling, transcription factors involved in hypoxia-driven metabolic regulation, and antioxidant pathways that respond to elevated ROS during increased mitochondrial respiration. Analyzing changes in these gene groups will clarify whether the compounds promote coordinated metabolic reprogramming toward OXPHOS. Overall, this study demonstrates the potential of targeting cancer metabolism to overcome drug resistance and highlights how shifting cells away from the Warburg phenotype may enhance therapeutic effectiveness.

Abstract Name: IS ARTIFICIAL INTELLIGENCE EFFECTIVE IN TESTING THE EXPLAINABILITY OF COURT ORDERS?

This study examines whether artificial intelligence (AI) can effectively explain court orders in ways comparable to human jurists, a question that has become increasingly important as AI systems gain prominence in legal analysis and judicial support. Building on research in explainable artificial intelligence, legal interpretation, and judicial communication, the paper develops a comparative framework that evaluates AI-generated explanations alongside those authored by judges, attorneys, legal professionals, and law students. The analysis focuses on four core AI capacities—legal interpretation, compliance with legal standards, neutrality, and level of detail—and three jurist attributes—legal expertise, interpretation of legal language, and communication skills. These variables are assessed against established measures of judicial explainability, including clarity, depth of legal analysis, identification of gaps, and consistency across cases. Using a mixed-methods design, the study employs structured evaluations from panels of legal experts and advanced law students to score AI- and jurist-generated explanations of standardized court orders. Quantitative ratings and qualitative commentary are analyzed to determine the relative strengths and weaknesses of each explanatory mode. Findings from this research aim to clarify whether AI can match jurists' reasoning quality or is better understood as a complementary tool that enhances judicial transparency, supports legal accuracy, and identifies gaps in legal decision-making. This comparison not only highlights AI's current capabilities but also identifies areas requiring further refinement before judicial integration. Insights from this research may inform the design of future legal technologies aimed at improving public understanding of court processes. By empirically assessing how AI and human jurists perform across key explainability dimensions, the study contributes to ongoing debates about the appropriate integration of AI in judicial processes and the evolving standards for transparent, comprehensible, and fair legal communication.

Abstract Name: "Temporary Roadblocks": Exploring how Individuals with Disabilities Navigate Social Inclusion in the UK

The research project will address how individuals with disabilities in the UK navigate social inclusion amidst systemic biases and policies that could pose a barrier to their full integration into society. Societal perceptions of disability can have profound effects on policy and the stigmatization of individuals with disabilities, leading these individuals to adapt necessary strategies to preserve agency while working towards individual goals and desired outcomes. Current literature discusses barriers individuals with disabilities face, including limited employment and socialization opportunities; the project will therefore explore the strategies individuals with disabilities employ to navigate these barriers. The project will apply the social model of disability to explore how systemic barriers and mindsets impede upon the daily lives of individuals with disabilities. A group of three individuals with a physical disability and three individuals with a cognitive disability will answer a series of open-ended questions to gain first-hand accounts of the individuals' perspectives and experiences. The responses will then be thematically coded and analyzed using the social

model of disability to uncover the barriers individuals with disabilities face and the strategies individuals use to navigate these barriers. Findings may highlight common barriers to social inclusion as well as the similar strategies individuals with disabilities use to overcome these barriers and maintain agency. The project will shed light on the lived experiences of individuals with disabilities, therefore informing policymakers on the future of disability policy and encouraging shifting mindsets regarding disability.

Abstract Name: Reward-Based Neurocognitive Biases in Probabilistic Reinforcement Learning and Unconscious Visual Perception

Conscious perception allows people to subjectively experience their surroundings, but it is unclear what stimuli will be consciously perceived and by what mechanisms. Because rewarding stimuli often capture attention, probabilistic reinforcement learning—which allows people to incrementally learn which stimuli are likely to be rewarding—may offer a mechanism through which the visual system prioritizes such inputs for conscious perception. The present study tested whether reinforcement learning shapes conscious perception by enhancing neural responses to probabilistically rewarding stimuli. Twenty-one college-aged participants completed ten iterations of combined ‘learning+perception’ study blocks while electroencephalography (EEG) was recorded. During learning blocks, participants identified which stimulus type (face or house) was probabilistically more likely to yield a reward. During perception blocks, participants localized a briefly presented, perceptually masked face or house stimulus and rated how clearly they saw it (perceptual ratings). The findings showed that participants successfully learned which stimulus type was likely to be rewarding. Importantly, during the perception block, previously rewarding stimuli elicited enhanced event-related potential (ERP) responses that have been previously associated with conscious visual perception, namely a greater occipito-parietal visual awareness negativity (VAN; ~200-300 ms) and a greater centroparietal late positivity (LP; > 400 ms), compared to stimuli that were not previously rewarding. However, subjective perceptual ratings did not differ between rewarding and non-rewarding stimuli. These collective findings suggest that neural processing was enhanced for the rewarding stimuli but that this enhancement did not translate into changes in reported awareness. This study provides initial evidence that reinforcement learning can influence the neural correlates often associated with conscious perception, offering a potential mechanism by which the visual system prioritizes inputs for conscious perception based on reward history.

Abstract Name: Comparing Machine Learning and Game-Theoretic Strategies in No Limit Texas Hold ’Em

This research compares the outcomes of playing a No Limit Texas Hold ’Em poker variant using machine learning algorithms with outcomes obtained from classical probability and game theory. Currently, there are few publicly available findings on machine learning–based poker strategies because of their complexity, and

many high-performing results are proprietary or sold commercially. To explore this gap, we built a custom game environment in Python and collected large-scale data from thousands of simulated games. The environment records detailed game states and outcomes in a tab-separated table, which is then used to train and evaluate machine learning models. Our study compares results obtained from these machine learning approaches to strategies in game theory, including approximations of Nash equilibria in simplified game states. We evaluate overall strategy performance by analyzing metrics such as win rates and expected returns. In addition, we examine whether machine learning algorithms exhibit game-theoretic behaviors, including bluffing and value betting. The expected results of this project include identifying scenarios in which certain strategies outperform others and determining the extent to which machine learning models align with or diverge from game-theoretic predictions. Ultimately, this research aims to help readers better understand how game theory can inform decision-making in poker and to provide insight into choosing effective strategies for their own gameplay.

Abstract Name: Kinetic Characterization of the Type IV Pilus Extension ATPase PilB1_CD from *Clostridioides difficile*

Clostridioides difficile is a major cause of antibiotic-associated infections and a leading source of illness in healthcare settings. A key factor in its ability to colonize and spread is the Type IV pilus (T4P), a flexible filament that allows bacteria to move across surfaces and attach to host tissues. The motor that powers pilus extension, known as PilB, is an ATPase enzyme that converts the chemical energy of ATP into mechanical work. Although this process has been studied in several Gram-negative bacteria, it remains poorly understood in *C. difficile*, a Gram-positive pathogen with distinct cell surface architecture. This project aimed to investigate the catalytic behavior of PilB1_CD, a T4P extension ATPase from *C. difficile*. The protein was produced in *Escherichia coli*, purified using nickel affinity and size-exclusion chromatography, and assayed for ATP hydrolysis activity. A colorimetric phosphate detection assay was used to measure the rate of phosphate release at varying ATP concentrations, and the data were analyzed to determine the enzyme's Michaelis-Menten parameters (V_{max} and K_m). Preliminary findings show that PilB1_CD follows classic enzyme kinetics and exhibits measurable ATPase activity, suggesting a conserved catalytic mechanism among T4P ATPases. Understanding the energetic properties of PilB1_CD helps clarify how *C. difficile* assembles its pili and may reveal new targets for disrupting surface colonization. This work contributes to a broader understanding of how bacterial movement and attachment are powered at the molecular level, highlighting a potential link between enzyme activity and infectious capability.

Abstract Name: The Impact of U.S. Section 201 and 301 Tariffs on China's Solar Panel Exports and Global Trade Diversion Effects

This study investigates the effects of U.S. tariff policies, particularly Section 201 and Section 301 measures, on China's solar panel exports and potential trade diversion patterns. The research aims to determine whether higher U.S. tariffs significantly reduce direct Chinese exports to the U.S. and whether these measures cause Chinese exporters to redirect their products to other major importing countries. Using monthly panel data from 2018 to 2025 collected from UNNCUR Travel Grant Comtrade, Ember, the U.S. International Trade Commission, and the World Bank, this paper constructs a fixed-effects panel regression model at the country-product-year level. The dependent variable is the export value of Chinese photovoltaic (PV) products, while key explanatory variables include U.S. tariff rates under Section 201 and 301. Control variables consist of exchange rates, GDP, solar commodity prices, trade exposure, and installed solar capacity. Empirical results confirm that U.S. tariffs sharply cut China's PV exports to America, while sparking a clear rerouting of shipments to fast-growing markets like Indonesia, Vietnam, and Bangladesh. Using a gravity-model setup, I map exactly how these barriers are rewiring renewable-energy supply chains. Policymakers now have hard evidence: tariffs do protect domestic industry, but they also push clean-energy hardware into new corners of the globe. This will reshape both who trades with whom and what the global PV map looks like in the future.

Abstract Name: "Solugender": Reimagining Gender Beyond the Binary as Individualized Metaphor

This paper introduces what I tentatively call solugender, an exploratory framework that reimagines gender as an individualized metaphor. Building on feminist and post-structuralist critiques of essentialism (Butler, Haslanger, Shelby) and trans and queer theory's insistence on self-definition and first-person authority (Stryker, Bettcher), I experiment with solugender as both diagnostic and generative—a way to articulate lived experiences shaped by race, class, migration, and mental condition. In this framework, gender functions less as a label than as a symbolic language through which individuals translate and reconfigure their social and affective realities. Methodologically, I examine solugender alongside gender pluralism, fluidity, and abolitionism, using criteria of minimizing oppression, practical feasibility, and fostering well-being. While solugender is future-oriented, it remains aware of the historical conditions under which gender has been named and policed, using them as empirical baselines. I juxtapose three examples testing the framework's utility (1) Samoa's fa'afafine, where gender operates as a social role embedded in kinship, (2) 2010s–2020s digital folksonomic practices; and (3) online emergent identity practices among neurodivergent Gen Z, such as xenogender formations. Reading these as shifting naming regimes with both poetic autonomy and collective adaptability of gendered meaningmaking, I ask and argue what kinds of futures they make imaginable—and whether an individualized grammar of gender might de-regulate without erasing power, and empower without re-essentializing. As an undergraduate researcher, I present solugender as a developing framework open to critique and refinement. My goal is not to finalize a theory, but to test whether this metaphorical reorientation of gender can contribute to social justice—by resisting normative regulation, enabling inclusive self-expression, and reframing gender as a resource for psychological well-being and collective flourishing. I ultimately hope this concept can serve as a heuristic that other researchers might adapt in gender studies, cultural analysis, and social policy contexts.

Abstract Name: Macrocyclic Chromophores as a Novel Class of Fluorescent Molecules

Fluorescent proteins are extremely useful in biological imaging techniques that enable the observation of cells and biological processes. Green Fluorescent Protein (GFP) is widely considered the most commonly used fluorescent protein for biological imaging due to its accessibility and compatibility with biological molecules. The portion of the protein that is responsible for the fluorescent response is an imidazolidinone-based chromophore that is not fluorescent outside of the restrictive protein structure, limiting the development of this compound as a scaffold for advanced fluorescence-based imaging techniques. This research aims to demonstrate that restricting the free rotation of the chromophore via macrocycle formation will enable fluorescence outside of the protein environment and establish imidazolidinone-based chromophores as scaffolds for fluorescent molecule development. Here we describe progress toward the synthesis of macrocyclic imidazolidinone-based chromophore molecules with restricted rotation. We expect the rotational restriction to allow fluorescence in a GFP chromophore macrocycle to yield a new class of small molecules that can be tailored for imaging applications. Efforts to convert a synthetically accessible oxazolidinone intermediate into the final imidazolidinone core will also be described. The optical properties of all synthesized molecules will be investigated using UV-Vis and fluorescence spectroscopy, highlighting differences between linear and macrocyclic structures and oxazolidinone and imidazolidinone cores to illustrate the advantages of macrocycle formation and nitrogen-swapping. Together, the synthetic efforts and optical characterization of novel fluorescent molecules described here will result in the development of new imaging techniques to improve our understanding of biological processes in living systems.

Abstract Name: A Vignetted Life

The connections we make throughout our lives shape who we are. Friends, family, and romantic partners all play a role — big or small — in how our personality and behavior take form as we grow older, for better or worse. It's not just the bonds we form and maintain that change us but also the ones that break, wither, or change in some way. It is all of those connections that I seek to implement within my story. In my novella, "A Vignetted Life," I translate into narrative the research done by multiple experts in the fields of behavioral science and psychology, with emphasis on Erik Erickson's theory of psychosocial ego development. My presentation will showcase how my main character, Forest O'Berry, exemplifies these psychological concepts as he recalls moments of his life at the ripe old age of 85. Forest talks about the rocky relationship with his immediate family, the father figure he finds in his gym teacher, and friendships that form and fade as the years progress. All of this leads to him coming to terms with who he is at the tail-end of his life. To understand the influence our friends and family have on us is to understand our friends and family themselves. This action creates a stepping stone to understanding others outside of ourselves and our close relationships embracing empathy and differing perspectives.

Abstract Name: Identifying Enrichment Methods for Bacteria within the Midguts of *A. vexans* Mosquitoes from the Oklahoma City Metro Area

Mosquitoes are common vectors for diseases such as West Nile Virus. Mosquitoes' midguts contain a complex microbial community, playing a significant role in mosquitoes' innate immune systems. Analyzing the microbiome within the midgut of mosquitoes could reveal bacteria that impact the transmission or suppression of viruses. One approach to this analysis is cultivating microbes from the midgut. Microbial cultivation is challenging because many microbes rely on complex, often unknown environmental factors, making it difficult to replicate their natural habitats. To overcome this, an experiment was designed to test media formulated to mimic the mosquito midgut environment, aiming to enhance the cultivation of microbes adapted to that niche. Bacterial diversity within the midguts of the *Aedes vexans* mosquitoes caught within Oklahoma City's Stinchcomb Wildlife Refuge was analyzed via 16S rRNA analysis of bacterial communities and isolates. Bacterial profiles from the community composition prior to inoculation were compared to enrichments using Mosquito Enrichment Medium (MEM). Bacteria were then plated onto MEM agar. Comparing species richness at 0 and ~45 hours after inoculation revealed a significant difference. Additionally, 37 isolates were cultivated. Genera, such as *Providencia* and *Citrobacter* are widely represented in community analysis, while only *Providencia* were isolated, along with a potentially novel species. Overall, these findings demonstrate that distinct media conditions enrich various bacterial species from the *Aedes vexans* midgut, including those that had yet to be cultivated. Collecting cultivable mosquito microbes is critical to studying the bacteria involved with the mosquito's ability to transmit viruses to a human host.

Abstract Name: Investigating Environmental Drivers of Toxin Gene Expression in Harmful Algal Bloom-Forming Species Along the Coast of New Hampshire

Harmful algal blooms (HABs) caused by the dinoflagellate *Alexandrium* spp. pose serious risks to coastal ecosystems, aquaculture, and human health through the production of saxitoxin, a potent neurotoxin responsible for paralytic shellfish poisoning. Despite their global impact, the environmental and molecular mechanisms driving saxitoxin remain unclear. This research investigates how temperature and salinity influence the expression of the *sxtA* gene, a key component in the saxitoxin biosynthetic pathway that initiates toxin formation. To address this question, *Alexandrium* cultures were grown under controlled laboratory conditions that varied by temperature (15°C and 18°C) and salinity treatments (21 ppt and 26 ppt). DNA was extracted from each culture and analyzed using quantitative polymerase chain reaction (qPCR) to measure *sxtA* gene expression. A synthetic gene block standard and a culture dilution curve were used to develop a reliable qPCR assay and ensure accurate quantification. To evaluate whether *sxtA* gene activity corresponded with actual toxin production, enzyme-linked immunosorbent assays (ELISA) were performed to measure saxitoxin concentrations in the same experimental cultures. Preliminary results suggest that *sxtA* gene expression was the highest at 18°C, indicating that warmer temperatures may enhance saxitoxin biosynthesis. Salinity differences showed less consistent effects on gene expression, suggesting temperature is a stronger environmental driver. These findings help bridge molecular biology and ecological monitoring by revealing how environmental changes can regulate toxin production in harmful algal blooms. Ultimately, this research aims to improve predictive tools for bloom toxicity and support the development of faster, gene-based monitoring strategies for coastal management. By linking environmental factors, gene expression, and toxin output, this study contributes to a deeper understanding of how climate-driven changes may influence the frequency and severity of harmful algal blooms.

Abstract Name: The price of Sleep: How Rest Influences Worker Preferences

With rising unemployment rates, the job market has become increasingly competitive, compelling workers to enhance their productivity and efficiency. However, this raises the question of whether such demands come at the cost of adequate sleep. The topic of sleep has long been associated with health behavior, however recent studies prove that it has economic implications as well. Specifically, the literature has evaluated the relationship between sleep duration/quality and labor-market outcomes such as wages, employment, absenteeism, and presenteeism. Many advancements have been made regarding how sleep affects the economy on a national level, however the question remains: How does variation in sleep quantity and quality influence self-reported productivity among working-age adults? To answer this question, a 15 question survey was distributed using Repdata and 386 responses were collected. This study found that when participants were asked whether they would take a lower paying job that guaranteed more consistent sleep, respondents across sleep brackets, not just those with low sleep, would accept the position: suggesting that workers place intrinsic economic value on adequate sleep, even at the expense of income.

Abstract Name: Exploring the Feasibility of Detecting Physics Student Misconceptions Through Writing Assignments Using Large Language Models

Students in notoriously difficult STEM courses often hold misconceptions due to the emphasis on problem-solving over conceptual understanding. Writing assignments can help instructors uncover these misunderstandings, but grading them is time-consuming and impractical, particularly in large classes. Large language models (LLMs) offer a promising solution for automating the identification of misconceptions in student writing. In this study, we analyzed student responses from an introductory physics short written response assignment, focusing on misconceptions related to motion. We evaluated multiple prompting techniques using two open-source LLMs, Meta's Llama 3.2 and Microsoft's Phi4, through in-context learning, where the models learn their tasks directly through the prompting. This assesses the LLMs' ability to accurately identify student misconceptions at the sentence-level. As an alternative, we employed supervised fine-tuning, where the models are explicitly trained with the gold-standard data, with BERT and ModernBERT models. BERT and ModernBERT are pre-trained open-source LLMs by Google. Experimental results indicate that fine-tuning outperforms in-context learning. However, filtering the training data to include only sentences relevant to the misconception as opposed to full student response improved in-context learning performance. In contrast, using synthetic data generated using another LLM for expanding the training data for fine-tuning had inconsistent effects. The best-performing models were evaluated using F1 scores, an evaluation metric that measures accuracy, and reached scores of 0.6 out of 1.0. This suggests that with additional refinement and more training examples, LLMs could potentially reach a level suitable for instructor use in identifying student misconceptions. This work demonstrates the potential for leveraging LLMs to provide scalable, automated feedback in STEM education, ultimately supporting instructors in addressing conceptual gaps more efficiently.

Abstract Name: Oral Histories on Local Nurses

Many people experience formative moments in childhood that inspire them to pursue careers in the medical field, often influenced by family members in healthcare or pivotal events during high school. Oral histories are a valuable method for gathering personal accounts and insights into individuals' life experiences and significant historical events. This research explores the question: How are oral histories used to reveal patterns in nursing over time? Conducting oral histories requires audio and video equipment to record interviews, which are later transcribed—converting spoken language into written documentation. All materials will be preserved for future research at the University of Wisconsin-Milwaukee Archives. The UWM College of Nursing houses a dedicated museum featuring artifacts such as nursing tools from WWI

and pins awarded to graduating nurses. Gaining an understanding of nursing history over centuries helps contextualize the evolution of the field. In this project, nurses from the Milwaukee area are invited to share their educational and professional journeys through guided interviews. For example, a typical question might be, “How did technology change from the start to the end of your career?” To date, nine oral histories have been completed. Completing these oral histories provides valuable resources for connecting nursing experiences across generations, highlighting both similarities and differences in nurses’ lives. Additionally, this research will bring greater attention to the UWM Center for Nursing History and the significant influence nurses have had in healthcare.

Abstract Name: Comparison Between the Effects D-Frame Nets and Kick Nets Have on Stream Quality Metrics and Macroinvertebrate Diversity

Accurate stream biological assessment is essential for monitoring freshwater ecosystem health, and the reliability of these assessments depends on both the biological indicators and the methods used to collect them. This study investigated how the sampling equipment, specifically D-frame nets and standard kick nets, may affect the assessment of macroinvertebrate diversity and stream quality metrics. Kick nets, with their larger collection surface and angled design, are expected to yield higher taxa richness and more consistent results compared to D-frame nets. To test this, macroinvertebrate samples were collected from Lily Cache Creek riffles at two sites in Plainfield, IL (Van Horn Woods and Four Seasons), using both net types across three sampling dates. Each sample was analyzed for total abundance, taxa richness, EPT (Ephemeroptera, Plecoptera, Trichoptera) taxa, MBI (Macroinvertebrate Biotic Index), SDI (Shannon Diversity Index), and pollution tolerance classifications. Kick nets consistently produced higher total organism counts (574 vs. 129), significantly greater total taxa richness, and a higher percentage of pollution-intolerant taxa was recorded at Four Seasons (80%), while Van Horn had a higher percentage of intolerant taxa (60%). The resulting EPT to non-EPT ratio yielded a p-value of 0.163 when the data from all three kick net samples and all three D-frame net samples were combined. D-frame nets yielded more variable results, especially in open-canopy sites with slower flow. These findings suggest that while both nets are effective for capturing EPT taxa, kick nets provide more reliable and comprehensive data for stream quality assessment, especially in cobble-dominated riffles with moderate to fast current. Procedure consistency is critical in ecological monitoring, and this study highlights the importance of net selection in maintaining data integrity for long-term stream management.

Abstract Name: Is Newer Always Better?: A Comparison of Two Methods for Collecting and Analyzing Canopy Cover Data

When conducting field research, time and money are limiting resources, so finding more efficient and cost-effective methods to collect and analyze data is an important goal for many researchers. App-based methods are rising in popularity because they often are free or cheap and claim to be more user-friendly. These new tools can be especially tempting when older methods are frustrating to use, like the densiometer, a device traditionally used to measure tree canopy cover. Since canopy cover plays an important role in tropical ecosystems due to its influence on climate, habitat, biodiversity, etc., it is important to have trustworthy methods when assessing this biotic factor. This study compares a new app-based method (CanopyApp) to the traditional densiometer, to see whether the app is a suitable replacement in terms of accuracy and time saved in data collection and analysis. We sampled sixteen tropical forest research sites, since there were no previous studies using CanopyApp in tropical ecosystems, and both methods were used while being timed. After field work, the time needed to analyze the data from each method was also recorded. Thus, canopy cover percentage, time to collect data, and time to analyze data are the main variables being compared. Statistical analysis was conducted to compare the results. In the end, CanopyApp was not an accurate tool for assessing canopy cover compared to the densiometer, and its analysis time was significantly slower. In its current form, CanopyApp is not yet a suitable replacement for collecting and analyzing canopy cover data. Although many researchers may be eager to abandon the densiometer, our research shows that a newer method does not always equal a better one.

Abstract Name: Tracking Iron Nanomineral Changes to Improve Water Quality Management in Freshwater Reservoirs

Freshwater drinking reservoirs are vital to public water supply, with approximately 74% of U.S. freshwater derived from surface sources. These systems often experience seasonal anoxia driven by thermal stratification, promoting the reductive dissolution of iron (Fe) minerals and the subsequent release of associated contaminants. Iron, a redox-active metal, not only imparts aesthetic and taste issues in drinking water but also facilitates the mobilization of toxic elements such as arsenic and lead. Two freshwater reservoirs near Roanoke, Virginia, Falling Creek Reservoir (FCR) and Beaverdam Reservoir (BVR) serve as test sites due to their comparable hydrologic and geologic settings. To prevent anoxia, FCR uses a hypolimnetic oxygenation (HOx) system that delivers oxygen to deep waters, oxidizing dissolved Fe and causing it to precipitate as ferrihydrite (Fhy) and settle back into the sediments. Ferrihydrite (Fhy), a poorly crystalline Fe(III) oxyhydroxide, is metastable and can transform into lepidocrocite and eventually into more stable goethite in the presence of Fe(II). Characterizing the iron mineralogy within these reservoirs is therefore critical for understanding redox-driven mineral transformations and their influence on water quality. Confirming the presence and extent of these transformation pathways provides key insight into biogeochemical cycling in drinking water reservoirs. High-resolution transmission electron microscopy (HRTEM) was used to image and identify Fe minerals at the atomic scale. HRTEM allows precise measurement of d-spacings, the unique structural fingerprints used to identify minerals. Preliminary results indicate the presence of abundant ferrihydrite and goethite, minor lepidocrocite, and trace magnetite. Ongoing work focuses on quantifying uncertainty in d-spacing measurements, which is particularly complex for nanocrystalline samples containing multiple, coexisting mineral phases.

Abstract Name: The Spark of Memory: When a Neuron Whispers, I Remember

How does the brain link one moment to the next? Although cortical neurons respond rapidly to stimulation, it remains unclear whether a single activation leaves a short-lived intracellular “residue” that later influences subsequent activity. This project investigates whether individual cortical neurons retain fast, measurable traces of recent stimulation, functional signatures that could represent one of the smallest building blocks of time-binding in neural systems. To examine this, we combine high-resolution calcium imaging with rapid early-gene expression analysis. Using GCaMP-based fluorescence and confocal microscopy, we track intracellular calcium dynamics following controlled stimulation and quantify whether a detectable after-signal lingers beyond the immediate response window. Additionally, we perform qRT-PCR on established immediate-early genes like *c-fos* and *Arc* to determine whether molecular markers of recent activation display similar short-interval changes. Together, these approaches allow us to analyze both fast biochemical events and early transcriptional events associated with neuronal activity. Our analysis compares responses across brief delay intervals in both isolated neurons and small network cultures. To organize these effects, we utilize two quantitative measures: a Residual Response Index capturing changes in calcium decay dynamics, and a Calcium Residue Index describing post-stimulus persistence. Evidence of even a subtle, rapid residue supports the hypothesis that cortical neurons possess intrinsic mechanisms for linking closely spaced events, providing insight into how the brain organizes continuous experience. This work contributes to broader efforts to understand neural plasticity, time-binding, and memory feedback.

Abstract Name: Identity Valence and Social Contexts in Autistic Emerging Adults.

Drawing on social identity theory, this study examines how the positive or negative feeling associated with an identity (identity valence) interacts with various social contexts for autistic emerging adults. Emerging adulthood (ages 18–25) is a critical developmental period characterized by identity exploration, increasing independence, and heightened vulnerability to mental health challenges. This study aims to deepen the understanding of this marginalized population, as well as identify valence in specific contexts. Data will be drawn from an ongoing survey study of 350 participants recruited through Simons Powering Autism Research for Knowledge (SPARK). Participants rate their feelings about their autism/autistic identity in several contexts, including family settings, friend settings, healthcare settings, and workplace settings, on a scale from 0, indicating “Extremely negative,” to 100, meaning “Extremely positive.” Preliminary results of paired-sample t-tests with 73 participants (Mage = 22.68; 55% female; 30% heterosexual) indicate more positive feelings about their autistic identity in family context ($M = 69.68$; $SD = 28.63$) compared to both work ($M = 40.94$, $SD = 26.96$; $t(72) = 7.35$, $p < .001$) and healthcare environments ($M = 57.38$, $SD = 25.85$; $t(72) = 3.17$, $p = .001$). In addition, participants rated friend contexts as more positive ($M = 68.63$, $SD = 24.92$) compared to both work ($t(72) = 7.50$, $p < .001$) and healthcare settings ($t(72) = 3.32$, $p = .007$). The findings are expected to inform more inclusive practices and identity-affirming support in contexts for autistic emerging adults.

Abstract Name: Algal Growth and Macroinvertebrate Community Structure in a Piedmont, Urban Stream.

Algae influence freshwater stream food-webs by contributing to primary production and nutrient cycling. Algal community structure has been shown to be heavily influenced by consumer interactions, specifically macroinvertebrate grazing. Although reductions in algal biomass by grazers has been repeatedly demonstrated, facilitative interactions are often overlooked despite their importance, and grazers may play a key role in shaping the structure of algal communities. Our project aims to evaluate facilitative relationship between macroinvertebrate grazers and algal communities in streams. Previous research found that grazers were absent in an urban stream, suggesting they are particularly vulnerable to urbanization. We hypothesize that the absence of grazer species from an urban stream will result in altered algal community structure and abundance, compared to non-urban streams. To begin to test this hypothesis, we described macroinvertebrate community structure and algal growth in an urban stream in the Piedmont of Virginia. We measured algal biomass on unglazed ceramic tiles placed in pool, run, and riffle habitats, weekly over a four-week period. Algal biomass was quantified as chlorophyll-a concentration and ash-free dry mass (AFDM). In addition, we collected macroinvertebrates from duplicate Hess samples in each habitat, on week-one of the study. Comparing macroinvertebrate community structure, specifically grazer abundance, and algal growth will inform future research on how top-down and bottom-up processes shape freshwater stream ecosystems.

