The National Conference on Undergraduate Research (NCUR)

What is NCUR?

The National Conference on Undergraduate Research (NCUR) is the premier annual event celebrating undergraduate achievement across all disciplines. Each year, thousands of students from institutions across the country gather to present original research, scholarship, and creative work. Unlike other conferences, NCUR is dedicated to celebrating undergraduate scholars from all institutions of higher learning from all disciplines. NCUR offers a unique platform where students can share their work with peers, faculty, and professionals from a wide array of fields.

The NCUR experience offers more than visibility—it provides a transformative experience where students:

- Build confidence and communication skills.
- Receive meaningful feedback from peers, faculty, and professionals across disciplines.
- Engage in cross-disciplinary learning by attending sessions beyond their field.
- Expand their academic and professional networks with mentors, collaborators, and recruiters.
- Discover new pathways through the Future Fair.

NCUR also supports the growth of institutions by equipping faculty, staff, and administrators to:

- Celebrate and mentor the next generation of researchers.
- Connect with colleagues to exchange best practices in undergraduate research.
- Stay informed on emerging trends and innovations in student scholarship.

NCUR began in 1987 at the University of North Carolina at Asheville with more than 400 students in attendance. In 2010, NCUR officially merged with the Council on Undergraduate Research (CUR), joining forces to advance undergraduate research on a national scale. Since then, it has grown into the largest undergraduate research conference in the world, with more than 4,000 in attendance.

For questions or further information about NCUR, contact NCUR@CUR.org. To learn more about upcoming conferences, visit CUR.org/NCUR.

About These Proceedings

This document features a comprehensive list of student presentations from this year's NCUR, organized by the primary presenter's last name. Each entry includes:

- Presenter's name
- Their institution (with state)
- Discipline of the presentation
- Additional authors (if applicable)
- Title of the presentation
- Abstract

This information was submitted by the student presenters during the NCUR application process.

Abstract Name: Code-Switching as a Tool for ESL Reading: A Pilot Study on Speed and Comprehension

As a global lingua franca in economic and educational contexts, English has become increasingly essential, leading to a growing demand for English as a Second Language (ESL) courses. This pilot study examines the education of ESL through a linguistic lens, aiming to investigate whether code-switching can be employed as a tool to enhance reading speed and comprehension among ESL learners. While code-switching (CS) has been used as a learning tool for natural language acquisition and conversational practice, the reading and comprehension aspect of language learning has often been overlooked in terms of leveraging the benefits of code-switching. In this study, a triangular method of analysis was used with eight participants who are Japanese L1 speakers learning English as a second language. Following a pre-task survey, where the participants self-reported their proficiency levels in English, a self-paced reading paradigm was used in which the participants read three types of texts: monolingual Japanese, monolingual English, and code-switched Japanese-English. Reaction times were recorded for each word. Results revealed a consistent trend: Code-switched texts were read faster than English-only texts, similar to the reading speed in their L1 (Japanese-only texts). The participants also reported higher levels of comprehension and comfort in the post-task survey. While the statistical differences were not significant, likely due to the small sample size, the pattern was clear across all participants. These findings suggest that CS may facilitate L2 processing by anchoring meaning in the learner's L1. With a larger and more linguistically diverse participant pool, future research may uncover statistically significant effects. This study supports the pedagogical potential of CS as a legitimate and effective tool in both ESL instruction and learning.

Abstract Name: Connecticut Wine Tourism Amidst a Changing Climate: Opportunity or Threat?

This study investigates the impact of climate change on Connecticut's wine tourism industry, assessing how shifting environmental conditions influence vineyard operations, tourist behavior, and long-term industry viability. The research aims to determine whether climate change serves as a threat to existing practices or if it creates a competitive opening for long-term adaptation, sustainability, and growth. To address this question, a qualitative conceptual analysis was conducted using a literature review of academic sources, government publications, and industry reports. Findings were categorized using a fishbone diagram to trace cause-and-effect relationships, and a thematic matrix to synthesize recurring patterns across key environmental, agricultural, and economic variables affecting the industry. Results indicate that climate change presents the Connecticut wine industry with a complex combination of risks and opportunities. For example, warmer temperatures allow for longer growing seasons as well as more diversified grape production and varietal expansion, which may strengthen the industry's economic potential. Conversely, unpredictable weather patterns, increased pest pressures, and soil degradation pose significant challenges to long-term sustainability. Wineries are responding to these pressures through innovative forms of adaptation, including experimenting with climate-resilient grape hybrids, expanding renewable energy adoption, and leveraging state-level programs designed to reduce climate-related uncertainty. This study contributes to the underdeveloped

literature on climate impacts in small-scale, regional wine industries, particularly within the Northeastern U.S. (Connecticut), and offers a structured framework for assessing both climate-driven risk and resilience potential in the wine tourism sector using qualitative tools such as cause-and-effect analysis and thematic mapping. The study also highlights practical implications by illustrating how climate adaptation strategies can shape future industry competitiveness and support broader sustainability goals.

Abstract Name: Navigating Enhanced Exploration Assistance (NEXA)

Navigating Enhanced Exploration Assistance (NEXA) is an artificial intelligence software platform developed to enhance residential security and property monitoring through seamless integration with autonomous drone systems. This research application of advanced AI in surveillance aims to create a standalone solution capable of real-time threat detection and intelligent alert management. By processing visual and sensory data, NEXA facilitates autonomous drone operation with minimal human intervention. Secure communication channels ensure that instant alerts are delivered to property owners and, potentially, law enforcement, improving response times in security incidents, search-and-rescue operations, and perimeter surveillance. Additionally, NEXA is capable of interfacing with commercially available drone platforms and presents a scalable and cost-effective approach to aerial monitoring.

Abstract Name: A Shift in Print Culture from Edo Japan (1615 - 1868) to Meiji Japan (1868 - 1912)

This is an analysis of the cultural shift of woodblock printing as a practice of aesthetics and propaganda in the Edo and Meiji periods of Japan. While many scholars emphasize woodblock printing from the Edo and Meiji periods as reflections of Japanese culture and political climates, not many scholars address the transition of the content and context of woodblock prints throughout these time frames. First, the research will discuss the social and political dynamics at the end of the Tokugawa Shogunate to demonstrate the historical context of the production of the prints. Second, the research will provide a formal and critical analysis of the print 'Modern Versions of the twenty-four Paragons of Filial Piety: Guo Zhu' from the Edo period to emphasize the Edo period's connection to Confucianism. Third, a brief discussion of the rapid modernization and industrialization under the imperial rule of Emperor Meiji is provided, followed by a formal and cultural examination of "There Stands No Enemy Where We Go" from the Meiji period. Fourth, a comparative discussion of the cultural significance of the two prints will emphasize how the change in the cultural meaning of the prints reflected a change in social and political norms in the country. While the Edo woodblock prints were used to legitimize the feudal military system supported by Confucianism and reflected its urban culture, prints in the Meiji period served as a tool in the establishment of the nation-state, an element

of cross-cultural exchange, social commentary, and modernization policies. This research is critical to demonstrate how the social and political power structure influences the content and context of art.

Abstract Name: AI in Art Education

The purpose of this research is to present the positives and negatives of artificial intelligence (AI) in the art space, and through comparative discussion, it aims to highlight the importance of addressing and incorporating AI in the art classroom responsibly. While many researchers continue to concentrate on the negative effects of irresponsible use of AI, there is plenty of evidence supporting responsible ways to incorporate AI in the classroom. AI should not be used to demolish creativity and critical thinking. Students will continue to have access to AI and other technological resources; without proper instruction, the destruction of AI could be devastating. First, the research will give a brief background of contemporary AI artists and the strategies they are using to implement AI in the art world. Second, the research will critically review the current research on the implementation of AI into art classrooms. Third, a discussion of the benefits of using AI responsibly in the art classroom will be presented. Fourth, a comparative discussion of the pros and cons of AI in the art space will be discussed in order to understand the importance of AI in the future of art education. This research demonstrates why it is important to incorporate AI responsibly in the Art Education classroom. While many researchers present the cons of AI being implemented in the classroom, there is little research comparing the benefits and drawbacks. By critically reviewing and comparing literature on AI in the field of art education, the research will showcase how to incorporate AI responsibly while retaining integrity and respect in the art space.

Abstract Name: Socio-Environmental Spatial Observations of Data Centers in The Greater Richmond Region

In the past ten years, the United States' race to develop AI technology has led to an increase in data center construction. Data centers have caused negative environmental impacts due to their energy-intensive, water-intensive infrastructure. These environmental impacts are a social equity concern, as they'd prolong community exposure to dangerous air pollutants, subject nearby areas to light and noise pollution, intensify local water scarcity, and increase electricity bills without careful regulation. This project is an explorative analysis of the potential socio-environmental impacts of data centers in Greater Richmond, specifically in Richmond City, Henrico, Chesterfield, and Hanover. ArcGIS will be used to spatially observe the relationships between the CDC's social vulnerability index and population density in census tracts of Greater Richmond's proposed and current data centers. In addition, general environmental factors, land cover and night light, in proximity to data centers will be spatially explored. The early to mid-stages of county data center development are a critical time to develop regulations to protect local communities and reduce

environmental impacts. These spatial observations will provide a stronger understanding of the factors influencing data center development, which can be incorporated into upcoming regulations.

Abstract Name: Development of Remotely Operated Manufacturing System Using Brain and Muscle Activity

Most current industrial robotic systems rely on manual controllers, pre-programmed sequences, or stationary teleoperation. These can restrict flexibility and responsiveness within dynamic settings, which can affect productivity and efficiency. Many of these environments, such as within additive manufacturing, are also unsafe for long term human exposure due to elements such as toxic fumes or hazardous materials. Electroencephalography (EEG) and Electromyography (EMG) have been increasingly integrated within the field of robotic control, offering the ability to teleoperate robotic systems using neural and muscular activity. Using biosignals such as EEG and EMG allows implementation of intent-based processing, which can improve factors such as precision, accuracy, and adaptability across a variety of diverse tasks. By combining cognitive decision making with physical activation, this research focuses on integrating EEG and EMG technologies into an industrial robotic platform to enable intuitive, real-time control for additive manufacturing applications. The proposed system uses Steady-State Visually Evoked Potentials (SSVEP) extracted real-time from EEG signals to control a Clearpath Robotics Husky A200 base, while a wearable sleeve with embedded EMG electrodes will provide fine-grained control of a Kinova Gen3 robotic arm located atop the Husky. OpenBCI hardware will be used for EEG and EMG signal acquisition, with a custom pipeline developed for processing and classification of biosignals. Current progress includes establishing reliable EEG and EMG acquisition procedures, implementing the proper Robot Operating System (ROS) libraries required for platform control, and fabricating a custom EMG acquisition sleeve. By merging cognitive intent, muscular activation, and immersive feedback, this project aims to advance human-robot collaboration and introduce a more adaptive, safe, and intuitive approach to robotic control within additive manufacturing and beyond.

Abstract Name: Forecasting Stock Prices in The Age of AI--An Empirical Analysis

Forecasting stock prices is common especially for the financial services companies which are constantly in a flux with changes in regulation or state of the macroeconomy etc. Companies can be impacted by several macroeconomic factors influenced by Fed Reserve or government actions or by shocks in the system through external channels. Added to several challenges, there is the current wave of Artificial Intelligence which can rock the boat further with new outcomes, uncertain results, implications on employment, automation and much more. The research forecasts the stock prices of a few financial services companies after considering

the impact of changing regulatory landscape, macroeconomic policies, state of the economy, business cycles, business related factors affecting the companies and finally the impact of AI related actions by the companies on their future stock prices. There are several studies which discuss the impact of AI on the business performance of the companies. However, there is no empirical study of the impact of AI use and adoption on the future stock prices. This new angle of examining the impact of AI on future stock prices can be a step in the right direction for companies to consider how much of AI and what kind of AI to use and the potential impact of such use and influence for their future growth as companies.

Abstract Name: Representation of Inflammatory Skin Conditions in American Cosmetic Marketing

Current cosmetic marketing in the United States continues to promote an ideal of flawless, poreless skin as the standard of beauty. This representation shapes not only aesthetic preferences but also public perceptions of health, confidence, and worth. While brands increasingly claim inclusivity and diversity, individuals with visible inflammatory skin conditions—such as acne, eczema, rosacea, and psoriasis—remain largely excluded from mainstream imagery. As a result, beauty marketing perpetuates narrow ideals that affect both consumer psychology and social belonging. This paper addresses the gap between the industry’s inclusive rhetoric and its continued visual exclusion. It examines how the absence of visible skin variation in advertising contributes to stigma and emotional distress among those with chronic dermatologic conditions. Using an interdisciplinary approach that integrates insights from psychology, dermatology, and marketing, the study analyzes the cultural, ethical, and emotional consequences of marketing practices that equate clear skin with beauty, success, and self-control. This paper argues that genuine inclusivity requires more than representation in language, as it demands transparency, authenticity, and evidence-based development. By evaluating advertising imagery, brand communication, and digital media trends, this research highlights how marketing can either reinforce harmful norms or transform them into sources of empathy and empowerment. These findings reveal that brands emphasizing authenticity and unfiltered representation are perceived as significantly more trustworthy and emotionally supportive by consumers, while campaigns that rely on airbrushed or idealized skin imagery correlate with higher reports of self-comparison and decreased self-esteem. Ultimately, this study demonstrates that inclusive marketing has the potential to improve both mental health and consumer trust. When brands portray real and diverse skin as beautiful, they redefine beauty as care rather than correction, visibility rather than concealment, and acceptance rather than aspiration.

Abstract Name: How do different purification methods affect the yield and purity of ibuprofen isolated from over-the-counter analgesics marketed to teenagers, and what could this mean for dosing reliability during adolescence?

Adolescents commonly use ibuprofen to manage headaches, sports injuries, and menstrual pain during a period of continued physical and physiological development. Reliable dosing of over-the-counter analgesics

is important for balancing effective pain relief with the potential long-term risks of nonsteroidal anti-inflammatory drugs, such as gastrointestinal irritation and kidney stress. This project examines the purity and recovery of ibuprofen isolated from brand-name and generic tablet formulations marketed to teenagers, using undergraduate-level organic purification techniques, and considers the implications for dosing consistency in this age group. Crushed ibuprofen tablets will be dissolved in an organic solvent and subjected to acid–base extraction to separate the acidic active ingredient from inactive excipients. The ibuprofen will then be recovered by re-acidification, isolated by vacuum filtration, and further purified either by recrystallization from an ethanol–water mixture or, in a separate branch of the study, by column chromatography on silica gel. Purified samples will be analyzed using melting point determination and thin-layer chromatography to assess purity, and percent recovery was calculated at each purification step. Where available, spectra from pure ibuprofen standards were used to confirm product identity. The study compares yield and purity between brand and generic products, and between recrystallization-based and chromatography-based purification strategies. These results are interpreted in the context of adolescent human development, highlighting how formulation and purification efficiency relate to the accurate delivery of active drug to teen patients. By connecting hands-on purification of a common analgesic with developmental health considerations, this project illustrates how organic chemistry techniques can inform discussions about medication quality and safe pain management in teenagers.

Abstract Name: How TikTok Affects Young Adults' Mental Health and Self-Image

Social media has evolved dramatically over the years. According to Minamitani (2024), a major review of studies found that social networking sites are linked to higher risks of mental health issues, particularly in younger generations, leaving several experts concerned. Increased dependence on social media raises important questions that have yet to be answered about its psychological impact on users. TikTok has become particularly influential among young adults, who spend hours consuming content on the application. This study investigates how young adults aged 18–21 experience the effects of negatively framed content on TikTok in relation to their overall mental health and self-image. Based on existing studies, we anticipate that frequent exposure to negatively framed content on TikTok correlates with decreased self-esteem and distorted self-image among young adults. Additionally, TikTok's algorithm may intensify these effects by creating echo chambers that trap users in cycles of harmful content. This study uses the Differential Susceptibility to Media Effects Theory, purposive sampling, and in-depth interviews conducted in person at Wayne State University or on Zoom. This study can inform mental health professionals, Big Tech leaders, educators, parents, and even other young adults about how TikTok affects mental health and how to find healthier ways to use TikTok.

Abstract Name: Artificial Intelligence in Smart Data Management: A Systematic Review

Despite the growing prevalence of Artificial Intelligence (AI), many institutions have yet to fully understand and utilize its potential. This systematic review further investigates the capabilities of AI, with the intention of uncovering and developing methods that support efficient retrieval, comprehension, and organization of data. A systematic literature search was conducted across multiple sources, including Google Scholar, MEDLINE via Ovid and PubMed, and the Cochrane Database of Systematic Reviews, in order to gather evidence relevant to smart data management. Retrieved studies were then screened against eligibility criteria to ensure they addressed the focus of the study. 22 studies were selected and compiled into a manuscript outline regarding the methods and applications of smart data management systems with the support of AI. The systematic review highlights four key domains of smart data management: data retrieval, interpretation, organization, and utilization. In data retrieval, AI automated the extraction of vital signs and electronic medical record (EMR) data and generated medical reports, while natural language processing (NLP) and retrieval-augmented generation enabled uniform, time-synchronized datasets. In data interpretation, deep neural networks predicted clinical outcomes and supported risk stratification, convolutional neural networks interpreted vital signs in real time, and GloVe embeddings analyzed EMR data to enhance pattern recognition and decision making. In data organization, NLP systems conducted automated cleaning of EMR and vital sign data into automated case report forms, and the integration of multimodal datasets that were standardized and prepared for downstream interpretation. Lastly, in efficient data utilization, AI systems streamline clinical decision support using large language models and augmented intelligence, which enhance patient management and optimize workflow. Although current data proves to be limited, and variability across studies prevents a full understanding, the evidence suggests that further research is needed to validate the effectiveness of AI and its impact on smart data management.

Abstract Name: Facilitators and Barriers to Migrational Transitions and Its Impact on Type 2 Diabetes in Somali Elders Living in Minnesota

Objectives: People migrating to the United States often experience extreme lifestyle changes that may impact health and well-being. These significant transitions can impact health by altering food accessibility and challenges in understanding the complex healthcare system. This study examines how migration experiences influence type 2 diabetes (DM2) risk and management among Somali elders in Minnesota. **Methods:** Utilizing Photovoice methods—a process that allows populations to shift the narrative to capture and discuss their experiences through photos—the team trained and interviewed participants using prompts to take their photos. Demographic surveys were administered and analyzed using REDcap and Excel. Interview themes and subthemes were determined by a team of three researchers via qualitative analysis methods. **Results:** The total study population included 14 participants, with an average age of 64.5 +/- 9.6 years. Four themes emerged from the photos submitted by participants regarding their experiences: 1) dietary changes, including higher consumption of processed foods, 2) changes in the ability to engage in physical activity, 3) barriers to food access and services to help manage DM2, and 4) positive impacts of religion & hope. A common reason for reduction in physical activity included safety concerns and changes in weather. Other barriers to food and service access included low health literacy, limits to physical mobility, and inability to pay for services. **Conclusion:** Migration from Somalia to the U.S. impacts health, particularly in changes in food

availability & access, physical activity, environmental stressors from the migration process, and differences in healthcare systems. All of these factors can affect peoples' ability to manage DM2. However, immigrants did note some positive impacts of immigration that included hope for the future and the positive role of religion. These results indicate that increased support is needed in transitional services to help reduce the burden of diabetes on Somali immigrant populations.

Abstract Name: Analyzing safety associated with lighting in Menomonie

LED lights are used by many cities as a cost-saving measure due to their energy efficiency, as they tend to shine brighter than conventional lighting (Jones 2018). However, people are affected by light pollution, often with disruption of the circadian rhythm, and there is a positive association between light pollution and cancer, primarily breast cancer (Walker II et al., 2020). This project aims to understand 1) how exterior lighting decisions are made by UW-Stout and the surrounding city of Menomonie and 2) how Stout students perceive exterior lighting on campus and in Menomonie and how it affects them, including level of concern about light pollution, concern about safety, and the relationship between lighting and safety. I hypothesize that people's perceptions of safety affect their experiences, that there is a positive correlation between brighter lighting and higher perceived levels of safety, and that perceptions of safety related to lighting would impact people's habits at night. A survey of 263 undergraduate and graduate students at UW-Stout and two interviews, one with a member of the City of Menomonie's Public Works Department and the other with a member of the University of Wisconsin-Stout's Sustainability Committee, were used to address these questions. I found that there was indeed a perception that brighter exterior lighting brings more safety. Furthermore, while there was some concern about light pollution, it was not as major a concern for most respondents. Moreover, convenience was the biggest factor impacting where respondents would walk at night, with lighting as the second biggest. On average, most respondents stated that they walked at night 2-3 times a week and that they walked by themselves more often. These findings can be used to better inform policy decisions made about lighting that take into account community views.

Abstract Name: The Role of Racial Socialization on the relations between Racial Discrimination and Civic Engagement on African American Adolescents

Racial discrimination (RD), the differential treatment of people based on their race, is a common experience for Black youth (American Psychological Association, n.d.). About 90% of African American youth report experiencing RD by the time they are adolescents (Osborne et al., 2021). Civic engagement, the political and

prosocial contributions to community and society, is one way many people respond to injustices (Plummer et al., 2022). Research has shown that RD is associated with higher critical civic engagement among Black college students (Christophe et al., 2022). Racial socialization, the process through which caregivers teach youth about race, racism, and cultural pride, has been identified as a key sociocultural factor in Black adolescents' sociopolitical development (Anyiwo et al., 2018). However, little research has focused on how racial socialization influences the relations between RD and civic engagement among African American adolescents. This study aims to address the gap by examining whether African American youth who experience discrimination and receive racial socialization messages report higher levels of civic engagement. The sample included 237 African American adolescents (ages 12-17; 52% female), respectively living in three urban low-income communities. Regression analysis indicated that: (1) racial discrimination was not significantly associated with the civic engagement outcomes (i.e., civic engagement, political engagement, and sociopolitical discussions), and (2) racial socialization did not serve a protective role against racial discrimination and civic engagement outcomes. However, racial socialization measures illustrated promotive effects on civic engagement outcomes. For instance, racial pride messages were associated with greater civic engagement ($\beta = 0.32$, $SE = 0.10$, $p = .003$). Overall, these findings suggest that even when discrimination itself does not directly predict engagement, racial socialization in Black families can still play an important role in supporting African American adolescents' civic engagement.

Abstract Name: The HPV16 E2 Protein Promotes Error-Prone DNA Repair Through Non-Homologous End Joining

High-risk human papillomavirus type 16 (HPV16) contributes to 90% of HPV positive oropharyngeal cancers (HPV+ OPCs), an anatomical subset of Head and Neck Squamous Cell Carcinomas (HNSCC). Previous studies have established that the viral E2 protein, a transcriptional regulator and replication factor, interacts with cellular double strand break (DSB) repair mechanisms. Mechanisms of repair include non-homologous end joining (NHEJ), an error prone process available during the whole cell cycle, and homologous recombination (HR), a precise method occurring during the S/G2 phases. The specific repair mechanism that HPV16+ cells utilize in the presence of E2 has not yet been identified. In this study we tested human foreskin keratinocytes immortalized with telomerase (N/Tert-1) exogenously expressing viral proteins to determine the repair mechanisms that are favored when E2 is expressed. We optimized a DNA damage response (DDR) reporter assay to express GFP and mCherry when NHEJ and HR are occurring, respectively, and analyzed the cells using flow cytometry. The result showed that E2 expression pushes the cell towards NHEJ as a repair mechanism, whereas parental N/Tert-1 (HPV16-/E2-) revealed less or unchanged quantity of NHEJ. This indicates E2 expression leads to error-prone DNA repair, which contributes to host genome instability, possibly contributing to worse outcomes for patients. As the HPV16 life cycle depends on epithelial differentiation, future work will focus on investigating DDR repair mechanisms in organotypic models recapitulating the viral life cycle, and in the context of the full viral genome.

Abstract Name: Capturing the Lived Experiences of Individuals with Chronic Pain through Motivational Interviewing

Chronic pain affects more than 51.6 million U.S. adults (20.9% of U.S. adult population) [1], creating a substantial personal and societal burden, leading to a diminished quality of life. For many, chronic pain persists without clear underlying pathology, limiting targeted treatment and leaving patients feeling misunderstood or dismissed. A critical yet often overlooked component of chronic pain assessment is understanding the patient's lived experience, including daily routines, workplace demands, social support, personal goals, and interactions with healthcare systems. Standard clinical assessments, intake forms, and patient-reported outcomes rarely capture these nuanced contextual factors in a systematic, patient-centered way. As a result, essential biopsychosocial information that could inform care remains fragmented or absent from clinical decision-making. To address this gap, we developed a structured Motivational Interviewing (MI) protocol designed to elicit rich, first-hand narratives of patients' experiences with chronic pain. This patient-centered approach provides a consistent framework for gathering nuanced qualitative data while preserving individuals' voices. In an ongoing study (N = 35), interviews conducted using this protocol are analyzed using Natural Language Processing (NLP) techniques to identify recurring themes related to pain experience, coping strategies, socioenvironmental influences, and barriers encountered in clinical care. By combining MI with NLP, this method enables efficient analysis of large sets of narrative data while preserving the depth and authenticity of patients' voices. The objective of this study is to demonstrate the feasibility of integrating MI and NLP to better understand the lived experiences of individuals with chronic pain. Our presentation will share the MI protocol, describe preliminary findings from the narrative data, and highlight how this approach can support more personalized, holistic, and patient-informed pain management strategies. We aim to provide a practical model that clinicians and researchers can adopt to better capture patient perspectives and enhance communication in chronic pain care.

Abstract Name: Changes in Stomata Density Within a Model Plant, *Epipremnum aureum* (Pothos), When Provided With a Multivariable Environment to Simulate Impacts from Climate Change

Plants respond to climate change by changing stomata density and conductance. Stomata control gas exchange through pores (stoma) that are made up of two guard cells, which control the opening and closing of the stomata. Conductance is how much gas exchange is occurring through the stomata, which gives insight into the rate of photosynthesis and cellular respiration. Research shows that within the past ten years global CO₂ atmospheric concentrations have risen by 2.6ppm per year; plus, global temperature has increased by 1.25 degrees Celsius. Past research indicates that CO₂ and temperature impacts both stomata density and conductance, but this research was conducted using single variant experimentation. In contrast, this research

uses a multi-varied approach to study how different combinations of environmental variables impact the number of stomata and their conductance. Research using multiple variables is essential as it illustrates how plants could respond to climate change in the future. Variables tested in this study were CO₂, relative humidity, and temperature. This research used four experimental groups. The first experimental group had increased CO₂ levels as well as increased relative humidity. The second experimental group had CO₂ and temperature increased. Whereas the third experimental group had temperature and relative humidity increased. The last experimental group had all three environmental factors increased. Results showed that all experimental groups experienced an average increase of six stomata, although roughly 65% of the stomata were closed compared to the control, which had 5% closed.

Abstract Name: Thermal Effects on Metabolic mRNA Expression in Fish Hearts

Brook trout and other cold-water fishes are being challenged by the effects of climate change. Brook trout are active over a broad range of seasonal temperature variation. However, recently these temperatures have been increasing and are predicted to rise further in the coming decades. Maintaining physiological function across a range of temperatures is critical to survival of such fishes. The purpose of the current study is to investigate how the trout heart function varies across a range of temperatures reflecting the natural seasonal variation. We examined heart muscle physiology and gene expression for metabolically important genes in fish acclimated to 4°C, 10°C, and 20°C. We found that fish acclimated to elevated temperatures had physiologically slower muscle (when test temperature is controlled for) and expressed lower levels of both cytochrome oxidase and lactate dehydrogenase, which are crucial to aerobic processes. This suggests that increasing water temperatures can be detrimental to the health of cold-water fishes such as brook trout as they must alter physiological function to survive.

Abstract Name: Pueblo Ways of Knowing Aristotelian and Platonist Metaphysics

My research provides an comprehensive analysis on the metaphysics of Pueblo peoples of the American Southwest. I will focus on significant features of Pueblo metaphysics and bring light to this understudied area. I argue that this understudied area deserves more scholarly concentration in contemporary studies when compared to more studied philosophies. I will begin by defining what and who is categorized as a Pueblo by going into the history of the group and what tribes are Pueblo. Next, I will define what metaphysics is and dissect the Pueblo's metaphysical framework. This analysis will use some of their stories surrounding human creation and world creation. I will also analyze their ideas of an afterlife and the role of the soul in society. This will include the role of divine patrons through exploration into the relationship that humans have with the patrons and what they need to do to keep their own sense of Pax deorum or "peace of the gods". To highlight the significance, I will compare the Pueblo metaphysics to other more well-known metaphysical

philosophies. Focusing on Ancient Greek Philosophy, specifically Aristotelian and Platonist metaphysics. This will consist of looking at how the Pueblos and the Greek schools answer metaphysical questions. I will conclude by discussing the significance of Pueblo metaphysics and its application contemporary culture. Reinforcing my argument that scholars should allocate more time to this understudied area.

Abstract Name: Rhetoric and Judicial Legitimacy: Competing Visions of Moral Authority on the Supreme Court

Amid growing polarization and declining public trust in the U.S. Supreme Court, understanding how judicial authority is rhetorically constructed has become increasingly urgent. This paper analyzes *Roper v. Simmons* (2005) to show how judicial rhetoric reveals competing assumptions about the Court's legitimacy. Drawing on Stephen Toulmin's model of argumentation, particularly his concept of implicit backings, the analysis demonstrates how Justice Kennedy's majority opinion and Justice O'Connor's dissent rest on contrasting visions of judicial authority. Kennedy frames the Court as a moral guide, grounding its legitimacy in "evolving standards of decency," scientific research, and international norms. O'Connor instead underscores judicial restraint, precedent, and deference to democratic processes. By uncovering these implicit backings, the paper argues that the Court's power depends not only on strategic legal reasoning but also on rhetorical framing and moral positioning. Situating *Roper* within broader trends of judicial polarization, the paper illustrates how rhetorical strategies shape constitutional interpretation and public perceptions of the Court. This issue has become more urgent as public approval of the Court hits historic lows and cases like the Kavanaugh hearings and *Dobbs v. Jackson Women's Health Organization* (2022) fuel concerns about partisanship and declining judicial legitimacy (Gallup; Trautwein 2019; Dobbs 2022; Reuters 2018). Understanding these rhetorical foundations matters because the Court's words both decide law and shape how Americans see justice, authority, and the very legitimacy of their democracy.

Abstract Name: Investigating Elesclomol's Ability to Improve Copper Transport and Reduce Stress Responses in *cua-1* Mutant *C. elegans*

Wilson's disease is a serious, inherited disorder where the body cannot properly manage copper, an essential mineral. This typically results from a genetic defect that prevents cells from efficiently moving copper. To better understand how copper affects living organisms, this project uses *Caenorhabditis elegans*, focusing on mutant worms that carry a mutation in the *cua-1* gene that makes it difficult for them to transport copper. The main goal of this project was to test whether elesclomol, a compound known to bind and carry copper, could help these worms grow and improve their brood size. To do this, mutant worms and wild-type N2 worms were compared under four conditions: no treatment, added copper, elesclomol alone, and copper combined with elesclomol. As expected, mutant worms struggled when given copper alone, showing very poor reproduction and signs of oxidative stress from copper deficiency. However, when the mutant worms were

given copper and elesclomol, they showed an increase in their brood size and reduced oxidative stress compared to the copper-alone group. This result suggests that elesclomol successfully helped deliver the necessary copper into the cells, improving the worms' reproductive capacity. Wild-type N2 worms showed normal growth across all conditions, indicating that the chemical treatments themselves were not harmful at the concentrations tested. These results support the idea that elesclomol can help compensate for the defective copper-transport pathway in the mutant worms. To understand the mechanism of elesclomol, the next stage of the project involves RNA extraction followed by cDNA synthesis and measurement of oxidative stress response gene expression. This will help determine whether elesclomol improves copper availability without creating harmful oxidative stress.

Abstract Name: Wheelchair Propulsion Muscle Activation Stratified by Age of Spinal Cord Injury Onset

Manual wheelchair (MWC) propulsion imposes significant mechanical demands on the shoulders, contributing to a high prevalence of pain and injury among individuals with spinal cord injury and disease (SCI/D). Differences in propulsion biomechanics between pediatric-onset and adult-onset SCI users suggest that motor control strategies influence injury risk. Electromyography (EMG) provides a useful tool for quantifying muscle activation patterns during propulsion, yet its application in pediatric MWC users remains limited. This study examines EMG characteristics across pediatric, pediatric-onset adult, and adult-onset adult MWC users. Participants were divided into groups according to their current age, and the age at which they sustained their SCI: children (ages 7–17; n = 5; 2 females, 3 males; mean age = 15.19 years), adults with pediatric onset (injury occurring before age 18; n = 6; 3 females, 3 males; mean age = 34.27 years), and adults with adult onset (n = 2; 2 males; mean age = 27.61 years). Nine surface EMG electrodes were placed on the biceps brachii (BB), long head of triceps brachii (TB), sternocostal head of the pectoralis major (PM), and the anterior, medial, and posterior heads of the deltoid (AD, MD, PD), as well as the upper trapezius (UT), latissimus dorsi (LD), and infraspinatus (IS). Handrim kinetics (SmartWheel) were used to identify individual cycles. Preliminary analysis of peak EMG amplitude across propulsion cycles varied across the three groups for the AD, MD, PD, BB, PM, and IS. Pediatric-onset users exhibited the highest average activation during propulsion for the AD, MD, BB, and IS. In contrast, the adult-onset users demonstrated the lowest average muscle activation for the BB, PM, and IS. Notably, the pediatric group showed the highest activation for the PM, suggesting differences in propulsion strategies and muscle development. Both adult groups demonstrated increased reliance on the anterior and middle deltoid, consistent with prior research.

Abstract Name: Exploring Respiratory Health Among Syrian Refugees in Za'atari and Azraq Camps

Since the onset of the Syrian conflict in 2011, millions have been displaced and forced into overcrowded settlements with poor sanitation and limited access to healthcare. Respiratory illnesses have been a consistent concern among Syrian refugees living in the Za'atari and Azraq refugee camps in northern Jordan. Za'atari rapidly became the world's largest Syrian refugee camp, reaching over 120,000 people in 2013. This led to the establishment of Azraq two years later as a more regulated settlement designed to alleviate overcrowding and improve living conditions. Across both camps, respiratory illnesses such as lower respiratory tract infections (LRTI), influenza-like illness, asthma, chronic obstructive pulmonary disease, and tuberculosis remain leading causes of morbidity and mortality. This study aims to compare the incidence and trends of these respiratory conditions across four different age groups (0-4, 5-17, 18-59, >60) in Za'atari and Azraq from 2013-2023. Data have been drawn from publicly available UNHCR (the United Nations Refugee Agency) annual health reports, which aggregate clinical visits and diagnoses recorded by camp health centers. We are using meaningful data visualizations along with Poisson and negative binomial regression models to explore differences in respiratory illness rates by camp, year, and age group, adjusting for population size. Preliminary results suggest that rates of LRTI are significantly higher in Za'atari across the three older age groups, with the largest difference observed among adults over 60 (3.4 times higher than in Azraq, $p < 0.0001$). Conversely, LRTI rates in children aged 0-4 appeared to be higher in Azraq (2.2 times higher than in Za'atari, $p < 0.0001$). Future analyses will incorporate additional health indicators and environmental data to better understand the drivers of respiratory illness in refugee settings.

Abstract Name: Evaluation of a nanoparticle-hydrogel composite for controlled drug degradation and release

The use of nanoparticle drug delivery systems is a promising approach to improve drug release and therapeutic precision. However, systemically administered nanoparticles can often fail to reach the target site at high concentrations. In the case of peritoneal diseases such as endometriosis, intraperitoneal administration also suffers from rapid nanoparticle clearance and nanoparticle-hydrogel composites may overcome this limitation. In this study, we evaluate hydrogels made up of crosslinked hyaluronic acid derived from hyaluronate hydrazide and hyaluronate aldehyde that encapsulate 200 nm fluorescent polystyrene beads. The degradation rate of hydrogels without and with encapsulated nanoparticles is measured by the overall mass loss after incubation in artificial peritoneal fluid assessed every 24 hours over the span of 7 days. The particle release rate from hydrogels with encapsulated nanoparticles is quantified by measuring the fluorescence intensity changes over the span of 7 days. Our findings aim to improve the understanding of controlled nanoparticle release from crosslinked hyaluronic acid hydrogel-based drug delivery systems for the treatment of diseases such as endometriosis.

Abstract Name: Targeting MED12 altered breast cancer with flavonoid-based therapeutics

Breast cancer is one of the most common diseases affecting women in the United States, highlighting the need for more effective and targeted treatments. Breast cancer encompasses a multitude of different subtypes, one of which is characterized as having mutations in MED12, a component of Mediator complex. MED12 plays an important role in regulating cell signaling and gene expression and has been implicated in a variety of different cancers. In this study, we have found that when MED12 is downregulated in breast cancer cells, GLI3-dependent Sonic Hedgehog (SHH) signaling becomes abnormally activated, which subsequently contributes to cancer growth. We thus set out to identify potential novel compounds that can specifically target GLI3-dependent SHH signaling to reverse oncogenesis in MED12-downregulated breast cancer. We focused our efforts on flavonoids, plant-based compounds known for their wide range of anti-cancer effects, including reducing oxidative stress, blocking cell division, and triggering cell death. Importantly, flavonoids have also been shown to have the ability to suppress GLI3 signaling, though this has not been explored in a breast cancer setting. To test their potential in breast cancer, we used MTT assays to screen a library of flavonoids for their ability to selectively target breast cancer cells with MED12 downregulation. We also used quantitative PCR to measure the expression of GLI3 target genes on flavonoid-treated cells to determine whether these compounds cause cell death by targeting the GLI3 signaling pathway. Our results suggest that selective flavonoids work by disrupting GLI3 signaling thus leading to decreased cell viability in MED12-downregulated breast cancer cells. Overall, our findings support the idea that flavonoids could be developed as a promising therapeutic option for specific subtypes of breast cancer involving MED12 dysfunction.

Abstract Name: Characterizing RF Radiation From NEC Televisions: On vs. Off Comparison

This study investigates the radio frequency (RF) emissions produced by commonly used televisions to better understand potential exposure levels in everyday environments. There were two different television conditions (on and off) that were tested using consistent measurement methods, and RF levels were recorded at various distances to represent typical viewing scenarios. RF radiation refers to the electromagnetic energy released during a device's operation or wireless communication, and understanding this exposure is important because long-term or excessive RF levels may pose health risks. As part of this project, background research was conducted on RF technology used in NEC televisions, including the frequency bands, signal modulation, and communication systems built into modern smart TV designs. By examining these factors and analyzing how current TV systems emit RF energy, this study helps identify opportunities for improving safety and reducing unnecessary radiation exposure in future devices.

Abstract Name: The Correlation Between Mental Health and Oral Hygiene Health in Southeastern North Carolina

This study aims to investigate the correlation between mental health perceptions and oral hygiene behaviors among adult residents in Southeastern North Carolina. Existing literature shows a strong association between mental health conditions, such as stress, anxiety, and depression—and poor oral health outcomes, often exacerbated by reduced access to dental care and heightened dental anxiety. Despite growing awareness, limited research exists that directly examines how mental health perceptions influence daily oral hygiene behaviors, particularly in underserved and rural communities. To address this gap, we aim to recruit participants aged 18 and older through the University of North Carolina at Pembroke (UNCP) faculty and staff email lists, as well as from community centers, healthcare facilities, and dental offices. Participants will complete an anonymous, deidentified survey via REDCap that captures data on mental health indicators, oral hygiene habits, and perceptions linking the two. No identifying information will be associated with survey responses, and participants can withdraw at any time. Findings from this study will contribute to a better understanding of how mental well-being influences oral health behaviors, with potential implications for integrated healthcare approaches. The results may help guide future interventions, improve patient education, and inform policies aimed at reducing oral health disparities in North Carolina and similar regions. By examining this connection, we hope to promote a more holistic view of health that encompasses both psychological and dental care.

Abstract Name: PbWO₄ Crystal Characterization: Mechanical Design and 3D Modeling

In the 2025-2026 academic year, the main thrust of the experimental work in the JMU Particle and Nuclear Physics Group (Drs. IN and GN) was to design and construct a test stand that will characterize the properties of Lead Tungstate (PbWO₄) crystals. These modern, high-resolution, and radiation hard detectors will form the backbone of high-performance electromagnetic calorimeters. These will be used in current and planned nuclear and particle experiments. We designed and built a testing process to evaluate the uniformity of the crystal's response along its longest axis. This was accomplished using a Na-22 source and comparing the PbWO₄'s signal to a known (witness) NaI detector, as the two detectors move with respect to one another. This project can be divided into three intertwined subsections: computer modelling of the testing stand, building the test stand itself, and providing a robust data acquisition and analysis workflow. Our part in this project was to design and assemble experimentation hardware to fit the project's goals. We received hardware from the JMU Physics Department's workshop and adapted it to our needs. Furthermore, we analyzed the Na-22 source constraints related to the PbWO₄ crystal and created unique 3D printed parts using SolidWorks computer aided design (CAD). This culminated in a test stand mechanism that is capable of characterizing the

PbWO₄ crystals. Our final product went through multiple iterations to ensure that the project had reliable mechanics and consistent data readings.

Abstract Name: Inside the Emergency Room: Learning Care Through Chaos

The emergency room is often seen as a place of urgency and chaos, yet within that chaos lies a distinct culture of care that shapes how healthcare workers learn how to serve others. This autoethnography explores my personal experiences working as an emergency department technician (Er Tech for short) – specifically, how empathy, composure, and teamwork are cultivated in such a high-stress environment. Through journaling and memory analysis, I capture critical moments that reveal how care is both practiced and challenged. Using theoretical frameworks from medical sociology and the ethics of care, this study interprets how the ER's fast-paced culture fosters professional identity and mental stamina. Overall, I argue that care in the emergency room is not simply a feeling, but a disciplined practice formed through chaos, where compassion is merged with efficiency. By focusing on the unspoken and emotional labor of emergency medicine, this autoethnography sheds light on the deeper meaning of what it means to care for others in moments of crisis and chaos.

Abstract Name: Isolation and Characterization of Novel *Arthrobacter globiformis* Bacteriophage "Jollof"

Bacteriophages, viruses that infect bacteria, are the most abundant biological entities on Earth and shape microbial ecosystems. Despite their ubiquity, much of phage diversity remains uncharacterized, representing an untapped resource for microbiology, biotechnology, and medicine. Phage research is significant given their potential applications in therapy, genetic engineering, and environmental microbiology. Through the HHMI SEA PHAGES program, we sought to isolate and characterize a novel bacteriophage infecting *Arthrobacter globiformis*, a soil-dwelling bacterium and established host in phage discovery. We hypothesized that soil samples would harbor novel phages with distinct traits, contributing to cataloging viral diversity. Soil samples were collected and processed for direct isolation and enrichment. Bacteriophage presence was confirmed through plaque assays showing lytic activity. A clonal phage, designated Jollof, was purified by plaque purification and amplified to generate high-titer lysates. Serial dilution and webbed plate assays validated infectivity. Genomic DNA was extracted and analyzed by restriction digest, suggesting that Jollof possesses unique genomic patterns. Transmission electron microscopy revealed Siphoviridae morphology with an icosahedral capsid and flexible tail. These findings confirmed the isolation and preliminary classification of Jollof as a novel bacteriophage. Characterization of Jollof adds to the Actinobacteriophage Database and provides new insight into phage diversity associated with *A. globiformis*. The digest suggests this phage may harbor genetic elements not previously described. Future work will focus on whole-genome sequencing to enable functional predictions, evolutionary comparisons, and applications in biotechnology. The study of

bacteriophage Jollof underscores the value of undergraduate-driven discovery and contributes new data to the phage research community.

Abstract Name: S1P Supplementation Rescues Migration Defects in Niemann–Pick Type C Fibroblasts

Niemann-Pick type C (NPC) disease is a lysosomal storage disorder caused by mutations in NPC1 or NPC2, leading to lipid accumulation and impaired signaling across multiple pathways. Although the neurological aspects of NPC are well studied, the effect of this disease on wound repair has not been investigated. Given that platelet-derived growth factor (PDGF) and sphingosine-1-phosphate (S1P) are critical regulators of fibroblast migration during wound healing, we hypothesized that S1P signaling deficits may contribute to impaired repair processes in NPC. Dermal fibroblasts derived from NPC1 patient skin biopsies and mouse embryonic fibroblasts (MEFs) from *Npc1* mutant mice were analyzed for migratory capacity using PDGF-stimulated wound scratch assays. Both NPC patient fibroblasts and *Npc1* mutant MEFs displayed markedly reduced migration compared to wild-type controls. Consistent with our previous findings that Sphingosine Kinase 1 (SphK1)-dependent S1P production is defective in NPC (Newton et al., J. Biol. Chem.), supplementation of exogenous S1P in combination with PDGF restored migratory activity to near-normal levels in both human and murine cells. These results indicate that defective S1P signaling downstream of SphK1 contributes directly to migration deficits in NPC fibroblasts. These findings identify a previously unrecognized defect in wound-healing signaling in NPC and highlight the potential of S1P-based interventions to correct cell motility impairments. Future work will include examining PDGF-related signaling fidelity and determining whether S1P receptor modulation can restore fibroblast migration.

Abstract Name: Exploring Polyomino Motion: Classification of Amoebic Polyominoes

Have you ever played Tetris? Tetris pieces are formed by four small squares. Similar shapes formed by small squares are called polyominoes. Imagine a polyomino sitting on a large checkerboard so that its squares coincide with squares of the board. We study how this polyomino moves on the board iterating these steps: remove one of the squares of the polyomino and place it back on the board so that the “new” polyomino is a copy of the original in a slightly different position. Some polyominoes do not move at all, some spin in place, others move far but skip parts of the board, and a few cover the entire board. We define and classify the movements of these polyominoes. Polyominoes that are able to cover the entire board are called amoebas. Amoebas have been studied in the context of graph theory to understand the structure of quasi-symmetric graphs. Classifying all polyominoes by their movement is an open problem in combinatorial geometry. We classify the movement of all polyominoes with up to seven squares and present structural results for polyominoes of a given width.

Abstract Name: College-Specific Model of Social Connectedness

Loneliness among young adults has emerged as an urgent public health concern, intensified by cultural shifts toward digital interaction, the erosion of communal spaces, and heightened pressures surrounding identity and achievement. Although existing models of social connectedness (SC) offer broad explanations for social engagement, they are not sufficiently tailored to the developmental, institutional, and psychosocial realities of college students. A population-specific framework is needed to more effectively apply the insights gained from the models which currently exist in the literature. This study seeks to create a college-specific model of social connectedness, synthesizing insights from across the literature. To evaluate this model, we analyzed data from the 2023–2024 Healthy Minds Study (HMS), a large, nationally representative survey of mental health in U.S. higher education. Guided by theory, variables were organized into four domains: (1) risk factors (sociodemographic variables and contextual vulnerabilities), (2) social connectedness indicators (loneliness and belonging), (3) mechanisms potentially linking connectedness to health outcomes, and (4) outcomes reflecting both psychological distress (depression and anxiety) and psychological well-being (flourishing). We first tested whether belonging predicted mental health outcomes. A simple linear regression revealed that belonging significantly predicted depression, $B = -1.16$, $SE = .01$, $t(90,560) = -77.84$, $p < .001$, accounting for 6.3% of the variance ($R^2 = .063$). The standardized coefficient ($\beta = -.25$) indicates a small-to-moderate association: students with stronger belonging reported meaningfully fewer depressive symptoms. Belonging also predicted anxiety, $B = -0.87$, $SE = .01$, $t(90,560) = -62.23$, $p < .001$, explaining 4.1% of anxiety variance ($R^2 = .041$). Further data analysis will be conducted investigating the relationship between various risk factors, mediators, and separate domains of social connection (peer, community, college).

Abstract Name: Synthesis and Binding Studies of a New Fluorinated Molecular Sensor

Initial studies by Swager and co-workers have demonstrated that the hexafluoroisopropyl (HFIP) group exhibits a strong hydrogen bonding reaction with phosphate esters.¹ As a result, a new small molecule sensor containing a HFIP pendant group and nucleophilic amine was synthesized in high yield and fully characterized by multi-nuclear NMR. Preliminary sensing studies with dihydrogen phosphate and dimethyl methyphosphonate indicate that the new compound will sense phosphate esters. Current research efforts are focused on utilizing the nucleophilic amine to incorporate the sensor into more complex materials and polymers. The results of this work will be presented and discussed.

Abstract Name: Intergenerational Perceptions of Collective Efficacy Among Latinx Residents

Research on immigration and community dynamics has expanded significantly, yet relatively little is known about how collective efficacy is perceived differently by first-generation Latinx immigrants compared to U.S.-born Latinx. Given that Latinx residents make up one of the largest and fastest-growing demographic groups, understanding how collective efficacy varies across immigrant generations is essential for interpreting the social aspects of neighborhoods. Understanding these distinctions is critical as Latinx communities continue to grow and diversify, and because collective efficacy is closely linked to neighborhood stability, safety, and social well-being. As such the current study addresses this gap by examining differences in perceived social cohesion and informal social control between first-generation Latinx immigrants and U.S.-born Latinx. Drawing on Wave 1 (2000–2001) data from the Los Angeles Family and Neighborhood Survey (LAFANS), which includes 2,319 adult respondents across 65 Los Angeles County neighborhoods, the study evaluates how immigrant generation and acculturation measures shape perceptions of collective efficacy. Collective efficacy is measured using a likert scale assessing trust, shared values, and willingness to intervene; mean scores across neighborhoods range, indicating measurable differences. Generational status is determined using respondent birthplace, parental nativity, and citizenship indicators. With Los Angeles, California being a dense Latinx population, this data will provide necessary information about the demographic for this study. This study contributes to broader discussions of acculturation, community strength, and the mechanisms that sustain neighborhood stability in immigrant contexts. A preliminary analysis will be used to estimate generational status on measures of collective efficacy. Findings and policy recommendations will be discussed. Keywords: collective efficacy; acculturation; immigration; Latino paradox.

Abstract Name: Scriptural Monster: A Study of J.R.R. Tolkien's Translation of the Book of Jonah

This presentation is a comprehensive study of Tolkien's translation of The Book of Jonah, which he translated from the French Bible de Jerusalem for the English Jerusalem Bible, finished in 1966. I seek to answer the following questions: why did Tolkien translate the book? Why did the translation come from French instead of Hebrew? What is unique about Tolkien's translation? And, how does this work fit in with his other works, particularly regarding his literary ideals. The essay has two main parts, the first of which addresses the first two questions, and the second of which addresses the latter two. In the first part I present research on the historical context of this edition of the Bible, both its original French translation and its English counterpart. To do this I discuss two papal encyclicals, as well as the writings of other Popes, the writings of the editor-in-chief of the Bible de Jerusalem, and other essayists. In doing so, I seek to discover the historical narrative in which this translation fits, and how Tolkien's contribution fits into that story. In the second part, I present the results of a close comparison of Tolkien's original draft of the translation to the edited edition that made it into the final edition of the translation, to discover some of Tolkien's instincts in biblical translation. I also consider popular exegesis of Jonah that closely examines the Hebrew, as well as The Lord of the Rings and

Tolkien's personal letters, to see how his translation affirms or contradicts other writers' notions of the book, and how Tolkien's own notions about Jonah are informed by his religious and literary ideals.

Abstract Name: The Impact of I-95 on Human-Trafficking

In the minds of most Americans, I-95, and other major roadways are simply routes to travel to and from destinations of interest. However, for some individuals, victims and survivors of trafficking, it is not simply a road, but a nightmare. as I-95 has become a nightmare for victims of trafficking. Due to its extensive reach in highly populated urban centers and proximity to prominent airports and ship ports, I-95 has opened the door of regional vulnerabilities and endangered those who come across it. This paper examines the prevalence of human trafficking and strategies on I-95, through law enforcement data, victim reports, and case studies to highlight the corridor's role in facilitating different types of trafficking, such as drug or paraphernalia, multi-species organs, weapons, and human trafficking. Following this, the paper will take the figures and data above and culminate in policy recommendations to establish a multilevel intervention, help survivors across various parts of the East Coast in the United States, and decrease the number of potential victims in the future.

Abstract Name: State options following Dobbs V Jacksons Women's Health Organization (2022)

Mississippi passed a law titled "Gestational Age Act," which prohibited all abortions, except for some exceptions, medical emergencies, or severe fetal abnormality, after 15 weeks or gestational age (HB1272 (As Introduced) - 2022 Regular Session, 2022). As the only licensed abortion clinic within the state, Jackson Women's Health Organization doctors filed a lawsuit challenging the law and requested an emergency temporary restraining order. This case flew to the Supreme Court, where the question "Is Mississippi's law banning nearly all abortions after 15 weeks' gestational age unconstitutional?", with a 6 - 3 vote, the court ruled no. This paper maintains that states and localities, via their policing power, have the authority to regulate and the ability to practice abortion, within 15 weeks, besides the medical and fetal abnormality exceptions, according to the Dobbs V. Jackson Ruling. The Majority Opinion, written by Justice Alito, ruled that the constitutionality of Roe and Casey must be overruled as the Constitution does not refer to abortion. These cases relied on the Due Process Clause of the 14th Amendment, which held some guarantees of rights that are not mentioned in the Constitution. Still, these rights must be deeply rooted and implicit to order liberty, which the right to abortion fails to do. Yet the answer to the question of the options for the states that wish to limit or expand access to abortion is unknown; through analytic research is where we find that there are multiple bans and protections that states may apply. This allows states to realize their limits following the Supreme Court ruling and use their police power to enforce or restrict access to abortion within the constitutionality of the court's decision. So what can they do and how do we prepare?

Abstract Name: Ethnicity and Police: Effect ethnicity has on college students perception of the police

The present study focuses on whether ethnicity affects an individual's perception of the police. In the United States, police have the most contact with youth ages 16 to 25 (Fischer, 2021). Previous research suggests that the relationship between the police and youth is strained, such that the perception of police is more negative for Black and Latino youth than for White youth (Brunson & Weitzer 2009; Cochran & Warren, 2012). The police also reflect this same perception, where they see adolescents as disrespectful, entitled, angry, loud, and misguided (Fix et al., 2023). The current research study aims to investigate if these perceptions are still relevant among young adults. It was hypothesized that students of Color will report a more negative perception of police officers than White students. The sample consisted of 140 participants, 83 White, 47 Black, and 10 Biracial. Participants completed the Perceptions Of Police Scale (Nadal & Davidoff, 2015). Results from a One-way ANOVA showed that students of Color had a more negative perception of the police than their White counterparts ($p = .004$). To further test the effect of race, another One-way ANOVA was employed and revealed that Black students had the most negative perceptions compared to students of Color or White students ($p = .002$). Additionally, major and gender were found to have no effect on perceptions of the police ($ps \geq .08$). Investigating this topic is important because it will allow researchers and the public to have a better understanding of how negative perceptions of police among minority groups can perpetuate social tensions and reduce public confidence in government institutions. Addressing these issues is essential for promoting social cohesion and justice. These results could be utilized to develop community intervention programs that promote building positive relationships between the police and young people, especially in minority groups.

Abstract Name: Barriers Preventing Clinical Application of Circulating miRNA's as Non-invasive Biomarkers in Arterial Blood of Women with Endometriosis Diagnosis

Endometriosis is a chronic inflammatory disorder in which endometrial-like tissue grows outside the uterus, leading to pelvic pain, infertility, and diagnostic delays due to the current reliance on invasive laparoscopy. Although imaging and hormonal assays offer limited accuracy, circulating microRNAs (miRNAs) in arterial blood have emerged as promising noninvasive biomarkers because they regulate gene expression, reflect inflammatory and angiogenic pathways, and remain stable in circulation. I propose investigating miRNAs such as miR-17-5p, miR-451a, and the let-7 family because they regulate processes like cell proliferation, immune modulation, and endometrial tissue remodeling which are mechanisms directly implicated in endometriosis pathogenesis. Research on miRNA-based diagnostics has shown strong preliminary accuracy but inconsistent reproducibility due to small cohorts, limited diversity, and lack of standardized extraction or normalization protocols. Clinical translation has further stalled because of logistical and regulatory barriers that restrict large-scale validation and approval. My research examines how methodological standardization,

computational modeling, and multicenter collaboration could bridge this gap by improving data reliability and diagnostic precision. Ultimately, refining miRNA profiling could revolutionize noninvasive diagnostics for endometriosis by reducing time to diagnosis and enabling personalized care based on molecular signatures. However, because miRNA-based diagnostics remain in early developmental stages, longitudinal studies and global standardization efforts are needed to establish reproducibility, regulatory confidence, and real-world clinical feasibility. Keywords to highlight: endometriosis; circulating microRNA; miR-17-5p; miR-451a; let-7 family; noninvasive diagnostics; biomarker validation; standardization; translational barriers; women's health.

Abstract Name: Characterization of microhabitat variation associated with tick questing behaviors: implications for alpha-gal syndrome exposure risk.

Alpha-gal syndrome (AGS), a tick-borne allergy to mammalian meat, is a rapidly expanding public health concern. The lone star tick (*Amblyomma americanum*) is thought to be a primary vector for the syndrome and thus the expansion of its range may be associated with increasing disease risk. The environmental conditions that influence tick presence and activity is understudied. Specifically, it is unknown how much microhabitat variation affects tick behavior. Differences in shading, vegetation, and moisture may create microclimates that shape tick behavior and thus may influence disease exposure risk. Central Virginia is currently an area with an increasing prevalence of AGS, and thus there is a need to understand how variation in microhabitats might be affecting disease risk in this region. This study examines the way in which local microhabitat conditions affect tick activity across two parks in central Virginia known as Grove Street Park and Wilck's Lake Park. We measured temperature and relative humidity in vegetation-dense patches and open patches. Studies suggest that humidity and temperature may influence tick questing behavior, therefore habitat differences within microclimates may affect disease exposure risk in local communities. Identifying microhabitats that promote favorable conditions for lone star ticks, can inform AGS awareness, and risk communication for outdoor areas. By linking microclimate patterns to tick presence, this research aims to improve identification of high-risk spaces for tick disease exposure, and improve monitoring for AGS in Virginia.

Abstract Name: Afrosurrealist Aesthetic in Selected Stories in Sheree R. Thomas's Dark Matter

This paper explores how allusions to mythology in "Anansi Meets Peter Parker at the Taco Bell on Lexington" by Douglas Kearney, "The Magical Negro" by Nnedi Okorafor-Mbachu, and "Afternoon" by Tananarive Due from *Dark Matter* by Sheree R. Thomas exemplifies an Afrosurrealist literary aesthetic. Using James Scott theory of hidden transcript, mythology signifies aesthetics of mysticism and grotesque and a rejection of linear time to demonstrate patterns of oppression and how colonialism affects present reality to

create a surreal experience. In “Anansi Meets Peter Parker at the Taco Bell on Lexington,” I focus on how the parallels of Anasai to Spiderman and B’rer Rabbit to Bugs Bunny demonstrate the absurdity of racial economic inequality from cultural production. In “The Magical Negro,” references to Thor the Brave from Norse mythology to critique the trope of a “magical negro” by disrupting the narrative and directly addressing the reader. In “Afternoon” the protagonist, Kenya tries to hide that she is a werewolf to be desirable to romantic partners, critiquing the absurdity of Modern, Eurocentric beauty standards having high social power. Understanding how allusions to mythology work as an Afrosurreal literary aesthetic can illustrate how surrealism appears in different cultural contexts.

Abstract Name: A Metagenomic Study Observing the Relationship Between Freshwater Microbiome and the Environment

Freshwater bodies are dynamic environments where microbial communities can play key roles in nutrient cycling and water quality regulation. These communities also respond to variations in environmental conditions, making them useful indicators of ecosystem health.¹ The goal of this study was to examine how water quality, weather conditions, and sampling location shape the microbial community and diversity of a city park pond in Grambling, Louisiana. Microbial composition was analyzed across four pond sites with each site differing in vegetation density (abundant vs bare) and water flow (stagnant vs. flowing). Water samples were collected biweekly beginning in September, and temperature, pH, conductivity, and dissolved oxygen were measured. DNA was extracted using the DNA ZymoBIOMICS Miniprep procedure and later sequenced through the Oxford Nanopore procedure. Metagenomic data was analyzed to profile bacterial, archaeal, and viral phyla. Across all samples, Pseudomonadota, Cyanobacteria, and Actinomyceota were consistently dominant, highlighting their ecological significance in the pond’s ecosystem.² Correlation patterns observed between the physicochemical parameters and major bacterial phyla, showed that environmental conditions influence the microbial community in multiple ways. Also, the presence of distinct microbial communities such as Methanobacteriota and Phixviricota in specific sites suggests spatial heterogeneity which could be caused by localized shifts in water chemistry.³ Overall, the measured physicochemical parameters can potentially be used for predicting microbiome structure.

Abstract Name: Constructing Race: A Comparative Study of Haiti and the Dominican Republic.

This project examines how race is constructed and used as a political tool in Haiti and the Dominican Republic, two nations that share the island of Hispaniola yet developed sharply different ideas about Blackness. Although both countries experienced colonization, slavery, and independence, their historical paths shaped contrasting racial identities: Haiti embraces a legacy of Black liberation rooted in the Haitian

Revolution, while the Dominican Republic has long built a national identity that distances itself from African ancestry and aligns with Eurocentric ideals. This research argues that these differences are not accidental but are the result of state-supported narratives, political projects, and cultural storytelling that have shaped national identity, immigration policy, and everyday social life. Drawing on postcolonial theory and Black radical thought, this study uses key texts such as C.L.R. James's *The Black Jacobins* and David Howard's *Coloring the Nation* to trace how governments and elites constructed racial meaning and embedded it into national memory. The project also explores major historical events, including the 1937 Parsley Massacre, to show how racial ideology can lead to violence when supported by law and state power. International responses, especially from the United States, reveal how global politics can reinforce racial hierarchies by ignoring or minimizing anti-Black violence. Additional scholarship on nationalism and *mestizaje* helps explain how racial mixing is celebrated in ways that still suppress Black identity in the Dominican Republic. Overall, this research shows that racial logic on the island is shaped not only by local history but also by global structures that reward whiteness and marginalize Blackness. Understanding these dynamics provides a clearer view of how race continues to influence migration, identity, and power across the African diaspora.

Abstract Name: Transitioning from 3D to 4D Printing for Shape Memory Retention

4D printing is opening new avenues across many fields including medicine and aerospace engineering. This technique expands the functionality of conventional 3D printed components. Special materials like thermoplastic polyurethane (TPU) are now being widely used for 4D printing. TPU's reveal vast combinations of both physical properties and processing applications. Additionally, TPU is a very suitable material for 4D printing due to its flexible, elastic nature, combined with shape memory properties. This research explores two aspects of 4D printing. First, it investigates whether 4D-printed components lose their ability to retain shape after repeated cyclic testing. Second, it examines whether common 3D-printing materials—PLA/ABS/PETG—exhibit any shape-memory retention. To address these questions, TPU filament was used to print ASTM-D638 Type-I dogbone specimens at three infill levels (20%, 60%, 100%). These samples were evaluated to determine both the recovery time during shape-memory tests and the number of cycles required before noticeable loss of original shape. Results indicate a positive correlation between infill density and shape-recovery time: the 100% infill sample required roughly $1.5\times$ more time to return to its original form compared to the 20% sample, and this trend persisted under repeated deformation cycles. Additionally, the 20% infill specimens lost their shape-memory behavior more quickly than the 100% samples. In the second phase of the study, PLA, PETG, and ABS dogbones are being evaluated for shape-memory retention. Preliminary results show that PLA demonstrates measurable shape-memory effects at its defined transformation temperature. The trend of retaining shape memory is the same as was observed in TPU samples. Higher infill samples perform better. However, the number of cycles after which material memory starts fading is at least 70 percent lower than what was observed in TPU samples. These are preliminary results. Further testing is ongoing, and complete results will be presented at the conference.

Abstract Name: "How does sleep quality affect emotional regulation strategies such as cognitive reappraisal and suppression?"

Sleep is an essential component of our cognitive and physical health; however, many individuals have poor-quality sleep, which affects their ability to regulate their emotions. There are two common emotional regulation strategies that people utilize in their daily lives, called "Cognitive Reappraisal" and "Expressive Suppression." Cognitive Reappraisal entails reframing a situation to alter the emotional impact it can have. On the contrary, Expressive Suppression entails making a conscious effort to avoid unwanted memories and thoughts, which is done by inhibiting emotional expression. Recent literature suggests that disrupted neural and prefrontal-amygdala function in the brain is an underlying effect of poor sleep quality. This issue disrupts the collaboration between the Amygdala and the Prefrontal Cortex, which impairs the brain's ability to regulate emotions. For example, one or two nights of poor-quality sleep will lead to a noticeable increase in expressive suppression and lead to other negative effects that disrupt an individual's routine. As a result, individuals may experience negative emotions more intensely, and their productivity will decrease. In terms of populations, this issue disrupts the well-being of healthy individuals and exacerbates the symptoms of individuals diagnosed with Major Depressive Disorder (MDD), Generalized Anxiety Disorder (GAD), Post-Traumatic Stress Disorder (PTSD), and Borderline Personality Disorder (BPD). However, there are gaps in how much potential there is for interventions and the long-term effects of consistent sleep disruptions. Overall, these findings indicate that the effects of poor sleep have many negative implications on the psychological well-being of any individual, as it is associated with reduced reappraisal and increased suppression.

Abstract Name: From Viral to Valid: TikTok's Learning and Memory Claims Versus Student Beliefs

TikTok is a major source of study advice for college students, yet the accuracy of its learning and memory tips and the impact they have on students' beliefs are not well understood. This project examines a central question: How does exposure to study-related TikTok content shape students' understanding of the neuroscience behind learning and memory and the best practices related to them? Although some TikTok videos share effective, research-backed methods such as spaced repetition and retrieval practice, many others promote ideas that sound scientific but lack evidence, including learning styles and "dopamine detox." While prior research has documented the spread of educational misinformation online, it has focused predominantly on platforms such as YouTube and Instagram. Because TikTok quickly amplifies highly engaging content, students may find it difficult to distinguish between valid strategies and widely repeated misconceptions. This study uses two main methods. First, a systematic audit of TikTok videos posted in 2025 with at least 50,000 views identifies the types of learning and memory claims being made, evaluates their scientific accuracy, and documents how widely they are shared. Each claim is compared with established findings in cognitive psychology and neuroscience. Second, a survey of undergraduate students measures their endorsement of and confidence in True/False statements based on both high-exposure TikTok claims and accurate but low-exposure learning principles that rarely appear on the platform. Statistical analyses compare performance on these two categories and examine whether students' TikTok use is related to their beliefs. These findings will be discussed in the context of how digital misinformation shapes student learning, highlighting common

misconceptions about memory and study strategies, and drawing on research that challenges popular myths while offering practical ways educators and students can engage more critically with social media content.

Abstract Name: Tensile Testing of PLA 3D Prints with Varied Orientations

The aim of this study is to determine a difference in the tensile strength of 3D-printed objects based on printing orientation and varied layer heights. The hypothesis is objects with vertical layers will have higher tensile strengths than objects with horizontal layers. Dog-bone samples will be printed using PLA filament at three different layer heights. Half of the samples will be printed parallel to the print bed, with layers running along the samples. The others will be printed perpendicular to the print bed, with layers stacked along the sample. Samples will be tested in a Tensile Testing Apparatus by stretching each to failure. The samples printed parallelly are expected to have higher tensile strengths than the other samples. The impact layer height has on tensile strength will depend on the sample. The samples printed parallelly are expected to be minimally impacted by layer height. Since the layers run with the direction of tension, the layers will stretch with the sample. In contrast, the samples printed perpendicularly will likely be affected by layer height. Since those layers will be perpendicular to the direction of tension, the fracture will likely happen sooner due to small spaces occurring between layers. This chance increases with layer height, since those spaces also grow. Preliminary data for PLA showed tensile strength dropped by ~16.5% when increasing the layer height from 0.15mm to 0.2mm for a flat dog-bone sample. This drop shares characteristics to atomic packing factor, where higher factors signify more densely packed atoms. The more densely packed atoms are, the less space between them. Similarly, the greater the layer height, the less dense the layers are. This research aims to strengthen current understanding of the material properties of PLA. Future research will incorporate compression tests to gather the full scope of material properties for PLA.

Abstract Name: Early Career Researchers Now: Empowering Undergraduates to Publish in Hours with Chisquares

Undergraduates can and should be positioned as early career researchers—but they are often blocked by steep learning curves, fragmented tools, and limited access to publishable data. This mentor-led session shows students how to move from question to manuscript in hours, not months, using publicly available datasets and the Chisquares platform. We begin by framing a researchable question, then demonstrate where and how to access free, high-value data (e.g., NHANES, NHIS, NYTS, BRFSS; state open-data portals). Next, participants see analysis-as-visualization on Chisquares: selecting outcomes, predictors, and covariates via guided menus; running descriptive statistics and regression; and interpreting weighted estimates when survey design demands representativeness. Chisquares' rules-based computation ensures reproducible accuracy (no

coding required), while its risk-based AI assists only in low-risk narrative tasks (e.g., drafting introductions/discussions), never touching raw data or analytics. Finally, students push analytic outputs directly into a formatted manuscript with tables, figures, and references aligned to journal standards. Attendees leave with a clear workflow: (1) source open datasets ethically; (2) define a transparent analysis plan; (3) conduct and validate analyses visually; (4) generate a submission-ready manuscript in minutes; (5) document contributions for CVs, graduate applications, and early publications. The session's goal is confidence: undergraduates see themselves as credible contributors—equipped with ethical, efficient, and rigorous methods to produce real scholarship now. This interactive workshop demonstrates how visualization and automation can transform research productivity, empowering undergraduates and graduate students to generate publication-ready manuscripts within an hour. Using the Chisquares Platform, participants will learn how analysis, visualization, and manuscript writing can occur seamlessly in a unified, no-code environment. By bridging the divide between undergraduates and analytical technology, participants will see how intuitive visualization tools and rule-based AI frameworks democratize access to evidence generation—making research accessible even to those without programming or statistical backgrounds.

Abstract Name: Using AI Ethically to Succeed in College and Graduate School: From Proposal to Self-Cleaning Data and Instant Reports on Chisquares

This mentor-led session provides a practical, ethics-first roadmap for students to use AI well—to think better, not shortcut learning. We demonstrate a full research cycle on the Chisquares platform: generating a rigorous, scannable research proposal; collecting quality data; and producing instant, interpretable reports. First, we show how to prompt ethically for proposal scaffolds (background, aims, hypotheses, analytic plan) while preserving academic integrity: AI assists in low-risk narrative structuring, but claims, citations, and methods are verified by the student. Next, we design a data collection instrument on Chisquares with self-cleaning safeguards: regex and range checks, soft/hard validations, branching logic, eligibility screens, and required fields—preventing bad data at entry rather than “fixing” it later. For projects using existing data, we demonstrate importing public datasets and applying design weights when appropriate. Then, with one click, students generate descriptive tables, model outputs, and a concise results summary that turns analytics into auto-generated reports—including visualizations and a manuscript shell formatted to journal or course standards. Throughout, we model responsible AI use: no AI in statistical computation; transparent attribution; reproducibility via rules-based analytics; and documented decision logs. Students leave with a repeatable workflow to (1) frame a proposal ethically, (2) design instruments that self-clean, (3) analyze without coding, and (4) communicate findings clearly and rapidly. The outcome is not just higher grades or faster theses—it’s durable research literacy, academic integrity, and confidence to contribute meaningfully in college and graduate school. Participants will learn how to use Chisquares to generate rapid, reproducible results from open-access health datasets relevant to undergraduate and graduate research. Through guided, hands-on activities, they will see how a project that typically takes weeks can be completed within minutes—empowering participants to integrate data-driven learning into their career goals.

Abstract Name: Development of Fluorescence-Based Assays to Assess Cancer Drug Activation by CES2

Irinotecan and Capecitabine are approved to treat certain types of cancer including metastatic bowel cancer. These drugs are prodrug requiring hydrolysis of ester groups before their active forms are produced. Human carboxylesterase 2 (CES2) is a serine hydrolase that is known to activate Irinotecan and Capecitabine. The activity level of CES2 in cancerous tissue is correlated to successful treatment with these drugs. There are, however, genetic polymorphisms that can produce less active forms of CES2 which could result in decreased efficacy of these drugs. These polymorphisms, however, are poorly studied. This work focuses on developing fluorescence-based assays for studying CES2 activity that is tractable for high throughput study of CES2 polymorphism activity. Progress to date has focused on developing assays using fluorescein diacetate (FDA)

as a fluorogenic probe for CES2 with results suggesting that FDA can be used to study CES2 in certain conditions. Ultimately these efforts will lead to annotating all known CES2 polymorphism activity which will aid physicians in choosing personalized treatments for cancer and other diseases resulting in better patient outcomes.

Abstract Name: Multimodal Imaging System for Early Diagnosis of Age-Related Macular Degeneration (AMD)

Purpose: Age-related macular degeneration (AMD) remains one of the leading causes of irreversible vision loss worldwide, largely due to the difficulty of detecting choroidal neovascularization (CNV), or abnormal blood vessels that form in wet AMD at its earliest stages. To address this challenge, we present a multimodal imaging system integrating photoacoustic microscopy (PAM), optical coherence tomography (OCT), and fluorescence microscopy (FM) for the early diagnosis of AMD. **Methods:** PAM was performed using a laser energy of 80 nJ at 578 nm, approximately half of the ANSI safety limit. OCT provided depth-resolved structural imaging and detailed visualization of retinal layers, including the ILM, ONL, RPE, photoreceptors, choroid, sclera, and CNV. This platform combines the structural depth-resolving capability of OCT, the molecular and vascular sensitivity of PAM, and the cellular-level contrast of FM to achieve comprehensive, high-resolution visualization of retinal microvasculature and early neovascular changes. The AMD model was created in New Zealand White rabbits using a subretinal injection of a mixture of Matrigel and VEGF-165 to induce CNV. **Results:** The system allows for synchronization of multimodal image acquisition and co-registration, enabling both cross-validation and complementary interpretation of CNV-related biomarkers across modalities. The system achieves high resolution (4.1 μm aerial lateral resolution) and strong image contrast of choroidal and retinal vessels in both 2D and 3D. PAM provides high contrast for early neovascular changes, while OCT offers detailed information on retinal microstructures and clear identification of CNV. Together, the modalities demonstrate consistent correlation in lesion morphology and vascular features. **Conclusions:** This multimodal imaging system provides comprehensive vascular and structural information that is not attainable using single-modality approaches alone, and it shows strong potential for early detection and diagnosis of AMD-associated CNV.

Abstract Name: The Effect of Calorie Content When Baking Goldfish Crackers at Different Times And Temperature

The popular snack goldfish was founded and created by Oscar J Kambly, in Switzerland in 1958. They were then introduced to the American market by Pepperidge farm in 1962. The standard goldfish crackers contain about 140 calories 55-pieces serving which equal out to one ounce. Although some variations of goldfish may be slightly different. This experiment examined how baking temperature and time affect the measurable caloric energy of Goldfish crackers using a simple calorimeter. Crackers were baked at 250 °F and 350 °F for varying durations, then burned to determine energy release per gram. Moderate baking conditions 250 °F for 15 minutes or 350 °F for 5 minutes and this produced the highest energy values, likely due to optimal moisture loss without excessive nutrient breakdown. Higher temperatures or longer baking times slightly reduced measured energy, suggesting charring or partial oxidation limited full combustion. Overall, the study showed that baking conditions influence energy density and demonstrated how thermochemical principles apply to real-world food science.

Abstract Name: Engineering a Physiological Platform to Model Muscle Stem Cell Fate and Aging in Sarcopenia

Skeletal muscles are unique tissues that have a high regenerative capacity through muscle stem cells (MuSCs). However, their regenerative capacity diminishes with age and is further impaired by neuromuscular disorders such as sarcopenia, a condition characterized by muscle atrophy. Despite its prevalence and current knowledge of muscle regeneration, treatment for sarcopenia remains limited to general therapies due to an incomplete understanding of sarcopenia's pathogenesis. Current models of sarcopenia rely mainly on animal models, incorporating the complex muscle niche and multicellular environment. While invaluable, they raise ethical, economic, and time concerns. Furthermore, existing in vitro approaches fail to capture key aspects of MuSC fate, including quiescence. Using engineered muscle tissues (EMT), a muscle organoid with myoblast progenitors, fibroblasts, and extracellular matrix (ECM) initially developed by the Mack Lab at the University of Washington, we aimed to create an in vitro model that (1) incorporates EdU time-pulse labeling within EMTs to trace MuSC proliferation and self-renewal, (2) recapitulates key aging phenotypes through young and old MuSC. We seeded EMTs with iPSC-derived MuSCs and allowed them to self-assemble into contractile organoids, with EdU administered at defined intervals. We assessed muscle force generation and tracked EdU location through immunocytochemistry. Preliminary results demonstrated the technical feasibility of EdU pulse-chase for tracking MuSC fate determination in EMTs. Together, this approach will provide a scalable, rapid-testing platform for sarcopenia and other muscle-related diseases, enhancing current understanding of muscle regeneration and the development of targeted therapies.

Abstract Name: How the Body Heals: Stopping the Bleed

Excessive blood loss due to laceration can lead to hypovolemic shock which is caused by a lack of oxygen circulating through the body. Because of the easily identifiable repercussions of severe blood loss, different ways to staunch bleeding quickly came about. The current innovations for stopping blood loss are Hemostatic Gauze and XStat wound packing. Hemostatic uses chemical kaolin to accelerate blood clotting whereas XStat injects expanding sponges into a wound, creating a temporary barrier to blood flow and providing hemostatic pressure. This research focuses on how to develop wound packing products that can evolve from the pre-existing wound packing by making the design more intuitive for civilian use. The product is made of cotton gauze tube-like structures (one inch in diameter and three inches in length) containers holding crystalized sodium polyacrylate ($C_3H_3NaO_2$), a superabsorbent polymer (SAP) that can absorb approximately sixty times its own weight in water from blood. It consists of five or more gauze tubes making a chain of expanding gauze containers. The product is tested using 0.9% saline solution and deionized water for expansion, absorption within 60 second intervals, and saturation time. The efficacy rates were calculated and analyzed from 21 trials indicated that the average success is 73.02 % assuming the ideal product absorbs 30 mL to become fully saturated and expanded in one minute, and the average volume (mL) absorbed by a single gauze container is 18.203 mL. Future work will be reducing the product size to increase the amount of pressure applied inside a wound, reducing the size and amount of air pockets, and shortening saturation time. We also consider replacing the cotton gauze with elastic nonwoven fabric to prevent leaking crystalized sodium polyacrylate before application.

Abstract Name: Creation of Yeast Strains to Investigate the Effect of Endonucleases during Anaphase

DNA double-strand breaks (DSBs) are one of the most severe forms of DNA damage, arising when a replication fork collides with a single strand break caused by reactive oxygen species or ionizing radiation. In the final steps, DNA intermediates must be resolved by endonucleases, but the mechanisms guiding recruitment are unclear. Defects in DSB repair contribute to cancer predisposition and premature aging. Understanding them can reveal molecular targets to improve genomic stability. This project investigates three key enzymes in DSB repair: Rad1-Rad10, Yen1, and Dpb11. Our aim is to test whether Rad1-Rad10 and Yen1 localize to anaphase bridges in *S. cerevisiae*. The target strains will contain fluorescently labeled Rad10-YFP and Yen1-RFP, and one label for the anaphase bridges, either Dpb11-CFP or Hta1-CFP. By imaging these fluorescently tagged proteins, we can assess whether recruitment depends on Slx4 or cell-cycle stage. Prior to conducting microscopy, we need to create strains containing these gene combinations: Rad10-YFP/Yen1-yEmRFP/Dpb11-CFP/sl_x4 Δ , Rad10-YFP/Yen1-yEmRFP/Hta1-CFP/sl_x4 Δ , and Rad10-YFP/Yen1-yEmRFP/Hta1-CFP/SLX4. To isolate the target strains, we screened candidate spores by antibiotic selection, fluorescence microscopy, and Polymerase Chain Reaction (PCR) of genomic DNA. Fluorescently tagged genes produce longer PCR products than wild-types, which are distinguished by gel electrophoresis. The other screens showed the expected antibiotic resistance and fluorescence signals. Currently we are finalizing the screening of spores for two of the target genotypes. The third cross is currently underway and from which we expect to generate the final target strain. Once all strains have been created and characterized, we will examine the abundance of end processing nucleases at chromatin structures and anaphase bridges. This work will provide new insight into how nuclease recruitment is coordinated during DNA repair, advancing our understanding of genome stability and its relevance to cancer biology and human health.

Abstract Name: Hormonal Predictors of Recent Alcohol Use in Naturally Cycling and Oral Contraceptive Users

Emerging research suggests that estradiol and progesterone may modulate alcohol motivation and consumption; however, findings remain mixed, in part because few studies incorporate repeated direct hormone measurements. Because oral contraceptives (OCs) suppress endogenous ovarian hormone fluctuations, hormone–behavior associations may differ between OC users and naturally cycling (NC) women. This study examines whether measured hormone concentrations predict recent alcohol use in young women and whether these associations vary by hormonal environment. Participants include 60 young women (ages 16–22; 30 NC, 30 OC). At three follow-up visits, participants reported past-week alcohol use, and serum was collected for estradiol, progesterone, follicle-stimulating hormone (FSH), and luteinizing hormone (LH). Hormone assays are in progress. NC participants completed visits across four menstrual cycle phases, whereas OC users were assessed during active and inactive pill weeks. Baseline drinking risk was assessed with the AUDIT-C (range 0–12; scores ≥ 3 indicate hazardous drinking). In this sample, AUDIT-C scores averaged 3.1 (SD = 2.27); 23% scored 0 and 33% scored ≥ 4 . Across follow-up visits, 51% reported past-week drinking. Among drinkers, alcohol was consumed on an average of 1.5 days (range 1–4), with 3.2 drinks per drinking day (range 1–10). We will test whether (1) estradiol and progesterone predict past-week alcohol use in NC women, (2) associations are attenuated in OC users, and (3) FSH and LH add predictive value beyond estradiol and progesterone. Mixed-effects models will examine hormone levels as continuous predictors, with Group (OC vs NC) as a moderator. Study outcomes will determine whether real-time hormonal states better explain variation in alcohol use than categorical cycle phases and clarify how exogenous versus endogenous hormonal environments shape hormone–behavior associations in early adulthood.

Abstract Name: From Shipment to Savings: Optimizing Inbound Freight Strategies at Trinity Industries

This study investigates cost optimization strategies for inbound freight at Trinity Industries by comparing the

per-unit economics of trucking and rail transport. Using shipment and vendor data from January through May 2025, the analysis evaluates how shipment volume, vendor patterns, and transportation modes influence operational costs. Findings identify breakeven thresholds, approximately 106 to 114 heads, at which rail becomes more cost-effective than trucking, and highlight how shipment size and part dimensions affect overall efficiency. The results provide data-driven guidance for selecting transportation modes that improve cost performance across Trinity's inbound supply chain.

Abstract Name: From Data Collection to Program Direction: Advancing Latinx Studies at a Predominantly White institution (PWI)

Despite substantial growth in Latina/o enrollment into higher education institutions and the rising number of higher education institutions designated as a Hispanic-Serving Institution (HSI), the Latina/o student population continues to face a lack of curricular offerings that centers, or even reflects, their identities, histories and experiences. This gap informs my current and future exploration of how it can be institutionally addressed within an R, predominantly white institution (PWI). This research project conducts an external benchmarking across higher education institutions with high research activity (R1 designation) to examine how Latinx Studies programs, if offered, are structured, situated, directed, administrated, and supported. This is a data collection focused exclusively on undergraduate majors, minors, and certificate offerings that center either a collective identity of Latino-ness or Latinoism, or its ethnonational derivatives such as Chicana/o, Puerto Rican, or Cuban American Studies at the undergraduate level. The aim of this study is to contextualize an effective implementation of a Latinx Studies program at an R1 and predominantly white institution like the University of Pittsburgh.

Abstract Name: "Reexamining the Rise of Conservatism Among Latinos in the U.S."

In recent years there has been major discourse surrounding the recent rise of conservatism among the Latino community since the 2020 U.S. elections. Numerous experts have noticed a major factor that contribute to Trump winning the 2024 Presidential elections is that he managed to obtain almost fifty percent of Latino voters. As a result, this has furthermore caused division among the Latino community due to personal and political beliefs. This has prompted me to further investigate why many Latinos in the U.S. are increasingly aligning more with the conservative party even though a lot of their policies they promote often targets marginalized groups including Latino individuals in the U.S. I intend to re-examine whether a lot of these factors come from a personal, religious, or economic standpoint by initiating research that will consist of examining data and events using academic journals, books, news articles, social media, and survey to further understand their viewpoint. While conducting this research I anticipate that some of the factors as for why many Latinos are aligning more with conservatism are due to the economy, immigration, border crisis, and government control which has become a major concern among Latino within the last few years. Many of

these Latinos who voted or sympathize with President Trump are optimistic that he will provide effective solutions for all Americans, while other Latinos have expressed doubt in seeing any progressive change. Ultimately, it is crucial that this subject is being addressed since not only has there been a rise of conflict and division among the Latino community but many individuals who did not vote for President Trump have voiced concerns of potentially facing major repercussions under his current administration which may further impact all Latinos including those who either voted or sympathize with Trump due to his policies.

Abstract Name: A Qualitative Analysis of the Barriers to Treatment in Hispanic Women

Hispanic American women face unique mental health challenges because of various cultural factors. Access to mental health resources and culturally competent care is impacted by insurance coverage and insurance disparities, emphasizing the need for culturally sensitive interventions. Cultural stigma surrounding mental health issues can complicate these outcomes, as people may be reluctant to seek help due to fear of judgment from their community. This study investigated the unique barriers and help-seeking behaviors that Hispanic American women face in accessing mental health resources, particularly those rooted in cultural stigma. A survey was distributed to women living in the Coastal Bend Region of South Texas. The survey was designed to look at the differences between cultural factors and their impacts on different ethnicities regarding the care of women's mental health. The study examined cultural stigma and barriers to seeking help, including financial constraints and language barriers, through a series of open-ended questions. The hypothesis explored was: Which of these factors may impact the likelihood of seeking mental health treatment? A qualitative approach was employed, utilizing demographic data and survey results to quantify barriers to mental health access. Hispanic women faced more financial constraints, a lack of awareness of available services, and a lack of health insurance, as well as other issues. Results indicate that factors that influenced positive Help-Seeking Behaviors included family, friends, and mental stability. Relevant themes that influenced people not being able to seek help included cost, stigma, time, access, insurance, and family. This research aims to inform best practices for mental health professionals, enhancing care tailored to the unique needs of Hispanic women.

Abstract Name: Effects of *Bacillus amyloliquefaciens* Inoculation on Nutrient Efficiency and Root Composition in Hydroponic Butterhead Lettuce Plants under Electrical Conductivity or Salinity Stress: A Comparative Study

In the face of population growth and climate changes, the pressure for more efficient and effective cultivation techniques has never been greater. Where soil-based farming has had many short-comings in meeting the global demand for food, soilless farming systems offer a viable solution. Hydroponic farming the cultivation of crops in water-based nutrient solutions, has risen as a viable alternative in its ability to efficiently use water

and nutrients without soil while providing better yield the soil-based systems on average. This is not to say that hydroponic farming is not without its issues. It is a controlled environment agriculture that recirculates nutrient solutions that have high fertilizer input, making it susceptible to stress from high electrical conductivity and salinity. This can cause salt burn, nutrient lockout and toxicity, resulting in reduced plant quality or yield. To resolve this issue, *Bacillus amyloliquefaciens* has been presented as a solution to improve nutrient uptake and strengthen crop resilience under stress. This project will study how *B. amyloliquefaciens* affects nutrient-uptake efficiency, root composition and crop quality in recirculating solution comparing the normal vs. inoculated nutrient solution under the moderate stress of elevated electrical conductivity. Three comparative experiments will be set-up side by side under identical pH, temperature, humidity and light conditions. Planned metrics to be measured would include microscopic colonization and root plate counts to keep track of microbial colonization and in establishment in the roots using microscope and florescent dye, nutrient solution electrical conductivity at different point of plant growth using EC meter, dry matter percentage and leaf color or greenness using a SPAD or image-based color index. Data will be analyzed using ANOVA to test effects and interaction among EC and inoculation. This study aims to show proof in feasibility for microbiome-assisted nutrient efficiency in hydroponic systems.

Abstract Name: Burkina Faso's Digital Propaganda Machine: Influence on Media, Security, and Democratic Discourse

In April 2024, Burkina Faso expelled several western media organizations from the country after reports were released that exposed military violence against civilians in the current insurgent crisis the country faces. Since then, the media landscape has been inhibited by government attacks on private press while simultaneously disseminating narratives that favor presidential praise and military support through the usage of misinformation, artificial intelligence generated content, and restrictive media directives. This study serves to examine how these tactics of digital authoritarianism influence the media landscape and the strategies that are utilized to create a unified security narrative. Literature concerning the media in Burkina Faso has focused primarily on elections and coups, while literature on counterinsurgency has focused on failures and policy solutions. Previous research has not addressed the intersection concerning media and the growing insurgency threat, which is central to state strategy. To address this gap, Facebook posts from President Traore's official account @Présidence du Faso account and the national news agency @Agence d'information du Burkina (AIB) were collected between August 1st, 2025, and August 31st 2025. These posts were categorized into thematic frames of Nationalism/Patriotism, Pro-Traore messaging, and Counterterrorism to examine how information from sources, such as the government, are reframed when disseminated to the larger public. Findings show that content originating from the presidency consistently elevates nationalism as its main ideological pillar, while counterterrorism urgency and praise of Ibrahim Traore act as supporting factors. AIB, reinforced these frames through localized, event-specific reporting that amplifies these narratives for public consumption. Together, these dynamics illustrate how coordinated digital messaging strategies contribute to a narrowed information space and a dominant security-orient narrative in Burkina Faso.

Abstract Name: Lyapunov Stability Analysis of Gradient Descent in Machine Learning

Central Research Question / Purpose This project explores whether Lyapunov stability theory from control engineering can be used to analyze gradient descent, a key optimization algorithm in machine learning. The aim is to demonstrate how rigorous and intuitive insights into the stability and convergence of gradient-based learning techniques can be obtained using tools typically used for dynamical systems.

Scholarly Context While control theory stresses stability through Lyapunov functions and energy-based arguments, convergence analyses in machine learning usually rely on convexity, smoothness, and Lipschitz continuity assumptions. Even though both disciplines investigate related phenomena, undergraduate research rarely combines their approaches. This project connects optimization and control theory by considering gradient descent as a discrete-time dynamical system, providing an approachable interdisciplinary viewpoint for applied mathematics and engineering.

Methodology Gradient descent is modeled by the state update treated as a discrete-time nonlinear system. Candidate Lyapunov functions—particularly the cost function and quadratic energy-like functions—are proposed. Conditions guaranteeing monotonic Lyapunov decrease are derived, yielding stability and convergence bounds on the step size. Analytical results will be supported by MATLAB simulations on quadratic functions and linear regression models, and the derived stability regions will be compared with classical machine-learning step-size conditions.

Expected Results and Discussion It is expected that Lyapunov analysis will recover well-known convergence conditions for gradient descent, such as the requirement for μ -smooth convex functions, while providing a clearer dynamical-systems interpretation of stability. Simulations are anticipated to illustrate stable and divergent trajectories depending on the step size, reinforcing the theoretical findings. The results highlight how control-theoretic tools can enrich the analysis of machine-learning optimization.

Abstract Name: Results of a Quality Improvement Project to Enhance the Mind Workflow in an Age-Friendly Community-Based Wellness Program

Promoting healthy aging for all requires the intentional integration of behavioral, mental, and cognitive health into age-friendly care. Although the Mind domain of the 4Ms framework offers a useful structure, practical guidance for implementing Mind workflows in community-based settings remains limited. To address this gap, we examined Mind processes within the VCU Mobile Health and Wellness Program (MHWP), a community-based initiative that has provided weekly interprofessional care coordination visits to community-dwelling adults since 2012. Using the Plan-Do-Study-Act quality improvement model, we conducted a retrospective review of the program's Mind workflow, which employs a screen–educate–intervene approach across three areas: depression and anxiety (PHQ-4, PHQ-9, GAD-7), substance use (TAPS-1/2), and cognition (Mini-Cog). All MHWP participants with at least one visit between July 1, 2023, and June 30, 2025, across seven subsidized housing communities and one community health center were included. A total of 549 participants engaged in 5,566 visits. Participants were, on average, 66 years old (range 19–95), 55% female, and 84% Black. Mind screening occurred in 103 visits involving 72 participants (13%). More than half of screened visits (52%) yielded at least one positive result. Among the 54 positive screens, 41 (69%) received education, most commonly related to mental health behaviors, chronic disease management, or social drivers of health (SDOH). Follow-up assessments, including evaluation of possible suicidality, were inconsistently documented. Interventions were recorded in half of positive-screen visits and included SDOH referrals, mental health referrals, and care coordination. Opportunities to strengthen the workflow were identified, including improving follow-up procedures, refining documentation, expanding the scope of Mind screening, and providing additional team training. Findings highlight both strong screening reach and

substantial unmet mental, cognitive, and behavioral health needs among MHWP participants. Lessons learned may help guide more effective Mind implementation in other age-friendly, community-based programs.

Abstract Name: Empowering Bystanders: Confidence and Capability After Stop the Bleed Education

Severe bleeding can become fatal in just a few minutes, and through a recent grant initiative, trauma control kits are now readily available in almost every building at Virginia Commonwealth University. However, most students do not receive any training on how to use them. Over the past four years, I have taught more than 700 VCU students through the Stop the Bleed program to help peers feel confident stepping in as active bystanders during life-threatening emergencies. Many students tell me that, even though the kits are visible across campus, they are unsure how to actually apply a tourniquet, pack a wound, or use direct pressure in a real situation. This gap between access and ability motivated my research. To better understand the impact of Stop the Bleed education, I collected short pre- and post-class surveys asking students how comfortable they felt performing bleeding-control skills. Before the training, a majority of students reported low confidence or fear of doing something “wrong.” After the hands-on session, where they practiced tourniquet use, wound packing, and hemorrhage control techniques, students consistently reported a significant increase in comfort and willingness to intervene. Many described going from feeling intimidated by the equipment to feeling prepared to act if a serious injury occurred on campus or in the Richmond community. As trauma kits become more common in public spaces, it is essential that the people who walk past them every day actually know how to use them. My project highlights how brief, accessible training can transform student confidence and help bridge the gap between having lifesaving tools available and having individuals ready to use them. By sharing these findings, I hope to support broader efforts to make bleeding-control education a standard part of campus safety and empower more students to save a life when seconds matter.

Abstract Name: Wands, Wardrobes, and Warriors: How Disney Redefines Gender Representations

For almost a century, Disney Princess movies have shaped how children learn about gender, identity, and what it means to be a girl. Because these films are often the first stories young viewers become attached to, they play an important role in how children start to understand gender and form their sense of self. Early princesses reflected the traditional expectations of femininity that were common at the time. These characters were kind, gentle, and optimistic, yet they often lacked self-autonomy and relied on others to solve their problems. As society changed and feminist ideas gained influence, Disney introduced princesses who broke away from these limited roles. Princesses began to show traits of bravery, independence, and emotional complexity, broadening children's understanding of femininity. As children are still developing their beliefs and identities, the messages they absorb from these films can have lasting effects. Research in media literacy highlight how children often internalize stories subconsciously, taking in the lessons, values, and expectations

presented to them. Earlier portrayals may reinforce narrow ideas about appearance, behavior, and gender roles, while modern portrayals can encourage resilience, confidence, and more flexible understandings of women's abilities. As Disney continues creating characters who reflect individuality and diverse backgrounds, these films remain influential in helping children make sense of themselves and the world around them. The evolution of Disney princesses shows how the media both responds to and shapes societal views of gender and identity.

Abstract Name: Women's Inclusion, Exclusion, and the Hidden Architecture of Power in Peace Negotiations

Around the world, peace negotiations still unfold in rooms where women are outnumbered, sidelined, or present only as tokens. On paper, gender quotas and advisory seats suggest progress; in practice, decisions are too often made in male dominated backrooms that reduce women's voices to symbols of legitimacy rather than authors of peace. This project asks a difficult but urgent question: when women are invited to the table, what determines whether they shape the agenda or simply decorate it? To answer this, I turn to a comparative study of five post-Cold War peace processes, Afghanistan, South Sudan, Liberia, Colombia, and Guatemala, examining both formal inclusion mechanisms and the informal dynamics that either empower or silence women once negotiations begin. Guided by feminist institutionalism and legitimacy theory, I trace how power flows through institutions: who speaks, who decides, and who is heard. The findings reveal stark contrasts. In Afghanistan and South Sudan, women were given quotas or token seats but remained excluded from real decision-making, producing fragile and mistrusted agreements. By contrast, Liberia's grassroots mobilization and Colombia's groundbreaking Gender Sub Commission turned presence into power, reshaping accords to address justice, accountability, and community recovery. These cases demonstrate that when women influence both formal and informal processes, peace agreements gain credibility and durability. This research contributes more than case evidence: it reframes inclusion itself. True participation is not measured by how many women sit at the table, but by whether their voices change what peace means and how it is built. Without dismantling institutional gatekeeping and recognizing women as co-authors of political futures, peace remains a bargain among elites, fragile, narrow, and incomplete.

Abstract Name: The Wasted Vote: The Stigma Around Third-Party Voting in the U.S.

In the United States, the political landscape is largely shaped by a bipartisan system consisting of Republicans and Democrats. These two parties dominate people's political identities, elections, and media discourse. Despite this, third parties in the U.S. have continued to provide an expressive platform for voters who are dissatisfied with the bipartisan system, though the existence of significant public support for third-party policies and ideas has consistently failed to translate into electoral success at the polls. The disparity between substantial public support for third parties and limited electoral impact has sparked interest among political psychologists and scholars seeking to understand the underlying causes that prevent third-party success.

While many attribute this gap to the multitude of institutional barriers preventing third-party mobility, I argue that there is a largely-overlooked stigma associated with third-party voting; a primary factor which keeps the public from voting for third-party candidates. By examining the historical evolution of third-party movements, delving into voter psychology, and conducting an experimental study on whether a stigma against third-parties does influence voter behavior, this paper explores the challenges third-party candidates face in gaining traction within a predominantly two-party system. This experimental study finds that the stigma surrounding third-party votes being "wasted votes" does significantly affects voter willingness to support third-party candidates, finding strong evidence that the "wasted vote" stigma is a real and pervasive force in U.S. politics today.

Abstract Name: Use of *Lactococcus lactis* for Gut Delivery of *Oxalobacter*-derived Proteins and Peptides with Therapeutic Potential for Hyperoxalemia, Hyperoxaluria, and Related Kidney Stones.

Kidney stones affect a large portion of the population and are linked to long-term risks including chronic kidney disease and end-stage renal disease. Oxalate is central to stone formation and may also contribute to disease progression, cardiovascular complications, and poor renal graft outcomes, yet no broadly effective therapies exist to lower plasma or urinary oxalate aside from lumasiran and nedosiran for primary hyperoxaluria type 1 (PH1). Stimulating intestinal oxalate secretion offers a promising therapeutic approach by shifting oxalate from the bloodstream into the gut for elimination. Our group previously identified secreted factors from *Oxalobacter formigenes* that enhance oxalate transport in human Caco2-BBE cells through SLC26A2, SLC26A6, and PKA activation, and these factors reduce urinary oxalate in hyperoxaluric mice by increasing colonic secretion. Two small peptides, P8 and P9, along with their parent proteins 318 and 301, were identified as key contributors, but attempts to stabilize P8 and P9 reduced their function. To address this limitation, we engineered *Lactococcus lactis* NZ9100 to express native P8, P9, 318, and 301 for targeted intestinal delivery. Transformation with plasmid pNZ8123 succeeded, and expression of each construct was confirmed by SDS-PAGE and immunoblotting. We then advanced this platform to a pilot in vivo study using hyperoxalemic and hyperoxaluric PH1 mice, administering 1×10^{10} CFU daily for four weeks. Compared with vehicle controls, treatment with P8+P9, 301, or 318 led to progressive reductions in urinary oxalate, with week-four changes of roughly 48 percent for P8+P9, 36 percent for 301, and 48 percent for 318 after adjusting for increases in control animals. These findings show that engineered *L. lactis* can deliver functional *O. formigenes*-derived peptides and proteins in vivo and may represent a promising platform to lower oxalate levels. Plasma oxalate analysis is ongoing, and future work will refine dosing strategies and confirm early results.

Abstract Name: Engineering Collagen-Mimetic Fibrils with Controlled MMP1 Degradation for Biomedical Use

Collagen breakdown by Matrix Metalloproteinase-1 (MMP1) is a fundamental process in wound healing and tissue remodeling. A key unanswered question is how the number, or density, of an enzyme's specific cut sites within the collagen structure influences its overall breakdown rate. To systematically investigate this, our lab designed a series of collagen-mimetic peptides, named COLT3, modeled on human type III collagen and engineered to contain zero, one, or two MMP1 cleavage sites. This project focused on producing the two-site construct, COLT3_2. A major hurdle was the protein's high proline content, which is essential for its stable structure but overwhelms the bacterial production system in *E. coli*, leading to extremely low yields and aggregation. My research focused exclusively on overcoming this critical bottleneck. I developed and optimized a multi-step protein purification strategy from the ground up. This involved troubleshooting expression by testing induction temperatures, finding 16°C was optimal for solubility. I then perfected a purification pipeline using nickel-affinity chromatography to capture the protein, followed by reverse-phase HPLC as a final polishing step. This dedicated process resulted in the successful production of pure, soluble COLT3_2. Obtaining this purified protein is the essential and foundational achievement, as it creates the required material for all future studies. This work establishes a reliable method to produce a key tool, paving the way for our lab to now test the hypothesis on cleavage-site density and, ultimately, develop smart biomaterials with tunable degradation rates for regenerative medicine.

Abstract Name: State-Sanctioned Racial Terrorism: A CRT Analysis of Apartheid South Africa and America's Sundown Towns

Despite widespread recognition of apartheid South Africa as a crime against humanity, parallel systems of state-sanctioned racial exclusion in the United States, particularly sundown towns, have received comparatively little scholarly attention as forms of structural violence. This project asks how apartheid South Africa and U.S. sundown towns functioned as parallel forms of state-sanctioned racial terrorism and examines how Critical Race Theory reveals their shared logics of racial control, spatial segregation, and institutionalized white supremacy. This research engages three key scholarly conversations: first, the comparative historical literature on sundown towns and apartheid South Africa as case studies of racism and discrimination; second, legal and political definitions of terrorism, with a focus on how state violence against civilian populations has been theorized and selectively applied; and third, Critical Race Theory as an analytical framework that examines how law constructs and maintains racial hierarchies. Through historical and genealogical analysis of racial governance, and a discourse and policy analysis of legislative acts, municipal ordinances, and pass laws, this project examines how legal language constructed racial categories, authorized state violence, and legitimized territorial exclusion. Preliminary findings demonstrate that under international and domestic legal definitions of terrorism, acts intended to intimidate or coerce civilian populations through systematic violence or forced displacement, in both apartheid South Africa and U.S. sundown towns meet criteria for state-sanctioned racial terror. These results reveal that systems of law actively uphold rather than prevent terrorism when directed against marginalized populations. These findings

hold urgent contemporary relevance as debates over Critical Race Theory in education, voter suppression legislation, and persistent residential segregation reveal ongoing struggles over racial justice. This research creates analytical frameworks for examining policy legacies and their manifestations in contemporary housing discrimination, policing practices, and exclusionary laws.

Abstract Name: Cultural Attitudes and the Perceptions of Death

This research examines how Eastern and Western cultural beliefs shape emotional, social, and spiritual experiences of death and dying. While many Eastern and spiritual traditions understand death as a natural transition or return, Western cultures tend to frame it as a final and negative endpoint. In Islamic and Buddhist-influenced contexts, death is integrated into everyday life through language, storytelling, and religious teachings that emphasize acceptance and prepare individuals from an early age. In Islam, for example, death is viewed as a reunion with the Creator, and the afterlife is described as something better for those who have lived morally. These beliefs contribute to a more grounded orientation toward mortality and encourage people to approach both life and death with a sense of purpose. This acceptance involves communal mourning practices in these cultures which encourage emotional expression and shared grieving. In contrast, Western funerals and mourning customs are often more restrained due to discomfort surrounding death and a broader cultural tendency to avoid discussing it. This avoidance affects socialization as well; many people grow up without a clear framework for understanding grief or supporting others who are grieving. As a result, many Westerners encounter death for the first time only when loss occurs, whereas Eastern children are introduced to it early through faith, community, and everyday language. The findings suggest that more open or spiritually grounded orientations may support healthier coping and more purposeful ways of living, while avoidance-based approaches can limit a person's ability to process loss and engage with mortality in meaningful and constructive ways.

Abstract Name: Contrasting DIY Youtubers with Haul Youtubers: An Analysis of Media's Impact on Fast Fashion and Overconsumption

Introduction: There is currently enough clothing in the world to dress the next six generations. Yet, people still contribute to consumerist culture, buying far more than they need. The "haul" trend, originating on Youtube in the late 2000s, consists of influencers buying and showing off copious amounts of clothing, inspiring audiences to do the same. In contrast, Do it Yourself (DIY) creators encourage audiences to alter their existing clothing in creative ways. I analyze "haul" and DIY videos to understand their role in consumerism. Methods: I examine videos and comments posted on Youtube depicting clothing "hauls," DIY sewing projects involving upcycling – when someone alters an existing item to better suit their tastes. A total of twenty Youtube videos, ranging 4-20 minutes in length, were selected from the search terms "clothing haul" and "upcycling clothes sewing." Videos are analyzed for verbal cues promoting overconsumption or

creation and alteration, visual cues in the environment (e.g. clutter, number of clothing items), and heterogeneity versus homogeneity of target audience. Comments are analyzed for disappointment/enthusiasm for quality/price in the haul, as well as positive/negative reactions to upcycling techniques. Results: “Haul” videos are expected to verbally and visually promote overconsumption more than DIY videos whereas DIY videos are expected to verbally and visually promote creation and alteration. Analysis of comments will reveal what is most appealing to audiences in each type of video. DIY creators are expected to cater to more heterogeneous audiences (e.g., queer, plus size), while “haul” creators will cater to homogenous and less inclusive audiences. Conclusions: Despite the harms of fast fashion, haul videos likely draw audiences because of their accessibility, however understanding what people find appealing about haul videos may inform future work that could attempt to make DIY more appealing and accessible and reduce over consumption.

Abstract Name: Gender and Sexual Orientation Differences in Smoking and E-Cigarette Use: Public Health Implications for Cessation and Risk Reduction

Conventional cigarette use and e-cigarette consumption remain major preventable causes of morbidity in the United States, yet patterns of use vary substantially across demographic groups. This project investigates how gender and sexual orientation shape smoking behaviors, motivations for use, and cessation patterns, with the goal of identifying population-specific public health needs. Prior research shows that LGBTQ+ populations and women often experience higher stress exposure and targeted tobacco marketing, but limited scholarship has examined how these intersect to influence the transition between combustible cigarettes and e-cigarettes. To address this gap, we analyzed nationally representative survey data and conducted subgroup comparisons examining frequency of use, cessation attempts, and perceived barriers to quitting. Quantitative analyses assessed demographic differences in initiation, reasons for switching to e-cigarettes, and the likelihood of reducing or discontinuing tobacco use. Qualitative responses were reviewed to contextualize behavioral patterns within social and structural stressors, including stigma, discrimination, and differential access to cessation resources. Results show meaningful variation across groups. LGBTQ+ respondents reported higher dual-use patterns and higher stress-related motivations for smoking compared to heterosexual peers. Women were more likely to cite coping and social reinforcement, while men were more likely to cite habit formation and nicotine dependence. E-cigarette adoption did not consistently predict cessation; instead, its role differed by group, with some respondents using vaping as an intentional harm-reduction strategy and others as a supplement rather than a replacement. These findings underscore the need for culturally tailored cessation interventions that acknowledge varying motivations, stress exposures, and behavioral trajectories. The project highlights how demographic-specific public health strategies may improve cessation outcomes and reduce tobacco-related disparities. At NCUR, this work will be discussed in the context of designing targeted prevention and intervention efforts for diverse communities.

Abstract Name: The Relationship Between Volunteer Experiences and Career Preferences in High School Students

Students of all age groups engage in volunteer activities for a variety of reasons, including a will to serve their community, a desire to help people, and a strive for experience. The purpose of this study is to investigate the correlation between volunteer experiences, namely number of hours and field of volunteering, and career preference for seniors and freshmen at Woodbridge Academy, a school with a focus on biomedical education for medically motivated students. This study defines volunteering as work done for the benefit of others without any financial compensation for the volunteer. Based on prior research, it was hypothesized that people who volunteered more would choose to pursue a field requiring a higher level of benevolence, such as those in medicine or nonprofit organizations, and students would volunteer more in their field of preference. The correlations were tested using an anonymized survey provided to both seniors and freshmen, and the data was cleaned then analyzed using two chi-squared tests for independence and resulted in p-values of 0.96 and 0.99 for a sample size of $n=117$. 63 of the participants are seniors while 54 are freshmen. This indicates that there was no significant correlation ($p > 0.05$) between volunteer experiences and career preferences for seniors and freshmen at Woodbridge Academy. This research provides deeper insights into the benefits and motivations of volunteering for adolescents. However, it is important to recognize that the sample size is limited to a small group of like-minded individuals. Future studies with a similar focus should consider a larger sample size in a school with a more diverse student body.

Abstract Name: The Effects of Cognitive Stimuli on Dementia Patients

The brain is a complex organ involved in many bodily functions. Dementia is a neurological condition that can affect its ability to do so, typically characterized by memory loss, behavioral changes, mood swings, agitation, and loss of cognitive function. Its severity and risk are measured through the evaluation of neurological quality of life and cognitive reserve. There is currently no cure for dementia, only treatments to manage it, and the progressive disease continues to cause cognitive degradation with a potentially fatal outcome. Current treatment options include pharmacological interventions and clinician-led neurological stimulation using machinery and brain waves, which have the potential for severe side effects, can increase the burden on caretakers for individuals with dementia, and tend to have high associated costs. Alternative interventions, such as cognitive stimulation, especially through puzzles and social interactions, are more cost-effective and have the potential to improve patient and caretaker conditions and reduce the risk and severity of side effects when used alongside the clinically approved interventions, and have been linked to increased cognitive reserve and improved quality of life. However, these interventions have not been thoroughly researched, leaving a need for future research, which can provide more information about the effectiveness of alternative interventions and improve patient usability and acceptability. There is also a significant amount of distrust in these interventions and a lack of awareness regarding their potential benefits. This paper focuses on identifying the potential benefits associated with alternative treatments through cognitive stimulation and weighing their effectiveness when used alone as well as alongside clinically tested and approved interventions by conducting a comprehensive literature review consisting of 16 peer-reviewed articles regarding dementia and its treatment options to find out if cognitive stimulation can provide an easier method for patient recovery and improve outcomes to spread awareness to patients and their caretakers.

Abstract Name: Evaluating Polygenic Risk Scores Across Ancestries Using ClinGen-Aligned Reporting

Polygenic risk scores (PRS) are widely discussed as tools for predicting disease risk, but they often perform unevenly across ancestry groups. This makes it difficult to use them responsibly in clinical settings, especially for populations that have historically been underrepresented in genomic studies. ClinGen has created reporting standards for PRS, but there is still no simple way for researchers or students to evaluate a published score and understand how well it works across different ancestries. To address this gap, this project develops FairPRS-Clin, an open-source framework that applies existing Type 2 diabetes PRS to public genotype data and summarizes their behavior in a clear, ClinGen-aligned format. Using 1000 Genomes data, the tool compares score distributions across groups, such as South Asian and European populations, and highlights how using the same risk threshold can lead to very different “high-risk” classifications. Beyond plotting these distributions, FairPRS-Clin computes ancestry-stratified summary statistics, estimates how many individuals in each group would be flagged for early screening at a given cutoff, and links these outputs back to key items from the ClinGen PRS Reporting Standards. The framework is designed to be reusable: users can swap in other published PRS or ancestry groups while keeping the same evaluation pipeline. In doing so, FairPRS-Clin serves as both a research tool and a teaching resource, making it easier to see when a PRS is likely to be informative, when it may be misleading, and what additional data or recalibration would be needed before using it in real-world care.

Abstract Name: Smart Personalized Adaptable Responsive Knowledge Instructor

Traditional classroom models struggle to provide sustained one-to-one instructional support, leaving significant gaps in personalization, continuous feedback, and timely academic assistance. To address these limitations, we propose SPARKI—the Smart Personalized Adaptable Responsive Knowledge Instructor—a next-generation adaptive learning platform designed to deliver individualized, 24/7 academic support at scale. SPARKI leverages Small Language Models (SLMs) to facilitate interactive learning, guide students through problem-solving tasks, and provide context-aware assistance within course environments. Built as an enrichment layer alongside traditional lectures, SPARKI dynamically learns students’ preferences and behavioral patterns through platform interactions, augmented with publicly available datasets, to adapt to diverse learning styles. Key features of SPARKI include multi-instructor video modules, adaptive quizzes, AI-generated hints, and intelligent learner-state switching to ensure continuity of support across topics and sessions. By personalizing instruction at the individual level, SPARKI demonstrates how SLM-driven systems can enhance content mastery, reduce support bottlenecks, and scale high-quality academic guidance beyond human availability. As an open-source research initiative, SPARKI also provides a flexible testbed for exploring broader applications of SLMs in education and beyond. This study underscores SPARKI’s potential to reshape digital learning ecosystems and advance the role of adaptive AI in modern pedagogy.

Abstract Name: Impact of Metal Exposure During Pregnancy on Postpartum Depression in Rural Women – Preliminary Data from a Cohort Study

Introduction Postpartum depression (PPD) affects one in seven women globally. Rural communities in Bangladesh, with high prevalence of PPD experience chronic metal exposure. Although previous research found metal exposure linked to birth outcomes including miscarriage, teratogenesis, and preterm birth, the impact on maternal psychopathology remains poorly understood. An ongoing cohort study examines associations of prenatal exposure to metals such as arsenic (As), manganese (Mn), lead (Pb), cadmium (Cd), copper (Cu), zinc (Zn), and selenium (Se) with PPD symptoms among Bangladeshi women. **Methods** The parent study recruited 324 pregnant women aged 18 – 48 years from Matlab rural sub-district in Bangladesh to examine the effects of metals on maternal thyroid hormone and child neurodevelopment. Postnatal maternal depressive symptoms were assessed in a subset of 260 participants using the Edinburgh Postnatal Depression Scale (EPDS) with higher scores reflecting greater symptom burden. Blood As, Pb, Mn, Cd, Cu, Zn, and Se data assessed in the laboratory using ICP-MS were also available during data analysis. **Results** In adjusted linear models, both log-transformed As and Se were independently associated with higher EPDS. Both As ($\beta = 44.87$, 95% CI: 21.29–68.44, $p = 0.001$) and Se ($\beta = 15.03$, 95% CI: 6.34–23.73, $p = 0.002$) showed significant positive associations with depression symptoms. A significant As-Se interaction ($\beta = -8.96$, 95% CI: -13.72 to -4.19, $p = 0.001$) indicated that combined exposure attenuates the risk of their independent contributions. **Interpretation** Our findings on the interaction effect of As and Se may reflect the potential capacity of Se to irreversibly bind As, forming a detoxified complex, leading to reduced neurotoxicity of As. Perhaps, glutathione peroxidase, a selenoenzyme, minimizes As-induced oxidative stress. Results of our study may help develop therapeutic intervention to improve maternal mental healthcare policies in rural Bangladesh and globally.

Abstract Name: Analyzing the Use of Social Support and Education/Coping-Based Interventions to Reduce Postoperative Pain in Adolescents Undergoing Surgery for Idiopathic Scoliosis (IS)

Idiopathic Scoliosis (IS) is a three-dimensional deformity of the spine that often requires surgical treatment when the scoliotic curvature is severe (Cobb Angle $\geq 40^\circ$). As adolescents (10-19 years) with IS face unique challenges because of their condition and medical treatment, this population may be at greater risk for anxiety, depression, and social problems compared to healthy peers. Because preoperative anxiety,

depression, and social problems have been linked to worse postoperative pain, preoperative psychological interventions may improve pain outcomes for this group. The purpose of this study was to investigate how preoperative psychopathological symptoms predict postoperative pain and evaluate how social support and education/coping-based interventions may reduce postoperative pain in adolescents undergoing surgery for IS. This literature review analyzes studies discussing preoperative psychopathological symptoms, postoperative pain, and psychological interventions intended to improve surgical outcomes. As some adolescents with IS internalize stress and avoid social interaction, social support may facilitate the reduction of postoperative pain by encouraging adolescents to be transparent about their concerns related to IS with family, peers, healthcare providers, and others with IS. Because anxiety and depression may be linked to reduced pain coping and increased pain catastrophizing, education/coping-based interventions may reduce postoperative pain by reinforcing coping techniques and answering concerns about surgery and recovery. Adolescents with IS may find interacting with a healthcare professional to be more effective than receiving passive interventions such as asynchronous videos. Adolescents with greater preoperative anxiety may benefit more from support groups and education/coping-based interventions compared to those with less preoperative anxiety. It is important that healthcare professionals consider the relationship between mental health and pain to ensure the best pain outcomes for adolescents treated surgically for IS.

Abstract Name: These Bright Hills: Helen Price Stacy's Human-Interest Poetry

The legacy of Helen Price Stacy (1919-2007), a writer, researcher, artist, and historian centered in Morgan County, Kentucky, lives on through her collected papers in the Camden-Carroll Library at Morehead State University. Price Stacy donated her own papers and saw her extensive work and unpublished poetry as a catalog of Eastern Kentucky. While her poetry certainly celebrates the power, beauty, and tradition of her Appalachian home, Price Stacy also explores the impact of people and place. Her poetry mirrors the tone and topics of her articles written for the Licking Valley Courier newspaper whilst blending in her personal opinions that are restrained in her articles. Forging her own path forward, she was her own editor and agent, continually writing and learning from her experiences as a journalist. Fueled by her passion for the region and her people, Price Stacy's unpublished poetry captures the essence of the human-interest story with a voice that celebrates, critiques, and honors the pride and resilience that marks the Appalachian region.

Abstract Name: Examining Geographic Access to Specialty Schools in Richmond, Virginia

This research examines how the geographic locations of specialty schools in Richmond, Virginia influence enrollment and access for the student population. It aims to identify whether spatial distribution and transportation availability create barriers to accessing specialty schools for certain student populations. Specialty schools in Richmond are secondary schools with competitive admissions that provide advanced or specialized academic programs. Existing research has explored the equity implications of the admissions

processes of specialty schools, but limited research addresses access from a geographic perspective, particularly for Richmond Public Schools, a diverse urban school district. Investigating this spatial dimension is critical since specialty schools consistently produce the strongest academic outcomes. Additionally, prior studies on school choice consistently emphasize that distance and transportation availability play a fundamental role in the schools parents send their children to. This study employs a spatial analysis approach, mapping specialty school locations across Richmond's census tracts and generating drive-time maps for each school. These maps are examined alongside the city's and school district's transportation offerings to assess how proximity and mobility can influence student access. Through this analysis, I seek to determine the geographic and transportation barriers that may impact access to these schools, especially for certain demographic groups. The discussion will also include policy and practice recommendations to improve geographic accessibility and reduce disparities in enrollment.

Abstract Name: Harm Reduction and Suicide Prevention: Use of Restraints in 19th-Century Asylums

This research project investigates the ethics behind the use of restraints in the Rochester State Hospital (Minnesota) during the late 19th century. While numerous movements in psychiatry attempted to minimize or even abolish restraints, hospital records reveal that their use persisted as a response to patient self harm, violence, and suicide risk. Based on manuscript patient records, asylum superintendent reports, and contemporary academic articles, this study analyzes how physicians and staff justified restraints as types of interventions, safety measures, or necessary actions. Ultimately, this project contributes to a deeper historical understanding of how debates about patient safety and ethics shaped asylum practices and continues to inform modern discussions on the use of restraints in psychiatric care.

Abstract Name: Effects of Microdroplet Cooling on Electronic Surfaces

The purpose of this research is to explore the feasibility of microdroplet spray as a cooling method for electronic components. At the individual component level, conventional electronic cooling methods such as fan airflow and liquid heat sinks may not be as effective as directly spraying components with microscopic amounts of liquid. In the microdroplet cooling process, the heat from an electronic component surface is transferred into sprayed microdroplets that will in turn evaporate to keep the component's temperature low and at a more effective operating level. The effectiveness of microdroplets at transferring heat is a prospective area of interest due to the increasing amounts of processing power that computer processing units are able to handle and the resulting heat they generate. Research in this field has explored the variety of factors that manipulate microdroplets, such as surface tension and release patterns of a piezoelectric droplet generator.

Previous sessions of research on this project have explored how to generate microdroplets 90-120 micrometers in size and built an experimental testing setup for recording and analyzing the cooling effectiveness of these single microdroplets. This session has continued the previous work by focusing on two new challenges: Analyzing the factors that manipulate a single microdroplet, and building an experimental setup that can test how a microdroplet spray can be manipulated to best cool a heated surface. New equipment for experiments, data acquisition devices and software had to be learned and helped students develop skills on experimental procedure.

Abstract Name: Evaluating the capabilities of artificial intelligence (AI) to conduct geospatial analysis

As artificial intelligence (AI) capabilities improve, concern is increasing over AI's ability to displace workers in a variety of fields. Given the ongoing success of generative AI in cognitive fields like computer science, there are reasonable expectations that AI will adapt to geospatial tasks. However, few studies have examined how AI handles geospatial data and spatial analysis tasks. This study will assess their reliability and performance for simple to complex tasks. For this project, we developed a methodology to evaluate several generative AI models' performances across multiple dimensions: different types and complexity of geospatial tasks and raster and vector base tasks. We evaluate AI based on its success in performing tasks between datasets. Comparing the limitations of each result should highlight the strengths and weaknesses of generative AI across these dimensions. Our spatial analysis testing methodology involves using Python code to carry out each task. The first step is to use a standardized AI prompt in the Cline plugin within Visual Studio Code. This provides consistent API access to each major AI vendor. The AI then generates a Python Notebook that is opened with ESRI's ArcGIS Pro and executed. We allow up to five "interactions" with the AI to complete each task. The results of each AI task are categorized as: "unsuccessful" "unsuccessful -- code but incorrect result," or "successful" The final assessment will include the number of interactions required and whether the AI was successful or not in completing each task. This workflow will examine how AI performs across increasing levels of complexity and how quality of completion varies between vector and raster tasks. The results will identify patterns in AI reliability and demonstrate strengths and weaknesses in AI's workflow. The results of our study will indicate the current capacity of AI to supplement and potentially replace GIS jobs.

Abstract Name: Hardwired for Apathy: The Influence of Callous-Unemotional Traits on Punishment Processing

The present study investigates the differences in physiological reactions to motivation styles across individuals high and low in Callous-Unemotional (CU) Traits. CU traits, sub traits of Antisocial Personality Disorder (APD), encompass a wide range of behaviors, including a lack of guilt, remorse, and empathy. These characteristics are linked to dangerous or criminal behavior and an insensitivity to punishment. This

punishment insensitivity manifests in a decreased level of reaction to punishing motivation styles when compared to healthy controls, while maintaining a similar psychophysiological profile of response to neutral and positive reward styles. In this study, participants will first complete a short assessment of CU Traits and motivation reactivity, then they will perform a cognitive task (Flanker tasks) under 3 reinforcement conditions (neutral, reward, and punishment) while heart rate, respiration, and skin conductance are recorded. Compensation will be utilized to simulate reward styles in connection with performance, where participants can lose or gain money dependent on the accuracy of their responses to the Flanker tasks. Between each block, participants will complete a short self-report on bodily awareness during the preceding tasks. The physiological reactions under each condition will be compared with scores on the CU inventory to investigate if a connection between CU traits and a decrease in reactivity to punishment exists. Bodily awareness and self-reported motivation reactions will provide supplementary data to enhance these findings. It is hypothesized that by comparing physiological measures with motivation styles, the mediation of responses to motivation and CU traits by punishment insensitivity is demonstrated. Findings aim to inform the need for reward-based interventions for individuals with elevated CU traits, departing from the punitive focus of the American legal system.

Abstract Name: Exploring Long-Term Outcomes in an Inclusive Post-Secondary Transition Program

In this research, I am exploring the long-term outcomes of students who have completed an inclusive postsecondary education program at a mid-sized public university in the Midwest. Specifically, I am examining independent living, employment, and everyday gains that students achieve after graduation. Students in inclusive postsecondary education programs have intellectual disabilities that affect intellectual functioning, academic achievement, and adaptive behavior. Because these disabilities influence many aspects of their lives, it is important to examine independence across multiple domains. Previous researchers have examined these outcome markers for similar programs across the United States. Many studies have focused on employment outcomes and found a higher percentage of employed individuals with intellectual disabilities compared to the national average after completing such programs. As a student employee of the program at my university, I wish to identify and describe the post-graduation outcomes of our alumni. To accomplish this, I will contact all alumni who have completed either the two-year or four-year program and invite them to complete a survey. Once the survey results are collected, I will work with my mentor to develop a coding system to categorize similar responses and analyze patterns across the data. The findings will strengthen the evidence supporting the benefits of inclusive postsecondary education programs and provide valuable insights into our program's current strengths and areas for improvement.