Abstract Name: Algal Turf Scrubbers: The use of diverse microalgae for the removal of contaminants from freshwater resources

Fresh water is a finite resource, and scientists look for sustainable treatment methods to filter out pollutants and biological contaminants. With more than 2/3 of our wastewater being released into the environment, this task proves difficult as these contaminants continue to significantly impact ecosystems, disrupt aquatic life, and threaten human health. Current pre-treatment methods use chemical precipitation and reverse osmosis; while effective at removing pollutants, these treatments are energy-intensive and often inaccessible. Algae are mostly photosynthetic prokaryotic and eukaryotic organisms, forming the foundation of aquatic food webs and global nutrient cycles. And research has shown certain microalgae can be utilized to remove pollutants from wastewater. Thus, algae-based bioremediation presents an innovative and eco-friendly solution to minimize the impacts of pollution from wastewaters. The goal of this project is to screen diverse microalgae

for use in algal turf scrubbers (ATS), sloped systems designed for the cleanup of water from point-source pollution. An effective ATS system should be low maintenance, while providing rapid uptake of nutrients. Resulting biomass may also be utilized for downstream applications, e.g., biofertilizer and biochar. Due to their documented high growth rates and rapid nutrient uptake, the following strains were acquired from the UTEX Culture Collection: *Chlamydomonas reinhardtii* (LB 90), *Spirogyra maxima* (2495), *Scenedesmus* sp. (1591), *Gomphonema intricatum* (FD386), *Synechococcus elongatus* (2973), *Chlorella vulgaris* (LB 2714), *Merismopedia* sp. (1902), and *Chlorococcum* sp. (3181). Cultures were grown under temperature and nutrient stress (BG11 vs. BG-11/20) to measure robustness, growth, and viability for deployment. Cultures were grown in 250-mL flasks containing 100 mL of culture with shaking at 125 rpm ($n = 3$). Cultures were measured by spectrophotometry at A680 nm over time at 23, 25, and 28 °C. Outcomes of this project should define microalgal strains suitable for ATS and the mitigation of nutrients, minimizing pollution to surrounding waters.

Abstract Name: Elementary School Gifted Program Participation and Secondary School Academic Outcomes for Black Students

Gifted children show high potential to achieve but need specialized services to develop their capabilities. Black students specifically have been persistently under-identified as gifted and the efficacy of gifted programs for Black children is unknown. This psychology honors thesis will explore the impact of gifted identification on secondary school outcomes (6th through 12th grade) with data from the Miami School Readiness Project, a longitudinal study of students that attended Miami-Dade County Public Schools. Research questions include (1A) To what extent does being identified as gifted in elementary school contribute to secondary school academic outcomes for Black students?, (1B) Are positive effects mediated by elementary school academic performance?, and (2) Are the observed differences between gifted and not gifted Black students in secondary school the same for students in poverty vs. not in poverty, and for boys vs. girls? The sample for this study includes Black students that had data for at least one year of high school ($n \approx 11,198$). Of the sample, ~13% were identified as gifted in elementary school. Outcome data include cumulative high school GPA, standardized math and reading test scores in 8th and 10th grade, grade retention, attendance from 9th and 12th grade, school suspension, and on-time graduation. Multiple regression and logistic regression analyses will be done, controlling for child cognitive skills and social skills at age 4, gender, English language learner (ELL) status, poverty status, and early school performance. Results are expected to show gifted identification to be correlated with positive secondary school outcomes when compared to non-gifted students. It is expected that gifted education will show stronger positive effects for students in poverty and for boys. Finalization of data cleaning and variable making will be done in December. Data analyses will be done in January. The complete paper will be ready by the conference.

Abstract Name: Tuning the proton-coupled electron-transfer (PCET) reactivity of synthetic high-valent iron(IV)-oxo models through axial ligation

Heme-based metalloenzymes facilitate fundamental oxidation reactions by activating dioxygen and hydrogen peroxide to form high-valent intermediates, such as Compound I (oxo-iron(IV) porphyrin π -cation radical) or Compound II (ferryl porphyrin). Although the reactivity of Compound I has been the focus of thorough investigation, the reactivity capabilities of Compound II analogs remain relatively underexplored, despite their abilities to abstract hydrogen atoms from organic substrates such as xanthene. These reactions typically proceed through a proton-coupled electron-transfer (PCET) mechanism, which can occur via concerted or stepwise pathways (i.e., ET-PT or PT-ET). Growing evidence points to asynchronous PCET mechanisms, where proton and electron transfers are not perfectly synchronized, ultimately lowering activation barriers and elevating reaction rates. Here, we describe the PCET reactivity of [(F8TPP)FeIV(O)] and its axially ligated derivative [(F8TPP)FeIV(O)(DCHIm)]. Kinetic studies indicate that axial coordination considerably enhances reactivity, with this ligated ferryl complex reacting roughly six times faster with xanthene. When incorporating substrates of varying bond dissociation energies (BDEs), a linear correlation between substrate BDEs and log(kobs) was observed, corresponding to a strong thermodynamic basis for these reactivity differences. Intriguingly, high kinetic isotope effects (KIEs > 60) suggest that quantum tunneling contributes to the reaction pathway. Moreover, computational studies reveal that axial ligands modulate spin-state energetics, accounting for changes in PCET behavior and further corroborating an asynchronous PCET pathway. Overall, this research demonstrates the critical role of axial ligation on the reactivity patterns of ferryl intermediates, their mechanistic pathways, and relevant thermodynamic parameters. These insights further elucidate how enzymes employ axial ligands to regulate oxidative chemistry, which holds significant relevance in physiological and pathogenic pathways.

Abstract Name: Beneath the Mask: Exploring the Hidden Experience and Wellbeing of Female Neurodivergent Students at UW-Eau Claire

Neurodiversity is defined as any deviation from the norm in brain functioning. Neurodiversity remains underdiagnosed and underresearched among females due to the societal expectations, pressures, and gendered stereotypes that are placed upon women. Female-identifying neurodivergent college students often report elevated anxiety, depression, and social isolation relative to neurotypical peers, yet their voices remain underrepresented in campus research. Their suppression contributes to masking, increased pressures, and burnout, which has contributed to heightened concerns for students' overall well-being, mental health, and retention while pursuing higher education. This research team aims to create a conceptually driven mixed-methods design utilizing anonymous surveys and focus group formats to understand how neurodivergence shapes well-being across academic, social, and health domains in females at UW-Eau Claire (UWEC). We will collect demographic information and use the Ryff Psychological Wellbeing scale in our quantitative portion to understand this population on campus more broadly. We will then use the measure's six domains of wellbeing and happiness, including autonomy, environmental mastery, personal growth, positive relations with others, purpose in life, and self-acceptance, to create the interview questions for our focus groups. Through thematic analysis of semi-structured interviews, elements of well-being will be evaluated for recommendations to improve campus culture and possible targeted interventions for female neurodivergent students. We intend to build upon the previous research that has demonstrated the gendered disparities in the

experience of male and female neurodivergent folk and use our findings as a call to action for what needs to be done to make success on our campus achievable for UWEC students.

Abstract Name: Digital Migration and Intercultural Communication: American TikTok Users on RedNote

This study focuses on the digital migration of American TikTok users to a Chinese local social media RedNote, following the 2025 U.S. TikTok ban and its impact on intercultural communication between American and Chinese users. Through a qualitative analysis of 50 selected bloggers, their posts, comments, and constructed a timeline using public data, the research identifies three key areas: (1) primary interaction themes, (2) opportunities and challenges in cultural exchange, and (3) the sustainability of RedNote for the U.S. users. The findings reveal that lifestyle and language-learning content dominate cross-cultural exchanges, enabling users to develop mutual curiosity, informal cultural learning, and opportunities for clarification of misunderstandings. Regarding the timeline, the sustainability of RedNote for American users may be limited. This study demonstrates how platform design, linguistic accessibility, and sociopolitical conditions could collectively shape the sustainability of intercultural interactions online. Although digital migration can facilitate initial cultural engagement, long-term participation depends on the development of shared community norms and meaningful cultural resonance.

Abstract Name: Constructions Of Macaulay Distributive Lattices

Given a collection of elements, we are interested in ordering them. When this collection with its order satisfies particular conditions, we call it a partially ordered set. An example is the positive divisors of an integer, ordered by divisibility. In particular, we consider lattices, which are posets with the additional condition that for any two elements in our collection, there exists a smallest possible element that is greater than our chosen two elements and there exists a biggest possible element that is smaller than our chosen two elements. Our research is on finding lattices that satisfy the Macaulay property, where we have both a partial order (not all elements can be compared) and a total order (all elements can be compared) on our collection. We show that all distributive lattices of height 3 are Macaulay. We construct non-Macaulay distributive lattices of height 4 and more.

Abstract Name: Web-browser-based Visualization of Wildland Fire Data

Wildfires increasingly threaten public safety due to their volatile nature and changing climate conditions. In 2024, there were 64,897 wildfires that burned 8,924,884 acres of forested land (Data from NICC Wildland Fire Annual Report 2024). Such a staggering scale highlights the importance of effective planning and response training. Hands-on firefighter training is challenging, given the costs, risks, and dangers of setting up realistic training environments. In such a case, virtual 3D visualizations offer a compelling alternative. We present an immersive, browser-based, low-cost, ready-to-deploy visualization of wildland fire using data from QUIC-Fire, a physics-based cellular automaton fire progression simulator developed at Los Alamos National Laboratory. QUIC-Fire outputs binary files representing realistic fire spread in real-world forested environments for firefighter training and emergency planning. Our solution, created using A-Frame and Three.js, is built to make these simulations visually comprehensible. It renders the simulation's terrain, trees, fire, wind, and smoke progressions directly in a web browser, within an immersive virtual forest environment that the user can enter, walk through, and observe in first person. Users can also view the scene from above to obtain a bird's-eye view of fire spread, smoke, and wind dynamics. Our tree database, with four representative tree species models, enhances realism and allows us to manipulate parts of the trees directly (for example, trunks and leaves). Through a combination of data-handling and rendering optimizations, our solution renders simulations on a forested domain spanning roughly 10,000 square meters and containing over 40,000 trees — even on commodity hardware. It supports VR headsets and runs on desktops, laptops, tablets, and mobile devices. With plans for further development in collaboration with the firefighter community, we hope to make this product readily usable in real-world training settings in the near future.

Abstract Name: A Structural Analysis of Largest Independent Sets in Families of Circulant Graphs

The Frequency Assignment Problem (FAP) involves assigning frequencies to devices on a wireless network optimally, i.e., using as few frequencies as possible for the network. Shashanka et al. characterized networks modelled as infinite graphs induced by the square and triangular grids, and showed that these can be tessellated by finite tiles T_k of size k , such that an optimal frequency assignment on T_k is an optimal assignment on the infinite grid. Furthermore, they exhibited frequency assignments that were optimal, and achieved $s_1 = k^2$, where s_1 is the minimum separation between frequencies assigned to neighboring devices. Since it is desirable that s_1 be as large as possible, our work aims to provide an upper bound on s_1 . If $s_1 \leq k^2$, then Shashanka et al.'s frequency assignment maximizes s_1 . We model the tiles T_k as families of circulant graphs S_k and H_k for the square and triangular grid respectively, and show that an upper bound on the independence number (the size of a largest independent set) of these graphs, denoted $\alpha(S_k)$ and $\alpha(H_k)$, also provides an upper bound on s_1 . For the square grid family, we show that $\alpha(S_k) = k^2$, proving that Shashanka et al.'s work does indeed maximize s_1 . For the triangular grid family, we show that $\alpha(H_k) \leq k^2 + \text{floor}(k/2)$, and conjecture that $\alpha(H_k) = k^2$. Finally, we show that S_k and H_k belong to a larger two-parameter family of graphs $G(r,k)$, where $G(2,k)$ is S_k and $G(3,k)$ is H_k . We show that $G(4,k)$ is isomorphic to the toroidal king's

graph, and thus $\alpha(G(4,k)) = k^2 + \text{floor}(k/2)$. Lastly, based on heuristic computational results, we conjecture that for all $r \geq 4$, $\alpha(G(r,k)) = k^2$ when r is odd and $\alpha(G(r,k)) = k^2 + \text{floor}(k/2)$ when r is even.

Abstract Name: The Battle of Belleau Wood and the Forging of the Modern Marine Corps Identity

The central question of this research is how the United States Marine Corps shifted from an auxiliary naval force to an elite, mobile fighting force, and the role that the Battle of Belleau Wood play in that transformation. The Battle Belleau Wood, fought from June 1-26, 1918, in France during the First World War, was a pivotal engagement where untested American forces were able to stop and drive back the German advance in the Chateau-Thierry sector. While there were both Marines and Army soldiers present at the battle, newspapers disproportionally showed the Marines' actions, which created a public image of an elite and effective fighting force. This publicity that the Marines received would then be used after the war to show their relevance as a force. For this research, I looked at a wide range of primary sources in addition to some trustworthy secondary sources with some key sources including *With the Help of God and a Few Good Marines: The Battles of Chateau Thierry and Belleau Wood* by Albert Caitlus and *And They Thought We Wouldn't Fight* by Floyd Gibbons. In addition to those sources, interviews, letters, and Congressional hearings were examined. I was able to use the sources to examine the Marines effectiveness in the battle, the media attention that then followed, and the post war fight to remain a force. Additionally, research showed that because of Belleau Wood talks were started about reshaping the Marine Corps into a rapidly deployable, elite, amphibious assault force compared to just a naval auxiliary force. Ultimately, while the United States Marine Corps has been in existence since 1775, it was Belleau Wood that turned the Corps into what it is today.

Abstract Name: How Governance Structures Shape K-12 Technology Adoption During Crisis: Comparing Edmonds School District and NYC Department of Education

Why do school districts with similar federal funding respond so differently to emergencies? This comparative case study examines how governance structure shaped technology adoption during COVID-19 remote learning in Edmonds School District, Washington (21,000 students) and New York City Department of Education (1.03 million students). Both drew on Elementary and Secondary School Emergency Relief (ESSER) funding, yet achieved starkly different outcomes in implementation speed, community participation, and resource allocation. The study analyzed six primary documents from March through November 2020: four Edmonds board meeting records and two NYC DOE planning documents. Systematic content analysis identified technologies adopted, decision-making actors, deliberation factors, and implementation timing. The findings reveal three governance effects. Institutional structure determined implementation speed: NYC's centralized committees distributed 675,000 devices within six months through coordinated programs, while

Edmonds' board governance prioritized community deliberation over rapid deployment. Participation mechanisms reflected different institutional capacities. NYC systematized engagement through Parent Coordinators reaching thousands of families, while Edmonds enabled direct testimony that created accountability but limited scale. Both districts emphasized equity and infrastructure, yet governance shaped how resources were allocated. NYC focused on civil rights compliance including multilingual support and disability accommodations, while Edmonds prioritized teacher training and connectivity gaps raised through public comment. This study demonstrates that governance structure operates as an independent factor shaping policy outcomes even under similar funding conditions. The findings have implications beyond the pandemic: districts should establish governance protocols balancing decision speed with community participation before emergencies strike, rather than improvising under crisis conditions.

Abstract Name: A Python Tool for Accessible Inference of Selection in Human Genomes

Human evolutionary genomics draws on genetics, anthropology, and computer science to understand how genes have changed across time and across different populations. Yet for many early scientists, especially those new to computational research, these conceptual constraints can make entry into this field feel inaccessible. To help lower this barrier to studying human gene evolution, we developed a pipeline combining four methods used to study selection parameters. The pipeline (1) calculates the frequencies of alleles in present-day populations, (2) applies extended haplotype homozygosity (EHH) and integrated haplotype score (iHS) to detect the presence of selection, and (3) uses a method to reconstruct genealogical trees using Relate and the CLUES2 add-on to determine the strength and timing of selection. Using three large publicly available present-day human genomic datasets—the 1,000 Genomes Project, GenomeAsia100K Project, and the Human Diverse Genome Project—we created a user-friendly Python tool that accepts multiple parameter inputs for investigating selection in human genes and walks users through each step with a dynamic progress log. This system provides real-time feedback in a dynamic summary file of analysis outputs and results, flagging errors and offering troubleshooting suggestions if an error is encountered. To support interpretation, we also devised a new strategy to compare and visualize the fit of CLUES2 temporal models, allowing users to identify which modelling frameworks best capture changes in the timing and intensity of selection. Here, we describe the pipeline and share two case studies illustrating how it can be used to trace the evolutionary history of genes across worldwide populations.

Abstract Name: Automated Weed Segmentation in Lawn Environments Using Deep Learning

Everybody wishes for a weed-free, healthy lawn, but the weeds won't cooperate. It takes time for manual pulling and other conventional methods of weed management, and spraying herbicides across the entire lawn wastes chemicals, time, and the environment. Although past work has investigated machine learning-enabled weed detection from data on big farms; the models presume expensive imaging hardware, stage lighting, or expert crop data, which limits their applicability to residential lawns. This work challenges such constraints through the development of a light and mobile weed-searching system on lawns using Detectron2, an advanced object detection framework. The model was then tested on the combined lawn scene dataset and was found to be 92.4% accurate, accurately labeling 89.7% of the weeds and scoring an overall F1-score of 0.91. In trials, the system accurately picked out three patches of weed with high-confidence values (0.96, 0.93, and 0.88) which comprised approximately 14% of the picture. This measurement can enable selective treatment rather than blanket spraying, with considerable cost saving in the use of chemicals. The results demonstrate that artificial intelligence has the potential to automate one of the most time-consuming procedures of lawn care—detection of weeds—in a manner that helps maintain environmental sustainability. The project is currently engaged in the completion of the system by incorporating real-time detection capability by means of smart cameras and adaptive treatment algorithms to achieve optimal chemical utilization efficiency and accuracy in suppressing weeds.

Abstract Name: Doodle-to-Image: Enhancing Text-Guided Image Generation with Sketch Prompts in ComfyUI

This project looks at how KSampler settings, specifically classifier-free guidance (CFG) and control (randomised and fixed), interact with sketch inputs and text prompts to improve image controllability. By refining prompt structure alongside parameter tuning, the study explores how multimodal guidance can better enforce targeted visual characteristics while balancing composition fidelity and output consistency. Stable Diffusion has become an effective approach for generating images from text prompts. To explore this, multiple image samples were generated using the same prompt while changing only one variable at a time. The ComfyUI software was used to test low, medium, and high CFG values, and compared fixed control inputs to randomised ones. Results were compared between text-only prompts and sketch+text prompts, where a simple doodle offers additional structure. Changes in how closely the prompt was followed by the model, the consistency of shapes and layout, and the amount of variation between outputs were observed across each experiment. From these observations, lower CFG values tended to produce more creative but less accurate images, while higher CFG values made the results more literal and very distorted. Fixed control inputs created more stable images across samples, and randomised control inputs made each output noticeably different even when everything else stayed the same. When comparing prompt types, sketch+text inputs were more reliable for keeping the structure of the subject, especially when CFG was set higher in Stage C (Text-conditional image generation) and lower in Stage B (image decoder). This combination of pretrained models gave the most balanced and predictable results.

Abstract Name: From Classroom to Community: Rethinking Educational Interiors Through Neurodiversity

While the industry is constantly evolving to be more accessible and inclusive, there is still a major lack of understanding when it comes to neurodiverse students in the educational arena. The educational environment can be a major stressor for students. These stressors can be eliminated by implementing proven practices that create comforting environments. Using third-place theory and environmental psychology as a framework, inclusive design strategies can promote sensory accessibility, flexible spaces, and community-oriented areas. Third place theory emphasizes the importances of informal, safe spaces that encourage communication, and autonomy; these qualities are vital in educational settings. Environmental psychology focuses on designed spaces that influence behavior and emotional regulation such as acoustics, lighting, and space planning. This research incorporates neurodiversity, education, psychology, and interior design principles. To develop programming to curate a high school environment that promotes belonging, well-being, and adaptive learning for all students.

Abstract Name: Structural and Procedural Determinants of Sentencing Disparities in the Juvenile Justice System: Implications for Equity and Rehabilitation

Youth involvement in the juvenile justice system presents multifaceted challenges that implicate procedural equity, rehabilitative efficacy, and long-term social trajectories. This study interrogates the extent to which structural and procedural determinants such as pretrial detention, differential access to competent legal counsel, and plea bargaining mechanisms influence judicial outcomes for justice-involved youth. Contrary to conventional assumptions that adjudication severity is primarily offense-driven, evidence increasingly suggests that systemic factors exert a determinative influence, often reinforcing disparities along socio-economic and racial lines. Employing a mixed-methods framework, this research integrates quantitative analyses of publicly available juvenile court datasets with qualitative syntheses from extant literature on legal advocacy, procedural justice, and youth development. Preliminary findings indicate that pretrial detention markedly correlates with more punitive sentencing outcomes, even when controlling for offense severity, prior adjudications, and demographic variables. Concurrently, overburdened public defense infrastructure constrains juveniles' capacity to navigate plea agreements effectively, thereby exacerbating inequities and perpetuating cycles of system involvement. These dynamics not only compromise the principles of procedural justice but also precipitate collateral consequences, including educational disruption, psychosocial stress, and heightened recidivism risk. The study foregrounds the imperative for policy interventions that recalibrate the balance between accountability and rehabilitation. Potential reforms include the expansion of community-based alternatives to detention, augmentation of resources for competent juvenile defense, and standardization of sentencing protocols to mitigate discretionary disparities. By elucidating the mechanisms through which procedural and structural variables shape judicial decision-making, this research contributes to critical discourses on systemic equity, youth advocacy, and evidence-based criminal justice reform. The findings offer actionable insights for policymakers, legal practitioners, and scholars committed to fostering a more just, equitable, and rehabilitative juvenile justice system.

Abstract Name: Testing the Function of Sulfated Glycosaminoglycans During Anterior Neurulation in Zebrafish

The neural tube is the precursor to the vertebrate central nervous system. Neurulation is the process by which the neural tube closes during early embryonic development. Failure of the neural tube to close results in neural tube defects (NTDs), which are among the most prevalent human birth defects. The causes of human NTDs are multifactorial, making NTDs challenging to study in humans. Neurulation in zebrafish occurs by similar mechanisms as in humans, and zebrafish embryos can be manipulated genetically and pharmacologically, making them an established model system for studying NTDs. Previous research in our lab has shown that the extracellular matrix (ECM) is required for anterior neural tube closure in zebrafish. When the ECM is deficient, the anterior neural tube fails to close causing a phenotype like the fatal human NTD anencephaly. Glycosaminoglycans are major components of the ECM, serving to provide structure and coordinate tissue movements. Most glycosaminoglycans in the ECM are sulfated by O-sulfotransferases, enzymes which are inhibited by chlorate salts. We hypothesized that embryos exposed to chlorate before and during neurulation would have a higher frequency of anterior NTDs than untreated controls, and that the frequency of NTDs would depend on chlorate concentration. We used molecular techniques to stain the pineal organ. We assessed the pineal organ's morphology to screen for NTDs. The pineal is normally a single oval-shaped structure and elongated or divided morphology indicated an NTD. ANOVA showed no significant difference in the frequency of NTDs found in chlorate-treated embryos compared to untreated controls. However, chlorate-treated embryos had a dose-dependent, incompletely penetrant phenotype similar to embryos deficient in ECM proteins. Chlorate-treated embryos and ECM deficient embryos had misshapen pineal organs, truncated tails, malformed yolk-sac extensions, and cardio edema. Higher concentrations of chlorate increased the frequency of these abnormalities but the frequency of NTDs remained low.

Abstract Name: Checkered Past: The Shifting Anthropological Collections of the Field Museum

The Field Museum of Chicago is a highly respected institution nationally and internationally with an important legacy in scientific, ethnographic, and anthropological history. The legacy of their anthropological collections, however, is currently being questioned and is in flux. The anthropological exhibition Alsdorf Hall of Northwest Coast and Arctic Peoples is a clear example of this. The shifting collection displayed and discourse of how the exhibition is presented is a historiographical artifact that illustrates the museum practices of the past transitioning into the museum practices of the present. I explore the history of the current exhibition, installed in 1983 that largely has remained unchanged, along with previous iterations. Drawing on sources such as Museum Politics and Stewards of the Sacred, interviews with Field staff, and the perspectives of museum visitors, I develop the general public and academic perception of the exhibition. I also compare the Field's most recent anthropological exhibition Native Truths: Our Voices, Our Stories and Northwest Coast within the lens of museum exhibition style and context to convey the change in museum exhibition practices over time. NAGPRA specifically is the main cause for the changes in the exhibition, and is explained as a whole and in this context. Compared to previous practices, the primary concerns of current

exhibitions that regard Indigenous Americans are establishment and explanation of NAGPRA, personal stories or artifacts rather than sweeping, impersonal displays, and an emphasis on current Indigenous Americans and their lives. Northwest Coast has the NAGPRA element currently but lacks the other two. The exhibition is artifact-rich, but utilizes theatrical techniques to display the cultures of the Arctic and Northwest Coast, which may seem offputting to some visitors. This can be seen in the mask exhibits or the shaman diorama. This makes the exhibition an excellent learning tool, though not as intended.

Abstract Name: Growing Into Adulthood: The Role of Future Time Perspective and Social Support in Psychological Well-Being

The present study explores the associations between future time perspective and perceptions of social support and their influence on psychological well-being in emerging adulthood. The sample consisted of 334 emerging-adults between the ages of 18-25 (average-age 18.76 years, 267 women). Subjects completed self-report measures of future time perspective, perceptions of social support, and psychological well-being. Regression results indicate that social support and future time perspective together predict psychological well-being. Follow up tests using the procedures recommended by Aiken and West (1991) indicate that social support moderated the links between future time perspective and psychological well-being. Specifically, emerging-adults with low-medium family support who see their future as limited were less. Further, the results indicate that seeing the future as open is linked with increased personal growth at all levels of support from friends, family, and significant others. However low-medium –perceived support from significant-other coupled with seeing the future as ambiguous was linked with lowered positive relations in emerging-adulthood. Also, viewing the future as ambiguous was also linked with reduced purpose in life at all levels of support from friends, family, and significant others. While these preliminary results do suggest that future-time-perspective and social-support together influence psychological-wellbeing in emerging-adulthood, one needs to be cautious with any conclusions that may be drawn given that the data are concurrent-correlational, and hence causal interpretations cannot be drawn; however, these results suggest that it is important to consider the combined effects of future orientation and perceived support to understand psychosocial development in emerging-adulthood.

Abstract Name: Hydrochloric Acid-Induced Lung Injury in a Murine Model of Alzheimer's Disease

Alzheimer's disease (AD) is a progressive neurodegenerative disorder marked by memory loss, chronic neuroinflammation, and protein aggregation in the brain. The 3xTg-AD mouse model recapitulates many features of human AD and displays increased immune sensitivity. Acute lung injury (ALI) is a severe respiratory condition characterized by damage to the alveolar epithelium, impaired gas exchange, and intense

neutrophilic inflammation, and can progress to acute respiratory distress syndrome (ARDS). The hydrochloric acid (HCl) aspiration model is a widely used preclinical method for simulating acid-induced ALI in rodents. HCl exposure leads to rapid injury of the airway epithelium and recruitment of inflammatory cells. This study investigates how HCl-induced ALI affects lung mechanics and inflammatory responses in 3xTg-AD mice. Experimental procedures were conducted on nine-month-old female 3xTg-AD mice. Mice were anesthetized, intubated intratracheally, and instilled with HCl to induce acute lung injury. Mice recovered off-ventilator for 24 hours. Control animals were undosed. At the endpoint, mice were re-anesthetized, and lung mechanics, including compliance (Crs), resistance (Rrs), elastance (Ers), and pressure-volume loops, were recorded. Bronchoalveolar lavage fluid (BALF) was retrieved, and cells from the BALF were isolated, counted, and fixed via cytopspin. HCl exposure significantly altered lung mechanics and inflammatory responses in 3xTg-AD mice. Mechanical ventilation measurements showcased elevated respiratory system resistance, increased elastance, and decreased compliance in HCl-treated mice compared to controls. Elastance was significantly higher, and compliance was significantly reduced. HCl-treated mice showed higher BALF cell counts compared to controls. Cytopspin staining confirmed inflammatory cells in the BALF of HCl-treated animals. HCl aspiration in 3xTg-AD mice significantly impairs lung mechanics and promotes pulmonary inflammation. These results highlight the susceptibility of AD models to peripheral injury and support further investigation into lung-brain immune signaling pathways.

Abstract Name: Stem Cell Based Therapies for Charcot-Marie-Tooth Disease: A Systematic Review of Preclinical and Early Clinical Studies

Charcot-Marie-Tooth (CMT) disease is an inherited peripheral neuropathy that gradually damages the nerves responsible for movement and sensation. Despite its prevalence, no treatment currently slows or reverses this decline. CMT causes chronic myelin loss, reduced support from Schwann cells, and progressive degeneration of peripheral nerve fibers. Stem cells are being explored as a potential treatment due to their ability to release supportive factors, reduce harmful inflammation, and may help repair damaged nerves. The purpose of this review was to systematically evaluate published evidence on stem-cell-based therapies for CMT. The scientific literature was searched for studies involving animal models or human participants with genetically confirmed CMT, identifying eleven eligible studies: eight animal studies and three human studies (one case report and two early-phase clinical trials). All human studies involved individuals with CMT1 or CMT1A. Across animal studies, most treatments led to improved coordination, stronger limb strength, faster nerve-signal conduction, and/or healthier myelin structure. Some studies found that repeated dosing or using Schwann-like cells produced the strongest effects. A few studies also tested molecules naturally released by stem cells and observed similar biological benefits. Human studies focused mainly on safety. Early findings showed that treatments were generally well tolerated, with only mild short-term side effects. One case report described functional improvement, but this single example cannot establish effectiveness. Overall, current evidence suggests that stem-cell-based approaches may offer a promising path for addressing nerve damage in CMT, but the data remains limited. Because the studies differed widely in methods, cell types, and sample sizes, larger and well-controlled clinical trials are needed to determine whether these therapies can provide consistent and meaningful benefits.

Abstract Name: Exploring Cyber Accounting Data in Extended Reality

As more businesses digitize their operations, accountants are no longer just number crunchers, they're also data managers and cybersecurity-aware professionals. Cyber accounting is an emerging field that combines accounting practices with modern digital and cybersecurity technologies. Using Extended Reality (XR) in accounting is a new idea that blends immersive technology with financial operations. XR turns complex financial data into 3D, interactive visual dashboards. Accountants can walk through a virtual environment showing a company's cash flow, balance sheet, etc. in 3D. That makes it easier to analyze trends, anomalies, or fraud by seeing patterns rather than reading numbers. Using XR for accounting is not yet widespread, but it offers huge potential by turning abstract numbers into interactive experiences and enhancing both cybersecurity and collaboration. Our primary data source is the Electronic Data Gathering, Analysis and Retrieval (EDGAR) system, used by companies and individuals to submit filings to the U.S. Securities and Exchange Commission (SEC). The data is retrieved using EDGAR API and cached by a backend server that uses GraphQL as a query language. The server is used to streamline the data collection and processing. We are currently exploring several metaphors for presenting the data provided by the backend, among which are the Forest and City metaphors. The goal is to leverage user mental models and minimizing cognitive load. For example, in City metaphor each building represents a company. To populate the city, buildings could be arranged per their respective company's metrics, including revenue and earnings per share. Our future plans include incorporating MCP with audio input. This way users can make data and representation selections through the implemented voice assistant. For example, a user would be able to call out the assistant and request it to chart quarterly profits for Apple, Google and Tesla across a decade starting from 2011.