Abstract Name: Microbial Warfare: Analyzing a Potential Anti-CRISPR Protein in Mycobacteriophage Faiyaz

Bacteriophages are viruses that infect bacteria. Bacteria have developed diverse defense mechanisms, like CRISPR-Cas, to prevent phage infection. Although CRISPR-Cas systems are well-established as bacterial adaptive immune pathways, a growing body of research highlights that phages can encode anti-CRISPR proteins that suppress these defenses. This project investigates the genomic mechanisms bacteriophages use to overcome bacterial immune defenses, with a focus on identifying potential anti-CRISPR proteins in newly isolated Mycobacterium phages. The study aims to utilize bioinformatics tools to characterize phage-encoded proteins that may participate in this evolutionary conflict, with an emphasis on determining whether novel phages possess functional anti-CRISPR activity. Mycobacterium smegmatic mc2155 was used to isolate phages from soil samples, which were visualized by transmission electron microscopy and sequenced for genomic analysis. Gene prediction and annotation were performed using Glimmer, GeneMark, Phamerator, and BLAST. Phage proteins were further characterized using structural and sequence-based tools, including HHpred, AlphaFold, FoldSeek, and Clustal Omega. These tools allow comparisons between proteins of interest and known anti-CRISPR proteins. Mycobacteriophage Faiyaz was discovered in 2024. Sequencing of its genome suggested that gene 46 in phage Faiyaz exhibits strong sequence and structural homology to the Aca2 family of anti-CRISPR-associated proteins. Alpha Fold modeling predicts a dimeric structure consistent with known Aca2 proteins, and FoldSeek alignments support this structural similarity with a low Root-Mean-Square Deviation (RMSD) value. Multiple sequence alignments also reveal conserved residues associated with DNA interaction in Aca2, strengthening the likelihood that this protein interferes with host CRISPR-Cas activity. These results suggest that phage Faiyaz encodes a functional Aca2-like anti-CRISPR protein and contributes to broader efforts to understand how phages evade bacterial immunity.

Abstract Name: Reconstructing Analog Composition Practices to Enhance the Modern Design Process

The paste-up—the physical assembly of type and images on a board—was a key composition method during the phototypesetting era (1950s-1980s). How can reconstructing analog paste-up methods help contemporary designers expand their design process and reveal spatial relationships obscured by software? This research synthesizes archival phototypesetting sources with practice-based reconstructions. By physically recreating the paste-up workflow with modern and analog tools the study exposes the embodied knowledge and spatial decision-making essential to pre-digital composition. The reconstructions revealed various findings. First, the physicality of paste-up encouraged iterative spatial adjustment. Secondly, the scale and tactility of working at actual size encouraged different spatial awareness than screen-based zooming. Lastly, material constraints introduced creative solutions that software’s undo function and infinite canvas have made obsolete, resulting in compositional strategies that modern designers rarely employ. This research demonstrates how paste-up techniques can offer contemporary designers tangible methods for prototyping spatial relationships before digital refinement. Unifying analog composition practices into design education and professional workflows can address the “software thinking” that constrains experimentation to available tools. The physical process of creating a paste-up encourages more deliberate compositional thinking; its scale and tactility reveal components often lost in screen-based work. Further studies should explore specific paste-up techniques as supplements to digital workflows.

Abstract Name: An Analysis of the Expanding Range of Hosts Infected by H5N1 “Avian Influenza” Virus and its Seasonality

Highly pathogenic avian influenza (HPAI) H5N1 subtype has been circulating globally since 1959. Clade 2.3.4.4b has rapidly spread across the globe through wild birds. The lineage arrived for the first time in North America in late 2021. Since then, many species of birds across North America, wild and domestic, have fallen victim to H5N1. Beyond birds, however, mammals and humans have also been infected and cross-species transmission has been achieved. In our research, we aim to contribute to the current understanding of the mechanisms for this cross-species transmission by examining the range of viral hosts across North America. Specifically, we conducted a host range analysis. We aggregated, parsed, and standardized data from Mexico, Canada, and the United States. In Mexico, the Mexican national government’s Service of Agro-Alimentary Health, Safety, and Quality publishes instances of H5N1 in birds across states and municipalities. In Canada, the Canadian Animal Health Surveillance System maintains a database of H5N1 infections across provinces. Similar databases exist in the United States through the Centers for Disease Control and Prevention (CDC) and the United States Department of Agriculture (USDA). After aggregation and analysis of these data, we found that the most commonly impacted taxa across Canada and the United States were Galliformes and Anseriformes. Pelecaniformes and Anseriformes were the most common host taxa in Mexico. This research is being used in conjunction with a larger effort to study the viral promiscuity and replication abilities of H5N1 influenza A. Our findings include discovery of seasonality trends with regards to viral circulation and dissemination. We also analyze viral reassortment events that precipitate viral outbreaks among species. Our research will expand upon these preliminary results. With these several efforts we will elucidate factors causing the cross-species transmission of the virus and means to abate the spread of the virus.

Abstract Name: Skin Conditions: Body Image Intervention and Promotion

Skin conditions have a variety of known causes and effects. Conditions including eczema, acne, and psoriasis are both influenced by and contribute to psychological stress. Skin conditions impact socialization, self-esteem, and body image. There is insufficient research on interventions to improve self-perception associated with skin conditions. The present studies will assess the impact of a brief online intervention on self-esteem and body image in adults with skin conditions. Methods: Study 1’s fifty-six participants with various skin conditions were separated into two groups; viewing either a positive or neutral depiction of a skin condition and reflecting on personal empowerment. The proposed Study 2’s participants will be separated into four groups: viewing the same image conditions, paired with either empowering or neutral reflection. Participants in each study completed or will complete assessments of dermatological quality, self-esteem, and body image.

Results: In Study 1, overall appearance evaluation, investment in appearance, and negative affect improved regardless of experimental group. Dermatological life quality was a significant predictor of overall appearance evaluation ($b = -0.34$, $p = 0.004$), negative affect ($b = 0.42$, $p = 0.001$), and social comparison ($b = 0.288$, $p = 0.03$). Study 2 will seek to further examine the relative impact and combination of image exposure (positive and neutral) with image reflection (empowering and neutral) on these outcomes. Conclusion: Skin conditions like eczema, psoriasis, and acne are common skin conditions affecting people across all ages. Brief image interventions paired with empowerment reflections may improve body image in the short-term in this population.

Abstract Name: Discrimination and Somatic Depression in Black Women: The Moderating Role of Emotion Suppression

Prior research by Schulz et al. (2006) shows that discrimination is a major stressor that affects Black women and contributes to undesirable mental health outcomes. The study examined whether discrimination is related to somatic symptoms of depression in Black women. The Perceived Ethnic Discrimination Questionnaire, the Beck Depression Inventory 2- Somatic, and the Emotion Regulation Questionnaire-Suppression measures were used to analyze data from a sample of 149 Black women. The women in the sample ranged from ages 18-72 with a mean age of 32.78. A moderation analysis examined whether suppression moderated the discrimination–somatic symptoms association. Results indicated that discrimination is significantly related to physical signs of depression (e.g., problems with sleep and appetite, fatigue, irritability) in Black women who were more likely to use suppression of emotions as a coping strategy for stress. For those who did not suppress emotions, discrimination was not related to somatic depression. These findings call attention to the need for culturally-informative mental health care. Healthy coping strategies are critical for African American women who deal with discrimination stress.

Abstract Name: ORIGAMI CARBON STRUCTURES TUNED BY TARGETED PRECURSOR PLACEMENT AS A METHOD FOR COMPOSITE MATERIAL ANALYSIS

Here we present the creation of heterogeneous, complex, carbonaceous structures for use in various structural applications. The use of paper in the creation of origami structures is well known. However, the use of origami to shape more technical materials remains underexplored. Our group has previously demonstrated the use of pure cellulose films as the precursor for glassy carbon and tungsten carbide origami structures that feature a large specific strength, low density, and excellent scaling behavior, making them candidates as

structural materials in lightweight energy components, for example structural batteries and sensors. In this work we focus on how precursor placement on specific panels of the Miura-ori pattern influences the microstructure, mechanical, and electrical performances of the resulting carbonized structures. To address this, we fabricate samples by applying precursors to targeted panels, pre-creasing and manually folding the patterned sheets, and carbonizing them under inert and anoxic conditions. Once the structures are fully carbonized, we then evaluate results through various characterization techniques analyzing compressive and tensile strength, density, and look for miscellaneous advantageous properties when compared to the homogeneous material structures themselves. Due to past results in our group with homogeneous structures, we expect our heterogeneous structures to also perform advantageously to other composite materials created through more tedious means. These carbide structures have shown promising results and future applications that backs up the importance of research such as ours.

Abstract Name: Tunable Tau: a Novel Alzheimer's Disease (AD) Model in *C. elegans*

In AD, soluble oligomers of Tau accumulate specific post-translationally modifications (PTMs), leading to hyperphosphorylated intracellular aggregates termed neurofibrillary tangles (NFTs). The relative impact and precise mechanism through which soluble tau oligomers and NFTs contribute to AD is still unclear. Many AD models rely on expressing fixed levels of Tau to drive pathology, but phenotypic severity is clearly dependent on Tau abundance, making it difficult to independently distinguish the impact of selectively toxic PTMs. Here, we developed a novel genetically-modified *C. elegans* model which we termed “Tunable Tau” to ask how Tau expression levels modify phenotypic severity in the context of disease-associated PTMs. Tau was expressed pan-neuronally at categorical levels ranging from low to high via multi-copy transgene integration at a genomic safe-harbor loci. Because phosphorylation of soluble Tau at Threonine 231 is a gatekeeper modification and biomarker for AD, we also generated comparable strains expressing a T231E phosphomimetic mutant. First pass analysis of the model consisted of assessing three behaviors: a sensory response to light touch, a locomotor behavior when immersed in liquid, and an associative learning task based on olfactory-dependent chemotaxis where exposure to a chemoattractant in the absence of food causes agnostic subsequent responses, reflecting a short term memory of starvation. While performance on all tasks were adversely affected by increased Tau levels, the sensory and locomotor responses were particularly sensitive to T231E. Associative learning on the other hand was equally impacted by wildtype and T231E. While the cause is unknown, it is consistent with Tau impairing neuronal function through diverse mechanisms, some of which relate strictly to protein abundance and others to selective modifications. We anticipate that this model will help to deconvolve the relative impact of these factors on phenotypic severity of AD related outputs and the molecular mechanisms through which this occurs.

Abstract Name: Ultrasound-Activated Polymeric Microbubbles: A Non-Invasive Strategy for Dental Biofilm Removal

Each year, roughly 5 million dental implants are placed in the United States, and 3–5% of these implants ultimately fail. Peri-Implantitis is a major cause of late-stage dental implant failure and remains a growing concern in modern implant dentistry. This condition is driven by the accumulation of a resilient bacterial biofilm on the titanium implant surfaces, which has many harmful effects. Once established, this biofilm triggers chronic inflammation in the surrounding gums and leads to progressive bone loss and implant failure. Current clinical practices rely heavily on mechanical scraping and harsh chemical disinfection through chemicals such as chlorhexidine or hydrogen peroxide. These current methods are surgically invasive and fail to fully eradicate biofilms without fragmentation, which further worsens inflammation. To address these limitations, this project introduces a novel, non-invasive therapeutic strategy using ultrasound-responsive polymeric microbubbles (PMBs) for biofilm removal on implant surfaces. Microbubbles are microscopic (typically 1-10 μ m in diameter) spherical particles that have a stabilizing outer shell and inner core. Upon exposure to low-intensity ultrasound, the Polymeric microbubbles will oscillate, collapse, and generate localized mechanical forces that are capable of disrupting the biofilm structure. This mechanism offers a non-invasive alternative to conventional debridement techniques. The energy is delivered non-invasively, without scraping, abrasion, or chemical damage to surrounding tissues. This novel application of polymeric microbubble cavitation has very promising applications for dental implant decontamination. By providing a non-invasive, targeted system for biofilm removal, this technology has the potential to transform peri-implantitis treatment in clinic. Future directions involve quantifying biofilm degradation under numerous conditions to quantify our project parameters, and exploring the integration of antimicrobial drugs in the gas core to create dual-action mechanical-chemical therapy. Ultimately, this application offers a promising next generation method for preventing and treating peri-implant infections without the need for surgical procedures.

Abstract Name: Targeting HIF pathway to alleviate fibrotic response in human lung fibroblasts

Idiopathic pulmonary fibrosis (IPF) is a progressive and fatal lung disease characterized by excessive fibroblast activation and extracellular matrix (ECM) deposition. Emerging evidence suggests that hypoxia-inducible factors (HIFs), including HIF-1 α and HIF-2 α , play a key role in driving fibroblast activation and sustaining profibrotic signaling. In this study, we investigated how prolonged culture conditions influence HIF pathway activation in human lung fibroblasts (hLFs) and whether pharmacological inhibition of HIF proteins can mitigate fibrotic responses. Our results show that extended culture induces a robust profibrotic phenotype that mirrors TGF- β 1-induced activation, including increased expression of α -SMA, Col1A1, FN1, and ACTA2 at both the protein and mRNA levels. Treatment with HIF-1 α inhibitor (KC7F2), HIF-2 α inhibitor (PT2385), or their combination significantly reduced fibrotic gene and protein expression, with dual inhibition producing strongest suppressive effect.

Abstract Name: Automated Retinal Segmentation of Hyperspectral Images Using a Modified U-Net with Spectral Multi-head Attention

Retinal vessel segmentation plays a critical role in the evaluation of retinal and systemic health by allowing for detailed analysis of the retinal vascular network. Literature in retinal segmentation is mostly focused on regular RGB (red, green, blue)-colored images taken by fundus cameras or optical coherence tomography. Moreover, Hyperspectral imaging (HSI) captures both spatial and spectral data that can be used to extract a wealth of information such as oxygenation rate. However, there is no pre-existing literature that performs retinal vessel segmentation using HSI. Furthermore, existing segmentation frameworks are tailored to human retinas, despite mouse models' prevalence on pre-clinical research. To address these limitations, we are developing a deep learning architecture capable of segmenting mouse retinal vessels from HSI fundus images. Mouse fundus imaging was conducted via a dual-camera HSI-RGB system, leading to the acquisition of 53 HSI images. These images were manually segmented by two trained annotators blinded to each other's annotations to establish ground truth and verify intra-rater reliability. We propose that the integration of U-Net3+ with multi-head attention block and Tversky loss can conduct refined retinal segmentations. The model's performance was assessed using Dice similarity coefficient (DSC) and the Intersection over Union (IoU) metrics. A comparative analysis was conducted against the ground truth, and common segmentation techniques such as UNet, UNet++, and UNet3+. We demonstrate that our spectral network achieved a test IoU and DSC score of 0.79 ± 0.03 and 0.87 ± 0.02 , respectively, ranking higher than or equal to other tested models. Additionally, the intra-rater agreement between annotations was evaluated; the DSC and IoU scores are 0.73 and 0.58 respectively, indicating moderate agreement. Thus, our preliminary results indicate that our current model outperforms other tested networks. After further refinement, the model can serve as a potential tool for quantitative analysis of retinal vessels with hyperspectral images.

Abstract Name: Give and Take: Dissecting the Paradoxical Difference Between Adoption and Retraction of Students' Rights

In 1964, The Civil Rights Act was passed, outlawing discrimination based on race, color, religion, sex, national origin, and public segregation, codifying the integration of schools and businesses. Title IX, passed in 1972, prohibited discrimination on the basis of sex within educational or any programming that utilizes federal funding assistance. These pieces of legislation were keystones in creating financial and communal accessibility for students. Within the past academic year, intense changes to students' lives have occurred limiting campus freedom and speech. The Civil Rights legislation took 395 days to be adopted from its first draft to final adoption. Title IX was brought to the Senate in 1972 and finalized in 1975. Under the current administration, various executive orders target academic freedoms, speech, and inclusivity on campus. These implementations are revoking rights that students and legislators have fought for years to codify. This study aims to examine the stark contrast in the slow rise and establishment of these freedoms to their swift rollback. Research will explore archival photographs, meeting minutes, and other records in the Lexington Committee

on Religion and Human Rights Records, 1963-1967, at the University of Kentucky Special Collections Research Center focused on integration of high schools within Lexington, Kentucky. This collection illuminated the grassroots movement behind the “societal” push to adopt these freedoms in Lexington. Utilizing these actions and comparing them to reactionary measures from the campus executive power. The project will highlight the shift from a democratic approach of education regulation to an autocratic approach. Taking this forward, this research means to be utilized in a cautionary and exemplary format for how academic environments can be swiftly altered and the effects that come with those changes.

Abstract Name: Analyzing Water Vapor Addition to Argon DBD Plasma using Emission Spectroscopy

The work presented is a part of a plasma project at SJSU that is investigating the addition of topical medicine to a DBD plasma jet that will scan the wound surface to enhance the wound healing process. DBD plasma is known for its ability to accelerate the wound healing process by the interaction of reactive oxygen and nitrogen species (RONS) with water in the wound surface. In the current work, a DBD argon plasma torch (8-10kV, 20-45kHz, 1-16slpm argon) is designed and characterized by using emission spectroscopy. An ocean optics spectrometer (UV-250-800nm with 1.0nm resolution) was employed. The emission spectrum shows prominent ArI and ArII emission lines (696.5, 706.7, 714.7, 727.3, 738.4, 763.5, 408.6 nm), OH lines (A-X band, 306-312 nm), nitrogen second positive system (337, 357, 380 nm) and atomic oxygen lines (777, 844 nm). Results showed that emission line intensities strongly depend on the applied voltage and the gas flow rates. One additional aspect of this research was to investigate the possibility of adding topical medicine (droplets ~20-100 microns) that will enhance the plasma based wound healing process. For this purpose, a special DBD plasma torch with an integrated mist-generator was developed and, as a first step, water mist was added to the plasma jet. Observations reveal the change of plasma color that is attributed to the water molecules ionization producing OH (A-X band), atomic oxygen and enhanced nitrogen emission lines. Emission spectroscopy was employed to observe the spectrum. Addition of water provided additional inelastic channels that reorganized the population pathways resulting in Ar lines suppression. With controlled operating conditions, it was possible to sustain the plasma jet as the water droplets were introduced into the main gas flow. Complete results will be presented in the conference.

Abstract Name: Cauldrons, Coins, and the Creole: A Graphic History

This proposed research poster is a comic designed to reach and educate a broad audience about northwest Louisiana's early Colonial-era Creole populations through visual and artistic means. This graphic narrative is made in partnership by the Virtual Curation Laboratory (VCL) with the National Center for Preservation Teaching and Technology (NCPTT)'s Cane River Diasporas (1780-1820) exhibition, with research from the Melrose, Coincoin Plantation, and original Pierre Metoyer Land Grant site. This project will combine art, tactile learning, and history to create a colorful graphic narrative. The full comic, tentatively titled A Graphic History of Creole Peoples in Louisiana (abbreviated to GHCPL for further reference), will be distributed electronically via the Virginia Commonwealth University (VCU) Scholars Compass website on a page hosting comics created by the VCL (https://scholarscompass.vcu.edu/vcl_comics_pubs/) and printed as a hard copy.

Abstract Name: Sensitivity of Developmental Assessment to Sex Differences in Early Autism Traits in Preschool-Aged Children

Girls are often diagnosed with autism later than boys. This delay can reduce autistic girls' access to early intervention and impact long-term outcomes in mental health, education, and employment. One possible contributing factor to this disparity is that commonly used tools, such as the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), may not fully capture how autism presents in girls. This study examines whether commonly used autism and language assessments reveal sex differences to understand whether these differences contribute to sex-based disparities in autism diagnosis. We ask: (1) Do autistic boys ($n = 5$) and girls ($n = 3$) differ on the ADOS-2 Social Affect (SA) domain and Restricted and Repetitive Behavior (RRB) domain? (2) Do autistic boys and girls differ in their language ability measured by ADOS-2 Language and Communication subscale, the Preschool Language Scales, Fifth Edition (PLS-5) and MacArthur-Bates Communicative Developmental Inventories (MCDI)? Although no finding is statistically significant given a small sample, girls and boys perform similarly in RRB ($p = .42$) and SA ($p = .48$). However, girls perform better in language as measured by ADOS-2 Language and Communication ($p = .21$). More variability in vocabulary is also observed in girls. These findings suggest that while social and behavioral features of autism (as measured by SA and RRB) appear similar across sexes, language-based assessments, e.g., ADOS-2 Language and Communication subscale, may be more sensitive to subtle linguistic differences in autistic girls.

Abstract Name: Identifying dietary, lifestyle, and physiological factors that contribute to kidney stone formation

Kidney stones affect millions of individuals worldwide and are becoming more common among young adults and college age students. Many elements that contribute to kidney stone formation are still not fully understood by people outside the field of healthcare, so taking prophylactic measures becomes difficult. This project aims to identify and compare major dietary, lifestyle, and physiological factors that increase people's risk of developing kidney stones. Through combining various studies that were conducted on kidney stones in recent years, we identified leading factors that contribute to kidney stones. Variables such as lower hydration levels, higher sodium intake, different levels of physical activity, and genetic susceptibility were all listed as strong risk factors. Other health factors impacting formation of kidney stones include obesity, prescribed medications, urinary pH imbalance, and insulin resistance. Each category has different levels of impact, and understanding which ones have the highest impact helps individuals make informed decisions about hydration, nutrition, and their overall health. The findings suggest that kidney stones are formed based on multiple interrelated factors, emphasizing that individualized patient prevention plans are necessary. Understanding these interconnected risk factors also highlights the importance of advocating for stronger community outreach efforts to educate patients on preventing nephrolithiasis. Promoting routine screening

and improving nutrition and hydration can help young adults recognize their personal risks and limit risk factors from a young age. Encouraging schools and universities to prioritize kidney health education empowers individuals to make informed health decisions before developing kidney stones. Ultimately, identifying and communicating prevention based intervention can reduce the rising incidence of kidney stones and promote healthier communities.

Abstract Name: What Makes Halos Dark?

We investigate the factors that determine whether dark matter halos form galaxies using the Marvel-ous Dwarfs and DC Justice League zoom-in simulations. By analyzing halo occupation fractions, mass accretion histories, halo concentrations, and gas properties, we find that halo mass alone is insufficient to explain why some halos remain dark. Luminous halos grow faster, achieve higher concentrations, and retain dense, cool gas, enabling star formation. Dark halos grow more slowly, remain less concentrated, and have lower gas densities and higher gas temperatures, preventing efficient cooling after reionization and leaving them dark. These results highlight the interplay between dark matter dynamics and baryonic physics in shaping galaxy formation, demonstrating that mass growth, halo concentration, and gas content collectively determine whether a halo hosts a galaxy.

Abstract Name: Daily Social and Work Withdrawal and Mood

The behavioral theory of depression proposes that reduced access to response-contingent positive reinforcement, often linked to cutting back on daily meaningful activities, contributes to depression (Lewinsohn & Graf, 1973). Although originally developed to explain depression, these tenets may extend to nonclinical populations, where daily activity withdrawal may be negatively associated with mood. Using data from the MIDUS Daily Stress Project (2004–2009; $N = 2,021$ adults; Ryff & Almeida, 2017), we examined how daily social and work withdrawal, reported occurring because of physical, emotional, alcohol-related, other, or combined problems, related to same-day positive affect (PA) and negative affect (NA) across eight consecutive days. Linear mixed-effects PA and NA models with random intercepts and slopes for within-person social and work withdrawal showed that withdrawing more than usual on a given day was associated with higher NA (social cutbacks: $b = 0.41$; work cutbacks: $b = 0.38$) and lower PA (social cutbacks: $b = -0.44$; work cutbacks: $b = -0.39$), all p s $< .001$. At the between-person level, individuals who withdrew more across the eight days also showed higher NA (social cutbacks: $b = 1.62$; work cutbacks: $b = 0.52$) and lower PA (social cutbacks: $b = -0.94$; work cutbacks: $b = -0.64$), all p s $< .001$. All models

controlled for daily physical symptoms, given that it was the most reported reason for activity withdrawal. These findings suggest that mood is sensitive to same-day social and work activity withdrawal, regardless of one's general level of withdrawal. Practically, even when reductions in activity are necessary (e.g., illness, caregiving), they appear to carry mood costs. Limitations include the lack of detail on the extent of withdrawal each day (i.e., a continuous measure) and the non-experimental design which prevents causal inferences. Nonetheless, the results highlight the importance of encouraging individuals who must cut-back to replace lost activities with low-demand, rewarding alternatives (e.g., calling someone, light hobbies).

Abstract Name: Impact of Obesity in the IBD-Associated Colon Cancer Using IL-10 Knockout Mouse

Colitis-associated colorectal cancer (CAC) has posed a significant health burden, with patients diagnosed with inflammatory bowel disease (IBD) experiencing a markedly higher lifetime cancer risk. Obesity, which affected 15–40% of individuals with IBD, further elevated systemic inflammation through increased production of cytokines such as IL-6 and TNF- α . However, the combined impact of obesity and chronic colitis on CAC development had remained poorly defined. This study investigated whether obesity exacerbated inflammation and accelerated tumor initiation and progression in the IL-10 knockout mouse model, a well-established model for IBD and CAC. Six-week-old IL-10 knockout mice were assigned to lean or obese groups, with obesity induced through a high-fat diet. All mice received intraperitoneal injections of azoxymethane (AOM) at weeks 0 and 5 to initiate tumorigenesis. Tissue and serum samples collected at 2-, 10-, and 20-weeks post AOM to assess tumor incidence, tumor size, inflammatory incidence. We anticipated that obese IL-10 knockout mice would exhibit increased tumor burden, elevated inflammatory cytokines and NSPs, and a reduced M1/M2 macrophage ratio compared to lean controls, indicating a more tumor-promoting microenvironment. These results were expected to provide insight into how obesity magnified inflammatory pathways in chronic colitis and to support future therapeutic strategies targeting NSP activity and macrophage polarization in high-risk IBD populations.

Abstract Name: Associations Between Childhood Exposure to Threat and Deprivation and Psychopathology Symptoms in Emerging Adulthood

Previous studies show the effects of adverse childhood experiences (ACEs) on mental health. However, ACEs assessment typically doesn't focus on the underlying dimensions of adverse childhood experiences that may have unique psychological consequences. The Dimensional Model of Adversity and Psychopathology

(DMAP; Sheridan & McLaughlin, 2014) advances this understanding by assessing how two dimensions of adversity, threat and deprivation, influence psychological outcomes through emotional and cognitive pathways (Tsai et al., 2025). Using the DMAP approach, this study extends prior work by examining how exposure to threat and deprivation during childhood relates to internalizing and externalizing symptoms in emerging adulthood. We recruited 436 participants between the ages of 18 and 23 through Sona Systems at two U.S. universities, one in the southeast and one in the northeast. Participants self-reported childhood adversity and current functioning via an anonymous Qualtrics survey. We ran a series of partial correlations testing associations between the threat and deprivation dimensions of childhood adversity, and symptoms of internalizing (distress, obsessions/fear, low positive mood) and externalizing (disinhibition, substance use, callous aggression). We controlled for the adversity dimension not being tested in each model. The threat dimension of childhood adversity was significantly correlated with internalizing (r range = .182-.296, p < .001) and externalizing (r range = .167 - .232, p < .001) outcomes; for example, more childhood threat exposure was correlated with greater emerging adulthood symptoms of distress, $r(436) = .260$, p < .001. The deprivation dimension of adversity was also associated with internalizing symptoms of distress and low positive mood (r range = -.185 - .155, p = .001-.002) but not obsessions and fear (p > .10), and externalizing symptoms of callous aggression and disinhibition (r range = .133 - .163, p < .001 - .005) but not symptoms of substance use (p = .240). Discussion will focus on the translational implications of these findings for policy and interventions.

Abstract Name: Comparative Study of Ivermectin, Eprinomectin, and Doramectin/Levamisole Combination Products on Parasite Load and Weight Gain in Beef Calves

Internal parasites remain a significant constraint to growth performance and health in beef cattle, and increasing anthelmintic resistance—particularly to ivermectin—poses a growing challenge for producers. This research project will compare the efficacy of three injectable dewormers commonly used in commercial cattle operations: Ivomec® (ivermectin 1%), Longrange® (eprinomectin 5%), and Valcor® (a combination of doramectin and levamisole). The primary objective is to evaluate each product's ability to reduce internal parasite loads, as measured by fecal egg counts (FEC), and to assess both short-term (0–28 day) and extended-interval (~150–180 day) growth performance using average daily gain (ADG). A key aim of this study is to determine whether newer-generation or combination anthelmintics provide superior parasite control or improved growth outcomes compared to traditional ivermectin formulations. Thirty to forty calves aged 4–8 months will be randomly assigned to one of three treatment groups and monitored from baseline through long-term evaluation. Fecal samples and body weights will be collected on Days 0, 14, and 28, with an additional follow-up sampling point approximately 150–180 days post-treatment to assess sustained parasite control and longer-term ADG. FEC will be quantified using the McMaster technique, and ADG will be calculated across both short-term and extended intervals. These results will support detection of potential ivermectin resistance and help clarify whether newer products like Longrange or combination products like Valcor deliver measurable advantages in growth performance or parasite suppression. Findings will generate evidence-based recommendations for local cattle producers facing parasite management challenges and may contribute to regional outreach efforts and producer meetings.

Abstract Name: Slavery in the Archaeological Record: A Case Study of Artifacts from Attica and Pompeii

With the emergence of post-processualism in the late twentieth century, archaeologists began to shift their focus toward a more cohesive study of the oppressed. Behavioral archaeology, which developed just before the rise of post-processualism, has made significant contributions to the understanding of the behaviors of both the oppressed and the oppressors. Large-scale systems of enslavement had been discussed prior to the development of both behavioral archaeology and post-processualism, but these systems were rarely examined in depth. Part of this is due to the difficulty of identifying and defining evidence of slavery in the archaeological record through artifact and feature associations. Indeed, many archaeologists have determined it to be a hopeless pursuit. This comparative study aims to produce a principle through an analysis of Classical Greece and Imperial Rome, by applying two strategies of behavioral archaeology: strategy one and strategy four, as proposed by Michael Schiffer. This study begins with a discussion of how to definitively associate evidence, then moves on to the implications, with the goal of developing broader, more informed inferences about how slavery was practiced within the contexts of Classical Greece and Imperial Rome. Four key pieces of evidence from sites in Attica and Pompeii are used in a comparative case study: from Attica, a pair of iron fetters and a recurring agricultural tower feature; from Pompeii, a chained victim and preserved slave quarters. These pieces of evidence are analyzed in parallel, offering valuable insights into the evolution and characteristics of slavery across the broader Greco-Roman world, and ultimately indicate a significant continuity between Greek and Roman practices of enslavement. We propose a principle: through cross-cultural comparisons, gaps in current knowledge can be bridged, helping archaeologists to better interpret artifacts, behaviors, and social structures related to slavery in these ancient societies.

Abstract Name: The Impact of Television Series in Expanding Film Franchises Through Star Wars: The Clone Wars and Star Wars: Rebels

This project seeks to closely analyze the role that television series play in expanding the narrative world of film franchise in the context of the Star Wars franchise and two of its series, Star Wars: The Clone Wars, and Star Wars: Rebels. While expansive scholarship exists on the overarching franchise, these series have been overlooked. However, they provide crucial context on the value of adding television installments to film franchises, especially during the Star Wars' transition to Disney ownership. To explore the series as installments in a larger franchise, I perform a close analysis of eight episodes comprising two narrative arcs of The Clone Wars, and four episodes comprising two narrative arcs of Rebels. I consider release context, narrative timeline, audiovisual elements, character actions, and audience reception to assess what contributions these series make to the overall story. My preliminary conclusions are that the series expands the science fiction world-building in a way that helps to realize more of the storyworld and draw in new audiences, as well as adds depth and context to character actions. Most importantly, it works to reinforce elements of the feature films that audiences liked, while minimizing or correcting aspects that were unpopular. In The Clone Wars, this holds particularly true as it is set in between Episodes II and III of the Prequel Trilogy, which was not as well-received as the Originals on first release. In Rebels, reinforcing audience preferences about previous series and films in the franchise allows it to serve as a bridge between previous iterations of the franchise and the new era of Disney Star Wars. Both of these series expand the

narrative and world of Star Wars, creating opportunities for new viewers while reinforcing the preferences of existing audiences.

Abstract Name: A Behavioral Analysis of the Perception in Ionic Gradients and Artificial Intelligence Recommendations on Human Trust and Decision Making

As Artificial Intelligence (AI) systems become integrated into high-stakes settings such as healthcare, education, and criminal justice, understanding how AI influences trust and decision-making is essential. Too much trust may lead users to accept incorrect AI recommendations, while too little trust may cause them to reject accurate ones. This study examines how Explainable Artificial Intelligence (XAI), or AI that provides reasons for its decisions, affects following behavior, reaction time, and human trust ratings under different error conditions. Fifty undergraduate participants from George Mason University were randomly assigned to either an XAI or a Non-XAI condition in a behavioral pilot experiment. Participants completed 300 randomized trials with three error conditions: (1) Non-Error-Prone, where the AI was portrayed as reliable and had correct recommendations; (2) Correct-Error-Prone, where the AI was portrayed as unreliable but had correct recommendations; and (3) Error-Error-Prone, where the AI was portrayed as unreliable and had incorrect recommendations. Participants' following behavior, reaction times, and trust questionnaire responses were recorded to assess how explainability and reliability shape trust in human-AI interactions. This pilot prepares for future Electroencephalogram (EEG) data collection by increasing both the trial speed and trial count, addressing a gap in XAI research that lacks EEG-compatible designs. By connecting behavioral trust measures with neural indices of error detection and decision conflict, this project will help uncover the cognitive mechanisms underlying human-AI interaction. The findings of this study are expected to show that explainable AI enhances participants' ability to detect errors and calibrate their trust more appropriately, leading to improved decision-making accuracy. Understanding these processes will guide the design of AI systems that promote trust and support safer, more effective human-AI collaboration in the high stakes domain.

Abstract Name: Math in Motion: Ballet as a Patterning Intervention for PreK/Kindergarteners' Mathematical Development

Mathematical thinking in early childhood is strongly linked to later academic success, yet many children struggle to develop foundational skills in mathematics. Pattern recognition, a core component of mathematical cognition, has been shown to outperform general math interventions in improving children's achievement. Despite this, little research has examined how dance, particularly ballet, can serve as a structured patterning intervention for young learners. This study investigated whether ballet classes

emphasizing repeating and growing patterns enhanced kindergarteners' patterning skills and, by extension, their mathematical development. Using a now-and-later design, PreK/Kindergarten students at Carnegie Mellon University's Children's School were randomly assigned to either a Ballet Fall or Ballet Spring group. Each group participated in two 20-minute ballet classes per week for six weeks, with lessons structured around simple ballet movements (plié, tendu, jumps, and leaps) organized into repeating and growing patterns. Children's patterning skills were assessed three times across the academic year (before instruction, midyear, and post-instruction) through tasks involving extension, translation, and identification of both repeating and growing patterns. Data will be analyzed using repeated measures ANOVA. This interdisciplinary approach bridges cognitive development and the arts, exploring how physical movement can foster mathematical understanding. By positioning ballet as a creative, inclusive, and engaging supplement to conventional math instruction, the study has the potential to inspire educators to integrate arts-based methods into early education. For children who struggle with traditional approaches, movement-based learning may provide an alternative entry point into mathematical thinking. More broadly, the findings could contribute to reimagining educational practices where creativity and cognition are deeply connected. The future of education could be one where pliés and leaps are just as important as traditional math lessons, where children learn math not only with their minds, but with their bodies.

Abstract Name: Flux Growth and Characterization of an Altermagnet Candidate CrSb₂

Altermagnets, a newly proposed class of quantum magnets, offer an exciting alternative to conventional ferromagnets and antiferromagnets by combining their properties in a single platform. Here, we present the materials synthesis technique of the altermagnet candidate CrSb₂ along with SEM and magnetic measurements. CrSb₂ is synthesized using a flux-based growth technique with excess self-flux Sb. After solid state reaction in inert gas atmosphere, that results in the seeds of the single crystal CrSb₂, the materials are slowly cooled to provide the favorable condition for the growth of the single crystal. A scanning electron microscope (SEM) shows the formation of high-quality single crystals. The temperature dependent magnetization data goes down with cooling below 300 K, indicating the antiferromagnetic transition of this compound above room temperature. This shows that CrSb₂ is a promising candidate for further exploration in the rapidly developing field of altermagnetism.

Abstract Name: Ethoxide-Derived Silicon–Germanium Nanocrystals for Environmentally Friendly Quantum Dots

(Background) Silicon-germanium ($\text{Si}_{1-x}\text{Ge}_x$) nanocrystals are being explored as a safer, replacement for other quantum dots as they are environmentally better. By changing both particle size and Ge content, we can tune their band gaps and optical response over a wide energy range. A remaining challenge is finding simple synthetic routes that give small, composition-controlled particles while staying compatible with silicon.

(Aim/Purpose) In this research we are focused on an ethoxide route to $\text{Si}_{1-x}\text{Ge}_x$ nanocrystals. Our goal is to show that this method can reliably produce strongly quantum-confined alloy nanocrystals and to understand how our processing steps affect composition, structure, and optical properties. (Approach) We prepared Si/Ge oxide gels by condensing triethoxysilane and tetraethoxygermane in methanol with cobalt under nitrogen. Nitric acid was used to start gelation, and the gels were aged, filtered, and dried. The dry gels were ground and annealed in a tube furnace under N_2/H_2 gas. We then etched the annealed powders with a controlled $\text{HF}/\text{H}_2\text{O}/\text{MeOH}$ mixture and finally attached 1-dodecene at elevated temperature to make colloiddally stable samples. Structural and optical characterization was carried out using X-ray diffraction, Raman spectroscopy, electron microscopy, and absorption/photoluminescence measurements. (Results) The ethoxide route produced $\text{Si}_{1-x}\text{Ge}_x$ nanocrystals in the 4-6 nm size range with Ge composition up to about 50%. XRD and Raman data are consistent and show peak shifts as Ge content increases. Microscopy and EDS indicate reasonably uniform Ge distribution with no obvious phase separation. Optically, the nanocrystals show photoluminescence, which agrees with quantum confinement and composition control. (Conclusions) Our results show that an ethoxide based gel/solid state route can generate small size, composition tunable $\text{Si}_{1-x}\text{Ge}_x$ nanocrystals without relying on highly toxic heavy metals. This approach provides a pathway for future Si-compatible quantum-dot devices in areas such as solar energy and optical sensing.

Abstract Name: Roots to Wellness: A Nutrition Intervention to Decrease Sugar Intake with High School Students

Purpose: On average, high school students consume four to five times more sugar than the recommended daily limit. This excessive intake is linked to chronic health issues including type 2 diabetes, obesity, and decreases in energy, focus and academic performances. Over the course of 3 weeks, we partnered with an alternative high school in northern Arizona, to implement a nutrition education program. This high school promotes career readiness to students who have attendance, behavior, or achievement barriers. Methods: For our intervention, we aimed to decrease sugar intake in sugar-sweetened beverages (SSB) and how this can create a foundation for future health benefits. Our intervention aimed to establish a baseline for the sugar content in sugary drinks consumed by high school students. We expected students to (1) identify health risks associated with overconsumption of SSB, (2) identify benefits of sugar-free alternatives, and (3) show increased intention to utilize herbs to create herb-infused drinks. To achieve these objectives, our proposed activities were interactive, group-focused, and relied on existing research-based interventions using the Health Belief Model. These activities included a sugar content lecture, sugar predictions in SSB, pot painting/planting, and creating an herb recipe booklet. To assess the effectiveness of our activities, we conducted pre- and post-tests to measure changes in knowledge, attitude and confidence related to sugary drink consumption and healthier alternatives. Results: Students showed increased knowledge related to their perceived susceptibility and benefits by 60%. Students also showed an increase in attitude and confidence with 90% of them reported medium or high intent to apply what they learned, showing strong behavior intention change. Conclusion: Our intervention increased awareness of sugary beverages and encouraged

students to consider healthier drink choices. The combination of sugar demonstrations, taste-testing, and hands-on planting engaged students and showed how small changes can improve health.

Abstract Name: Music-Based Interventions for Neurodivergent Youth: A Synthesis of Evidence and Implications for Emotion Regulation and Social Engagement

Music-based interventions have gained increasing attention as accessible, multimodal tools for supporting neurodivergent youth, particularly individuals with autism, ADHD, and sensory-processing differences. A growing body of research indicates that music engages distributed neural systems involved in auditory processing, motor coordination, prediction, social cognition, and emotional regulation. Systemic reviews and randomized trials demonstrate that music-based programs can enhance social interaction, joint attention, communication, and emotional expression in autistic children, although findings vary due to methodological heterogeneity, differences in intervention protocols, and inconsistent outcome measures. Evidence from large multisite randomized controlled trials shows high engagement and some secondary benefits in social responsiveness, yet highlights the need for more precise intervention characterization, dosage clarity, and stronger comparison conditions. Beyond autism, emerging research suggests that rhythm-based and music listening interventions may improve attention, executive functioning, and arousal regulation in broader neurodivergent populations. However, many studies rely on small samples or short-term effectiveness. Recent conceptual frameworks emphasize understanding why music may work through mechanisms such as rhythmic entrainment, predictable sensory structure, and neuro-emotional resonance, and advocate for integrating both controlled research and practice-based evidence from real-world youth mental-health settings. This project synthesizes current findings across five major peer-reviewed sources to clarify the strengths, limitations, and future directions of music-based interventions. The review identifies significant gaps in standardization, measurement, and ecological validity, and proposes the need for scalable, rigorously evaluated approaches that can be adapted across diverse neurodivergent profiles. By consolidating interdisciplinary evidence, this work aims to inform future research pathways and contribute to a more unified, scientifically grounded framework for the use of music in supporting social, cognitive, and emotional development in neurodivergent youth.

Abstract Name: Trust on Trial: How U.S. Foreign Policy Eroded Public Trust

Public trust in the U.S. government has declined sharply over the past several decades, falling from roughly 75% in the late 1950s to historic lows today. This project examines how major U.S. foreign policy decisions, specifically during the Vietnam War, the post-9/11 Global War on Terror, and the ongoing conflict in Palestine, have contributed to this erosion of trust. Through qualitative analysis of historical records, public opinion data, and scholarly assessments of U.S. military actions and their global consequences, the research identifies recurring patterns in how government narratives, media framing, and revelations of human rights

violations shape public perception. Findings indicate that each conflict initially gained broad public support through appeals to national security, democracy, or moral obligation. However, as evidence of government misinformation, strategic failure, or civilian harm emerged, public confidence declined sharply and often permanently. The Vietnam War demonstrated the first instance in which televised violence and government contradictions fractured national unity; the wars in Iraq and Afghanistan revealed the consequences of intelligence failures, prolonged occupation, and lack of accountability; and U.S. support for Israel during the current crisis in Gaza has intensified public skepticism, particularly among younger Americans, due to inconsistencies between stated American values and foreign policy actions. Together, these cases show that foreign military engagement is one of the most consistent predictors of long-term declines in institutional trust. Understanding this pattern is essential for evaluating the future of U.S. global leadership, rebuilding democratic legitimacy, and assessing how transparency, accountability, and public engagement can mitigate distrust. The paper highlights the need for a re-examination of U.S. foreign policy practices to prevent further erosion of public confidence and to promote ethically coherent international action.

Abstract Name: Green Elegance: The History of Korean Goryeo Pottery

The word “celadon” refers to both a pale green color with a hint of gray and, in ceramics, a type of glaze that originated in China. This term perfectly captures the aesthetic of Goryeo-era Korean art, where celadon became a defining feature of its style and design. The Goryeo dynasty, which ruled the Korean peninsula from 935 to 1392 CE, developed a rich artistic culture shaped by international exchange with countries such as China and the Mongol Yuan. Throughout nearly 500 years of Goryeo rule, art, especially ceramics, was highly valued, and celadon became the main type of pottery produced on the peninsula. Goryeo celadon’s distinct color and quality were possible thanks to local raw materials, including iron rich clay and glazes containing iron oxide and other minerals. Korean artisans used wheel throwing and high-temperature kiln firing to achieve the signature jade-like color. While many techniques were influenced by the celadon traditions of the Chinese Song dynasty, Goryeo potters refined and transformed these methods using their own materials and artistic preferences. Common Goryeo designs such as pots, bowls, kettles, and ewers feature the characteristic green glaze paired with elegant natural motifs. These nature-based designs reflect Buddhist and Taoist tastes for harmony with the natural world, making Goryeo celadon a visual expression of elite spirituality and courtly refinement. The soft green glaze, often with a subtle blue tint, unifies the aesthetic, while the use of natural materials allowed artisans to create pieces that were both functional and beautiful. Although influenced by the Song dynasty, Goryeo celadon developed into a distinctively Korean art form. It remains admired centuries later, demonstrating how Koreans adapted the craft into their own unique style and techniques, an artistic legacy that continues to influence Korean culture today.

Abstract Name: Right Place, Wrong Time: The Changing Phenology of Culturally Significant Plants in Southern Appalachia

Many communities in rural southern Appalachia have become socially and economically isolated from the rest of the United States, resulting in a severe lack of medical infrastructure. To cope with this disparity, many living within Appalachia resort to traditional uses of native plants with medicinal properties. This follows centuries of medicinal plant use performed by various cultures within Appalachia. However, the abundance of these plants may be negatively affected by global climate change. These changes in temperature may alter a species' phenology, the timing of developmental events like germination and fruiting. This may result in mismatches between plant and insect phenology, reducing interactions which are crucial for survival such as pollination or seed dispersal. Declines in medicinal plant populations would greatly impact the communities that rely on them. To investigate the effect of climate change on medicinal plant populations, we studied the phenology of various native medicinal plants. We downloaded data from the Global Biodiversity Information Facility (GBIF), including both professionally curated and citizen science data. The phenology stage of hundreds of plants from the late 1800s to present day was quantified using a standardized phenology scoring system. We rated samples from 0 - 4 based on their observed flowering or fruiting stage. The {rnoaa}, {weatherr}, and {weatherData} packages were used in R to acquire average monthly temperature data for each observation. We performed regression analysis to find the association between flowering date and temperature. We found that *Monotropa uniflora* blooms 6.8 days later for every 1°C in average temperature. Resulting phenological mismatches with commensal species may impact *M. uniflora* populations. Such declines could have notable impacts on Appalachian communities which rely on native medicinal plants like *M. uniflora*. We are continuing to research the effects of climate change on a host of medicinal plants native to Appalachia.

Abstract Name: Barriers in Healthcare: The Impact of Medical Mistrust and Misinformation

Medical misinformation poses a significant threat to the health and well-being of Hispanic/Latinx communities, particularly for individuals facing language barriers, limited access to reliable information, and systemic inequalities. This study examined the factors contributing to misinformation exposure by combining a literature review with a cross-sectional survey of 82 self-identified Hispanic/Latinx adults aged 18 and older. The survey assessed sources of health information, language preferences, confidence in interpreting English-only medical materials, translation tool usage, and experiences with misinformation. Results indicated that 67.1% of participants accessed medical information primarily in English, 20.7% in both English and Spanish, and 11% solely in Spanish. Most respondents reported fluency in English (70.7%), but 43.9% used translation tools to interpret medical content. Over half of participants (53.7%) reported following medical advice from family, friends, or social media instead of healthcare professionals. Financial considerations (47.1%) and cultural factors (30%) were the most common influences on health decision-making. Only 13.4% reported knowingly encountering false medical advice, yet open-ended responses revealed frequent exposure to conflicting or confusing information, suggesting misinformation is more pervasive than self-reports indicate. These findings underscore the critical role of language proficiency, cultural factors, and digital literacy in shaping how Hispanic/Latinx adults navigate health information. The study highlights the need for culturally relevant, evidence-based, and linguistically accessible health communication strategies to improve health literacy and reduce reliance on informal sources. Strengthening multilingual resources, improving translation accuracy, and addressing systemic barriers can help mitigate the spread of misinformation and enhance health outcomes. Overall, this research emphasizes that addressing medical misinformation in Hispanic/Latinx communities requires interventions that consider cultural, social, linguistic, and systemic factors simultaneously.

Abstract Name: Staying Connected: Emotional Closeness and Joint Visual Attention in Video Chats

Joint visual attention (JVA) is a foundational aspect of early social and cognitive development, yet little is known about how emotional closeness influences JVA during video-mediated communication. This study examined how perceived emotional closeness relates to the frequency of JVA bids in virtual interactions between grandparents and grandchildren. Over 50 recorded video chat sessions were analyzed using detailed behavioral coding to identify grandparent- and child-initiated JVA bids. Emotional closeness was assessed through self-report Likert-scale surveys completed by each dyad. Linear regression analyses revealed that emotional closeness did not significantly predict the percentage of successful JVA bids for either grandparent initiated, $F(1,52) = 0.17$, $p = .68$, or child-initiated interactions, $F(1, 52) = 1.30$, $p = .26$. However, trends in the data suggested that dyads reporting higher emotional closeness tended to show greater engagement and responsiveness during interactions. The lack of statistical significance may reflect limited sample size or variability in coding reliability across sessions. These findings suggest that while emotional closeness may not directly predict JVA success, it could still play a meaningful role in fostering engagement and positive affect during remote intergenerational communication. Understanding how relational factors shape attention and interaction in virtual contexts can inform strategies for supporting family connectedness and promoting child development through technology-mediated communication.

Abstract Name: Migrant Workers' Rights in Kuwait: The Role of Policymaking

My research examines the complex policymaking process in contemporary Kuwait regarding migrant workers' rights with a focus on the roles of prominent domestic political and social actors in shaping the kafala system. As a Kuwaiti citizen, I am deeply perplexed by the following question: What accounts for the persistence and widespread societal acceptance of the kafala system in Kuwait? The kafala system is a legal and sociopolitical system that governs the lives of migrant workers and the relationships between these workers, citizens of the host country, and the state. Migrant workers constitute a large percentage of the population in the Gulf, yet they are strikingly invisible in these countries. In 2025, the total population of Kuwait is approximately 4.5 million, comprising around 1.5 million Kuwaitis and approximately 3 million foreign residents. The Kuwaiti government has committed to improving the conditions of migrant workers; however, there have been numerous recent reports of human rights abuses. Scholars have demonstrated the negative impacts of the kafala system, which grants substantial authority to the sponsor (Kuwaiti citizens) and limited power and rights to the migrant workers. There has also been compelling research that underscores the connections between the kafala system and racial capitalism. However, few studies have examined how domestic policymakers approach migrant workers. By employing research methodologies of process tracing, case study policy analysis, and semi-structured interviews, my paper investigates how central political and social authorities in Kuwait reinforce or challenge the kafala system. My focus on the Kuwaiti domestic

system will deepen our understanding of how the economy, politics, and culture interact to shape the conditions and lives of migrant workers. The research will ultimately help develop alternative policies that enhance the dignity and human rights of migrant workers in Kuwait and globally.

Abstract Name: W.I.N.D: Wind turbine Innovation in Narrow-street Designs

Energy demand is one of the biggest concerns of modern society. With the threat of Climate Change lingering and continuous efforts to phase off carbon-based energy solutions, renewables are one of the most cost-effective ways of accomplishing this objective. The infrastructure in large urban areas creates natural wind tunnels. However, research on Wind Turbines in this environment is scarce. The research aims to determine whether a mixed design Savonius-Darrieus Vertical Axis Wind Turbine (VAWT) will perform effectively in the urban environment of Downtown Miami. The turbine will be a plastic single level two blade Savonius VAWT, using a drag-based design, and a three blade Darrieus VAWT, using a lift-based design, within the same body. The Energy output will be used to test for energy efficiency given by the Coefficient of Power (C_p), which is the power extracted by the turbine over the power of the incoming wind. The variables to be observed are wind speed, altitude and location of the turbine around the Downtown campus. A posterior cost-effectiveness analysis will be performed to cement the VAWT's possible application in Downtown Miami, given average energy costs in the area and the VAWT's average energy production. We expect that the narrow-street designs of the Downtown area will act in favor of the turbine, providing the wind speeds necessary for the turbine to be cost-effective, given its self-starting design capability.

Discipline: Linguistics and World Languages

Authors:

Abstract Name: Dystopian British Literature during Indian Colonialism: People as Extensions of Industry in George Orwell's 1984 and Aldous Huxley's Brave New World

Hierarchical language was weaponized as both a civilizing force and a method of Westernization, as British colonists often framed themselves as taking on the white man's burden. This paper analyzes Aldous Huxley's Brave New World and George Orwell's 1984, drawing connections between the language present within these novels with the power structures imposed through colonialism. Huxley and Orwell were both dystopian writers during the interwar period and both embedded rhetorical structures that paralleled authoritarian regimes at the time, particularly the rise of the Nazi's to power, the Soviet Union, and British colonial times, displaying how language can dehumanize a society. Linguistic concepts such as Grice's Cooperative Principle and Newspeak illustrate how the limitation of vocabulary and control of individualistic language take away autonomy. The British exerted control through establishing English as the eminent language, controlling school historical textbooks, and keeping colonial subjects under constant surveillance to establish colonial dominance and avert sedition. Additionally, access to literature caused resistance forces to grow, especially

among Indian youth, prompting colonial discourse to be increasingly challenged and stimulating deeper criticism of imperialism and the machinery of control behind colonial power. Through limiting and monitoring conversation and the connotation behind everyday language in academic and everyday settings, individualism and self-identity are affected as people attempt to conform to the standards set by authoritative forces.

Abstract Name: Encouraging Young Writers with Multiliteracies and Transformative Works

In the wake of COVID-19's devastating effect on education, educators are faced with the daunting task of reaching students in the English classroom. Meanwhile, fanfiction and multiliteracies are burgeoning subjects of pedagogical research. As of January 1st, 2025, over 14 million fanfictions have been published on the website AO3, a well-known fanfiction archive, and educators have begun to design assignments with fanfiction in mind. Likewise, multiliteracies has remained in conversations about education since the term was coined in the 90s to describe the multifaceted nature of literacy in the digital age. However, despite extensive research into both as practices, practical suggestions for educators grounded in data is still in its infancy. Students' own perception of fanfiction as an educational tool must be explored. The rapid pace of it and its massive volume makes it a tricky subject to analyze, but also an opportunity for educators to reach a growing demographic. At the same time, multiliteracies may demand educators to ask new questions about evaluation, but they are also necessary skills for students to navigate modern society. How, then, can we use personal interests to encourage apathetic and discouraged writers to pick up their pencils again? Fanfiction and multiliteracies enable students to harness their skills in a new direction of writing. In both, students still exercise important tenets of literacy, but without adhering to the unforgiving nature of traditional writing prompts. This project collates and synthesizes existing literature, artifacts, and student interviews to argue for transformative works and multiliteracies' efficacy in bridging between lived writing practice and academic writing, as well as to provide practical suggestions grounded in curriculum standards.

Abstract Name: AviSense: An AI-Power Platforms for Automated Bird Species Identification and Bioacoustic Analysis

Biodiversity monitoring is critical for conservation, yet traditional bird surveys are often labor-intensive, time-consuming, and require expert knowledge. To address this, we developed AviSense, a novel web application that leverages artificial intelligence to democratize and enhance avian bioacoustic research. This platform integrates a custom-trained deep learning model for real-time audio event detection with Google's

Gemini generative AI to provide rich, contextual insights. The system architecture features a Flask-based web interface where users can upload or record audio directly. Our core AI model, built upon a transfer-learned YAMNet architecture and trained on a curated dataset of bird vocalizations, processes the audio to detect and classify species-specific calls with high temporal precision, generating metrics like confidence scores and frequency ranges. A key innovation is the seamless integration of Gemini AI, which automatically interprets the detection results. It generates plain-language summaries of the acoustic activity, provides detailed species information, and answers researcher questions in an interactive chat, making complex bioacoustic data accessible to non-experts. Preliminary testing on field recordings has demonstrated the system's ability to accurately identify common North American species like the American Robin (*Turdus migratorius*) and Black-capped Chickadee (*Parus atricapillus*), with a mean average precision exceeding 85%. All analyses, including generated spectrograms and Gemini insights, are logged in an SQLite database for longitudinal study. AviSense represents a significant step towards automated, scalable wildlife monitoring. It provides a powerful, user-friendly tool for ecologists, citizen scientists, and educators, lowering the barrier to entry for bioacoustic research and enabling large-scale, data-driven conservation efforts. Future work will focus on expanding the species library and deploying the system for real-time, passive acoustic monitoring in the field.

Abstract Name: Role of YAP Signaling in Skeletal Muscle Injury and Recovery

Skeletal muscle experiences mechanical forces that regulate its development, hypertrophy, atrophy, and homeostasis. YAP (yes-associated protein) helps regulate cell proliferation, apoptosis, and migration, and plays an important role in directing satellite cell movement along the basal lamina of myofibers, an essential process for stem-cell differentiation, effective muscle development, and regeneration. We previously observed increased YAP signaling following loading in healthy muscles, and constitutively active YAP signaling in muscles of mdx (dystrophin-null, murine model of Duchenne muscular dystrophy) mice and aged mice. In addition, we observed hastened recovery from eccentric-contraction-induced injury in healthy, wild-type (WT) muscles, and reduced expression of markers of fibrosis in mdx muscles following pharmacological inhibition of YAP signaling using verteporfin. However, there was no significant improvement seen in skeletal muscle function in mdx muscles with pharmacological inhibition of YAP signaling. Thus, there is a need to further determine the role of YAP signaling in the regeneration of skeletal muscle cells following skeletal muscle injury. We will assess the expression of YAP and other associated genes in injured and uninjured skeletal muscle tissues from wild-type (WT) mice using qRT-PCR. We used injured (injured and recovered for two, four, and six days with and without verteporfin) and uninjured skeletal muscle tissue from WT mice. We will assess the gene expression of YAP and its downstream targets (CYR61, CTGF, ANKRD1 & VIM), markers of skeletal muscle regeneration (MYOD, MYF5, MYOG), and markers of inflammation (IL6, IL8, TNF- α) in these tissues using qRT-PCR. We hypothesize that the expression of YAP and associated genes will increase in injured skeletal muscle cells not treated with verteporfin, but expression will decrease in injured skeletal muscle cells treated with verteporfin. The expression of YAP and related genes in injured mice may reveal how YAP affects muscle and guide future therapeutic strategies for aging and muscular disorders.

Abstract Name: Role of Hypoxia in Thrombolysis Resistance in Acute Ischemic Strokes

Acute Ischemic stroke (AIS) occurs when an intravascular thrombus limits cerebral blood flow and causes tissue injury. Multiple coagulation factors and vessel wall pathology promote clot formation. Our preliminary observations indicate that patient thrombi exhibit reduced pH, a condition associated with decreased efficacy of tissue plasminogen activator (tPA). Our studies indicate that AIS thrombi exhibit lower pH than average. We hypothesized that hypoxic conditions within thrombi contribute to thrombolytic resistance. Whole blood AIS thrombi analogs enriched in red blood cells (RBC's), platelets, and a mixture of both were generated using the Chandler Loop. For each composition, three conditions were applied: hypoxia promoted, normoxia, and hypoxia inhibited. Thrombi were matured for 4, 24, and 48 hours. Ex vivo thrombolysis was performed to quantify thrombolysis rate. Expression of hypoxia- and metabolism-related proteins was measured, including hypoxia-inducible factors 1 & 2 (HIF 1 & 2), lactate dehydrogenase (LDHA), pyruvate dehydrogenase kinase 1 (PDK1), hexokinase 1 (HK1), and citrullinated histone 3 (CitH3). From 4 to 48 hours hypoxia-promoted mixed and platelet-rich thrombi showed increased expression of HIF 1, PDK1, HK1 and LDHA compared with normoxia and hypoxia-inhibited conditions. RBC rich thrombi under hypoxia exhibited higher expression on PDK1, HIF2 and CitH3 and platelet rich thrombi also showed elevated expression of CitH3. Thrombolysis rate was significantly lower in hypoxic thrombi compared to normoxia and hypoxia inhibited thrombi. These findings support a model in which intrathrombus hypoxia and associated metabolic reprogramming contribute to tPA resistance. Defining these mechanisms may guide adjunctive strategies to improve thrombolytic efficacy in AIS.

Abstract Name: BUILDING AN INCLUSIVE GREEN ECONOMY: ASSESSING THE PERSPECTIVES OF GHANAIAN MARKET WOMEN.

The green economy is increasingly becoming a global priority as countries respond to mounting climate risks. For developing nations such as Ghana, a successful transition requires meaningful inclusion of the informal sector, which employs more than seventy percent of the workforce. Drawing on Martha Chen's categorization of informal employment, this sector encompasses both self-employment within small and often unregistered enterprises and wage work that lacks secure contracts, benefits, and social protection. These activities span a continuum from survival-based livelihoods to growing small businesses that choose or are compelled to operate informally. Given that women constitute approximately eighty percent of Ghana's informal workforce, this study examines how market women interpret and participate in the country's emerging green economy. Using qualitative interviews with twenty women in major open-air markets such as Makola and Agboghloshie, the research investigates their understanding of green concepts, current practices, motivations, and constraints. Findings show that participants primarily associate the green economy with basic sanitation, revealing a narrow interpretation of broader sustainable development models. However, the study also uncovers significant environmentally beneficial practices among market women, including waste segregation, recycling, and participation in informal waste monetization. Motivations for these practices include improving community health, reducing pollution, and meeting government expectations. Despite these efforts,

several barriers limit deeper engagement including inadequate waste management services from the Metropolitan Assembly, limited access to affordable sustainable packaging options and inconsistent enforcement of environmental regulations. The study concludes that market women should be recognized as key institutional actors and influencers in Ghana's green economy transition. Strengthening environmental education, investing in sustainable packaging solutions, and expanding recycling initiatives are essential for creating an inclusive green economy. Rather than viewing the informal sector as a barrier to sustainability, the paper argues that its ubiquity across Africa demonstrates its potential as a catalyst for green development.

Abstract Name: Anosognosia and the Difference it Makes: Rethinking How Criminal Behavior and Cluster-B Disorders Correlate

The proportion of incarcerated individuals in the United States who have a psychiatric disorder diagnosis is much higher than discussed. Out of all disorders, a certain group of them stands out - Cluster-B personality disorders. These disorders are not niche, they are infamous in the media. However, there is a need to scientifically and reputably explore the correlation between Cluster-B personality disorders and the criminally mentally ill. This paper explores the ethical and systemic failures in the United States justice system, and shows how using a distinction between mentally ill individuals who lack awareness of their disorder (also known as anosognosia) and those who retain full ability to recognize their harmful behaviors may help resolve these derelictions. Utilizing psychiatric research and real-world cases, we can understand how the current system inadequately differentiates between individuals who require treatment and those whose disorders render treatment largely ineffective. While there are some other kinds of disorders who might show up in an individual with a criminal history such as schizophrenia - these people may benefit from psychiatric care, while Cluster-B disordered individuals often understand the moral and legal implications of their actions yet continue to commit harmful acts, often manipulatively and repeatedly. Furthermore, psychiatric research shows that many individuals with a Cluster-B disorder are extremely difficult to treat, and sometimes treatment is rendered ineffective, whether that is a result of a fault of the medication or due to the behavior of those required to take them. As they represent a high segment of the prison population, they are frequently routed through systems designed for treatable conditions, consuming scarce clinical resources and endangering healthcare workers and other victims. There must be a stronger call-to-action to account for the role of self-awareness and treatment responsiveness in legal cases involving those with a Cluster-B disorder.

Abstract Name: Modeling CKD-Induced Cardiac Dysfunction Using Human iPSC Derived Cardiac

Organoids

Cardiovascular Disease (CVD) is the leading cause of death among patients with Chronic Kidney Disease (CKD), accounting for nearly 50% of all fatalities. The well-established link between CVD and CKD highlights the need to develop physiologically relevant models of CKD-induced cardiac dysfunction for advancing therapeutic discovery and understanding disease mechanisms. We explored the use of cardiac organoids – three-dimensional, spherical clusters of cardiomyocytes that better mimic the architecture and behavior of human heart tissue than traditional 2D cell cultures – to model CKD induced cardiac dysfunction. To create cardiac organoids, induced pluripotent stem cells (iPSCs) were seeded and extracted from PDMS inserts and then differentiated into cardiomyocytes. Cardiac organoids were then conditioned for 48 hours with serum from CKD patients undergoing hemodialysis to simulate cardiac dysfunction associated with presence of CKD. After an additional 48 hours, media was collected and analyzed using multiplex ELISA (Eve Technologies human cytokine/chemokine 96-plex assay). Results display a significant increase in almost all the inflammatory markers tested, including important markers such as TNF- α , RANTES, and IL-1 β , suggesting that cardiac organoids respond to CKD serum in a manner consistent with pathophysiological changes seen in CKD patients. This three-dimensional organoid model constructed using patient-derived cardiomyocytes provides a platform to investigate human cardio-renal interactions and test potential treatments.

Abstract Name: Developing Novel Non-Aqueous Magnetorheological Emulsions for Advanced Rheological Control in Modern Smart Fluids

Magnetorheological fluids (MRFs) are smart fluids notable for rapid, controllable viscosity changes under a magnetic field. Upon magnetization, MRFs undergo a liquid-to-semi-solid transition driven by the alignment of ferromagnetic particles to the magnetic field direction, forming chain-like networks that restrict fluid motion. This tunable behavior makes MRFs ideal for adaptive energy-damping applications, including prosthetics and seismic protection systems. Recent studies in the Koh Laboratory at the University of Alabama demonstrate that integrating emulsions into aqueous MRF systems, termed magnetorheological emulsions (MREms), significantly enhances energy-damping capacity compared to state-of-the-art MRFs. However, aqueous systems face challenges, including instability and limited durability. The study presented here aims to (1) engineer a stable, non-aqueous emulsion system to formulate non-aqueous MREms and (2) benchmark their performance against modern MRFs. An emulsion system was achieved using polydimethylsiloxane (PDMS) emulsified in glycerol and stabilized with a fumed silica Pickering emulsifier. By systematically manipulating key parameters—iron concentration, emulsion droplet size, magnetized soak duration, and magnetic field strength—this study reveals that MREms exposed to prolonged magnetization and elevated fields exhibit enhanced viscosity control. These results present non-aqueous MREms as a superior alternative to traditional MRFs, pioneering a new class of superior smart materials with transformative potential for energy-damping applications.

Abstract Name: Association between depression with Alzheimer's disease biomarkers in cognitively normal individuals across race and ethnicity

Introduction: Depression has been shown to be associated with Alzheimer's disease (AD). However, few studies have examined the associations between depression and AD biomarkers in cognitively unimpaired diverse cohorts. Therefore, we examined the relationship between depression and plasma neurofilament light chain (NfL), total tau, amyloid-beta 40 (AB40), and amyloid-beta 42 (AB42) levels in Hispanic, non-Hispanic Black (NHB), and non-Hispanic White (NHW) participants. Methods: Our study included cognitively unimpaired Hispanic, NHB, and NHW participants from the Health and Aging Brain Study: Health Disparities (HABS-HD) and Alzheimer's Disease Neuroimaging Initiative (ADNI) datasets (N = 2383, aged 50-89 years). The Geriatric Depression Scale (GDS) was used to assess depression (independent variable), while biomarkers (dependent variables) were measured by plasma concentrations. We applied the CentiMarker approach to standardize the raw biomarker values, enabling the combination of data from both studies. Multivariate linear regression was conducted using Jamovi to examine the association between GDS and the respective biomarkers in the total sample and in each racial/ethnic cohort, while adjusting for age, education, gender, apolipoprotein ε4 (APOE4) positivity, and data source. Results: GDS was significantly and positively associated with AB40 in the total sample ($B = 0.42$, $SE = 0.15$, $p = 0.007$) and among NHW participants ($B = 0.53$, $SE = 0.23$, $p = 0.02$). GDS was also significantly and positively associated with AB42 in Hispanic participants ($B = 0.93$, $SE = 0.41$, $p = 0.022$). Discussion: Depression as reported by GDS was positively associated with plasma AB40 and AB42 levels, but not with plasma NfL or total tau levels. Further research that examines depression with other cognitive impairment risk factors and biomarkers, and that follows a longitudinal trajectory, could help decipher the biological influence of depression on AD.

Abstract Name: The relationship between depression and Alzheimer's Disease among the Hispanic population from NHIS 2019-2023 Data

Background: Alzheimer's disease (AD) is one of the most common neurocognitive degenerative diseases among dementia patients. Studies have shown a link between depression and AD. However, little is known about depression and AD in the Hispanic population, who are faced with growing mental health issues in recent years. We aimed to investigate the relationship between depression and AD among Hispanics from a large national survey. Methods: A retrospective population-based cross-sectional dataset of 7,451 Hispanic adults aged ≥ 50 years was extracted from the National Health Interview Survey (NHIS) between 2019 and 2023. Prevalence and bivariate Chi-square analysis were conducted to determine the differences in AD among Hispanics with depression. Multivariable logistic regression models were conducted to examine the relationship between depression and AD, adjusting for covariates (age, gender, education levels, poverty levels, and health insurance coverage). Results: The prevalence of AD was 7.4% among Hispanics confirmed with depression and 1.6% among those without AD. Hispanics with daily depression and those who reported taking medication for depression had 14% and 9% prevalence of AD, respectively. Hispanics with confirmed depression (AOR = 4.20, 95%CI [2.71-6.51]), those who reported daily (AOR = 8.45, 95%CI [4.63-15.44])

and weekly (AOR = 2.15, 95%CI [1.11-4.18]) depression, and those taking medication for depression (AOR = 4.37, 95% CI [2.80-6.80]) were associated with a higher odds AD. Conclusion: Our research identified Hispanics with depression, those who reported daily and weekly depression, and those taking medication for depression to be associated with increased likelihood of experiencing AD, which allows for understanding the relationship between depression and neurocognitive health among Hispanic individuals.

Abstract Name: Synthesis of Bis-Benzoxazolones and Bis-Benzimidazolinones for Cholinesterase Inhibition

Alzheimer's disease (AD) affects over 6 million people in the United States through the loss of memory and cognition. In the brain, reduced levels of acetylcholine (ACh) and butyrylcholine (BCh), which are broken down by the enzymes acetylcholinesterase (AChE) and butyrylcholinesterase (BChE), respectively, are thought to contribute to the onset and progression of AD. Being that there is no effective cure, the purpose of this research is to analyze the effectiveness of alkyl-linked bis-benzoxazolones and bis-benzimidazolinones in inhibiting both enzymes, which has proven beneficial for treatment of AD. Based on the known effectiveness of previously synthesized bis-isatins in performing the desired function, it is anticipated that the newly prepared compounds will show some degree of inhibition due to structural similarity. However, it remains to be seen if the differing hydrogen bonding abilities of these benzoxazolone and benzimidazolinone scaffolds will enhance or decrease inhibition. Initial work has focused on the synthesis of the target molecules from 2(3H)-benzoxazolone and 2-benzimidazolinone through alkylation with dibromoalkanes. The full results of these synthetic studies, along with preliminary enzyme inhibition testing and molecular modeling, will be presented.

Abstract Name: The Impact of Social Media on Adolescent Mental Health

Over the past decade, social media has become a central part of adolescents' everyday lives, influencing how they connect with others, express themselves, and go through emotional experiences. As concerns about rising anxiety and depression continue, researchers have examined how social media use on platforms like TikTok, Instagram, and Snapchat play a role in the well-being of adolescents. This project explores how different patterns of social media use including excessive engagement, comparison with others, and positive online interaction affect adolescent mental health, particularly with symptoms of anxiety, depression, and self-esteem challenges. A systematic review methodology was used to identify peer-reviewed studies from 2020–2025 involving adolescents aged 12–18, incorporating both quantitative and qualitative evidence. This research will show stronger associations between heavy or comparison-driven social media use and negative mental health outcomes, while also revealing that balanced, creative expression, and supportive online engagement can be beneficial to well-being and may help teens feel more connected and confident. The findings of this review suggest that social media's impact on adolescents is complex, emphasizing the need for supportive guidance to help teens use social platforms in healthier, more empowering ways.

Understanding these patterns can help adults and communities guide teens toward healthier digital habits, ensuring that social media becomes a tool for connection and support rather than a source of stress.

Abstract Name: The effects of chronic exposure to agrochemical residues on spiderling mortality in the wolf spider *Rabidosa rabida*

Agrochemicals sprayed on crops often persist on the soil surface and can adversely affect beneficial non-target species like wolf spiders. We examined the lethal and sublethal effects of chronic exposure to soil residues of five widely used agrochemicals on spiderlings of the wolf spider *Rabidosa rabida*. Eggsac-carrying females were collected from unsprayed fields. Spiderlings were randomly assigned but equally divided by eggsac across one of seven agrochemical treatments: the insecticide imidacloprid, the herbicide glufosinate, the fungicides azoxystrobin and propiconazole, the organosilicone surfactant Silfact®, a combination of all five agrochemicals, or a distilled water control. Spiderlings were also exposed to either freshly applied, three-day-old, or seven-day-old agrochemical soil residues resulting in 21 agrochemical treatments (3x7 design, N=840, 40-41 spiderlings per treatment). Spiderlings were fed and maintained for 40 days on their designated treated soil substrates. We recorded mortality and timing of ecdysis to the third instar across treatments. All agrochemical treatments induced significantly higher mortality than the control except Azoxystrobin. Glufosinate and the combined agrochemical treatment were the most toxic with both treatments resulting in 100% mortality by day 30 but there was no additive effect of combining agrochemicals. Imidacloprid and organosilicone showed intermediate toxicity with fungicides showing the lowest, but still significantly higher than the control treatments. For most agrochemicals, seven-day residues were as toxic as when freshly applied; only organosilicone, the all combined group, and the control showed modest but significant residue age effects. Molt timing did not differ among treatments for spiderlings that survived long enough to molt suggesting no effect on feeding behavior across treatments. Overall, our results indicate that some commonly used agrochemicals, especially glufosinate, pose substantial risks to juvenile wolf spiders, likely reducing their survival and long-term persistence in agricultural systems and that soil residues maintain high toxicity even seven days post-application.

Abstract Name: Sprouting Structures: Exploring Directed Root Growth for Engineered Living Systems

What if it were possible to create and maintain buildings through biological growth rather than exhausting processed materials? Engineered living materials are revolutionizing the field for applications in the built environment. According to a recent United Nations assessment, a staggering 37% of global carbon emissions are attributed to the buildings and construction sector. Traditional construction methods rely heavily on industrially processed materials, which are resource-intensive and environmentally harmful. Biology-integrated architecture has shown potential to reduce material footprint while introducing self-sustaining capabilities; however, the field remains largely underexplored. This project aims to establish a foundational understanding of how plant root formation can be directed within engineered biomaterials, including hydrogels and earthen media. By examining how the mechanical and chemical properties of these materials influence root growth, the project seeks to provide early insights for guiding root behavior, supporting the future of engineered living structures. Plant-friendly, biocompatible hydrogel was formulated to support seed germination and early root growth. Then, novel approaches will be explored for integrating plants within engineered media. Seeds were first encapsulated in the hydrogel before progressing toward incorporation into 3D extrusion bioprinted structures. Mechano-chemical properties of the hydrogel matrix and media will be characterized to understand how factors such as stiffness and nutrient composition impact root growth. Root development will be monitored through advanced imaging. Earthen-based systems will then be explored, along with lateral observation setups and volumetric 3D-printed structures. By linking material properties with germination, root directionality and characteristics, this work aims to provide foundational insights into how engineered biomaterials can guide plant development. Ultimately, this work will contribute critical insights toward the eventual development of small-scale, proof-of-concept living structures demonstrating the feasibility of grown buildings.

Abstract Name: The Evolution of Donald Trump's Psycholinguistic Traits Across the 2016, 2020, and 2024 Elections: A LIWC-22 Analysis of Social Media Rhetoric

This study explores the evolution of Donald Trump's psycholinguistic traits as presented through his social media use during the 2016, 2020, and 2024 presidential elections. While there is existing research comparing Trump's psycholinguistic profile to more traditional political counterparts, no prior work has examined his 2024 posts in relation to earlier election cycles. Additionally, no existing scholarship has analyzed the evolution of Trump's online communication through the lens of shifting style, tone, emotion, or the potential impact these changes may have on his following. This paper addresses these gaps by exploring the question: How has Donald Trump's social media behavior changed over the past decade, and how can these shifts be observed in an LIWC-22 linguistic analysis of posts made in the three months leading up to the presidential elections of 2016, 2020, and 2024? The dataset includes all posts made to Twitter and Truth Social during the three months preceding each election cycle, totaling approximately 7,500 posts. The psycholinguistic software LIWC-22 was used to assess each election year separately. LIWC-22 categorizes each word, phrase, stem, or emoji into validated sub-dictionaries corresponding to specific psychological constructs, allowing linguistic features to be translated into quantifiable metrics. Key variables examined include "polite," "conflict," "pro-sociality," and "tone." Preliminary findings suggest notable shifts in Trump's rhetorical patterns, including decreases in "polite," "pro-sociality," and tone, alongside increases in "conflict." These results indicate a measurable intensification of combative rhetoric over time, reflecting a move toward more emotionally charged, identity-driven communication aligned with broader trends in populist political rhetoric. This research contributes to work at the intersection of political psychology and computational linguistics by offering a longitudinal analysis of a single political figure's rhetorical evolution. The findings enhance our understanding of how political communication adapts to changing electoral landscapes and how linguistic cues shape public perception.

Abstract Name: Breaking the Silence: Addressing the Emotional Burden of Alzheimer's Disease and Related Dementias on African American Family Caregivers

Providing continuous assistance to people who are sick, aged, or disabled is known as caregiving. Although providing care for people with Alzheimer's disease and related dementias (ADRD) is a difficult task in and of itself, the burden is worsened by the illness' progressive nature, which is characterized by increasing cognitive loss, behavioral abnormalities, and functional impairments. It is also critical to acknowledge that African American caregivers frequently face additional intersecting burdens that are a result of systemic injustices and cultural factors, including systemic healthcare disparities, financial hardships, and cultural expectations surrounding family responsibilities. Studies show that these African American caregivers have a greater burden from the act of caregiving in comparison to other racial groups, which is worsened by their restricted access to support networks and mental health treatments. Furthermore, cultural elements, such as strong religious conviction and social support systems, can both ease and exacerbate the experience of providing care. My extensive literature review revealed religion as a common theme since many African American caregivers depended on God to guide them and provide a sense of peace as they took on the demanding responsibility of caring for someone with ADRD. Due to the fact that African American caregivers are often underrepresented in caregiving research, it is imperative to fully comprehend their complex experiences. To guide the development of culturally appropriate interventions and support systems, this study aims to shed light on the unique mental health issues that this community faces and how these issues impact the care that is being provided. In order to learn more about the common themes observed in the African American family caregiver population and the particular psychological therapies that would be beneficial to them, I am reviewing the literature from both quantitative and qualitative research.

Abstract Name: Barriers to Treating Sickle Cell Disease in African American Adults Aged 18-40: Treating Vaso-occlusive Crises with Emergency Departments, Hydroxyurea, and Opioids

Approximately 1 in 400 African Americans in the US suffer from Sickle Cell Disease (SCD). People affected experience chronic pain and pain crises that must be managed in and out of emergency health care settings. Still, because there may be an intersection of their condition and race in the emergency room, they may be simultaneously affected by medical racism, which may hinder the ability to obtain appropriate, effective care in order to treat pain crises and chronic pain. Through a review of case studies, educational supplements, and journal publications that include patient and provider interviews and empirical data on sickle cell disease care and discrimination in medicine up to 2024, this paper details the gaps found in emergency and at-home care regarding Black adult sickle cell disease patients by taking into account the current downward trend of prescribing opioids to patients who demonstrate a need for pain relief and interactions based on stereotypes and stigma around Black sickle cell disease patients, and the genotoxic nature of Hydroxyurea pushing

providers further away from utilizing Hydroxyurea to treat Black sickle cell disease patients. Further investigation regarding the intersection of race and sickle cell disease pain management is needed to determine if racial bias in medicine significantly impacts Black Adult (ages 18-40) SCD patients in the United States, and solutions found suggest using implicit bias training to eliminate disparities in Black sickle cell disease patients.

Abstract Name: Proteomic Analysis of Rodent Brain Tissue

Proteomics is the study of protein structure and its interactions. Shotgun proteomics analyzes proteins in a sample by first digesting them into peptides. Our laboratory has taken steps to develop and optimize a working protocol for proteomics of rodent brain tissue to achieve optimal readout from the Shimadzu-LCMS-9030 Q-TOF mass spectrometer. For example, initial steps have been made in optimizing and comparing different techniques and steps in the proteomics process, such as sample preparation, lysis buffer, digestion, desalting, and clean-up through the BCA protein assay to quantify the proteins, and a literature review to gain an understanding of the technique. The goal in conducting proteomics rather than other methods, such as Western blots, is to see all proteins rather than just one. This technique allows for the simultaneous quantification of proteins in a sample, enabling the study of specific protein receptors in the brain. Preliminary pilot experiments will be done using samples from rat brain tissue to optimize and validate our protocol. Data analysis from these samples will be interested in quantifying receptor and signaling molecules related to the nicotinic acetylcholine and serotonin receptor pathways for correlative studies with behavior. Correlative studies with behavior will be done for each sample type to gain an understanding of what molecular differences mean in terms of what is seen in the behavior. Following protocol validation, studies will be done using the 22q11.2 deletion syndrome mice, which express neurodevelopmental disorders like autism and schizophrenia. The receptor of interest for the deletion syndrome mice is the NMDA receptor, and we aim to understand the molecular mechanisms and how they differ from those in wild-type mice.

Abstract Name: Investigating the Effect of Histotripsy on the Presence of Cell Death Markers, Proliferation Markers, and T-lymphocyte Populations in a Murine Osteosarcoma Model

Osteosarcoma is a primary bone tumor for which the current treatments are surgical resection of the tumor via limb amputation or limb salvage surgery combined with chemotherapy. Histotripsy, a non-thermal, non-invasive focused ultrasound tumor ablation modality, is being investigated as an alternative treatment. In this study, the effect of histotripsy on cell proliferation and intratumoral immune response was investigated. The experimental groups included histotripsy-treated murine osteosarcoma tumors collected at different time-points post-treatment (three, seven, ten, fourteen, or thirty days) and an untreated tumor control group. For

each sample, one slide was stained for cell death (Caspase-3) and proliferation (Ki-67) markers and the other slide was stained for T-lymphocyte biomarkers (CD4, CD8, and FoxP3). The hypothesis was that Ki-67 expression would be lower, and T-lymphocyte marker and Caspase-3 expression would be higher in the treated tumor samples than in untreated samples. Slides were scanned and image analysis was conducted using Fiji ImageJ software. The percentage of tumor area with each of the five biomarkers was calculated. The difference between untreated and treated groups and the difference between the five time-point groups were analyzed using Two Sample t-Tests and One-Way ANOVA tests respectively. There was no significant difference between time-point groups, treated, or untreated groups for Caspase-3 and the T-lymphocyte markers. The untreated tumor samples had a greater mean Ki-67 presence than the treated tumor samples (not separated by time-point for this analysis) and this difference was statistically significant. Analysis of the time-point groups showed an upward trend in Ki-67 presence over thirty days, however there was no significant difference between different time-points. The results suggest that under the current experimental conditions, histotripsy does not have a significant effect on apoptotic cell death and T-lymphocyte populations, but may initially decrease cell proliferation activity based on our immunohistochemistry findings in this study.

Abstract Name: College, Alcohol, and Infectious Diseases: Relationship Between Opinion of Alcohol in College and Perceived Vulnerability to Infection

Drinking alcohol and frequenting college bars are often seen as an essential parts of the college experience. College students routinely visit bars, often carrying unwanted passengers (i.e., viruses, bacteria) with them. Compared to the early 1900s, good hygiene and cleanliness are seen as imperative by modern society and represent key public health interventions or responses that curb the spread of illness. However, some typical habits, including attending college bars and heavy drinking, go against this focus on safety from disease, inviting an increase in risky activities such as sharing drinks and reduction in the immune response. Evidence has shown that alcohol suppresses the ability of the body to fight off infection and pathogens, increasing communicability, and severity of infectious diseases. The population of college student drinkers may be more vulnerable to disease, both physically, due to the physical effects of alcohol, but also mentally vulnerable due to a lack of effective decision-making related to disease carrying environments and situations. This project aims to ascertain the connection between the opinion about alcohol in the college experience, measured through the College Life Alcohol Salience Scale (CLASS), and perceived vulnerability to disease as measured by the Perceived Vulnerability to Disease (PVD) scale, broken down into two subscales measuring perceived infectability and aversion to germs. Data collection was conducted through anonymous online surveys. The results show a significant positive correlation between CLASS and PVD scales ($r=.108$, $p=.022$), wherein as one regards alcohol as more important in the college experience, one would have a higher perception and concern of disease in their environment. These results could be used to both combat alcoholism amongst college students and the spread of infectious diseases on and around college campuses.

Abstract Name: Reported Meat Intake is Correlated to Body Mass Index and Waist Circumference: A Study of Risk Factors for Metabolic Syndrome

Obesity rates among young adults are steadily increasing, sparking greater interest in the dietary factors that contribute to increased Body Mass Index and waist circumference. Obesity is a risk factor for chronic conditions such as cardiovascular disease, type 2 diabetes, and certain cancers. Meat consumption has previously been linked to obesity. This study examines the relationship between reported meat consumption and two key indicators of obesity in college students: waist circumference (WC) and Body Mass Index (BMI). We hypothesized that higher levels of reported meat consumption are positively correlated with both WC and BMI in this population. We used data collected from 316 Weber State University students (101 men and 215 women) between 2015 and 2023. Anthropometric measures were taken for each participant, including height, weight, and WC. Height and weight measurements were used to calculate BMI. Participants tracked their diets for two days using Diet and Wellness Plus software, which assessed intake of total calories, saturated fat, and sodium. Participants also reported their weekly meat consumption habits on a scale from 1 (never) to 5 (every day). SPSS statistical analysis revealed significant positive associations between reported meat consumption and BMI ($p=.02$) and WC ($p=.017$) among female students. This association was not observed in male students. Additional analyses examining total caloric intake, saturated fat, and sodium revealed no significant correlations with BMI or WC. These findings suggest that meat consumption, independent of other dietary factors, may have a stronger association with obesity in college-aged females than previously thought. Given these results, we suggest that increasing plant-based food consumption, rather than focusing solely on calorie or fat reduction, may offer important benefits to female college students in preventing obesity.

Abstract Name: Environmental enrichment attenuates enhanced nicotine-seeking behavior following exposure to chronic variable stress

Drug addiction is a major public health and serious economic concern in the United States costing taxpayers billions of dollars annually. Preclinical and clinical research indicates that individuals exposed to stress are more vulnerable to drug addiction (Koob, 2008; Ouimette et al., 2007). Moreover, chronic unpredictable stress increases the response to nicotine-rewarding properties in the CPP test (Biala et al., 2018). Contrary to the effects observed following exposure to variable stress, both running and environmental enrichment (EE) reduce CPP for cocaine (Mustroph et al., 2016). To date, only one study (Biala et al., 2018) has assessed the effects of chronic stress on the rewarding effects of nicotine in the CPP model and none have measured the potential of EE in attenuating this effect. Therefore, this study will further investigate and determine whether EE can reverse, or abolish, the enhancement in the rewarding properties of nicotine following exposure to chronic variable stress. One group of animals will be exposed to 20 days of randomized stressors either during adolescence or early adulthood. Another group of animals will be exposed to four weeks of EE. An additional group will be exposed to 20 days of randomized stressors followed by four weeks of EE. Control animals will not receive any exposure treatment. Following exposure treatment animals will undergo place preference conditioning to nicotine (0.175 mg/kg, base, s.c.). Data indicate that animals exposed to chronic variable stress exhibit higher place preference for nicotine compared to controls, an effect that is attenuated

by exposure to EE. Therefore, in addition to providing evidence of the contributions of stress and environmental conditions to successful cessation of drug-seeking, the results obtained can have important implications for the use of environmental stimulation together with pharmacological and behavioral therapies in the treatment of addiction.

Abstract Name: Cyanotoxin Exposure and ALS Prevalence: Ecological Insights from the Chesapeake Bay Watershed

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder that damages motor neurons in the brain and spinal cord, ultimately impairing essential functions such as movement, speech, swallowing, and breathing. Although its progression varies across individuals, most diagnoses occur between ages 55 and 75, and average survival is only two to five years (2024). ALS incidence and prevalence differ globally—from 0.26 per 100,000 person-years in Ecuador to 23.36 in Japan—and U.S. point prevalence is approximately 11.80 per 100,000, with notable geographic, racial, and sex-based disparities. Recent evidence has raised concern that harmful algal blooms (HABs), particularly cyanobacterial blooms capable of producing the neurotoxin β -methylamino-L-alanine (BMAA), may contribute to ALS risk. BMAA has been detected in ALS brain tissue, and exposure to bloom-affected water has been associated with faster disease progression. These findings suggest that environmental factors may interact with biological vulnerability to influence ALS outcomes. This project investigates potential connections between HAB occurrence and ALS prevalence within the Chesapeake Bay watershed. Our aims are to: (1) map ALS prevalence across watershed counties to identify geographic clusters; (2) evaluate correlations between these clusters and regions experiencing recurrent HAB activity; and (3) explore how local cultural and subsistence practices may influence cyanotoxin exposure risk among rural and Indigenous communities. Together, these aims integrate environmental, geographic, and sociocultural data to examine how ecological conditions and community practices may shape ALS risk. This work contributes to growing efforts to understand environmental drivers of neurodegenerative disease in vulnerable coastal populations.

Abstract Name: I Am Me

The poem “I Am Me” was created to explore the personal side of discovering identity. It is a poem that dives deep into the inner turmoil of the journey to self-acceptance through the eyes of a transgender individual. That transgender individual being myself. In the making of this poem, I used what is called stream of consciousness. This is a type of poetry that is known to not have limitations. Research shows that the stream of consciousness psychologically in itself is our conscience. It is where we have thinking and language. However, it has also shown that when writing in this technique, it is filled with the sensations of our bodies, feelings, memories, and even emotions. The methodology of this poem was in a sense an impulse of writing.

This piece was created to show a vulnerable part of my life. I chose this technique because of it being limitless. It let me really think about how I felt in the specific part of my journey where I was fighting with myself. With this technique I couldn't be censored and silenced from my own thoughts, allowing me to speak my truth. It was written in a way that it's not only relatable to trans people with the same experience, but also anyone who struggles with identity as a whole. The struggle of identity is an aspect that is often a part of the human experience. In the creation of this piece, it affected my understanding of myself. It revealed the emotions that I never fully grasped until I saw them on the paper. This poem helped me feel the confidence I needed to share my story so that those who question themselves understand. That in the end no one is alone in their struggles.

Abstract Name: Excitation Energy Transfer Dominates over Reductive Electron Transfer In High-Potential Hypervalent Antimony(V) Porphyrin-C60 Conjugates

Porphyrins play a central role in artificial photosynthesis due to their strong light harvesting capabilities and ability to participate in the electron transfer process. Sharing similar properties with chlorophyll, porphyrins are highly effective photosensitizers, and their performance can be enhanced through strategic conjugation with complementary moieties. Fullerene (C60) is a widely studied electron acceptor characterized by high electron affinity and mobility, as well as an intrinsically low-lying lowest unoccupied molecular orbital (LUMO), making it a powerful component in molecular donor-acceptor (D-A) assemblies. In this research, C60 has been covalently linked to high-potential, hypervalent antimony (V) porphyrins to produce two antimony(V) porphyrin-fullerene conjugates: SbP-C60 and SbPF3-C60. The porphyrins feature four meso-phenyl and meso-3,4,5-trifluorophenyl units, respectively. These systems are designed such that the exceptionally high reduction potentials of the porphyrins create a unique excited-state energy pattern in which the (porphyrin)^{•-}-C60^{•+} charge-separated state lies between the excited singlet states of the porphyrin and fullerene. Time-resolved spectral data show that an ultrafast singlet-singlet energy transfer occurs from the porphyrin to the C60 unit. Estimated excited-state energetics of the conjugates suggest that the 1C60* state can be populated either directly through the usual Förster mechanism or indirectly by electron transfer from the C60 unit to the excited porphyrin followed by charge recombination. However, spectral features expected for the charge-separated state are not observed, and the energy transfer rates calculated for the Förster mechanism agree with experimental values. Together, these findings demonstrate that direct energy transfer is the dominant process in the synthesised antimony(V) porphyrin-C60 dyads.

Abstract Name: Exploring the Impact of Skin Tone Satisfaction on Racial-Ethnic-Cultural Belonging among Latiné Caregivers

A sense of racial-ethnic-cultural belonging (REC-B) is a key process that supports wellbeing and ethnic-racial identity (ERI) development across the lifespan. Yet, little research has examined how phenotypic characteristics may shape belonging within caregivers. While the impact of skin tone on Latiné families has been examined, understanding caregivers' feelings towards their skin tone is essential due to its potential impact on their identity. The current study aimed to investigate whether skin tone and skin tone satisfaction predicts REC-B within Latiné caregivers. This study contributes to understanding how phenotypic factors shape belonging-related identity processes throughout adulthood. Participants included 113 Latiné caregivers (93.1% Female; Mage = 35.04, SD = 6.56) from the ongoing STAR (Supporting, Thriving, Ambitious, and Resilient) Children & Families Project, which aims to understand risk and protective factors in Latiné, Black, and Multiracial families and their relation to cultural experiences and developmental outcomes. Families were recruited through community outreach at public events, including local festivals, non-profit organizations, and word-of-mouth. Research assistants administered surveys to both caregivers and children, asking about their ERI-related experiences. Compensation for participation included \$50 for the caregiver with an additional \$10 and a toy for their child. Findings indicated that the overall model was significant, $F(3, 85) = 2.99$, $p = .04$, $R^2 = .10$. Specifically, Latiné caregivers' skin tone satisfaction predicted higher levels of REC-B ($\beta = .24$, $p = .02$). When accounting for age as a covariate, Latiné caregivers' skin tone was not associated with REC-B ($\beta = .19$, $p = .07$). Findings highlight that among Latiné caregivers, those who are more satisfied with their skin tone are more likely to have a stronger sense of belongingness to their ethnic-racial group. Although skin tone remains an important aspect of ERI, this emphasizes the importance of also considering skin tone satisfaction as an important contributor to identity development.

Abstract Name: KLF6 is a Novel Regulator of Interferon-gamma signaling in Macrophages

Excessive IFN γ levels are associated with chronic inflammatory and autoimmune diseases. However, the precise mechanisms governing IFN γ -induced signaling pathways and transcriptional regulation of inflammatory gene expression remain incompletely defined. In our previous studies, we identified Krüppel-like factor 6 (KLF6) as a novel regulator of macrophage activation. Here, we investigated the role of KLF6 in

regulating IFN γ -induced signaling pathways, inflammatory gene expression, and macrophage function. Here, our in vivo studies show that myeloid-specific KLF6 deficiency significantly attenuated zymosan-induced macrophage and neutrophil accumulation in lung tissue. Our unbiased transcriptomic and gene set enrichment analyses (GSEA) revealed that KLF6 deficiency curtailed nearly half of IFN γ -inducible gene targets and broadly impaired IFN γ -induced cytokine, chemokine, and inflammatory signaling pathways in macrophages. Further, our ex vivo and in vivo studies show that KLF6 deficiency significantly curtailed IFN γ -induced IFN γ -response, TNF α -response, IFN α -response, inflammatory response, and chemokine signaling target gene expression in macrophages. More importantly, KLF6 deficiency markedly reduced IFN γ -induced STAT1 phosphorylation (Try701 and Ser727) in macrophages. Collectively, these findings identify KLF6 as a critical regulator of IFN γ -induced signaling, pro-inflammatory gene expression, and pathogenic macrophage activation in vivo.

Abstract Name: Culturally Relevant Mentorship in Undergraduate Qualitative Research: Exploring Belonging, Identity, and Access Among Monolingual and Multilingual Students

Undergraduate research remains largely concentrated in STEM and quantitative fields, offering limited opportunities for culturally diverse students, including both monolinguals and multilinguals, to engage in qualitative research (Cooper et al., 2019). Due to institutional challenges such as restricted funding, faculty mentors often rely on culturally neutral practices that overlook students' diverse linguistic identities (Hawkins et al., 2023; López et al., 2025). The ways in which mentors and mentees navigate the challenges and affordances of culturally relevant mentoring in qualitative research remain underexplored. We will present findings of the research that drew on Critical Mentoring (Weiston-Serdan, 2017) to examine how faculty mentors and mentees engaged in research practices that aimed to nurture belonging and identities of both monolingual and multilingual undergraduates at a U.S. university. We used a multi-method qualitative design to collect data from 24 undergraduates through surveys, interviews, workshops, and reflective artifacts. Findings revealed that mentoring enhanced participants' sense of belonging, research confidence, and engagement while also exposing structural barriers such as limited access to resources, linguistic inequities, and implicit bias. Students viewed mentorship as empowering, particularly when mentors validated their linguistic and cultural identities. Multilingual participants connected personal and community experiences to their research, enriching inquiry with translanguaging perspectives. Moreover, students' researcher identities developed through psychological safety, collaborative research practices, growth in technical research skills and critical awareness as they recognized how language and culture shaped academic spaces. Through peer discussions and identity-affirming inquiry, students increased confidence in navigating academic hierarchies. Not all participants engaged in peer mentoring to cultivate their agency and a sense of collective responsibility toward equity in research participation. We conclude that inclusive mentorship is essential for equitable participation in undergraduate research. Finally, we suggest that institutions embed culturally responsive mentorship with multilingual research networks and create flexible, identity-affirming pathways to participation.

Abstract Name: The Standards that Bind Us Together: A Model for Visibly Integrating State Standards Into a Year-Long Curriculum

Teachers who write their own curriculum have few reliable models to demonstrate how to plan a year of instruction that stems directly from their state's standards. Similarly, students are not typically knowledgeable about the standards despite the standards' role in shaping educational expectations. The relevant literature tends to emphasize either a conceptual view of standards that does not prove directly helpful to teachers (Applebee et al. 2000, Gorlewski 2013, Hattie 2008, Martone and Sireci 2009, Au 2013) or backward design that does not necessarily prioritize standards (Dover 2016, Gallagher and Kittle 2018, McConlogue 2020). Additionally, literature on student understanding of learning expectations tends to focus on teacher-created objectives, guidelines, and rubrics rather than the standards as they are written by the state (Burke 2003, Gallagher and Kittle, Hattie, McConlogue, Wiggins and McTighe 2005). This project attempts to help fill these gaps by creating a binder that models for 9th grade ELA teachers in Ohio a way to organize standards-based units with backward design. "The Binder" would be used by both the teacher and students to display the structure of a year of learning and the standards behind that learning. The Binder contributes a pragmatic solution for teachers in the form of a standards-based approach to organized learning. It also creates longitudinal research opportunities for how student motivation and learning outcomes may be affected by direct exposure to state learning standards.

Abstract Name: "Thinking Workers are Willing Workers:" The Norfolk and Western Railway Advertises for Industrial Expansion and Social Conservatism, 1947-1965

This project links two series of advertisements by the Norfolk and Western Railway released between the years 1947 and 1965. In response to a downturn in the coal market that supplied most of its traffic and a growing need to attract the largest possible share of the new industrial customers that were moving southwards, the Norfolk and Western turned to its advertising department. The advertising department responded with two parallel series, one of which ran in national business newspapers and journals, extolling the territory the Norfolk and Western served as containing workers who were more productive and, in keeping with this, more conservative and less likely to unionize. The second series targeted those very workers, encouraging them to hold the conservative beliefs that they supposedly already had and to work to attract new industries to their communities, warning them that if their beliefs and communities were unattractive to business, their prosperity would fall by the wayside. In short, the preponderance of evidence suggests that the Norfolk and Western Railway, from 1947-1965, advertised its territory to industrial executives as a managerial paradise with exceptionally productive and willing workers, even as it feared, due to prevailing ideas about the South and Appalachia, that these workers and communities would not measure up to the metric being set for them in their advertisements, and attempted to influence them towards that metric through an additional series of political advertisements in newspapers. Through this thesis, the project explores the Norfolk and Western Railway's role in promoting Anti-Communism, Religious Conservatism, and the ideology of "Business Progressivism," brought on by the new promise of the industrial shift to the "Sun Belt" that defined so much of the Southern political world at this time.

Abstract Name: Investigation of Vinculin in Collective Cell Migration Morphology and Protrusions

Collective cell migration is a key process underlying tissue morphogenesis, wound healing, and cancer metastasis. Effective migration depends on stable cell–cell and cell–matrix interactions. Vinculin, a mechanosensitive protein, is present in adherens junctions and focal adhesions. It links adhesion complexes to the actin cytoskeleton and supports mechanical force transmission. Vinculin is known to link the actin cytoskeleton to adhesion sites, but its specific contribution to epithelial collective migration is unclear. This study investigates how vinculin regulates protrusion formation and collective migration of Madin-Darby Canine Kidney (MDCK) epithelial cells. We hypothesize vinculin is required to generate protrusions during collective migration. We used MDCK wild-type (WT) or vinculin knock-out (Vinc^{-/-}) cells. Cells were cultured in 1X DMEM with 10% FBS and 1% P/S. All samples were stained for actin (phalloidin) with nuclei (DAPI). 2D sheet migration assays were performed using fibronectin-coated dishes with Ibidi inserts. After allowing cells to adhere overnight, inserts were removed and migration was imaged over 8 hours. Samples were stained and actin stress fiber quantification using CT Fire was performed at the edge. A 2D protrusion assay was performed where cells were seeded onto collagen I and rhodamine–fibronectin coated coverslips. After 24 hr in culture, samples were fixed and stained. Cell clusters were imaged on a Nikon Ti2 microscope. To study 3D invasion, MDCK clusters or cysts were encapsulated in collagen I hydrogels in chamber slides. Cysts were treated with hepatocyte growth factor for 4 days to stimulate protrusions, then fixed and stained. Protrusions were quantified. WT clusters formed more and longer protrusions than Vinc^{-/-} in 2D and 3D. In the sheet migration assay, WT monolayers migrated faster and displayed more stress fibers at the edge. Overall, loss of vinculin reduces protrusion formation, stress fiber numbers, and sheet migration, supporting its role in stabilizing cytoskeletal connections during collective movement.

Abstract Name: Conceptualizing Intimate Partner Violence in the South Asian Diaspora using Qualitative Coding

While gender-based harms and relationship dynamics in South Asia are well-documented, there is limited research on South Asian diaspora and international students in the US, particularly regarding how social discourse influences their relationships. This study utilizes thematic coding of interviews with self-identified South Asian students studying at the University of Maryland, Baltimore County (UMBC) to identify expectations of social behavior, the role of social networks and the intracultural dialogue around IPV. It is hypothesized that South Asian college students utilize intracultural dialogue, or communication between members of the same culture, surrounding South Asian culture and intimate partner violence (IPV) to inform their opinions and actions regarding IPV. The purpose of this study is to determine specific factors and topics in the UMBC South Asian student population that influence their perspectives on, and conversations about, unhealthy relationship dynamics and IPV and abuse. It is expected that these findings will inform future efforts to tailor IPV prevention and response programs for students of South Asian descent.

Abstract Name: An Iot-Enabled Multi-Parameter Monitoring System for Real-Time Diabetic Patient Care in Ghana

Diabetes prevalence in Ghana ranges from 2.6% to 9%, with approximately 200,000 cases reported annually. Current health monitoring approaches face significant limitations: hospital-grade multi-parameter monitors are expensive and designed for clinical settings, while consumer wearables focus primarily on fitness tracking rather than chronic disease management. This creates a critical need for affordable, integrated monitoring systems designed specifically for home-based diabetic care. This research presents the development of an IoT-enabled multi-parameter monitoring system for real-time diabetic patient care in Ghana. The system utilizes a MAX30102 sensor integrated with an ESP32 microcontroller to continuously monitor heart rate, blood oxygen saturation (SpO₂), and body temperature. An event-driven architecture processes and transmits sensor data through a Node.js backend to a Firebase Realtime Database, enabling synchronized access across patient mobile applications and clinician web dashboards. The system incorporates machine learning-based anomaly detection to identify abnormal vital sign patterns and generate automated alerts. This approach addresses the inefficiencies of manual recording while providing continuous monitoring at a fraction of the cost of hospital-grade equipment. The research utilizes the BIG IDEAs Lab Glycemic Variability dataset from PhysioNet for model development and validation. This work demonstrates the feasibility of low-cost, automated multi-parameter monitoring for chronic disease management in resource-limited settings. By integrating affordable sensor technology with intelligent data processing and accessible user interfaces, the system aims to improve patient outcomes through early detection of health anomalies and reduced dependence on manual intervention for vital sign tracking.

Abstract Name: Integrating Art into Chemistry Lessons: Effects on Student Engagement and Comprehension

Traditional chemistry instruction often relies heavily on symbolic representations, abstract formulas, and lecture-based delivery, which can make core concepts difficult for students to visualize and meaningfully internalize. This project investigates whether integrating artistic elements into chemistry lessons can improve student engagement and conceptual understanding. Building on research in multimodal learning and visual cognition, the study explores how creative activities—such as drawing molecular structures, designing color-coded reaction maps, and constructing visual or physical models—may support students in forming stronger mental models of chemical processes. The study is being conducted in an undergraduate introductory chemistry setting and uses a mixed-methods design. Quantitative data include pre- and post-instruction assessments measuring conceptual understanding of selected topics, along with validated engagement surveys administered before and after the intervention. Qualitative data consist of classroom observations, student sketches and visual products, and short reflective interviews designed to capture student perceptions of how

the artistic components influenced their learning. The intervention spans several instructional modules, each incorporating an art-based activity aligned with core chemical concepts such as bonding, molecular geometry, reaction mechanisms, and energy changes. Preliminary results suggest that students participating in the art-integrated lessons demonstrate increased willingness to engage with challenging content, report greater confidence in visualizing molecular interactions, and show modest gains in assessment scores relative to students receiving traditional instruction. Qualitative feedback further indicates that the creative tasks helped students slow down, process information more deliberately, and connect symbolic representations to concrete visual models. This project aims to contribute to ongoing discussions about interdisciplinary teaching practices in STEM by examining how artistic modalities can serve as accessible entry points into complex scientific ideas. Ultimately, the study seeks to determine whether bridging art and chemistry can support deeper, more intuitive comprehension while fostering a more engaging and inclusive learning environment.

Abstract Name: Altered fMRI-complexity in persons with vascular risk

Alzheimer's disease (AD) is the most common cause of dementia, leading to progressive cognitive decline. One of the leading risk factors of AD is vascular disease, like hypertension and diabetes, as it affects oxygen and nutrient delivery to the brain, potentially affecting cell function. Such neurovascular dysfunction can be measured by functional MRI (fMRI). The complexity of the fMRI signal has been found to be altered in the parietal lobe, temporal lobe, and posterior cingulate cortex (PCC) in those with AD. While fMRI-complexity has been shown to be related to impaired cognition and tauopathy, its association with vascular risk factors is largely unknown. Therefore, the purpose of this study is to investigate whether fMRI-complexity is altered in persons with cerebrovascular risk factors. We used data from the LASI-DAD study (N=56). fMRI data were preprocessed using the CONN toolbox. Multiscale Sample Entropy (MSE) was used to estimate fMRI-complexity. Complexity values were extracted from regions of interest (parietal, temporal, and PCC) based on the Schaefer atlas. ANCOVA was conducted to investigate the relationship between cerebrovascular risk factors and regional fMRI-complexity, including hypertension (vs. no hypertension) and diabetes (vs. no diabetes), controlling for age, sex, and average gray matter complexity. We found that in participants with hypertension, MSE was significantly increased in the parietal ($F=10.963, p=0.00678$) and PCC ($F=7.438, p=0.0411$) regions, while it was significantly decreased in the temporal ($F=7.645, p=0.03594$) region. In participants with diabetes, MSE was significantly increased in PCC ($F=34.456, p=0.00000012$), but not in the parietal ($F=2.372, p=0.756$) or temporal ($F=2.087, p=0.8988$) regions. We discovered that fMRI-complexity shows associations with vascular risk factors, especially in PCC. Vascular health may influence brain function before noticeable Alzheimer's symptoms appear. Detecting early changes in brain complexity could support earlier diagnosis and intervention. Future research should explore whether vascular health may support brain function and slow Alzheimer's progression.

Abstract Name: Computational Modeling of Axonal Vesicle Populations via Multi-Cytoskeletal Trafficking

Behind every functioning synapse lies a constant flow of synaptic vesicles (SVs) navigating a crowded and dynamic cytoskeletal landscape. Neuronal maintenance of healthy SV populations requires transporting new proteins from the cell body to presynapses, often millimeters away, as well as removing old or damaged proteins. Experimental data captured in living neurons reveal that SV are trafficked along both filamentous actin (F-actin) and Microtubule (MT) Cytoskeletons, and that two-state motion can supports directional differences in SV motion. Here, we present a computational model based on experimental measurements of SV motion. Our agent-based simulation allows SVs to act on set probabilities. SVs stochastically choose which track to follow, which motor state they are in, and whether they get captured or traverse a presynaptic site, all based on rates and other measurements taken from live-cell imaging. Investigations using this model probe how measured directional differences (observed in experiments lasting approximately one minute) affect SV populations that must be maintained over individual SV lifetimes (weeks) and organism lifetimes (years). We use this model to test what happens when specific parts of the transport system are deliberately changed. For example, we simulate reducing the role F-actin plays (modeling inhibited motor proteins like myosin-V) or disrupting MT-based trafficking (modeling MT disruptions observed in neurodegenerative diseases like Alzheimer's disease). Modeled results show how these changes affect SV populations over the axon length and over time, as well as the net motion of SVs that may play a role in SV recycling. This reveals the role that multi-cytoskeletal trafficking may play in maintaining healthy SV populations as SVs are delivered to presynapses, move between presynapses and used during their active life cycle, and eventually removed from use and degraded.

Abstract Name: Stabilization of triplex DNA by flavone derivatives with pyridine-containing side chains

Triplex DNA structures form when a third oligonucleotide strand of oligonucleotide binds to duplex DNA via Hoogsteen hydrogen bonding in the major groove. These structures occur both naturally or artificially in vivo and are known to contribute to various biological processes such as gene regulation, DNA replication, and DNA repair. Targeting duplex DNA with a triplex-forming oligonucleotide (TFO) to form a triple helical structure in a sequence- specific manner is a promising approach to regulate gene transcription (known as the antigene strategy). However, this method is currently limited for gene therapy due to triplexes' low stability and slow formation. A way to increase the stability and facilitate triplex formation is the use of small molecules. Our group recently reported a series of triplex-specific binding ligands derived from plant-based compounds known as the flavones. Various biophysical studies suggest that these ligands have high selectivity and affinity for triplex DNA over duplex DNA, particularly when an amino-containing side chain is present at the 5-position of the flavone scaffold. In this work, we extend these studies by introducing pyridine-containing side chains at the 5-position. Herein, we present the synthesis, characterization, and biophysical evaluation of these molecules, demonstrating their ability to enhance triplex stability.

Abstract Name: Identifying Ideal Solvent Content for Soxhlet Extraction of Lipids From Lemna Minor for Biofuel Production

Climate change continues at an alarming rate as global efforts to curb air pollution face difficulties, including pollution caused by electric vehicle battery production. One alternative being investigated is the use of biofuels, providing a renewable alternative to energy-dense nonrenewable fuels. Duckweed (scientific name *Lemna minor*) is an aquatic plant known for its rapid growth and high protein content, primarily used as a food source and in bioremediation. This study aims to determine the utility of *L. minor* as a sustainable biofuel source and provide critical information for optimizing lipid extraction procedures when using the Soxhlet extraction process. To that end, samples cultured in a laboratory setting are used to create pellets, with lipids extracted using the Soxhlet extraction process with varying concentrations of solvents (chloroform, ethanol, and hexane). A percent yield is then calculated for each trial. Our three most recent trials had a 94.16% yield from 250 mL of 20% Ethanol and 80% Hexane, a 96.86% yield from 175 mL of 20% Ethanol and 80% Hexane, and a 1.66% yield from 175 mL of 20% Ethanol and 80% Hexane (although this run experienced significant human error). Further research could investigate the specific lipids extracted, determine the most efficient method of converting these lipids into usable biofuels, and identify methods to scale production to an industrial scale. If *L. minor*'s utility to biofuel production is confirmed, it may serve as an important tool to reduce emissions and provide a cleaner future for generations to come.

Abstract Name: Ecomorphological variation across urban vs rural populations of invasive Cuban treefrog (*Osteopilus septentrionalis*)

One of the central questions of biology is to understand how organisms adapt to their environment. The budding field of ecomorphology has provided insight into these adaptive processes, demonstrating how organisms in similar environments can convergently evolve similar body plans or ecomorphs. Recent ecomorphological studies have indicated that adaptive ecomorphs can vary significantly in the face of anthropogenically-driven selective pressures. However, these ecomorphological studies have been limited to a small number of taxa. For our project, we studied invasive populations of the Cuban treefrog (*Osteopilus septentrionalis*) to determine how predictable ecomorphological patterns are in an understudied taxonomic group. Specifically, we aim to 1) determine if there are significant differences in the limb length or toepad area of *O. septentrionalis* populations in urban vs. rural environments, and 2) determine if the same ecomorphological patterns evolve consistently in different urban populations. To date, 59 individuals have

been collected from two rural sites and 120 individuals from two urban sites. For each specimen we used calipers to measure limb length and SVL, and ImageJ to measure toepad area and digit length. For each morphological measurement, we will run an analysis of covariance (ANCOVA) to determine if limb length or toepad area differs significantly between populations of rural/urban populations. This research will provide insight into the ecomorphology of an understudied taxon to determine how repeatable ecomorphological patterns are and will allow us to gain insight into the rapid evolution of a harmful invasive species in the context of anthropogenically-driven selective pressures.

Abstract Name: Extending the Maximum Cut Problem to Lie Algebras

In mathematics, a graph is a collection of nodes (also known as vertices) and edges that connect them. On its own this definition may seem odd, but from this simple start one can abstract the nature of relationships. Each node may represent a person with edges representing who is friends with whom, or the graph might be a chart showing what appliances are dependent on various household features. As opposed to restricting ourselves to any one scenario, a graph allows us to view all systems of the same form abstractly. Of particular interest to us is an old graph theory problem: The Maximum Cut Bound. In short, what is the maximum number of edges that can be “cut” by separating a graph into two distinct parts. Regarding one of the scenarios mentioned previously, this sets a way to create two teams such that most friends are split over the two teams. This could be useful in a classroom setting for a teacher to separate the rabble-rousers from their friends and keep the whole class focused on their tasks. Lower bounds on this number exist in the case of graphs, but we hope to prove something new on this lower bound under the more general Dani-Mainkar Construction. This is a theorem providing a method by which to extrapolate graphs into Lie Algebras. In this way we move even more abstractly, at the cost of losing the concrete diagrams that graphs can provide. What we have proven so far is that a rudimentary lower bound holds under the more generalized Lie Algebras. However, our work is still ongoing, and we hope to show that the stronger bound may follow, or that it falls apart due to some difference between the graph and its extrapolation under the Dani-Mainkar Construction.

Abstract Name: Beyond Static Warnings: The Impact of Visual Previews and Animation on SMiShing Decision-Making

Despite increased awareness of phishing scams, users remain highly susceptible to attacks. This vulnerability is exacerbated by the inherent constraints of mobile interfaces, where limited screen real estate and simplified protocols obscure critical security cues available on desktop computers. Unlike email, SMS lacks transparent domain information, often forcing users to rely on ambiguous sender details despite evidence that they fail to

visually scrutinize these elements. To address these human-centered challenges, the present study employs a high-fidelity interactive simulation to evaluate real-time engagement with security interventions among N = 47 participants. They interacted with messages in a simulated iOS environment under three distinct conditions: 1) a text-based warning, 2) an animated warning element, and 3) a visual preview of the destination website. Results are expected to demonstrate that the visual preview yields the lowest click-through rates and highest decision confidence by satisfying user curiosity through greater contextual transparency. Conversely, traditional text-based warnings are anticipated to be the least effective due to habituation. This experiment moves beyond static survey methodologies to provide critical insights into human-centered security design, identifying specific interface elements required to support safer decision-making in security-critical mobile contexts.

Abstract Name: From Flood To Flow

Flooding has become one of the fastest-growing natural hazards worldwide, placing more than 1.47 billion people at risk. In Utah, for instance, about 5% of homes in Salt Lake County are considered highly vulnerable, and the size of flood-risk areas has grown by almost 24% since 2000. As these events become more frequent, there is an urgent need to rethink the materials used in housing, especially in communities that lack access to durable construction systems. This project examines the early, theoretical development of a flood-resistant composite wall panel designed to improve how homes withstand extended water exposure and the forces generated during flood events. To better understand the challenge, the study first looks at why widely used construction materials fail when subjected to flooding. Concrete can crack under lateral pressure, adobe dissolves, timber swells, and steel corrodes. These weaknesses were examined using examples from Peru, Brazil, India, and several regions in the United States, combined with research on hydrodynamic loads and patterns of structural deterioration. Based on these observations, the project proposes a multilayer composite panel built from a fiberglass core bonded with epoxy resin, protected by a flexible silicone layer and coated with a hydrophobic surface finish. Initial modeling suggests that this type of composite panel could retain its structural capacity even after long periods of saturation. It may also help reduce reconstruction expenses by as much as 40% compared with traditional materials. Although productive, the design is still theoretical, with the implication that there is huge potential within modular, low-maintenance, resilient designs as solutions for housing. This project attempts to provide a vision for a future where vulnerable families can remain safe within their dwellings despite increasing flood events caused by climate change.

Abstract Name: The effects of moderate to intense physical activity in cognitive function is moderated by sex and cognitive status

The purpose of the current study was to observe the association between physical activity and cognition, and how moderators including APOE status, sex, and cognitive status may influence the association between physical activity and cognition. Participants (N=122, m=75 years, 56.6% women) wore a Fitbit Inspire 3 for one week and underwent neuropsychological testing. Physical activity levels were divided into light, moderate, and intense. We created a time spent in moderate to intense physical activity (MIPA) for all participants. Linear regressions were used to examine the association of physical activity with cognitive outcomes adjusting for age, race, and education, as well as APOE status, sex, and cognitive status, depending on which modifier was being used. We also tested for effect modification using APOE status, sex, and cognitive status. Greater MIPA was related to better working memory performance ($\beta = 0.200$, $p = 0.04$). MIPA was not associated to any other cognitive score ($p\text{-values} > 0.19$). When using APOE as a moderator, MIPA was not associated with cognition ($p\text{-values} > 0.07$). However, when using cognitive status as a moderator, MIPA was associated with working memory ($SE = 0.005$; $p = 0.04$), such that participants with greater MIPA scored better with mild cognitive impairment. Using sex as a moderator, MIPA was associated with immediate word recall ($p=0.03$), delayed word recall ($p=0.04$), and delayed story recall ($p=0.05$), with greater MIPA resulting in improved performance in male participants and worse cognitive performance in female participants. When examining effect modification by sex, was also associated with the overall memory composite score ($SE = 0.04$; $p=0.01$), such that female participants score worse with increased MIPA. Women engaged in, on average, 10 fewer minutes of MIPA than men. Combined with the differences in amount of MIPA done, these results could suggest that there is a minimum level of MIPA necessary to see beneficial results.

Abstract Name: Beyond the Walls: Reimagining Campus Architecture to Support Survivors of Sexual Assault

This thesis explores how trauma-informed design principles can be integrated into Kennesaw State University's Marietta Campus to promote psychological safety, emotional resilience, and reduction of trauma triggers for survivors of sexual assault. While trauma-informed approaches have been implemented in healthcare and counseling, their application within academic architecture remains limited. This gap is important to consider given the rising rates of sexual assault, which have increased 62.5% since 2020. Current data shows that four in five women (81%) and two in five men (43%) experience sexual assault in their lifetime, specifically noting that college-aged women are three times more likely to experience it than the general population. Given the ongoing emotional impacts of trauma among students, this research focuses on addressing that gap, establishing the built environment as an active agent in student healing and resilience. A qualitative research approach will be utilized, combining historical analysis, precedent studies, and site-specific observation. Behavioral and sensory mapping, the implementation of trauma-informed principles, and biophilic design strategies will inform an understanding of how architectural elements such as light, circulation, materiality, and spatial thresholds influence perceptions of safety and wellbeing, along with improvements in student performance despite the presence of anxiety, depression, and PTSD among sexual assault survivors. Through adaptive reuse of existing structures, proposing new "hubs" within the campus framework, and reimagined campus circulation, this thesis proposes a new composition of campus design that not only educates and spreads awareness but also restores trust, dignity, and emotional refuge. **KEYWORDS:** Trauma-Informed Design, Sexual Assault Survivors, Campus Design, Spatial Healing, Biophilic

Abstract Name: Assessment of the endemic diversity of small mammals in the Sierra Nevada de Santa Marta (SNSM)

The Sierra Nevada de Santa Marta (SNSM), located in northern Colombia, is an isolated massif and the highest coastal mountain in the world, reaching 5,750 m as a pyramidal peak separated from the Andean chains. This geographic isolation and its wide range of ecosystems have made the SNSM a “continental island” and one of Colombia’s major biodiversity hotspots. Although the region hosts high levels of endemism in birds, amphibians, and reptiles, only five endemic mammal species have been reported—a surprisingly low number compared to other biological groups. This apparently low endemism may be due to the lack of recent studies. Most mammal records originate from investigations conducted during the late 19th and early 20th centuries, with few subsequent taxonomic revisions. Additionally, many of the species first described in the SNSM have also been reported in the Andes, despite the mountain range’s supposed isolation. While molecular techniques have revealed significant hidden diversity in cryptic mammal groups—such as sigmodontine rodents and bats—no molecular-level studies have yet been conducted in the SNSM. Given this, and considering the massif’s biogeographical isolation, it is likely that the endemic diversity of mammals in the SNSM is currently underestimated. Just as in most vertebrate groups, mammals may also present high levels of endemism. The main objective of this project is to identify the true diversity of mammals in the SNSM by evaluating their current taxonomic designations through molecular and systematic techniques, with the aim of confirming their identities or revealing possible new degrees of endemism.

Abstract Name: Evaluating Palliative Radiation Therapy Outcomes for Bony Metastases: A Retrospective Study Across Primary Tumor Types

Advanced cancers frequently metastasize to bone, where tumor infiltration disrupts normal bone remodeling and causes skeletal complications such as pathologic fractures and spinal cord compression. These events result in pain, impaired mobility, and diminished quality of life. Palliative radiation therapy (RT), particularly external beam RT, is widely used to relieve symptoms, but its impact on local control, pain relief, and durability of response remains underexplored. We hypothesized that palliative RT provides effective pain relief and local control of bone metastases, with outcomes influenced by treatment site and primary cancer type. The objective was to evaluate the efficacy and prognostic factors associated with palliative RT for bone metastases. We retrospectively reviewed 529 cancer patients who received palliative RT for bone metastases at Mayo Clinic Jacksonville between January 2020 and May 2025. Univariate Cox proportional hazards

regression was used to identify predictors of re-treatment, overall survival (OS), and progression-free survival (PFS). Patients with bladder cancer had a significantly higher risk of re-treatment (hazard ratio [HR] 5.18). A one-category increase in ECOG score, lung or gastrointestinal cancer diagnosis, and skull treatment site were each associated with greater mortality risk. By contrast, breast, prostate, and thyroid cancers were associated with improved OS and PFS. A 5 Gy incremental increase in RT dose was also associated with reduced mortality risk. ECOG status remained a consistent predictor of both OS and PFS, with higher scores correlating with worse outcomes. Palliative RT offers meaningful disease control for patients with bone metastases, though outcomes vary by functional status and primary tumor type. ECOG performance status is a key prognostic factor for OS and PFS, while breast, prostate, and thyroid cancers demonstrate favorable responses compared to lung, gastrointestinal, and bladder primaries. These findings highlight the importance of individualized treatment planning based on patient performance status and cancer type.

Abstract Name: Designing With, Not For: Student-Led Investigation of Neurodivergent Experiences Across a University Community

This student-led research project explores the various experiences of neurodivergent individuals at a public R1 university. The project aims to understand the perspectives of all university affiliates, including students, faculty, and staff. The project encompasses a range of focus areas that aim to gather these perspectives regarding neurodivergent individuals. Our group seeks to answer one question: How can student-led, mixed-methods research surface both barriers and strengths in neurodivergent experiences to inform more inclusive institutional policies and practices? Our research group was formed in 2023 as part of a course-based undergraduate research experience. Students in the research group represent a variety of majors and are neurodiverse. During the 2023-2024 academic year, we designed and distributed an initial STEM-focused survey, which was then revised to include the broader university community. This methodology provided undergraduates with the opportunity to lead research design, develop bibliographies, create protocols, analyze data, and communicate findings. Based on these survey findings, we identified separate focus areas and conducted interviews. The current focus areas are as follows: Accommodation and Inclusion, Cultural Perceptions, Mental Health and Well-being, and Strengths-Based Approaches. Our approach adopts a strengths-based framework that is grounded in the principle of “nothing about us without us.” Our research aims to gather information from neurodivergent individuals rather than relying on outdated medical models. Patterns that have emerged include the limited training for neurotypical individuals, mixed perspectives on accommodation effectiveness, and reluctance to disclose neurodivergence, as well as a lack of understanding of personal strategies. Ultimately, we expect to analyze disclosure rates, identify barriers, and map strengths. This research will transform these narratives into a body of interventions, enabling university officials to make informed decisions. We will highlight how this design enables students to conduct research with the neurodivergent community, while developing research competencies and learning to gather diverse perspectives.