Abstract Name: Investigating Intense Plasma Drifts and Associated Optical Emissions Using Swarm and TReX RGB All-Sky Imager Observations

Subauroral ion drifts (SAIDs) are fast (>500 m/s) westward plasma flows that occur equatorward of the auroral oval. Previous studies have established a statistical correlation between intense SAIDs (>4 km/s) and STEVE (strong thermal emission velocity enhancement), an unusual optical emission which appears as a mauve arc stretching east/west across the subauroral sky (Archer et al., 2019). Unlike typical auroral emissions, which have narrow emission features associated with distinct atomic or molecular transitions, STEVE emissions are a continuum that spans the optical spectrum, and their specific emission mechanisms are still debated. This project aims to investigate the relationship between SAIDs and subauroral optical emissions to better understand the physical conditions required for such emissions. We identified extreme (>3 km/s) westward plasma flows using data from the ESA Swarm satellite mission. We compiled a catalog of these events from 2019 through March 2025. We then cross-referenced these events with available RGB all-sky imager and spectrograph data from Canadian sites in the TReX network to search for

conjunctions between these observed fast flows and available ground-based imagery. We have identified 20 conjunctions which occur under favorable observing conditions (clear skies, no moon), some of which contain optical emission features. For cases with optical emissions, we are applying magnetic field-line mapping to different altitudes to estimate the emission heights and determine the spatial relationship between the optical features and the plasma flow channels. These results will enhance our understanding of how intense plasma drifts relate to optical emissions and may help refine models of magnetosphere-ionosphere coupling. This work also contributes to identifying conditions favorable for STEVE and may support future observational campaigns targeting subauroral phenomena.

Abstract Name: Intimate Partner Violence Among LGBTQ+ Women: It is not all Rainbows and Pride

The purpose of this short presentation is to explore the under-researched topic of intimate partner violence among LGBTQ+ women and the lack of support and visibility faced by this community when it comes to IPV. To preface, while I will focus on the experiences of LGBTQ+ women, those in the community who also identify as male and all gender identities that fall under the umbrella term of “nonbinary” are notably affected, too. The community as a whole faces high rates of IPV. While I have gathered research from eight peer-reviewed articles and have come up with main themes: "The Stigma Surrounding IPV and Receiving Help for LGBTQ+ Women," "The Diverse Experiences of LGBTQ+ Women who Face IPV," and "The Effects and Lack of Support for LGBTQ+ Women Who Have Been Through IPV," specifically, I will focus on the second theme. Within the theme of “The Diverse Experiences of LGBTQ+ Women,” there are three groups I will explore when it comes to IPV: LGBTQ+ University Students, LGBTQ+ Veterans, and LGBTQ+ Women in Turkey. When choosing what groups to research, my goal was to cater to a variety of ages and lived experiences outside of Western culture. This presentation engages not only with a research lens but with a mental health lens. Intimate partner violence is known to cause an onset of mental health disorders like Major Depressive Disorder, Generalized Anxiety Disorder, Posttraumatic Stress Disorder, and Substance Abuse Disorders. The examination of how those with different and intersectional identities' mental health is stigmatized and treated is also considered, as we are tackling diverse perspectives.

Abstract Name: Unexpected Striatal Activation from GHSR Stimulation by Ibutamoren

Ghrelin is a peptide hormone well known for stimulating appetite and regulating energy balance by binding to the Growth hormone Secretagogue Receptor (GHSR). This hormone acts largely through the hypothalamus- a brain region central to hunger, metabolism, and homeostasis. Ibutamoren (IBU) is a synthetic compound that mimics the growth-hormone stimulating effects of ghrelin and also binds on GHSR. IBU is widely used to

study the effects of GHSR stimulation as opposed to ghrelin due to enhanced stability, and a much longer half-life. To examine IBU's influence on GHSR activation, cFos immunohistochemistry (IHC) was used to measure neuronal regions across hypothalamic subregions of the brain. IHC is a technique which detects c-Fos protein expression as a molecular marker on neuronal activity. One subregion that was examined is the arcuate nucleus (ARC), which involves appetite- stimulating and appetite-inhibiting neurons. Using a dose of 1mg/kg, IBU did not significantly alter cFos expression in the arcuate nucleus. As this was an unexpected finding, our analysis spread to 50 other brain regions, where robust activation was identified in the dorsomedial striatum (DMS). This subregion is involved in motivation and decision making. To determine if these effects arise directly from GHSR activation, in vivo calcium imaging using GCaMP viral construct was performed. This technique showed that IBU strongly impacts striatal neural activity in live animals. These findings suggest IBU's influence goes beyond regulating feeding circuits as the hormone also impacts networks in the brain regulating motivation and decision making.

Abstract Name: AeroRAG: Offline Retrieval-Augmented Generation Application for Aerospace Documentation Using Llama 4

I developed a Retrieval-Augmented Generation (RAG) application using the advanced open-source LLaMA4 language model. The main objective is to deliver an offline RAG model on aerospace content and obtain insights. This application would be deployable across different operating systems using Ollama and would not require an internet connection. The developed model would be secure, not hallucinate, and would respond only to the knowledge base on which it is trained. I would be utilizing the NASA STI Repository's public metadata dataset, delivered annually as NDJSON bulk downloads. It contains structured fields such as titles, abstracts, keywords, authors, publication dates, and PDF URLs. I built an innovative retrieval model using the foundational Llama 4 model. I also created a step-by-step guide for deploying the model and making it executable across different operating systems. The results obtained will be made publicly available.

Abstract Name: Navigation- and Landmark-Related Memory in Virtual Reality versus 2D Displays

Research has shown that successful navigation and memory for that navigation is impacted by a variety of factors. Active involvement in navigation and the presence of effective landmarks along the route have been identified as key elements. Although many studies have been conducted in a real world environment, the majority of the studies depend on laboratory research with studies varying widely in their level of fidelity. This study explores how simulation immersion might impact the effects of active navigation and landmark distinctiveness. Feelings of presence in the environment will be manipulated by assigning the participants to navigate in either an immersive 3D display condition using an HTC Vive Pro 2 virtual reality headset or a nonimmersive 2D condition on a computer monitor. Participants will both actively navigate one environment using an Xbox controller and passively navigate another environment by watching a pre-recorded video. Distinct and nondistinct landmarks will be present in each route. We anticipate presence will be higher in the immersive display type, more accurate route memory for portions of the route with distinctive landmarks, and more accurate route memory for active navigation than passive navigation. The results from this research will help inform decisions about study design in relation to participant presence and immersion in navigation and route memory research. The results will also show the relative benefits of active navigation and landmark distinctiveness in navigation and route memory.

Abstract Name: Optical control of protonmotive force in mammalian cells

Mitochondria play a central role in ATP production through oxidative phosphorylation. This process is driven by an electrochemical gradient across the inner mitochondrial membrane known as the protonmotive force (PMF). Alteration of this gradient has been directly associated with metabolic dysfunctions in neurological and cardiovascular disorders. Advances in optogenetics have shown that the use of old mtON to increase mitochondrial PMF can increase ATP production in *C. elegans* and isolated mitochondria. However, this tool has demonstrated limited mitochondrial localization and low efficiency in mammalian cells (HeLa cells), resulting in inconclusive outcomes. To address these limitations, we conducted a comparative study between a newly developed mitochondria-targeted light-activated proton pump called “mito-glow” in order to enhance PMF in HeLa cells. We showed that mitoGlow exhibits better mitochondrial localisation than mtON and that mitoGlow selectively increases PMF upon light activation. Overall, we demonstrated that the newly developed light-activated proton pump exhibits high mitochondrial localization, and its photoactivation supports the generation of the PMF compared to mtON. This improvement enables optical control of mitochondrial PMF dynamics in mammalian cells, opening new avenues for understanding mitochondrial energy regulation and dysfunction.

Abstract Name: Inequity in Maternal Care for Ecuadorian Women: Prevalence of Preeclampsia in a High-Altitude Environment and Lack of Access to Preventative Healthcare

Preventive healthcare is fundamental to promoting health equity worldwide, particularly in maternal care. Within this context, preeclampsia is a critical example of how preventive strategies mitigate the disparities in maternal care. Preeclampsia remains a leading cause of maternal and fetal mortality rates worldwide, affecting 2-8% of pregnancies. While social and demographic factors have been widely studied within preeclampsia, the environmental determinants, specifically high altitude exposure, are often overlooked in maternal health research. This study investigates the relationship between high altitude environments and the prevalence of preeclampsia rates in Ecuador. A large portion of its population resides at high altitude due to the location of the Andes Mountains within the country. An elevation above 3500 meters exposes pregnant individuals to chronic hypobaric hypoxia, reducing oxygen availability and uteroplacental blood flow. Using a population-based set of over 400,000 births from 2015-2017, in an observational study setting, results showed a statistically significant association between higher altitude and increased rates of preeclampsia. This project utilized the 95% Confidence Intervals to estimate the unknown statistical parameter, calculating a p-value below our alpha significance level, rejecting the null hypothesis. The adjusted odds ratios suggest that women living above 3500 meters were 2.4 times more likely to develop preeclampsia than those at lower elevations. These results support our hypothesis that high altitude is an independent risk factor for preeclampsia. Although this research is geographically limited to Ecuador, it expands on prior smaller studies, highlighting the need for tailored maternal care initiatives. Women in remote high-altitude regions often face reduced access to early diagnosis and prevention. This research emphasizes the need for access to preventive measures for the advancement of healthy equity in high-altitude regions.

Abstract Name: AC Electrokinetic Focusing and Trapping of Nanoparticles in a Ratchet Microchannel

Insulator-based dielectrophoresis (iDEP) has emerged as a crucial technique for the manipulation of micro- and nano-sized particles, making it essential to prefocus these particles into a tight stream for subsequent manipulation in microfluidic devices. We report, in this study, AC iDEP focusing of nanoparticles in a ratchet microchannel, where the focusing behavior is strongly influenced by the frequency of the applied AC voltage and the ionic concentration of buffer. By adjusting the AC field frequency, particularly at lower frequencies, nanoparticles can be effectively focused into a narrow stream along the channel's centerline. It has also been observed that particles can be focused at different positions within the channel, either near the tips or at the centerline of the ratchets, depending on the ionic concentration of the buffer. This variation in focusing positions underscores the potential of the AC iDEP technique for nanoparticle separation and led us to pay special attention to conditions where particles become trapped near the constrictions. Therefore, we extend our study to examine the flow pattern around the ratchet tips. In this part of the work, we use particles as tracers to visualize how flow first appears near the constrictions, how recirculating motion develops, and how these flow structures change as we vary the electrical conditions and ionic concentration of buffer. By linking flow regimes with where particles focus or become trapped, we aim to show that focusing and trapping can be used together to control and separate particles in an iDEP microdevice.

Abstract Name: Subunit-Specific Roles of PP2A in Ceramide-Responsive Phosphorylation Networks in Breast Cancer

Bacterial sphingomyelinases (bSMases) are enzymes produced by certain bacteria that hydrolyze sphingomyelin, a lipid present in animal cell membranes, generating bioactive sphingolipids such as ceramide. Ceramides can modulate cancer progression, either promoting or inhibiting tumor growth depending on the bacterial species, cancer type, and cellular context. In breast cancer, Protein Phosphatase 2A (PP2A), a critical serine/threonine phosphatase, is frequently inactivated. PP2A regulates numerous key signaling proteins, including Akt, p53, c-Myc, and β -catenin, and its dysregulation contributes to irregular oncogenic signaling, driving tumor development and progression. Despite its central role, the specific contributions of the ceramide-activated PP2A to phosphorylation networks and downstream signaling remain poorly understood. The present study aims to systematically characterize how knockdown of PP2A- α , PP2A- β , or neither subunit affects kinase-phosphosite relationships in breast cancer cells. We analyzed a dataset of

eighteen samples divided into three groups corresponding to PP2A- α knockdown, PP2A- β knockdown, and control, with each group further subdivided into bSMase-treated and untreated conditions. Mass spectrometry was used to quantify phosphosite abundances across all samples. Using R-based computational workflows, we plan to assess differential phosphorylation, kinase-phosphosite enrichment, and pathway-level signaling changes across conditions. Kinase-phosphosite interactions will be evaluated using a combined scoring approach, integrating Pearson correlation of phosphorylation profiles with motif-based predictions, where higher combined scores indicate stronger predicted regulatory relationships. This study provides a framework for dissecting subunit-specific effects of PP2A on breast cancer phosphorylation signaling and establishes a foundation for future investigations into how ceramides influence phosphatase-regulated pathways. These insights may ultimately guide targeted therapeutic strategies aimed at modulating kinase-phosphosite networks in cancer.

Abstract Name: Innovative Alumni Communication and Engagement: Connection Across Cohorts to Create a Lasting Legacy of Belonging and Success

Efforts to advance educational equity increasingly depend on communication systems that foster community continuity, make equitable student experiences visible, and sustain long-term program impact for first-generation and limited-income college scholars. The project team, working in Grant Writing and Advocacy within the Center for Educational Opportunity (CeO) in collaboration with the internship program at the Office of Experiential Learning (OEL) at UW-Madison, identified a significant gap in the program's outreach: the lack of a centralized system for tracking alumni engagement and connecting alumni back to current students. This gap created challenges for efficient communication across the broader alumni network and among stakeholders committed to student success, fellowship, and support structures. The purpose of this initiative is to design and implement conduct landscape research on how comparable student-support programs structure alumni engagement through CeO's quarterly alumni newsletters and establish the framework for a new CeO alumni website. To develop these tools, this research will explore qualitative methods including interviews with alumni, collaborative conversations with staff and scholars, and review of internal documents to understand what narratives, data, and communication gaps mattered most. The emerging results show that structured storytelling, especially when centered on alumni experiences, plays a measurable role in strengthening program identity, increasing students' sense of belonging, and improving the program's ability to document long-term impact for the future success of alumni engagement and their relationship to the university and its scholars as a larger ecosystem. This project will reflect and educate NCUR's 2026 theme by demonstrating how communication innovation can support equity-driven programs and expand student opportunity. Building a lasting infrastructure for alumni engagement positively contributes to a broader model for community-rooted education support programs seeking to strengthen belonging and long-term student success.

Abstract Name: The Examination of Coaching Behaviors Effect on Athletes with Attention Deficit/Hyperactivity Disorder

Research has found a link between different coaching behaviors and levels of self-esteem and motivation in young athletes. Deficits in self-esteem and motivation are common symptoms of Attention Deficit/Hyperactivity Disorder (ADHD). The present research aimed to examine the moderating role of different coaching behaviors on the self-esteem and motivation of college-age athletes with ADHD. The two coaching behaviors being examined in this study are autonomous and controlling. Westminster College student-athletes were recruited through email. The athletes were given a battery of online, self-report assessments that aim to examine symptoms of ADHD, self-esteem, motivation, and their perceptions of their head coach's behavior. It is predicted that athletes with ADHD who have a coach that supports an autonomous coaching style will have higher motivation and higher levels of self-esteem. It is also predicted that athletes with ADHD who have a coach that supports a controlling coaching style will be less motivated in their sport, have lower levels of self-esteem, and more impairment. Results from this study indicate that athletes with higher levels of ADHD symptoms reported higher levels of self-esteem, even under the moderating effect of both coaching styles. Also showed a strong positive correlation between autonomous coaching behaviors reported and sports motivation, as well as a relationship between controlling coaching behaviors reported and higher levels of amotivation. Further research should continue to explore the effects of coaching behaviors on athletes with ADHD and other psychopathologies. Increased knowledge on this topic will aid in creating better coaching habits that support the needs and development of all athletes.

Abstract Name: Physics-Based Constitutive Modelling of Plastic Deformation in Machining

Machining- specifically metal-cutting is one of the most used and versatile manufacturing techniques. The metal-cutting process can create high strain and strain-rate environments with extreme temperature gradients that can have a large impact on the properties and durability of the part, cutting tool, and machine. Recent studies have shown that plastic deformation mechanics are governed by underlying deformation mechanisms such as dislocation motion, dynamic recrystallization, and adiabatic shear banding. However, most machining models still rely on phenomenological constitutive models that do not incorporate these underlying physics. This research addresses this limitation by developing a constitutive model that accounts for internal deformation mechanisms. Orthogonal cutting allows for the complex three-dimensional cutting dynamics to be simplified to a unidirectional cut observed in a two-dimensional plane. A custom in-situ orthogonal cutting experimental setup was designed and constructed to collect synchronous high-speed visible and thermal imaging and cutting force data. Data was collected from Ti-6Al-4V orthogonal cutting trials. This data was processed using digital image correlation and particle image velocimetry tools to acquire velocity, strain-rate, and temperature data within the primary deformation zone. From this, plastic flow, vorticity, and heat generation throughout the cut can be mapped. A general yield equation within stress-space was derived analytically, providing a quadric yield-surface that interpolates between von Mises and Drucker-Prager yield behavior. A physics-informed neural network (PINN) was used to integrate experimental data into the analytical model, evaluate the Taylor-Quinney coefficient, validate the yield-surface equation and develop an inverse hybrid model. This model drastically improves the accuracy of material behavior prediction in Ti-6Al-4V. Future research will evaluate more materials and more extreme cutting conditions. This research will allow for significant improvements to product quality, tool life, and energy efficiency in metal-cutting machining and manufacturing.

Abstract Name: The Politics of Pity: Language-Induced Essentialism and Race on Public Attitudes towards Foreign Atrocities

Historical and psychological evidence alike can testify to the covert, yet highly powerful influence of language, metaphor, and rhetoric on attitudes towards intergroup conflicts and atrocities. However, there is a gap in literature in how generic language and essentialism may have a similarly influential effect on public attitudes in conflict scenarios. Essentialism is the idea that a social group has a distinct, innate, and immutable “essence” about them that permeates all members of the group, and recent research suggests that it is related to prejudice along in-group and out-group lines in intergroup conflicts. To measure how essentialism and victim race may affect American attitudes and willingness to help in intergroup atrocities, I invented a fictional social group called “Tarovas,” about whom participants will read a series of neutral facts about their lives and culture. In this slide deck, essentialism will be manipulated by using generic language to describe Tarovas (e.g. “Tarvos love to swim”) or specific language (e.g. “This Tarova loves to swim”). Race will be manipulated by the Tarovas being described as either native to Eastern Europe or Eastern Africa. At the end of the slide deck, participants will read a brief paragraph about the Tarovas recently falling victim to an intergroup atrocity committed by the U.S., and then complete a survey to measure the extent of their sympathy towards and willingness to help the Tarovas.

Abstract Name: Coral Decline and Fish Community Homogenization: Insights from Three Florida Keys Reefs

In the Florida Keys, declines in live coral have been linked to altered community composition in associated species (Thanopoulou et al., 2022). Globally, coral cover and structural complexity have been shown to enhance fish productivity and sustain diverse assemblages, with higher coral cover supporting greater species richness and functional diversity (Morais & Bellwood, 2020). To evaluate the relationship between live coral cover and associated fish assemblages in the Florida Keys, surveys were conducted at three reef sites in the Atlantic Florida coral reef track in November 2025: Grecian Rocks; Alligator Reef, and Looe Key. The purpose of this study was to determine if live coral cover in these near-shore reef communities impacts fish species diversity. In this study, the proportion of live coral cover was quantified using belt transects, while

fish species richness was recorded through stationary point analysis and belt transects. Comparative analyses revealed significant variation among sites with the highest coral cover supporting the greatest fish diversity, including a higher proportion of reef-associated herbivores and small carnivores. In contrast, sites with reduced coral cover exhibited lower species richness and were dominated by generalist species. Thus, analyses indicated a positive correlation between coral cover and fish community complexity and declines in coral cover were associated with homogenization of fish communities. These findings underscore the importance of live coral in maintaining fish biodiversity and highlight the vulnerability of Florida Keys reefs to ongoing stressors.

Abstract Name: TEST-RETEST RELIABILITY OF A SELF-PACED TREADMILL PROTOCOL TO ASSESS MAXIMAL OXYGEN CONSUMPTION

Self-paced exercise testing protocols (SPPs) have emerged as a valid alternative to traditional ramp protocols for assessing $\dot{V}O_2$ max. This study aimed to evaluate the test-retest reliability of a 10-minute treadmill SPP for the assessment of $\dot{V}O_2$ max. Apparently-healthy adults ($N=8$; 22.9 ± 3.8 yrs; 24.2 ± 2.4 kg/m²; 50% females) completed 3 SPPs on a treadmill on 3 separate days 48 hours apart. The SPP consisted of 5 x 2-min stages (10-min total test time) where the subject self-selected a treadmill speed and grade for each stage to elicit work rates corresponding to the following rating of perceived exertion (RPE) values: 11 (light), 13 (somewhat hard), 15 (hard), 17 (very hard), and 20 (max). Subjects were blinded to the self-selected speed and grade and oxygen consumption (ParvoMedics TrueOne 2400) was continuously measured during the SPP. After a 10-min recovery, subjects completed a 4-min $\dot{V}O_2$ max verification trial. One-way repeated measures ANOVA was used to compare $\dot{V}O_2$ max values across the trials. Intraclass correlation coefficients (ICCs) were also calculated to assess the reliability of the SPP protocol for assessing $\dot{V}O_2$ max. $\dot{V}O_2$ max values (mean $\pm$ sd) were 44.1 ± 5.0 , 44.1 ± 5.3 , and 44.3 ± 4.1 mL $\cdot$ kg⁻¹ $\cdot$ min⁻¹ for trials 1, 2, and 3, respectively. There was no significant difference in $\dot{V}O_2$ max values across the three SPP trials, $F(2, 14) = 0.075$, $p = 0.928$, $\eta^2 = 0.012$. ICC analysis using a two-way mixed-effects model (ICC[3,1], single measures) showed excellent reliability for $\dot{V}O_2$ max across the three trials, with an ICC of 0.935 (95% CI: 0.78–0.99). In our small sample, the SPP demonstrated excellent test-retest reliability. By allowing participants to regulate their own work rates, SPPs eliminate the need for researchers to estimate starting intensities, stage durations, and workload increments necessary to reliably achieve volitional fatigue within 8-10 minutes.

Abstract Name: Gaussian Decomposition Framework for High-NA Optical Cavities

How can we accurately model optical cavities with high numerical apertures (high-NA), where traditional paraxial approximations fail? These cavities are central to next-generation quantum photonic systems, enabling stronger atom–photon interactions, faster entanglement generation, and scalable quantum technologies. Modeling high-NA cavities is challenging because standard Gaussian beam methods assume small angles and slowly varying fields, which break down when light propagates at wide angles or encounters strong curvature. Accurately predicting the behavior of such cavities is crucial for designing experiments, improving resonator performance, and developing devices for quantum computing, advanced microscopy, and precision sensing. We introduce the first application of Gaussian beamlet decomposition to cavity analysis, rather than free-space propagation. This method decomposes the optical field into a set of localized Gaussian components, each remaining paraxial locally. Collectively, these components reconstruct the full non-paraxial field inside the cavity. By propagating them through the cavity and combining their transformations, we construct a round-trip operator. Solving the operator’s eigenvalue problem reveals the cavity’s self-reproducing transverse modes, mode spacing, and spatial field structure, even in geometries inaccessible to traditional models. This approach provides a systematic framework for analyzing highly non-paraxial cavities with predictive power and efficiency. We validated the method using analytically solvable cavities, confirming accuracy and computational efficiency. To further improve performance, we developed a beamlet-generation scheme adapted to the initial field curvature and applied the Lagrange invariant to ensure local paraxiality during propagation. Ongoing work focuses on mitigating errors introduced by reflections from strongly non-paraxial surfaces, optimizing beamlet sampling strategies, and extending the framework to more complex cavity geometries. This tool offers a flexible platform for high-NA cavity design, with applications across quantum optics, microscopy, and photonic engineering, where precise control of light fields and efficient mode matching are critical.

Abstract Name: Investigating the Effects of Sphingosine-1-Phosphate on Bone and Vasculature Cell Function

Ischemic stroke impairs neurological and motor function, leading to significant bone loss and increased risk of falls and fractures. While bone deterioration post-stroke is commonly attributed to reduced mechanical loading, the cellular mechanisms that contribute to stroke-related bone loss remain unclear. Our previous experiments in a mouse model of stroke revealed dysregulation of the sphingosine metabolic pathway in the bone marrow microenvironment. In this, we observed reduced expression of sphingosine-1-phosphate (S1P), a lipid metabolite known to support osteoblast survival, angiogenesis, and endothelial barrier integrity. Reduced S1P is known to produce inflammation and disrupt vascular endothelial barrier integrity, but its effects on osteoblast behavior remain unknown. This study is investigating cellular interactions between human osteoblasts and endothelial cells in a vascularized bone microdevice, a controlled microenvironment that enables cellular communication and regulation of flow and metabolite concentration. We hypothesize that reduced levels of S1P mimicking ischemic stroke will reduce osteoblast activity and production of proangiogenic factors, impairing endothelial growth and function. By mimicking post-stroke conditions in vitro, this approach allows examination of how metabolic disruption contributes to cellular dysfunction.

Understanding how S1P downregulation affects bone-vascular interactions can help identify potential therapeutic targets to prevent stroke-related bone fragility and improve long-term recovery.

Abstract Name: Lessons from the past: Leveraging museum specimens to advance freshwater biomonitoring

The unique conditions of a freshwater ecosystem are reflected in its biological assemblages. Changes in condition from natural variation or anthropogenic alteration can modify the composition of resident organisms. Therefore, an assessment of biological organisms (i.e., biomonitoring) can be used to complement water quality monitoring as these organisms can predictably shift in occurrence or abundance in response to environmental change. In Wisconsin, the practice of using aquatic macroinvertebrates for biomonitoring was systematized by entomologist William Hilsenhoff whose extensive collection (750,000+ specimens) obtained from hundreds of freshwater ecosystems across all 72 Wisconsin counties is housed at the Wisconsin Insect Research Collection at the University of Wisconsin – Madison. This collection can continue to provide a vital resource for future freshwater biomonitoring innovation, but its data remain largely inaccessible.

Fundamentally, the accurate interpretation of biomonitoring data requires updated taxonomic information so changes in assemblages can be appropriately linked to environmental perturbations. Furthermore, shifts in occurrence patterns may reflect fluctuations in geographical distributions indicative of larger scale change or management actions. Therefore, our aims are to 1) harmonize historic and current taxonomic data for sensitive invertebrate taxa and 2) document changes in occurrence through an examination of recent records available from the combined collections of all partner institutions and publicly available records in the Wisconsin Department of Natural Resources Surface Water Integrated Monitoring System database. These activities will support the accurate calculation of richness values and metrics for regulatory and community science monitoring efforts while also identifying strategic locations and habitats for contemporary sampling needed for evaluating long-term trends. In addition, the digital records of specimens generated from across the state will, like the Hilsenhoff collection itself, become an on-going and growing asset for regulatory professionals, members of the public involved in community water monitoring efforts, and other freshwater researchers.

Abstract Name: Building RAG Agents to Enhance Difficult Conversations among Undergraduate and Graduate Nursing Students

Effective communication is a critical nursing competency, yet students often experience anxiety and limited opportunities for practice before clinical encounters. Traditional teaching methods and standardized patient interactions provide limited, one-time practice and feedback, hindering confidence and transferability of skills. The findings from this study indicate that integrating an AI chatbot into nursing education can serve as an effective preparatory tool to enhance students' confidence, readiness, and communication skills for navigating challenging clinical conversations. While the chatbot experience had its limitations, it provided most students with a valuable opportunity to practice, reflect, and apply feedback before engaging in live simulations. The combination of positive Likert-scale results and qualitative reflections underscores the chatbot's roles in reducing anxiety, promoting skill development, and offering structured, accessible practice in a low-stakes environment. As nursing education continues to explore innovative technologies, RAG-driven simulation tools have the potential to complement traditional training methods, bridge the gap between theory and practice, and better prepare future nurses for the complexities of real-world patient care. Further research should explore strategies to enhance emotional engagement in AI simulations, examine the long-term impacts on communication competency, and enhance chatbots' adaptability and realism.

Abstract Name: Capturing ultra-rare CRISPR-Cas9 off-target editing events in single cells

CRISPR-Cas9 genome editing offers powerful opportunities for therapeutics, but unintended off-target edits are a major concern. The McVicker Lab developed Superb-seq, a single-cell assay jointly profiling genome edits and transcriptomes to evaluate off-target editing and its consequences. However, the current pipeline's stringent filters miss potentially meaningful ultra-rare events. I developed a statistical framework to evaluate ultra-rare candidate edits identified using relaxed Sheriff filtering conditions. Allowing single-cell events and removing certain constraints generated an expanded catalog of low-frequency sites. To differentiate true Cas9-mediated events from technical artifacts, I implemented a guide homology scoring pipeline. This performs global sequence alignment between each candidate site and all known guide RNAs, assigning an alignment score based on sequence similarity and PAM proximity to reflect Cas9 targeting likelihood. To assess statistical significance, I developed an adaptive empirical p-value method. This approach compares observed alignment scores against a scrambled null background of randomized guide-site pairs to estimate per-site significance. The adaptive procedure dynamically increases permutations for initially significant candidates, providing high statistical resolution for promising sites while remaining computationally efficient. This analysis enabled the identification of 11 new significant off-target sites on chromosome 1, all of which were missed by the default Sheriff pipeline. Manual validation confirmed at least two of these sites as genuine, ultra-rare Cas9 edits, and the full set of significant sites showed a statistical enrichment in intronic and promoter regions. This framework enhances Superb-seq's sensitivity to detect ultra-rare CRISPR-Cas9 off-target edits and provides a more rigorous statistical foundation for distinguishing true Cas9-mediated events from background noise, contributing to safer and more precise genome editing analyses.

Abstract Name: Privacy-Preserving Tax Analytics

As electronic tax systems are increasingly adopted worldwide, they face critical privacy and security risks due to reliance on cloud infrastructures and exposure of sensitive financial data. Traditional platforms often require raw access to taxpayer information, making them vulnerable to cyberattacks, breaches, and insider threats. These risks reduce public trust in digital tax systems. To address these challenges, we propose a privacy-preserving framework for secure tax calculation and risk assessment without revealing personal data. Our solution integrates Fully Homomorphic Encryption (FHE) and the CKKS scheme for approximate arithmetic to enable encrypted evaluation of income, deductions, and risk. Last year we showed simple calculations with encrypted data and trained SVM with plaintext data. This year we want to continue working on this project and take the model weights from SVM trained on plain data and perform inference on encrypted data. For future work, we aim to generalize this approach to additional machine learning models and explore the development of a user-facing application or web platform that integrates secure encrypted computation into real-world tax workflows.

Abstract Name: Land, Development, and Tribal Identity in India: The Heavy Engineering Corporation (HEC) and tribal land acquisition

Tribal land in Jharkhand, India, has been cultivated for generations by Adivasis, one of the largest aboriginal tribes of India. After India's independence in 1947, the government-owned Heavy Engineering Corporation (HEC) was established as a tomb to the industrial development of a new India. Land for the massive project came from acquiring large tracts of Adivasi land. Even in cases where compensation was paid, the social and cultural costs borne by Adivasis far exceeded the land's market value. Our research (a) traces this history of how the discourse of modernization and development was used to justify dispossession of land; (b) how this led to the spatial displacement of tribes, separating extended families, affecting livelihood, and impacting tribal identity; and (c) how this loss has been transmitted intergenerationally over the past 70 years and become part of Adivasi folklore, deeply entrenched into the Adivasi psyche. A qualitative research design examines the discourse on development, dispossession, and tribal identity. This will be integrated with the results of 20 semi-structured interviews with tribal leaders, community members, social activists, urban planners, lawyers, and subject-matter experts, including anthropologists and historians. A content analysis will identify key patterns from this integrated data. We expect our results to provide substantial evidence of how the rhetoric of modernization and development influenced HEC's acquisition of tribal land and how this loss of land impacted tribes by distancing and eventually eliminating them from their communities, traditions, and even their identity as agrarian tribes. Overall, our research findings will contribute to the discourse on development and help policymakers to understand Adivasi sentiments regarding land.

Abstract Name: Temporal Encoding for Fanning Detection of Honeybees

Honeybees are critical to our biosphere as a highly efficient pollinator. In recent years, an alarming number of hives have collapsed due to a variety of causes referred to as Colony Collapse Disorder (CCD). A crucial way honeybees maintain the health of their hive and the quality of the stored honey is by fanning. During fanning, bees remain stationary in front of the hive entrance and rapidly flap their wings to increase airflow. This results in regulating humidity and temperature, dispersing pheromones, and removing excess moisture from the stored honey before capping the cells. The time spent fanning, the number of bees participating, and the frequency of fanning events can provide important insights into a hive's health, longevity, and adaptability. Machine learning tools can be used to automate the detection and analysis of these events; however, video processing models are often quite large and computationally expensive. Models designed for single images have historically received more attention and are often more efficient and scalable. To take advantage of this, this paper proposes two techniques. One that encodes temporal data into the individual layers of an image before processing with an object detection model, and a second that does the same but instead uses a full convolutional network to encode an intermediary representation before parsing. Both are expected to reduce the model's size and computational complexity while achieving similar results. Also, this approach is expected to apply well to other events, such as washboarding, as well as more generalized action detection problems. With some adjustments, this technique could also be used in real time, providing another advantage over other video processing techniques.

Abstract Name: The Multivariate Analysis of Childhood Maltreatment and Adversity on Adult Functioning and Well-Being

Research has indicated that there is a strong relationship between adverse childhood experiences (ACEs) and negative outcomes in adulthood. Research has also indicated that there is a positive correlation between ACEs and adolescent deviance. Exposure to ACEs during childhood can lead to deficits in decision making, well-being, and overall life satisfaction. The purpose of this study is to assess the relationships among ACEs, adolescent deviance, and school-related deviance in predicting adult functioning and well-being. Participants (n=255) were recruited through the crowdsourcing platform CloudResearch and completed a series of online self-report assessments measuring their ACEs, adolescent behaviors, school-related behaviors, and adult functioning and well-being. Demographic variables, including age, gender, race, ethnicity, sexual orientation, and educational attainment, were also examined as potential moderating factors. Results from this study indicate that individuals who experience more ACEs in childhood are strongly correlated with committing adolescent deviance and school-related deviance. On the other hand, results indicated that there was no significant correlation between ACE scores and adult functioning and well-being. Future research should continue to analyze how early life adversity and adolescent deviance impacts long-term functioning and well-being across different facets of adulthood.

Abstract Name: Building Beyond Function: The Impact of Prosthesis Aesthetics on Post-Amputation Depression

Despite many modern advances in healthcare, amputees still struggle with maintaining mental well-being post-amputation. While functional prosthetic design has advanced significantly, cosmesis dissatisfaction remains a largely overlooked psychological factor. Amputees face high rates of depression, anxiety, and reduced quality of life following limb loss. Post-amputation depression is widely recognized, but few studies have explored whether aesthetic dissatisfaction contributes directly to negative mental health outcomes. Much of this psychological burden comes from disrupted body image, social stigma, and difficulty adjusting to a changed sense of self. While modern prosthetics greatly improve mobility, they do not always address the emotional and identity-related challenges of amputation. This research draws on Maurice Merleau-Ponty's Phenomenology of Perception, and conducts an analysis of existing medical and psychological studies to determine whether dissatisfaction with prosthesis appearance correlates with high rates of depression. When a prosthetic seems unnatural or draws unwanted attention, it can worsen self-consciousness and contribute to long-term emotional distress. While a healthy mental state is important for all patients, amputees require strong motivation and a positive outlook even more than other cases, because of the physical therapy and musculoskeletal training that they must undergo to attain a full recovery. I propose that prosthesis aesthetics play a significant role in mental health, with realistic and artistic prosthetics often leading to better psychological adaptation than purely functional designs. The findings will show that aesthetic dissatisfaction is a significant psychological stressor, and these results will be discussed within the broader context of identity reconstruction and future prosthetic design. Even slight improvements in prosthetic design could help patients get back to a full, healthy life more quickly and with less mental anguish. The conclusions will serve to advocate for the need for aesthetic considerations in prosthetic development as a mental health intervention for amputees.

Abstract Name: The Social Construction of Cemeteries and Grief in the Chippewa Valley

Cemeteries serve as an important physical space of culture and history within communities across the United States. Due to changing trends in funeral rites, examining the use of cemeteries in the present can be a gauge for how they reflect grief within the community they are a part of. Through visual analysis of cemeteries' material conditions such as decorations, grounds maintenance, and infrastructure, this paper finds that cemeteries within the Chippewa Valley are given attentive care relative to the ages of those within. In other words, cemeteries with more recent graves were observed to be better cared for. This is further confirmed by interviews with funeral directors and groundskeepers who interact with these locations daily. Finally, the

paper concludes with a discussion of how families expressing grief use cemeteries in spite of the ways cemeteries are becoming more distant from the rest of the community with time. Considering the rapidly changing perspective of death within the broader context of society, this project found local patterns of grief that can be expanded upon by other scholars to further to better refine how death is socially constructed in other locations.

Abstract Name: Efficacy and Cytotoxicity of Honey and Honey-Coated Ag₂Se Nanoparticles on Wound Healing

Chronic wounds and bacterial resistance to conventional treatments have created an urgent need for safer and more effective wound healing materials. This study explores the therapeutic potential of honey, silver selenide (Ag₂Se) nanoparticles (NPs), and honey-coated nanoparticles (hNPs) of Ag₂Se as advanced materials for wound healing. Honey is widely recognized for its antimicrobial, anti-inflammatory, and antioxidant properties, while Ag₂Se nanoparticles possess notable antimicrobial activity and have shown promise in promoting tissue regeneration. Nanoparticles of Ag₂Se were synthesized and coated with honey using Pulsed Laser Ablations in Liquid (PLAL) method. By coating these nanoparticles with honey, we aimed to enhance their biocompatibility, reduce potential cytotoxic effects on human cells, and leverage synergistic effects to improve wound healing outcomes. Human dermal fibroblasts (HDFa) were used to evaluate cytotoxicity, proliferation, and cell migration using standard viability and scratch wound healing assays. Antimicrobial efficacy was assessed through zone of inhibition tests against *Staphylococcus aureus* and *Escherichia coli*, utilizing honey samples with varying levels of bioactivity. To make sure that the honey was attached to the NPs and to determine the specific compounds attached from honey to nanoparticles, we performed Liquid Chromatography-Mass Spectrometry (LC-MS), which is a powerful and accurate technique to determine exact molecules in a sample based of their masses. This comparative approach enabled us to assess the individual and combined effects of natural and nanomaterial-based agents on wound healing performance. Statistical analyses ensured the reproducibility and precision of our findings. Overall, the results support the development of innovative biomaterials that integrate honey with nanotechnology to promote safe, effective, and biologically synergistic wound care strategies.

Abstract Name: From Puritans to Progressives: Comparing Political Culture Between Massachusetts and

Across the American political landscape, Massachusetts and California occupy an intriguing place—both states are considered metaphorical “front lines” for liberalism, consistently voting for Democratic candidates and supporting progressive policies. Despite the similar “sea of blue” when looking at recent electoral maps, they do not experience, perform, or incorporate politics into society the same way. Understanding that distinction historically, culturally, as well as its impact currently, requires looking beyond maps or data to uncover concealed meanings, values, and habits that shape how communities imagine their relationship to power and democracy. It requires an examination of lived political culture and how history has worked to shape it. This paper explores the root causes of these divergences by examining the historical evolution of political culture in each state, with a particular focus on the cultural components of each state’s foundational periods. Firstly, a specific definition of political culture will be devised using various political and cultural theorists and accounting for discursive elements as well as levels of political participation and action. Using this definition, the key cultural elements present during the founding years of each state will be analyzed, juxtaposing colonial Massachusetts and the Puritan tradition that emerged in the state with the expansionist, pioneering mentality of California’s settlers. This paper will demonstrate how these distinct cultural remnants live through collective memory and in turn affect how each state’s contemporary political cultures reproduce these historical elements. Through this comparative analysis, this research aims to provide a nuanced understanding of how historical differences contribute to diverging understandings of liberalism within American politics. By examining how cultural foundations have influenced these two distinct ideas of civic engagement, we can better understand the clash between the traditional and modern understanding of what it means for a state to have a culture that is politically engaged.

Abstract Name: Ovarian Cancer Cell-Driven Reprogramming of Fibroblasts to Induce Collagen Remodeling and Promote Differential Monocyte Infiltration

Within the tumor microenvironment (TME), an abundant cell type, cancer-associated fibroblasts (CAFs), critically regulates ovarian cancer progression by altering the extracellular matrix (ECM) through protein secretion and modulating immune cell infiltration through paracrine signalling. This study investigated how ovarian cancer cells reprogram dermal fibroblasts (NIH 3T3) into CAFs and how this reprogramming affects monocyte recruitment. Understanding these mechanisms is essential for developing therapies targeting the TME. We used a transwell co-culture system where NIH 3T3 fibroblasts were exposed to conditioned media from three ovarian cancer cell lines (UPK10, 2F8, ID8 p53 KO) for 72 hours. Fibroblast reprogramming was quantified by immunofluorescence staining for aSMA. We then embedded these activated fibroblasts into 3D collagen droplets (rat tail type I, 1 and 2 mg/ml concentrations) and performed a monocyte infiltration assay using isolated bone marrow monocytes. We tracked fibroblast proliferation (CellTracker CMFDA) and monocyte infiltration (CellTracker Deep Red) at 0, 24, and 48 hours using confocal microscopy. Results demonstrated that ovarian cancer cell lines induce differential CAF phenotypes. Fibroblasts exposed to UPK10 cells exhibited significantly increased aSMA intensity compared to control, indicating reprogramming into an activated CAF phenotype. Conversely, fibroblasts exposed to ID8 p53 KO showed markedly reduced aSMA expression. Correlating to the activation status, fibroblasts reprogrammed by UPK10 showed the highest monocyte infiltration compared to the other conditions. Furthermore, all co-culture conditions promoted increased fibroblast proliferation. These findings confirm that ovarian cancer cells utilize paracrine signaling to reprogram fibroblasts, inducing specific CAF phenotypes that functionally

modulate immune cell recruitment into the TME. The results underscore the critical role of specific tumor factors in driving CAF diversity, which has direct implications for regulating the composition of the TME.

Abstract Name: Not Just Gear: How Safety Climate and Self-Efficacy Shape Oil and Gas Workers' Perceived Value of PPE

Fatality rates in the oil and gas extraction industry far exceed those of all U.S. workers, yet research on personal protective clothing (PPC) and personal protective equipment (PPE) remains limited. Guided by the Customer Perceived Value framework, this study examined how field workers evaluate PPC/PPE. An online survey was conducted with 57 U.S. field workers (100% male; 75% with ≥ 6 years of industry experience). Composite 1–5 Likert scores were computed for hazard mitigation, design attributes (comfort, fit, mobility), self-efficacy, safety climate, perceived burdens/risks, and overall perceived value. Workers reported positive evaluations of PPC/PPE (overall value $M=3.61$; hazard mitigation $M=3.99$; safety climate $M=3.64$), alongside moderate concern about maintenance burden, donning/doffing risks, and performance interference ($M_s \approx 3.2\text{--}3.6$). Multiple linear regression models showed that safety climate was the strongest predictor of overall perceived value ($\beta=0.47$, $p=.003$; $R^2=.36$), whereas comfort and fit were not uniquely associated with value after accounting for other beliefs. Hazard-mitigation beliefs were most strongly predicted by self-efficacy ($\beta=0.41$, $p=.003$; $R^2=.38$), and PPE-related anxiety reduction was positively associated with safety climate ($\beta=0.31$, $p=.054$; $R^2=.30$). Content analysis of open-ended responses identified slips, trips, falls, chemical and toxic exposures, heavy equipment, noise, and heat as salient hazards. Workers described gloves, flame-resistant clothing, and safety footwear as essential yet often hot, heavy, and uncomfortable, and called for lighter, more breathable, better-fitting designs that maintain protection and dexterity. These preliminary findings suggest that organizational context and worker competence may be as important as equipment design in shaping how workers value and use PPC/PPE. Future research should replicate these models in the full sample, examine subgroup differences, and link perceived value and self-efficacy to incident data.

Abstract Name: Measuring the impact of a sit-spot mindfulness practice on connectedness to nature using multiple instruments

Spending a short amount of time outside can benefit college students' mental health and connectedness to nature. College students undergo an overwhelming amount of stress due to school work, family and social life, just to name a few. Time spent outside in nature helps increase a sense of mindfulness and groundedness that was not previously present. In addition to the mental health benefits of nature exposure, there are also

pro-environmental effects. Those who spend more time outdoors feel a stronger connection to nature, and thus are more likely to show increased care for the health of the environment. Our study focuses on how exposure to nature through multiple, short sit-spot activities can improve mindfulness and nature relationships. Sit-spot practices involve spending ten minutes sitting outside in a preferred location eight times in the duration of one month. To observe how these exposures affect students' wellness and connectedness to nature, we conducted a pre-post-study in three classes during the Fall 2025 semester. The students completed similar questionnaires at the beginning and end of the study, allowing us to compare how their answers have changed as a result of the practice. This survey included multiple different quantitative and qualitative measures. We have equipped the PANAS (Short Form Positive and Negative Affect Scale), MPQ (Mindfulness Practice Questionnaire), IINS (Illustrated Inclusion of Nature in Self Scale), and NCI (Nature Connectedness Index). Results will illustrate the degree to which mindful time spent outside affects students' mental health and relationship with nature in order to inform universities of ways in which this can improve students' wellbeing.

Abstract Name: Enhancing Unmanned Aerial Vehicle (UAV) Based 3D Reconstruction Using Multi-Objective Loss Functions in Neural Radiance Fields

In an effort to improve scene reconstruction for Unmanned Aerial Vehicle (UAV) data in three-dimensional (3D) models, this work explores how Neural Radiance Field (NeRF) reconstruction methods can be applied to generate continuous 3D renderings of UAV imagery. This research asks whether integrating perceptual loss functions with a dynamic weight function, specifically Learned Perceptual Image Patch Similarity (LPIPS), with traditional pixel-level metrics can improve the structural and perceptual quality of UAV-based NeRF reconstructions. We examine how UAV-captured images allow for the generation of spatially coherent models using Multi-Layer Perceptron (MLP) networks, which map 5D coordinates, like spatial position, viewing direction, radiance and density values, along each camera ray. This enables high-fidelity novel-view synthesis. To assess reconstruction quality, quantitative error metrics, like Mean Squared Error (MSE), Peak Signal-to-Noise (PSNR), Laplacian-based sharpness, and Structural Similarity Index (SSIM) were implemented to evaluate pixel-level and structural accuracy between generated and ground-truth images. Preliminary results show that integrating LPIPS, particularly when applied at controlled frequencies, improves perceptual fidelity without sacrificing pixel accuracy. These reconstructions when made with aerial drone data create more photorealistic automatic imaging of topology, allowing for better understanding of real-time changes in topology and thus monitoring of those areas. Keywords—NeRF, MSE, LPIPS, SSIM, PSNR, 3D scene reconstruction, topography

Abstract Name: Analyzing Factors Leading to the Outbreak of World War Two.

Before the outbreak of World War II, many issues were present. Three factors that were present were tension built up from global conflicts, ideologies, and alliances. This research paper will analyze how 1900s ideologies, along with global tension and the powerful alliances, affected the outbreak of the war and the full extent of it. It focuses on figuring out just how much those elements pushed the big powers to act the way they did, and how they built up tensions between nations. Historians have discussed before that fascism, communism, and Western ideologies all have tried ruling the world, yet this work digs deeper into how those beliefs actually drove the alliances that formed, the diplomacy and cooperation that fell apart, and the aggression that heated things through the 1930s. The studies/sources look into the historical context of the war while looking at multiple factors within the three main factors. It makes the case that World War II did not come from just one problem alone, but rather it grew out of how extreme ideologies mixed with countries chasing their own goals and the messy politics of alliances. That combination really laid the foundation for the fighting to spread throughout Europe, and then later on the whole world. When you see how those factors worked together, it helps make sense of how wars can break out from differences in views and the failure of diplomacy. Seeing how all of these factors can impact the outbreak of a war is an important lesson that could be used in order to analyze or prevent modern wars.

Abstract Name: Interkingdom Interactions as a Platform for Antifungal Drug Discovery

Introduction: The extent of microbial interactions is influenced by their environment (e.g., nutrient availability, oxygen concentration, temperature). While we are just beginning to understand how bacterial microorganisms communicate with each other, interactions between members of different kingdoms (interkingdom) such as those between bacteria and fungi are underexplored. *Candida albicans* is an opportunistic pathogenic fungus and a common colonizer of the human gastrointestinal (GI) tract. Previous studies have shown that *C. albicans* interacts directly with bacterial organisms and these interactions can be synergistic (e.g. *Streptococcus mutans*) or antagonistic (e.g. *Pseudomonas aeruginosa*). Hypothesis/Goal: We hypothesize that understanding how fungi and bacteria interact can reveal novel druggable targets. The goal of the present study is to co-culture a library of bacterial species with *C. albicans* to identify interkingdom interactions. Methodology: *C. albicans* SC5314 was co-cultured with one of 18 distinct bacterial strains using a biofilm formation assay in 1:1 media (TSB:RPMI). A concentration of 2×10^6 cells/mL of *C. albicans* was combined with a 1:20 or 1:200 dilution of an overnight culture of each bacterium and seeded into 96 well plates. Plates were incubated for 24 hours at 37 °C in 5% CO₂. Biofilm biomass was quantified using the Crystal violet assay. Results: We have identified interactions that enhance overall biofilm biomass (synergistic) or prevent biofilm formation (antagonistic) with some recapitulating previously reported findings (e.g. *Enterococcus faecalis* and *Streptococcus pyogenes*) while others are novel phenotypes (e.g. *Alcaligenes faecalis*). Further, all the interactions reduced or fully inhibited *C. albicans* filamentation, underscoring their complexity. Conclusions: Overall, our findings i) validate our screening platform, ii) identified interkingdom interactions that inhibit *C. albicans* filamentation, a key virulence factor, and iii) yielded multiple novel interactions. In future studies, we will test distinct culturing conditions (e.g. media) and characterize interactions in the context of mature *C. albicans* biofilms.

Abstract Name: Evidence for Bivalent Amino Acid Chemoreception: The Effects of Solvated Basic and Neutral Class Amino Acid Blends on the Feeding Behavior of Koi Carp, Goldfish and Brown Bullhead

Solvated amino acids are known to induce an enhanced feeding response among a broad cross-section of fish species, including members of the Carp (Cyprinidae) and American catfish (Ictaluridae) families. Through both aquaria studies and field work, we have shown that solvated binary blends of basic (Lysine, K) and neutral (Valine, V or Alanine, A) amino acids invoke a greatly enhanced feeding response within koi (*Cyprinus rubrofuscus*) and goldfish (*Carassius auratus*) for V: K or A: K ratios of ~1:1.5, with a completely attenuated response being observed for V: K or A: K ratios of ~2:1. For bullhead (*Ameiurus nebulosus*), optimal feeding behavior is observed for a blends possessing V:K or A:K ratios of ~1:2, with a completely diminished response also being observed for V:K or A:K ratios of ~2:1. These results strongly support the hypotheses that that amino acid chemoreception within these respective species utilize a bivalent receptor system dedicated to the concomitant detection of amino acids from the basic and/or neutral classes. Importantly, the complete attenuation of feeding response, for effectively equimolar blends of basic and neutral amino acids, strongly supports the hypothesis that the bivalent receptors' basic and neutral binding sites exhibit an EOR Boolean type relationship with respect to the expression of net stimulatory response. This interpretation is supported by the results of a 100 bivalent (EOR) statistical model of the proposed chemoreceptor system, which furnishes maximized and fully attenuated net stimulatory responses consistent with the analogous amino acid blends' experimental results.

Abstract Name: Prevalence of Bacterial Tetracycline Resistance Genes in Virginia Soils

The spread of antibiotic resistance in bacteria is a growing health concern as it can make bacterial infections harder to treat. An increased prevalence of antibiotics in ecosystems due to overuse in agricultural and urban settings creates a selection pressure in bacteria for antibiotic resistance genes (ARGs). Bacteria can also pass these resistance genes to other bacteria through horizontal gene transfer, speeding up the spread of the ARGs. Environmental samples, including soil, can act as reservoirs for these antibiotic resistance genes (ARGs) because they house many different types of bacteria. By studying these environments for ARGs, we can better understand where resistance may be developing and how it could spread outside clinical settings. This study surveyed for the presence of tetracycline resistance genes in soil samples collected from across Virginia. Sampling locations included a livestock farm, a heavily used recreational trail, and a dog-walking field near a residential neighborhood. These environments were selected because they experience frequent human and animal activity and may be more likely to come into contact with antibiotics or fecal contaminants. Using primers targeting ARGs, genomic DNA isolated from the soil samples was tested to determine the presence of tetracycline-associated ARGs. Several of the soil samples collected were positive for tetracycline-associated ARGs, indicating that some environments may harbor bacteria with antibiotic resistance.

Abstract Name: Investigation of Electron Radiation Effects on HeLa cells expressing APOBEC3A

The purpose of our research is to study the effects of ionizing radiation by direct electrons on HeLa cells. The radiation source is AN-400 Van De Graaf particle accelerator at the Minnesota State University Applied Nuclear Science lab, modified to provide electron beams. The 350KeV electrons are extracted through a 25mm aluminum window to provide a broad external beam suitable for irradiation of biological samples. HeLa cells are prepared in a standard MTS assay plate with the liquid medium removed prior to irradiation. Separate regions of the plate can be irradiated, with the remainder including controls behind lead shielding. After irradiation the liquid medium is replaced and the cells incubated for 48 hours. Cell survival curves and repeated dose variance was measured up to near 90% cell death. Typical biological studies are performed at the experimentally determined LD-50, the radiation dose at which 50% of the cells survive at 48 hours. Preliminary studies comparing HeLa cells expressing APBOC3 (experimental) vs. control group expressing the catalytically dead mutant version show a significant (p value 0.0364) lower viability in irradiated experimental samples, suggesting that not only is APOBEC3A cytotoxic, but it accelerates irradiation-mediated cell death.

Abstract Name: Authorship Via Preponderance: Integrating AI-Assisted Creative Outputs into Copyright Law

As technology evolves faster than our legal system can adapt, courts and lawmakers are increasingly forced to apply decades-old statutes to brand-new realities. Nowhere is this tension more apparent than in the realm of copyright law and artificial intelligence. Recent cases like *Thaler v. Perlmutter* — which denied copyright protection to works created entirely by AI — have set important precedents but left fundamental questions unresolved. Chief among them: how much human involvement is enough for an AI-assisted creation to qualify for copyright protection? This uncertainty exposes a critical gap in current copyright doctrine. Without a clear threshold for what constitutes “human authorship” in the age of AI, we risk both stifling innovation and undermining the core principles of copyright law. To close this gap, I propose courts and the Copyright office implement the preponderance standard: copyright protection should extend to AI-assisted

works when a human's creative contribution is both demonstrable and constitutes over 50% of the final output. Adopting this evidentiary standard preserves Thaler's case precedent, supports the structure and core principles of the Copyright Act, and harmonizes the capability of AI as a powerful tool without undermining the creative thought process. Applying the framework on Thaler's fact pattern and NICE, an AI integrated robust scheduling platform, demonstrates its ability to perform for both creative and scientific outputs, recognize responsibility, and align with other key components of the Copyright Act such as the Fair Use Doctrine. The preponderance standard gives a recognizable and predictable legal test that resolves authorship questions for AI-assisted outputs, preserving the protection of human creativity while fostering innovation.

Abstract Name: AES-256 and Naïve Bayes for Encrypted Reporting under Venezuela's Censored Telecommunications Landscape

This study evaluates whether an encrypted digital evidence library utilizing the Advanced Encryption Standard (AES) with a Naïve Bayes Classifier can pseudonymously secure reporting against censorship in Venezuela. From 1991 to 2025, Venezuela's telecommunications landscape has been regulated by the government agency CONATEL. By limiting access to open-source software such as virtual private networks, CONATEL has created barriers to unrestricted digital communication. As a secure alternative, AES, published by the National Institute of Standards and Technology (NIST), uses modular arithmetic to transform plaintext bytes, represented as polynomials, into unreadable ciphertext. The transformed data can be categorized using a Naïve Bayes Classifier to identify feature vectors into classes, with accuracy potentially improving on larger datasets. To contextualize the importance of this framework, a literature review of governmental reports from the U.S. Department of State, policy research by David Aragort, and industry data from ProtonVPN emphasizes the need for censorship-resistant systems. Practical implementations were assessed through a personal case study, in which reports were submitted to a Python program utilizing AES and Naïve Bayes classification. The results concluded that training the Naïve Bayes Classifier on more reports improved classification accuracy, highlighting the need for larger, more balanced datasets to reduce bias. Simultaneously, AES encryption served as a robust algorithm for securing reports. Future research could explore the scalability of this model and its adaptability to other machine learning classifiers, further validating its effectiveness as a framework for secure, private reporting under digital repression.

Abstract Name: Measuring rare earth content in industrial solid waste

Industrial waste streams are a domestic source of critical materials such as rare earth metals. Recovery of critical materials from waste streams is a focus of current research. Many industrial processes use holding ponds as a containment space for solid waste. These solid waste products commonly contain critical materials

that can be isolated and purified. Carbon-based waste samples from an industrial plant were collected before placement into holding ponds, and after placement in holding ponds. The waste samples were filtered to remove most of the liquid content before being placed into a drying oven to remove any remaining water content. Samples were then roasted in a muffle furnace to burn off organic material and leave behind any inorganic products such as critical materials. The roasted solids were analyzed using x-ray fluorescence to identify the elemental composition of the solids. The roasted solids were digested with concentrated nitric acid to solubilize critical materials. The nitric acid solution containing critical materials was then analyzed using ICP-OES. The ICP analysis indicates that the samples have 50-100 micrograms of light rare earth materials per gram of solid sample. This analysis was used to determine which carbon source from the industrial plant had the highest concentration of critical materials to be used to develop further recovery processes.

Abstract Name: The Right to Live (or Die)

The early twentieth century saw much debate over the legalization of euthanasia. After Progressive-era reforms attempted to legalize euthanasia, also known as physician-assisted suicide (PAS), the fear of association with the Nazi party caused support in both the UK and the US to dwindle. It wasn't until the late 20th century, when Jack "Dr. Death" Kevorkian broadcast himself lethally injecting a patient, and the Netherlands completely legalized assisted suicide, that PAS became international news again. Today, many countries around the world are considering legislation to legalize PAS, hoping to deter the use of unsafe and unapproved methods such as suicide pods. Joining these countries are most family members of the chronically ill, as well as a select group of medical professionals, who argue that PAS allows patients to die with dignity. The opposition sees a majority of countries, major religions, and doctors who argue that legalized PAS will create a suicide contagion and a slippery slope that we are unable to recover from. These arguments are explored through the eyes of Dr. Daniel Sulmasy, who suggests that the inherent value of life supersedes personal desire, and Professor David Benatar, who parallels the necessity of having the choice to die with our basic rights. These academics are paired with voices from Morrie Schwartz, a man who chose life over death, to members of the National Youth Rights Association (NYRA), an organization that enables the slippery slope by pushing to expand the medical opportunities provided to youth. While NYRA's efforts are admirable, and I believe, as Dr. Sulmasy does, that society's priority should be to sustain life, I also believe that we need to switch our way of thinking and look at how we have failed those who are forced to resort to physician-assisted suicide to alleviate their pain.

Abstract Name: Is the "Gen Z Stare" Really a Thing?: An Exploration of Facial Expressions in Service Encounters

Service marketing quality can be difficult to measure as, unlike a physical product, it is intangible. Parasuraman et al.'s (1988) seminal work found that customers perceive quality based on five dimensions:

tangibles, reliability, responsiveness, assurance, and empathy. This study focused on empathy, specifically on how customers perceive facial expressions. The recently reported phenomenon of the “Gen Z Stare” has implied that this ‘blank’ expression by younger employees in service delivery encounters has produced uncomfortable and even antagonistic responses in their customers. This research studied whether there is a generational effect among consumers in how they perceive the stare along with eight other facial expressions, including a ‘fake smile.’ Gender and service context treatments were also considered in the analysis of correlations. Significant findings include that when being serviced by an employee in any service situation, as age of the customer increased, the likelihood of appreciating a ‘fake smile’ from the employee also increased in almost all generational cohorts and gender groups of the customer, corroborating prior research findings that younger generations are less appreciative of inauthentic or ‘performative’ expressions of feelings. Another notable finding was that the only instance the fake smile demonstrated weak to no significance was with a male service employee. This finding suggests that performance expectations are uniquely gendered, reinforcing the notion that female customer service representatives are subject to certain emotional and performativity expectations, specifically in professional settings. Interestingly, there was no significant correlation for the Gen Z Stare facial expression across service context, employee or customer gender, or generation was found. Future research is recommended to corroborate this finding or examine whether experimental bias in the generalization of the expression used to measure the stare was present.