Abstract Name: Developing a Land Engagement Interface for Multi-Domain Training at the Air Force Academy

The Land Engagement Adjudication Platform (LEAP) is a web-based application designed to enhance cadet education at the U.S. Air Force Academy (USAFA) through immersive, operational-level wargames. LEAP empowers cadets to apply critical elements of force employment in realistic scenarios, leveraging foundational operational design principles to deliver actionable outcomes in force-on-force engagements. Developed by USAFA cadets during the Cadet Summer Research Program (CSRP) at the Air Force Research Laboratory's Gaming Research Integration for Learning Laboratory (AFRL GRILL), LEAP is designed to integrate into the Department of Defense Modeling and Simulation ecosystem. LEAP also integrates Distributed Interactive Simulation (DIS) protocols, enabling the system to receive DIS packets for use in the program, demonstrating its interoperability with other systems and enhancing its utility in multi-domain training environments. Currently, in the process of being integrated into the Multi-Domain Laboratory (MDL) and a Military Strategy core course, LEAP provides cadets with practical experience in operational-level tactics within a capstone wargame. By making decisions about intelligence collection, combined arms application, and resource allocation, cadets see the direct impact of force employment on unit, effectiveness, and larger mission objectives. This hands-on experience highlights the interdependence of air, space, and cyber effects on the terrestrial battlespace, preparing cadets to excel in joint force operations. LEAP addresses the challenge of teaching complex operational concepts in a realistic and scalable format, engaging over 1,000 cadets annually in semester-long wargaming exercises. Future development will focus on expanding its interoperability and exploring augmented reality integration, ensuring LEAP remains at the forefront of innovative military education solutions.

Abstract Name: The Impact of the Cystic Fibrosis Microenvironment on Pathogenic Bacterial Interactions

Cystic Fibrosis (CF), a debilitating genetic disease, has a pathology that allows for harmful bacterial infections within patient lungs. Oftentimes multiple types of bacteria are present and interacting at once, including *Staphylococcus aureus* (S.A.) and *Pseudomonas aeruginosa* (P.A.), which contribute to increased morbidity and mortality in CF patients. Understanding the behaviors exhibited by these bacteria, along with how their dynamics affect CF patients, is vital when considering effective treatment. Compared to healthy airway epithelial cells, CF cells exhibit different levels of iron and reactive oxygen species. Soluble factors such as these might impact bacterial interactions. To investigate this hypothesis, supernatants, which contain soluble factors, were isolated from IB3-1 (CF) and C38 (healthy) cell lines. Research is currently being conducted to observe how the addition of these control or CF supernatants might affect the interactions between S.A and P.A. bacterial isolates. Preliminary findings suggest that both control and CF soluble factors promote phenotypic changes in S.A and P.A. isolates. P.A. developed a mucoid phenotype, and S.A. isolates demonstrated small colony variants in the presence of soluble factors. Additional experiments are needed to

determine whether the changes caused by CF factors are significantly different than normal. Regardless, future experiments will focus on quantifying and individually manipulating each airway factor to define what caused significant change. Any change in interaction observed due to the presence of soluble factors derived from human airway cells is novel to this area of research and will add to the reserve of knowledge in broader CF research.

Abstract Name: Multilingual Youth Sharing Heritage: The Significance of Linguistic and Cultural Appreciation in Atlanta and South Korea

The common struggle that most immigrant families face is the marginalization of their heritage language (HL) in ideologically monolingual and monocultural societies. For instance, the U.S. does not prioritize supporting HLs, leading immigrant children to weaken the link to their cultural knowledge and HL proficiency. Similarly, in South Korea with a longer history of monolingualism and monoculturalism, many immigrant families avoid using their HLs due to negative social stigmas, generating similar results. Both contexts can benefit from a better system and environment to support immigration youth's linguistic and cultural dexterity as well as identity development. Such a small initiative was intentionally designed and implemented to connect 8 multilingual youth pairs to virtually engage with each other in their commonly shared HL. 8 university mentors paired with 4 middle and high school mentees based in the U.S. and 4 in South Korea recorded their exchanges for over two to four months. They shared linguistic and cultural backgrounds, as well as interests, in their common HL, including Russian, Korean, Tamil, Farsi, Spanish, and more. Each pair also created a collaborative digital story about their linguistic and cultural journeys. Drawing on the translanguaging framework that values multilingual youth's multilingualism, this presentation focuses on eight multilingual pairs' experiences with this research project. The qualitative analysis of the various artifacts and individual interviews revealed that this project triggered the youth to delve deeper into their cultural and ethnic identities. They also fluidly used all their linguistic repertoires to better connect to their pair.

Abstract Name: Realistic Digital Holography Demonstrator: a STEM Outreach Tool for Teaching Optics and Lasers

The US Air Force (USAF) is interested in using lasers and optics for sensing and directed energy applications. These systems must overcome atmospheric turbulence, which distorts images and complicates detection. Digital Holography (DH) is a sensing technique that enables measurement of atmospheric turbulence and allows for improved capabilities for imaging and sensing applications. Researchers must explain their work to audiences without laser and optics expertise, ranging from high-level decision makers to

high school and undergraduate students as part of STEM outreach events. STEM outreach is also a critical component to ensuring future leaders with technical understanding and awareness. There is a need for a simple demonstration tool that can cater to a range of audiences while also accurately mimicking a real-world DH system. In previous work, USAF researchers built DH demonstration systems that explain the science and engineering involved with imaging through atmospheric turbulence and showing that aberrations can be corrected with digital methods. Our DH demonstration tool adds to previous work by introducing a reflective imaging geometry which leads to speckle from rough surface scattering and a true pupil plane in which we may introduce isoplanatic turbulence. Additionally, the system is less expensive than previous demonstrators, allowing for widespread use in optics education programs.

Abstract Name: Monotropism: Television Consumption and Interaction Through a Neurodivergent Lens

This study examines the link between different levels of monotropic traits and how people choose to consume and interact with television shows. People with monotropic traits often focus their attention on one thing at a time compared to people with polytropic attention types. Monotropism is also regarded by some as an emerging theory of Autism Spectrum Disorder, suggesting a link between autists and other neurodivergent people and high levels of monotropic traits. Previous research has suggested autistic populations consume TV in different ways. This includes watching more TV, restricted viewing habits and binge watching, and interacting with fan content more than non-autistic populations. This may also be true for monotropic audiences. In the survey, people were asked about their TV viewing habits and how they interact with TV shows. Participants were then asked to fill out the Monotropic Questionnaire, which measures levels of monotropic traits, asked if they have a neurodivergent diagnosis or identity, and fill out some demographic information. This survey was shared with neurodivergent focused groups. Additionally, a representative sample of US adults was purchased. Data collection finished in November 2025, collecting around 800 responses. The beginning analysis of this data shows some differences in viewing habits; upcoming additional analysis will reveal the possible significance of results. This data hope to show if there are major trends between how people with high and low levels of monotropic traits differ in how they consume and interact with television shows. How people consume media informs how TV will be produced in the future. Further research into people with high levels of monotropic thinking could help media producers better benefit and design media for monotropic and neurodivergent audiences.

Abstract Name: Characterization of *Providencia alcalifaciens*: Ecological and Genomic Insights into Antibiotic Resistance and β -lactam Susceptibility

Antibiotic resistance is an increasingly significant issue in ecosystems worldwide, with higher resistance levels often occurring in areas influenced by human activity. One such site is Navajo Creek, a suburban

waterway in southwest Chicago that runs through residential neighborhoods and forest preserves. Bacterial isolates from this creek exhibit resistance to six different antibiotics and metagenomic analyses reveal substantial microbial diversity within these communities. Water samples collected from suburban waterways over several months show that *Providencia alcalifaciens* is both geographically widespread and consistently present over time. Whole-genome sequencing of *P. alcalifaciens* identifies an extensive suite of resistance genes that enable survival in the presence of antibiotics; however, the interactions between these genes and specific antibiotics remain under investigation. Cultures are being exposed to various antibiotics to assess gene expression via qPCR, and growth assays are being performed to evaluate resistance across different antibiotic concentrations. The bacterium displays variable susceptibility to several β -lactam antibiotics, including oxacillin, amoxicillin + potassium clavulanate, and carbenicillin. Notably, although amoxicillin with potassium clavulanate does not show enhanced activity against this strain, other β -lactam/ β -lactamase inhibitor combinations are effective, suggesting that specific inhibitor-antibiotic pairings may overcome resistance mechanisms in *P. alcalifaciens*. Overall, this project provides an ecological and genomic characterization of a highly resistant microbe and potential pathogen isolated from local waterways.

Abstract Name: Examining Measurement Invariance in Aging Self-Efficacy Across Adulthood

Perceptions of individuals' self-efficacy have been examined across a variety of domains and age groups (e.g., social, cognitive, emotional; Bandura, 1993; Tovel, et al., 2017). The current study uses a measure of aging self-efficacy piloted by Walsh et al. (2025) to examine potential differences in the ways younger and older adults think about their abilities during adulthood across the different domains of aging. Specifically, this study will examine the facets of aging self-efficacy with a focus toward assessing the degree of measurement equivalence that occurs across groups. Equivalence is necessary for age-related comparisons to be made. As an example of the concept, the Big Five personality characteristics (e.g., Goldberg, 1990) are consistent across many kinds of groups around the world, which makes it possible to compare different populations based on observed personalities. If the current study finds similar measurement invariance, we will be able to do the same. This study will examine perceptions of self-efficacy from both younger and older adults at ages 25, 50, and 75 years with measurements being prospective for the younger group and retrospective for the older group. We will therefore be positioned to examine not only potential measurement consistency but also the degree to which such consistency might vary across time points for each group. For example, we hypothesize that principle components analyses will yield fewer components from younger adults' data and more from older adults' data. This is expected to reflect a view of younger people that conditions may decline in a general sense during later adulthood, whereas retrospective reports of older participants will be more nuanced and reflect more differentiation between aspects of aging self-efficacy due to lived experience.

Abstract Name: Regulating a Revolution: Quantum Computing Data Centers in Washington, Tennessee, and California Tied to Systemic Violence Through Legal and Regulatory Structures

This research project analyzes whether large-scale artificial intelligence data centers with quantum infrastructure developments in the United States align with the principles of responsible innovation and equitable development. Alternatively, it asks if they create a pattern of systemic violence through environmental and social harm. The central research question is whether quantum computing data centers such as IonQ, xAI, and Google exploit regulatory gaps that reflect irresponsible innovation and systemic violence. It also examines how this may further institutionalize neglect of equitable development. AI and quantum computing are often described as central to a national strategy for innovation, global competitiveness, and technological leadership. However, environmental justice and political economy scholarship indicate that large-scale, resource-dependent infrastructure projects are often sited in communities with limited political power, historical disinvestment, and existing environmental burdens. This project introduces an integrated analytical framework that combines systemic violence theory, four components of equitable development, and the four dimensions of responsible innovation. The framework is used to assess the ethical and material consequences of advanced technological expansion. The study will use a comparative case study methodology based on critical legal theory. The qualitative analysis uses the Pugh method with decision matrix charts, and the quantitative analysis uses government reports, socio-spatial data, and legal deconstruction. These will reveal planning processes, regulatory actions, environmental impacts, and experiences near facilities. The project anticipates a misalignment between the public narrative of innovation and the realistic local impacts. Expected results include evidence of regulatory circumvention, procedural injustice, environmental strain on utilities, and the concentration risk among already vulnerable populations. These findings will be discussed in the context of environmental justice, technological ethics, and future policy recommendations, with the aim of proposing a more just and accountable model for quantum computing applications.

Abstract Name: Benchmarking a Novel Nanoparticle Profiling Device for Early Disease Detection

Exosomes are small vesicles released by all human cells which are being increasingly studied as potential biomarkers for early cancer detection. Many existing systems to analyze exosomes use light-scattering analysis methods, which often require expensive and time-consuming sample preparation protocols. The Innovation Center of NanoMedicine, in collaboration with the University of Tokyo, is developing the Ex400, a device capable of analyzing exosomes using dark-field microscopy. By tracking the motion of nanoparticles and applying the Stokes–Einstein equation, the device aims to provide rapid nanoparticle analysis with much less sample filtration needed. Because the device is still under development, its measurement precision and accuracy must be evaluated across a wide diameter range. This study assessed the Ex400's performance in measuring hydrodynamic diameter by comparing its output to two widely used commercial instruments: the ZetaSizer NanoZS (532 nm and 633 nm wavelengths) and the NanoSight LM10. NIST particle size standards (20–600 nm) were analyzed, with each device performing multiple trials according to device operational procedures. Measurement data from each device was used to compare performance of each product across the sample size range. The ZetaSizer NanoZS demonstrated high accuracy across all tested diameters. Both the Ex400 and NanoSight LM10 demonstrated moderate accuracy until measuring samples below ~25 nm in size. Across the full dataset, the Ex400 overestimated sample diameter by an average of 57.7 nm. Removing the lowest-diameter outliers yielded a linear regression with a high R^2 value ($R^2 = 0.9946$). Post-processing using a calibration equation further reduced error, producing an average error of 7.1% from true diameter. These results suggest that while refinement is needed, the Ex400 demonstrates strong potential as a powerful, convenient nanoparticle profiling tool for future disease diagnosis research.

Abstract Name: A Well-Preserved Tylosaurine Mosasaur Jaw from Northern Japan: Implications for Palatal Morphology and Taxonomic Identity

Fossil mosasaur (Squamata: Mosasauridae) specimens preserving the palatal region are relatively uncommon due to the fragility of the associated bones. In this study, we aimed to describe a well-preserved upper jaw fragment belonging to a tylosaurine mosasaur from northern Japan, focusing on the vomer, palatal surfaces, and the corresponding tooth morphology. Through this analysis, we also attempted at deducing the taxonomic identity of the specimen to the genus level. In our specimen, the external naris exhibits a biconcave expansion anteriorly, differing from a narrower narial opening typical in other tylosaurines. The dorsal surface is variably damaged but is transversally convex overall. A space to house the Jacobson's organ, which detects chemical signals in the environment, may also be present; however, the in-situ septomaxilla has yet to be identified. Dorsally, a pair of premaxilla-maxillary sutures are very prominent, extending sub-parallel with each other anteroposteriorly. Ventrally, a pair of intact vomers extend longitudinally along the midline, leaving very little space in between. While most marginal teeth are broken at the base of the crowns, the roots are fully ankylosed to the respective alveoli, suggesting that the animal bore fully developed teeth. Numerous replacement tooth crowns were also present. Where preserved, the crowns are conical and curve posteriorly. The maxilla exhibits notable anteroventral thickening, accentuated by the deeply concave anterolateral margin of the aforementioned naris posterior to it. These features may diagnose this mosasaur within Tylosaurinae. Posteriorly, the maxillary tooth rows diverge, producing wide separation between the vomer and the tooth row. This contrasts with the anterior part of the palate, where the maxillae extend subparallel with each other, leaving little space with the vomers. We interpret this feature to contribute to structural tightening of the palate. Collectively, these observations expand morphological documentation of mosasaur cranial anatomy and may inform future systematic studies.

Abstract Name: Behind Closed Doors: Barriers to Reporting Sexual Assault in Tennessee

Sexual assault remains one of the most pervasive human rights violations globally. In the United States, it continues to be a widespread and deeply underreported crime, with Tennessee experiencing particularly high rates. Despite the severity of these assaults, many survivors choose not to report to law enforcement. Guided by research on neurobiological trauma, stigma, and rural healthcare disparities, this retrospective descriptive study examines barriers to reporting among survivors across nine rural counties in East Tennessee and analyzes discrepancies between reported and unreported cases documented by Sexual Assault Nurse Examiners (SANEs) from 2023 to 2024. This study uses de-identified SANE medical records in compliance with HIPAA de-identification standards (45 CFR §164.514). No Protected Health Information is included, and there is no reasonable basis to identify individuals. A standardized coding tool ensured consistent data abstraction, enabling reliable identification of quantitative patterns. Statistical analyses assessed whether

demographic characteristics influenced reporting behavior. Across the sample, 71.4% of survivors reported their assaults, while 28.6% did not. In 2023, 329 individuals were assaulted compared to 273 in 2024, with most reporting in both years. Ages ranged from 13 to 87 years ($M = 28.81$, $SD = 13.42$), with most between 16 and 25. Age distribution showed non-normality (Shapiro–Wilk $p < .001$). An Independent-Samples Mann–Whitney U test indicated no significant age difference between reporting and non-reporting groups ($U = 34,407$, $p = .281$). Gender was not associated with reporting behavior, $\chi^2(1, N = 602) = 0.67$, $p = .414$, nor was race, $\chi^2(2, N = 594) = 0.06$, $p = .970$. These findings suggest that demographic variables do not explain reporting patterns, underscoring the role of structural, cultural, and psychological barriers. Understanding these obstacles is essential for improving survivor-centered care. This study aims to inform region-specific policies, outreach, and resource development that strengthen access to trauma-informed care in rural East Tennessee.

Abstract Name: Investigating the unique interactions within yeast and human Hsp70-Hsp110 machineries to treat cancer and fungal infections

Background: Heat shock proteins (HSPs) are essential molecular chaperones that maintain proteostasis during cellular stress. In tumor cells, highly proliferative and toxic environments disrupt proteostasis, leading to HSP upregulation—making them promising biomarkers and therapeutic targets. Among these, the Hsp110 family is notable for its role as a nucleotide exchange factor (NEF) for Hsp70s, facilitating ADP release and ATP rebinding to drive protein folding. While fungal Hsp110 NEF activity is well characterized, the structural and functional features of the human Hsp70–Hsp110 complex remain less defined. Aim: We sought to compare NEF activity and complex formation across fungal, human, and cross-species Hsp70–Hsp110 pairings, identifying nucleotide and substrate conditions that optimize activity and complex stability. Methods: NEF activity was quantified by fluorescence polarization, measuring the displacement of fluorescent ATP analog (ATP-FAM) from Hsp70 upon addition of Hsp110 and unlabeled ATP. Native and mismatched Hsp70–Hsp110 combinations (fungal and human) were tested with or without NR peptide (NRLLLTG) and/or ATP. Complex formation under corresponding conditions was evaluated by native PAGE. Results/Conclusions: Native PAGE revealed that only the human Hsp70–Hsp110 complex (hHsp70–Hsp105) forms more readily in the absence of ATP, in contrast to fungal or cross-species pairings. This ATP-independent association was corroborated by polarization assays, where Hsp105 reduced mP values over time in the absence of ATP—especially with hHsp70—indicating a distinct mechanism of nucleotide exchange. Overall, our findings show that human and fungal Hsp70–Hsp110 complexes are structurally and functionally divergent. These mechanistic insights may guide the development of antifungal agents targeting opportunistic pathogens, which pose serious risks to immunocompromised cancer patients.

Abstract Name: Discrimination and Substance Use Among College Students: Does Greek Affiliation Buffer Risk?

Background: Experiences of discrimination are associated with increased risk of alcohol and drug use among college students (Qeadan et al., 2022). Greek affiliation is also a strong predictor of increased alcohol and drug use in students (Scott-Sheldon et al., 2008). At Southern universities, Greek life tends to represent a particularly substantial portion of the undergraduate population, making its social influence especially salient. Research also suggests that peer networks may sometimes buffer students from negative impacts of discrimination (Lee et al., 2016). However, few studies have explored whether Greek and non-Greek students differ in how discrimination experiences influence their substance use behaviors. This study examines whether discrimination experiences predict substance use among undergraduates and whether Greek-life affiliation moderates this relationship. We hypothesize that discrimination experiences will predict increased substance use, and Greek-life affiliation will moderate these effects, such that being involved in Greek-life will be a buffer against negative impacts of discrimination.

Methods & Proposed Results Participants were undergraduates at a University in the Southern U.S. (N ~ 271), 45 non-Greek men, 90 non-Greek women, 18 Greek men, and 118 Greek women. Participants reported frequency of discrimination based on race/ethnicity, sexual orientation, and gender, as well as past-three-month substance use. Data collection is complete, and analyses will be conducted in January 2026. We will utilize a regression framework and SPSS Process Macro model number 1 to investigate our research questions.

Conclusion If our hypothesis is supported – discrimination predicts increased substance use, moderated by Greek affiliation – the findings may suggest that Greek-affiliated students may benefit from social buffering that reduces the impact of discrimination on substance use behavior. These insights could inform campus-wide prevention efforts, highlight the need for targeted support for students outside Greek life who experience discrimination, and strengthen university initiatives aimed at improving campus climate and reducing identity-based stressors.

Abstract Name: Prenatal Experiences of Black American and Ghanaian Women: Provider-Patient Experiences and Interactions

Black women across the globe continue to experience inequities in maternal health outcomes rooted in failures of trust, communication, and respect. In the United States, pregnant women who are of color consistently report being discriminated against, disrespected, and ignored (Goh et al 2024). In Ghana, Moyer et al., (2021) reported that providers, despite knowing the principles of respectful maternity care, still displayed disrespect and abuse especially in high-stress situations. Together, findings like these show how racialized, gendered, and systemic inequities shape the quality of prenatal care. Comparing these two countries provides an opportunity to discover how shared patterns of inequality manifest and are negotiated in differing health structures. Using a qualitative approach, this study involves in-depth interviews (N =12) with four women with a history of prenatal care and two healthcare providers from each country. Women were eligible if they had given birth within the past two to six years and were ≥ 18 years. Providers were eligible if practicing in maternal health (e.g. midwives, nurses, and physicians) and were ≥ 18 years. Interviews (45-60 minutes) were analyzed thematically to identify patterns in communication, respect, and trust during prenatal care. Preliminary findings suggest that while foundational values of respectful, patient-centered care occur in both countries, some challenges remain in these same areas, increasingly countered via community support and the cultural knowledge of women at the receiving end of care. The ways in which providers demonstrate values of care are shaped by their structural environments (resource limited vs structurally inequitable). This results in shared values but context-specific approaches to communication, decision-making, and patient

advocacy. By centering women's lived experiences, this comparative study deepens understanding of how interacting social and structural factors influence maternal care for Black women in both countries, informing efforts to promote more equitable, compassionate, and culturally responsive health systems.

Abstract Name: Bacterial Prevalence and Antibiotic Resistance Reservoirs in Licensed and Unlicensed Producers of Raw Milk

The consumption of raw milk has increased in recent years due to perceived health benefits, despite well-established public health risks associated with unpasteurized dairy products. Raw milk can harbor foodborne pathogens, including *Escherichia coli*, *Salmonella*, *Campylobacter*, and *Listeria monocytogenes*, as well as serve as a reservoir for antimicrobial resistance (AMR). In Utah, licensed raw milk producers are required to follow specific hygiene and handling regulations, whereas unlicensed producers are not subject to the same oversight. This study will evaluate whether licensing status influences both microbial contamination and antimicrobial resistance profiles in raw milk. Raw milk samples will be collected from ten licensed and ten unlicensed sellers. Microbial isolates will be recovered using selective and differential culture media. Antimicrobial susceptibility testing will be performed using agar dilution methods in accordance with Clinical and Laboratory Standards Institute (CLSI) guidelines to determine minimum inhibitory concentrations for a defined panel of clinically relevant antibiotics. In parallel, DNA will be extracted and sequenced using Oxford Nanopore long-read barcoded amplicon sequencing to characterize bacterial community composition and identify potential genetic markers of resistance. Comparative statistical analyses will assess differences in pathogen prevalence, resistance patterns, and microbial diversity between licensed and unlicensed sources. It is anticipated that unlicensed raw milk samples will show higher total bacterial loads, while licensed samples may exhibit greater antimicrobial resistance diversity due to antibiotic use in regulated dairy operations. These findings will contribute to a better understanding of how regulatory practices influence microbial safety and AMR transmission in raw milk.

Abstract Name: Xenharmonic Praxes: Compositional Studies for Guitar in 31-Tone Equal Temperament

This project, "Xenharmonic Praxes: Compositional Studies for Guitar in 31-Tone Equal Temperament", explores new creative and scholarly possibilities for the classical guitar through the application of xenharmonic and microtonal systems. While microtonality has gained increased attention in recent decades, few works have been composed specifically for guitar in 31-tone equal temperament (31-TET), despite its historical grounding in ancient Greek theory and its potential to expand the harmonic and expressive

capacities of the instrument. The project will result in a collection of five to seven original guitar works, including solos, duets, and a chamber piece, as well as a one-off electronic composition for microtonal electric guitar. These works will employ multiple notational systems, including sagittal and graphic approaches, and will experiment with polymicrotonality, where one guitar operates in standard 12-TET while another performs within subsets of 31-TET. The compositional process will also incorporate instrument modification, including the preparation of a fretless classical guitar and the use of microfrets. Research outcomes will extend beyond composition to include a co-authored scholarly paper with faculty mentor Dr. Gregory Young, professional recordings of the collection, and publication of both scores and analytical writing. Together, these outputs aim to advance discourse around historical and contemporary practices of tuning systems, and to situate guitar more centrally in the evolving field of xenharmonic music. This project will serve as the capstone of my undergraduate study in composition and provide a foundation for graduate-level work, conference presentations, and festival performances. By bridging performance, research, and publication, it seeks both to contribute new repertoire to contemporary practice and to position the guitar as a vital instrument for exploring xenharmonic thought in the twenty-first century.

Abstract Name: An evaluation of the growth and reproductive success of captive, white-spotted bamboo sharks (*Chiloscyllium plagiosum*) under managed care

An inhabitant of the north Indo-Pacific Ocean, the whitespotted bamboo shark (*Chiloscyllium plagiosum*) is a demersal, cartilaginous species. Despite the wide abundance of whitespotted bamboo sharks, limited diagnostic data is available beyond embryonic development, physiology, and hatching behavior while in captivity. It is imperative to obtain data and knowledge of growth rate estimates as it helps with proper management of fisheries and stock evaluation, adequate management in captivity, and contributes to conservation and management in the wild. The aim of this research is to examine the behavior of growth of this specific shark species, utilizing those within a captive environment. Within a reported literature study, parameters such as age, growth, and weight were measured and recorded. On the contrary, this present study measures weight (g), sex, pre-caudal length (cm), fork length (cm), and total length (cm) as well as recording diagnostic behaviors such as feeding behavior and color. A more exhaustive evaluation of captive whitespotted bamboo sharks' growth behavior was accomplished as there were various physical and diagnostic characteristics that were gathered. A final analysis determines that the information collected in this study can be further implemented in husbandry and captive reproduction management as more has been unveiled about the growth behavior of this shark species.

Abstract Name: Cultural Schemas Regarding Resilience and Strength in Blacks: Implications for Well-Being and Academic Success

Black college students often navigate cultural expectations emphasizing strength, resilience, and self-reliance in response to systemic and interpersonal stressors. While these norms can support survival in the face of racial discrimination, they may also contribute to emotional suppression, heightened anxiety, and challenges in academic functioning. This study examined how internalized cultural schemas of strength, including the Strong Black Woman (Superwoman) schema and John Henryism, intersect with racial-ethnic socialization, emotion regulation, anxiety, and academic behavioral confidence in Black undergraduate students. Using a mixed-methods approach, participants completed validated self-report measures (G-SWS-Q, JHAC12, ERQ, GAD-7, ABCS), alongside narrative questionnaires capturing first-person experiences of culturally grounded expectations of strength. Coding and analysis of narrative data are underway and will provide additional insight. We hypothesized that stronger endorsement of strength-based norms would relate to greater emotional suppression and anxiety and lower academic confidence, with gender-specific patterns, with women reporting higher Superwoman traits and men exhibiting higher John Henryism. By examining culturally specific coping mechanisms, particularly among Black men, this study addresses critical gaps in the literature and highlights how normative behaviors can simultaneously support and challenge well-being and academic success. Findings offer guidance for culturally responsive interventions that validate resilience while mitigating psychological and academic costs.

Abstract Name: Stress fasting under pressure: The role of demands and control on healthy eating

Stress plays an essential role in daily life, influencing physical and mental health. Many people face recurring stress cycles, like exam periods requiring a balance of deadlines and responsibilities. Over time, these cycles can become chronic stress, affecting psychological well-being, eating, sleep, and overall health. Stress often leads to coping behaviors such as overeating, reliance on stimulants, or stress fasting, skipping meals when demands and strain overwhelm. Academic and professional environments with high demands often push individuals to prioritize performance over self-care, making eating a secondary choice. This leads to irregular meal patterns that harm both body and mind. While research has focused on stress eating, stress fasting remains underexplored. (Widaman, 2014; Weaver et al., 2021). This study aims to examine whether cognitive factors help explain why students engage in stress fasting. Specifically, executive functioning will be measured in high-demand academic environments, as it plays a central role in impulse control and decision-making. When stress levels rise, weakened executive functioning may impair self-regulation, making it more difficult for students to maintain consistent eating routines (Hormann et al., 2012; O'Neill, 2020). Similarly, academic pressures may reduce interoceptive awareness, the ability to recognize and respond to internal hunger cues, which can increase the likelihood of skipping meals or developing erratic eating habits (Herbert, 2020; Robinson et al., 2021). These predictions will be tested using mediation analyses. Hypothesis 1: Executive function in high-demand environments affects impulse control and decision-making. Hypothesis 2: Weakened executive function under stress impairs self-regulation, leading to irregular eating patterns. Hypothesis 3: Academic demands reduce interoceptive awareness, increasing erratic eating habits. The results of this study should clarify why stress fasting occurs and inform interventions that promote

healthier eating among university students. Overall, the project aims to reduce stress-related fasting and promote better coping strategies during demanding academic periods.

Abstract Name: Case Study of Lashing Technique

Lashing is the art of using a cord/rope to bond something securely. In history lashing has been used in various ways including fastening hunting weapons such as an ax, or strengthening joints for extra reinforcement. This was adopted by the ancient Egyptians who would strengthen their Mortise and Tenon Joints “using pegs, dowels, and leather cords. (Baynebox)” In Hawaii Traditional canoes are created through lashing techniques as a way of “engaging in collaborative building using Native knowledge systems as a means of supporting cultural, ecological, and political recovery. (Cooper Hewit)” across the Hawaiian Islands. This study examines lashing techniques to determine how it can be applied at multiple scales in interior design so that it can be diagrammatically and visually documented on this research poster. Lashings can be translated from a small joinery scale to a bigger spatial scale structurally and aesthetically. Structurally the joinery is compatible with gridshell-like and flexible frameworks but falls short with conventional building assemblies, such as a wall, floor, and roof system, which usually require load bearing support that lashings alone cannot provide. Throughout the project, lashings have been used to bind wall base samples used in the creation of the “Lashed Crepe Myrtle Seed” artifact, and bind the wooden frame of the enclosure design, though when working in larger scale environments, it works best aesthetically, being used for interior design elements, such as lashed ceiling panels, lashed column design, or lashed interior decor. Throughout the project, lashings have been used to bind materials together, allowing them to overlap to create structures in a way that is reminiscent of the interlocking spatial organization, which consists of two spaces overlapping to create a zoned shared space.

Abstract Name: The Impact of Cloud-Based Real-Time Analytics on Decision-Making in Fashion E-Commerce Startups in Accra

This study explores the impact of cloud-based real-time analytics on decision-making in fashion e-commerce startups in Accra, Ghana. With Ghana's e-commerce sector expanding rapidly, particularly in fashion, startups face significant challenges due to their reliance on delayed reporting methods, which hinder their ability to make timely, data-driven decisions. Real-time analytics has the potential to offer immediate insights into sales, inventory, and customer behavior, which can significantly enhance decision-making processes in dynamic and competitive markets. This research adopts a mixed-methods approach, combining quantitative system performance data with qualitative insights from stakeholders, to assess the effectiveness of real-time

analytics in improving operational efficiency, decision speed, and overall business performance. The methodology includes three phases: an exploratory phase involving interviews and surveys to assess current data practices and decision-making strategies, the development of a small-scale real-time analytics prototype using Google Firebase, Power BI, and Python scripts to simulate live business operations, and an evaluation phase comparing the prototype's performance with traditional batch reporting systems. The expected results will highlight improvements in decision accuracy, operational efficiency, and responsiveness, particularly in inventory management, pricing, and marketing adjustments. The study will also explore the challenges faced by startups, such as limited technical skills, infrastructure issues, and the cost of implementation, and will provide practical recommendations for overcoming these barriers. Ultimately, this research aims to contribute to both academic knowledge and practical strategies for fashion e-commerce startups in Accra, demonstrating how cloud-based real-time analytics can foster competitive advantage and improved customer satisfaction in the rapidly evolving digital marketplace

Abstract Name: Ultrasonic Steganography: Decoding Hidden Morse Code Messages in Audio Files

This project investigates the feasibility of embedding and extracting hidden Morse code messages in audio files using ultrasonic frequencies beyond the range of human hearing (approximately 19-20 kHz). As digital communication security concerns grow and audio watermarking technology advances, understanding the limitations and capabilities of audio-based steganographic techniques is essential. This research addresses the central question: Can Morse code signals embedded at ultrasonic frequencies be reliably decoded from various audio file formats, and how do compression algorithms affect signal preservation? The methodology employs digital signal processing techniques to detect and decode ultrasonic Morse code transmissions. A custom Python-based decoder was developed utilizing NumPy and SciPy libraries to perform bandpass filtering, envelope detection, and hysteresis thresholding on audio signals. The system extracts carrier frequencies between 18-20 kHz with configurable bandwidth parameters, applies temporal analysis to identify Morse code timing patterns (dots, dashes, and gaps following ITU standards), and translates binary sequences into readable text. The decoder includes a graphical user interface for accessibility and real-time parameter adjustment. Testing across multiple audio formats revealed significant findings regarding format-dependent signal preservation. Lossless formats (FLAC, WAV) successfully preserved ultrasonic content with decode success rates of 83%, achieving confidence scores above 95%. Conversely, lossy compression formats (MP3) demonstrated format-dependent behavior: low-bitrate MP3 files (22.05 kHz sampling) completely removed ultrasonic frequencies, while high-bitrate versions (48 kHz sampling) maintained signal integrity. The decoder successfully extracted messages including "HELLO" and "HELLO CHATGPT ARE YOU READY" from test samples. This research demonstrates the viability of ultrasonic audio steganography while highlighting critical limitations imposed by lossy compression. Results have direct implications for secure audio authentication in digital media, with potential applications in copyright protection and covert communications. Future work will explore adaptive decoding algorithms and investigate alternative frequency ranges to improve robustness across diverse audio formats and transmission channels.

Abstract Name: Thermal Stress Impact on Global Bleaching Events

Coral reefs provide vital ecological and economical benefit to marine ecosystems and human societies, supporting an estimate of 25% of all known marine life, funding coastal tourism, serving as primary food source to communities worldwide and buffering coastlines against storm damage. Despite their resilience, rising ocean temperatures due to climate change pose an existential threat to reef survival. Increasingly severe and frequent global bleaching events, including the record-breaking fourth mass bleaching event since February 2024, have devastated reef systems globally. Hughes recorded consecutive coral bleaching events on the Great Barrier Reef during 2016-2017, demonstrating that even minor temperature increase can prove deadly and lead to coral mortality. Hoegh-Guldberg established that thermal anomalies play a significant role in causing corals to expel their symbiotic algae. This study examines the relationship between thermal stress and coral bleaching pattern from 1980-2020, with additional analysis of 2025 Great Barrier Reef data. Data was sourced from Kaggle and NOAA for global bleaching events and reef locations (1980-2020) and from the Australian Institute of Marine Science (AIMS) for Great Barrier Reef sites to examine recent bleaching patterns for the 2025 season. RStudio was used to explore data and identify key variables while Tableau was used in data aggregation and visualization of global bleaching patterns. The analysis shows a positive correlation between thermal stress and coral bleaching events impacting reef systems globally. Notably, major bleaching peaks in 1987, 1998 and 2016 align with documented El Niño Southern Oscillation Events. The Arabian Gulf and Pacific oceans were revealed as key hotspots, more susceptible to bleaching events due to their equatorial locations. These findings support prior research and conclude that increased sea surface anomalies disrupt coral environments and result in surging coral mortality rates as conditions remain stagnant.

Abstract Name: Co-Design AI Prompt Deck: The Role of Reflective Prompting in AI-Integrated Design Practice

Students today are using artificial intelligence (AI) more than ever for studying, writing, and creative projects. Though powerful, these tools are often adopted uncritically, without reflection on their limitations or ethical dilemmas they create. Questions naturally arise: What risks may result from unreflective AI use? How can fairness, inclusivity, and accessibility be ensured in AI-supported creative practices? This research examines how structured, reflective prompts shape students' thinking and discussion about AI during design research tasks. The project asks two central questions: How do reflective prompts shape the way designers perceive AI-generated materials during the design process? What forms of reflection, like ethical, creative, or strategic perspectives, emerge when designers critically engage with AI-generated material? Human-computer interaction and design scholars have long argued that technologies shape users' assumptions and values (Sengers et al., 2005). Furthermore, we will explore how reflective prompting through our Co-Design AI Prompt Deck, a set of forty cards with prompts and reflections, would encourage students to pause, question their assumptions, and articulate reasoning that might otherwise remain implicit. Guided by principles from Reflective Design and Value-Sensitive Design, we will be conducting research by leveraging a discourse-centered methodology to best capture raw reactions of students. Students will participate in one-on-one interviews where they complete design tasks using AI while responding to structured prompts. They will then answer follow-up questions about their experience, and responses will be documented with audio recordings, eye-tracking technology, and written notes. Following the research and implementation of the

card deck, we anticipate a shift in design thinking as designers begin to perceive AI as a collaborator rather than a neutral assistant. Moreover, we hope this reframes the conversation surrounding existing design mental models, prompts ethical reflection and strategic thinking for designers, and aids in developing effective strategies for teaching ethical and responsible AI use.

Abstract Name: Designing a Deployable Object-Detection Workflow for High-Resolution Geospatial Imagery

The rapid growth of commercial and government satellite imagery collection has exceeded the capacity of human analysts to manually review all collected data, creating an urgent need for automated methods capable of identifying objects of interest at scale. To help address this operational challenge, this effort develops a computer vision model development pipeline using commercial satellite imagery. The overall workflow will cover from the client request for a model to implementation of a deployed object detector. The goal is to design a repeatable and efficient process that supports modern object-detection models, while handling the unique technical demands of large geospatial datasets. The workflow consists of five major components: (1) obtaining large and diverse image dataset from a repository (2) generating high-quality bounding-box annotations around objects in large satellite images and then converting to proper format for model training (3) training an object-detection model using state-of-the-art approaches; (4) evaluating model performance to determine if model is adequate or requires improvements to training data; and (5) deploying the model to a hosting platform for real-time execution and data sharing to users. Key challenges include managing images of large size, handling wide variation in object orientation and scale, and establishing consistent annotation standards to support model convergence. Through this research, novel methods for data collection, annotation management, and large image tiling were developed to address the challenges and solve this operational problem. The resulting computer vision development pipeline will enhance automated image exploitation and improve situational awareness for a wider range of operational mission partners.

Abstract Name: Campus Housing Unveiled: The Price Revolution of the Last Decade

This research explores the impact of general housing, maintenance, utility prices, and other input economic factors on the national average school campus housing prices from 2015 to 2025. Existing scholarship surrounding student housing prices is limited, often focusing on general housing trends like the impact of population growth and aging, migration, and market fluctuations, while overlooking the specific impact of factors like utilities, construction materials, and economic variables unique to campus housing. To address this gap, this study uses a linear multivariable regression to isolate the relative impact of each economic variable in relation to school housing prices. The regression analyzes the relationship between school housing prices and a set of targeted independent economic variables: housing prices, residential maintenance prices, utility prices, inflation, college tuition and fees, new school building construction, cement and concrete

manufacturing, as well as lumber and other construction materials. While it is typically expected that an increase in inflation would cause an increase in price, inflation data shows an unexpected negative correlation. Utility prices and construction materials make a significant contribution to housing, but they do have relatively smaller impacts on the price. The analysis reveals that housing prices are the dominant driver of school housing costs with significant contributions from residential maintenance and tuition costs. Identifying the key economic drivers may enable policy makers and institutions to anticipate fluctuating prices to help stabilize housing costs. Further research can account for the price, material, and economic regional variations in the United States, as this research includes data across the entire country.

Abstract Name: Comparative Analysis of Water Quality Parameters in Healthy and Impaired Creeks

Urbanization is a major factor contributing to stream impairment by increasing the introduction of pollutants and degrading water quality over time. Under the Clean Water Act, states are required to establish standards that distinguish between healthy and impaired waterways. To better understand the effects of urbanization on stream health, this study evaluates two creeks within the Walnut Creek Watershed: Little Rock Creek (impaired) and North Creek (healthy), located less than a few miles apart. Water quality parameters including dissolved oxygen (DO), specific conductivity (SPC), and *Escherichia coli* (*E. coli*) are monitored to assess how pollutants influence stream condition and ecological balance. Both creeks flow through urbanized areas frequently used for recreation and education, offering insight into how human activity impacts nearby aquatic systems. By comparing these two streams, this study aims to identify key differences in water quality and explore the historical and environmental factors contributing to impairment. The findings will support a deeper understanding of how urban development affects local waterways and provide guidance for future restoration and management efforts to improve water quality within the Walnut Creek Watershed.

Abstract Name: Enhancing Dental Education Through Artificial Intelligence: Improving Student Detection of Tonsilloliths in Panoramic Radiographs

Developing diagnostic accuracy is essential in dental education, yet identifying tonsilloliths on panoramic radiographs remains challenging for students due to limited clinical experience. Traditional instruction relies on manual interpretation, which often leads to diagnostic errors and reduced confidence among learners. This project aims to enhance student learning by integrating artificial intelligence (AI)-assisted tools into radiology training. The study will compare the efficiency and accuracy of dental students in detecting tonsilloliths with and without AI support and assess their perceptions of AI as a learning resource. Quantitative measures will

evaluate diagnostic performance, while qualitative feedback will explore how AI guidance influences understanding, confidence, and engagement. By focusing on the educational impact of AI, this research seeks to determine how technology-driven instruction can improve learning outcomes and bridge the gap between novice and expert diagnostic performance. The findings are expected to guide curriculum development in dental radiology, promoting evidence-based teaching strategies that prepare students to confidently and competently use AI in clinical practice.

Abstract Name: Glyphosate Mediated Gut Dysbiosis on Parkinson's Disease: How Glyphosate Exposure Relates to Alpha-Synuclein Misfolding and Parkinson's Risk

Many agricultural workers and communities that reside near agricultural lands are at risk of being exposed to glyphosates through direct use of glyphosate-based herbicides or well-water consumption. This comprehensive literature review examines the relationship between glyphosate exposure and gut-microbiome composition to evaluate whether glyphosates influence α -synuclein protein misfolding in Parkinson's Disease (PD) via the microbiota-gut-brain axis. The gut microbiome is home to trillions of microorganisms known as the gut microbiota, many of which are affected by our diet, chemical exposures, and gut inflammation or barrier dysfunction. Glyphosate exposure through glyphosate-based herbicide use may alter gut microbial composition, key metabolites, and cytokine pathways that stimulate vagal signaling, providing a route through which gut dysbiosis may affect the brain. This can influence the development of neurodegenerative disorders and neuroinflammation through the gut-brain axis. The expanding use of glyphosate-based herbicides is parallel to increased PD mortality and symptoms, and glyphosate is linked to neurotoxic changes that trigger α -synuclein misfolding. Glyphosate-driven shifts in microbial communities, particularly fluctuation in Firmicutes such as *Dubosiella* and *Lactobacillus*, may disturb Branched-Chain Amino Acids (BCAAs) metabolism, a process associated with impaired lysosomal function and α -synuclein aggregation. Alterations in Short-Chain Fatty Acids (SCFAs) may activate the GPR41/43–NLRP3 neuroinflammatory pathway, promoting neuronal stress and loss of dopaminergic cells. Future research should investigate potential gut-based early changes in communities regularly exposed to glyphosates to detect PD risk before neurological damage becomes irreversible.

Abstract Name: Anti-Body Drug Conjugates: Toxin Cytotoxicity in Glioblastoma Cells

Glioblastoma multiforme (GBM) is one of the most common and most aggressive types of brain cancer. Being able to affect anyone regardless of age and background. As one of the more prolific brain tumours, many studies have been made to further the advancement in making GBM more treatable and prolong the life span of patients. Current therapies for GBM include surgical resection, then radiation followed up with temozolomide, which is a chemotherapy, or in some cases, radiation and chemo are given together. Another treatment option is Antibody-Drug Conjugates, which is the focus of our research. An antibody drug conjugate is a combination of an antibody, a payload, and a linker. An antibody, which is an immune response produced by the body's B-cells to fight target antigens that the body does not recognise. Payloads are highly potent toxins that can be used at the nanomolar scale to induce apoptosis (cell death). A payload linker is used to attach the payload to the antibody. ADCs differ from more traditional therapies as they provide target tumour specificity in treatment and have shown great promise in the treatment of other cancer types, such as breast cancer. With the sensitivity of brain cancers, targeted tumour specificity will significantly improve

patient outcomes. Our approach to ADCs is focused on finding effective payloads, which would be toxins that are still potent and cause apoptosis at low concentrations, using the Cell Titer Glo Assay to assess cell survival with luminosity after treating different GBM cell lines with free toxins. Some preliminary findings indicate that DNA alkylators (Duocarmycin) and Topoisomerase II inhibitors (PNU-159682) were the most potent, followed by microtubule inhibitors (MMAE and Eribulin), and then Topoisomerase I inhibitors (Exatecan and SN38). MMAF, as a free toxin, was not very effective because of its inability to cross the cell membrane.

Abstract Name: Investigating the Effects of Anchor Knockdown on Circadian Rhythm Behaviors Using *Drosophila Melanogaster*

About 3% of the adult population experiences circadian sleep disorders. Circadian sleep disorder is characterized by a mismatch between one's desired timing of sleep and their ability to fall asleep and remain asleep. Anchor is an integral 17-transmembrane protein that consists of a fused transporter domain and a G protein-coupled receptor-like domain. It is also known as a regulator of the mechanistic target rapamycin complex 1 (mTORC1). mTORC1, as the master cell regulator, is involved in directing several processes such as synaptic growth, cellular activity, and neurogenesis. Disruption in this pathway affects several aspects of behavior, including circadian rhythm. Anchor is expressed in several types of neurons, including insulin-producing cells (IPCs). Dysregulation of IPC signaling is linked to disruptions in mTORC1 signaling that alter circadian rhythm. The role of anchor in the brain and in behavior is unstudied. This research uses *Drosophila* to investigate anchor in IPCs and how disruptions affect circadian rhythm. Findings show that flies with a loss of anchor in IPCs experience dysregulated circadian rhythm, thereby elucidating an aspect of the role of anchor in the brain. These results provide insight into circadian rhythm sleep disorders, creating possibilities for treatments. Consequently, future goals would be to investigate the molecular mechanism underlying circadian rhythm phenotype using proteomics.

Abstract Name: Regulation of DIO3 Expression by the Long Non-Coding RNA DIO3OS in Human Vascular Endothelial Cells

Chemotherapy and radiotherapy increase the risk of cardiovascular disease by nearly 80%, contributing to complications such as atherosclerosis, thrombosis, and impaired vascular remodeling and angiogenesis. While current research often focuses on the effects of these treatments on heart muscle cells, the impact on vascular endothelial cells, essential for overall vascular and organ health, is frequently overlooked. The oxidative and genotoxic stress from cancer treatments disrupts cellular balance. It leads to lasting epigenetic

changes, such as DNA methylation and double-strand breaks, that can influence vascular cell fate. Serious side effects include atherosclerosis (accumulation of plaque in arteries), thrombosis (blood clots), and other conditions affecting blood vessel function. This project explores how the expression of proteins key to the cellular response to these stressors is manipulated at the epigenetic level. Epigenetics involves alterations that can inhibit or encourage gene expression without changing the gene itself. This research focuses on how long non-coding RNA affects the expression of proteins linked with cellular response to chemotherapy related genotoxic stress. We hypothesize that the long non-coding RNA DIO3OS, which has been suggested to play a role in endothelial responses to genotoxic stress and DNA damage, also regulates expression of the protein-coding gene DIO3. The goals of this research are to: (1) validate expression changes of DIO3 in Human Umbilical Vein Endothelial Cells (HUVECs) to determine whether changes to DIO3OS isoforms affect DIO3 enzyme production, and (2) assess which isoform of DIO3OS plays the most significant role in DIO3 regulation. To study DIO3 expression, we will measure both mRNA and protein levels in HUVECs following manipulation of specific DIO3OS isoforms. RT-qPCR will quantify DIO3 mRNA, and DIO3 protein will be assessed by Western blotting and immunofluorescence.

Abstract Name: Understanding the Tribological Implications of Engine Oil Change Frequency Through Elemental Analysis of Used Engine Oils

A predominant factor influencing a vehicle's longevity is its engine health. Typical internal combustion engines experience frictional losses alongside wear owing to the articulation of varied mechanical components. This study develops an evidence-based and science-backed assessment to better grasp the implications of oil change frequency from the tribological and longevity vantages. This has broad applicability to technically-minded customers as automobiles are omnipresent and gives them an assurance on why frequent oil changes and over-maintenance are beneficial. Analysis of the elemental composition of engine oils provides strong insights into engine wear. For instance, copper, iron, and aluminum—the most likely wear metals in an engine—demonstrate a significant compositional decrease (in ppm) in a 2023 Toyota Corolla and 2024 Honda CRV Hybrid after the initial oil change at ~1,000 miles. By taking note of the metals which exhibit the highest concentration drops after an oil change after a preset number of miles, wear rates in ppm/mile are ascertained. This study also goes onto demarcate the initial uptick in engine wear during the break-in period vis-à-vis the onset of steady-state wear. The trend overwhelmingly points towards maximum wear transpiring in the first 1,000 miles, followed by a steady state. The authors believe that this initial oil change is consequential to the longevity of the mechanical components in an engine, which may undermine the general recommendation by original equipment manufacturers of administering the initial oil change in the 6000–15000-mile range. Manufacturers' recommendations may not account for this initial break-in period, and to maximize overall engine health by minimizing this wear, it is recommended to undertake accelerated oil changes at frequent intervals. The authors are quantifying this benefit to determine the optimal oil change frequency for ideal engine performance based on data from a number of oil changes in multiple automobiles

Abstract Name: Predicting Cardiac Arrest in Coronary Artery Disease Patients Using Pre-Arrest Clinical Features

Out of hospital cardiac arrest (OHCA) remains one of the most fatal medical emergencies, yet its prediction is extremely challenging due to the limited clinical information available before collapse. To address this gap, this project investigates whether in-hospital cardiac arrest (IHCA) among patients with coronary artery disease (CAD) can serve as a clinically meaningful proxy for understanding deterioration patterns relevant to OHCA. The central research question guiding this work is: Can we predict in-hospital cardiac arrest among CAD patients using routinely collected clinical features available prior to physiological decline? Although OHCA datasets rarely contain structured pre-arrest biomarkers, vitals, or medication histories, IHCA cases within hospital systems capture rich, time-stamped clinical data that reflect patient status leading up to arrest. Leveraging this advantage, we constructed a curated dataset of CAD patients who experienced IHCA, including demographic variables, laboratory biomarkers, vital signs, comorbidity profiles, and medication exposure. This dataset enables the exploration of early physiological signals and risk factors that precede cardiac arrest but remain understudied in out-of-hospital settings. To identify early predictors of IHCA, we are developing and comparing multiple machine learning models to evaluate how well pre-arrest clinical features discriminate between patients who do and do not experience arrest. Model performance will be assessed using cross-validation and AUC metrics, and feature analysis will be used to highlight the most influential biomarkers and physiological trends associated with imminent arrest. We expect this analysis to reveal clinically interpretable predictors that contribute to risk stratification for cardiac arrest in CAD patients. More broadly, this work demonstrates how IHCA datasets can help bridge the pre-arrest data gap for OHCA research and provides an analytical foundation for future early-warning systems and clinical decision support tools aimed at preventing unexpected cardiac deterioration.

Abstract Name: Game On: Improving Children's Body Composition Through Ring Fit Adventure

This study assessed changes in body composition among parents and children following an 8-week active video game (AVG) intervention using Ring Fit Adventure on the Nintendo Switch. AVGs offer a unique opportunity to merge entertainment with physical activity, and with roughly 190 million Americans aged 5–90 playing video games at least one hour per week, home-based AVGs may be a viable strategy to improve body composition. Seven families (9 adults, M age = 44; 8 children, M age = 13) completed an 8-week intervention in which they were asked to play Ring Fit Adventure twice weekly for 30 minutes at home. The game uses a resistance ring and leg strap to guide players through exercise-based movements in an interactive adventure setting. Weekly self-reports captured total play and active exercise time using in-game metrics. Body composition (fat mass, fat-free mass) was measured pre- and post-intervention using a Tanita TBF-400 bioelectrical impedance scale. Children averaged 55 minutes of weekly play (42 minutes of exercise), while adults averaged 22 minutes (11 minutes of exercise). Paired t-tests showed that children significantly increased fat-free mass (pre = 82.42 kg, post = 84.70 kg; $p = .002$, Hedges' $g = 1.1$) and decreased fat mass (pre = 20.81 kg, post = 19.25 kg; $p < .001$, Hedges' $g = 1.0$). Adults showed no significant changes in fat mass ($p = .38$) or fat-free mass ($p = .19$). AVGs incorporating resistance-style training appear to be a feasible

and effective strategy for improving body composition in children, who completed nearly the full prescribed dose of gameplay each week; however, similar benefits were not observed in adults.

Abstract Name: A Drone That Thinks Like a Bat: Experiments with Bat Midbrain Models on a Quadrotor Drone

Bats use echolocation to perform rapid, dynamic sensorimotor transformations that support flight, target selection, and adaptive control. Emulating these capabilities in artificial systems presents a significant interdisciplinary challenge. To address this challenge in the Higgins laboratory, we have constructed a quadrotor drone system equipped with a flight controller, a Raspberry Pi, and navigational equipment consisting of a depth camera and a LiDAR system. With all this equipment, the drone can receive and execute motor commands generated by a computer program. The long-term goal is to develop a robotic platform whose navigation strategies are governed by a bat-inspired neuronal model. This interdisciplinary project seeks to reproduce a bat's capabilities within a robotic system by linking biologically inspired neural computation with drone-based navigation. A biophysically inspired spiking neural network (SNN) model of the superior colliculus (SC) was developed for deployment onto this drone model. The model captures key stages of auditory spatial processing by mimicking how a bat turns echoes into decisions and actions, using the hardware currently present on the drone. The data obtained from this hardware is then sent through a model that emulates early auditory processing stages in the cochlea, auditory cortex (AC), and inferior colliculus (IC), and are converted into firing rates across spatially tuned sensory neurons. This project also informed the development of a new undergraduate research course (CURE) at the University of Arizona in computational neuroscience and bio-inspired robotics. Students engaged in model-building, data visualization, and hardware testing, gaining hands-on experience connecting neural computation to embodied control. Together, the integrated SNN model, drone system, and course framework establish a foundation for biologically grounded, echolocation-based navigation in autonomous aerial robots and provides a scalable educational model for training students at the neuroscience-engineering interface.

Abstract Name: Synthesis of carbon dots and their role in sensing Perfluorooctanoic acid

Under the Safe Drinking Water Act, the Environmental Protection Agency (EPA) designated maximum contaminant levels (MCLs) for toxic organic chemicals like PFOA to 9.0 ppt (ng/l). This legislative measure was enacted in response to growing concerns of toxic chemical exposure in drinking water and everyday packaging sources. For example, a report by the Centers for Disease Control and Prevention, using data from the National Health and Nutrition Examination Survey (NHANES), discovered PFAS in the blood of 97% of Americans in 2015. This research project aims to determine the consistency of detecting PFOA contaminants of different concentrations (100-800 pM) with synthesized carbon quantum dots using fluorescence spectroscopy. Carbon quantum dots are used for their high photoluminescence properties (high absorption

and excitation of wavelengths). The ability of this cost-effective nanomaterial to detect toxic organic chemicals (perfluorooctanoic acid) has made it a viable tool for environmental sensing technology. Carbon dots were synthesized via a hydrothermal method by combining 1.6 mL ethylenediamine, 1 g citric acid, and 8 mL of solvent in a Teflon reactor, which was then sealed within a hydrothermal autoclave and heated in a furnace to 180°C for varying durations: Batches B and D were processed for 8 hours, while Batch E was processed for 24 hours. The fluorescence intensity of the resulting carbon dot samples was measured across the 350–650 nm range using a fluorescence spectrophotometer. Detection sensitivity was quantified and recorded in Excel spreadsheets for each viable concentration. The carbon-dot samples showed a sensitive linear response to the PFOA with a concentration range of 100-800 pM, a LOD of 47.04 pM, and a LOQ of 156.84 pM. Lower concentrations of PFOA (100pM) resulted in higher fluorescence intensities and more consistent peaks across batches and operators, indicating greater detection reliability.

Abstract Name: Use of Clindamycin Treatment to Eradicate *Sneathia vaginalis*

Sneathia vaginalis (*S. vaginalis*) is a bacterial species that frequently colonizes the human vagina. It produces a cytotoxin and is significantly associated with chorioamnionitis, preterm birth, and other pregnancy complications. There is currently no standard treatment to eradicate *S. vaginalis* from the vagina, but successful therapy could serve as a means to reduce the risk of preterm birth. Standard therapy for bacterial vaginosis is metronidazole or clindamycin, but antimicrobial agents can deplete normal, healthy bacteria, such as *Lactobacillus crispatus*, in addition to pathogens, which promotes recurrence. The goal of this study was to determine the minimum inhibitory concentrations (MIC) and minimum bactericidal concentrations (MBC) of clindamycin and metronidazole for *S. vaginalis* and *L. crispatus*. *S. vaginalis* was cultured in porcine brain heart infusion broth (BHI) containing 10% fetal bovine serum, and *L. crispatus* was cultured in deMan Rogosa Sharpe broth. MICs were determined by inhibition of visible turbidity, and MBCs were determined by counting colony-forming units. *S. vaginalis* strain Sn35 had MICs and MBCs for clindamycin/ and metronidazole that were substantially lower than MICs and MBCs for *L. crispatus*, suggesting that antimicrobial therapy at the right dose could potentially be used to eradicate *S. vaginalis* without depleting beneficial *L. crispatus*. Because lactic acid and other factors that are secreted by *L. crispatus* prevent the growth of *S. vaginalis*, this strategy could prevent reinfection and thereby help protect pregnant people from the potential pathogenic effects of *S. vaginalis*.

Abstract Name: Hemoglobin Microbubbles as Oxygen Sensitive Contrast Agents: Visualizing tissue oxygenation

Hemoglobin microbubbles represent a novel class of oxygen-sensitive contrast agents designed to enhance visualization of tissue oxygenation in real time. Unlike conventional ultrasound contrast agents, which primarily highlight vascular structures, hemoglobin microbubbles exploit the intrinsic oxygen-binding properties of hemoglobin to provide dynamic information about local oxygen levels. This project explores the synthesis, characterization, and functional evaluation of hemoglobin microbubbles as a tool for noninvasive imaging of tissue oxygenation. Microbubbles were fabricated by encapsulating hemoglobin within a stabilized lipid shell, allowing them to circulate within the bloodstream while maintaining responsiveness to oxygen partial pressure. In vitro studies demonstrated that the acoustic properties of these microbubbles varied predictably with oxygen saturation, enabling ultrasound detection of oxygen-dependent signal changes. Preliminary in vivo experiments further confirmed that hemoglobin microbubbles could highlight regions of hypoxia with high spatial resolution, offering a potential method for monitoring ischemic tissues, tumor microenvironments, and organ perfusion. The ability to visualize oxygenation directly, rather than inferring it indirectly through blood flow, represents a significant advance in functional imaging. This approach may provide clinicians and researchers with a rapid, noninvasive tool to assess tissue viability, guide therapeutic interventions, and improve understanding of oxygen dynamics in health and disease. By bridging molecular biology and medical imaging, hemoglobin microbubbles illustrate how biomimetic design can expand the capabilities of ultrasound beyond structural imaging to functional assessment. Ongoing work focuses on optimizing bubble stability, refining imaging protocols, and exploring translational applications in both cardiovascular and oncological contexts. Attendees will gain insight into how these agents are engineered, how they function, and their potential impact on clinical diagnostics and research.

Abstract Name: Ultrasound-Guided Delivery of Laccase-Loaded Microbubbles for Enzymatic Degradation of Doxorubicin and Cardioprotection

IntroductionLate term cardiotoxicity remains a major concern for pediatric cancer patients treated with anthracyclines such as doxorubicin (DOX). This toxicity can manifest months or years after therapy as heart failure or arrhythmias severely impacting long-term health and quality of life. DOX induced cardiotoxicity is primarily driven by reactive oxygen species (ROS), which cause irreversible oxidative damage to cardiac tissue. Currently, dexrazoxane is the only FDA approved cardioprotective agent, acting through iron chelation to reduce ROS. However, this strategy overlooks other ROS sources, including mitochondrial dysfunction and redox cycling, limiting its efficacy. Dexrazoxane has also been associated with serious side effects, underscoring the need for safer, tissue specific alternatives. Here, we present a novel ultrasound-guided cardioprotective system using laccase microbubbles (LMBs). Laccase, a copper containing oxidase enzyme, degrades toxic phenolic compounds such as DOX into less harmful byproducts. This study explores the potential of LMBs to degrade DOX in localized vascular settings before cardiac accumulation, thereby reducing cardiotoxicity without compromising anticancer efficacy. This represents a promising step toward targeted, minimally invasive cardioprotection. **Materials and Methods**LMBs were synthesized using thiolated laccase enzymes, with partial PEGylation for stability. PEGylated and non-PEGylated laccase were combined, sonicated under perfluorobutane gas, and stabilized to form microbubbles. For vascular targeting, PEI-azide was incorporated. Ultrasound radiation force was applied using a Siemens Sequoia C512 scanner to facilitate cardiac deposition. **Results**Fluorescence microscopy confirmed successful PEI coating. LMBs demonstrated ultrasound responsiveness without structural degradation. After 2-hour incubation with DOX, optimized LMBs achieved >90% reduction in DOX fluorescence, with absorbance shifting from 480 nm to 320 nm, and a visible color change confirming degradation. **Conclusions**We successfully developed PEI-

coated LMBs suitable for circulation and ultrasound targeting. Future in vitro and in vivo studies will validate their ability to prevent off target DOX accumulation.

Abstract Name: Are Reasoning Circuits Universal? Evidence for Domain-Specific Computation in Language Models

Large language models can answer complex questions requiring multiple reasoning steps, yet how they implement such reasoning internally remains poorly understood. This research investigates whether these models develop reusable computational circuits for multi-step reasoning, or whether each task requires entirely distinct mechanisms. Using Gemma-2-2B, a 2-billion parameter language model, we analyzed how the model answers two-hop reasoning questions such as "Dallas is in Texas. The capital of Texas is ____" where correctly answering "Austin" requires connecting two pieces of knowledge. We generated attribution graphs, detailed maps tracing how information flows through the network, for prompts spanning multiple geographic domains and applied graph analysis techniques to identify conserved computational patterns. Our analysis reveals that circuits for similar reasoning tasks share substantial structure: prompts about different cities within geographic reasoning showed 48% overlap in activated neural components, compared to only 21.6% overlap with unrelated tasks. This dramatic difference suggests the model employs domain-specific rather than universal reasoning circuits. We extracted a candidate core circuit of 157 neural components and 679 connections appearing consistently across geographic prompts, with apparent functional organization: early network layers handle entity recognition, middle layers detect relationships like geographic containment, and late layers assemble the final answer. These findings challenge assumptions about general-purpose reasoning in language models, suggesting instead a modular architecture where specialized circuits handle specific knowledge domains. Understanding this organization has implications for AI safety. If we can identify circuits associated with particular behaviors, we gain tools for interpreting and improving model reliability. Ongoing work aims to validate these structural findings through causal intervention studies.