Abstract Name: A Novel Elastohydrodynamic Seal for Supercritical CO₂ Power Cycles

Supercritical carbon dioxide (sCO₂) power cycles are emerging as a leading candidate for next-generation energy systems due to their high thermal efficiency, compact turbomachinery, and potential for reducing carbon emissions. However, effective shaft sealing remains one of the most significant technical barriers to realizing the full potential of sCO₂ power generation. Leakage in sCO₂ turbomachinery can reduce overall efficiency by up to 0.65 percent, translating into substantial economic losses for utility-scale systems. These losses highlight the need for advanced sealing solutions engineered for dense-fluid, highly compressible sCO₂ environments. This research investigates an elastohydrodynamic (EHD) seal concept that passively adjusts its clearance through pressure-induced deformation to reduce leakage and improve durability. A coupled fluid–solid interaction model was developed using finite-element analysis and computational fluid dynamics to predict seal behavior under varying operating conditions. The model was validated through proof-of-concept experiments using a 2-in. static shaft seal subjected to pressures up to 1.2 MPa, with polytetrafluoroethylene (PTFE) selected as the sealing material. Simulations and benchtop experiments revealed a quadratic leakage trend: leakage increased with pressure, peaked near 6 g/s, and then decreased to about 1.5 g/s at maximum pressure. The baseline model converged in about 2 seconds, providing rapid insights into seal deformation, clearance, pressure distribution, and stress behavior, while a modified model achieved improved accuracy with convergence under 20 seconds. Complementary analytical modeling and parametric studies demonstrated how key geometric and material parameters influence leakage performance, with trends aligning well with expectations. The results indicate that EHD seals can reduce leakage by more than 50 percent compared with conventional dry gas seals. By introducing a new approach to passive leakage control, this research advances the development of cost-competitive sCO₂ technologies and supports ongoing national efforts toward high-efficiency, low-emission power systems.

Abstract Name: Pick Up Your Books and Pens: A Study of the Fluctuations of Educational Inequality in the United Kingdom, France, and Germany Using PISA Data from 2000-2022

Education is a human right, but barriers to education, such as class, racial, and gender inequalities, create an environment where educational institutions limit disadvantaged students' educational potential. In response to this barrier, the proposed study analyzes the fluctuations of educational inequality in the United Kingdom (UK), France, and Germany using the Programme for International Student Assessment (PISA) data from 2000 to 2022. As previous literature identified, educational policies differ in their impacts depending on their respective countries. Additionally, previous researchers have shifted from using educational success and attainment to measure educational inequality and have begun utilizing educational achievement levels. This exemplifies the importance of the proposed project, as PISA collects scores in mathematics, language arts, and science from 15-year-olds in all participating nations, as well as demographic, social, economic, and educational variables to provide researchers with the data to make sound conclusions about international educational inequalities. The proposed study utilizes the International Database Explorer (IDE) to compile and compare variable indices before completing an exploratory time series analysis. Results could show an overall reduction in educational inequality in terms of the differences between the mean educational achievement of the extremities of variable indices. Institutionally-reinforced inequalities should never hamper a child's education; moreover, decision-makers knowing the overall trends of inequality and the policies influencing inequality is an intrinsic step in lessening institutional impacts.

Abstract Name: Optimizing Computer Vision Tools for the Rapid and Objective Assessment of Subtle Parkinson Disease Motor Symptoms

Parkinson's disease (PD) is a common neurodegenerative disorder that can produce significant physical and mental health challenges over time. Motor symptoms of PD can include tremors, bradykinesia, rigidity and postural instability and can be difficult to quantify with precision. Standard clinical assessments, such as the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) rely heavily on clinical observation and are therefore susceptible to subjectivity. Computer vision-based assessments offer a conducive way to provide objective measurement, but these methods require further validation to ensure accuracy. In this study, 6 individuals with PD and 7 healthy older adult controls were video-recorded while completing the finger tapping task of the MDS-UPDRS. Joint coordinates were extracted from each participant's left and right hands using the open-source MediaPipe computer vision algorithm. We applied a range of Savitsky-Golay filters to the coordinate data, systematically testing filter parameters including polynomial order and frame length, to determine the most accurate filter for extracting finger tapping frequency. Preliminary analysis indicates that specific combinations of Savitsky-Golay parameters yield the highest accuracy in measuring dominant hand finger tapping for both PD participants (82.5%) and adult

controls (92.8%). The filter was less accurate in estimating finger-tapping frequency for the non-dominant hand (PD participants: 55.6%, controls: 87.1%). These early results suggest that open-source computer vision tools, paired with optimized filtering parameters, could potentially serve as effective and objective measures of assessing left and right motor severity and subtle Parkinson's Disease deficits. Continued analysis with the full dataset is underway. Future research is necessary to ensure accuracy and validate these findings across participants to assess clinical utility and implement these tools in clinical practice.

Abstract Name: Associations between Black & Latine Caregivers' Academic Socialization and Children's Academic Self-Efficacy

Caregivers instill educational and academic values through socialization practices within marginalized Black and Latine families, influencing children's academic self-efficacy. Caregivers engage in academic socialization by repeating messages about perseverance in class, the importance of education for advancement in society, and suggesting strategies to navigate racialized barriers. These socialization practices can further affect children's academic self-efficacy outcomes. While prior studies have examined academic socialization, few have focused specifically on how Black and Latine caregivers' academic practices predict the development of children's academic self-efficacy. Many caregivers encourage their children to pursue higher education. However, caregivers' academic socialization varies across families, as some may use different approaches, strategies, and messages with their children. To address gaps, the current study examined how Black and Latine caregivers' academic socialization practices influence children's academic self-efficacy. The current study included 284 Black and Latine caregivers and their children (5 to 11 years of age) from a larger ongoing study. Caregivers completed an 8-item measure of academic socialization, and their children completed a 5-item measure of academic self-efficacy. We used SPSS to conduct a linear regression to examine the relationship between caregivers' academic socialization and children's academic self-efficacy. The overall model was significant, $F(1, 261) = 12.94$, $p < .001$, $R^2 = .05$. Results indicated that caregivers' academic socialization significantly predicted children's greater academic self-efficacy, $\beta = .22$, $p < .001$. Our results suggest that caregivers' messages about academics contribute to children's beliefs about their academic abilities. Findings highlight the importance of programs that bolster parents' academic socialization efforts in order to enable children to feel efficacious in navigating academic challenges and thrive in learning environments.

Abstract Name: Online Radicalization and Perversion of Public Discourse: An Analysis of "Debate Culture" and Political Engagement in Youth

The first televised debate in the US between presidential candidates Richard Nixon and John F. Kennedy changed the way that American youth engaged in participatory politics. That first televised event, which was a civil exchange of ideas and proposals based on truth and facts has been replaced by online spectacles, exchanges of insults, and the radicalization of ideas. Political pundits, social influencers, and news agencies have since adopted argumentative programs and use social media algorithms to reinforce radical ideologies by way of deliberate confirmation bias. American youth are no exception and have become increasingly more susceptible as social media has made political engagement more readily available than ever. As youth become more engaged in online spaces, where political content is targeted to them based on their viewing habits, their own political ideology and identity has become increasingly radicalized. This loop has created a debate culture where perception is more valuable than fact and propaganda is easily accepted. The arguments put forth in this current article discuss the potential causes, implications, and impacts of how this commercialization of public debate through technological platforms has contributed to increasingly polarizing arguments and the perversion of public discourse.

Abstract Name: The Beauty of Uniquity: A Statistical and Biomechanical Analysis of Pitchers with Unique Arm Angles

In today's modern age of analytics, fans have more information than ever before about anything in the world of sport. Starting with the introduction of Statcast to Major League Baseball, the push toward analytics has reached new heights in the last decade. One such analytical addition is new metrics for pitching mechanics, specifically a comprehensive understanding of things like release point, spin, rotational axis, and arm angle. This initial study examined the factors that contributed to the success of qualified pitchers from the 2025 MLB season with unique arm angles, specifically below 30°, compared to their counterparts with a more traditional arm angle. Using public data available on BaseballSavant.com, a dataset for the study was collected that contained a variety of different factors that were believed to be indicative of pitcher success. These factors included some traditional metrics, such as handedness, velocity, and physical size, as well as new certain attributes that have recently surfaced as valuable measures of success, such as horizontal and vertical break, spin rate, and strike zone metrics. After an initial study, the research has since been expanded to other areas of pitching and biomechanical analysis. The initial study has been conducted by using linear regression and other high-level statistical analysis techniques, primarily through the open-source coding language R. The current study has the same goal, aiming to determine the factors that lead to success for pitchers, but contains a heavier focus on biomechanical and physiological factors after finding in the initial study that success cannot be measured simply by an athlete's pitch profile. It is predicted that other factors alongside arm angle will be more indicative of pitcher success, including external shoulder rotation, wrist pronation or supination, and peak braking force in the plant leg.

Abstract Name: The Math Behind Google's Page Rank Algorithm

This project investigates how mathematical principles can be translated into real-world computing by reconstructing Google's PageRank algorithm and applying it to a simulated search engine. PageRank, introduced by Larry Page and Sergey Brin in 1998, ranks webpages based on their link structure and models user behavior through Markov chains. Although commonly associated with computer science, the algorithm relies heavily on linear algebra concepts such as eigenvectors, stochastic matrices, and iterative convergence. The purpose of this research was to understand how these mathematical ideas work together to measure webpage importance and how they can be implemented programmatically. To do this, I built a six-page mini-web, constructed its hyperlink matrix, and created the Google matrix by incorporating the damping factor that simulates random page jumps. I then used Python to run the power-method iteration until the PageRank vector stabilized. The results were used to develop a small search engine prototype, MDC-Google, which ranks pages based on their long-term visit probability. Through this process, I observed how changes in the hyperlink structure affect the final ranking and how quickly the algorithm converges for small networks. This project demonstrates that mathematical modeling plays a central role in modern information retrieval and shows how undergraduate research can connect theoretical mathematics with practical software development.

Abstract Name: Examining the Influence of Obesity Assessment Techniques on Obesity Prevalence in Middle-Aged Women

Excess body fat increases the risk for serious health conditions, yet body mass index (BMI), the standard measure for classifying obesity, does not directly assess body composition. As a result, individuals with high body fat but a "normal" BMI may be misclassified, a condition known as normal weight obesity (NWO). NWO is defined as having a BMI between 18.5–24.9 kg/m² and body fat greater than 30%. Misclassification can lead to inadequate treatment and missed opportunities for early intervention. This data analysis aimed to examine the prevalence of NWO in a sample of middle-aged women. Participants included women aged 40–64 years who were weight stable for at least three months, had a BMI between 18.5–45.0 kg/m², were non-smokers, lived independently, and were able to safely undergo body composition and physical function assessments. Data were collected over two in-person visits and additional at-home tasks. At the first visit, anthropometric measures (height and weight), vital signs, questionnaires, and objective physical function assessments were completed. Body composition, including percent body fat, lean mass, and fat-free mass, was measured using dual-energy X-ray absorptiometry (DXA). Among 106 participants (mean age = 53.0 ± 6.2 years), 33 women were classified with NWO (BMI 18.5–24.9 kg/m² and body fat >30%). Fifteen women had a normal BMI and normal body fat percentage (<30%). Thirty-seven women were classified as overweight (BMI 25.0–29.9 kg/m²) and had elevated body fat, while 21 were obese (BMI ≥30.0 kg/m²) with high body fat. These results demonstrate that body composition varies widely across BMI categories and underscore the limitations of relying on BMI alone to assess obesity. Incorporating body composition assessments earlier in the lifespan may improve early detection of risk and support more individualized, effective health interventions.

Abstract Name: Magnetically Actuated Platforms for Tissue Assembly and Modeling

A 3D-printed origami-inspired magnetic scaffold was developed to explore how physical cues guide cellular proliferation in a 3D microenvironment, leveraging magnetic actuation via embedded iron oxide nanoparticles in the cellulose acetate (CA) matrix to enable precise remote folding under an external magnetic field, driving the hinge to reorient the upper face predictably while the bottom face remains fixed to the substrate. Microscale channels were fabricated, seeded with bioprinted NIH/3T3 fibroblast and/or A549 cancer cell clusters, and folded using a permanent magnet once fully confluent. Channel tapering created localized fluid shear stresses ranging from 0.1 to 1.5 dyn/cm², promoting convective nutrient transport and waste removal that enhanced cell viability (max. 40%) compared to static conditions. By adjusting channel width, adding an intermediate extracellular matrix hydrogel (IE) layer with tunable stiffness that introduces viscoelastic resistance during folding and mimics physiological tissue compliance while amplifying contact guidance cues, the scaffold delivered geometric and gravitational cues to modulate multicellular growth and interaction. This was further supported by the scaffold's tunable compressive strength (0.5 MPa at 7.5 wt% Fe₃O₄ NPs) and tensile strength (1.2 MPa at 2.5 wt% Fe₃O₄ NPs) that balanced mechanical torque opposition and structural integrity during repeated actuations. In coculture trials, fibroblast clusters proliferated within their seeded channels with matrix remodeling increasing local permeability by 25% and establishing chemotactic gradients that drive cancer cell invasion akin to tumor-stroma interactions under biomechanical forcing, thus promoting cancer cells into unseeded channel regions. This origami scaffold provides key insights for tissue engineering and cancer studies, acting as a flexible platform to study cellular interactions and proliferation dynamics, while its physics-informed design underscores the interplay of magnetic torque, hydrodynamic flow, gravitational body forces, and mechanotransduction in orchestrating 3D cellular assemblies and offering a scalable model for probing nonequilibrium growth in engineered microenvironments.

Abstract Name: The Textile Maker's Heirloom

Everyone has a sentimental item passed down from the maternal side of the family. In the IRB approved project, "The Textile Maker's Heirloom," I will be compiling a series of interviews to discuss the impact of fiber heirlooms in families and the relationship that the owners create with the object. Interviewees will be questioned about who made the item, what the item is, and their feeling towards the item. Topics of what an heirloom is, memorialization, and the socialization of women will be discussed during the presentation. These topics are analyzed through "The Material Kinship Reader: Material beyond extraction and kinship beyond the family" by Clementine Edwards and Kris Dittel. From this analysis I will also curate a collage of the textile items from interviewees to create a cohesive scene from what I gather from interviews. Oftentimes, fiber items that are used daily aren't mentioned unless prompted by a sentimental memory of the maker. This question was posed from my own experience as a fiber artist and having items from my grandmother as well

as noticing that everyone has an item from a maternal figure in their life. These items hold stories that are passed down through generations and held close to families.

Abstract Name: Fertility Rituals and Cultural Transformation: From Tenochtitlan to Present Day Mexico City

This essay investigates the transformation of fertility rituals in Mesoamerica from the pre-colonial era to the post-colonial period, specifically in Tenochtitlan and present-day Mexico City. By comparing the city's cultural practices across these two periods, this study asks how colonisation, shifting religious systems, and modern biomedical developments have reshaped cultural understandings of fertility, childbirth, and women's reproductive roles. Through utilising existing historiography, anthropology, and archaeological scholarship, this project examines a pre-colonial artwork and a post-colonial artwork as evidence of long-term continuities and transformations within reproductive symbolism. Through a combined visual and historical analysis within a comparative study to discuss how ritual meanings have changed through colonisation, the findings reveal that colonial rule and modern medicalisation altered ritual practices and legal boundaries. Still, themes of suffering, renewal, purity, and resilience persist across centuries. This observation will be further explored in relation to cultural resilience, religious assimilation, and ongoing politics of reproduction in Mexico.

Abstract Name: Famine, Art, and Authority: Art and State Power in the Irish and Chinese Famines

This essay investigates the effects of Mao's Great Famine in China and the Great Famine in Ireland through the art created during and after each of these catastrophes. Although many scholars examine each famine respectively, this study provides a comparative analysis of the two famines, their political and economic contexts, and artists' responses during and after the periods of tragedy. A brief historical survey of the circumstances leading up to, during, and after each famine examines the political, social, environmental, and economic factors that contributed to mass devastation and the long-term consequences of famine. Drawing from this overview, this essay analyzes four notable artworks: 'The Real Potato Blight of Ireland' by John Leech, 'Famine' by Rowan, 'Memorial' by Wu Yongkuan, and a propaganda poster by an unknown artist titled 'Chairman Mao', to demonstrate how artists interpreted and represented personal and collective experiences of famine. The comparative analysis asserts that both governing parties created the environment that led to famine, contradicted their extremity, and failed to provide adequate aid. As a final analysis, the artworks expose that censorship, propaganda, and state control forcibly shaped public memory and cultural narratives surrounding both famines.

Abstract Name: The Two I's of the Brooch: Identity and Intimacy

The use of a brooch has been historically utilitarian. Where does the contemporary use come into play? Contemporary jewelry primarily serves as an identity marker that can discreetly or boldly communicate a statement in intimate and public settings. For "The Two I's of the Brooch: Identity and Intimacy" I will present an overview of what brooches are used for and allow viewers to create their own brooch through social art practice. By looking at "Behind the Brooch" by Lorena Angulo and utilizing the elements of design I will be analyzing the contemporary usage of the brooch. The back of this piece of jewelry is in contact with the wearer. With no one on the outside being able to see it, there is power that comes into play. Eina Ahluwalia is an artist that crafts brooches with no information on the front with an extravagant personal quest on the back. Her choice to only detail the back of the piece amplifies her personal message. With the background knowledge of the artists in this book and participants crafting their own brooch I will gain insight on how people present themselves when prompted to make their own piece. This will give me anecdotal data on the impression brooches leave on them that I can apply to my personal art practice. Participants will be prompted to think about parts of their identity that they will want to be presented on the front and the back of the brooch. The anticipated result of this project is to get people thinking more about how they wear jewelry for adornment and to open up a discussion of what they know about brooches.

Abstract Name: Aquatic Vertebrate Model Exposure to Methiocarb Insecticide at Varied Temperatures

Anthropogenic pollutants introduced to aquatic environments pose a risk to aquatic life already challenged by rising global temperatures. The effects of the insecticide methiocarb on a modeled aquatic ecosystem were determined at three different temperatures (28.5 °C, 24 °C, and 33 °C) to further study the relationship between the dissolved pollutant and variable temperatures. Methiocarb is a carbamate insecticide that can dissolve into water, where it can interact with aquatic organisms. Zebrafish, *Danio rerio*, were used as a model system for aquatic vertebrates that could potentially be impacted by the insecticide. The model specifically focused on the early developmental stages of aquatic vertebrates, measuring the effects of being exposed 24 hours after fertilization until 72 hours post exposure. This timeframe allowed for an analysis of the stressors on multiple variables including survival, hatching rate, yolk sac size, and body length. The fish were measured lengthwise daily using images taken on a microscope, with pixel measurements calculated by virtual software. Exposure to methiocarb at concentrations of 3mg/L yielded a significant decrease in length compared to the control group (day 3 average of 3.25mg/L vs. 2.57mg/L). This demonstrated that the insecticide impairs the early stages of development of aquatic vertebrates. Cold temperature exposure resulted in significantly shorter body lengths than the higher temperatures, indicating a slowing of development. The high and low temperature groups both decreased the effect of the methiocarb treatment on total length, evidencing that temperature can influence, and in this case reduce, the harmful effects of methiocarb.

Abstract Name: Musok and Film: Korean Shamanism and its Expression Through Film

Throughout South Korea's history, Shamanism has played a major role in understanding the universe, the spirit, and the self. Korean Shamanism, also called Musok, is a deeply personal religious practice which draws on the spirit of the ancestors for protection, and requires extensive initiation to take part in. Though still prevalent in the modern day, Musok has dwindled in popularity within the shadow of modernity and organized religion. According to Korea's 2015 census, just over half of South Korea's population does not identify with any religion, with the second most prevalent belief being Protestant Christianity. Despite this reduction in religiosity, influences of Shamanism can be seen across Korea's culture to this day. While Korea takes a largely secular, rationalist stance among popular culture, there is still a strong element of magic which enlivens society and is expressed through the arts. Korean film is one medium through which the spirit of Musok tradition is displayed. Through long, tense shots, quiet landscapes, and often heavy subject matter, Korean cinema aims to paint a more realistic and complex picture of Korean life, with strong themes of domestic disputes, financial struggle, and injustice in popular films. Across genre and region, the intense and mysterious nature of Korean film works hand in hand with a ripe, ancient history of spiritual practice to create a unique environment onscreen. I argue that portrayals of Musok and ritual in Korean film exist as tools of enchantment for modern society, which functions within a hypermodernized framework. Through analysis of *Exhuma* (2024), *The Wailing* (2016), *Memories of Murder* (2003), and *Manshin: Ten Thousand Spirits* (2013), I aim to illustrate Korean film as a source of cultural enchantment in the modern age, and the ways in which film intends to portray folk magic in the country.

Abstract Name: Barometers & Brushstrokes: Reimagining Lexington's Historic Weather Records Through Art

Originating in 1849, the Smithsonian Institution supplied weather instruments across the nation and developed an extensive network operated by volunteers to record wind, temperature, atmospheric pressure, rain, and snow by hand in standardized ledgers that were telegraphed back to the Smithsonian to produce national weather maps. The U.S. National Weather Service Lexington Bureau Records, 1873–1988, at the University of Kentucky Special Collections Research Center, documented extreme floods, tornadoes, and storms that shaped the region's environmental history, and today the collection serves as both scientific artifacts and cultural reminders of Lexington's meteorological past. This collection of ledgers inspired the central question of the project, which attempts to connect environmental research and artistic expression: How can historical weather data be turned into artworks that enhance climate awareness, emotional reflection, and discourse engagement? Inspired by artists such as Natalie Miebach and Dana Montlack, whose exhibitions translate climate science into organic visual forms, this research responds to urgent cultural and ecological issues by inviting introspection, conversation, and renewal. The methodology involves visualizing original weather bureau reports through data physicalization producing 2D and 3D artworks with supplies sourced from the LEX Center for Creative Reuse, a local nonprofit that creatively upcycles art materials. The intention shaping the project is to use meteorological data and reflect it through various media to create art that implicitly visualizes climate data. This project offers viewers an engaging and philosophical experience of environmental history while aiming to expand public understanding of climate change through interdisciplinary storytelling rooted in place, memory, and resilience to spark contemporary dialogue about climate.

Abstract Name: Comparative Analysis of Single-Stage and Multi-Stage Lipid Extraction from *Chlorella vulgaris* for Biofuel Applications

The continued reliance on fossil fuels contributes significantly to climate change, yet current biofuel production methods remain inefficient and unsustainable. This urgency underscores the need for viable eco-friendly alternatives to support a sustainable future. Microalgae have emerged as a promising source for biofuel production due to their high lipid content and rapid growth in diverse environments which can allow for minimal growth competition. This study investigates the potential of *Chlorella vulgaris* as both a biofuel source and a potential agent for wastewater treatment, contributing to water purification while generating lipid-rich biomass. A key focus of this work is optimizing the lipid extraction process. The central goal is to compare the efficiency of single-stage versus multi-stage extraction methods, with lipid yields measured through gravimetric analysis. Several experimental trials were conducted under varied culture conditions and extraction parameters to determine the most effective strategy for lipid production and extraction. The results are expected to show that the multi-stage extraction method yields a higher lipid content than the single-stage process because of its improved solvent saturation control, and it allows for a more complete extraction process. Anticipated obstacles such as contamination, cultivation inefficiencies, and cost barriers are

addressed. The findings aim to provide crucial insight into scalable biofuel production systems and contribute foundational data for the future of algae-based technologies involving renewable energy. These outcomes will enable a quantitative comparison of extraction methods and highlight the practical implications for sustainable fuel development.

Abstract Name: Understanding Workload and Trust in Collaborative Human-AI (WATCH) Tasks

Human-Artificial Intelligence (AI) collaboration is rapidly expanding across domains, yet how people trust and interact with AI remains a critical research question. For the military, future operational environments will require Warfighters to interact with and adapt intelligent systems under compressed time horizons. Understanding human-AI collaboration for dynamic decision making is essential to ensure effective, responsible AI deployment enabling appropriate human workload, calibrated trust, and high system performance. A multi-modal framework offers a promising approach to predicting trust and workload by integrating subjective, behavioral, and physiological measures such as eye tracking and heart rate. We combined this multi-modal approach with a computer-based serious game where participants could play with and without an AI partner to examine how visual attention, workload and trust fluctuate in human-AI collaboration for dynamic decision making. Using the NASA-TLX survey to understand subjective workload, cognitive workload subscales suggested responses related to mental demand, temporal demand, and effort were all lower for the scenario performed with AI along with ratings of frustration. There was no difference in subjective rated physical demand or performance suggesting in both conditions, participants were able to accomplish task goals for the computer-based task. An area of interest analysis of eye movements provides an approach for understanding differences in gaze patterns across conditions, which suggested significant shifts in visual attention allocation in information areas related to AI interaction and monitoring the AI task execution. This research demonstrates that a multimodal framework for evaluating performance, trust, and workload with AI can be used to evaluate future AI tools and to develop real-time measures that allow for the bi-directional adaptation of future AI and machine systems to foster calibrated trust, maintain system performance, and balance human workload. Specifically, using eye movements allows for meaningful insights into the dynamics of human-AI collaboration.

Abstract Name: Radical Queer Subtlety: Non-Explanation, Refusal and Resistance

In 2025, the U.S. is a country wherein the rights and dignities of minoritized groups are getting stripped away at a dizzying pace. Since his inauguration, Trump has signed numerous executive orders stripping the rights of queer and trans people. Making explicitly political art is one of the only routes to enacting political change as a queer artist. However, with more and more social media platforms prohibiting explicit content, and more and more bills attempting to make all depictions of queerness “explicit” and therefore prohibited, the shape

political art takes may need to change. My project, radical queer subtlety, is based on the idea that there is room for queer art that is not immediately recognizable as queer to all audiences. “Radical queer subtlety” is a concept that reframes queer code-switching and argues for “subtlety” as a powerful tool the queer community can utilize through visual art and craft. Both José Esteban Muñoz and Jack Halberstam have argued the existence of a queer visual language, created through a shared experience of minoritized identity, and composed of spliced times and places. Julia Bryan-Wilson also noted a particular emphasis on craft within the queer aesthetic, and discussed the many queer connotations fibers arts can have. These scholars describe queer coded visuals as a product of minoritization, and while on one hand this is true, “radical queer subtlety” considers ways of recontextualizing this through the analysis of scholarly works, and through the creation of a body of artwork. These artworks encompass not only a reinterpretation of queer aesthetics, blending contemporary and historical queer symbols, fiber arts, and varying times and places, but also the ultimate goal of the project: to contribute to giving power back to the queer and trans community – an urgent effort in these times of political and social turmoil.

Abstract Name: Comparative Structural Analysis of LilSmirk Minor Tail Proteins Using Mycobacterium Bxb1

Bacteriophage tail proteins are essential for host recognition, yet many remain uncharacterized in newly isolated phages. We compared the minor tail proteins of Mycobacterium phages Bxb1 and LilSmirk using Phamerator, AlphaFold, HHpred, and ChimeraX, with Bxb1 serving as a functional and structural reference. Sequence-based tools showed little detectable similarity, but structural analyses identified several potential relationships, including a notable alignment between LilSmirk gene 33 and Bxb1 protein 9d93_8, a known tail wing brush protein. Other minor tail proteins showed weaker but potentially meaningful structural overlaps. These findings suggest conserved features that may be functionally significant, providing a foundation for improving LilSmirk’s functional annotations. Overall, structural approaches can reveal functional clues when sequence data are insufficient, supporting continued efforts to refine LilSmirk’s annotations and deepen our understanding of phage tail evolution.

Abstract Name: Structure and composition of forests in the Leon and Salado Creek Greenways

Greenways are protected natural areas within urban centers that preserve biodiversity of local flora and fauna and provide passive recreation opportunities. Leon and Salado Creeks are ephemeral streams surrounded by forest habitat located in northern San Antonio. Both greenways have unpaved and paved hiking and biking trails that receive moderate to high recreational activity and a diversity of shrubs and trees. Within two

greenways, we hypothesized there will be vegetation difference among the upper and middle slopes, and ephemeral stream within and between the greenways. We further hypothesized that a greater number of facultative and obligate wetland shrubs and trees will be documented in the ephemeral creeks. We sampled the upper slope, middle slope, and dry creek (ephemeral stream) on the east and west sides using the point-quarter method during May 2024 to August 2024, Eighteen point-quarter plots were placed in each of the 8 locations surveyed in both greenways. Based the point counts, tree and shrub mean richness, diversity, density, d.b.h., basal area, and biomass will be estimated by species. cursory observations indicate difference between the structure and composition of forests in Leon and Salado Creek Greenways. Results are currently being analyzed and will be presented at the meeting.

Abstract Name: Intersectionality and the Trad Wife Phenomenon: Understanding the Role of Race, Class, and Gender

This research project investigates the "traditional wife" or "trad wife" phenomenon, focusing on homemaking roles through the lenses of Gender, race, and class. In today's digital age, social media has a significant impact on societal norms, and this study examines how these factors influence the behaviors and attitudes of women who adopt traditional wife roles. Interviews were conducted with University of Central Oklahoma (UCO) community members, including professors from the Women's, Gender, and Sexuality Studies program, students familiar and unfamiliar with the traditional wife movement, and individuals who identify as traditional wives. The research aims to contribute to the discourse on intersectionality by expanding our understanding of the trad wife movement. The researcher draws from personal experiences in a non-traditional family structure, contrasting her grandmother's adherence to conventional marriage ideals with her own feminist values. This exploration seeks to illuminate the interplay of race, class, and Gender in shaping experiences within the trad wife movement. Additionally, the project will assess the resurgence of traditional gender norms on platforms like TikTok and Instagram and how academics and journalists interpret the role of the Trad Wife movement in perpetuating these norms. The findings aim to enhance feminist scholarship on the Trad Wife phenomenon, fostering critical discussions on its implications for contemporary society.