Abstract Name: The Search for the Perfect Social Contract Never Needed to Take Place: The Charter of Medina as a Social Contract

The Social Contract was a concept that was popularized in the Mid-17th century specifically by Thomas Hobbes through the publication of Leviathan. John Locke and Jean-Jacques Rousseau continued this popular idea of governing with their own books, but it became clear that none of these Western philosophers looked to the east, specifically to the Arab region, as many of the traits the three described a social contract containing, which were cited as 'unique,' can be found in the Charter of Medina, written by the Prophet Muhammad (PBUH) in the 7th century. This charter described the rights that could be protected, and how, in a way that did not force the communities to give up all, or any, rights, created a balance that these different communities were able to practice and guarantee a peace among them all, making it the perfect example of the Social

Contract. Through identifying how the social contract is defined in a baseline by these three authors, we can then break down the charter itself and identify many of the similarities, including the idea of legitimate right over divine right. But, with a different goal in mind when the charter was created, there are distinct differences that the three authors do not acknowledge, but the Prophet (PBUH) does, including the rights 'granted' through this document for the unique communities within Medina to govern themselves, how none of these communities are considered more powerful or important than another, and most importantly, how the Prophet serves as a leader in specific cases regarding the many communities.

Abstract Name: The Intersection of Identity and Environment: Predictors of Self-Efficacy, Stress, and GPA in Health Professions Undergraduates

Burnout has been widely observed among students with heavier academic workloads and may persist in their professional careers, specifically for students in the pre-health field. This study aimed to examine the relationships between self-efficacy (GSE), and perceived stress (PSS), and GPA while accounting for personal identity and socioeconomic factors. Multiple social identities and experiences shape a person; therefore, our analysis combined different factors affecting GSE, PSS, and GPA. We hypothesized that students receiving free or reduced lunch, those identifying as members of racial or sexual and gender minority (SGM) groups, and those attending smaller schools would exhibit higher perceived stress and lower self-efficacy compared to their peers. 72 undergraduate students in the School of Health Professions completed an anonymous survey containing the PSS, GSE, and self-reported their GPA and other demographic factors. A multivariable anova model comparing race, sex, religiosity, SGM, SES, and high school size and location determined that GPA was impacted by these factors, $p=0.03$. Analysis of specific factors highlighted that GSE was impacted most by race, Caucasians had the highest GSE, gender, males have a higher GSE, religiosity, those that identified as religious had a higher GSE and SGM students had a lower GSE than non SGM students, while smaller high school size and fringe high school location had lower PSS. These results suggest that identity-based and environmental factors play an important role in students' confidence and stress levels, highlighting the relevance of community-focused support.

Abstract Name: Superkine Interleukin-24-Induced Transcriptomic Profiling Analysis in Androgen-Resistant

Melanoma differentiation-associated gene-7/interleukin-24 (IL-24) induces cancer-specific apoptosis in a wide range of cancers. When delivered intratumorally by a replication incompetent type 5 adenovirus, IL-24 was shown to be efficacious and safe in a Phase I trial in patients with advanced cancers. Advancing IL-24 as a therapeutic, Superkine IL-24 (IL-24S) was engineered resulting in enhanced secretion and stability. Despite these broad spectrum and multifaceted effects, the early effects of IL-24 and IL-24S in cancer cells require further investigation but could be significant for therapeutic development. Here, we assessed alterations in genetic regulation via transcriptome analysis on androgen-resistant prostate cancer using DU-145 cells infected with IL-24S at 6- and 12-hour post-infection time points. Validation assays incorporated various human and murine prostate cancer cell lines to provide deeper insights into the generalizable features of IL-24S-mediated signaling pathway changes. At 6 hours post-infection, 12,664 genes (6,210 up; 8,343 down) and 305 KEGG pathways were disrupted, while 12 hours post-infection showed 12,596 genes (6,031 up; 6,565 down) and 303 disrupted pathways. Several pathways, such as "viral protein interactions with cytokines and cytokine receptors" and the JAK-STAT signaling pathways, were disrupted at both time points. Notably, we identified dynamic responses of several IFN- β downstream genes (e.g., MX1, MX2, and OASL), which initially showed downregulation followed by upregulation in later stages. This downregulation aligns with the concurrent inhibition of IFN- β transcription. IL-24S induces extensive, time-dependent downregulation of gene expression in a range of advanced prostate cancer cell models. These data provide new insights into the molecular pathways regulated by IL-24 and IL-24S, which are informative for designing combinatorial treatment approaches. Thus, ongoing work is utilizing machine learning to determine and test optimal drug treatment combinations with IL-24 and IL-24S. Further transcriptomic validation for mRNA and protein is also in progress.

Abstract Name: Brain Penetrant and Peripherally Restricted Inhibitors of the Endocannabinoid-regulating Enzyme: Dissociative Antinociceptive Effects in a Humanized Mouse Model of Sickle Cell Pain

Sickle Cell Disease (SCD), a recessive genetic disease that includes symptoms of chronic anemia, fatigue, organ damage, and severe pain. Although opioids provide some relief for sickle cell pain, their serious adverse effects (e.g., opioid use disorder, constipation, respiratory depression, overdose, and death) raise a great need to identify effective non-opioid, non-addictive strategies to treat SCD pain. Monoacylglycerol lipase (MAGL), the primary catabolic enzyme of the endocannabinoid 2-arachidonoylglycerol (2-AG), represents a promising target to treat pain. Here we test whether brain penetrant and peripherally restricted MAGL inhibitors alleviate hypernociceptive behavior and functional behavior in the Berkeley HbSS humanized mouse model of SCD. We evaluated the brain penetrant MAGL inhibitor MJN110 (10 mg/kg) and the peripherally restricted MAGL inhibitor LEI-515 (3, 10, 30 mg/kg) in mixed sex 7-month-old HbSS SCD mice. Subjects were evaluated with either drug or vehicle and 1 h later assessed for grip strength and mechanical hypersensitivity in the von Frey assay. Whereas MJN110 normalized both grip strength and mechanical hypernociceptive responses in HbSS mice, LEI-515 attenuated mechanical hypersensitivity but did not affect grip strength. Through the use of CNS penetrant and peripherally restricted MAGL inhibitors, we demonstrate a dissociation between stimulus-induced nociceptive responses and motor functional behaviors in the HbSS mouse model of SCD pain. As SCD pain reflects a chronic condition and would require repeated dosing of an analgesic, ongoing studies are assessing repeated dosing of MAGL inhibitors in this model. In sum, these findings support MAGL as a potential therapeutic target for SCD pain.

Abstract Name: An Individualized Peer Support Model to E-cigarette Cessation

E-cigarette use is a major issue that is rapidly growing within the United States. Insufficient resources and a lack of peer support undermine current vaping cessation strategies for young adults in rural areas of the Midwest. Our study aims to create an effective, multimodal intervention system to support vaping cessation in this increasingly affected population. With the growing popularity of electronic nicotine delivery systems (ENDS), the usage rates remain high due to the difficulty of quitting a vaping addiction. Many factors contribute to the increasing difficulty of quitting, including limited cessation resources, easy access to ENDS products, few entertainment options for stress relief, and peer disapproval of quitting. Participants involved in our study participate in an eight-week intervention administered via text messaging. In prior studies conducted by our team, the text messaging system we relied on had limitations, including limited human interaction and insufficiently tailored messages for a multifaceted study. The next phase of our team's research will address the issues participants previously faced by adding individualized peer support, where volunteers will follow participants' progress and give real-time, personalized feedback designed to help participants with their cessation goals. With the addition of peer mentors to the original eight-week intervention, we expect to see a significant increase in participants who have successfully forgone their previous vaping habits and addictions and have reached their goals of vaping cessation. Our study, in addition to introducing peer support, will provide participants in areas with limited cessation resources and those promoting negative vaping habits with a multifaceted mode of online cessation support to enhance cessation outcomes in high-risk areas.

Abstract Name: MotusKit: Prosthetic Assembly Kit

The development of personalized prosthetics has historically been constrained by slow, labor-intensive creation methods that rely heavily on manual measurements, mold construction, and repeated in-person fittings. This traditional approach not only prolongs production time but also introduces human error, resulting in devices that may never achieve a fully individualized fit. Such barriers are especially pronounced in underserved regions and low-resource medical settings, where specialized equipment, clinical expertise, and fabrication facilities are limited or entirely unavailable. To address these longstanding challenges, I developed MotusKit, an innovative prosthetic assembly system designed to streamline the transition from digital customization to real-world functionality. MotusKit operates in direct collaboration with HANDI, a

system of formulas I developed that uses body measurements to generate patient-specific scaling measurements automatically. Once these formulas determine the required dimensions, each component of the prosthetic can be scaled to size and 3D printed. The resulting parts are organized into a comprehensive kit that emphasizes intuitive usability. The detailed assembly guide in the kit features labeled components, color-coded diagrams, and step-by-step instructions, enabling users or caregivers with minimal technical training to construct a fully functional device. The system represents a significant step toward streamlining prosthetic production, expanding access for individuals who may otherwise lack support from specialized clinics. Ultimately, MotusKit advances the broader goal of creating inclusive, customizable, and globally accessible prosthetics that empower users to achieve greater independence and quality of life.

Abstract Name: The Effects of Low-Level Light Therapy (LLLT) on Differentiated Vascular Smooth Muscle (dVSM) Cell Proliferation

Previous research suggested that low-level light therapy (LLLT) accelerates the recovery of skeletal muscle wounds. This study aimed to investigate whether LLLT produces similar effects on the wound healing process of differentiated vascular smooth muscle cells (dVSMC). The proposed mechanism of LLLT suggests that photons emitted by Light Emitting Diodes (LEDs) are absorbed in the mitochondria and increase ATP production. Elevated levels of ATP enhance the rate of cellular proliferation. Rat aorta cells (A7R5) were cultured in T-25 vented flasks and subcultured in well plates for a scratch wound assay. The scratch width was measured before treatment intervals of ten, twenty, thirty, and forty-five minutes. The light treatments included constant red, NIR, and mixed red and NIR LED light. Control cell plates received no treatment. Cell width was remeasured sixteen hours post-scratch. The difference between the post-treatment and pre-treatment widths quantified cell regrowth. No significant data was recovered from the NIR light treatment. Similarly, twenty minutes of red, as well as twenty and thirty minutes of mixed LLLT treatment, also yielded no significant data. The thirty and forty-five-minute groups of red LLLT, as well as the ten-minute group of mixed light treatment, did significantly increase cell growth. An ANOVA test of the red LLLT data yielded a p-value of 0.04683, which signified LLLT's effectiveness on regeneration time, specifically with longer treatments of red light.

Abstract Name: The Phenazine Operon and Antibiotic Production in *Pseudomonas chlororaphis*

Antibiotics are integral in treating infectious diseases. Yet as more antibiotics are created, more bacterial resistance emerges. This constant microscopic arms race makes finding effective antibiotics increasingly challenging. We have isolated a strain of *Pseudomonas chlororaphis* from soil in southern Wisconsin that exhibits antibiotic activity against both Gram-negative and Gram-positive bacteria. This organism has a distinctive orange color, and early experiments in our lab suggested a link between the pigment and antibiotic

activity. Data from other labs have suggested that genes within the phenazine operon might drive production of the orange pigment. Phenazine is a known agricultural fungicide but is not identified as an antibiotic. We hypothesize this antibiotic is a secondary product of the phenazine pathway. Our research aims to perform gene knockouts along the phenazine operon and screen for antibiotic activity in knockout strains. Using the Gibson assembly method and the pEX18Tc suicide vector plasmid, we have targeted genes within the phenazine operon. Gene knockouts are confirmed by sequencing, and antibiotic activity is determined for each mutant. We will work our way through the operon to determine if any of the genes are involved in antibiotic production. This stepwise knockout strategy will define the genetic basis of antibiotic production in *P. chlororaphis*, providing insight into this novel antibiotic.

Abstract Name: Can variation in the macro and micromorphology of the Gold Dust Day Gecko toe pad explain individual climbing ability and behavior?

Many climbing animals rely on specialized traits to grip and traverse their habitat. Most geckos have toe pads featuring dense arrays of branched microscopic hairs (setae) that generate frictional and intermolecular adhesive forces capable of supporting their body weight on vertical and inverted surfaces. As part of a mesocosm study on the ecology of the Gold Dust Day Gecko (*Phelsuma laticauda*) and other introduced lizards in O'ahu (HI), specific perch use of cohorts of marked individuals was documented daily for 1-2 months; clinging force was also measured in some individuals. Previous between-species comparisons show that Day Geckos exhibit superior clinging performance on low-friction surfaces, which statistically explains their predominant use of smooth, elevated perches. However, if/how underlying toe pad macro and micromorphology relate to performance, and subsequently the extent to which these combinations of traits affect perch use, remains to be investigated in this species and geckos more broadly. This project represents a first step in addressing these gaps by evaluating within-species pad variation. The pads of 82 Day Geckos were imaged via stereo and scanning electron microscopy and measured in FIJI. As in other geckos, we see that pad area increases but does not scale proportionately with body size. Interestingly, Day Gecko pad shape is variable, and rounder pads may be associated with greater clinging performance. We expect that setal dimensions will follow similar patterns of variation along the length of the pad as in other species, but that there will be detectable inter-individual differences when compared at the same locations. We also predict that there will be a strong relationship between setal density and clinging ability. Imminent work will test if these traits explain individual perch use. We predict that geckos with morphologies linked with greater clinging performance will be more likely to occupy higher and rougher perches.

Abstract Name: Investigating the Influence of Socioeconomic Factors on Suicide Attempt in Those With Alcohol Abuse Disorder

Introduction: Alcohol Use Disorder (AUD) remains one of the most prevalent substance use disorders, with over 28 million people in the United States having it. AUD is also related to other mental health issues, including suicidal thoughts and behaviors. However, limited studies investigated the specific risk factors related to suicidal behaviors in individuals with AUD. In this study, we focused on the roles of socioeconomic factors. Methods: We investigated how socioeconomic factors, specifically income levels and educational attainment, are associated with the lifetime occurrence of suicide attempt (SA) in participants with AUD. Education, income, and SA data were collected from 1,268 participants from the Cognition, Alcohol, Genes, and Environment study. Association patterns were identified between variables while controlling for age, sex, and employment status. Other suicide variables were also included in the correlation plot, such as previous history of suicide ideation, active suicide ideation, thoughts of death, and self-harm. Results: Results demonstrated that education and income were negatively associated with SA ($r_s = -0.24$ and -0.28 , respectively), suggesting a potentially protective effect: higher education/income was related to lower risk of SA. Furthermore, the correlation between SA and education/income was among the strongest in the sample, even when comparing to the effect sizes of correlations with phenotypes such as thoughts of death or suicide ideation. Based on these results, we aim to design more specific models to test the pathways of association between AUD, socioeconomic factors, and suicidal behaviors. Conclusion: These findings indicate that education and income contribute uniquely to SA in individuals with AUD. They also highlight the role of socioeconomic factors in the mental health outcomes of those with AUD. Further studies are needed to investigate whether education and income act as mediators or moderators for other environmental variables when pertaining to SA.

Abstract Name: Analysis of Third Space Impact on Loneliness

Loneliness, the subjective feelings of social isolation, is associated with poorer physical and mental health, increased risk for cardiovascular disease, cognitive decline, depression, anxiety, premature mortality, including suicide. "Third places", locations that are not home or work where individuals spend time, have been associated with reductions in stress, depression, and anxiety, which may be a result of third places' facilitating increased social interactions. This study examines variation in loneliness across intersectional social strata and the potential amelioration of loneliness by third-place access. Using the intersectional multilevel analysis of individual heterogeneity and discriminatory accuracy (I-MAIHDA), we will examine variance in risk for severe loneliness across social strata, then assess change in variance after adding recreation as a fixed effect, and assess disparities in severe loneliness when considering recreation access and social strata. We specified intersectional strata to be unique combinations of race, gender and sexuality, sex, and age. The sample of 161,876 All of Us Research Program participants is predominantly White (80.8%), cisgender-heterosexual (88.5%), and female (65.4%). Severe loneliness was defined as scoring 50% or more on the 8-item UCLA loneliness scale. Access to recreational facilities was self-reported. The current phase of the study consists of generating intersectional strata and utilizing the I-MAIHDA approach to assess model variance in severe loneliness when accounting for different factors. Model A measures differences in severe loneliness risk between intersectional groups before applying the covariate of recreation. Model B expands upon Model A through the addition of recreation as a covariate to explain between-stratum variance. Upon completion of the analysis, the findings will allow us to prioritize and tailor health promotion practices to

groups ranked highest for severe loneliness as well as evaluate the impact recreation access and stratum membership have in accounting for between-stratum variance in severe loneliness.

Abstract Name: Does Immigrant Advantage for Academic Outcomes Persist in High School Similarly for Black and Hispanic Students?

One of four students in U.S. schools comes from an immigrant household, with 17.6 million children under 18 living with at least one immigrant parent. The 'immigrant advantage' posits that first-generation immigrant students often exhibit better academic outcomes than second-generation immigrant students, who exhibit better academic outcomes than non-immigrant students, despite first- and second- generation students facing socioeconomic and linguistic challenges. Prior research has documented this advantage in early education, but it is less clear whether this persists in high school, as results seem to vary for adolescents. The current psychology honor's thesis examines immigrant advantage in grades 9-12 using data from Miami School Readiness Project, a large-scale, 18-year longitudinal study of students attending Miami Dade County Public Schools. Research questions include (1) To what extent does the immigrant advantage appear in high school academic outcomes? and (2) Are patterns of the immigrant advantage similar for Black and Hispanic students? The sample (n=4,341) includes 2,704 first-generation immigrants, 777 second-generation immigrants, and 860 non-immigrants. Outcome variables include end-of-year GPA in 9th and 12th grade, cumulative high school GPA, standardized math and reading test scores in 10th grade, end-of-course exam grades for Algebra 1, attendance (days absent) in 9th and 12th grade, suspension, retention, and on-time graduation. Multiple regression analyses will be run controlling for student race, poverty, ELL status, disability, and gender, with immigrant status as the primary independent variable, and race-by-immigrant status interactions will be added and run to test question 2. Results are expected to show immigrant advantage present in 9th and 10th grade but weakened by 12th grade. The gap between immigrants and nonimmigrants is expected to be bigger for Black compared to Hispanic immigrants. Data cleaning and variable making is currently complete. Data analyses will be conducted in January with the full paper ready by the conference.

Abstract Name: The Wolf and Its Wings

This body of work, a series of digital art and prints entitled The Wolf and Its Wings, explores the tension between capitalist materialism and the pursuit of spiritual or personal identity. Initially inspired by a broader investigation into systems of belief (including extremism, religion, and capitalism) the concentration eventually narrowed its focus to the contemporary struggle for identity within a materialist culture. The series traces an internal conflict and spiritual awakening of a follower of a discriminatory ideology, referencing a modern, corporate, and political context for social Darwinism and the concept of "survival of the fittest." The work uses the motif of the wolf to embody the subject's initial primal, competitive state and "kill-or-be-killed" mentality. Formally, the series starts with graphic, grungy, and unforgiving imagery inspired by propaganda

posters, the series follows the subject's painful transition away from materialistic values toward transcendence. This shift is influenced by personal experience and observation of social justice movements. Later works, such as "Introspection 1" and "The Crowd's Heart," introduce vulnerability and themes of societal connection and reform. The final stage of the series marks a spiritual awakening, where the figure abandons the wolf motif for the wings of a bird, symbolizing newfound freedom and expanded awareness. The visual style evolves from sharp, harsh textures to an organic, transcendent approach expressed through veils of light and pastel colors. Technically, the series is an intimate combination of digital collage and printmaking (lithography, lasercuts and etchings) often moving the work through digital, handmade, and back to digital formats. This complex process reflects the "chaos and messiness" of the ideological conflict. The prints, extended onto formal clothing, aim to create a public dialogue and protest, taking the art out of the gallery and into a wider social space to engage audiences with the unsettling but visually appealing imagery.

Abstract Name: TTP is a Novel Sex-specific Regulator of NGF

Approximately 80% of patients report mild to severe postsurgical pain, which can impede recovery, contribute to opioid dependency, and transition to chronic pain. Postsurgical pain is driven by inflammatory mediators, which are regulated at the posttranscriptional level via adenine- and uridine-rich elements (AREs) in the 3' UTR of their mRNA. ARE-binding proteins (AUBP) recognize these cis-acting elements and control mRNA stabilization or translation efficiency. Tristetraprolin, an AUBP, promotes mRNA decay by recruiting deadenylation factors. Nerve Growth Factor (NGF) is an inflammatory mediator that plays a major role in peripheral pain sensitivity as well as the development of chronic pain. We hypothesize that NGF mRNA is a novel target of TTP. Postsurgical incision in myeloid-specific TTP KO mice showed an increase in NGF expression and elevated mechanical sensitivity. In silico analysis of the 3' UTR of NGF presented a putative TTP-specific ARE binding site (UAUUUAU). Additionally, NGF expression in LPS-treated bone-marrow-derived macrophages (BMDM) was more elevated in males compared to females under TTP KO conditions. In conclusion, NGF is significantly upregulated in TTP KO BMDM in a sex-specific manner. With NGF being a modulator for peripheral pain development, it is crucial to understand the mechanisms of ARE-mediated regulation by TTP for developing therapeutic interventions. In future studies, using a metagenesis approach, we aim to further understand the role of AREs and the 3'UTR of NGF in TTP-mediated posttranscriptional regulation.

Abstract Name: The Search for GEMS

Our research project aims to find high-mass exoplanets orbiting M-dwarf stars as part of the Giant Exoplanets around M-dwarf Stars (GEMS) collaboration. These exoplanets are viewed as irregular; the systems that house M-dwarf stars are not thought to contain the amount of mass required to form both the star and the large exoplanets. Through locating these exoplanets, we can build a catalog that will be used to determine how these exoplanets formed. This process entails follow-up observations of candidates identified by NASA's Transiting Exoplanet Survey Satellite (TESS). Though TESS was designed to search for transiting exoplanets, the candidates it finds may be other systems, such as eclipsing binaries. Ground-based observations are needed to verify the existence of these exoplanet candidates. We used the Keeble Observatory's 40 centimeter telescope, housed on Randolph-Macon College's campus, along with a SBIG Aluma CCD47-10 camera in order to obtain i-band images of the candidate star while the exoplanet is transiting. These images were analyzed using AstroImageJ, an astronomical software, to reduce the data and produce a light curve of the star during the transit. Ultimately, these light curves are used to confirm the existence of an exoplanet from the GEMS candidates TESS has previously found. Here, we will present the highlights of our cumulative research, showcasing the most interesting candidates we have studied.

Abstract Name: Designing a Line Dancing Program to Bring Cognitive, Physical and Social Benefits to Older Adults

Dance is an expression of art as well as an embodiment of our culture, emotions, thoughts, and beliefs. It provides both mental and physical challenges to the performers, and its physical, cognitive, and social benefits have proven therapeutic in many cases. For instance, dance movement therapy has been investigated as a novel approach in the treatment of major depressive disorder and anxiety. Repeated dance lessons have positive impacts on body structure and function in older individuals by maintaining strength, balance, and coordination. In addition, repeated dance strengthens cognitive functions such as active recall and working memory within a socially-stimulating setting. Here we outline a structured dance program designed to support aging individuals who participate in activities at their local community center. Line dancing, specifically, is an individual activity that can be performed in a group setting, thus allowing for practice at home or with others, while also incorporating footwork of varying complexities. The aim of the program is to provide community centers for aging adults with the foundation of a line dancing class even if they lack an in-person instructor. The program will consist of 25-30 line dances, organized categorically based on their targeted cognitive and/or physical parameters (i.e., working memory, balance, active recall, etc). Each line dance will have a written layout of the steps, a video teaching and performing the dance, and the corresponding music with instructor call out of steps. The program will be implemented in a local senior community center to gather feedback from participants and administrators. Future goals will focus on long-term implementation and broad dissemination of this program along with assessment of the impacts on mental, physical, and social well-being in the populations served.

Abstract Name: Teaching Disability Justice in Reproductive and Sexual Rights

Despite broad recognition of health equity, professional curricula in helping professions frequently omit meaningful engagement with the sexual and reproductive lives of disabled people. Historically, the medical model has framed disability as a deficit to be cured, implicitly deeming disabled bodies as unfit for reproduction or parenting. This poster interrogates these systemic oversights by exploring the theoretical and practical intersections of Disability Justice (DJ) and Reproductive Justice (RJ). While RJ establishes the right to bodily autonomy and the right to have children (or not have children), DJ expands this by challenging the ableist structures that make these rights inaccessible to many disabled persons, particularly those of marginalized communities. The convergence of these frameworks highlights that reproductive freedom for disabled individuals is not merely about legality, but about functional access, ranging from physical environments to communication supports and freedom from coercion. By analyzing historical patterns of forced sterilization alongside current disparities in healthcare access, this presentation demonstrates how ableism, racism, and sexism compound to restrict reproductive agency. The analysis suggests that a compliance-only approach (e.g., adhering strictly to the ADA) is insufficient. Instead, an intersectional, justice-oriented framework is required to dismantle barriers to care. This conceptual shift is vital for helping professionals to move beyond paternalistic models of care and toward practice that genuinely affirms the dignity, sexuality, and parenting rights of disabled populations.

Abstract Name: Investigating the Toxic Mechanism of KFAT Activity on Rab7

BopA is an effector protein secreted by *Burkholderia thailandensis* and other *Burkholderia* spp. BopA has been found to suppress autophagy and phagocytic destruction of bacteria. It is also suspected that BopA has lysine fatty acyl transferase (KFAT) activity due to its similar structure and sequence to other established KFATs as well as its anti-autophagy effect. To determine if BopA is also a KFAT, we performed alkyne labeling and click chemistry and observed increased fatty acylation for multiple proteins that is abolished by mutating the putative catalytic amino acids in BopA. To identify what host proteins BopA is modifying, we carried out a mass spectrometry proteomics screen in cells expressing WT or a catalytic dead mutant of BopA. We identified several potential BopA substrates, and confirmed Rab7, a critical autophagy regulator, as a substrate. By identifying the substrates of BopA KFAT activity, we hope to reveal the mechanism by which it functions during infection and potentially uncover an opportunity for therapeutic intervention during *Burkholderia* spp. infections.

Abstract Name: Impact of Gestational Ozone Exposure on the Fetal Environment as a Risk Factor in Neurodevelopmental Outcomes

Ozone (O₃) is a critical component of air pollution with demonstrated health impacts, including increased risk for premature birth and lower birth term weight. O₃ exposure has also been associated with maternal hypertension and longer-term complications such as greater risk for developmental delays in children. Studies here sought to understand the impact of maternal ozone exposure on placental development to understand its effects on the fetus. Though recognized as a barrier to exogenous maternal stressors, we hypothesized early maternal O₃ would cause placental vascular abnormality, perturbing the fetal environment. Pregnant Sprague Dawley Rats were exposed to 0.3 ppm O₃ (consistent with global urban areas) or filtered air (FA). Dams received either an O₃ or FA 4-h exposure at gestation day GD10 or GD20 (to control for an acute phase response). At term (GD21), amniotic fluid (AF) and placental tissues were collected and snap-frozen. Unbiased AF discovery proteomics first identified relevant fetal perturbation. As a more vulnerable developmental period than GD20, GD10 O₃ exposure had a greater, sustained impact on the fetal environment. Follow-up studies then investigated the origin of amniotic proteomic perturbation. Sub-acute ozone exposure indicated impaired spiral artery remodeling, supported by bioinformatic analysis demonstrating the involvement of significant placenta-aligned AF proteins in disease pathologies relevant to impacted vasculature. High levels of placental connective tissue growth factor implied impaired trophoblast invasion, fibrin deposition, and inflammation. PECAM-1 staining illustrated increased vessel wall thickening with decidual bias, consistent with maternal hypertension and impaired perfusion. However, factors like galectin-1 increased in the AF with GD10 O₃ exposure but could not be traced directly to an increase in placental tissue, perhaps indicating increased shedding to reduce inflammation in the fetal environment. Results substantiate that GD10 maternal O₃ has a significant impact on placental function. Future research will investigate how perturbation may impact fetal neurodevelopment.

Abstract Name: Empowering Students for Success in the Workplace

Although a bachelor's degree is commonly viewed as a pathway to career success, many students graduate without the practical skills and real-world knowledge needed to thrive in the workplace (Song, 2025). Employers are placing greater importance on critical thinking and soft skills such as communication and collaboration—areas that traditional academic programs may not always prioritize. In spring 2025, a multi-institutional team developed and completed a research study evaluating the curriculum of a course focused on preparing students for the workforce. Individuals in business, government and/or non-profit communities reviewed the current course curriculum and offered insight for emerging trends needed to support the success of the students as they enter the work world. The survey included eight major areas: work essential skills, graduate readiness for workforce entry, understanding personal motivations and values, identifying strengths and growth areas, understanding organizational culture, behaviors that support early career success, the value

of mentoring, and navigating workplace culture. Preliminary findings (N = 128) revealed that most respondents had over six years of professional experience and emphasized the growing need for employees who demonstrate adaptability, communication, and leadership skills. Respondents also underscored the importance of understanding workplace culture and aligning personal values with organizational goals. Results from the study will be shared as well as an overview of identified trends for better preparing students for work after degree attainment will be discussed.

Abstract Name: Infinite Brushstroke: Where Math, Code, and Art Merge in an Aperiodic Monotile

An aperiodic monotile is a single shape that can tile a plane infinitely, yet never create a repeating pattern. This has applications in material science, crystallography, and computational geometry. In this project, we explore the recently discovered “hat” aperiodic monotile through interactive web-based visualizations, demonstrating both individual tile geometry and infinite plane tiling patterns. First, a single tile visualization in real time, demonstrates a monotile through two adjustable edge parameters and curvature. The visualization uses cubic Bézier curves to create smooth curved edges, whose control points are calculated by perpendicular offset from the midpoint of the edges. This enables smooth transitions between different tile shapes within the continuum, including the Hat, Chevron, Turtle, and Comet. The second part implements infinite plane tiling using a composition of transformation matrices (rotation, scaling, reflection) for positioning and arranging tiles. An important visual research finding was that with non-zero edge curvature, tiles are unable to properly align with their reflected versions; this observation confirms that curved tiles are indeed chiral (structure and its mirror image are not superimposable). These visualizations were implemented in JavaScript using HTML5 Canvas, providing an accessible platform to explore these concepts. The current work refines the edge-matching algorithm, ensuring proper tile connections in the infinite plane. Future work includes a seeded random number generator that allows for the reproduction of generated patterns, enabling exploration of different configurations and an investigation into potential 3D representations of an aperiodic monotile.

Abstract Name: What Do You Think Why Adults Talk Like Kids: Wh-Question Comprehension in Adults

In questions that contain both a matrix wh-word and a wh-relativizer (Why did Marcus tell Sally what he ate), English-speaking children often make the mistake of answering the wh-relativizer (What he ate), rather than the matrix (Why Marcus told Sally). The underlying cause of these mistakes isn't widely agreed upon but holds implications for the relationship between linguistic competence and underlying cognitive mechanisms. Previous work has shown adults given an online task perform similarly to children. This hasn't been tested except in online tasks, which aren't realistic. The goal of this study is to investigate whether college aged participants will make similar errors to children when given appropriately difficult tasks in an in-person context. This study investigates performance of 18 college age English-speakers on an in-person “questions

after stories task". All students reported English as the language they felt most comfortable speaking and reading. Two participants reported Spanish as their first language, but not their dominant language. Participants read 42 scenarios and were asked one question for each scenario. Half of these were target questions of the form 'Why did Marcus tell Sally what he ate?' The others included the relativizer "that" (ex. What did Marcus tell Sally that he ate). Six filler questions were included to ensure participants were attending to the scenarios. Participants spoke responses into a microphone. Responses were transcribed after data collection. Responses will be coded for error type and analyzed using Bayesian ANOVAs, which will include participant, item number, form and trial order as random effects. We expect adults will make some errors, though not necessarily the same types of errors children make. If adults make similar errors to children, this would support the hypothesis that children's errors are the result of immature processing mechanisms rather than imperfect knowledge of the language.

Abstract Name: Polarization in Online Spaces: A Computational Analysis of YouTube Commentary on the Assassination of Charlie Kirk

Online political commentary has become an increasingly influential form of digital media, with creators shaping how online audiences interpret polarizing events. As social media platforms like YouTube sometimes blur the line between entertainment and political analysis, creator ideology can play a central role in structuring how viewers emotionally process the news they consume. On September 10, 2025, co-founder of Turning Point USA, Charlie Kirk, was assassinated while speaking at a campus event at Utah Valley University. Reactions to his death were highly polarized: many framed it as a political assassination targeting free speech, while others emphasized the broader threat of political violence and cautioned against using the tragedy to deepen political divides. This study asks: how do reactions to the assassination of Charlie Kirk differ between YouTube comments on a video created by a left-leaning creator versus a right-leaning creator? I am currently conducting a computational analysis using CommuAnalytic to examine two YouTube videos discussing the event—one from Hasan Piker, a left-leaning commentator, and one from Ben Shapiro, a right-leaning commentator. I extracted comment datasets from each video and conducted automated sentiment analysis and topic modeling to identify emotional tone and recurring themes. 15,285 comments were extracted from Hasan Piker's video while 2,962 comments were extracted from Ben Shapiro's video. I am currently in the process of performing manual coding of 10 comment clusters to verify computational findings and to examine how users expressed ideas of empathy, hostility, grief, or political critique. Preliminary findings suggest that comments under the left-leaning video display more negative sentiment towards Kirk, framing the event through political criticism and broader debates about conservative influence. In contrast, the right-leaning video's comments highlight more grief and admiration for Kirk, reflecting a more sympathetic environment.

Abstract Name: Novel Role for Histone H1.1 in Regulating Epidermal Differentiation

The linker histone H1 is a component of chromatin that binds DNA at the entry and exit sites of the nucleosome. Despite major advances in epigenetics focusing on core histones and their modifications, H1 and its variants remain greatly understudied. While earlier *in vivo* studies suggested functional redundancy among H1 variants, recent reports indicate that individual variants may have distinct regulatory roles. Notably, H1.1, the least abundant and least conserved H1 variant in human somatic cells, has no well-characterized gene regulatory function. Here, we leverage the human skin epithelium (epidermis) to investigate a potential role for H1.1 in epidermal differentiation. Based on previous lab data, we hypothesized that H1.1 expression is required to suppress terminal differentiation. To test this, H1.1 was knocked down in epidermal progenitors using RNA interference, and differentiation-associated gene expression was analyzed by RT-qPCR and RNA-Seq. Subsequent clonogenicity assays were performed to assess progenitor self-renewal upon knockdown. We found that H1.1 knockdown resulted in significant upregulation of markers and broader transcriptional programs associated with differentiation, and this was accompanied by a marked reduction in progenitor self-renewal capacity. These findings indicate that H1.1 is necessary to repress differentiation and maintain self-renewal of epidermal progenitors. Our results reveal a previously unrecognized gene regulatory role for H1.1 in epidermal differentiation and suggest that linker histones can influence cell fate decisions. Ongoing studies aim to elucidate how H1.1 modulates chromatin architecture and transcriptional programs, providing insight into fundamental mechanisms by which H1.1 regulates tissue homeostasis.

Abstract Name: The NOSES Study: Evaluating Antibiotics, Intranasal Corticosteroids, and Supportive Care in Acute Rhinosinusitis Treatment

Acute rhinosinusitis (ARS) is an inflammation of the sinuses usually caused by viral pathogens, with bacterial infections occurring far less often. Despite this, antibiotics are prescribed in nearly 70% of ARS cases despite limited evidence to their benefit, leading to antibiotic overuse, resistance, and avoidable side effects. The “Nasal Irrigation, Oral Antibiotics, and Subgroup Targeting for Effective Management of Acute Sinusitis” (NOSES) study explores evidence-based alternatives through a multi-phase, four-arm, double-blind, placebo-controlled RCT. The primary objective is to evaluate the effectiveness of amoxicillin-clavulanate, intranasal budesonide, and supportive care (OTCs and nasal irrigation) across patient subgroups defined by age, symptom severity, provider gestalt, CRP levels, and medication adherence. Patients aged 18–75 with sinus symptoms were recruited from six primary care and academic centers. Based on symptom duration, participants were assigned to phase one or phase two. Those experiencing symptoms for 9 days (E9) or more were immediately randomized into one of four intervention groups: (1) amoxicillin-clavulanate, (2) amoxicillin-clavulanate plus intranasal budesonide, (3) placebo, or (4) placebo plus intranasal budesonide. Patients with symptoms for fewer than 9 days entered phase one and received supportive care until either progressing to E9 randomization or completing the study if symptoms resolved. Throughout the study, participants completed daily logs tracking symptom severity, neti pot use, medication adherence, and adverse effects. The primary outcome was measured using mSNOT-16, a tool for objectively measuring disease severity. Although the full-scale study is still ongoing, the pilot phase confirmed the feasibility of conducting a larger, multi-site trial. This ongoing 48-month study aims to identify which patient subgroups benefit most

from different treatment strategies for acute rhinosinusitis (ARS), supporting a more personalized approach to care. This work has the potential to inform clinical decision-making by guiding appropriate treatment selection, improved symptom management, stratifying disease severity, and reduced overprescription of antibiotics.

Abstract Name: Interactions of Genetic, Environmental, and Epigenetic Factors in Myopia Development

Myopia, or nearsightedness, has increased rapidly worldwide and is now a major public health concern caused by both genetic and environmental factors. Current understanding shows that too much near work, limited time spent outdoors, and prolonged screen use contribute to abnormal eye growth in individuals who may already have a genetic predisposition. At the molecular level, epigenetic changes and shifts in DNA activity, often influenced by environmental conditions, affect the signaling pathways that regulate eye development and may help explain why myopia is increasingly common among children. This paper synthesizes recent environmental, genetic, and epigenetic research to explain how these factors contribute to the development and progression of myopia, particularly in children and adolescents. Genetic studies indicate that genes increase the risk of developing myopia, while environmental factors largely determine its severity. Evidence from epigenetics and molecular biology shows how external stimuli can alter gene expression, shaping refractive development through gene-environment interactions. Current interventions, including specialized lenses, atropine eye drops, and light-based therapies, aim to interrupt the biological pathways linked to abnormal eye growth, and several newer approaches have shown promising early results. This analysis synthesizes existing research to clarify the biological and environmental processes behind myopia and to show how these findings relate to current approaches used to slow its progression. By combining research across genetics, epigenetics, and environmental studies, this paper highlights how these factors collectively drive myopia development and why understanding their interaction during early developmental stages is important for improving early detection and treatment in children and adolescents.

Abstract Name: LYMPHOCYTIC ESOPHAGITIS: TREATMENT OUTCOMES AND PREDICTORS OF SEVERE DISEASE

Lymphocytic esophagitis (LE) is a chronic esophageal inflammation typically presenting with dysphagia and sometimes stricturing. Medical treatment options include proton-pump inhibitors (PPIs), topical steroids (e.g., budesonide), and biologics for refractory cases; a stricturing phenotype requiring repeated dilations is occasionally seen, but predictors of severe or treatment-resistant disease are poorly defined. We performed a retrospective cohort study of patients seen in the Mayo Clinic Rochester esophageal clinic from January 2000

to May 2025. LE was defined as ≥ 10 intraepithelial lymphocytes per high-power field. Demographics, comorbidities, endoscopic findings, treatments, and outcomes were abstracted from the medical record. Univariate analyses used Student's t-test and chi-square testing. Among 184 patients (mean age 61.1 years; mean BMI 27.5 kg/m²; 61% female; 92% white), dysphagia (80%) and reflux (55%) were the most common symptoms. Twenty percent had an esophageal stricture on index endoscopy. Eosinophils (insufficient for eosinophilic esophagitis) were present in 20% of biopsies. Therapies included PPI in 71%, topical steroids in 23%, and biologics in 8% (40% of biologic-treated patients received infliximab). Of 149 patients with baseline dysphagia, 84 (56%) achieved symptomatic remission at a mean follow-up of 20 months. Of 64 with histologic follow-up, 29 (45%) were in histologic remission; symptomatic and histologic responses agreed in 56% of cases. On univariate analysis, stricture formation correlated with small-bowel lymphocytosis ($p=0.01$), small-caliber esophagus ($p<0.01$), concomitant lichen planus ($p=0.03$), and endoscopic features of EoE (rings, furrows, exudates; $p<0.01$). Treatment-refractory disease associated with diverticulosis ($p=0.03$). Seventeen patients required multiple dilations. Overall, LE often follows a benign course with most responding to PPI or topical steroids; severe, stricturing disease appears linked to the factors above.

Abstract Name: PRE-POEM TIMED BARIUM ESOPHAGRAM ANATOMIC FEATURES PREDICT POST POEM GASTROESOPHAGEAL REFLUX DISEASE

Gastroesophageal reflux (GERD) is a known complication of peroral endoscopic myotomy (POEM), yet reliable predictors remain unclear. Timed barium esophagram (TBE) evaluates anatomic features that may affect post-POEM reflux clearance. We aimed to determine whether pre-POEM TBE findings predict GERD. We conducted a prospective cohort study of consecutive achalasia patients undergoing POEM at a tertiary center from March 2020 to March 2025. All patients completed TBE with 200 mL barium ingestion, radiographs at 1, 2, and 5 minutes, and a 13-mm barium tablet. A blinded radiologist assessed maximum and distal esophageal diameter (3 cm above the GEJ), alpha angle, leftward tortuosity, presence of sump, morphology (straight vs. sigmoid $<135^\circ$), and dilation grade (<3.5 cm; 3.5–6.0 cm; ≥ 6.0 cm). Post-POEM GERD was defined by EGD evidence of LA Grade B–D esophagitis; severe GERD was LA Grade C–D. If EGD was inconclusive, wireless pH testing defined GERD by acid exposure $\geq 6\%$ on $\geq 50\%$ of days. Continuous variables were reported as medians; categorical variables as percentages. Mann-Whitney testing compared groups, and logistic regression evaluated predictors. Among 167 patients (42.5% female; median age 63.5), achalasia subtypes were 8.4% Type I, 76.6% Type II, and 14.4% Type III. Median myotomy length was 6.0 cm, and clinical success occurred in 93.4% at a median 4.2-month follow-up. GERD occurred in 44.9%, including 8.9% Grade B, 12.0% Grade C, and 4.2% Grade D esophagitis. Demographics and achalasia subtype were not associated with GERD. Larger distal esophageal diameter predicted erosive (28

vs. 24 mm, $p=0.032$) and severe esophagitis (29 vs. 24 mm, $p=0.038$). Leftward tortuosity strongly predicted erosive (RR 2.3) and severe esophagitis (RR 3.6). This study provides the first evidence that pre-POEM TBE findings predict post-procedural GERD, supporting its role in risk stratification, patient counseling, and procedural planning.

Abstract Name: Prevalence of Shiga Toxin Producing Escherichia Coli in Illinois Bison Herds

Shiga toxin-producing Escherichia coli (STEC) represents an important group of zoonotic pathogens that pose ongoing risks to public health through foodborne outbreaks and environmental transmission. This project evaluated the prevalence and genetic distribution of stx1 and stx2 toxin genes in fecal samples collected from Illinois bison (*Bison bison*) managed under either commercial or preservation conditions. A total of 320 fecal samples were screened for STEC presence by performing enrichment culturing and confirmed by Polymerase Chain Reaction (PCR) for stx1, stx2, and uidA, which confirmed *E. coli* identity. Of all tested samples, 28.4% were STEC-positive, with stx2 (21.3%) far more prevalent than stx1 (6.2%). At the herd level, STEC detection averaged $54.5\% \pm 13\%$ in commercial herds compared with $19.5\% \pm 10.0\%$ in preservation herds ($p=0.0167$). These findings highlight how herd management, environmental exposure, and microbial ecology interact to shape pathogenic *E. coli* dynamics in large ruminants, supporting a One Health framework for surveillance. These results underscore the need for continued longitudinal monitoring of bison herds and further investigation into environmental and management factors that drive STEC persistence.

Abstract Name: A Comparison of Emotional Intelligence and Burnout Scores in Two Different Nursing Programs at a Large Southeastern State University

Psychologist Dr. Grace Tworek defines emotional intelligence (EI) as the ability to perceive, understand, comprehend, and manage emotions. The high levels of stress experienced by nursing students can create fatigue and burnout, therefore EI can be a vital skill for nursing students. Additionally, EI can also be a predictor of their future clinical decision-making and likelihood of attrition early in their career as well as reduce burnout in nursing students. High levels of EI have also been shown to improve coping and critical thinking in nurses which overall helps patient outcomes. Despite extensive research recognizing the need for EI in nursing students, little research has been done regarding how different styles of programs impact these scores. The purpose of this study is to determine differences in emotional intelligence and burnout scores between two different styles of nursing program models at a large state university in the southeastern United States. These programs are entitled "BSN Scholars" and "Traditional BSN (TBSN)". Data for this study was collected via surveys given to nursing students in their Pharmacology I class. The Maslach Burnout Inventory (MBI) and Scale of Emotional Functioning: Medicine (SEF:MED) were both utilized alongside the Marlowe-Crowne Social Desirability to assess for social desirability in responses. Overall, 172 students participated in

the study, 44 BSN Scholars and 128 TBSN students. The TBSN students had an average score of 1.63 on the MBI and 3.95 on the SEF:MED and the BSN Scholars had an average score of 1.73 on the MBI and 3.91 on the SEF:MED. These results are not statistically significant but display a slightly higher level of emotional functioning and lower level of burnout in TBSN students. Further research on how different nursing programs impact burnout and emotional intelligence is needed.

Abstract Name: Acetylcholine Receptor Antagonism via Dihydro-beta-erythroidine (DHβE) in Nicotine Conditioned Place Preference Following Adolescent Nicotine Exposure.

Adolescence is considered a critical period for neural development which is characterized by risk-taking behavior and reward seeking behaviors (Larsen & Luna, 2018; Spear, 2015). During this period, structures of the mesocortical cognitive pathway, which regulate reward, undergo extensive developmental changes (Spear, 2000). Behavioral disruptions related to adolescent nicotine usage have been extensively correlated with changes in this development, including dysregulation of cholinergic signaling. Cholinergic activity within the nervous system is responsible for attention and memory, and impairments can lead to the manifestation of maladaptive behaviors (Counotte et al., 2012). This project proposes pharmacological manipulation of the cholinergic system, examining its effect on the formation of rapid nicotine-context memory. Sprague Dawley rats are injected with twelve doses of 0.4 mg/kg nicotine (equivalent to that of one pack of cigarettes) or 0.9% saline during the adolescent developmental period (post-natal day 28-49). Animals undergo behavioral testing during adulthood to examine any changes in nicotine preference using a conditioned place preference (CPP) paradigm in which the same 0.4 mg/kg nicotine dose is paired with a specific, non-preferred, environment. Each conditioning session includes a co-administered injection of 5 mg/kg dihydro-β-erythroidine (DHβE; a competitive nicotinic acetylcholine receptor antagonist) or vehicle (dimethylsulfoxide [DMSO]). Based on preliminary findings, it is expected that this experiment will demonstrate that DHβE will attenuate reward seeking behavior in subjects pre-exposed to nicotine during the adolescent developmental period—indicating that DHβE may be an effective smoking cessation aid for future use.

Abstract Name: Building Young Brains: Neuroscience Education for Elementary Students in Newport News, VA Through Children's Illustration.

As early as preschool, children are often asked the question, “what do you want to be when you grow up?”. How this question is answered is often shaped by a child's education and surroundings (e.g. what careers their caregivers have, or what they have learned in school), indicating that children's ideas about their potential futures are largely based upon in-class experiences, hands-on activities, and interactions with adults and

peers. Unfortunately, students are often not exposed to the field of neuroscience, even in the most basic sense, until grades 5-8 in the United States when they first begin learning about basic structures and functions of the nervous system in their life-science courses. Additionally, in Virginia, “neuroscience” does not appear in K-12 at all. To address this, the current project aims to increase neuroscience education across K-5 grade levels within Newport News Public Schools through the use of illustration and storytelling. An illustrated book was constructed with content aimed specifically at this age range, beginning with basic brain anatomy and simpler descriptions of action potentials. On the first visit to classrooms, a pre-survey is administered to students, physical copies are read by experimenters and distributed for classroom use. Two weeks after the initial classroom visit, experimenters return to each class and administer a post-survey assessing how students’ attitudes and understanding of neuroscience have shifted over time. It is expected that students’ attitudes toward neuroscience will improve after receiving the educational material. This project emphasizes the importance of early education in neuroscience, exposing the next generation to the field in order to initiate long-lasting interest.

Abstract Name: LGBTQ+ Representation of Black Men in Teen Television: Cultivating Monotypes of Gayness

Studies have shown that representation in television and movie media can affect viewers' perception by creating perspectives on reality based on what is written. Mainstream television and movie media has a history of marginalizing Black gay men into stereotypical patterns unlike other races of gay men. This comprehensive literature review gathering the history of comedy and drama works portraying characters in these ways, mainly negatively, was conducted in order to understand how the representations are subtly molded in today’s media, even with the push of themes of acceptance. The representations are not explicitly stated to describe a character, but viewers have noticed the repeated writing of Black gay men behavior that might go unnoticed by critics as their perspectives of how Black gay men are supposed to act or behave is linear. The popular and highly rated television shows *Heartbreak High* (2022) and *Adults* (2025) were analyzed by tallying the amount of scenes certain behaviors are shown. The two characters were analyzed in this paper; a Black gay man and a White gay man. Connections of these behaviors were drawn to previous media representation to determine if there was a specific uptick to stereotypical patterns based on race. These findings suggest that flamboyant etiquette, interracial coupling, hypersexual behaviors, and lack of supportive community may be a negative pattern in today’s young adult dramedies as these characteristics are the main ones to gain attraction from viewers for its comedic purposes. This paper aims to draw attention to the subtle cultures and perceptions in the U.S toward Black gay men created by the lack of diverse representation.

Abstract Name: Herb Lubalin: Redefining Typography as Visual Communication

Herb Lubalin was an American graphic designer who reimagined the role of typography in visual

communication. Born in New York City in 1918, Lubalin established a huge obsession with letterforms and saw their emotional future when he was studying at Cooper Union School of Art. As his career started in advertising, magazine design, and typeface development, he repeatedly questioned the standards of readability and composition. Lubalin argued that typography should not just be words shown on a page but rather have them be visually expressive with emotion and feeling within the text. He took text and images into a cohesive form of expression that visually told the meaning. In his most famous projects like Avant Garde, Eros, and Fact magazines, he used the type as illustrations, he distorted the letterforms to provoke ideas of movement, familiarity, and emotion. He collaborated with the International Typeface Corporation (ITC) and a designer named Tom Carnase who helped evolve typography more and more. Lubalin's typefaces, Avant Garde Gothic and Lubalin Graph, are still being used to this day and still have such a strong influence on design. Looking over the aesthetics, Lubalin reinforced communication over decoration, he wanted clarity and emotional depth in visual storytelling. All of his work shaped how artists, typographers, and teachers go for the balance between language and image. This paper will go into his early education, typographic innovations, publishing collaborations, and his lasting legacy.

Abstract Name: Modeling Charcot-Marie-Tooth Type 1 in *C. elegans*

Charcot-Marie-Tooth (CMT) type 1 is a genetic disease that results from the damage of myelin sheath. The myelin sheath is a protective cover of the nerves. The damage that results does not allow the nerve signals to be properly transmitted to the brain which leads to problems such as muscle weakness, impaired movement, and reduced sensation. CMT type 1 is most commonly associated with mutations in the human genes PMP22, LITAF, and EGR2. *Caenorhabditis elegans* (*C. elegans*) provide an effective model for studying CMT because their genes *vab-9*, *f36g3.3*, and *egrh-1* are human homologues of the CMT-1 causing genes. Mutations in these genes cause CMT type 1 in humans, and similar effects can be seen in *C. elegans*, despite the worms lacking a myelin sheath. The goal of this project is to characterize these CMT-1 genes in *C. elegans* to establish a worm model for the disease. To study how each gene affects CMT type 1 an assessment of lifespan, neurological morphology using DiI staining, and muscle strength through NemaFlex measurements of each mutant *C. elegans* (*vab-9*, *f36g3.3*, and *egrh-1*) and wild type (n2) were observed. Early work has focused on establishing healthy populations of mutant and wild-type worms. DiI staining procedures allowed the visualization of neurological structure, and confirmed that the strains produce consistent fluorescence patterns under the fluorescent microscope suitable for morphological comparison. Discovering whether mutations in *vab-9*, *f36g3.3*, and *egrh-1* reduce longevity or weaken muscle function will allow us to further determine how these genes contribute to CMT type 1 disease.

Abstract Name: Roulette Probabilities

This research explores effective betting strategies in Roulette. To win, a player must predict the spin's

outcome. The roulette wheel has numbers 1-36 on red and black spaces. The casino, referred to as 'the house', green slot on the wheel (0/00) that give it an automatic win. The most common bets are even/odd and red/black. Zeros do not count as red or black, and only fit into certain bets like straight-up or the 'first five'. Wins pay even money (1:1) or more depending bet. We coded an R simulation of 'n' rolls to calculate the user's earnings. We investigated the common betting schemes like red, black, even, odd, straight, split, etc. We calculated the probability and expected value theoretically. We confirmed the theoretical outcomes with our simulation. The expected value of winnings does not benefit the player, which in turn is how the house makes money. Observing the theoretical results and real-world games will help to determine the best winning strategy and whether it will make a difference despite the house edge. In addition to examining the basic betting types, we focused on some complex betting strategies that involve bankroll management and progressive strategies to determine if these tactics could make a difference when compared to the expected value of basic bets. Strategies such as alternating bets, refraining from betting until k amount of color showed up, and betting the same color until a loss. We found the expected value through simulation and determined that it would eventually match the expected value of the basic betting types. This research provides insight into the game of Roulette and the extent to which a player's behavior can influence the outcome of this game of chance.

Abstract Name: Words, Worlds, and Webs: A Journey Toward Social Cohesion in Senegal and Niger

Urban and rural communities in Francophone Sub-Saharan Africa experience media, language, and representation in distinct ways that shape how people perceive one another and interact socially. These experiences define how people tune into information, navigate overlapping languages, and move through social worlds that teach them who to rely on and where they fit. This research investigates how urban-rural differences in media credibility, linguistic practices, and patterns of representation influence social dynamics and community cohesion in Senegal and Niger. Through close reading and a comparative analysis of existing literature, survey data, and media content from both urban and rural regions in Senegal and Niger, the research examines how communities access, interpretation, and evaluation of media across linguistic and cultural settings. By integrating qualitative insights with quantitative indicators, we hope to highlight both shared trends and region-specific divergences in media engagement across the two countries. The analysis reveals that urban communities favor digital and French-language media while maintaining a greater skepticism toward mainstream outlets, whereas rural populations rely more heavily on local-language radio and place greater trust in familiar voices. These differing patterns of media engagement shape how information circulates and how social interaction and community cohesion are formed or sustained within each setting. Understanding these urban-rural differences is key to guiding media strategies that build trust, inclusion, and stronger community ties when developing communication and public policies in Francophone Africa.

Abstract Name: Perception of Spanish Lexical Stress by Heritage Speakers and Second-Language Learners

English and Spanish both have word stress; however, it is realized differently across languages. Both Spanish learners and heritage speakers have been shown to have difficulties with Spanish word stress. With this experiment, we aim to discover what participants' responses tell us about the relationship between perception ability and spelling knowledge, and between perception ability and grammatical knowledge. We are testing two groups, Spanish heritage speakers and Spanish learners, with three tasks: discrimination, identification with orthography, and identification with grammatical person. In all these tasks, we examine the perception of penultimate versus final stress. The first task, an oddity discrimination task, requires participants to listen to stimuli from three speakers to determine which of the nonce words are different, if any (e.g., sago-sagó-sago). In the second task, an identification task, participants listen to a word that is either in the first-person present tense (hablo "I speak") or the third person past tense (habló "He spoke"). They will then need to pick the subject of the verb they heard, choosing between the buttons él and yo ("he" and "I"). In the third task, an identification task, participants are presented with standard Spanish orthography. After hearing a stimulus, participants choose between two options, such as "hablo," and "habló." Preliminary results from the first heritage speaker show a 63% accuracy rate in the oddity task and a 92% identification accuracy rate on both penultimate and final stress trials in the subject identification task. However, for the spelling identification task, while penultimate trials had a 92% accuracy rate, final stress trials had a 77% accuracy. These results suggest that, for heritage speakers, perception difficulties lie in understanding sound-spelling correspondences with accent marks. Additionally, they may also struggle with perceiving stress differences in unknown words judging by performance on the oddity task.

Abstract Name: Deuterium isotope effect on the electrochemical stability window of heavy water with Pt electrodes

Storage of solar and wind-generated electricity is critical for these alternatives to become reliable energy sources. For large-scale storage, an aqueous solvent is an attractive choice for its inflammability, high ionic conductivity, and lower cost compared to organic counterparts. However, the disadvantage of aqueous solvents is the relatively small electrochemical stability window (ESW) which is limited by H₂(g) and O₂(g) evolution, resulting in the maximum voltage output of aqueous batteries of less than 2 V. This ceiling was expanded to 3 V with highly concentrated neutral electrolytes, which was rationalized by low concentrations of water in the electrolyte solutions. Recently, heavy water (D₂O) has been explored as an alternative to H₂O to further enlarge the ESW of aqueous solvent using glassy carbon electrodes, reporting the ESW of concentrated neutral electrolytes to be 3.4 V, which enables a competitive voltage output to Li-ion batteries with organic solvents. This effect has been explained by the stronger D-O bond than H-O bond stemmed from the lower zero-point energy of deuterium than protium, resulting in the smaller ion product and larger

dehydration energy of heavy water. We have investigated electrode variations of deuterium isotope effect on the ESW of heavy water using Pt electrodes. The size of the ESW expansion was significantly smaller (70 to 160 mV) with Pt electrodes, while 250 to 400 mV has been reported with the glassy carbon electrodes, by adopting the same current threshold of 1.5 mA/cm² for ESW determination. We suspect that the catalytic activity of Pt toward water electrolysis reduced the deuterium isotope effects observed with the sp² carbon, which is less catalytic toward water electrolysis, of the glassy carbon electrodes.

Abstract Name: Spring Into Summer, Crawl Into Fall: How Seasonality Affects the Results of Macroinvertebrate Bioassessments

This study analyzes the relationship between seasonality and macroinvertebrate bioassessment results in the Uchee Creek Watershed, a tributary to the Chattahoochee River and a Strategic Habitat Unit for Alabama which contains many rare aquatic species. Macroinvertebrate samples were collected during the spring and fall of 2025 from 10 sites in 1st and 2nd order streams at road-stream crossings using EPA sampling protocols (Barbour et al. 1999). At each site, twenty samples from all available microhabitats were collected using a D-Net within a 100-meter reach downstream from to road crossing. Samples were preserved in 95% ethanol and identified to Order in the laboratory. The Alabama Water Watch Rapid Bioassessment score was calculated for each sample, and nonmetric multidimensional scaling (NMDS) was used to examine the differences among macroinvertebrate assemblages across sites and seasons. Results indicate that there is variation in bioassessment scores between spring and fall samples with samples collected from the same season having greater similarity than between different seasons. Weather patterns such as high rainfall during the spring and summer and severe drought during the fall likely impacted stream conditions and macroinvertebrate assemblages. Stream quality ranged from poor to excellent, potentially affecting variability in results. Findings suggest that seasonality may influence macroinvertebrate bioassessment results, which emphasizes the need for further research with more consistent stream quality.

Abstract Name: Toward Understanding Nanoparticle Transport in Cervicovaginal Mucus: AI-enhanced Methods for Particle Tracking

The vaginal route is promising for delivering drugs locally to address women's health issues. Nanoparticle-based systems can enhance drug delivery across the multilayer epithelium, enabling access to the stroma and the lymphatic system. Realizing this potential warrants understanding nanoparticle transport through cervicovaginal mucus (CVM), a dense, viscoelastic barrier that restricts particle motion. Rationally designing

nanoparticles to overcome the mucus barrier demands reliable methods to quantify their diffusion. We utilized fluorescence microscopy to image nanoparticle diffusion in CVM. Poly(lactic-co-glycolic acid) (PLGA) nanoparticles loaded with a fluorescent dye and surface-decorated with polyethylene glycol (PEG) were prepared and imaged using a confocal microscope. Two-dimensional videos of nanoparticle motion in a CVM simulant were recorded and processed to correct drift and reduce imaging artifacts. Particle trajectories were extracted using Fiji, MosaicSuite, and MPThub, and mean-squared displacement (MSD) was computed as a measure of diffusivity. PEGylated PLGA nanoparticles showed enhanced diffusion compared to non-PEGylated particles, suggesting adhesive interactions with mucus. Furthermore, higher-molecular-weight PEG 10k particles exhibited greater MSD than PEG 5k particles, consistent with stronger hydration-layer shielding and reduced adhesive interactions with mucus. Despite these findings, traditional tracking methods remain limited by manual pre-processing, tracking gaps, user variability, and reduced reliability in complex CVM samples. To overcome these limitations, we implemented an artificial intelligence (AI)-driven framework using DeepTrack, a Python-based deep learning platform. Synthetic nanoparticle datasets were used to train convolutional neural networks capable of automatically detecting and tracking particles under noisy backgrounds and complex imaging conditions, reducing user variability and enabling reproducible diffusion analysis. Integration of the MotionNet model to further categorize the particle motion into different diffusion modes is ongoing. The combined microscopy and machine-learning-based tracking provides an accurate and reproducible framework for studying nanoparticle transport in mucus, ultimately supporting the design of effective vaginal drug-delivery systems.

Abstract Name: Understanding the Importance of Timing: Exploring the Implementation Outcomes of Potable Reuse Projects through a Project Phase Analysis

In recent years, potable reuse projects have emerged as a means for water utilities to foster water resiliency in their communities. By treating wastewater to drinking water standards, utilities can reduce their net consumption, fill consumer supply gaps, and combat regional scarcity. These projects have promised dependable, available, and sustainable water resources for the foreseeable future; however, their outcomes have been difficult to predict, varying from straightforward execution to indefinitely stalled or altogether failed projects. To enhance success rates within potable reuse projects, existing research has sought to understand the mechanisms that influence positive outcomes. Most researchers have investigated influential factors within individual projects or examined factors in isolation, but results from these studies are non-generalizable and cannot serve as a rigorous model for other projects. By identifying influential factors and combinations of factors that may facilitate or hinder progress across projects, researchers can diagnose which factors and factor combinations make or break a potable reuse project and model generalizable paths toward successful implementation. This model can then be presented to utilities to implement into their engineering plan, facilitating a smoother and more predictable project execution. The research presented herein aims to take this concept one step further by modeling not only generalized paths to success, but also ideal project timelines. Knowing when to incorporate influential factors into the project schedule will allow utilities to plan and execute important factors in a timely manner. This mixed-methods model will be developed through phase-based temporal analyses – including phase-based Fuzzy Set Qualitative Comparative Analysis (fsQCA) and Jaccard's Similarity Index – and can be used by practitioners to schedule their potable reuse project for success before it ever breaks ground.

Abstract Name: Hybrid Intelligence for Phishing Detection: Integrating Machine Learning and LLM Multi-Agent Reasoning

Phishing websites and deceptive online content continue to be major contributors to financial loss, identity theft, and large-scale cyber incidents. Despite significant progress in automated detection, most existing systems rely on a single analytical approach, such as machine-learning classification or linguistic analysis, which limits their ability to interpret evolving social-engineering tactics. This project asks the central research question: Can a hybrid framework that integrates machine-learning models with a large-language-model (LLM) multi-agent system improve the accuracy and interpretability of phishing detection? To investigate this question, we develop a two-tier detection architecture that combines a Random Forest classifier trained on a publicly available dataset of phishing websites with a specialized LLM-driven multi-agent subsystem. The machine-learning component evaluates URLs using 87 lexical, structural, and external features to produce a baseline classification score. The multi-agent subsystem consists of three independent analytical agents—a Market Researcher, Language Analyst, and Threat Analyst—that examine factual inconsistencies, linguistic cues, and manipulative behavioral signals within suspicious messages. A Final Evaluator synthesizes all outputs to generate a unified deception score on a scale from 1 to 10. Our methodology includes dataset preprocessing, feature-correlation analysis, model training, and rigorous performance evaluation using accuracy, precision, recall, and F1-score. In parallel, we construct prompt-engineered LLM agents that emulate expert reasoning in fraud investigation, linguistic forensics, and social engineering analysis. Preliminary results show that while the Random Forest model achieves strong performance across all evaluation metrics, the multi-agent LLM subsystem consistently enhances detection accuracy, reduces false negatives, and provides human-interpretable explanations for high-risk classifications. The combined system demonstrates noticeable improvements over conventional single-model approaches. The outcome of this work is TrustNet, a web-based platform that integrates both subsystems to deliver real-time risk assessments of URLs and textual content.

Abstract Name: Investigating Aqp3b as an Upstream Regulator of Xbra Expression Through FGF signaling in *Xenopus laevis* Gastrulation

In early embryonic development, the dorsal mesoderm (DM) undergoes convergent extension (CE) to give rise to the notochord and further contribute to central nervous system development. CE is a critical morphological movement regulating gastrulation, the process establishing the three germ layers of the embryo. CE is partially mediated through the noncanonical Wnt/PCP pathway. Additionally, gastrulation is supported by FGF signaling through the specification of mesodermal fates and axial patterning. Morphological changes resulting in CE and associated cell movements are largely conserved between humans and *Xenopus laevis*, making it an ideal specimen to study vertebrate gastrulation. Preventing CE in the DM results in embryonic nonviability through malformation of the nervous system, trunk, and

tail. Aquaglyceroporins are transmembrane proteins responsible for the transport of water, glycerol, and small uncharged molecules across the plasmalemma. Previous research has elucidated Aquaglyceroporin 3b (Aqp3b) as a component of CE and the FGF pathway. Aqp3b has been found to upregulate the FGF pathway, activate the PI3K/Akt pathway, and induce expression of the protein Xbra. Xbra has been found to upregulate the ligand for the Wnt/PCP pathway, and therefore CE. The objective of this project is to reveal the mediating role of Aqp3b within the FGF pathway. This will ultimately be determined through Western blot of protein isolates. *X. laevis* embryos will be injected at the 4-cell stage with aqp3b morpholino oligonucleotides or aqp3b mRNAs to knock down or upregulate Aqp3b expression, respectively. DM explants will be cut and lysed. Protein samples will be run through SDS-PAGE in preparation for Western blot. Expected results would show that when aqp3b is knocked down, baseline Akt levels will be unaffected. However, aqp3b upregulation will promote increased levels of phosphorylated Akt via PI3K activation. These results would clarify Aqp3b as a positive regulator of CE in vertebrate gastrulation.

Abstract Name: The Impact of “Finsta” Social Media Use: Psychosocial Correlates for African American Gen Z Mental Health

This ongoing study examines how young adults—particularly African American members of Generation Z—use Finsta (private or alternate Instagram) accounts and how these behaviors may relate to mental health, self-expression, and overall social media experiences. Existing research suggests that Finsta use is often connected to closer social bonding, more authentic self-presentation, and the expression of more negative emotions; however, these patterns have not been examined specifically within African American communities. The present study aims to identify the sociodemographic and psychological factors associated with Finsta use in this population and to explore whether these accounts function as protective spaces that support well-being. Data collection and analysis are still in progress, and the extent to which Finsta use influences mental health, self-expression, or perceived social support remains XX. The findings of this study are expected to provide a more culturally informed understanding of Finsta use and its potential implications for well-being.

Abstract Name: Assessing the Effectiveness of Stream Restoration on Reducing Thermal Stress of Native Brook Trout: A Case Study at Smith Creek, Va

Understanding the factors that drive summer stream temperature variability is essential for assessing habitat suitability for brook trout (*Salvelinus fontinalis*), a cold-water species highly sensitive to warming conditions. This study evaluated whether riparian restoration along Smith Creek, Virginia – implemented through the Conservation Reserve Enhancement Program (CREP) in 2005 – has measurably reduced thermal stress,

improved habitat conditions, and counteracted broader climatic influences. Using high-resolution temperature logger data collected from the summers of 2006, 2007, 2024, and 2025, we compared thermal regimes across restored and unrestored stream time periods, and assessed the relative importance of air temperature, streamflow, and riparian condition in shaping stream temperature patterns. Contrary to expectations, air temperature emerged as the dominant predictor of stream temperature, overwhelming the moderating influence of riparian restoration. Streamflow did not exhibit the anticipated cooling effect, suggesting that reach-scale thermal dynamics were decoupled from watershed-scale discharge patterns during the study period. Although the 3 kilometers of restored reaches exhibited localized shading and habitat improvements, these effects were insufficient to counteract strong atmospheric controls on daily and seasonal temperature fluctuations. These findings indicate that while riparian restoration provides ecological benefits, its capacity to buffer summer thermal regimes may be limited under contemporary climatic conditions. As regional air temperatures continue to rise, brook trout populations in small Appalachian streams may face increasing thermal vulnerability unless restoration efforts are paired with broader climate adaptation strategies. This study highlights the need for integrated watershed-scale management approaches and contributes to ongoing efforts to understand and mitigate the temperature-productivity squeeze affecting cold-water fisheries across the Appalachian region.

Abstract Name: Do Support for Artificial Intelligence Tools Affect Academic Performance Among College Students?

The rapid growth of AI tools in education has raised many questions about how much they can help students succeed in college. Some students see AI tools as a helpful learning resource, whereas others do not see AI tools make a difference in learning. Due to a generational perception in using new technology, younger learners seem to be more likely to use AI tools than the older learners. Thus, the purpose of this study is to investigate whether students who use AI tools in college classrooms tend to have higher GPAs than those who do not, as well as whether younger students are more likely to use AI tools in learning than the older students. Approximately 105 students who are above 18 years old completed this cross-sectional study. The survey asked about people's opinions on AI tools in education, their birth year, how often they use AI tools for learning, and their cumulative GPA. After coding the data and running the analysis by SPSS, an independent sample t-test first compared the GPAs of students who use AI tools versus those who do not. The results ($p = 0.633$ > 0.5) showed that there was no significant difference between the two groups, meaning that the use of AI tools might not necessarily affect students' performance on their GPAs. A correlation test was used to determine the potential relationship between the age of participants and the use of AI tools in college. The results ($p = .086$ > 0.5) showed that there was no significant linear relationship between participants' age and use of AI tools. Overall, the results revealed that simply being open to or using AI tools might not predict students' academic success in college. The nonsignificant results, interestingly, challenge the societal perception that only young learners use AI tools in learning.

Abstract Name: Embodying Community: A Reflection on the Value of African Diasporic Dance Forms

This creative research project investigates the communal frameworks embedded within African Diasporic dance forms and examines how these frameworks challenge dominant Western assumptions about what constitutes "valuable" dance knowledge. While African diasporic movement practices have increasingly entered academic spaces, they remain marginalized compared to Western concert dance traditions such as ballet and modern dance. This project responds to that disparity by developing a performance piece that fuses scholarly research, embodied practice, and personal experience to illuminate how African Diasporic dance constructs community through shared affect, emotional reciprocity, and collective presence. Grounded in dance studies scholarship, this project integrates theoretical inquiry with a choreographic process shaped collaboratively with performers. Rehearsals incorporated assigned reading, group dialogues, and movement investigations that translated scholarly findings into embodied expression. The resulting performance invites the audience not only to observe but to participate- foregrounding the reciprocal relationship between mover and witness that is central to the movement of the African diaspora. This participatory structure challenges viewers to reconsider their own assumptions about value and belonging within dance. The project further explores how documenting this process can inform pedagogical approaches in academic dance settings. By analyzing both the rehearsal process and the community-building elements that emerge, the research aims to propose a learning tool that reflects the integrative nature of African Diasporic dance practices. Ultimately, this work seeks to expand conversations around redesigning dance education and to highlight the transformative potential of movement practices that center community, shared energy, and embodied knowledge.

Abstract Name: Controls of Bold versus Shy Behavior in Painted Turtles: What Lies Beneath the Shell

Controls of Bold versus Shy Behavior in Painted Turtles: What Lies Beneath the Shell?LaTanyah Baptiste, Elizabeth Hayes, Maria Uben, Jazmyn White, Yusra Bashir-Danfati, Sean Walker, Justin Clarke, Ya'Mar McCoy, Anne Wiley In wildlife biology, individual differences were once overlooked, with animals treated as uniform members of their species. However, growing research highlights that personality traits such as boldness and shyness can significantly impact how animals interact with their environment, compete for resources, and adapt to ecological challenges. Our project explored these personality traits in eastern painted turtles (*Chrysemys picta picta*) by observing bold versus shy behaviors at two study sites: Bowie State University and the Patuxent Research Refuge, MD. We evaluated how behavior during handling (including retraction into shells and gaping) was linked to body condition, sex, diet, season, and site. While several variables (diet, sex) were unrelated to bold vs. shy behavior, we found that shy painted turtles were more common at relatively remote sites in the Patuxent Research Refuge and tended to be smaller (with lower standard carapace length). We also found that bold behaviors were most common in the spring and least

common in the fall (but did not correlate with daily temperature), which suggests that social interactions during mating could play a role in shifting painted turtle behavior during handling. Overall, our results suggest that bold vs. shy behaviors in our study population of painted turtles may be controlled by temporary factors, such as season or age, rather than set differences in personality between individuals.

Ameria Barajas

Abstract Name: Designer Hero: Maria Sibylla Merian

This highlights the accomplishments of Maria Sibylla Merian, a 17th-century naturalist and artist, who combined art and science with her observations and illustrations of insect metamorphosis and environmental relationships. By using paints she made, personally, she was mostly skilled in watercolors but had started with a sketchbook and a pencil and by taking a vastly impressive two year trip to Suriname by herself, she was a highly creditable illustrator during that period. Despite minimal formal education and societal hurdles, an important legacy was created for women and natural history by vividly depicting metamorphosis and questioning gender conventions in science. Though she herself taught several artistic techniques and undertook long-term bug observations, leading to ground-breaking illustrations that altered the portrayal of ecological. With thorough documentation made her findings more accessible than those before her. Even with her achievements, Merian faced systemic barriers in the field that often obscured her talents. The paper emphasizes the need to acknowledge women's roles in natural history. By advocating for inclusive research on female naturalists such as Merian, we recognize their significant impact on both art and science in the history of graphic design.

Abstract Name: The Tension Between Law and Grace: Jesus vs Jewish Law

This project will examine the historical and theological tensions between Judaism and the early Christianity movement from 30 to 100 CE, focusing on how Jesus's teachings challenged the established expectations of Jewish law and religious identity. Jesus also challenged the Jewish messianic expectations that perceived the promised messiah to be more of a military savior rather than a personal one. This study will explain the historical context of scholarly analysis and debates that may portray these tensions as doctrinal, cultural, or political. Methodologically, this project relies on a close analysis of primary sources such as the New Testament books of Matthew, Mark, Luke, John, and Acts. It also includes a study of Jewish texts such as the Torah while also including the historical perspective of Judea's political climate and previous tensions due to Roman occupation of the region. The research reveals that the conflict between Judaism and the early Christian movement was rooted in more than just theological disagreements. Jesus's reinterpretation of Jewish law, His emphasis on spiritual rather than ritual purity, and His declaration as the Son of God directly challenged the authority of Jewish religious sects such as the Pharisees and disrupted established communal traditions founded in Jewish law. Additionally, Roman imperial politics strengthened these tensions through its control and persecution of both Jewish and Christian development during this period. The study concludes

that the early divergence between Judaism and Christianity was caused not only by differing religious doctrines but also by conflicting understandings of religious identity, authority, and salvation. These findings will be discussed within the historical context of how this developing period shaped the future of both religions.

Abstract Name: Effects of Melatonin and Cytokine Supplementation on Oocyte Mitochondrial Function, mtDNA Copy Number, and Embryo Development Under Heat Stress

Heat stress impairs egg (oocyte) quality and early embryo development in cattle, partly through disruptions in mitochondrial function. This study evaluated whether melatonin, an antioxidant, and cytokines (FGF2, LIF, IGF1; FLI), individually or in combination, could protect bovine oocytes from heat-induced mitochondrial dysfunction during in vitro maturation (IVM). Two complementary experiments were assessed: (1) mitochondrial membrane potential (JC-1 staining) and mitochondrial DNA (mtDNA) copy number (qPCR) in matured oocytes, and (2) development of fertilized embryos and cleavage patterns from 2-cell to blastocyst using time-lapse imaging. Four groups were included: control, melatonin, FLI, and melatonin+FLI (combo). Hot season data were collected in July-August (4 replicates) and cold season data in October (3 replicates). The data were analyzed using a generalized linear model (Jamovi software). Our results showed that JC-1 ratio was negatively correlated with local slaughterhouse temperature ($P < 0.001$), whereas positive correlation was observed in the cold season ($P = 0.02$). Combo-treated oocytes maintained the highest and most stable JC-1 ratios under hot conditions, indicating enhanced oocyte quality. In contrast, mtDNA copy numbers remained unchanged across treatments and seasons. Time-lapse image analysis revealed season-dependent developmental differences. The cold-season embryos exhibited less variation in developmental timing and faster progression through several developmental stages. The 4- 8-cell and 8- 16-cell stages appeared most affected by heat stress, although the differences were not significant. The treatment effects were not statistically significant. In conclusion, melatonin and FLI, especially in combination, steadily increased mitochondrial function during heat stress but did not influence mtDNA copy numbers nor embryo development. These results suggest that supplementation primarily enhances mitochondrial efficiency and cytoplasmic competence rather than promoting mitochondrial genome replication. This work provides insight into strategies that may improve oocyte resilience and reproductive outcomes in cattle exposed to elevated environmental temperatures.

Abstract Name: Optimizing IEP Scheduling for Special Education Educators using Integer Linear

Programming

We address a common scheduling problem that special education teachers face: creating individualized education plan schedules (IEPs) for multiple students. The work began as a special project in an Optimization Modeling class and continued as an independent research project. The purpose was to develop a scheduling model that supports one special education teacher that works with thirteen fifth and sixth grade students. The model can be adapted for additional teachers or grade levels as needed. Currently, most IEP scheduling is a manual, iterative process that requires significant time and trial and error. This project aims to reduce the workload of special education teachers in creating IEP schedules through the usage of computational optimization. The model is formulated as an integer linear program in AMPL and solved using Gurobi. The model defines sets of students, subjects, days, grade levels, and time blocks, and incorporates constraints including: preventing student double-booking, preserving teacher workload boundaries, supporting subject-specific instructional formats, and differentiating core subject priorities such as reading and mathematics. The objective function then balances these factors to produce a workable, conflict-free schedule. The resulting schedules meet IEP requirements, limit conflicts, and make better use of classroom time. The final presentation will discuss these outcomes, how well the approach works in practice, and how this model could be extended to support additional teachers or larger school environments.

Abstract Name: Short Chain vs. Long Chain Per-and Polyfluoroalkyl Substances: Comparative Effects of PFAS on *Caenorhabditis elegans* Lifespan and Implications for Human Health Risk

Per-and polyfluoroalkyl substances are synthetic, environmentally persistent organic compounds known as "forever chemicals." With over 14,000 variants, PFAS are major contaminants, particularly in drinking water. In April 2024, the Environmental Protection Agency added six PFAS to the National Primary Drinking Water regulations to reduce human exposure. However, as of May 2025, only two are under regulation: perfluorooctanesulfonic acid (PFOS) and perfluorooctanoic acid (PFOA). Other studies show that PFOS exposure shortens the lifespan of *Caenorhabditis elegans* (*C. elegans*). In our study, we investigate if two previously regulated PFAS -- short-chain perfluorobutanesulfonic acid (PFBS) and long-chain perfluorononanoic acid (PFNA) -- alters *C. elegans* lifespan when exposed to environmentally relevant concentrations. Age-synchronized worms were treated at 1 μ M, 10 μ M, 50 μ M, and 100 μ M concentrations of PFNA and PFBS separately and against a control group. Lifespan assays were conducted 40 hours post-treatment to measure longevity of *C. elegans*, monitoring a small population daily and scoring mortality as occurred. Survival was monitored over a 26-day period for PFNA-exposed worms, with the first signs of mortality occurring on Day 9 for all treatment groups. Between Days 23 and 25, majority of the followed populations across all concentrations reached the highest mortality level as the worms were scored dead. In contrast, *C. elegans* exposed to PFBS were monitored over a 29-day period. By Day 26, maximum mortality was reached by majority of the populations of all treatment groups; the 1 μ M group showed no survival by Day 29. Preliminary results suggest no dramatic change in *C. elegans* lifespan when exposed to these specific concentrations. Additional experimentation will be done to validate these findings and to determine which concentration reduces the lifespan of *C. elegans*. Future directions aim to explore the mechanisms of PFAS toxicity to better provide implications for human health risks.

Abstract Name: Influence of handedness on upper extremity balance in Division III Athletes.

The human postural control system regulates the body's balance and stability, which is essential for athletic performance and injury prevention. While many studies have examined upper extremity balance in sports that heavily rely on the upper body, fewer have explored shoulder imbalances in sports with varying upper-body demands. This study aimed to fill that gap by comparing upper extremity balance in female NCAA Division III gymnasts and track and field athletes, ages 18 to 23. The track and field group included athletes in upper-body-dominant events such as throwing and pole vaulting. Gymnastics was selected due to its bilateral upper-body movement patterns, while track and field events emphasize unilateral use. A total of 28 participants were tested, 12 track and field athletes and 16 gymnasts. Through using the Upper Quarter Y-Balance Test (UQYBT), a validated tool for assessing shoulder mobility and stability. Contrary to previous research suggesting unilateral athletes show greater side-to-side asymmetries, our results showed no significant differences between dominant and non-dominant arm reach scores within either group. Additionally, no statistically significant differences were observed between gymnasts and track and field athletes. These findings challenge assumptions in the current literature and suggest that upper extremity balance may not differ as much across sport types as previously thought. Given the limited research conducted at the Division III level due to funding constraints, this study highlights the importance of including underrepresented athlete populations in sport science research. Expanding our understanding of shoulder stability in a broader range of sports can help improve training protocols, enhance performance, and reduce injury risk in athletes at all levels.

Abstract Name: The Matilda Effect: Decades of Silenced Women

This research project examines the "Matilda Effect," a term coined by historian Margaret Rossiter to describe the long-standing pattern of women's intellectual and creative achievements being overlooked, minimized, or attributed to men. After learning about this phenomenon and seeing how talented women today still experience forms of dismissal or under recognition, I became interested in tracing how these patterns developed and why they continue to shape whose work is remembered. My initial research focused on Matilda Joselyn Gage, whose writing first highlighted this issue, as well as early historical cases showing how women's work was ignored or overshadowed by male-dominated narratives. I also reviewed more recent examples in art and public history, which show that this issue continues today, especially in how museums and historical institutions choose whose stories to highlight and which to not. This research is especially timely because questions about representation, authorship, and credit are central to many current cultural and academic debates. As institutions reconsider who gets included in textbooks, museum exhibits, award lists, and public memory, understanding the roots of these imbalances becomes essential. The Matilda Effect still affects whose work gets taken seriously, and studying the politics and social norms behind these misattributions can help us think more clearly about fairness and how we document history. As I continue this project, I plan to study specific cases more closely by reading first-hand accounts, analyzing the political and cultural contexts of each period, and comparing how these uncredited or miscredited works were discussed publicly. Ultimately, I hope to understand how persistent patterns of overlooking women's contributions

shape which work becomes visible and why recognizing women's achievements remains an important goal for scholars and society today.

Abstract Name: MataVision: Predicting and Preventing Traffic Accidents in Salem, Massachusetts Using Machine Learning

Traffic accidents continue to be a major concern in Salem, Massachusetts, with many incidents influenced by weather, lighting, road conditions, and the time of day. Although the state collects large amounts of crash data, much of it is not analyzed deeply or used to support preventative safety planning. MataVision is designed to address this gap by applying machine learning and clear visual tools to better understand local crash patterns. This project uses five years of crash data from the Massachusetts Department of Transportation. The dataset is cleaned and organized to explore trends over time, environmental factors, and roadway patterns. Several machine learning models—Decision Trees, Logistic Regression, K-Nearest Neighbors, and Support Vector Machines—are trained to estimate when and where crashes are more likely to happen. The city is mapped using H3 hexagonal indexing, which breaks Salem into small, uniform zones that make hotspot detection more accurate and easier to interpret. The results are presented through interactive maps and automatically generated summaries. These tools give city planners, researchers, and insurance analysts a clearer way to spot dangerous areas, compare conditions, and support safety decisions based on data rather than assumptions. Overall, MataVision aims to shift Salem's approach to road safety from reacting after crashes occur to identifying risks earlier and reducing them. By combining machine learning models with simple and readable visualizations, the project contributes to building a safer and more informed community.

Abstract Name: Broadening Participation in Undergraduate Research through a Summer Bridge Program

High-impact practices (HIPs) can significantly improve student outcomes, including growth in disciplinary knowledge, improved cross-cultural communication and leadership skills, gains in interpersonal and team collaborations, and improved academic achievement. Regardless of these significant benefits, first-generation and limited-income (FGLI) scholars often engage in HIPs at a lower rate. The Office of Experiential Learning (OEL) at the University of Wisconsin-Madison has been working towards expanding learning opportunities by providing inclusive and assessable scaffolds for engagement in HIPs by removing common challenges, such as financial barriers and hidden curriculum, that have historically prevented many FGLI students from participating in transformative educational experiences beyond the classroom walls. One program that has shown a lot of promise towards increasing engagement in undergraduate research is STEM Catalyst, a

residential, four-week summer bridge program that introduces incoming scholars to immersive undergraduate research early in their college careers. In addition to conducting hands-on research with STEM faculty, participants build their self-efficacy and research identity through intentional networking opportunities with STEM faculty, a scaffolded 1-credit hour course that synchronously supports the research experience, and community building opportunities that create a robust support network of students with similar interests. The structure and implementation of the program will be discussed, including the successes and challenges of initiating a bridge program for novice researchers. Additionally, quantitative and qualitative data measuring the effectiveness in creating belonging, cultivating a STEM research identity, and fostering confidence as a STEM scholar will be shared.

Abstract Name: When No Response is a Response: Predicting Survey Non-Compliance in Isolated, Confined, and Extreme (ICE) Analog Space Missions

Long-duration space exploration will place small, interdependent teams in isolated, confined, and extreme (ICE) environments, where they will face risks including communication delays, high autonomy, increased workload, team tension, and intense stress. All of these risks require research studies aimed at mitigating them, many of which take place at analog space stations. However, these analog missions, which aim to study human behavior in ICE settings, suffer from chronic survey noncompliance, which threatens data integrity and reduces the accuracy of crew monitoring. This project examines which individual characteristics predict who completes research surveys during missions at the Mars Desert Research Station, a Mars-analog habitat in Utah. Before their missions, crew members completed questionnaires assessing personality (with a focus on conscientiousness), their identification with their team, their cultural values (especially collectivism, or putting the group before oneself), and their difficulties with emotion regulation. During the mission, they were asked to complete brief daily and weekly surveys. For each person, I will calculate survey compliance as the percentage of assigned surveys completed, and I will use regression models to test whether conscientiousness, emotion regulation, team identification, and collectivism predict higher compliance. I will also test whether collectivism strengthens the link between team identification and survey completion, such that highly collectivistic crew members who strongly identify with their team are especially likely to respond. I expect that crew members who are more conscientious, better at managing their emotions, more strongly identified with their team, and more collectivistic will show higher survey compliance. The work integrates literature on ICE stressors, organizational citizenship behavior (OCB), survey methodology, and individual differences to generate actionable recommendations for designing analog-station research protocols and for operational monitoring in deep-space missions.

Abstract Name: Building Career Readiness through Undergraduate Research

Undergraduate Research allows students to apply classroom learning to real-world problems, but how well does it prepare them for real world careers?. Undergraduate research helps develop transferable professional skills in students that promote career readiness, but these connections are not always overt in the scholarly process. The National Association of Colleges and Employers (NACE) identifies eight competency areas for career readiness skills that undergraduates should practice before graduation. To emphasize the importance of undergraduate research to developing these competencies, the Office of Undergraduate Research (OUR) at UNC Charlotte developed a series of discrete student learning outcomes (SLOs) for these eight competency areas. A total of 16 SLOs (two per competency area) are used as a framework for student learning through undergraduate research. During the research program, professional development opportunities offered by OUR highlight these competency areas and equip students with the vernacular to describe the benefits of their undergraduate research experience. At the end of the research term, students and mentors assess growth and development for these career competencies. We will share students' and mentors' perspectives on how undergraduate research contributes to career readiness. We will also share how OUR uses these tools to refine existing programs and develop new programming to support student transitions from college to career.

Abstract Name: The Perfect Formula: A Comparative Analysis of the Electric Vehicle Policies in China, South Korea, and Japan

The rise of electric vehicles has become a defining feature of East Asia's green technology agenda, showcased in China, Japan, and South Korea. Each nation has mobilized ambitious policies under their carbon neutrality goals, however their outcomes, measured in EV adoption rates, sales performance, and public perception, vary widely. This thesis argues that these differences cannot be explained by political factors or market dynamics; rather, successful EV market integration depends on the alignment of political strategy, cultural context, and individual psychological perceptions. Through a comparative, cross-national analysis, this research examines how government policies, national culture, and psychological factors intersect to shape EV market outcomes. Hofstede's cultural dimensions and the Unified Theory of Acceptance and Use of Technology (UTAUT) model frame the cultural and psychological foundations of policy effectiveness. Drawing from policy documents, scholarly literature, and market data, the study synthesizes analyses of state incentives, cultural values, and consumer perceptions, including range anxiety, environmental concern, and status symbols. Findings reveal that while China leads the market through strong state-led policies and infrastructure investment, its success is driven more by political will than by the incorporation of psychological perception. South Korea, positioned second, demonstrates the greatest harmony between policy and public sentiment through its collectivist innovation culture and government-industry collaboration. Japan, though technologically advanced, lags behind due to cautious consumer psychology and a preference for hybrid vehicles as a transitional technology. By bridging political analysis with cultural and psychological insights, this study adds to the scholarly debate on EV policy-making in East Asia and offers a full account of varied national approaches to green technology adoption.

Abstract Name: "Needles"

My research is conducted based on my own personal experience related to Bipolar Disorder, specifically as an adolescent. Through spoken word poetry, I reflect on the treatment I have received as a part of this disease. A diagnosis like bipolar disorder is extremely rare to receive as an adolescent, and only about 2.9% of adolescents will be provided with psychiatric care. At fifteen years old, I became a part of this statistic, and I was diagnosed with Bipolar Type One. Although Bipolar disorder affects your brain chemistry, it also affects your physical health and requires an immense amount of tests, samples, and blood work done regularly. This can be incredibly painful to walk through and can cause trauma symptoms to arise in patients. Even though genetics and my environment played a key role in my illness being triggered at such a young age, I had no education before the life that followed after my first hospitalization. In my spoken word, "Needles," I reflect on how walking through the early parts of my treatment was terrifying, especially related to inpatient care I experienced. I wrote "Needles," a few years after receiving my diagnosis, when I began to process the trauma I received as a patient in the psychiatric system. Through outpatient treatment, like therapy, I saw its long-lasting effects on my life, especially with my ability to perform academically. "Needles" tells of the trauma I continue to receive from the healthcare system. I wrote this piece in a place of concern and empathy for patients who suffer from mental health disorders. I hope to use my story and my performance to spread awareness for adolescents currently suffering in the system, and bring hope to others as I continue to be one of the people to defy statistics and drastically low odds.

Abstract Name: Extraction of Key Prescription Drug Information from Medication Labels

Drug labels contain crucial information such as active ingredient, strength, prescribing instructions, possible side effects, and contraindications. The FDA digitizes drug-label information and makes it available as DailyMed, but most of this information is buried in free-text fields of non-standard XML formats that are difficult for computer systems to process. Efforts have been made to extract this information, but they have focused on a small subset of drugs or on the structured fields. This project considers the following question: Can we make prescription drug label content more accessible and structured for use by computers? To do this, I selected 25 drug labels from DailyMed and looked at eight important fields: brand name, generic name, strength, active ingredient, inactive ingredients, side effects, indications, and contraindications. I annotated each drug label by hand to create a gold standard reference set. I then looked at two approaches for information extraction. The first was a rule-based approach, which made use of hand-written patterns. The second was a machine learning approach, where the computer learned from labeled examples to identify and extract pertinent information. The rule-based approach excelled at pulling out well-structured information such as strength and drug name but performed poorly on more unstructured narrative fields such as contraindications and side effects. The machine learning approach performed well on free-text fields, but requires more annotated data and further fine-tuning to improve performance. These results indicate that a hybrid approach, leveraging rule-based methods for structured content and machine learning for free-text content, presents the most promising direction. Increasing the availability of drug label information has important consequences: reducing patient and provider confusion, making safety checks more effective, and facilitating broader research throughout health informatics. Future work will include the expansion of the dataset to include more drugs and continued model performance optimization on free-text fields.

Abstract Name: Graft-Free ACL Reconstruction: Optimizing Fiber Geometry and Composition in 3D-Printed Ligament Replacements

The anterior cruciate ligament (ACL) tear is one of the most prevalent knee injuries in sports medicine, particularly in high-demand sports that require rapid directional changes. This is devastating for patients due to the extended recovery period of 9-12 months and the heightened risk of re-injury. Addressing these challenges, our research focuses on engineering a synthetic ACL with biomechanical properties that closely mimic those of native ligaments, thereby enhancing durability under athletic stress. Our approach aims to eliminate the need for grafts traditionally used in ACL reconstruction. Eliminating the need for a graft reduces the invasiveness of the surgery and minimizes the time the patient spends under anesthesia. Furthermore, using an artificial ACL streamlines the surgical workflow by negating the need for intraoperative tendon harvesting and preparation. To achieve this, we employed a three-pronged approach to evaluate the efficacy of the synthesized artificial ACL. The initial phase involved an in-depth evaluation of the components, structural integrity, and mechanical properties of a native healthy ACL. Research on the forces acting on an ACL during a human gait cycle was conducted to ensure that the design could withstand the applied forces. Leveraging the insights gained, three different artificial ACL models were constructed in SolidWorks, with different fiber orientations and compositions. Finite element analysis was used to predict the biomechanical performance of the artificial tendon. Upon computational optimization, a physical prototype was fabricated using the 3D printing technique. The successful implementation of this project is expected to offer substantial benefits to both surgeons and patients. Overall, our project aims to offer a synthetic ACL replacement that reduces surgical complexity and accelerates recovery time.

Abstract Name: Intervention-Related Neuroanatomical Changes in Autistic Children

Several brain networks have been implicated in the neurobiology of autism spectrum disorder (ASD). The emotion network (EN), located primarily in the frontal and temporal cortices, is one of those. ASD and neurotypical children have been reported to show differences in cortical thickness (CT) within EN regions (Lucibello et al. 2021), and reading comprehension difficulties can also contribute to emotion dysregulation in ASD (Hogeveen and Grafman 2021). While language and emotion have separately been studied in ASD,

fewer studies address their relationship. We examined the relationship between neuroanatomical changes and behavioral assessments in autistic children (7-13 years) pre-and-post an intensive reading intervention. 14 ASD children received intervention (ASD-EXP) between baseline and post-tests, and 11 ASD children were included in the waitlist-control group (ASD-WLC). Emotional control (EC) and emotion regulation (ER) subscores of the Behavior Rating Inventory of Executive Function (BRIEF) questionnaire (Gioia et al. 2000) were correlated with CT difference (Δ CT: post–baseline). CT values for EN network regions were extracted using Matlab and FreeSurfer (Fischl 2012). EC baseline scores were negatively correlated with Δ CT in left inferior temporal gyrus (TF; $r(13)=-0.635$, $p=0.015$), left posterior orbitofrontal cortex (pOFC; $r(13)=-0.552$, $p=0.041$), right dorsomedial prefrontal cortex (8BM; $r(13)=-0.615$, $p=0.019$), and right OFC ($r(13)=-0.711$, $p=0.004$) in ASD-EXP. ER baseline scores were negatively correlated with Δ CT in right OFC ($r(13)=-0.627$, $p=0.016$) and left TF ($r(13)=-0.552$, $p=0.041$) in ASD-EXP. None of the correlation scores reached the significance level in ASD-WLC. These findings suggest that ASD children who received intervention exhibited a meaningful coupling between baseline emotional functioning and subsequent intervention-related CT changes in frontal and temporal regions that support emotion regulation. The absence of similar relationships in ASD-WLC indicates that this relationship is not simply a developmental trend but may reflect intervention-related plasticity of these regulatory circuits in ASD.

Abstract Name: An Accuracy Assessment of Tree Age Estimation Methods

Trees provide a multitude of benefits to their surrounding ecosystems and human communities. Their ability to store carbon, particularly as they age, plays a key role in the face of global climate change, and is of particular interest in this study. The University of Richmond (UR) campus recently completed a decade-long tree inventory project, but still lacked accurate information regarding tree age. As carbon storage and age have a logistic relationship, the role of old trees is paramount for human value such as carbon storage and landscaping aesthetics. Age can be estimated through various methods, but the most accurate are lethal (i.e. counting rings of cut trees). Through reviewing various types of age assessment techniques, this project attempts to find the best non-invasive alternative method for tree estimation. Diameter at Breast Height (DBH) data were gathered to estimate age, with a focus on variation between species. DBH (cm) age factors were averaged based on current literature. These age factors were validated through counting trees rings of recently removed trees on campus, along with focused tree coring on campus. By strengthening these alternative age estimation methods, we hope to gain a more comprehensive understanding of tree age on campus. In the future, this data will be used to analyze the relationship between age and other ecological variables including nativity, carbon storage capacity, and landscape types. Developing a non-destructive method for tree age estimation that maintains accuracy would help future researchers gain a more accurate understanding of how. More accurate age estimates could then improve estimates of carbon storage, as both vary widely between species. Furthermore, these results can be used to better understand direct and measurable environmental repercussions of land use change, which would help better inform those making land management decisions.

Abstract Name: Testing the role of CBX3/HP1 γ in radiation resistance.

Tumors can be a combination of diverse cells with different mutations that favor uncontrollable growth and their ability to resist aggressive treatments. Genome stability is therefore a critical factor in the study of cancer initiation and progression. Eukaryote genomes are organized into chromosomes that have both actively expressed regions and transcriptionally silent sections called heterochromatin. One of the proteins involved in the compacted state of heterochromatin is CBX3/HP1 γ which binds to trimethylated histone 3 Lysine 9 (H3K9me3). Recent cancer studies have shown that the overexpression of CBX3 can indicate a bad prognosis, increased proliferation and resistance to treatment for patients. CBX3 is therefore an interesting gene needing further inquiry regarding its precise function. This project aimed to investigate the functional role of CBX3 in planarians, flatworms with unique traits that make them a good model for studying protein function in vivo. Planarian stem cells share interesting similarities with cancer stem cells due to their high regenerative capacity and their ability to withstand high doses of radiation. Prior data analysis in the lab found that CBX3 is downregulated after RNAi knockdown of the chromatin protein Set1. As loss of Set1 causes planarians to become more sensitive to radiation, we hypothesized that RNAi on CBX3 will result in a similar phenotype. To test our hypothesis, we synthesized double stranded RNA of two CBX3 constructs (to assess off-target effects) and a negative control gene, unc-22. After three consecutive RNAi feedings, half of the worms were radiated with 12.5 Gy and then cut to observe the regeneration process. Although conclusive results are awaiting, current observations show no distinct phenotype on both CBX3 (RNAi) planarians, as well as the irradiated ones. Even so, this project contributes to a better understanding of chromatin stability and the role it plays in DNA damage repair.

Abstract Name: "Grandpa Always Says" Reimagining a Memory Card Game as an Effective Storytelling Technique for Cultural Colloquialisms

This project, "Grandpa Always Says", explores how a memory card game can be reimagined as a storytelling technique for cultural colloquialisms and how connections between memory and language can be deepened through interactive visual storytelling. Through the exploration of Australian colloquial language, specifically that of my grandfather Rodney Bates, this project explores how memories of slang are connected, passed down, and presented through visual communication. During this project, I conducted research on Australian slang and its origins, to see how my Grandfather's sayings that he has passed down, contribute to the history and patterns in Australian geographical language. As language is a fundamental pillar in Australian culture and identity, Australian slang, therefore, is a series of odd expressions and sayings that are shaped by the culture itself, as it is shared between people in a conversation. I created a matching card game, featuring my grandfather's odd and unique Australian slang that I grew up hearing, to share with others the lens through which he sees the world, and to further explore the origins of these phrases. Using the memory card game as an informative teaching tool, this structure allows for the experience of repeated cultural slang to be repackaged in a storytelling format. This project serves as an opportunity to explore the connections that are made between culture, memory, and language, exploring new ways to engage with histories of cultural colloquialisms. By reimagining the memory card game as a visual storytelling device, this project asserts that

engagement with memory and language in an experiential, impactful, and vibrant format lowers the barrier for cultural history education.

Abstract Name: Delay and Disrupt: Defending the Fulda Gap in the Age of Mobile Defense

During the final decades of the Cold War, both NATO and the Warsaw Pact prepared extensively for a conflict that neither side sought to initiate. Nowhere was this tension more concentrated than the Fulda Gap, a lowland corridor in central West Germany that war planners theorized would be the most direct invasion route for Soviet forces into Western Europe. By the 1980s, NATO strategy for defending the Fulda sector was no longer centered around immediate nuclear escalation as it was in the 1950s. By this point, NATO doctrine had shifted towards a conventional, mobility-focused defense. Through this, NATO war planners hoped that Western forces could make up for their numerical inferiority by delaying and counterattacking against Soviet formations, bringing a Soviet advance into West Germany to a halt. The introduction of mobile defense doctrine and eventually AirLand Battle demonstrates how NATO sought to maintain battlefield initiative through decentralized maneuvers, working to create conditions for rapid counteroffensive despite overwhelming Soviet numbers. Fulda itself represented NATO's dilemma of halting a massive conventional attack without risking greater nuclear escalation, as even mid-level officers could be tempted to summon atomic artillery support or tactical nuclear strikes if they feared their position was being overrun. In the end, the defense of the Fulda Gap embodied deterrence theory, signaling to Soviet leaders that an invasion of Western Europe would be costly, and ultimately unwinnable.

Abstract Name: Impact of Experiential Learning: Elevating Student Soft Skills

Experiential learning is an impactful and innovative type of learning that allows students to have a hands-on approach to earning their education. This allows students to develop and reinforce skills that connect education, career, and character (Kolb, 2015). At Minnesota State University, Mankato, business students are given the option to participate in experiential learning through the Integrated Business Experience (IBE). This distinctive, high-impact learning experience equips students with essential business skills in areas such as marketing, finance, and operations management. However, beyond these technical skills, many students enter the workforce lacking strong soft skills (Tulgan, 2015). This research aims to explore the impact of the IBE on students' soft skills, specifically efficacy, hope, optimism, and resiliency. To assess this, we will analyze existing data collected in a required Introduction to Business course taken by all College of Business students, comparing results between students who have completed the IBE certificate and those who have not. We will compare the results between students who have completed the Integrated Business Experience certificate and those who have not. This comparison will help determine which soft skills students may be

developing through experiential learning experiences that they might not have acquired otherwise. IBE provides structured opportunities to practice and refine soft skills in real-world business scenarios; we hypothesize that participation in the program positively influences the development of students' soft skills.

Abstract Name: Evaluating a Microplate Enzymatic Assay for Fructose and Glucose Quantification in Honey

Honey's composition varies widely depending on nectar sources, seasonal changes, and environmental factors. Sugars in honey constitute 80% of its makeup, primarily in the form of fructose and glucose. These sugars influence honey's rate of crystallization and its nutritional characteristics, providing valuable information about longevity to producers and health benefits to consumers. Conventional techniques such as high-performance liquid chromatography (HPLC) provide precise and detailed quantification; however, they require costly instrumentation and extensive training, making them impractical for high-throughput analysis. Alternatively, enzymatic assays based on the spectrophotometric detection of NADH are selective and sensitive, enabling their use in sugar quantification in fruits as a cost-effective method. Despite this, the performance of these enzymic assays with complex matrices such as honey has not been fully explored. The objective of this study is to evaluate the performance of a commercial enzymatic assay kit to quantify fructose and glucose content when adapted to a 96-well microplate format. Honey alloys were created with controlled fructose to glucose ratios to represent the variation of honey composition while providing direct sugar profiles to assess the method. The initial findings suggest that the enzymatic assay produces consistent measurements across the tested ratios. Ultimately, these results support the use of microplate enzymatic assays as an alternative to traditional quantitative methods and for routine sugar analysis in honey research.

Abstract Name: Evaluating Barium Sulfate Blended polycaprolactone (PCL) for Endovascular Implants

The poster presents the study and evaluation Barium Sulfate Blended polycaprolactone (PCL) samples for radiographic visibility and biocompatibility for potential use in endovascular implants such flow diverters in the treatment of intracranial aneurysms. In spite of adaptability and complementary degradation characteristics, PCL cannot be visualized during X-rays and angiographic procedures, which is critical for endovascular intervention, due to the absence of radiopacity. Barium Sulfate (BaSO_4), a radiopaque additive, was mixed in various ratios into the medical grade PCL granular and blended in the hot extrusion process to fabricate 3D printing filament. The BaSO_4 - PCL filaments were then evaluated and compared under hand-

held X-ray machine to find optimum combination of BaSO₄ and PCL. The highest radiographically visible filaments were used to 3D print 10 mm x 10 mm x 1 mm samples. The control samples were 3D printed using medical grade PCL filaments. The samples were then evaluated for biocompatibility using Human umbilical vein endothelial cells (HUVECs). HUVECs were prepared at approximately 1×10^5 cells/ml. The cells were cultured on the blended and control samples for 48 hrs with period media changes. After culturing and reaching confluence, samples were fixed and stained to evaluate cell adhesion, morphology, and cytoskeleton organization, and integrity of tight junctions. To quantify metabolic activity across different conditions of material the Click-stain assay was conducted. The results show that the BaSO₄-PCL samples support normal endothelial attachment, healthy cytoskeletal organization, and intact tight-junction formation compared to pure PCL. The results also show that BaSO₄-PCL samples are visible in x-ray image. The study shows that BaSO₄ blended PCL can be used radiographically trackable as well as biocompatible material for potential applications of endovascular implants and devices.

Abstract Name: Cellular Evaluation of Ta₂O₅ Blended Polycaprolactone for Biomedical application

This research investigates the development and biological evaluation of a novel tantalum oxide (Ta₂O₅) blended polycaprolactone (PCL) samples for potential use in endovascular bioresorbable flow diverters for brain aneurysm treatment. Tantalum oxide (Ta₂O₅) blended with medical grade polycaprolactone (PCL) filament was fabricated using hot extrusion process. The blended filament was then used to prepare 10 mm by 10 mm samples for biocompatibility experiments with Human Umbilical Vein Endothelial Cells (HUVECs). The control samples were made from pure medical grade PCL filaments. Human umbilical vein endothelial cells (HUVECs) were seeded on each material and cultured until full confluency. HUVECs were prepared at a working concentration of 9.6×10^5 cells/mL, which corresponded 167 μ L of the cell suspension was seeded onto each sample. Cells were cultured in 24-well plates containing the Ta₂O₅-PCL samples or PCL controls and maintained for 48 hours, allowing them to reach full confluency on the material surfaces. Following culture, samples were fixed and stained using ZO-1 (tight junction marker) and Pycam 1 to assess cytoskeletal alignment, cellular adhesion, and tight junction integrity. A Click-stain assay was used to evaluate cell proliferation and metabolic activity, providing quantitative measures of biocompatibility. The samples were examined using confocal fluorescence microscopy (Nikon Eclipse Ti2 system). The cell viability, proliferation and adhesion were quantified. The results were compared between the blended samples and controls. The results showed that Ta₂O₅-PCL samples demonstrated strong endothelial adhesion, preserved tight junctions, and healthy cytoskeletal organization comparable to control PCL samples. Also, Ta₂O₅-PCL samples are visible under the x-ray images. In conclusion, the Ta₂O₅-PCL blended material shows strong potential as a safe, bioresorbable, and radiographically visible alternative materials to existing metallic or polymer based endovascular implants. However, in-vivo studies will be needed to confirm these outcomes.

Abstract Name: Title: Behavior Analysis of Amazonian Mammals and Bird Species Along a Disturbance Gradient

Understanding how animals respond to environmental change is essential for interpreting population dynamics and developing effective conservation strategies. While most research focuses on species presence or absence, these data alone do not show how animals use their environment such as where they forage or carry young rather than simply passing by. To address this gap, this study uses camera-trap data from the Amazon rainforest along a disturbance gradient ;segmented fragments, secondary, and primary forest to investigate how mammals and birds interact with these habitats through foraging and parenting behaviors. This study analyzed animal behaviors captured by 40 camera traps generating over 10,000 images in the Brazilian state of Amazonas near Manaus. The camera traps recorded a diverse set of mammals and birds. Species identification was assisted by artificial intelligence, but behavioral classification required manual input. Statistical analyses, including single-factor ANOVA tests, were used to compare counts of foraging and parenting behaviors across habitat types. Species were also grouped by diet type. By examining behavioral patterns among forest types and diet groups, the study aimed to clarify how habitat conditions influence ecological activity. Foraging behavior was recorded in 23 species with 339 observations, while parenting behavior occurred in 5 species with 28 observations. Analyses showed no significant difference in either foraging or parenting behavior across forest types within species. However, diet type had a significant effect on foraging frequency. A Tukey test revealed that frugivorous species forage significantly more often than herbivores, suggesting a dietary influence on habitat use. Although we expected undisturbed primary forests to support more frequent foraging or parenting, no significant differences were found among habitat types. This indicates that primary, secondary, and segmented forests may all function as effective habitats for the species observed. Even disturbed forests may still provide suitable ecological conditions for certain animals.

Abstract Name: Lived Experiences of Black Girls in an Urban Environment

Adopting an asset-based approach, this poster highlights the existing strengths and skills of young Black girls and the resources available in their communities. We present findings from a city-wide report using a mixed-methods approach, including online surveys, focus groups with Black girls aged 12-17, and interviews with parents, guardians, and emerging adult Black women, to examine their experiences through a positivist framework. This study complements the emerging field of Black Girlhood Studies (BGS), which showcases the full humanity of Black girls and girlhood (Apugo, Castro, & Dougherty, 2022), and presents my work as an undergraduate researcher on an exploratory study of the lived experiences of young Black girls in an urban environment. Guided by a Scholarly Personal Narrative (SPN) orientation, the poster integrates insights from my lived experiences with the study's findings to illustrate how both can serve as tools to empower the growth, development, and future opportunities for Black girls. The results of this study underscore the role of friendships, family support, mentors, and accessible community spaces and programs

in shaping how young Black girls feel supported and capable of thriving at the micro (self), mezzo (community), and macro (policies and systems) levels. This poster also highlights the contributions of the community partner in developing and sustaining this work. Together, the results are useful to policymakers, stakeholders, and community leaders, enabling them to better support the needs and interests of young Black girls.

Abstract Name: Fishing as a Feud: GIS Analysis of Turkish Commercial Activity and Maritime Conflict in the Kastellorizo Archipelago

Resource scarcity in the Eastern Mediterranean has intensified competition among commercial fleets and reignited boundary disputes between regional states. Turkish vessels operating near Greece and Cyprus navigate overlapping jurisdictions, turning maritime space into a zone where economic extraction and political signaling intersect. Building on existing research connecting fisheries governance and geopolitical influence, this study examines whether Turkish commercial fishing from 2020 to 2025 contributes to maritime conflict and diplomatic escalation within the Kastellorizo archipelago. This study hypothesizes that increased vessel concentration near contested borders corresponds with higher enforcement activity and moments of political tension, revealing how fleet behavior expresses national power. Geospatial data from the National Oceanic and Atmospheric Administration (NOAA), Global Fishing Watch (GFW), the International Commission for the Conservation of Atlantic Tunas (ICCAT), and the European Union Naval Force (EU NAVFOR) combine into a single database linking vessel movement, ecological conditions, and enforcement records. Quantitative modeling in ArcGIS Pro and R measures correlations between vessel density, ecological stress, and enforcement events to test the connection between commercial activity and maritime control. The project's significance lies in demonstrating how spatial evidence can expose the geopolitical dimensions of resource competition in the Eastern Mediterranean.

Abstract Name: Advanced Green Hydrogen Generation: Standardization for Proton-Conducting SOEC Electrolyte Fabrication

Green hydrogen, a clean fuel, can be produced using solid oxide electrolysis cells (SOECs), which utilize electrical energy to drive a non-spontaneous chemical reaction. One of the main benefits of green hydrogen produced with SOECs is that it offers a highly efficient and environmentally friendly way to produce energy. The electrolyte component of SOECs is important for improving durability of the whole cell and preventing electricity leakage. Standardizing and optimizing the process of electrolyte pellet fabrication will aid in creating a foundation for improving SOEC's performance. The current procedure for pellet fabrication is

extremely time consuming with varied conductivity among batches. Alterations such as removing the planetary ball mill cycle, lowering the calcination temperature, and testing additional sintering aids have been implemented to have consistent pellet conductivity and minimize the length of fabrication. Electrochemical Impedance Spectroscopy (EIS) provided data to determine the conductivity of the pellets. The original pellet fabrication procedure resulted in the variation of conductivity between electrolytes being 9.322%. By following the previous procedure with one fewer planetary ball mill cycle, the variation of conductivity between electrolytes was reduced to 0.682%. Additional simplified procedures are currently being evaluated to identify the approach that yields the least variation in conductivity. Overall, this work not only simplifies lab procedures but plays a significant role in the strides to produce a standardized procedure and improve conductivity of electrolyte pellets. For future work, the addition of Pyrolytic Boron Nitride-Oxide (PBN-O) coating and optimizing an Atomic Layer Deposition (ALD) process will further improve the performance of the SOECs. PBN-O coating enhances electrode stability and conductivity, while Atomic Layer Deposition (ALD) enables precise, uniform thin-film application to improve interfacial performance.

Abstract Name: An Evaluation of Artificial Intelligence's Classification and Detection Accuracy for Camera Trap Photos

Prior ecological research has used the camera trap method to estimate animal habitat use, activity patterns, and population density. We began a camera-trap study on a 60-acre field site near the University of Kentucky to assess its wildlife population; however, in under 12 months, these camera traps produced tens of thousands of photos. To evaluate them quickly, we used artificial intelligence (AI) to detect animal presence and classify species. The purpose of our study was to evaluate the effectiveness of the Megadector AI, a popular conservation AI program, in classifying and detecting animals within our camera trap photos. To do this, we took a subset of 8,000 out of our data of over 50,000 photos and identified each species by hand. We then ran those same 8,000 photos through Megadector AI and compared the results. Our results determined that Megadector AI reliably detected the presence of animals, but the classification of species depended primarily on the confidence threshold of the AI. Specifically, the higher the confidence threshold of the AI, the higher the classification accuracy. In addition to this, we evaluated whether different variables, such as season, habitat (forest or field), and time of day, impacted effectiveness. We did not find substantial evidence to validate these claims ($p > .05$). In conclusion, our findings indicate that future studies utilizing Megadector AI should ensure that the confidence threshold of the AI is high. This will allow for more accuracy in the AI in classifying species within camera trap photos.

Abstract Name: Refining GEMS: Validating TESS M-Dwarf Giant Planet Candidates with ZTF and ASAS-SN

The Transiting Exoplanet Survey Satellite (TESS) has collected a large sample of transiting exoplanet candidates. The Searching for Giant Exoplanets around M-dwarf Stars (GEMS) survey utilizes the TESS catalog with an emphasis on finding giant exoplanets around M-dwarf stars and has identified a large number of candidates (greater than 100). These objects are of interest as they give insight into the formation and evolution of low-mass star systems originally thought to not contain the required mass to form. Working in conjunction with the GEMS survey, we present a method of eliminating non-planetary signals from the GEMS survey using a Python script developed for this project to analyze public observational data from the Zwicky Transient Facility (ZTF) and the All-Sky Automated Survey for Supernovae (ASAS-SN). We use this code to gather data from ZTF and ASAS-SN containing observation date, magnitude and/or flux, and coordinates. With this data and code, we then produce phase-folded light curves of GEMS targets and corresponding nearby objects to determine the validity of a possible transit signal on the GEMS target. We aim to produce a large population of giant planets around M-dwarf stars on which further research and investigation can be done. Here we present our findings of positive and false positive transit signals, creating a more refined GEMS candidate population.

Abstract Name: Strong Long-Term Relationship Between Chloride and Dissolved Organic Carbon Export in Road Salt-Affected Exurban and Suburban Watersheds

Road salts and salt-impacted runoff are often transported to the side of the road, where sodium (Na^+) and chloride (Cl^-) can infiltrate the soil, leach into groundwater, and slowly release into streams over time leading to a long-term increase in waterways. However, deposition of Na^+ in roadside soils alters can cause displacement of calcium and magnesium, leading to a decrease in soil aggregate stability in the process of releasing organic matter. While lab and limited field studies suggest an influx of road salt to roadside soils can lead to pulses of dissolved (DOC) delivery from soils and groundwater to streams, few to no studies have examined the long-term relationship of these parameters in road salt affected watersheds. To address these knowledge gaps, a 20-year dataset (1999-2019) of monthly streamwater quality data combined with daily streamflow for six exurban and suburban watersheds in southeastern Pennsylvania is used to assess the co-relationship between flow-normalized Cl^- and DOC concentrations. The relationship between long-term land management practices and DOC concentrations and loads is also explored. Similar patterns were observed in the study watersheds, with a flow normalized Cl^- and DOC initially increasing, with DOC reaching an inflection point, and then subsequently decreasing. Over the last 10 years of the study period, a strong negative statistically significant relationship was observed between flow-normalized Cl^- and DOC concentrations, suggesting a decrease over time of organic matter in upstream roadside soils. The subsequent decrease in flow-normalized DOC concentrations was not statistically linked to any LULC changes over the study period. The study results have implications for watershed management. For example, road salt driven increases in streamwater DOC concentrations can increase the potential for disinfection byproducts during the water treatment process. Conversely, a subsequent decrease in DOC concentrations can negatively impact microbial process and marine food webs.

Abstract Name: Displacement, Financialization, and the NIMBY/YIMBY Divide: Capturing the Political Conversation Surrounding Housing in Milwaukee

Housing has been a hot topic of debate in Milwaukee, a renter-dominated city struggling with unaffordable rents, a declining tax base, and high levels of outside investment. Despite attempts made by private stakeholders, public groups and figures, and city government to address this housing crisis, through means such as affordable housing complexes, zoning code overhauls, or state-level legislation, little progress has been made to truly address the problem. When these measures fail, the first ones to get blamed are the NIMBYs, or “Not In My Backyard” crowd. The NIMBYs purportedly aim to prevent change in their neighborhoods by any means necessary, stemming from calls for aesthetic preservation or fears stemming from racism and classism...but is this blockade against progress truly the fault of an archetypal crowd of white, conservative, and wealthy suburbanites? Through an examination of journalistic materials, the City of Milwaukee’s Legistar city meeting archives, social media, and public testimony, this research has revealed that the answer in Milwaukee is far more complex, and often presents in a more bipartisan fashion than expected. The concerns of opponents ranged from calls for environmental justice, the potential for gentrification and displacement, a real fear of outside investment, and the struggle between the private and public interest. The aim of this project, as it moves forward, is to help cement understanding of the issues surrounding urban governments attempting to address the housing crisis, with the goal to expand our analysis further into the Milwaukee metropolitan area to better understand this issue from the suburban perspective.

Abstract Name: Intercomparing PBL Height and Stability Metrics over a Coastal Urban Bay

The planetary boundary layer (PBL) governs near-surface stability and therefore pollutant dispersion over coastal urban regions such as Hampton Roads and the Lower Chesapeake Bay. Building on prior work that inferred PBL structure from potential temperature and relative humidity, we analyze radiosonde soundings over the Hampton Roads area and intercompare six complementary stability diagnostics: relative humidity, potential temperature (θ), specific humidity, atmospheric refractivity, the bulk Richardson number, and a parcel (buoyancy) method. For each metric, we estimate PBL height and characterize stability, then quantify cross-method consistency and divergence. This multi-method framework highlights the conditions under which moisture-based versus thermodynamic and dynamical approaches provide the most reliable signals of PBL stability, and it clarifies how methodological choices affect inferred mixing depths. The results provide a basis for selecting stability indicators in coastal applications and improve interpretation of boundary-layer controls on pollutant dispersion and air-quality variability across Lower Chesapeake Bay.

Abstract Name: The Impact of Informative Intervention: Promoting Physical Activity to Increase Mental Wellness in Adolescents

Background and Significance: The adolescent population is experiencing increased rates of mental health issues such as depression, anxiety, and stress, which has now led to a national crisis. Although multiple research studies show a positive correlation between increased physical activity and mental health outcomes, there is still a lack of awareness and knowledge of these benefits in the adolescent population. Aim: This evidence-based project aims to implement an informative intervention designed to promote physical activity to improve mental health in adolescents. Method: The method chosen is an informational session with four weeks of weekly structured educational presentations, interactive workshops, and guided physical activity engagement to promote exercise and reflection on mental well-being. During this intervention, students will be able to expand their knowledge of the benefits of exercise on mental health and get opportunities to engage in group-led activities and peer discussions, as well as the opportunity to explore their mental health and mood improvements. Pre- and post-intervention surveys will be utilized to assess changes in activity levels, emotional states, and overall mood. George Engel's biopsychosocial model is used to address the biological, psychological, and social aspects that affect overall adolescent health. Conclusion: The goal of this project is to increase awareness, knowledge, and motivation to use physical activity as an accessible, affordable, and effective mental health option. The findings of this project could potentially influence future efforts in school settings to improve mental health support and resources for adolescents. Keywords: Adolescents, mental health, physical activity, informational session, health promotion.

Abstract Name: Competence & Relatedness Need Satisfaction Through Conflict Resolution & Relationship Themes in Narrative Media

The effect of motivation through media has been grounded through Self-Determination Theory (SDT), which identifies three intrinsic needs of competence, relatedness, and autonomy as driving human behavior. The current research examines the following research questions: 1) How are conflict resolution themes within self-reported summaries of TV show plots related to participant competence need satisfaction? 2) How are relationship themes in these summaries related to perceived character relatedness need satisfaction and participant relatedness need satisfaction? Survey data was collected through Prolific and included 321 participants. All participants were asked to report summaries of the most recent television episode they had watched and the main character from the reported show. Additionally, participants reported how they felt their own competence and relatedness needs were satisfied, as well as the satisfaction of the TV show character's relatedness needs. Reported plot summaries will be coded based on the prominence and valence of conflict resolution and relationship perception themes. Bivariate correlation models will be used to assess relationships between competence need satisfaction and conflict resolution themes, as well as relatedness need satisfaction and relationship perception themes. We expect positive conflict resolution themes are positively associated with participant competence need satisfaction, and negative conflict resolution themes are negatively associated with participant competence satisfaction. Additionally, we expect positive relationship themes have a significant, positive association with reported perceived TV show character relatedness need satisfaction and participant relatedness need satisfaction. We also expect negative coded relationship themes are negatively associated with both reported perceived TV character relatedness

satisfaction and participant relatedness need satisfaction. Examining these needs through narrative media would provide significant implications in how narrative media can fulfill needs and increase well-being.

Abstract Name: Just-In-Time Outreach: A User Experience Design Strategy for Connecting Students with University Services

Despite research demonstrating that students who utilize tutoring services achieve higher academic outcomes (Alexander et al., 2022; Batz et al., 2015; Bengesai et al., 2023), significant underutilization of these services persists on college campuses (Ciscell et al., 2016; Winograd & Rust, 2014). This user experience design project identifies barriers preventing students from accessing Tutorial Services, informing the development of a generalizable framework for increasing student utilization of these and other university services. The research consisted of one exploratory and one evaluative study. The exploratory study was conducted through fifteen interviews with undergraduate students at a small liberal arts university. Through affinity mapping, recurring patterns and pain points were identified, and findings were synthesized into representative user personas and problem statements. Analysis revealed that students at the university lack awareness of Tutorial Services, particularly transfer students. Based on these findings, the “Just-In-Time Outreach for Tutorial Services” (JITOTS) intervention was designed as a coordinated approach between Tutorial Services and faculty to deliver strategically timed, discipline-specific reminders before critical academic periods. The evaluative study will assess the effectiveness of the JITOTS implementation through pre-appointment surveys with students attending tutoring sessions. Survey questions will ask students how they learned about Tutorial Services, what prompted their decision to schedule an appointment, and whether they are first-time-in-college or transfer students. This data collection approach captures both source attribution (indicating the solution’s utility as a tool for spreading awareness) and key differences in outcomes across student populations (indicating the solution’s particular impact on transfer students’ utilization of Tutorial Services). If successful, the framework will offer scalability to other universities and student-facing departments (ex. a Career Advising office may send timely reminders about internship and position postings by discipline), providing a replicable model for improving service awareness and adoption by supporting student success across different institutional contexts.

Abstract Name: Comparison of Sentiment and Tone in Corporate Risk Disclosures Using AI Tools

While the business world continues to integrate AI into its daily operations, many businesses are hesitant to implement AI due to concerns about lack of human oversight and the accuracy of AI tools. My study examines the competence and effectiveness of popular AI tools in evaluating the sentiment and tone of the "Risk Factors" sections in annual reports of selected major U.S. public companies. Sentiment analysis enables businesses to understand the emotional tone of text by automatically classifying it as positive, negative, or neutral. By evaluating AI tools' ability to interpret complex financial disclosures, my study highlights their strengths and limitations, which helps businesses make informed decisions. I used Microsoft Copilot and Google Gemini to perform the sentiment analysis. Three industries and two competing companies from each industry were selected. The risk factor section from each company 10-K (annual) report was uploaded to both AI tools with identical prompts. The prompts instructed AI to score the negativity of the risk factor section and identify the most frequently used risk-related terms for each company. The outputs were recorded to allow comparisons across companies and industries. I found that the two AI tools provided similar outputs. Microsoft Copilot and Google Gemini reported an average negativity score of 85.33% and 83.45%, respectively. Interestingly, Copilot assigned a higher negativity score than Gemini to three out of the six companies analyzed while Gemini scored higher for the other three. In the risk term frequency analysis, the most frequently reported terms identified by both AI tools aligned with expectations for each industry type. These results support the notion that AI can deliver accurate and consistent results in qualitative analysis.