Abstract Name: Photophysical and Photochemical Studies of RNA as a Model for UV-Induced Damage in Nucleic Acids

Ultraviolet (UV) radiation is a well-known agent of nucleic acid damage, leading to structural and chemical modifications that affect biological function. These alterations play a crucial role in various fields, including molecular biology, medicine, and disinfection technologies. While extensive research has been conducted on UV-induced DNA damage, particularly using spectroscopic techniques such as fluorescence, circular dichroism (CD), and UV-Vis absorption spectroscopy, fewer studies have explored how RNA responds to UV exposure. Given that RNA serves as the genetic material for many viruses, understanding its photophysical

and photochemical behavior under UV irradiation is essential for advancing disinfection strategies, particularly in healthcare and environmental settings. This project aims to extend previous research by investigating UV-induced damage, photochemistry, and photophysics in RNA systems. Using fluorescence, circular dichroism (CD), and UV-Vis spectroscopy, we will analyze structural and electronic changes in RNA following UV exposure, comparing these effects to those observed in DNA. Additionally, this study will evaluate nucleic acids as potential virus mimics in UV germicidal applications, assessing their viability as surrogates for airborne and surface-disinfected pathogens. While the primary focus will be on solution-phase experiments, the research will also explore the feasibility of detecting and analyzing aerosolized nucleic acids, which could have implications for studying airborne viral transmission and optimizing UV-based air purification technologies.

Abstract Name: Acute Exercise and Episodic Memory Performance in Older Adults With Mild Cognitive Impairment

Mild cognitive impairment (MCI) is the disease state between normal cognitive function and dementia. Physical activity has been found to be beneficial for cognitive functioning in older adults, but less is known about the potential benefits of acute exercise for those with MCI. The current study examined cognitive abilities of 7 participants with MCI in sedentary and physically active states at two laboratory visits one week apart. Participants completed cognitive tests through the NIH Toolbox (i.e., the Picture Sequence Memory Test Form B) after exercise and sedentary states. The Picture Sequence Memory Test Form B was designed to assess episodic memory by asking participants to recall a series of illustrated events in a specific order on an iPad. Data collection was completed in August 2025, and data are currently being cleaned and prepared to be analyzed within the upcoming weeks. We anticipate that adults with MCI will perform better on the Picture Sequence Memory Test Form B on the days they were physically active compared to the sedentary test sessions. These findings could add to the understanding of the effects of acute exercise on cognitive performance for older adults with MCI.

Abstract Name: Building a Computing Infrastructure Digital Twin (CIDT) for Real-Time Monitoring, Log Analytics, and AI-Driven Anomaly Detection

Modern data centers generate massive amounts of telemetry and system logs that must be monitored continuously to maintain reliability, diagnose failures, and respond to emerging issues. This project presents a Computing Infrastructure Digital Twin (CIDT) designed to unify real-time telemetry, centralized log analysis, and 3D visualization into a single operational platform for a 600-machine data center. The CIDT integrates four core components: Prometheus for distributed metric collection, a PostgreSQL event store for searchable log data, NVIDIA Omniverse for interactive 3D visualization of system state, and automated alerting for anomaly detection. To explore whether small AI models can support automated log understanding within the CIDT, we evaluated nine small and small-reasoning language models (0.6–4B parameters) using 46,000 real system logs. The task involved predicting standard syslog severity levels under zero-shot, few-shot, and retrieval-augmented prompting. Qwen3 models showed the strongest performance, with Qwen3-4B reaching 95.64% accuracy when combined with retrieval. These results suggest that small language models, when paired with structured context, can provide efficient support for tasks such as severity classification, anomaly triage, and early-stage root-cause analysis. The CIDT prototype demonstrates how combining real-time data streams with lightweight AI reasoning can enhance monitoring workflows and provide clearer visibility into system behavior. As data volumes and system complexity continue to grow, this framework offers a scalable foundation for rapid diagnostics, operational insight, and informed decision-making. Future work will focus on adaptive retrieval methods, tighter integration of AI-driven alerts, and establishing a full feedback loop in which the digital twin continuously learns from system patterns and refines its recommendations over time.

Abstract Name: Formalin-induced mechanical hyperalgesia in mice

Neuropathic pain (NP) is a chronic condition that plagues many individuals and that is associated with diseases and trauma such as multiple sclerosis, diabetes and spinal cord injury. Currently, a few animal models are available for the study NP and involve extensive survival surgeries: spinal nerve ligation (SNL) and chronic constriction injury (CCI). Formalin is a well-known noxious stimulus that induces skin sensitization and inflammation, which typically resolves within a few hours. Therefore, formalin test is commonly used for the study of inflammatory and nociceptive pain in rodents. A recent study has shown that rats receiving a formalin injection developed hypersensitivity and spinal changes comparable to those observed following CCI and SNL but never developed and adapted in mice. In light of this and given the enormous contribution that the use of mice over rats could offer in research, we aimed to develop a novel animal model for the study of NP in mice. In our study, mice were injected with 20µl of 5% formalin in the dorsal right hind-paw and analyzed over the course of two weeks, to assess thermal pain using the Hargreaves test on days post-injection (DPI) 3, 7, 10, and 14. Formalin injected mice were found to have significantly lower pain thresholds on DPI 10 compared to vehicle-injected mice. Our study has proven that the subcutaneous, single injection of formalin is sufficient to cause sustained thermal hyperalgesia in mice. Further studies will investigate the molecular and cellular alterations in the spinal cord and brain of the formalin-treated mice.

Abstract Name: From Panic to Adaptation: A Mixed-Method Analysis of University Faculty Perspectives on AI

The rapid emergence of generative AI tools, particularly following ChatGPT's November 2022 launch, has sparked intense debate within higher education about academic integrity, pedagogical innovation, and teaching practices. This study investigates how university faculty attitudes toward artificial intelligence evolved from 2020 to 2025, capturing perspectives both before and after widespread AI adoption. Using a mixed-methods approach, we analyzed 3,866 posts from eight academic subreddit communities to identify temporal patterns, thematic concerns, and sentiment variations regarding AI in academia. Our methodology combined computational and qualitative techniques. We collected AI-related discussions using Python and the Reddit API, then conducted sentiment analysis to classify posts by emotional valence. To ensure methodological rigor, we hand-coded 70 posts using a 19-category coding scheme developed through iterative refinement. Categories included AI-generated work detection, academic integrity concerns, pedagogical strategies, course redesign, faculty burnout, and AI benefits. We analyzed highly-engaged posts (top 20 positive and negative by upvotes) alongside a random sample to capture both prominent and representative perspectives. Findings reveal dramatic shifts in faculty discourse following ChatGPT's release. Discussion volume increased 485% (from 16 to 95 posts monthly), with 2023 showing 184% more posts than 2022. Academic integrity concerns dominate, appearing in 33% of all posts and 45% of highly-negative posts, though declining from 51% in 2020 to 23% in 2025, suggesting adaptation. Qualitative coding revealed complex attitudes: academic integrity appeared equally in positive (43.5%) and negative (40%) high-engagement posts, indicating nuanced perspectives rather than polarization. Positive posts discussed teaching strategies and course redesign, while 30% of negative posts reflected faculty burnout. Overall, 49% of posts discuss pedagogical approaches, indicating growing constructive engagement with AI integration. These findings provide empirical evidence of faculty perspectives during technological transition, offering institutions data-driven insights for developing evidence-based policies and professional development addressing both concerns and opportunities.

Abstract Name: Evaluation of the association between GLP-1 receptor agonists and perioperative outcomes

Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are increasingly prescribed for Type 2 Diabetes Mellitus, obesity, and metabolic syndrome. While these agents improve glycemic control, cardiovascular health, and postoperative outcomes, their use in surgical patients raises concerns regarding delayed gastric motility and aspiration risk. Current literature presents conflicting data, with no definitive link established between GLP-1 RA use and elevated residual gastric contents or aspiration. This study evaluated the association between GLP-1 RA exposure and perioperative outcomes using the TriNetX global research

network. Adult surgical patients undergoing anesthesia or sedation were categorized into GLP-1 RA user and non-user cohorts. Patients with pre-existing gastrointestinal motility disorders unrelated to GLP-1 RAs were excluded. Propensity score matching was utilized to compare outcomes, including aspiration risk, delayed gastric emptying, hypoglycemia, mortality, and length of hospital stay. Post-matching analysis revealed no significant association between GLP-1 RA use and adverse perioperative outcomes. The lack of correlation between GLP-1 RA use and perioperative complications challenges the necessity of strict cessation guidelines. However, given the varying evidence base, further research is required to clarify risks and standardize anesthesia protocols for these patients.

Abstract Name: Russian Nationalism and Orientalism Demonstrated in Rimsky-Korsakov's "Scheherazade"

In the 19th century, during the age of Romanticism, Europe became fascinated with the mysteriousness and exoticism of Asian cultures. Many European composers wanted to incorporate this newfound fascination into their works by using stereotypical musical conventions to imitate or depict the Eastern world. These depictions of Asian cultures were rarely accurate and often caricatured. Russia was no exception to this trend, but it clearly differentiated from the other Western European countries when executing orientalism. This is because of Russia's geographical proximity to Asian countries, thus influencing and exposing them to the different cultures. Many Russian composers such as Miliy Balakirev spent time on the Southern borders of Russia for inspiration. From this, the five composers that defined the "Russian sound", known as the Kuchka, relied on the findings of their leader Balakirev and others to develop (often inaccurate) "oriental" conventions. Nikolai Rimsky-Korsakov, probably the most famous out of the Kuchka, is notably representative of the Russian music sound and Russian orientalism. His largest orchestral work, *Scheherazade*, drew inspiration from *The One Thousand and One Nights*, a collection of Middle Eastern and Indian stories. Currently, existing analyses of musical orientalism in Rimsky-Korsakov's *Scheherazade* exclusively discuss his use of Middle Eastern affiliated tunes. This raises the question: is musical orientalism only using preexisting melodies as a model or is it part of a more general system of musical conventions? In order to define *Scheherazade* as an example of Russian orientalism, I first identified orientalist conventions commonly used by the Kuchka. I then analyzed the work's score and identified any of the faux Asian conventions described by previous scholars. After analyzing all of his *Scheherazade*, I found that Rimsky-Korsakov's representations of musical orientalism extended beyond the use of preexisting melodies and featured a broader set of Middle Eastern affiliated musical idioms.

Abstract Name: Concentration Analysis on Angiogram Contrast Agents Infused in Polycaprolactone for Development of Flow-Diverting Stents

Bioresorbable polymers are becoming increasingly more popular in the development of medical devices that can perform well and are not permanent. However, polymers do not reflect X-Rays and are invisible under

angiogram as a result. In using polymers for medical devices due to their wonderful material properties, it is important that they are completely visible under X-Ray and angiogram in the body for safety and observational purposes. Polycaprolactone is mixed with three angiogram contrast agents (barium sulfate, bismuth trioxide, and tantalum pentoxide) to create an angiogram-visible 3D printer filament using the Filabot EX2 filament manufacturing machine. Three concentrations (33%, 25%, and 20% by mass of the angiogram contrast agent) were developed for each respective contrast agent and luminosity under X-Ray was analyzed using images captured on the Vector MaxRay camera. The luminosity was analyzed using a grayscale value on ImageJ after taking X-Ray images. The three contrast agents with their differing concentrations of PCL showed a direct correlation in their visibility under X-Rays and the concentration of the contrast agent. As the concentration of the radiopaque contrast agent increases, so does its visibility and luminosity under X-Ray. Using angiogram contrast agents is an effective way to make polymers, such as polycaprolactone, visible under angiogram and ensure that the developed medical devices remain visible and are able to be studied and observed in vivo.

Abstract Name: More than a Mural: Sustainability in Community Engaged Art

The South End of Albany has been divested from for generations, and students have not been empowered to be changemakers in their own community. Nevertheless, the people of the South End are resilient and have a strong sense of community, and we have tapped into their energy across two community engaged projects. Through partnerships with the Nonprofit Excellence and Transformation Fellowship at Siena University, we have worked to create public art projects based on the ideals of placemaking, reclaiming space, and generational wealth building. After partnering with the Community Investment Trust (CIT) over the last year, we successfully painted a mural on the second floor of the building. Throughout the partnership, we prioritized community engagement best practices, which led to a mutually beneficial and collaborative final project. The mural was so well received, and the relationships we built were so genuine, that the Capital Region BOCES reached out to us to paint a mural in their space in the same building, deepening our impact in the South End. Drawing on feedback from the students, staff, and teachers at Capital Region BOCES, we have created a plan to beautify the fourth floor with a mural reflecting both the community's and students' interests. Our work illuminates how community-engaged projects that leverage community assets can support community well-being in the neighborhood. By working alongside the Capital Region BOCES students and teachers, we will co-create a mural that is uplifting, motivational, and empowers students to do whatever their heart chooses with the education they receive in that space. The project's outcomes have been deeper and more meaningful than just paint on the wall because our approach to community engagement relies heavily on relationship-building, incorporating feedback, and sustainable university-community partnerships, which leverages the community as co-creators rather than merely recipients of a service.

Abstract Name: Examining Loneliness and Resilience in Children of Divorce

This study examines the relationship between parental divorce and self-reported levels of resilience and loneliness among individuals who experienced parental divorce, as well as the potential association between the timing of divorce and loneliness and resilience outcomes. Previous literature suggested a relationship between parental divorce and both loneliness and resilience (although conflicting literature exists regarding the latter) as well as a possible association between divorce timing and later-life outcomes. Based upon the literature, it was hypothesized that both resilience and loneliness scores will be higher in individuals from divorced families than in individuals from intact families. Secondly, it was hypothesized that there would be a correlation between levels of both resilience and loneliness in individuals from divorced families and the age of the individuals when their parents divorced. To test these hypotheses, the Brief Resilience Scale (BRS) and the Revised UCLA Loneliness Scale (R-UCLA-Loneliness Scale) were administered to 196 undergraduate students following IRB approval and the informed consent of each participant. It was found that resilience and loneliness scores were not significantly higher in individuals from divorced families than in individuals from intact families. Also, it was found that resilience and loneliness scores in individuals from divorced families and the age of the individuals when their parents divorced were uncorrelated. Limitations included the homogeneity and limited size of the sample. These findings may support future research on the effects of divorce and assist mental health care providers and children and family professionals in narrowing down long-term risk factors for children of divorce.

Abstract Name: P5score: Breaking the Barriers of Code and Choreography

This documentary is a deep dive into the world of p5.score — a creative coding project developed by media choreographer Kate Sicchio. Using the p5.js coding library, p5.score is a way for choreographers to visualize and interpret their art through complex coding and iconography. The documentary follows a two-day workshop led by Sicchio in which participants use p5.score to generate visual scores. Through collaboration and experimentation, participants push the boundaries of how technology and choreography interact, creating immersive performances that explored the intersection between the human body and code.

Abstract Name: Cross-cultural Research on Body Image and Life Satisfaction in the U.S and Egypt

Luke MattoxCo-authors: Dr. Safia Fathelbab (Suez University, Egypt) and Dr. Sherri Pataki12-04-2025NCUR Abstract Cross-cultural Research on Body image and Life Satisfaction in the U.S. and EgyptThis research examined the relationship between body image and life satisfaction between male and female undergraduates in Egypt (N=100) and the United States (N=91). All participants completed The Satisfaction with Life Scale (Diener, Emmons, Larsen, & Griffin, 1985) and the Objectified Body Self-

consciousness Scale (Mekinely & Hyde, 1996) using an Arabic translation of each measure for participants in Egypt. Based on gender-based norms related to the importance of being physically attractive, we predicted women in both the U.S. and Egypt would experience greater self-consciousness about their body image than men. We also predicted that body image concerns would be more pronounced among American women than Egyptian women because of sociocultural norms emphasizing women's appearance in the U.S. versus the emphasis on conservative dress and modesty in Egypt (Rahman & Rahman, 2023). In both countries, we predicted that body image concerns would be related to lower life satisfaction, particularly for men where appearance concerns may be seen as less normative. In analyzing participant responses on the Objectified Body Self-Consciousness Scale, we will also explore the different components of self-consciousness including feelings of personal shame about one's body, body surveillance, and perceived control over one's body.

Abstract Name: Comparing Kanji Learning Methods for Beginning Japanese Students

This mentor-led presentation describes the development and supervision of an undergraduate research project that examines how beginning Japanese language learners acquire kanji through four different learning strategies. The project grew out of students' curiosity about why certain study methods feel more effective than others, and how to measure those differences in a systematic way. In response, I worked with three undergraduate researchers to design an experiment that could be carried out within an actual language classroom while still producing meaningful, interpretable results. The study will take place in the second-semester of the elementary Japanese language class during spring term, with approximately twenty volunteer participants. Each student will cycle through four kanji-learning methods, spaced repetition, handwriting practice, mnemonic-based study, and short reading-based acquisition, over an eight-week period (two weeks per method). For each cycle, students will follow a structured weekly learning plan and complete short self-assessments measuring retention, speed of recall, and perceived difficulty. This design allows the student-research team to compare the effectiveness of the methods both across the cohort and within individual learners. My presentation will focus on how the project was conceptualized, how students were trained in research design and data collection, and how we balanced methodological rigor with the realities of introductory language instruction. I will also discuss how this project supports the broader goals of undergraduate research: fostering intellectual curiosity, building confidence in empirical inquiry, and helping students transform classroom questions into collaborative scholarship. The presentation aims to offer other mentors a practical model for guiding discipline-specific research that is accessible, scalable, and deeply engaging for students.

Abstract Name: Reconsidering the Safety of Distance in Daniele Evans' The Office of Historical Corrections

In today's sociopolitical climate there is tension around every corner, and oftentimes it feels like the safest place to be is far away. In the college classroom, for example, it's often easier for Americans to discuss social or political controversies that aren't connected to our own history or culture. Daniele Evans' novella from 2020, *The Office of Historical Corrections*, follows Cassie Jacobs, a stalwart employee for the fictional Institute of Public History, a civil department dedicated to correcting historical misinformation. Cassie is a black woman, and this story follows the complications in her journey to root out racism in the small, fictional Wisconsin town of Cherry Mill. Cassie is sent to this town by IPH because her oldest friend and rival, Genevieve, corrected a plaque by inserting the names of the white people responsible for setting fire to the home of a black man, Josiah Wynslow, who ostensibly died in the fire. The two old friends ultimately don't agree on the correction, even though Cassie acknowledges that there is some moral rightness in naming those responsible. Tensions continue to rise when the historical marker is vandalized by a supremacist, the novel's villain, White Justice. Ultimately, the interpersonal struggles Cassie faces, such as when she cheats on her black boyfriend Daniel with a white man named Nick, and when she alternately clashes and bonds with Genevieve, feel just as important as the historical justice Cassie pursues through her role as IPH. Including this novella on a university syllabus and examining how racial prejudice affects our closest relationships might just help more people realize the safety that distance appears to provide is only an illusion.

Abstract Name: The Effects of News Media Sentiment on Investor Risk Tolerance

Previous studies have shown that media plays a significant role in shaping individuals' behaviors. This thesis examines the response of investor risk tolerance to positive or negative news media sentiment. Investor risk tolerance is the level of potential loss an investor is willing to accept. It is proxied by stock volume, weights, volatility, and prices. The existing literature suggests that several cognitive biases induce costly investment behaviors in a way that investors deviate from Modern Portfolio Theory, which is a mathematical framework for selecting investments in order to maximize their overall returns with an acceptable level of risk. Previous research has also established that stocks with no media coverage earn higher returns than stocks with high media coverage and that a negative mood reduces the demand for risky assets. I build on this by analyzing individual investor choices in the context of news sentiment at the firm level. I use dynamic ordinary least squares regressions combined with Bloomberg news sentiment data and data from the Securities and Exchange Commission's Electronic Data Gathering, Analysis, and Retrieval (EDGAR) filings. These filings are documents submitted by companies, corporate insiders, and blockholders. Blockholders are those who own a significant amount of a company's shares, and are required to submit an EDGAR filing when their ownership reaches 5%. These filings give shareholder-level portfolio composition data for insiders, fund managers, and other large investors. I expect that investors being exposed to positive or negative news media causes an increased or decreased risk tolerance, respectively. Gaining insight into this topic allows investors to become aware of how behavioral economics impacts how they invest, allowing them to overcome emotional investing choices and instead rationally optimize their portfolios.

Abstract Name: RadAround: A Field-Expedient Direction Finder for Contested IoT Sensing & EM Situational Awareness

This paper presents RadAround, a passive 2-D direction-finding system designed for adversarial IoT sensing in contested environments. Using mechanically steered narrowbeam antennas and field-deployable SCADA software, it generates high-resolution electromagnetic (EM) heatmaps using low-cost COTS or 3D-printed components. The microcontroller-deployable SCADA coordinates antenna positioning and SDR sampling in real time for resilient, on-site operation. Its modular design enables rapid adaptation for applications such as EMC testing in disaster-response deployments, battlefield spectrum monitoring, electronic intrusion detection, and tactical EM situational awareness (EMSA). Experiments show RadAround detecting computing machinery through walls, assessing utilization, and pinpointing EM interference (EMI) leakage sources from Faraday enclosures.

Abstract Name: Optimizing Accuracy of AI-ML Models for Three Major Heart Conditions by Evaluating Data Split Ratios.

Heart failure is one of the leading causes of death in the world. With this in mind, we have conducted a study on the three primary heart conditions (heart disease, heart attack, and heart failure). Our hypothesis is that AI-Machine-learning models may be used to reveal the sequential progression of these three conditions. To validate this hypothesis, we conducted an experiment using IBM Watson's AutoAI tool in order to find out which algorithm can best detect the linking factors between the three major conditions, as well as predict whether the condition is present or not with a high accuracy. All three models provided ranked pipelines of algorithms used, as well as displayed all of the enhancements. The models were able to achieve accuracies of 85.6%, 86%, and 88.3% for heart disease, heart attack, and heart failure respectively. Chest pain type, chest pain, and cholesterol were the highest ranked diagnostic factors for determining the presence of the three conditions. We confirmed these results with a medical doctor, and established that there is indeed a link between these heart conditions, and proper early diagnosis is essential for saving patients' lives. In this research we will explore deeper into the machine learning models and try to optimize their accuracies by using different data split ratios, which is the ratio between the data being used to train the model, versus the data being used to test the model. This research will focus on optimizing data split ratios for the highest possible accuracy, as well as how this can scale to larger sized datasets similar to the ones hospitals will use. We will also provide the exact details for all other elements for the most optimized model, including algorithm type, enhancements, and build times.

Abstract Name: Examining How PTSD and Depression Mediate the Association Between Cumulative Trauma and Cognitive Functioning

Background: Trauma exposure is a public health concern with significant psychological and economic consequences¹. Exposure to trauma is associated with an increased risk of developing mental health disorders such as posttraumatic stress disorder (PTSD) and depression, which often occur both independently and comorbidly². In addition to these psychological outcomes, lifetime trauma exposure has been linked to impairments in cognitive functioning, particularly in executive functioning and episodic memory³. Notably, both PTSD and depression have been consistently associated with cognitive deficits, including difficulties in executive function, processing speed, and memory^{4,5}. Methods: 125 female participants completed 7 data collections over 26 years. Participants were 24 years old at psychopathology assessments and 37 at cognitive assessments. Lifetime trauma was assessed using the Comprehensive Trauma Interview (CTI)⁶. PTSD symptoms were assessed using the PTSD subscale of the CTI⁷. Depressive symptoms were assessed based on the Beck Depression Inventory⁸. Working memory was assessed using the Counting Span Task⁹. Processing speed was assessed using the Symbol Search Speed Task of the Wechsler Adult Intelligence Scale¹⁰. Results: The final model exhibited adequate fit ($\chi^2(5) = 9.45$, $p = .092$; RMSEA = .084, 90% CI [.00, .166]; CFI = .918; SRMR = .058). Lifetime trauma predicted higher depressive ($\beta = .37$, $p < .001$) and PTSD symptoms ($\beta = .38$, $p < .001$). In turn, depressive symptoms significantly predicted poorer working memory ($\beta = -.21$, $p = .009$) and processing speed ($\beta = .19$, $p = .049$), whereas PTSD did not ($p > .342$). Depression significantly mediated effects of trauma on working memory ($\beta = -.08$, $p = .034$) and marginally mediated effects on processing speed ($\beta = .07$, $p = .067$). Discussion: The results from the study indicate that depression symptoms rather than PTSD symptoms mediate the cognitive deficits associated with lifetime trauma. These findings can inform the importance of Cognitive Behavioral Therapy for Depression (CBT-D) for trauma exposed individuals and how it can buffer the link between lifetime trauma and cognitive deficits.

Abstract Name: Bacterial Microbiome Diversity Within Vineyard Groundwater

The application of fertilizers and pesticides on farms can have impact on ecosystems by changing soil and water chemistry. Many studies have focused on the impact of runoff from farm fields on surface watersheds, but farm applications can also modify sediment and ground water sources particularly thorough alteration of microbial communities. The objective of this study is to observe the microbiomes of six wells located on the Lake Erie Regional Grape Research and Extension Center vineyards to create an overall view of the groundwater composition during the summer season (June-August). Six wells from across the property were sampled from once every month (June 16th, July 17th, and Aug. 13th). Sediment was separated from the groundwater, both being used for DNA extraction, for a total of 36 samples. Bacterial 16S region V4 was amplified in 34 of the samples using PCR. Amplicons were sent to Novogene for Illumina sequencing. Preliminary sequencing data has shown the presence of bacterial communities within the groundwater and variation between the wells. This study looks at the diversity of groundwater and sediment-based microbial

life at a working vineyard. Changes to bacterial colonies will be compared between well locations and times they were sampled. Taxonomic analysis will be performed to assess specific diversity within each individual well.

Abstract Name: Heavy Metal Impacts on the Freshwater Clam Species *Corbicula fluminea*

Heavy metals play essential ecological and biological roles when present in trace concentrations, but have the ability to become highly toxic when present in excess. This poses significant risks to ecosystems, organisms, and human health. Anthropogenic activities, such as mining, wastewater discharge, and fossil fuel combustion, have exponentially increased heavy metal inputs into freshwater systems at a rate much greater than ecosystems are equipped to handle. The chemical properties of heavy metals, like their low degradability, facilitate bioaccumulation through food webs. Coal ash, which is a common by-product of coal-powered energy production, acts as a major source of heavy metals such as arsenic, chromium, mercury, and lead. Mountain Island Lake, NC, a hub for biodiversity and a critical drinking water reservoir, has been historically impacted by coal ash storage and disposal, raising concerns about the long-term ecological and public health implications of heavy metal contamination in the ecosystem. This project expands upon prior research that examined metal accumulation in the freshwater clam *Corbicula fluminea*, a sensitive bioindicator species. Clam tissue and sediment samples collected upstream, downstream, and adjacent to the coal ash basin sites will be analyzed using ICP-MS to quantify a much broader suite of heavy metal concentrations than previously available in the prior research. Metal concentrations will be statistically compared across sites and correlated with previously measured sub-lethal cellular toxicity assays to evaluate organismal stress responses and cell health. This study provides a comprehensive assessment of coal ash-derived heavy metal pollution and its ecological consequences. The findings of this work will contribute to improved biomonitoring methods and techniques, inform ecological management strategies, and further broaden efforts in the mitigation of heavy metal contamination in freshwater ecosystems.

Abstract Name: From Illness to Involvement: a Collaboration to Increase Student Engagement, Health Knowledge, and Success

Introduction: Illness-related absences are a significant barrier to success among college students. For example, in a national survey, over 50% of students reporting influenza (flu) infection also reported negative impacts on academic performance. Vaccination is an important tool to reduce common infectious illnesses like the flu. Our data shows a significant drop in first-year student vaccination compared to pre-college rates. As students transition to independent medical decision-making, they may experience barriers to vaccination, including cost, access, and questions about vaccine safety and infection severity. Our project described the effectiveness of a collaborative effort engaging first-semester college students, Undergraduate Research

Students (URS), faculty, and campus administrative units to promote student vaccination. Methods: First-semester students in a Course-Based Undergraduate Research Experience developed evidence-based public health messages promoting flu vaccination on campus. Campus wellness staff shared these messages via social media (Instagram) and print media posted in campus residential halls containing trackable QR codes directing students to additional flu-related information. Social media reach and QR code use were then analyzed by URS. Results: Social media messaging reached over 400 users. Print media potentially reached 3000+ residents, and QR codes were accessed by 25 students. An upcoming survey will describe first-year students' interest in pursuing further undergraduate research opportunities. Discussion: While it is difficult to determine precisely how many students were reached, prior evidence has shown that campaigns such as this one have improved vaccination rates. This pilot project leveraged existing resources across campus, including students and staff from several campus divisions, and demonstrated a novel faculty-student partnership approach to share information that supports student vaccine decision-making. The collaborations developed can increase the effectiveness of future outreach.

Abstract Name: Administration of Intracerebral Oxytocin and its Effect on Social Motivation in C57BL/6J Mice

How does the localized administration of oxytocin to the nucleus accumbens of C57BL/6J mice modulate peer-to-peer social motivation? Low social motivation is a characteristic symptom of autism spectrum disorder (ASD). Oxytocin has been proposed as a possible treatment for the social deficits observed in ASD. Yet, clinical trials involving oxytocin produce varied results which suggest context-dependent effects of oxytocin. Utilizing novel behavioral assays designed to measure social motivation, we plan to determine how oxytocin affects rates of peer-to-peer sociability in both high effort interactions and low effort interactions. In order to investigate this effect, we implanted guide cannulas into the nucleus accumbens of C57BL/6J mice. The mice were administered an infusion of either oxytocin or phosphate buffered saline (PBS) and then underwent behavioral testing. Our past research has shown that mice receiving an intranasal administration of oxytocin will exhibit an increased social motivation in a low effort context. However, when high effort is needed, social motivation decreases. We hypothesize that the administration of oxytocin to the nucleus accumbens will result in a similar effect, in which high effort context reduces social motivation and low effort context increases social motivation. Preliminary results suggest that social motivation is decreasing after the oxytocin administration to the nucleus accumbens. These findings support previous research findings in which oxytocin acts to decrease social motivation in peer-to-peer interactions.

Abstract Name: Long-Term Growth Dynamics of Naturally Regenerated Loblolly Pine (*Pinus taeda* L.) Stands in the Western Gulf Coast

Loblolly pine (*Pinus taeda* L.) is one of the most important timber species in the southeastern United States, yet plantation establishment remains the dominant management practice across the region. Natural regeneration can reduce planting costs, preserve genetic diversity, and support long-term sustainability, but it is used less frequently than artificial regeneration. This study examined the long-term growth patterns of naturally regenerated loblolly pine at the Crossett Experimental Forest in Arkansas. Two clearcutting approaches, block clearcutting and strip clearcutting, were implemented in five acre units between 1980 and 1995. Harvests occurred in five year intervals, and stand measurements were collected in June of 2025. These data were used to evaluate the influence of clearcutting method and stand age on growth. Mean diameter at breast height, trees per acre, and basal area were analyzed through one way ANOVA to test age effects, and F tests were used to compare the two regeneration methods. The results showed no significant differences between block and strip clearcutting (p greater than 0.05), which indicates that both approaches support successful natural regeneration under similar site conditions. In contrast, stand age had a significant effect on growth (p less than 0.05). Mean diameter increased with age, while trees per acre and basal area decreased. These patterns reflect density dependent mortality and natural self thinning processes that are typical of even aged loblolly pine stands. The overall trends demonstrate that naturally regenerated loblolly pine can maintain strong stand development throughout early and mid rotation ages. This provides landowners with opportunities for moderate and recurring income, especially in areas located near pulpwood markets. The findings also offer long-term evidence that natural regeneration is a practical and cost effective alternative to plantation establishment in southern pine management. Key words: natural loblolly pine; long term; growth dynamics; ANOVA

Abstract Name: Growing Minds: A 7-Week Intervention to Enhance Children's Metacognitive Skills

This project integrates a literature-based analysis with applied program design to explore how growth-mindset interventions can support children's metacognitive awareness and self-regulation in educational settings. Grounded in Carol Dweck's growth-mindset theory, which emphasizes that intelligence and ability can be developed through effort, reflection, and effective strategy use, the project synthesizes research identifying key components of successful mindset instruction. Studies consistently show that fostering a growth mindset enhances motivation, persistence, and metacognitive reflection, though long-term change depends on the structure and context of implementation. Building on these insights, a seven-week growth-mindset curriculum was created for upper-elementary students in a community-based learning environment. Weekly lessons targeted core themes such as goal setting, overcoming challenges, using feedback, and viewing effort as a path to mastery through interactive discussions and hands-on activities. To support future evaluation, a survey was designed to measure participants' mindset orientation, metacognitive awareness, and self-regulatory behaviors, though it has not yet been administered. By aligning the program's structure with evidence-based practices, this project demonstrates how theoretical principles from developmental and educational psychology can guide interventions that foster resilience, motivation, and positive self-beliefs. Overall, it bridges theory and practice by illustrating how literature on growth mindset and metacognition can inform real-world educational programming and highlight directions for future research and refinement.

Abstract Name: Provenance and Protocol: A Study of the De la Burde African Art in the Radford University Art Museum Permanent Collection

Museum collections often house many artifacts that have no discernable history or information that connect to their place of origin. This in turn makes it difficult to display these pieces due to not being able to fit them with a narrative to show the viewer. This research aims to determine the best course of action when confronted with this problem and to demonstrate the importance of acknowledging the background of these artworks and antiquities. The focus of this research is a collection of Colonial Era African artwork that is currently housed in the Radford University Art Museum Permanent Collection which will be used as a case study in order to reach the conclusion to this research inquiry. These works were all produced sometime during the 19th to 20th Centuries and were donated to the museum in 1992. Determining provenance, or the history of ownership, of pieces is of the utmost importance for museum collections in order to properly present the pieces in the correct context, and if necessary, return them to their place of origin. Research has been conducted on how museums should react when faced with pieces that may have been stolen or looted, as well as the importance of due diligence in the art market. However, there is little consensus on the right course of action, and it is difficult to determine provenance from pieces that were in private collections prior to being donated to museums. That is what this research seeks to address, a more direct approach to provenance research and accountability by museums on their collections. By using existing documentation on collections records and firsthand interaction with the collection at RUAM to provide a comprehensive history of the collection and a proposal for how to document acquisitions going forward.

Abstract Name: Interneuron Development in an Animal Model of Bipolar Disorder

Bipolar disorder (BD), a neuropsychological disorder featuring cyclical periods of depressive and manic behaviors. The Chase lab aims to establish the face validity of a novel animal model for BD by assessing its behavioral and morphological traits. So we can better understand the pathophysiology of the disorder, others have shown that BD results in a decrease in interneurons within the prefrontal cortex and hippocampus. We are currently using immunocytochemistry to measure the number of parvalbumin (PV) and somatostatin (SST) interneurons in the hippocampus and prefrontal cortex in our animal model relative to controls. Preliminary results suggest that HCA leads to an increase in PV interneurons in the dentate gyrus of the hippocampus in male rats, while decreasing PV interneurons in the same region in female rats. Similar findings were also observed in the subiculum and the CA2/3 region of the hippocampus. These findings are particularly intriguing given that male rats exhibit more manic behaviors in this animal model while female rats exhibit more depressive behaviors. We are currently assessing whether HCA also leads to changes in PV interneurons in the prefrontal cortex as well as SST neurons in the hippocampus and prefrontal cortex. Ultimately, this study will allow us to determine whether HCA-induced shifts in manic/depressive behaviors

are associated with changes in the distribution of PV and SST GABAergic interneurons in subregions of the hippocampus and prefrontal cortex.

Abstract Name: A Comparative Analysis of Green-Synthesized and Chemically Synthesized Silver Nanoparticles: Preparation Methods and Antimicrobial Potential

There is an increasing use of silver nanoparticles (AgNPs) in the medical and industrial fields. However, with an increase in potential applications, the antimicrobial effects of AgNPs on bacteria have sparked interest. Thus, by comparing how commonly found bacteria are affected by the type of synthesis, size and concentration of AgNPs, information can be gathered for future clinical use. This study investigates the impact of two distinct synthesis approaches, chemical and green, on the resulting AgNP characteristics and their subsequent antimicrobial action against a common bacterium. Chemical synthesis of AgNPs employed trisodium citrate as the stabilizing agent and sodium borohydride (NaBH₄) as the reducing agent. For the green synthesis, inner gel extract from Aloe vera leaves was utilized, with the gel's major bioactive components acting as both reducing and stabilizing agents. The characterization of the formed AgNPs was performed from the spectral analysis of UV-Visible spectrophotometer. Visible observation of color change and UV-Vis absorbance at 442 nm confirmed the formation of AgNPs. Spectral analysis confirmed the synthesized AgNPs maintained stability for up to two months. Antimicrobial effects of the synthesized AgNPs were determined against *Escherichia coli*. Bacterial cultures were exposed to AgNPs synthesized by both methods at various concentrations using disk-diffusion assay. Chemically synthesized 100 nm AgNPs exhibited a 0.6 cm zone of inhibition against *E. coli* at minimum inhibitory concentration of 500 µg mL⁻¹. Green-synthesized AgNPs created a zone of inhibition of 0.4 cm at minimum inhibitory concentration of 3500 µg mL⁻¹. According to these preliminary results chemically synthesized AgNPs demonstrated more antimicrobial efficacy towards *E. coli* than green synthesized AgNPs. In future studies the synthesized AgNPs will be characterized using DLS and XRD and the project will be expanded to test other microbial species.

Abstract Name: Street Art, Street Artists, and Public Art in Houston and Their Relation to the People and Law

Throughout the history of the public art in Houston, Texas, artists have used their art to express support and fight for change. From large pieces on the sides of buildings to graffiti on bridges above large roads, these artists have used many different methods to get their points across. This paper is an exploration of graffiti, murals, notable artists, and other sources public art and how they have transformed Houston's urban landscape. Street artists draw inspiration from places all around the world and have helped in spreading many different cultures through the city. This paper also talks about more formal ways to view art in Houston, like free to view collections, museums, and other buildings. Forty-three sources are referenced in this paper with

a focus on government websites, news reports, magazines, artists' websites, and interviews. In person research was also conducted by going around to view much of the art and places mentioned in this paper. I also experienced some of the events talked about in this paper first hand and have gotten to see how artists have helped to raise awareness and inspire hope around different situations. Part of my goal for this paper is to draw more attention to all the art around Houston and how it has followed Houstonians throughout the city and its history. Street art is a way to see the ideas of different kinds people in contrast or similarity to what the government promotes or allows. I took that into consideration when researching and made sure to feature both government promoted projects and those that have been removed by them as well.

Abstract Name: Evaluating Threats to Birds on Bowie State University Campus

Since 1970, North America has lost more than one in four birds—a decline with far-reaching consequences for ecosystem services such as pollination and insect control. As natural habitats are replaced by human development, understanding how to share built environments with vulnerable bird populations is crucial. Here, we present an initial assessment of bird mortality risks on the campus of Bowie State University (BSU) in Bowie, Maryland—a site of potential ecological importance to birds due to its proximity to the Patuxent Research Refuge and the largest contiguous greenspace in the D.C.–Baltimore corridor. We focused on the two leading, direct causes of anthropogenic bird mortality: collisions with building windows and predation by domestic cats (*Felis catus*). We conducted 228 surveys of campus buildings to document bird-window collisions from Mar to Nov 2025. We also deployed four trail cameras over a 1.5-week period to observe cat activity and estimate the proportion of the campus cat population that is neutered or spayed—a potential determinant of population growth. Bird presence was assessed using vocalizations identified via the Merlin Bird ID application. We detected 33 bird species on campus and recorded 46 avian fatalities attributed to window collisions. Collisions were significantly more frequent at buildings with a higher percentage of glass. Of the 10 cats observed, 40% were neutered or spayed—well below the estimated 70–90% threshold required to potentially reduce population growth. Additionally, we documented one instance of a cat scavenging a bird likely killed by a window strike, suggesting that cat scavenging may lead to underestimates of actual collision-related mortality. Based on our findings, we recommend assessment of night lighting on campus that may attract and confuse nocturnal migrants. We also recommend installation of UV-reflective window films on high-risk buildings as an initial mitigation strategy.

Abstract Name: The Presence of Antibiotic Resistant Bacteria in Water Samples in Richmond VA

Our research investigates the presence of antibiotic resistant bacteria in water samples collected from urban parks in Richmond, Virginia. Monitoring antibiotic resistance in these environments is quite critical because of its potential implications that could affect public health. When bacteria develop resistance to antibiotics used to treat infections this poses significant challenges to disease treatment and infection control. Urban parks are areas that experience high levels of human and animal activity, increasing the likelihood of water sources in these areas to come in contact with antibiotics used in both human and veterinary medicine. This exposure could facilitate the development or spread of antibiotic resistant bacteria. Three park areas connected to the James River in the city of Richmond Virginia were used in this study. Byrd Park which draws water from the James River was selected for its central location and heavy recreational use. Pumphouse park draws water from the Kanawha Canal alongside the James River, providing a distinct type of water source with similar environmental conditions to Byrd Park. The Reedy Creek area of the James River was included because it receives runoff from surrounding urban, industrial, and agricultural activity, creating a potential collection point for contaminants. To assess the prevalence of antibiotic resistant bacteria, water samples collected from each location were then diluted and plated on media containing varying concentrations of tetracycline. Resistance was measured by quantifying the bacterial colonies that remained viable and continued to grow in the presence of tetracycline.

Abstract Name: A Greener Synthesis of Squaraines

The fluorescent compounds known as squaraines are used for photodynamic diagnostics and therapy because they absorb and fluoresce in the infrared and near-infrared regions. Synthesized through a condensation reaction between squaric acid and electron-rich aryl groups, these reactions are typically conducted over several hours at reflux. Our research focuses on improving the synthesis of symmetrical squaraines by using greener methodology. Monowave heating has been substituted for traditional reflux heating, reducing reaction times from hours to minutes and decreasing the amount of solvent required. We are also investigating the use of greener solvents for both synthesis and recrystallization. By modifying the synthesis methodology, this research contributes to a more reliable, greener synthesis of squaraines for biomedical and chemical use.

Abstract Name: Providing Refuge and Comfort: Designed with Flexibility and Habitability for the Growing Concern of Natural Disasters

California continues to struggle with recurring natural disasters, including earthquakes, wildfires, mudslides, and flooding, that leave residents displaced and in search of a more reliable support system. The recent wildfire in the Palisades destroyed thousands of homes and businesses, making the need for safer and more resilient spaces impossible to overlook. Many temporary camps set up during emergencies still struggle to provide privacy, sanitation, and security, which makes it clear that a more thoughtful and humane approach is necessary. Research for this project was shaped by case studies, literature reviews, and online surveys, helping build a clearer picture of what displaced individuals need in both short- and long-term recovery situations. In response, this project proposes a community shelter with accompanying temporary housing units, designed to withstand extreme conditions while remaining inviting, supportive, and dignified. The design emphasizes access to clean drinking water, food services, recreational amenities, and safe, accessible accommodations for a wide range of users, including those with disabilities. Interior spaces are developed to be flexible, adapting to changing needs as communities move from immediate crisis into longer-term healing. Sustainability plays a central role in the project, especially as climate change intensifies the types of disasters Californians face each year, by combining resilient building strategies with environmentally responsible systems, sustainable materials, signage that promotes environmental awareness, and a focus on user well-being. This shelter aims to reduce additional strain on the environment while strengthening community preparedness. Ultimately, the purpose of this project is to create a place that offers more than temporary safety. It becomes a steady, restorative environment where people can regain their footing, reconnect with others, and rebuild hope after a disaster.

Abstract Name: Dielectric Differentiation of Clinically Relevant Candida Species Using Multi-Frequency DEP Profiling

Rapid identification of fungal pathogens continues to be a challenge in clinical settings. In this project, we examined whether Candida species can be differentiated based on their electrical behavior rather than through biochemical processing. Prior work in our lab has shown that individual Candida strains have responded differently in electric fields due to variations in cell wall and membrane structure, but full comparison across major clinical species has not been investigated. The main objective of this study was to determine whether six Candida species show consistent differences in their dielectric properties. With this in mind we investigated their membrane capacitance, membrane conductance, and cytoplasmic conductivity. These differences in values could serve as a reliable indicator of species supporting faster classification for fungal infections. To investigate this we cultured *C. albicans*, *C. glabrata*, *C. parapsilosis*, *C. tropicalis*, *C. dubliniensis*, and *C. krusei* in identical conditions and suspended them in the same low conductivity buffer. With this our key parameters include crossover frequency, membrane capacitance, membrane conductance, and cytoplasmic conductivity. To ensure the accuracy of our results we ran all experiments in triplicate so that

variation could be tied to membrane structure instead of error. Across all of these measurements, each species showed very distinct dielectric profiles. With this *C. krusei* displayed the strongest polarization and highest cytoplasmic conductivity, *C. parapsilosis* showed the highest conductance, and *C. tropicalis* showed the highest capacitance. Of these, *C. dubliniensis* had the lowest values in all electrical properties. Based on our results these patterns remained consistent across multiple concentrations with little variation. Overall, these results indicate that *Candida* species can be classified based on their electrical properties. This work helps establish a clearer understanding of how fungal structure relates to electrical behavior and supports the development of faster diagnostic strategies for clinically relevant *Candida*.

Abstract Name: Mother Death: Re-gendering Death as a Symbol of Agency in the Context of Twentieth-Century German Feminism

Der Tod und Das Mädchen (Death and the Maiden), a motif deeply rooted in Germanic artistic tradition since the Middle Ages, personifies Death as a voyeuristic, sexually aggressive male figure. At the turn of the century, however, many artists within these cultures began to re-gender Death as a woman. Scholars who identify this shift, including Kate Elswit in “Berlin...Your Dance Partner is Death,” Sandra M. Gilbert in “The Supple Suitor: Death...,” and Karl S. Guthke in *The Gender of Death*, understand it in terms of Sigmund Freud’s Death Drive (first published in *Beyond the Pleasure Principle* in 1920). However, this view overlooks the context of emerging German feminism, which often asserted the inherent power of women, specifically mothers, that derived from their biological potential. Positioning the re-gendering of Death in the context of contemporary gender politics in Germany poses the question: how might these new images of a motherly Death be reimagined as symbols of agency? This study references contemporary publications by first-wave German feminists, as well as the written and visual work of two prominent artist-mothers—Käthe Kollwitz (1867-1945) and Else Meidner (1901-1987)—to gauge how women in the early-twentieth century came to be associated with death. The project pairs close readings with a visual analysis of works on paper by Kollwitz and Meidner to identify their engagement in discourse concerning the relationship between motherhood and death. The project argues that understanding these ‘Mother Deaths’ as they were conceived by artist-mothers in the context of both first-wave feminism and the tradition of *Der Tod und Das Mädchen* positions them as figures of empowerment and agency.

Abstract Name: The Boogeyman Is Not Real: Disgust, Anger, and Anti-Transgender Tactics in Contemporary American Conservatism

In the years since the landmark Supreme Court case, *Obergefell v. Hodges* (2015), transgender people, along with the LGBTQ+ community as a whole, have gained considerably higher visibility. That visibility has led to greater acceptance by many members of the public, and yet, backlash to transgender rights has become a primary stance for conservative politicians across the United States. Despite little evidence to support

conservative elites' claims that the transgender community poses a danger, elites nevertheless have raised alarm on the grounds of moral, ethical, and religious concerns. That alarm has been operationalized in the form of disgust directed at the transgender community. Disgust has long been used as a political tactic in practice, and greater sensitivity to disgust is linked with an increased likelihood of conservative views towards the LGBTQ+ community. Past research on the impact of emotions in political behavior has placed emphasis on the emotion of anxiety as the primary response to perceived threats. Nuanced analysis reveals that, for some, the emotion of disgust can replace anxiety as the initial reaction to a perceived threat. Instead of seeking out further information, as is the case with anxious responders, disgusted responders reject new information. This makes individuals more vulnerable to the manipulation of political elites, who prey on individuals' disgust to create an environment of fear and anger. I argue that the current attention towards the transgender community is another example in a decades-long political strategy. Using historical analysis, I investigate how the conservative political elites have utilized disgust against the LGBTQ+ community to motivate the conservative voter base.

Abstract Name: Undersea Thermal Electric Generator Powered Profiling Floats

Imagine a self powered profiling float that could remain on station collecting ocean data for longer periods of time than any other battery operated device. This device will descend and ascend through thermal layers converting temperature changes into energy using thermal electric generators. This energy is then used to increase the floats duration in the field, collecting data, compared to simply relying on battery power alone. In this paper we discuss two prototypes, the first was to test depth control and water tightness. The second prototype used the lessons from the first and incorporated thermal electric generators to generate energy. From these prototypes we plan to show that thermal electric generators can be used in a way that increases the endurance of ocean monitoring probes and potentially other UUVs.

Abstract Name: Produced Water Critical Earth Element Extraction

Produced water is a major waste byproduct that is in the Oil and Gas industry, which is typically seen as something that can be an inconvenience. Government mandates for the purification of wastewater for proper recycling or removal has led to interest in finding monetary returns on produced water. Methods of characterizing water for valuable elements have become more of a real financial possibility with more and more attention being put on finding rare earth metals and critical elements. Our literature analysis has given us methods of extraction, but most of these are lacking in selection specificity or are technologies that have had advancements between the older research publications and now . With materials in our campus lab and

with the help from local labs such as Texas Pacific Water Resources, we intend to expand the understanding on the methods of characterization and extraction of rare and critical earth elements. So far we have learned how to use our lab equipment to characterize samples of produced water such as emission spectroscopy method. With the characterized samples, we will be able to partner with local labs to find the most efficient method of rare and critical earth metal extraction. With enough samples characterized and sample resources extracted, we intend to have a better idea of the modern technologies and can find where the processes can be improved.

Abstract Name: Called Without a Compass: Kierkegaard, Clarity, and The Sacred Ambiguity of Vocational Discernment

In modernity's obsession with certainty, vocational discernment—whether in professional trajectory, personal calling, or religious discernment—often transforms from a gift into a demand. In a culture that prizes clarity, control, and measurable identity as absolutes, the modern-self's demand seeks promised security but veils a deeper fear: choosing wrongly. This fear reflects an existential anxiety—the dread that one's choice could betray oneself, remove other potentialities, or sever one from divine purpose. Called Without a Compass: Kierkegaard, Clarity, and The Sacred Ambiguity of Vocational Discernment explores Søren Kierkegaard's concept of the “despair of infinitude” from *The Sickness Unto Death* as a framework for understanding this contemporary crisis of decision and identity. I situate vocational uncertainty within broader philosophical and psychological discussions of freedom, agency, and authenticity. When the desire for self-understanding becomes a desire for self-mastery, possibility gives way to paralysis. The very freedom sought through certainty becomes imprisonment within the self-constructed cell of infinite potential. Drawing on Kierkegaard's account of the self as a dynamic relation, I analyze how such entrapment arrives through disordered desire—whether divine, ethical, or existential. To extend this analysis, I engage the apophatic and relational epistemologies found in the works of Saint Teresa of Avila and Saint John of the Cross. Ultimately, I reframe vocation as a relational and receptive disposition rather than a mere intellectual problem of epistemic certainty. In light of this, I interpret Kierkegaard's ontological insight that despair arises when the self ignores or refuses its existence as a relation within a relation: vocational discernment, then, requires a posture of faith—“rest[ing] transparently in the power that established it.” (Kierkegaard 131).

Abstract Name: Coping Skills Among Women With PCOS: A Comparative Analysis

Polycystic ovary syndrome (PCOS), a chronic endocrinopathy, affects ~13% of reproductive-aged women globally. PCOS is a complex, heterogeneous collection of symptoms involving hormonal and metabolic dysregulation. Notable symptoms are hirsutism, menstrual irregularities, visceral adiposity, insulin resistance, and subfertility, which negatively impact the quality of life. Women with PCOS are at increased risk of anxiety and depression, as well as other mental health disorders. However, limited research exists on coping

strategies used among women with PCOS. The purpose of this study was to examine coping strategies used among women with PCOS and compare them to women with no chronic health conditions. Participants were recruited via flyers and social media. Implied informed consent was obtained. The survey was comprised of demographic questions, the BriefCOPE, and Adult Coping Inventories (ACI). Data was collected via REDCap. Means/standard deviations were calculated for continuous variables, frequencies for categorical variables, and independent-sample t-tests for mean differences between the PCOS group (n=121) and healthy control (HC) group (n=168) on inventory scores. Participants (N=289) were 33.73 (± 7.53) years and mostly White (69%). The groups did not significantly differ in baseline characteristics. On the BriefCOPE Inventory, women with PCOS used more emotion-focused coping and avoidance compared to the HC ($p < 0.001$). On the ACI, women with PCOS scored significantly higher than the HC for using maladaptive coping strategies and avoidance ($p = 0.002$ and 0.018 , respectively). Poor coping strategies in women with PCOS may be linked to the psychological distress of chronic PCOS symptoms such as hirsutism, acne, subfertility, and depression. For women with chronic health conditions, poor coping skills may reflect a perceived lack of control over the condition and feelings of helplessness. Future research is needed to understand the impact of PCOS on developing poor coping strategies, identify clinical timepoints and measures to promote healthy coping strategies.

Abstract Name: "I am Thou and Thou am I: Woolf's Critique of Unethical Imperative Using Socio-Environmental Analysis In To The Lighthouse"

Salah Bouregbi proposes that mysticism in Virginia Woolf's *To the Lighthouse* is sacred and exemplified in the characters of Mrs. Ramsay and Lily Briscoe. In his paper Bouregbi characterizes these characters as "rational mystics," who unite opposites and bring a rational aesthetic order to multiplicity. While understandable, this position ignores the social dimension of mysticism that Woolf implies is empowered by nature. Nature's binding quality results in two forms of mysticism that each character embodies. For Mrs. Ramsay it is a mysticism of absorption, in which other characters lose individuality in a broader reality. Lily's mysticism, on the other hand, emerges in and through social relations that are enabled by, yet stand apart from, an all-encompassing nature. In *To The Lighthouse*, Woolf highlights how mystical pursuit, specifically into social mysticism, enables the humanization of the character's experiences and maintains humanity through mystical progression. She does so through insight regarding nature's place in social interaction, bringing a dual vision of nature. Woolf sees humans as united in social obligation over and against nature; alternately, nature pervades all human social interactions providing a metaphysical unity. Woolf's embrace of what I call a socio-environmental mysticism emphasizes her argument on the importance of interpersonal connection. For this reason Woolf characterizes Mrs. Ramsay's mysticism as morally problematic while endorsing Lily Briscoe's socially responsive mysticism.

Abstract Name: Peak Accelerations Are Higher at the Foot Versus the Ankle in Rear Foot Strike Runners

Introduction- Running is a popular pastime worldwide. It is an accessible and healthy form of exercise: it requires minimal equipment and boasts favorable associations with longevity and cardiovascular health. However, prevalence of running-related injuries (RRIs) is around 45%. RRIs are associated with higher peak accelerations which are often monitored by runners, clinicians, and researchers to help reduce risk of RRI. However, it is unclear whether accelerations measured at the foot (commonly used by clinicians) can approximate those at the ankle (commonly used by researchers). Purpose- Our purpose was to evaluate differences in peak acceleration measured at the foot versus ankle during treadmill running. Methods- We included adult runners whose natural foot strike pattern was rear foot strike (RFS). Noraxon Myomotion sensors were placed on the right foot and ankle. Participants warmed up for 3 minutes at a self-selected pace to ensure they reached their natural running rhythm. Twenty seconds of data were recorded and filtered using a Butterworth filter with a cutoff of 50 Hz. Peak accelerations were averaged for all steps within the 20-

second window and compared at the foot and ankle using paired t-tests (IBM SPSS).Results- Results are expressed as mean (standard deviation). 30 runners (15 females) participated in the study (age 34(18) years, running speed 5.6(0.9) mph). Mean vertical accelerations at the foot (8.5(3.1)) were larger than at the ankle (4.7(1.9); $d=1.8$; $p < .001$). Mean resultant accelerations at the foot (10.4(3.3)) were larger than at the ankle (6.7(2.7); $d= 1.7$; $p < .001$).Conclusion- Accelerations measured at the foot were consistently higher than those at the ankle, demonstrating that these cannot be used interchangeably. These findings highlight the necessity of clearly reporting and justifying sensor placement to ensure methodological rigor. Furthermore, guidelines for target accelerations at the ankle cannot be used for foot-mounted sensors.

Abstract Name: The Effect of a Supportive-Oriented Parenting Style Compared to a Performance-Oriented Parenting Style on Young Adult Children's Intrinsic Motivation in Baseball Using Self-Determination Theory

This study seeks to examine how a supportive-oriented environment, fostered by parents, affects intrinsic motivation among male baseball players, compared to a performance-oriented environment, as they enter adulthood. The results of this study ideally would benefit parents seeking to instill in their children intrinsic motivation and a passion for baseball that lasts beyond their childhood. Previous studies, such as Ryan & Deci's study in 2000, sought to determine what drives people to engage in an activity with genuine interest, a concept known as Self-Determination Theory (SDT). The SDT is a psychological framework that compares internal motivation with external motivation. A 2022 study by Krommidas et al. found that higher perceived parental support significantly predicted higher intrinsic motivation and enjoyment among young athletes (ages 12-17). This study will specifically focus on intrinsic motivation among athletes aged 18-24 years and their correlation with parenting styles in accordance with the SDT. A questionnaire will be designed to glean specific information on the young adult child's parental involvement, the type of involvement (supportive vs. performance-fostering), and the athlete's perceived intrinsic motivation. The correlational design intends to identify the strength and direction of the variables to determine whether they are independent of one another. A random sampling of domestic and international collegiate baseball players will be the participants in this study. Anticipated outcomes are that collegiate-aged baseball players with parents who foster a supportive-oriented environment around baseball—one where learning, effort, and self-improvement are the focus—will have higher self-perceived intrinsic motivation for baseball. Additionally, athletes whose parents foster a performance-oriented environment in which winning and outperforming are strongly valued will have lower self-perceived intrinsic motivation for this sport.

Abstract Name: The Knowledge, Experiences, and Attitudes of Nurses Regarding Trauma-Informed Care for Sexually Abused Intrapartum Patients

Labor and delivery nurses care for women from diverse backgrounds who are preparing for a life-changing

event often marked by fear, excitement, sadness, and joy. Childbirth is one of the most vulnerable experiences a woman can undergo, and nurses must provide skilled, compassionate, and culturally competent care. However, 1 in 5 women in the United States have experienced rape or attempted rape, and for these survivors, labor can become re-traumatizing. Many report flashbacks, dissociation, and a sense of “being back in the rape” during childbirth. Routine procedures—such as patient positioning and cervical exams—are known triggers. Research further links prior sexual assault to unplanned cesareans, traumatic births, and childbirth-related PTSD. Trauma-informed care (TIC) provides a framework to reduce these risks by encouraging providers to understand trauma, recognize signs of distress, and act to avoid further harm. Although case reports show TIC can be applied successfully in obstetrics, there is no standardized TIC education for labor and delivery nurses. This gap represents an understudied but critical area of women’s health. This research will explore labor and delivery nurses’ knowledge, experiences, and attitudes regarding TIC for patients with a history of sexual trauma. Semi-structured interviews will be administered to 10 nurses and interpreted through Bourdieu’s sociological framework to identify potential educational needs. By revealing gaps in understanding, this study aims to support the development of targeted training programs that improve patient safety, promote positive birth experiences, and reduce psychological and physical harm for mothers and newborns.

Abstract Name: Creating a Sustainable Pathway for Undergraduate Research Experience and Mentorship in the Humanities

Building support for research opportunities in the Social Sciences, Humanities, and Arts (SSHA) is essential for a young research-intensive (R1) institution. The Undergraduate Research in the Humanities (UROC-H) program at the University of California, Merced (UCM) has operated to provide structure and support for humanities undergraduates to engage in research. Funded by the Mellon Foundation, UROC-H aims to expand undergraduate research in the humanities on a larger scale. Prior to the inception of UROC-H in 2016, the Undergraduate Research Opportunity Center (UROC) at UC Merced only housed STEM-focused research programs. UROC-H adapts the structure of these STEM programs to meet the needs and methodologies of the humanities fields. This cross-disciplinary approach has proven to be highly successful, leading to innovative outcomes. The program offers a full academic year of research fellowships, training, and conference travel, while also facilitating research project clusters that enhance faculty engagement and student receptivity to the research process. UROC-H has also contributed to strengthening the broader academic infrastructure by meeting the needs of undergraduate students, providing professional development for graduate students, and supporting faculty research. Notably, 87% of UROC-H participants plan to pursue graduate education, demonstrating the program’s impact on students’ academic and professional trajectories. Over the past decade, this data has shown that UROC-H not only helps humanities students connect to the research community but also empowers them to consider research in their professional or academic careers.

Discipline: Dance

Authors:

Abstract Name: Dance Movement Therapy as a Practice for Transitional Recovery Program

For many in addiction recovery, rock bottom isn't just a moment in time; it's a process, a state of being filled with depression, guilt, and pain. Those who live in sober living houses (SLH) are relearning and rebuilding their lives from that rock bottom. SLHs provide resources for staying sober, including talk therapy, group therapy, 12-step programs, AA, and many others. However, these are not always inclusive or enough to motivate individuals to commit to sobriety. Dance Movement Therapy (DMT) provides an alternative path out of rock bottom by using the body as a tool for recovery. In my research, I examine these programs and question their effectiveness and inclusivity. I hypothesize that DMT can be a useful optional program for addiction therapy. We can implement movement-based therapeutic practices like Mirroring, Motivational Interviewing, and Psycho-dynamic oriented dance therapy as complementary to those that are already offered. As a therapeutic practice, DMT can foster a safe space that encourages self-expression, community, motivation, and understanding of emotions to maintain sobriety within SLHs. Rachel Singer, a Dance Movement Therapist who has experience working with addict populations, finds a positive correlation between the healing of addicts and their participation in dance movement therapy. The majority of my research findings are based on reputable researchers such as Dr. Doug Polcin, a program director at the Public Health Institute, as well as field interviews with staff and social workers who work directly with patients at SLHs.

Abstract Name: Bridging Theory and Practice: Scaffolding Research Competencies and Career Readiness in Undergraduate Aviation Education

In technical fields such as aviation, engaging students in research-centered coursework can be challenging because learners often prioritize operational proficiency over scholarly inquiry. To address this gap, a two-course undergraduate series was developed to emphasize the value of research as a transferable professional skill. The curriculum is designed to cultivate competencies applicable across diverse career paths, particularly the ability to ask insightful questions, frame relevant problems, and apply evidence-based reasoning to issues faced by today's aviation industry. The first course introduces students to core research methods, including study design, data collection, and analysis, providing a structured foundation for scholarly investigation. Building upon this base, the second course serves as a capstone experience that allows students to collaborate with industry partners on authentic aviation challenges. This scaffolded design enables students to transition from theoretical understanding to practical application, fostering both technical and analytical proficiency. Student feedback demonstrates that this approach enhances confidence, critical thinking, and the integration of research with professional practice. In addition, the model promotes essential workplace competencies such as teamwork, communication, and project management, which students and industry mentors identified as critical for career readiness. Overall, this instructional framework bridges the divide between academic learning and professional application, ensuring that aviation graduates are equipped with the research literacy and applied problem-solving skills required in a dynamic and evolving field. Beyond aviation, this adaptable model provides a blueprint for integrating research engagement into other professional disciplines where evidence-based inquiry is essential but often underemphasized.

Abstract Name: Cooking With Dakota: Compressing Freeze Dried Egg Whites Prior to Pyrolysis

Freeze-dried egg white (EW) proteins have been used as a novel precursor for green and sustainably produced graphene aerogels that are scalable, template-free, and require less steps in their synthesis. These graphene aerogels consists of a network of carbon fibers and graphene sheets created by a self foaming mechanism, allowing for hierarchical porosity. Previous studies have shown heat rate affects the density and microstructure of the graphene aerogels. This study explores additional effects to the graphene aerogels density and microstructure via compression of the precursor into rounded tablets. The resulting aerogels maintained hierarchical porosity and rounded shape but exhibited unexpected foaming behavior and the formation of shell-like structures. These results implied compression to the precursor affected the self foaming mechanism, and future research will explore the underlying causes.

L. Nichole McKee

Discipline: Economics

Teresa Carrion

Abstract Name: Protectionism, Push Factors, and Service Sector Pull: A New Look at Low-Skilled Female Migration

This thesis investigates the causal relationship between U.S. trade protectionism, and the migration of low-skilled Hispanic women. While economic theory and recent empirical work, like Uprety (2020), suggest that trade barriers increase migration, these models attribute the effect to capital-skill complementarity. They predict a rise in high-skilled immigration, suggesting protectionism drives capital inflows which demand skilled labor. This finding presents a significant theoretical puzzle for the current policy landscape. It fails to explain the persistent and rising migration of low-skilled women despite protectionist measures that, in theory, should reduce demand for low-skilled labor in the U.S.'s tradeable sector. To resolve this tension, I propose a novel "Push-Pull" framework that disaggregates the drivers of migration for this specific group. My primary hypothesis challenges the standard view by arguing that tariffs on Latin American exports in female-intensive sectors act as a severe economic "push". By destroying employment opportunities in the origin countries, tariffs amplify economic insecurity and displace women from the local labor market. This "push" is met by a structural "pull" from the U.S. service sector. Using Cortés (2022), I argue that demand in this sector is driven by needs of high-skilled native women and remains insulated from policy shocks, creating an absorption mechanism for displaced workers. Methodologically, this study employs a panel data analysis using a Fixed Effects model on a Country-Year dataset constructed from IPUMS USA (ACS) migration microdata and USITC bilateral tariff data. This approach allows the isolation of tariff impacts while controlling for unobserved country heterogeneity and economic trends. The research design includes a Difference-in-Differences (DiD) specification to exploit tariff spikes. By empirically linking trade policy shocks to service-sector migration flows, this research demonstrates a policy paradox: that U.S. protectionism may increase low-skilled migration by destroying the export-oriented jobs that would keep workers in their countries.

Abstract Name: Can You Smell That Smell? ADHD, COVID-19, and Anosmia

Previous research has shown olfactory deficits in some people diagnosed with attention deficit hyperactivity disorder (ADHD). ADHD is a neurodevelopmental disorder that affects around 129 million adolescents and 366 million adults around the world. In the United States, there are approximately 22 million people that are diagnosed with ADHD. This disorder primarily affects the prefrontal cortex area of the brain. The prefrontal cortex is a specialized area of the frontal cortex that focuses on various executive functions: decision making, attention, memory, and impulse control. Likewise, olfaction is housed within the frontal cortex. This proximity to the prefrontal cortex can cause some of the dysfunctional aspects of ADHD to affect olfaction. ADHD has the typical hallmarks of a lower chemosensory perception in children and adults. This chemosensory perception includes olfaction (sense of smell), gustation (sense of taste), and chemesthesis (sensory systems that detects burning, cooling, tingling, and numbing sensations). Similarly, 60% of people diagnosed with COVID-19 experienced anosmia (loss of sense of smell) for an extended period. Around 24% of people never regained their sense of smell. This is due to the viruses SARS-CoV-2 neurotropism that can affect the tissue found throughout the nervous system of the body. This includes the smell pathways, otherwise known as the olfactory pathways. Since the pandemic happened so recently, very little research has been conducted related to ADHD and COVID-19 symptoms. In this study, undergraduates will answer questions in an anonymous online Qualtrics survey about their own neurodevelopmental disorder diagnoses, past COVID-19 diagnoses, and history of anosmia with their diagnoses. We hypothesize that participants diagnosed with ADHD were more likely to experience anosmia if they contracted COVID-19 than participants who had no ADHD diagnosis. This research will contribute to basic science and will help us better understand anosmia as it relates to ADHD and COVID-19.

Abstract Name: High-Throughput Isolation and Identification of Bacterial Strains from Environmentally Enriched 1,4-Dioxane Degrading Consortia

Bioremediation is a sustainable and environment-friendly strategy for contaminated groundwater. 1,4-Dioxane as a prevalent groundwater pollutant, possible carcinogen, and common industrial waste product can be biologically degraded via metabolic or co-metabolic pathways. However, the feasibility and stability of 1,4-dioxane biodegradation are still challenged. Here, we focus on the engineering of synthetic microbial communities (SynComs) method and present the critical steps of enriching and isolating the bacteria that can form 1,4-dioxane degrading SynComs. To enrich the natural 1,4-dioxane and byproducts degraders, we collected soil and freshwater samples from a natural restoration river and continuously added 1,4-dioxane.

Meanwhile, 1,4-dioxane degrading bacterium *Pseudonocardia dioxanivorans* CB1190 was augmented (10% v/v) to initialize the biodegradation. Two resulting microbial consortia, SL417 and FW118, were identified by 16S rRNA amplicon sequencing, and dominant species were *Mesorhizobium* sp. and CB1190, respectively. We further developed a high-throughput serial dilution technique to isolate the consortium's single strains. The optimal dilution was determined according to Poisson's distribution, where there was the highest possibility of a single strain in each well of a 96-well plate. With observed biomass, a well's content was plated on agar and re-streaked until purity was visually confirmed. These isolated strains were identified by colony PCR (16S rRNA gene amplification) followed by PCR purification, gel electrophoresis, sanger sequencing, and BLAST alignment. The high-throughput cultivation and isolation process successfully separated out representative and slower-growing or less prevalent strains from the original consortia, such as *Mesorhizobium amorphae* PD-5 and *Afipia broomeae* B2PC1. The identified strains were representative of their environmentally enriched consortia, therefore were strong 1,4-dioxane bioremediation candidates, both individually and in the context of their consortia strain-mates. These microbial seeds will pave the way for recombination in duos or larger SynComs, through in silico modeling and in vitro experiments, and further applied in the field scale bioremediation engineering.

Abstract Name: Human Transferrin Receptor Bispecific TREM2 Antibody Creation and Its Insightful Use in Alzheimer's Disease

Alzheimer's disease (AD) is the leading cause of dementia, affecting an estimated 7.2 million seniors in the United States. AD can develop in the brain for twenty years or more before symptoms appear, such as memory loss, which could enable a diagnostic window for intervention. AD causes neurons to be damaged or destroyed due to the accumulation of amyloid-beta protein fragments and an abnormal form of tau protein. The protein, Transmembrane Receptor Expressed by Myeloid Cells, TREM2, is essential in regulating the microglial response to amyloid-beta and tau accumulation in the AD brain. Microglia, the brain's resident immune cell, has two different paths of activation: one that is anti-inflammatory (M2), and one that is pro-inflammatory (M1). TREM2 is expressed in microglia and myeloid cells. It has a role in regulating microglial inflammatory responses. The TREM2 receptor is connected to DAP12—a signaling adaptor inside the cell that phosphorylates Syk (Spleen Tyrosine Kinase). By creating a TREM2 antibody, it stimulates SYK phosphorylation and phagocytosis. Portions of the antibody were developed from two different companies (e.g., Elana and Denali), who provided the aTREM2 and the hTfR (human transferrin receptor) binding domain, which was inserted in the aTREM2 fc portion. An hTfR receptor allows for two TREM2 antibodies to bind to TREM2 protein and mediate a stronger response via receptor clustering. The hTfR receptor also allows a therapeutic to surpass the blood-brain barrier—hTfR normally transports iron in the body. By inserting hTfR, then inversely, testing could show an elevated production of phospho-Syk using techniques like western blots, alphaLISA, and ELISA. Activating Syk matters because it activates the PI3K/AKT pathway that leads to M2 microglia, ultimately to provide data to collaborators and enable the construction of clinical-grade diagnostic assays.

Abstract Name: Law, Lying, and Self-Perception: An Exploratory Study

IntroductionSelf-Discrepancy Theory suggests that when people behave in ways that contradict their ideal self, their emotional well-being suffers, which can lead to feelings of self-disgust and a lower self-image. We expect this to apply to morally questionable behaviors as well, predicting that lying and criminal attitudes will be linked to higher self-disgust and lower self-esteem. We hypothesize that moral violations such as lying and criminal attitudes will correlate positively with self-disgust and negatively with self-worth.**Method**Using a correlational online survey, 115 undergraduate students at Texas Woman's University, including 104 females, seven males, and four declined to answer (M: 18.9, range: 18-34), participated. Measures assessing self-worth, self-disgust, lying, and criminal sentiments were administered to participants.**Results**The Self-Disgust Scale showed significant correlations with Pathological Lying Inventory(PLI) subscales ($r = -0.31$ to 0.45 , $p < 0.001$ to $p = 0.003$) and with Criminal Sentiments Scale Modified (CSS-M) subscales ($r = 0.28$ to 0.32 , all $p = 0.001$ to $p = 0.006$). The Contingencies of Self-Worth (CSW) subscales, others' approval, appearance, academic performance, family support, and virtue correlated with distress (PLI) ($r = 0.19$ to 0.36 , $p < 0.001$ to $p = 0.05$) along with others' approval and excessive lying ($r = 0.25$, $p = 0.012$). CSS-M's ICO correlated with the CSW subscales of family support, academic performance, and virtue ($r = 0.19$ to 0.24 , $p = 0.012$ to 0.049). Additional correlations emerged between police and family support, law and God's love ($r = -0.35$, $p < 0.001$), and TLV and virtue ($r = 0.296$, $p = 0.002$).**Discussion**The results validate the association between moral violations and increased self-disgust and decreased self-worth. Self-disgust showed strong correlations across all subscales, indicating a significant relationship between morally contemptuous behaviors and sentiments and self-disgust. Self-worth showed significant results in areas influenced by external pressures, including family, law, and religion. These findings support the Self-Discrepancy Theory, further indicating that acting against one's ideal self can cause harm to one's emotional well-being.

Abstract Name: Jaguar Symbolism in Aztec and Maya Deities

The jaguar (*Panthera onca*) is a shared symbol across Pre-Columbian cultures of the Americas. Although scholars have examined jaguar symbolism within a single culture, few have approached the concept of jaguar symbolism interculturally. The aim of this study is to explore the meaning of jaguar symbolism in Aztec and Maya deities in the postclassic period. This comparison is based on historical research, religious iconography, and anthropological sources to argue that although the Aztec and Maya both incorporated jaguar elements into their depictions of deities, those elements do not share the same meaning. First, a brief introduction to jaguar as a cross-cultural symbol of the Americas is provided. Following, the examination of the Aztec jaguar demonstrates that the jaguar signified the power and divinity of rulers, through association primarily with the god Tezcatlipoca. Since the Maya associated the jaguar with many deities, this study focuses on God G and how jaguar symbolism uses specific physical features to indicate meaning. Thus, the specific meaning of the Jaguar symbolism did not translate interculturally.

Abstract Name: Reconstructing 5000 Years of Hurricane Activity in Holyrood Pond Using Sediment Core Analysis

Hurricanes are hazardous and costly events that annually negatively impact people that live in coastal areas in North America. The current observational record of hurricanes is short (1970 - present) and does not offer insight into the effects of climate change on hurricane frequency. One method of improving and extending our observational record of hurricanes is to reconstruct paleohurricanes using sediment cores. These cores record hurricane activity in the form of coarse-grained overwash layers that are deposited when hurricanes move sand from beaches into backbarrier ponds. In this project, we analyzed sediment cores from Atlantic Canada to locate coarse-grained storm layers left behind by ancient hurricanes. Our sediment core was collected from Holyrood Pond on the southern shore of the Canadian province of Newfoundland. We identified storm layers in our core by sieving at one centimeter intervals at 125 microns. Radiocarbon dating suggests that our core from Holyrood Pond extends back 5000 years, with each centimeter representing approximately 29 years of deposition. Clustering of storm layers in time represent periods of increased hurricane activity. Using our new reconstruction and our current knowledge of the climate during the past 5000 years, we can determine trends in hurricane activity relating to climate change in the past to better predict changes in the future.

Abstract Name: How Family Functioning Influences the Coming Out Process Among LGBTQ+ Young Adults

The purpose of this study was to explore how coming out responses, family dynamics, race, life satisfaction, and resiliency intersect in the coming out process. We aimed to answer three questions: (a) Does one's coming out experience of positive or negative reactions contribute to overall life satisfaction and resiliency? (b) Does coming out influence family dynamics as compared to before and after disclosure? (c) Does race play a part in familial reactions to disclosure? We hypothesized that negative familial reactions would be associated with higher resiliency and lower life satisfaction compared to positive reactions, which would lead to lower resiliency but higher life satisfaction. That highly functioning families would respond more positively to their LGBTQ+ family members' disclosure. Finally, we hypothesized that Black and Hispanic individuals would experience more negative reactions as compared to White individuals. A total of 512 LGBTQ+ individuals aged 18-44 ($M = 22.90$, $SD = 4.48$) completed an online self-report survey that assessed their coming out experience and the impacts it had on the LGBTQ+ individuals. Participants responded to reliable Likert-type scales that analyzed coming out vigilance, positive coming out responses, family support, family adaptability and cohesion, life satisfaction, and resilience. Results indicated that positive familial reactions were associated with greater life satisfaction, but negative reactions were not associated with greater resiliency. Family functioning before disclosure predicted positive reactions, but family functioning itself did not differ before and after disclosure. Race, specifically Black and Hispanic families, did not predict differences in familial reactions to their LGBTQ+ family members' disclosure. These findings emphasize the importance of supportive families and suggest that strengthening family functioning prior to an individuals' disclosure may overall improve one's coming out experience as a whole. Keywords:

LGBTQ+, coming out, disclosure, family reactions, family functioning, life satisfaction, resilience, racial/ethnic differences

Abstract Name: Melatonin use: trends and implications for age-related diseases

Melatonin is a hormone produced by the pineal gland in a rhythmic manner that aligns with the light-dark cycle, with low levels during daytime and high levels at nighttime. While the primary role of melatonin is to facilitate synchronization of the body's rhythms with the 24-hour day-night cycle, it also manifests sleep-inducing properties. As such, melatonin is used by individuals with circadian rhythm disorders or sleep difficulties. In the US, melatonin is available as an over-the-counter supplement, and its use in the general population has increased in recent years. However, little is known about the prescription of melatonin by healthcare providers. The goal of this study is to assess temporal trends in prescription melatonin and potential patterns based on demographic and clinical patient characteristics. We will use the Rochester Epidemiology Project (REP), a population-based medical record linkage system that captures clinical encounters from the residents of Olmsted County, MN. Healthcare records of patients aged 18 years and older who were prescribed melatonin in a hospital or outpatient setting at Olmsted Medical Center or Mayo Clinic Rochester between 2007 and 2023 will be identified. We will abstract data on patients' characteristics, diagnoses, and other medications. Healthcare records will also be accessed to obtain information on the indication for melatonin prescription, to learn about healthcare concerns that prompt providers to recommend melatonin. Data collection is ongoing, and results will be analyzed upon completion. Preliminary data suggest that, although sleep difficulties are the most common indication for prescription melatonin, other medical reasons include headache and depression. Findings from this study will inform on trends in melatonin prescription over the past two decades and associated characteristics.

Abstract Name: Patterns of Ovarian and Gonadotropin Hormones in Emerging Adult Oral Contraceptive Users

Oral contraceptives (OCs) are often initiated during adolescence and emerging adulthood, a period of continued maturation of the hypothalamic–pituitary–gonadal (HPG) axis. Because hormonal exposure during this window may shape emotional, biological, and reproductive outcomes, it is important to understand the specific formulations young women take and the hormonal profiles these formulations produce. This study characterizes OC formulation features and measured hormone levels in young adult OC users (n = 30). Ethinyl estradiol (EE) doses ranged from 0.01–0.035 mg (mean = 0.022 mg), with 70% using ≤ 0.02 mg. Pill regimens included 21/7 packs (83%), 24/4 packs (10%), and 84/7 regimens (3%). Progestins included norethindrone (and acetate), levonorgestrel, norgestimate, desogestrel, and drospirenone. Duration of use ranged from 6–72 months (mean = 30.8 months). At both study visits, during the active and inactive pill, plasma estradiol, progesterone, luteinizing hormone (LH), and follicular stimulating hormone (FSH) were measured. Although OCs suppress the HPG axis, little research examines how formulation characteristics influence measured hormone levels in early-life users. Existing studies rarely compare hormone concentrations across modern low-dose versus standard-dose pills, and few evaluate whether duration of use or regimen structure affects estradiol, progesterone, FSH, or LH during active or inactive intervals. We will test three hypotheses: (1) Lower-dose EE formulations (≤ 0.02 mg) will show stronger suppression of estradiol and progesterone, (2) Longer duration of OC use will be associated with lower FSH and LH, and (3) Inactive-week hormone levels will vary systematically by estrogen dose and regimen type, not progestin type. Testing these associations addresses a gap in the early-life contraceptive literature.

Abstract Name: Prehistoric Mortuary Practices

Mortuary practices can be defined as how humans dispose of, and treat their dead. Many of us are familiar with elaborate burial practices such as the entombment of pharaohs, like the pyramids at Giza, and the Necropolises of the Valley of the Kings and Queens; elaborate tombs such as the Mausoleum at Halicarnosses; and the Taj Mahal in India; water burials such as sailors at sea, or funeral pyres on boats that the Vikings practiced; or even the modern Jazz Funerals of New Orleans. It would appear to us that caring for our dead is a modern concept, practiced by humans, Homo Sapiens, as part of our various cultures. However, archeological excavations and scientific analyses show burial practices to have predated modern man, practiced by our ancient ancestors such as Neanderthal and Homo naledi, dating back as far as 250,000 years ago. Decades of work in the field by Dr. Jane Goodall with her chimpanzees proved that they have emotions, and experience grief and loss. Since they are our closest relatives, it can be deduced that ancient hominids also experienced grief and loss, and engaged in mortuary practices. I will discuss some of the major discoveries, their timelines, and the conclusions anthropologists have arrived at, to give us a glimpse into how our early ancestors may have honored their dead.

Abstract Name: Exceptionally Flawed: A Look Towards Addressing Inequities of Identification in Gifted Education

Gifted education has been a part of our education system for over a century, and yet there continue to be ways we can work to improve the system to benefit all students. One way education professionals can achieve this is by implementing identification systems that cater to students of all races, ethnicities, genders, and abilities. This study aims to highlight and suggest solutions that school districts across the nation, as well as the Commonwealth of Virginia, can implement to make the gifted identification process more inclusive to all students. A comprehensive literature review of national and state data regarding current demographics of identified gifted students will include statistics about identification rates and percentages of students in gifted education to provide background information. Interviews will also be conducted to examine specific school districts in Virginia and investigate how they work to make gifted education more accessible to all students. Information about each method learned through these interviews will be highlighted, including data on the demographics of the involved students and the various identification and instructional methods used to engage students in gifted education. With these results, more school systems may be able to identify, evaluate, and implement new strategies for gifted identification and instruction to create a more inclusive gifted education environment. These findings also aim to provide practical recommendations for school systems that may be seeking to improve their gifted education systems. Through sharing these findings, this research will contribute ideas that seek to assist with improving gifted education standards to help all students reach their full potential.

Abstract Name: The Spirit Animal Series

The Spirit Animal Series is a research-based exploration examining the relationship between spirit, instinct, and self. This work investigates the central research question: how do human psychological and emotional states mirror the energies of the animals and insects to which we feel most connected? Drawing on theories of embodiment, symbolic communication, and visual semiotics, the series interprets the human experience through visual representations of strength, rebirth, vulnerability, intuition, and resilience. "Conceptually, the project is influenced by the vibrant textile storytelling of Bisa Butler, the emotive figuration of Damola Ayegbayo, and the color symbolism of early expressionism (Lloyd, 1991)." Together, these frameworks respond to contemporary dialogues around authenticity, self-awareness, and embodiment in a fractured cultural landscape. Methodologically, the series employs acrylic paint on art paper, integrating expressive brushwork, layered pigments, and experimental use of saturation to construct figurative dialogues between human and animal forms. The process begins with improvisational sketches that evolve intuitively, reflecting a methodology grounded in instinctive decision-making and emotional response. Each composition utilizes contrast, form, and chromatic intensity to create a third space of engagement, spotlighting a psychovisual environment in which viewer, subject, and symbolic spirit coexist. Works such as "Sunrise Partners," "The Wild Temptress & Her Serpent," and "In Her Swan's Eyes" employ deliberate tension between unconventional, vibrant hues and subdued backgrounds to handle both visual complexity and contemplative stillness. The findings emerging from this project underscore the value of intuitive process and vulnerability as instruments of meaning-making. The series contributes to ongoing scholarly conversations on artistic self-

reflection, emotional psychology, and the cross-species metaphors that shape visual culture. Future works will deepen this inquiry, exploring color, narrative, and emotional duality across the boundaries of self and spirit.

Abstract Name: Investigating the Oncogenic Activity of the FOXC2 Transcription Factor in Melanoma Cells Through Complimentary Genetic Ablation and Pharmacologic Inhibition Approaches

FOXC2, a member of the forkhead box family of transcription factors, is emerging as an important oncogene that has been linked to several hallmarks of cancer progression. Often dysregulated in cancers of epithelial origin, FOXC2 has also recently been found to promote the progression of melanoma, a non-epithelial-derived cancer. Though FOXC2 has been found to drive diverse oncogenic processes that include cell proliferation, metastasis, and drug resistance, the mechanisms by which this transcription factor does so remain poorly understood. To address these issues, we have employed two distinct approaches to study the oncogenic functions of FOXC2 in melanoma. First, using a dual guide RNA-targeting CRISPR-del gene editing strategy, we have engineered a *Foxc2* whole gene deletion variant of the murine B16-F10 melanoma that will serve as a useful tool for comparative studies with its parental FOXC2-expressing wild-type counterpart. To supplement this approach, we have also performed studies with the MC-1-F2 pharmacologic inhibitor of FOXC2, and we report herein a differential gene expression analysis of untreated versus MC-1-F2-treated B16-F10 melanoma cells. Our data provide valuable insights into not only the specific genes regulated by this transcription factor but also the biologic pathways and processes in which FOXC2-regulated genes are involved, suggesting potential mechanisms of FOXC2-mediated melanoma progression that can be further investigated in future studies with our engineered FOX2-deficient cell line.

Abstract Name: Identification of Fungi Isolated from Grand Caverns using DNA Barcoding

Bats, vital for biodiversity, face declines in North America due to White-Nose Syndrome (WNS), a fungal disease caused by *Pseudogymnoascus destructans*, and subterranean microorganisms show promise for producing antifungal molecules that may be useful in combatting this devastating disease. This study aimed to identify unexplored cave fungi isolated from Grand Caverns in Grottoes, Virginia, which could have potential bioactivity against *P. destructans*. Through DNA barcoding of fungal samples from four cave locations, we identified diverse genera such as *Mortierella*, *Linnemannia*, and *Aspergillus*. While no direct association with *P. destructans* was found, certain genera, like *Mortierella*, may have ecological connections to bat populations. Although the biological activities of these organisms have not yet been explored, members of these genera have been known to produce antifungal molecules, including those active against both human

and plant pathogens. Our findings support the growing evidence that caves host diverse fungal communities, and their utility as antifungal strains warrants further research. Understanding the role of cave fungi in these ecosystems could inform strategies for managing WNS and preserving bat populations.

Abstract Name: The Governmental Facilitation of the Color Line in Atlanta and Chicago During the Early Twentieth Century

Before the creation of the Federal Housing Administration during the New Deal, various levels of government facilitated residential segregation in Atlanta and Chicago, and Jim Crow laws influenced their approaches. This paper explores the multifaceted and complex nature of residential segregation by comparing residential segregation in Atlanta, a southern city, and Chicago, a northern city, in the early twentieth century. Furthermore, it demonstrates the influence of Jim Crow laws in racially segregating Atlanta and Chicago. While Atlanta's Jim Crow laws explicitly required the separation of Black and white Americans in every aspect of public life, Chicago did not impose this separation in the same way, but their laws implicitly developed and functioned in a similar way to Atlanta's official segregation laws did. These cities reflect national trends of residential segregation and their goals to racially segregate their populations without invoking moral upheaval. While residential segregation occurred on a national scale, state and local government policies contributed to the variance in how the governments manufactured it. Many scholars have explored residential segregation through a single-city case study, but a regional-scale comparative analysis provides insight on each level of governments' role in the advancement of residential segregation. This paper uses zoning maps, national homeownership campaigns such as the Own Your Own Home and the Better Homes Movement, and local newspapers to demonstrate federal, state, and local governmental facilitation of residential segregation. Residential segregation's legacy from the early twentieth century continues to shape the present, and each level of government has an obligation to rectify their actions through laws promoting integration. Integration and equity-based advancements must consider Derrick Bell's interest convergence theory, which reveals racial progress only occurs when it also benefits affluent whites. Bell's theory illustrates the importance of convincing affluent whites that residential segregation negatively impacts everyone before implementing policy reforms.

Abstract Name: Economic Impact on U.S. Pharmacies

This study examines the influence of key economic indicators on consumer spending in U.S. pharmacies and drugstores, comparing the pre-COVID (2015-2019) and post-COVID (2020-2024) periods. Studies have found that economic uncertainty drives complex changes in pharmacy spending patterns, with research showing an increase in the purchase of preventive medication during high unemployment (Kozman et al., 2012) and strategic consumer adaptations to inflation including bulk buying and greater use of cost-saving tools (Tichy et al., 2023). Using a multivariable linear regression analysis of 56 monthly observations per

period, the study investigated the relationships between retail sales and five economic indicators: price burden, pharmaceutical costs, general inflation, unemployment rates, and interest rates. This research revealed significant shifts in these relationships following the COVID-19 pandemic. Most notably, the interest rate coefficient reverses from negative (-216.097) to positive (1409.527), while the impact of the price burden substantially decreases from -2,734,438 to -244,251. The pre-COVID model demonstrated stronger predictive power ($R^2 = 0.921971$) than the post-COVID period ($R^2 = 0.804724$), suggesting more volatile economic relationships during the pandemic era. The unemployment rate impact weakened considerably, with its t-statistic declining from -4.94 to 1.63. These findings indicate a fundamental transformation of how economic indicators relate to retail sales, highlighting the need for adjusted business strategies and updated economic models in the post-pandemic retail pharmacy sector.

Abstract Name: Measurements of Radiation Damage Effects in DC-coupled Low Gain Avalanche Detectors

The effects of radiation damage on DC-coupled low gain avalanche detectors (LGADs) were studied. Measurements of leakage current, capacitance, and other characteristics, were taken of these detectors after exposure to 400 MeV protons of various fluences. These measurements were then compared to previous measurements of the same detectors before irradiation. These measurements will provide guidance for fast-timing instrumentation at future collider experiments.