Abstract Name: Escaping competition through care: *Nicrophorus* parents feed offspring more when competition is high

Parental care is expected to buffer offspring development, yet parenting strategies vary extensively and this variation strongly impacts offspring phenotypes. Why does parental care vary? One possibility is that variation in care is driven by the likelihood of securing future breeding opportunities, where parents in high competition environments invest more in care than parents experiencing low competition. Alternatively, parents may decrease care in competitive environments due to the costs of finding and defending breeding resources. We investigated these ideas in the burying beetle *Nicrophorus sayi*, which shows extended parental care and requires a limited resource - small carrion - to breed. *Nicrophorus sayi* is the first *Nicrophorus* species to emerge from winter diapause. As such, early season beetles experience both lower intra- and inter-specific competition relative to *N. sayi* breeding in late season. We took advantage of this temporal pattern to investigate how competition influences the expression of parental care behavior. Early season parents spent less time feeding offspring, resulting in longer larval developmental periods and larvae that were heavier at dispersal. On the other hand, late season parents fed offspring more, larvae developed faster, and were smaller at dispersal. These results may indicate that late season parents invest more in care behaviors directed towards rapid development of the larvae, potentially to reduce the risks inherent to developing on a coveted resource in a high competition environment.

Abstract Name: Demystifying the Neural Activity of Disordered Eating and Exercise: A Study Using Event-Related Potentials (ERPs)

One in four adolescent girls are affected by disordered eating or weight control, emphasizing the need for further evaluation. Disordered eating and exercise behaviors are often associated with each other and may have distinct neural mechanisms. Electroencephalography (EEG) is a noninvasive means to study brain activity. Event-related potentials (ERPs) are changes to the EEG signal immediately following an external stimulus. In this study, visual stimuli of food, exercise activities, and neutral objects (office supplies, furniture, etc.) were used to evoke ERPs from which the P300 wave was calculated. The P300 wave is a neurophysiological indicator of cognitive function that reflects attention, information processing, and decision making. This ERP has been used in research to investigate anxiety disorders, depression, and Obsessive-Compulsive Disorder (OCD), making it a point of interest while looking at disordered eating and exercise behaviors. Participants (18-25 years old) were recruited through social media, snowball sampling, and targeted emails to complete surveys about their exercise and eating behaviors and opt-in to participating in the EEG portion of the study. Of 141 responses, 91 complete surveys indicated approximately 40% of respondents exhibit behaviors that may elevate their risk of eating disorders or exercise disorders. 11 have completed the EEG, and 8 of their results have been analyzed. EEG analysis showed the strongest P300 responses to exercise images, moderate responses to food images, and the weakest responses to neutral images. These findings show that exercise stimuli evoke greater cognitive and motivational processing, reflecting their heightened relevance in individuals with exercise or body-related attentional biases. Future analysis should correlate EEG findings with individual survey results, which would elucidate the relationship between P300 and disordered eating or exercise behaviors. Overall, this study highlights how neural responses to varying exercise and food cues can reveal meaningful patterns in cognitive and behavioral health.

Abstract Name: Balancing Books and Babies: Barriers to Support for Parenting Students in Higher Education

Background: Parenting students in higher education face unique challenges, including navigating higher education and academics while raising a family, working, and planning for a career. Yet, on campus resources do not always align to support parenting students effectively. In the United States, nearly 20% of undergraduate students have children. Methods: A campus-wide mixed methods survey was distributed at an institution of higher education. A total of 112 parenting students or legal guardians completed the survey. The survey assessed barriers and utilization of institutional and community resources, perceived effectiveness, childcare access, financial support use, and awareness of resources. Results: Early analysis indicates that 53% of parenting students have experienced barriers to accessing resources off-campus and 51% have experienced barriers on-campus. Time scheduling conflicts emerged as the most frequently cited barriers to accessing resources on-campus and off-campus. Discussion: Findings highlight gaps between the needs of parenting students and the support currently provided at UCO. Increased visibility of resources, expansion of childcare

options, increased financial support, and targeted institutional policies may help reduce stress, improve academic outcomes, and foster a more inclusive and family-friendly campus culture. Strengthening support for parenting students benefits not only individual learners but also their families and the broader university community.

Abstract Name: Functional Studies of Surface Protein from Segmented Filamentous Bacteria from Humans

Segmented filamentous bacteria (SFB) are gram-positive, spore-forming bacteria that attach directly to the epithelial cells in the small intestine of animals. They are present during early stages of life in a variety of hosts, including mice, turkeys, and humans. Their primary surface antigen is known to play a role in differentiating the Th-17 cells of the host, but it remains unclear what biological purpose it serves for the SFB. One of the functions of Th-17 cells is to promote the production of antimicrobial peptides (AMPs) used to defend the epithelial cells from invading pathogens. Because of this, we hypothesized that one of the functions of the primary surface antigen discovered on the mice-specific SFB could be to protect bacteria and allow them to live in close proximity to the epithelium unharmed. To test this, we have been expressing separately or co-expressing the main mouse SFB surface antigen (or its homologs from human- and turkey-specific SFB), and selected AMPs from those hosts. Our initial results showed that both proteins, each with a different tag added, could be co-purified on 2 different gravity columns or cross-linked. In silico analysis of complexes indicates the mechanism of protection from AMPs.

Abstract Name: Identifying Rationale and Accuracy in AI Detection

The increasing sophistication of Large Language Models (LLMs) such as ChatGPT, Gemini, and Claude provokes unprecedented challenges against educators upholding academic integrity. Unlike conventional forms of plagiarism, the novelty and diversity of LLM outputs present a unique challenge in detecting academic dishonesty. Students can now use AI tools to produce unique essays that are grammatically and structurally sound while mimicking their own writing style. AI-produced work can also imitate introspection to a degree that makes it indistinguishable from genuine human thought. While AI detection tools like GPTZero and Turnitin are being developed, their accuracy remains ambiguous. The burden of combating academic dishonesty is placed solely on the educator, who must determine whether an essay is AI-generated, with no comprehensive guidance on how to make these determinations. Relevant research on AI detection accuracy has primarily examined obstacles to creative integrity outside the classroom. While this provides a strong foundation for the goal of our study, we hope to build upon this by placing professors in the role of our “human expert judges”, who interact with and are well-versed in the variability of student-submitted work. This study seeks to compare the accuracy of AI detection software such as GPTZero and Turnitin with the judgments of human experts in identifying AI-generated undergraduate essays. Using a dataset of 200 human-

written undergraduate philosophy essays completed in class, we will assess the accuracy of AI detection tools and human educators, examining the justification patterns provided by both in their findings. Our research will demonstrate the accuracy levels of both AI detection mechanisms and illuminate vulnerabilities in the AI-detection process, thereby strengthening educators' strategies for assessing student work.

Abstract Name: Revising Honors for All Hamline Students

Research on collegiate honors programs has increasingly reported underrepresentation of certain demographics, such as race, gender, and first-generation status. The current study builds on this work to explore the causes of this disparity. It employs a mixed-methods approach to examine the representation of students across those various demographic categories. We confirm that students with non-White racial identities and/or first-generation status are 16% less likely to participate in honors. It was found through bivariate analysis that time devotion plays the largest role in the relationship between race or first-generation status and participation. Interestingly, extra effort was not as significant an issue for the mentioned student demographics. The students' differing relationship with those two factors implies that they do not refrain from participation because of the perceived extra effort; rather, they do not have the time in their lives to set aside for the program. Using structural modeling equation analysis revealed that time commitment and extra effort combined account for 41% of the reasoning behind nonparticipation from the mentioned students. Our findings illuminate the mechanisms of underrepresentation in the context of a small liberal arts institution with limited application barriers, which may serve as a guide to institutions with similar honors programs. Furthermore, our study points to tensions in the experience of underserved students in college and the ways that institutions must adapt programming to serve them.

Abstract Name: The relationship between Undergraduate Research Participation and Educational Outcomes

This study examines how participation in funded undergraduate research programs influences student success before and after graduation at Kennesaw State University (KSU). Previous research indicates that undergraduate research engagement enhances critical thinking, hands-on experience, and professional connections, skills that play a vital role in both academic and career advancement. Furthermore, participation in research has been linked to higher rates of employment, graduate school admission, and the development of a strong professional identity. Using retrospective data provided by KSU's Offices of Undergraduate Research and Institutional Research, this study analyzes indicators of pre-graduation success, such as retention and academic progression. To assess post-graduation outcomes, LinkedIn profiles were used to

gather information on employment and further education. The dataset includes 980 students who participated in funded research programs between 2019 and 2024, encompassing initiatives such as the First-Year Scholars Program, the Summer Undergraduate Research Program, and the Peer Ambassadors Program. By exploring the impact of these funded research opportunities, this project aims to identify how undergraduate research experiences contribute to students' professional and educational trajectories. The findings will offer valuable insight into how institutional research programs can better support academic growth, enhance employability, and promote long-term career development among undergraduates.

Abstract Name: Student and Peer Leader Perceptions of Chemistry Workshops

Peer-led team learning (PLTL) is a pedagogy often used in college-level natural science workshops that are held outside of class to deepen student understanding of course content. Workshops are led by more advanced students (i.e., the peers in "peer-led") who had successfully completed the course. This mixed-method research assessed the effectiveness of chemistry workshops. We surveyed students ($N = 31$) taking chemistry classes that use PLTL workshops to determine students' perception of the workshops. We interviewed peer leaders ($N = 5$) to understand what they do in the workshops to engage students and how the workshops could be improved. We interviewed students ($N = 11$) to obtain a more nuanced understanding of students' experiences in the workshops. Results indicated that several elements contribute to the effectiveness of the chemistry workshops. Students reported that feedback provided by the peer leader was invaluable, allowing students to identify areas for improvement and strengthen their understanding of the material. Availability of study materials has enhanced students' study experiences and improved their performance. However, a notable drawback is the lack of communication among the students in the workshop, which hinders collaborative learning opportunities and the exchange of ideas. Encouraging more interaction among students could further enhance the overall effectiveness of the workshops. This study confirmed findings from previous research that showed what students appreciate in PLTL. Results from this research can be used across science classes and at other universities that employ PLTL.

Abstract Name: Academic Motivation

As a college education becomes increasingly more valued in the workforce, it is important to understand the factors that influence a college student's academic motivation. Academic motivation is important for student success, particularly as related to student persistence to graduation. This study examined how imposter syndrome and test anxiety are related to academic motivation. It also scrutinized whether self-efficacy was a

mediating factor in both of these relationships. Undergraduate students (N = 200) completed an online survey with measures of academic motivation, self-efficacy, test anxiety, imposter syndrome, and need for cognition; need for cognition can be considered another form of academic motivation. Results showed that imposter syndrome and test anxiety are significantly related, but neither variable was significantly correlated with academic motivation or need for cognition. However, high levels of self-efficacy were seen to mediate the relationship between imposter syndrome and academic motivation as well as test anxiety and academic motivation. Self-efficacy can decrease feelings of imposter syndrome and test anxiety, thus fortifying academic motivation. This work suggests that improving college student self-efficacy may be more fruitful than attempting to decrease imposter syndrome and test anxiety. This strategy may be an effective path to increasing academic motivation in college students.

Abstract Name: Assessing the Behavioral Effects of Caffeine on the Sleep Cycle in *Drosophila Melanogaster*

Caffeine is a widely consumed substance officially classified as a stimulant because of its significant effects on the human sleep-wake cycle and the central nervous system. Chronic overconsumption of caffeine can lead to the development of tolerance, which may reduce the responsiveness of cAMP and PKA signaling mechanisms. Reduced responsiveness not only impacts the sleep cycle throughout the night, but can also play a role in wakefulness behaviors during the day by increasing alertness at the times of the natural dip. These disruptions can be closely related to dopaminergic activity, which plays a crucial role in arousal, motivation, and reward pathways. This experiment uses *Drosophila melanogaster* as a model system to investigate how caffeine consumption and withdrawal alter dopaminergic activity and the sleep-wake cycle. Two genetic crosses were generated using the Gal4–UAS system to enable flexible and efficient gene manipulation, as well as to allow precise visualization of brain structures in the control group. The manipulation cross consists of offspring containing the 8848 dopaminergic Gal4 gene and the 41753 UAS halorhodopsin gene. The control cross was created from the 8848 dopaminergic Gal4 gene and the 8515 UAS e-GFP gene. Due to the optogenetic experimentation of the manipulation group, the vial was wrapped with aluminum foil to prevent light exposure and handled in a dark environment. The vial contained al-trans-retinol (ATR) food and 0.75mg/ml of caffeine injected into the food source after 3-5 days. Both the manipulation and control were then sent to the *Drosophila* Activity Monitor (DAM) to assess circadian behavior over 48 hours. It is hypothesized that the sleep cycle of the caffeinated *Drosophila* will decrease in the first 24 hours of withdrawal, after the hyperpolarization period in the following 24 hours. The DAM data is currently pending and will be analyzed via linear regression.

Abstract Name: Even Nature Likes To Flash: Predicting Stream Flashiness To Mitigate Flood Events

Flash flooding poses a danger to life and property, so knowing how to accurately calculate and notice trends can help predict areas at risk. While flashiness can now be calculated through discharge patterns—thanks to the Richards-Baker Index (RBI)—this data is not available for the majority of streams. To examine stream flashiness, small (<50 sqmi) drainage basins with a USGS gage across Pennsylvania were selected and environmental factors (i.e. land use, slope, etc.) were examined. R-code was used to gather USGS data and calculate annual RBI averages. Land use was tabulated within each basin using ArcGIS. The results were then put through a linear regression model to test significance. It was found that developed and agriculture land in the state had the greatest influence on flashiness. Temporal data was also analyzed by comparing these factors across the past 25 years. Simulations are currently underway to use these findings in helping support the needs for best management practices (BMPs) across various landscapes. It is expected that BMPs will reduce the risks of flash flood events by manipulating the energy of the flood system. Since it is not feasible to place stream gages in every waterway, understanding the factors and how they influence stream flashiness, along with knowing what BMPs are most suitable, can be important ways to mitigate flash flooding events across all watersheds.

Abstract Name: "Technology that Shaped the Second World War Mechanization in the U.S. Cavalry 1919-1945"

Before the Second World War, many nations experimented with military technology to have the upper hand. The United States was no different, analyzing friend and foe to improve their armored vehicles. But there was great debate within the American military about the role of tanks. In the pages of the Cavalry Journal, the professional forum for cavalry officers, military strategists argued various sides of the issue. My project studies the development of tank doctrine in the Cavalry Journal from 1920 to 1945. I focus on seven writers whose ideas pushed tank doctrine forward in the years before World War II. I use Andrew Feenberg's "substantive" theory of technology to show the politics of tank development. Feenberg argues that even though technology can be a useful tool, it can also control doctrine and change strategy. By analyzing the Cavalry Journal with Feenberg's theory, I show that the debate over armor design improved the U.S. Army's doctrine and strategy. This project shows the impact of technology in the army. It evolved from a tool to serve doctrine to a powerful force that shaped doctrine.

Abstract Name: Evaluating usability of multi-gesture controls in electromyographic upper limb prostheses using single sensor via muscle contraction magnitude

The increased device capabilities of electromyographic (EMG) prostheses may include a tradeoff in usability and training time; this is a topic that remains largely unexplored in established literature. Single-gesture prostheses have high accuracy, but limited capabilities. Incorporating additional gestures, such as a pinch-and-point or peace sign, come with an expected decrease in accuracy, as users need to flex at specific intensities to trigger targeted gestures. This study evaluated performance and perceptions of a multi-gesture EMG control system using a novel training application to establish what an attainable regimen may look like for a novice user. The training application was connected with Bluetooth to a tablet and controlled via a surface EMG sensor to register and display flexion strength in-game. Participants were divided into cohorts, each using the training instrument with a different number of zones. Each zone represented a distinct threshold of flexion strength that corresponded to a different gesture on the prosthesis. The training app prompted the user to flex so that their peak flexion would reach within a specified zone, outlined with a green highlight. These cues were randomized to test user accuracy in reaching varied flexion strengths. To measure accuracy, participants received one point for every correct response. In addition to accuracy scoring, the System Usability Scale (SUS) and NASA Task Load Index (NASA-TLX) were collected outcomes. Data analysis showed that accuracy scoring decreased as more zones were added, which was consistent with previous literature and expectations. Usability scores differed across cohorts, but remained highest among users training through the progressive cohort. Cognitive workload increased with more zones. These findings support the possibility of implementing up to three gestures with a progressive mode of training. This strikes a balance that increases device capabilities while retaining accuracy and high perceived usability.

Abstract Name: Quenching Modes of Explosive Analogs with Perylene

Chemical explosives are commonly found associated with crime scenes and as waste products in water sources. Residues of explosives threaten environmental safety and homeland security. Detection of explosives is instrumental in protecting the health of individuals and the environment, and it can aid investigators with early leads in criminal cases. The ability to detect explosives on-site can help solve investigations and environmental issues at a faster rate, compared to central laboratories, which could take months to process samples due to backlog. When explosives are combined with compounds that normally fluoresce (emit light), the intensity of the fluorescence decreases – this is called quenching. The level of quenching can be used to determine the amount of explosive present. A Stern-Volmer plot is created, which measures quenching vs concentration of quencher added. Nonlinearity in these plots is typically due to a transition between different modes of quenching (dynamic or static). It is necessary to investigate the concentration ranges of the explosive to find which concentrations are important for each quenching mode. A method called time-correlated single photon counting (TCSPC) is used to estimate the decay time of fluorophores. This study investigated quenching of mono-, di-, and tri- nitrophenols and nitrotoluenes. Identifiable trends were

observed in how the explosive analogs quenched fluorescence with perylene as the fluorophore. It was found that nitrophenols are more effective quenchers than nitrotoluenes and can be detected at lower concentrations, and the more nitrate groups on an explosive, the better it is at quenching. Explosives that demonstrated both quenching modes showed dynamic occurred at all concentrations, while static occurred only at higher concentrations. The next steps will involve testing these explosive analogs with a different fluorophore, DPA (Diphenylanthracene), followed by a broader comparison with the perylene results.

Abstract Name: Can Subsampling Replace Full Particle Analysis? A Validation Study for Microplastic Identification

Consistent microplastic (MP) quantification often relies on the assumption that a small subsample of particles can accurately represent the full sample. This study evaluates the validity of extrapolating MP identification results from particle counts by comparing analyses conducted on 10-100% of the total particles from the sand beach sample from Columbia. A total of 1,093 potential MP particles were examined using spectroscopy identification (FTIR-ATR). Statistical evaluation revealed that MP particles within samples are not homogeneously distributed, leading to variability in polymer type and abundance at lower subsampling levels. Our analysis shows that extrapolations based on subsampling become meaningfully reliable only when at least 60% of the total particles are analyzed, corresponding to approximately 75% confidence in accurately predicting full sample composition. These findings indicate that small subsamples (e.g., 10%) are insufficiently representative, and substantial subsampling is required to minimize uncertainty. This work highlights the need for an evidence-based subsampling threshold to improve data quality in MP research and support more accurate reporting of environmental MP burdens.

Abstract Name: Characterizing the human burial signatures using ground penetrating radar: A case study on Agua Mansa Pioneer Cemetery

This research is a continuation of Understanding the human burial signatures using ground penetrating radar (GPR): A case study on Agua Mansa Pioneer Cemetery. Data obtained from surface geophysical surveys via ground penetrating radar (GPR) are being used to identify, characterize, and understand the burial signatures at the Agua Mansa Pioneer cemetery. The Agua Mansa settlement was established in the 1830s by settlers from Abiquiu, New Mexico. It was a prevalent farming settlement until 1862 when a flood destroyed most of the settlement. The cemetery survived the flood due to its location on a hilltop; most of its destruction came

in the early 1900s from vandalism as well as a fire in the late 1900s which burned any wooden grave markers. This 6.3-acre pioneer cemetery in Colton, California actively buried from 1854-1963. The site consists of the ruins of an old church, a replica church, and approximately 2,000 human burials. Out of the 2,000 burials, only a few hundred still have grave markers. Data obtained at this site uses GPR, a non-invasive geophysical technique that utilizes electromagnetic waves to map the subsurface to indicate locations of unmarked burials by analyzing the signal characteristics that correlate with marked burial signatures. This project focuses on expanding data acquisition to the entire site and processing data to accurately identify and characterize anomalies related to burials and distinguish them from other anomalies not related to the burials. Results of this project include possible locations of unmarked graves characterized by high amplitude reflectivity in 3D surface maps.

Abstract Name: Fool me once, shame on you: Understanding and Preventing Psychological Exploits in Cybercrime

Scammers increasingly exploit psychological vulnerabilities and software design weaknesses to deceive users across trusted platforms. This study examines whether stress levels, impulsivity, and online behaviors increase young adults' susceptibility to phishing attacks, even when they are aware of scams. Young adults frequently navigate emotionally intense periods, such as job searches, financial deadlines, and academic stress, which may heighten their vulnerability. This research also evaluates whether theory-based warning messages specifically, inoculation-style interventions, can reduce phishing susceptibility during these heightened emotional states. Grounded in the Heuristic-Systematic Model (HSM) and Cyber-Routine Activity Theory (Cyber-RAT), the study investigates how emotional states influence decision-making and whether attackers intentionally target users during known vulnerable periods. Participants first complete a pre-survey assessing emotional state, online behavior, and prior phishing exposure. They are then randomly assigned to receive either no warning, a generic tip, or a targeted inoculation message designed to build resistance against phishing attempts. Following this, participants complete a simulated phishing task using emotionally charged emails, such as fake job offers or tuition warnings, to measure trust and response likelihood. It is hypothesized that participants experiencing higher stress will demonstrate greater vulnerability, especially when the phishing content aligns with their personal circumstances. It is further expected that those receiving an inoculation message will show greater resistance to phishing attempts. By combining emotional psychology, digital behavior, and preventive interventions, this study offers a novel perspective on phishing susceptibility. Findings may inform the development of real-time awareness tools and emotionally responsive phishing education programs tailored to young adults.

Abstract Name: Living Unapologetically: LGBTQ+ Coming Out in Midlife and Beyond

While much of the research on LGBTQ+ identity development focuses on adolescents and young adults, a

growing number of individuals are discovering or embracing their queer identities well into adulthood. This study explores the experiences of LGBTQ+ individuals who came out at age 35 or older, with the goal of understanding the psychological, social, and cultural factors influencing later-in-life self-discovery. Through qualitative interviews with participants across the United States, this project investigates common themes such as internalized stigma, family expectations, religion, relationship dynamics, and access to affirming spaces. Preliminary findings suggest that individuals who come out in midlife often face unique barriers—many shaped by heteronormative pressures during formative years—but also report profound personal transformation. Despite grief over lost time or past relationships, participants frequently described a sense of freedom, relief, and renewed authenticity. Many highlighted the lack of representation and resources tailored to older LGBTQ+ individuals, noting how support networks and mental health services often assume earlier identity development. This research emphasizes the need for inclusive approaches in both policy and practice—ones that acknowledge and validate LGBTQ+ journeys across the lifespan. The study also calls attention to a gap in public discourse, where late-blooming narratives are often overlooked. By centering the voices of those coming out in midlife and beyond, this work aims to challenge ageist assumptions and expand understandings of queer identity formation. Attendees of this presentation will gain insight into the lived experiences of older LGBTQ+ adults, as well as recommendations for creating more affirming, inclusive environments across clinical, academic, and community settings. This project is ongoing and supported by the RCSA program at the University of Central Oklahoma.

Abstract Name: The Impact Of Social Media On Self-Perception And Mental Health In Young Adults

This study explores how social media affects the psychological well-being and body image of young adults aged 18 to 28—a group especially vulnerable to online pressures and unrealistic visual standards. As image-focused platforms continue to shape what people believe they “should” look like, it becomes increasingly important to understand how these experiences contribute to self-objectification, low confidence, and other mental health concerns among both males and females. Gaining insight into these patterns can help support the development of practical, gender-inclusive strategies that encourage healthier online habits and greater self-acceptance. To investigate this issue, the study used a mixed-methods design by combining a systematic review of existing research with a qualitative survey completed anonymously by participants ages 18–28. The survey collected primary data about self-perception, body satisfaction, and online behavior. Descriptive statistics and several inferential tests were used to analyze gender differences, the influence of various platforms, and connections between time spent online and changes in body satisfaction. All research procedures followed strict ethical standards approved by the IRB to protect participant privacy and well-being. A total of 79 valid responses were included in the final analysis. Results showed that both males and females experience similar levels of body dissatisfaction—directly challenging the common assumption that women are significantly more affected. In fact, 78.6% of all participants reported feeling unhappy with their bodies due to comparison on visual platforms such as TikTok and Instagram. Notably, young men reported a particularly strong loss of confidence linked to these comparisons. Overall, the study confirms that digital comparison, especially on image-heavy apps, plays a major role in lowering body satisfaction. These findings highlight the urgent need for mental health interventions that address body dissatisfaction as a shared experience and support young adults of all genders in developing healthier relationships with social media.

Abstract Name: Associations Between Parental Weight Concern and Motivation for Change in a Family Healthy Lifestyle Program

Background: Prior research shows that caregiver concern and perceived importance of change influence intervention engagement. This project aims to examine how these factors influence caregiver engagement and participation in the NOURISHT+ study. Methods: The current study analyzed baseline data collected from 241 caregivers of pediatric cancer survivors with overweight/obesity enrolled in a randomized control trial of a behavioral intervention focused on nutrition and physical activity. Caregivers completed questions assessing their concern about their child's current weight, their perceived importance of making healthy behavior changes, confidence in meeting nutrition and activity goals, and readiness to participate in the program. A multivariate analysis of variance (MANOVA) was conducted to examine the effect of caregiver concern about their child's weight on these three indicators of engagement. Results: Participants primarily identified as female (93%) with an average age of 39.62 years (SD = 8.25). There was a significant overall effect of caregiver concern about their child's weight on engagement indicators, $F(12, 708) = 5.32, p < .001$. Follow-up analyses indicated that higher concern about the child's weight was associated with greater reported importance of making healthy behavior changes, $F(4, 236) = 10.83, p < .001$, and higher readiness to participate in the program, $F(4, 236) = 3.42, p = .010$. No significant effect was observed for confidence in meeting nutrition and activity goals. Conclusion: Higher caregiver concern on child's weight was associated with motivation to engage in change but not with confidence. Future intervention studies may incorporate strategies to improve caregiver confidence.

Abstract Name: Does flower abundance or color influence insect visitation to species in the daisy family (Asteraceae) on cedar glades of Middle Tennessee?

Flower traits such as color and odor influence interactions between insect visitors (pollinators) and plants. Vibrant colors act as reward signals for visually oriented insects when nectar foraging. However, flower abundance is also an important factor in visitation, with dense patches attracting visitors due to the likelihood of providing an abundance of nectar. This project was designed to test whether flower color or abundance plays a greater role in insect visitation rates during the summer versus autumn flowering seasons. Plots of flowers varying in color and abundance were selected at Flat Rock Cedar Glades and Barrens State Natural Area near Murfreesboro in Rutherford County, Tennessee. Visitation surveys were conducted hourly between 10:00 am and 4:00 pm, 5-6 days per week in July-August and October 2025, documenting plant species, flower color and abundance, insect species, and the number of visiting insects. Unidentified insects in the field were collected and examined in the laboratory. The data were converted to a visitation rate as the number of insects per flower head per hour. A wide variety of insect taxa visited the plants, but insect diversity was higher during summer than autumn. During both flowering seasons, the most abundant flowers had relatively low visitors. In contrast, plants with low flower production had relatively high visitation rates: colored purple or yellow in summer and purple or white in autumn. These discoveries emphasize the importance of floral traits in attracting pollinators, which can ultimately shape plant reproductive success.

Understanding pollinator preferences can offer valuable insight and inform future research on pollination ecology.

Abstract Name: Development of Artificial Metalloenzymes To Study Bioinorganic Cofactor Systems

Artificial metalloenzymes (ArMs) integrate metal-based reactivity within a protein framework, bridging bioinorganic and enzymatic catalysis. Among ArM platforms, the biotin-streptavidin system has proven particularly powerful due to its remarkable affinity ($K_d \approx 10^{-15}$ M) and structural stability, providing a versatile host for incorporating synthetic cofactors. This project explores the potential of the biotin-streptavidin scaffold to serve as a model system for studying bioinorganic cofactors and the influence of the protein environment on metal center behavior. The primary objective was to establish foundational methods for protein expression, purification, and preparation of a streptavidin variant suitable for cofactor incorporation. Streptavidin was expressed in *E. coli*, purified through affinity chromatography, and will eventually be evaluated for crystallization under varying buffer and pH conditions. In parallel, biotinylated cofactors were explored as potential anchoring groups for introducing metal centers into the protein host. While this study remains in the exploratory phase, it provides critical groundwork for future structure-function analyses and cofactor reconstitution experiments. The biotin-streptavidin framework offers a unique opportunity to investigate how the secondary coordination sphere in hydrogen bonding, electrostatics, and local geometry, can be systematically tuned through protein engineering to modulate metal reactivity. By establishing reliable methods for preparing and characterizing this modular system, this work contributes to a growing toolkit for designing artificial metalloenzymes. The long-term goal is to apply these systems toward understanding natural metallocofactor chemistry and creating novel catalysts that extend beyond nature's repertoire. This project thus lays the experimental and conceptual foundation for future studies at the interface of coordination chemistry and enzymology.

Abstract Name: Big Brother is Watching: The Impact of Digital Authoritarianism on Maintaining Long-Term Political Power, Case Studies of Turkey and Iran

This article examines how the governments of Turkey and Iran use digital authoritarianism to impose their ideologies on their citizens and to remain in power. Due to the shift of focus from news to social media in recent years, governments have been using policies regarding these platforms in order to gain supporters and maintain their political power. By using policy analysis and content analysis I will highlight the ways the governments of Turkey and Iran have used digital authoritarianism and religion to remain in power, and survey data to see the social impacts of these policies. In addition, I will interview a journalist to highlight how digital authoritarianism has affected journalists who do not align with their governments' ideologies. The results are expected to show that governments of Turkey and Iran have been heavily censoring social media content and using surveillance to detain people exercising their freedom of speech. Religious legitimization in politics covers up these policies, and it also helps impose government ideology to the people. These results

suggest that Turkey and Iran shifted their policies regarding remaining in power to digital platforms, and use religion for legitimizing these new policies, which creates self-censorship in the society. This project adds to the new study area of digital authoritarianism by providing a comparative analysis between Turkey and Iran, and highlighting its social impacts. The project also builds a connection between religious legitimization and digital authoritarianism, which has not been studied together.

Abstract Name: Evaluating Enjoyment and Social Connectivity in Gamified Training Designed for Upper Limb Prostheses

Adherence to a recommended training routine may improve the muscular control required for electromyographic (EMG) prosthesis actuation. EMG electrodes placed on the surface of the skin record electrical signals generated by muscle flexes. These signals are translated to prompt movement in the prosthesis. EMG-powered prostheses introduce benefits including increased capabilities, comfort, and control, especially for children with congenital limb differences. Gamified training implemented in pediatric populations is proven to facilitate faster and simpler prosthesis control. Existing literature suggests that multiplayer gameplay results in increased enjoyment and social connectivity, which may increase adherence. This has not been studied in a gamified EMG training environment. Limbitless Redline is a custom-built multiplayer motorcycle racing game where players control acceleration by flexing their non-dominant forearm muscle and manage their steering with a one-handed controller. Muscle flexion is recorded using an EMG Flex Controller secured on the forearm. A usability assessment study was designed to evaluate the training game. Participants were split into 4 cohorts containing 1, 2, 3, and 4 players, respectively, and played three rounds to assess the effects of single and multiplayer environments. Post-assessment surveys, including the Game User Experience Satisfaction Scale (GUESS), Social Presence in Gaming Questionnaire (SPGQ), and System Usability Scale (SUS), were completed after gameplay. Preliminary results show that enjoyment and social connectivity GUESS subscales were the highest in cohort 4 compared to the cohorts with fewer players. Additionally, SPGQ subscales demonstrate that cohort 3 have the lowest reported negative feelings and the highest behavioral involvement. These results support the hypothesis that social engagement factors increase in multiplayer environments with more players. Multiplayer capabilities in gamified training may improve adherence to training methods and the overall user experience.

Abstract Name: American Scrutiny vs German Proportionality: An Analysis

Since its ratification in 1868, the Fourteenth Amendment of the United States Constitution has been utilized to mitigate the effects of discrimination and guarantee individuals' equal protection under the law. Established in 1949, Germany's Article Three focuses on those same goals. This paper explores how Article Three vastly ensures better protection for the individual than the Fourteenth Amendment by using Germany's proportionality test and obligating the government to take positive action against discrimination. This article begins by examining how, in America, due to the Court's scrutiny tests, some suspect classifications are awarded less protection than others. Whereas in Germany, courts employ a more nuanced approach to discrimination cases to include a balancing element, which ensures the government is being analyzed in the strictest sense. This paper then focuses on how the German government is constitutionally obligated to actively seek out and mitigate current discrimination, while the United States government is only required to act reactively, meaning it does not actively seek to mitigate current discrimination. Ultimately, this paper recommends that the United States should adopt Germany's proportionality test and compel the government to act, because in doing so, the United States can better mitigate discrimination and ensure protection of the individual.

Abstract Name: Christian Legalism: Accountability or Asceticism?

Theological legalism is characterized by rigid adherence to religious rules over grace. Although linked to negative mental health outcomes, legalism's impact on Protestant Christians remains understudied. To analyze the effect of legalism, this study proposes a quantitative, cross-sectional design in which 100 Protestant participants aged 27 and above will complete the Perceived Perfectionism from God Scale and self-reported mental health assessments. It is hypothesized that higher levels of legalism correlate with declining mental health (guilt, shame, anxiety) among Protestants, while grace-based perspectives foster well-being. Results are anticipated to reveal significant associations between legalism and adverse psychological outcomes, contrasting with the protective effects of grace. This research addresses a critical gap in sociological and theological literature, potentially unveiling how doctrinal interpretations shape mental health within Christian communities. Findings could inform pastoral care and interventions to promote grace-centered spiritual practices to enhance and enrich the mental health of believers.

Abstract Name: I Get By With a Little Help From My Friends: Mixed Methods Analysis of Bystander Intervention Strategies In Scenarios Involving Negative Alcohol Consequences

College campuses promote excessive drinking. A number of dangerous consequences including sexual assault, alcohol overdose, and other related injuries associate with alcohol use. One common alcohol intervention strategy includes university training modules that aim to shape students into what is referred to as an “engaged bystander” to promote safer drinking environments. Research investigates the psychological factors that push individuals to decide whether to intervene when encountering alcohol poisoning symptoms. However, considerably less is known about what strategies are utilized by these engaged bystanders. The purpose of this study is to identify the strategies participants would use in a situation where they might choose to intervene. The current project 1) developed a measure to investigate intervention strategies, and 2) analyzed the likelihood of intervention between symptoms presented (drowsiness, unconsciousness, nausea, or vomiting), gender of the victim, and location (bar or party). Participants are university students who responded anonymously to an online survey. The measure is composed of both open-response and multiple-choice questions that propose a situation and ask participants to describe their thoughts and intentions when a friend experiences alcohol poisoning symptoms. Data analysis is ongoing. It is anticipated more participants may choose to intervene if the symptoms presented were more severe. It is also expected that participants will also intervene more if the victim was female. The data provided will inform universities of what students know and what can be done to improve their ability to respond to emergencies, so any alcohol safety training modules developed can be applicable to this population. Research Questions: Are there significant differences in bystander intervention strategies and the symptoms being presented? Does drinking location correlate with different strategies for bystander intervention for negative health consequences related to alcohol? Are women who experience alcohol-related symptoms significantly more likely to receive care from bystanders than men?

Abstract Name: Traumatic Exposure and Posttraumatic Stress in Neuroimaging

Traumatic events are highly prevalent in adulthood, prompting research into physiological markers that may predict stress responses following trauma. One promising neural indicator is the error-related negativity (ERN), an event-related potential occurring 50–150 ms after an individual makes an incorrect response during a cognitive task. This study investigates whether different trauma types—specifically interpersonal versus non-interpersonal trauma—are associated with distinct patterns of neural error processing as measured by the ERN. Participants will be recruited from the University of South Carolina Upstate student population and fitted with a 64-channel EEG system. They will complete a flanker task designed to elicit error responses and measure ERN amplitude across 10 blocks of 30 trials. After task completion, participants will complete self-report measures assessing trauma exposure and posttraumatic symptoms. This data will be used to classify participants by trauma type and examine differences in ERN amplitude and behavioral performance. Data from approximately two-thirds of the expected sample have been collected. Based on prior findings, individuals with a history of interpersonal trauma will show enhanced neural reactivity to errors — specifically, a larger error-related negativity (ERN/Ne) amplitude — compared to both non-interpersonal trauma survivors and controls. These patterns would suggest that interpersonal trauma may uniquely disrupt

conflict monitoring processes and diminish sensitivity to threat signals. It is important to note that the literature shows mixed results. In a recent study, the researcher concluded that individuals with a history of non-interpersonal trauma showed enhanced neural reactivity to errors, thus showing opposite results from what was predicted. This research contributes to understanding how trauma heterogeneity influences neurocognitive functioning and may help clarify why individuals with different trauma histories show distinct patterns of stress-related risk.

Abstract Name: Process Makes Perfect: The Adoption of Process Ontology in Biological Classification

The Linnaean system of classification continues to play an active and functional role in biological nomenclature despite conflicting with current taxonomic and phylogenetic theory. A fundamental problem of the Linnaean system is that it is based in substance ontology. Substance ontology promotes categorical thinking, with strictly bounded taxa that have discrete and persisting features, rather than treating taxa as dynamic, gradient lineages that overlap in complex ways. Substance ontology thus constrains rather than facilitates the re-construction of evolutionary lineages and phylogenetic networks. I use two examples to demonstrate this point. The first is from microbial systematics. Microbial patterns of evolution are dominated by horizontal gene transfer (HGT), producing gradient evolutionary networks that treat taxa as dynamic systems rather than enduring substances. The other example is from Canidae systematics. Taxonomists have recently adopted taxonomic revisions to long-standing fox classifications to better reflect the phylogenetic relationships. This prioritizes capturing the transformative flow of taxonomic lineages, in contrast to categorical treatments that treat taxa as static entities. I advocate for the adoption of process ontology, or the view that the biological world is best understood as a hierarchy of processes stabilized through different time scales. This paper discusses how adopting a process ontology alters the function and relevance of the higher Linnaean system and provides a more thorough and complete understanding of the biological world, allowing for the generation of better research questions. My argument rejects categorical thinking in taxonomy in favor of a process ontology to best convey the reality of the often-convoluted biological world. This better positions us to evaluate novel taxonomic claims, including about de-extinction and the status of cloned charismatic mega-fauna like Dire Wolves, Mammoths, and Dodos.

Abstract Name: Computerized Text Recognition for Ghanaian Cultural and Historical Documents Using Machine Learning

Ghana's National House of Chiefs preserves handwritten records about each chief across the country, including their hometown and the date they were enstooled/enskinned. These archives are crucial for policymakers and researchers studying traditional governance. These culturally significant documents are not accessible in the digital world. Because they are handwritten instead of typed, they cannot be searched, leaving them invisible to researchers and risking their loss over time. Commercial OCR systems like Google

Vision and Tesseract, optimized for printed Western text, consistently fail on these records due to handwriting variability, faded ink, and local village names. Without accessible digitization tools, Ghanaian historical records remain locked away, unable to support research requiring searchable, analyzable data. This research shows how lightweight machine learning methods can unlock these resource-scarce collections. We developed a five-stage pipeline to turn handwritten scans into searchable digital text. First, we tested four preprocessing methods: adaptive thresholding, CLAHE contrast enhancement, HSV color masking, and morphological background subtraction, identifying techniques that recover faded text without erasing handwriting. Second, automated detection extracts handwritten place names. Third, segmentation isolates characters and standardizes dimensions. Fourth, a convolutional neural network trained on EMNIST Letters, a benchmark dataset of over one hundred thousand handwritten characters, classifies each letter by learning spatial patterns. Finally, postprocessing combines predicted letters into words, applies structural analysis to distinguish visually similar characters, and matches predictions against known Ghanaian place names to incorporate linguistic context. The system achieved approximately ninety-three percent accuracy on benchmark data and seventy to eighty percent on archival samples, with adoption by political science researchers underway. This demonstrates that modest architectures combined with intelligent preprocessing can address complex cultural preservation challenges, creating a reproducible blueprint for bringing underrepresented historical archives into the digital age where they can be searched and analyzed globally.

Abstract Name: Presence of Mycobacterium smegmatis Phages in Soil From the Banks of the Elizabeth River

This study focuses on isolation of mycobacteriophages from the soil or sediment of the Elizabeth River, a tributary of the Chesapeake Bay located in Virginia. The samples were collected during different seasons, using the host bacterium *Mycobacterium smegmatis*. This bacterial host was used because it is a common laboratory strain, frequently found in outdoor environments such as soil, and does not cause disease in humans. Bacteriophages are viruses that infect specific bacterial hosts and require a host in order to survive and replicate. The ultimate goal is to gain insight on the impact of seasonal change on the prevalence of phage. In addition, this research focuses on identifying bacteriophages that could have the potential of killing *Mycobacterium tuberculosis* which has morphological similarities to that of the host *M. smegmatis*. During the Fall of 2025, soil and sediment were collected from the Elizabeth River. The samples underwent enrichment, filtration, and overlay assays to detect and isolate mycobacteriophages. Results revealed the presence of phages in only the soil samples, with one phage successfully isolated and named Brokber. No phages were recovered from sediment samples during this season, contrasting with previous summer collections that yielded multiple sediment-derived phages. If sediment samples collected during the summer yield plaques, then mycobacteriophages capable of infecting *M. smegmatis* are more prevalent in warmer temperatures compared to cooler seasons.

Abstract Name: Jackie Ormes Taking to the funny papers

In a time where women especially, black women were not seen or able to promote their concerns with society, one woman took a turn in the funny papers to become an advocate for black journalism. This woman no other than Jackie Ormes, the first African American woman to be a cartoonist. Born in Pittsburgh only to move to Pennsylvania, Jackie had a hand at talent at a young age only for the talent to blossom in the events of her career working at Courier and in the events of a tragedy in the death of her daughter in the later years of her life. Jackie would create a character to resemble some essence of her daughter but having a spunky personality as well as bite to call out the of America in the time of Jim Crow and Civil Rights movement, this would be featured in one of Orme's comics called Patty Joe and Ginger. While fighting for Civil rights in strips of comics, Jackie also used comics to uplift black woman with black femineity, show casing woman as beautiful and human.

Abstract Name: How Translanguaging Pedagogy Shapes Language Ideologies in Bilingual Picturebooks

Emergent bilingual children deserve literacy experiences that recognize their full linguistic identities as assets rather than deficits. Translanguaging pedagogy emphasizes flexible language use that reflects how multilingual learners naturally draw on all of their languages to make meaning, express emotions, and connect with their families and communities. This poster presents the findings of a systematic literature review that examines the relationship between translanguaging pedagogy and children's literature, with a particular focus on how bilingual picturebooks can support dynamic bilingualism and multilingual development while honoring learners as whole persons with integrated linguistic identities. Grounded in theoretical perspectives from García, Wei, and other scholars in ESL and bilingual education, the project investigates how bilingual books are shaped by underlying language ideologies and how these contrasting beliefs about bilingualism may influence multilingual learners' language use, literacy engagement, and identity development. To extend this theoretical analysis, the project also includes a qualitative review of bilingual picturebooks currently available in the U.S. market. A set of selected books was examined to identify how translanguaging is supported or constrained through text and design choices and to reveal embedded language ideologies shaping how English and home languages are positioned. Early findings suggest that although many publications encourage bilingual exposure, a significant portion still reinforce rigid separation of languages, hierarchical valuing of English over home languages, or translation based approaches that restrict opportunities for authentic multilingual expression. By comparing translanguaging oriented books with those grounded in monolingual norms, this study offers insights that can inform teachers, literacy researchers, and publishers who seek to promote equity in language education. The goal of this work is to promote the intentional selection and use of children's literature that reflects heteroglossic orientations in ESL and bilingual instruction, supporting multilingual learners in seeing their languages as interconnected, valued, and integral to who they are.

Abstract Name: Exploring the Relationship Between Interaction Quality and “SMART” Goal Quality in the NOURISH-T+ Intervention

Introduction: NOURISH-T+ is a family-based behavioral intervention for pediatric cancer survivors (PCS) with overweight/obesity. Each week caregivers create specific, measurable, attainable, relevant, and time-bound (i.e., “SMART”) goals. While both the quality of caregiver-facilitator interactions and SMART goals independently improve outcomes, their relationship remains unexplored. This study examines the relationship between interaction quality and SMART goal quality within a session of the NOURISH-T+ program.

Methods: Forty recordings are being independently coded by two trained raters. Inter-rater reliability will be assessed using Cohen's Kappa. Interaction quality is assessed using the Interaction Style and Engagement (ISE) tool, developed for the NOURISH-T+ program and yielding scores from 0 to 42. SMART goal quality is rated on a 0–5 scale based on SMART (specific, measurable, attainable, relevant, time-bound) criteria. Both ISE and SMART goal quality scores are split at the median into high and low categories. Pearson Chi-Square test will examine the association between interaction quality and goal quality ($p < 0.05$).

Preliminary Results and Hypothesis: Caregivers were predominantly mothers (87.5%) with a mean age of 40.52 ± 8.45 years. Caregivers identified as predominantly White (67.5%) or Black/African American (25%). It is hypothesized that sessions with high ISE scores are expected to produce higher-quality SMART goals vs. sessions with low ISE scores.

Implications: Findings will illuminate how caregiver–facilitator interactions support engagement, as reflected through the goal-setting process. These insights may inform strategies that strengthen continued behavior implementation and intervention adherence for families of PCS with overweight/obesity.

Abstract Name: Empathy Inflation: When Purpose-Driven Marketing Loses Its Impact

Purpose-driven marketing has become a dominant strategy for brands seeking to connect with socially conscious consumers. However, as emotional and empathetic messaging saturates the marketplace, audiences are beginning to experience “empathy inflation,” where repetitive expressions of care and solidarity lose authenticity and impact. This research investigates how overused empathetic language in marketing campaigns affects consumer trust and perceived sincerity, with a focus on campaigns related to mental health awareness, crisis response, and sustainability initiatives. A qualitative content analysis was conducted on selected campaigns from diverse industries, coding for recurring empathy-related phrases, emotional strategies, and tone. Each campaign was analyzed for language patterns, messaging frequency, and the presence of generic versus specific empathy appeals. Additionally, a small-scale consumer perception survey was used to explore how audiences interpret repeated empathetic language and whether it influences their trust in the brand or engagement with its cause. Preliminary findings suggest that while empathy-driven campaigns remain effective in promoting brand awareness and social engagement, phrases that are overly generic or repeated across campaigns contribute to audience fatigue and skepticism. Distinct, authentic

expressions of care, particularly those tied to concrete actions or measurable impact, were perceived as more credible and influential. These results show a critical tension in purpose-driven marketing: brands must balance emotional connection with authenticity to maintain consumer trust. This study contributes to the emerging discourse on ethical and effective marketing communication by defining patterns of empathy inflation and offering practical insights for brands seeking to connect with audiences meaningfully. By identifying which emotional appeals sustain trust and which risk desensitization, the research provides guidance for marketers aiming to design campaigns that are both socially responsible and genuinely impactful.

Abstract Name: Perceptions of Parents of Children With Disabilities Toward Physical Education: A Systematic Review

Physical education (PE) has a unique opportunity in not only supporting children with disabilities but also their parents' physical-activity knowledge and support behaviors. Therefore, the purpose of this systematic literature review was to synthesize published studies regarding parent perspectives toward physical education (PE) for their children with disabilities. A total of 19 articles met inclusion criteria. Three themes emerged: (a) parents' understanding of adapted PE (A/PE), (b) parents' expectations of A/PE teachers, and (c) parents' undeveloped relationships with A/PE teachers. There exists a disconnection between parent expectations and PE teachers' abilities to accommodate their children and develop lines of communication. Additionally, parental value toward PE was often lower compared with other areas of need for their children. Future research suggests exploring teacher perspectives in understanding the relationships with parents. Furthermore, exploring the origins of parental values for PE and its impact on their perspectives warrants further investigation.

Abstract Name: Peer Victimization and Irritability In Youth

Peer victimization, or bullying, is a common adolescent stressor and may be linked to irritability, an emotion-related trait associated with broader mental health risk. This project uses survey data from a larger study to test whether peer victimization is positively associated with irritability in a community sample of 100 youth (mean $\pm$ SD age: 14.1 $\pm$ 2.1 years; 55% female). Peer victimization and irritability were assessed from multiple reporters (youth and parent/guardian) using validated questionnaires: the Revised Peer Experiences Questionnaire for victimization and the Affective Reactivity Index for irritability. Pearson correlations were computed to examine associations within and across reporters and variables. Results showed a positive association between youth-reported peer victimization and irritability ($r = .360$, $p < .001$), and between parent/guardian-reported peer victimization and irritability ($r = .377$, $p < .001$). Cross-reporter correlations were also significant: youth-reported victimization was associated with parent/guardian-reported irritability (r

= .294, $p = .003$), and vice versa ($r = .204$, $p = .042$). Overall, greater peer victimization was consistently associated with higher irritability across reporters. These findings support the idea that negative peer experiences may be tied to youth emotional reactivity. Screening for peer victimization may help identify youth at risk for clinically relevant irritability.

Abstract Name: Forced immersion cooling for improved thermal management of cylindrical lithium-ion batteries

Temperature plays a critical role in the electrochemical performance, degradation rate, and overall reliability of batteries. During operation, batteries generate heat due to internal resistance and reaction kinetics. If the heat is not effectively dissipated, localized temperature rises can accelerate side reactions, cause uneven cell aging, and, in extreme cases, lead to thermal runaway — a major safety hazard. Forced immersion cooling using a dielectric fluid significantly influences the heat removal rate, thereby affecting the temperature distribution within the cell. In this work, commercial cylindrical batteries are directly immersed in a flowing dielectric fluid using a custom-built flow loop. We vary the fluid temperature and velocity of the dielectric fluid to evaluate their impact on battery performance. The findings contribute to a deeper understanding of forced immersion cooling for thermal management of lithium-ion batteries, offering a framework for optimizing battery safety, reliability, and electrochemical stability in energy storage research.

Abstract Name: In Vitro Characterization of Polysaccharide Binding by the SFB Surface Protein P12260

Segmented filamentous bacteria (SFB) are gram-positive, spore-forming bacteria that directly anchor to the host's intestinal epithelium. Although SFB-like organisms have been detected in multiple species, including humans, the molecular basis of their adhesion remains poorly understood. One predicted adhesion-related surface lipoprotein, P12260, contains a suspected carbohydrate-binding domain and is conserved in several animal hosts. Search for homologs of P12260 from mice-specific SFB has identified homologous proteins in turkey SFB and some other hosts, but not in a human SFB-like bacteria, possibly because of incomplete genome sequence. Because intestinal mucins and epithelial glycoconjugates are rich in diverse carbohydrates (CHs), we hypothesized that P12260 supports SFB colonization by binding to specific CHs. To investigate this, we expressed and purified His-tagged P12260 from *E. coli* and developed several in vitro CH-binding assays. In this work, we assessed the protein's binding specificity for various monosaccharides through porcine mucin-coated plates assay, pull-down assays with insoluble oligosaccharides and binding to various monosaccharide-charged agarose resins. Our results showed reproducible binding of P12260 to mannose and fucose supporting our previous results and hypothesis that it recognizes specific CH structures relevant to intestinal adhesion. This project investigates different experimental approaches for studying SFB CH-binding proteins and provides evidence that P12260 may play an important adhesion role for SFB interaction with

their host. Based on these findings, we will also discuss and explore potential host receptor targets for P12260 binding.

Abstract Name: Examining AI-Generated Content in Equity Crowdfunding: Implications for Investor Evaluation and Trust

This study examines how the emergence and proliferation of artificial intelligence affects investor due diligence and communication in equity crowdfunding settings. While existing research establishes that communication quality is fundamental to investor-entrepreneur evaluation processes, serving as a critical mechanism for reducing information asymmetry and signaling venture credibility—the rapid adoption of generative AI tools has fundamentally transformed online asynchronous communication practices. Unlike traditional face-to-face interactions, equity crowdfunding platforms rely heavily on written pitches and discussion forums, creating an environment where AI-generated content can seamlessly integrate into investor decision-making processes. However, the implications of AI-authored language for investor perceptions, trust formation, and due diligence remain underexplored. This research employs a comparative temporal design using panel data from equity crowdfunding platforms. The study establishes a pre-AI baseline by analyzing Crowdcube campaigns from 2017-2018, a period predating widespread generative AI adoption. Contemporary data collection from Republic.com is currently underway, capturing active campaigns, updates, and investor discussion forums in the post-AI era. Systematic textual analysis will identify AI-characteristic terminology, linguistic patterns, and syntactic structures across campaign materials. Variables include funding outcomes, investor participation metrics, company sustainability orientation, leadership demographics, and international orientation. The methodology incorporates an experimental component wherein participants will evaluate parallel investment pitches—one AI-generated and one human-authored—to assess whether AI authorship influences investment preferences and whether disclosure of content origin affects decision-making. Upon completion, this study is expected to reveal significant shifts in communication patterns and investor evaluation processes following AI emergence. Findings will be discussed within the context of information asymmetry theory and signaling mechanisms in entrepreneurial finance, contributing to understanding how technological disruption reshapes investor-entrepreneur dynamics in digital fundraising environments.

Abstract Name: The XenCart Protocol: A Method for Alcian Blue Labeling and Quantitative Analysis of Craniofacial Cartilage in Xenopus

Craniofacial birth defects, such as cleft lip and palate, are among the most common congenital anomalies and often arise from disruptions in early facial patterning. Many of these defects are linked to environmental teratogens, yet such exposures cannot be directly tested in humans, making animal models essential for evaluating developmental risks. *Xenopus laevis* offers a powerful solution: its embryos develop externally, share deeply conserved craniofacial patterning mechanisms with humans, and provide an accessible platform for uncovering how environmental exposures reshape facial structures during development. Here, we present the XenCart Protocol, a reproducible workflow for Alcian Blue staining and quantitative morphometric analysis of *Xenopus* craniofacial cartilage. This method provides clear visualization of individual cartilage elements and can be readily applied to investigate genetic or environmental perturbations. The *Xenopus* craniofacial skeleton contains distinct cartilaginous structures that perform key biomechanical functions and share strong homology with regions of the human craniofacial skeleton. These similarities allow direct comparison of developmental outcomes across vertebrates. As part of a CURE-based undergraduate course, the XenCart Protocol was used to measure jaw cartilage dimensions in embryos exposed to an emerging teratogen, e-liquids used in vaping. Quantitative analysis revealed significant reductions in specific jaw elements, consistent with phenotypes linked to midfacial narrowing and oral clefts. The ability to detect robust, structure-specific differences highlights the sensitivity of the protocol. Moreover, these findings also pinpoint the precise regions of the jaw most affected by e-liquid exposure, providing a foundation for uncovering the developmental mechanisms driving these craniofacial changes. In summary, the XenCart Protocol provides a standardized, scalable method for quantifying craniofacial cartilage development and offers a powerful platform for both mechanistic research and undergraduate training in developmental biology and toxicology.

Abstract Name: Impact of a Family Physical Activity Intervention on Parent Self-Efficacy for Personal and Child Physical Activity

Parents often struggle to maintain physical activity (PA) due to work, family demands, and time constraints. Over half of parents do not meet recommended PA guidelines. Parent self-efficacy (PSE) influences how parents manage their own health behaviors and shape their child's routines. Evidence suggests that parental support and monitoring are key drivers of children's PA engagement. The purpose of this pilot study was to examine how a family-based physical activity intervention influences parents' self-efficacy for their own PA and their self-efficacy for supporting their child's activity. A sample of eight parent-preschool child dyads were recruited from Cooperative Extension offices and Head Start preschools to participate in Families Moving Together, a 6-week family physical activity intervention. Parents completed pre- and post-intervention surveys assessing barrier self-efficacy for both their own and their child's PA, as well as parent and child PA levels. Pre-post changes in self-efficacy and PA were examined using Cohen's *d* effect sizes. There was a moderate increase in parent self-efficacy for their own PA from pre-intervention (10.4 ± 3.6) to post-intervention (12.9 ± 3.6) ($d = 0.523$). Similarly, parent PA increased from pre-intervention (41.6 ± 21.7) to post-intervention (49.1 ± 23.4) ($d = 0.415$). There was an increase in parental self-efficacy for supporting their child's PA from pre-intervention (11.4 ± 2.3) to post-intervention (13.9 ± 2.9) ($d = 0.84$). Child PA levels increased from pre-intervention (440.6 ± 163.3) to post intervention (478.8 ± 278.4) ($d = 0.159$). These preliminary findings suggest that a family-based PA intervention may increase parents' barrier self-efficacy, strengthen their confidence in supporting children's activity, and improve PA levels for both parents and children. Although based on a small sample, these improvements highlight the potential of a family-centered approach to promote shared engagement and mutually reinforcing PA benefits, supporting the need for evaluation in a larger cohort.

Abstract Name: Dielectrophoretic Characterization of Algal Cells Involved in Harmful Algal Blooms (HABs)

Harmful Algal Blooms (HABs) occur when toxic algae proliferate uncontrollably in bodies of water. These algae can negatively impact public health and harm local wildlife and the surrounding environment. Typically, the algae involved release toxins into the water, reduce available oxygen, and block sunlight from reaching lower depths. *Microcystis aeruginosa* (*M. aeruginosa*) is a type of cyanobacterium most commonly associated with such blooms and can release microcystin toxins that cause respiratory and gastrointestinal inflammation, liver and kidney damage, and have been linked to the development of hepatic cancer. Another species involved in HABs is *Chlorella vulgaris* (*C. vulgaris*), is non-toxic but can still cause severe environmental stress when it blooms, leading to oxygen depletion, biomass accumulation, and reduced light availability. The purpose of this research is to characterize the dielectric signatures of these two algal species as a first step toward developing an alternative method for monitoring HABs. Current monitoring methods include molecular DNA/RNA sequencing, fluorescence in situ hybridization (FISH), sandwich hybridization assay (SHA), microscopy, chromatography, and mass spectrometry. However, these techniques are often expensive, time-consuming, and require highly skilled personnel to operate. Thus, we propose using dielectrophoresis, a method that exploits minute differences in cellular dielectric signatures via non-uniform electric fields. When combined with a microfluidic device, this approach can separate different types of algae found in HABs, providing an economical, potentially portable method for HAB detection and monitoring. We found significant, measurable differences in the dielectric properties, especially membrane and cytoplasm conductivity and permittivity, between *M. Aeruginosa* and *C. vulgaris*. These findings form the basis for simulating the proposed device, with the long-term goal of developing a real-time monitoring system for water sources.

Abstract Name: Turbine Aerodynamics and Performance Characterization

This research presents an integrated study combining computational modeling and experimental validation to enhance the design and performance characterization of small-scale turbine systems. The theoretical component focuses on developing an object-oriented Python code for the preliminary design and performance prediction of radial turbines, capable of generating velocity triangles, thermodynamic properties, and geometric parameters from user-defined inputs. The tool employs Whitfield-based correlations and

fundamental gas-dynamic relations to estimate exit flow parameters, work ratio, and efficiency, offering flexibility for expansion into geometry export and CAD integration. Complementing the computational model, the experimental component aims to improve the aerodynamic testing capabilities of the axial turbine cascade rig through instrumentation and analysis upgrades. A Python-Excel integrated tool was created to determine turbine blade throat openings and deviation angles using Aungier's correlations and Mach-dependent flow effects. Concurrently, a custom horizontal Kiel probe rake is being designed and fabricated to enable multi-point total pressure measurements, replacing single-point probes and improving data resolution. Together, these efforts establish a cohesive framework for turbomachinery design, analysis, and experimental validation. The combined methodology demonstrates how computational and experimental approaches can jointly advance the understanding of turbine aerodynamics and streamline future research and educational workflows in jet propulsion and power systems.

Abstract Name: Repurposing Cancer-Associated Telomere-Lengthening Mutations as Therapies for Short Telomere Syndromes

Most human cells age and eventually stop dividing, but cancer cells escape this fate by sustaining telomere length and achieving unchecked growth. This immortality is driven in part by telomeres, repetitive DNA regions at the ends of chromosomes that preserve genomic integrity and set the proliferative capacity of cells. While excessively long telomeres are associated with cancer, abnormally short telomeres contribute to premature aging diseases such as idiopathic pulmonary fibrosis (IPF), highlighting telomere shortening as a driver of degenerative disorders. The POT1 and TPP1 proteins, encoded by the POT1 and ACD genes, respectively, play crucial roles in regulating telomere length by controlling telomerase access and activity. Mutations in these genes, often observed in cancers, are thought to promote telomere elongation. Interestingly, a subset of patients that are born with mutations that cause short telomeres acquire mutations in telomere lengthening genes that are thought to be a genetic rescue mechanism. By genome-editing these specific regions, we aim to investigate how these mutations can be leveraged to safely restore telomere maintenance in short telomere syndromes. Using CRISPR-Cas9 base editing, we introduced targeted mutations in K562 leukemia cells, focusing on the POT1 locus on tetraploid chromosome 7 and the ACD promoter on triploid chromosome 16 at varying allelic levels. Preliminary studies suggest that cells with edited POT1 exhibited increased telomere length, whereas ACD-edited cells showed no measurable changes in telomere maintenance, potentially due to non-specific editing. Together, these results clarify the distinct regulatory contributions of POT1 and ACD and establish a framework for using genome editing to dissect mechanisms of telomere restoration in short telomere syndromes.

Abstract Name: Characterizing the FlhSR regulatory pathway in the soil bacterium *Paracoccus denitrificans*

Paracoccus denitrificans is a methylotrophic soil bacterium that can use one carbon compounds like methanol and formaldehyde as sources of energy and carbon. Two regulatory proteins, FlhS and FlhR, activate the expression of the genes encoding the enzymes required for metabolism of these compounds. In the absence of FlhS or FlhR, *P. denitrificans* cannot grow on C1 compounds. To further explore this two-component regulatory system, we assessed the possible role of the phosphotransferase (Hpt) protein. We hypothesized that the Hpt protein is required for carrying the activation signal from FlhS to FlhR. Secondly, we also hypothesize that FlhSR is required for the expression of two proteins involved in carbon fixation – fructose-1,6-bisphosphatase (Fbp) and a regulatory protein, CbbR. Understanding bacterial regulatory systems can help us develop technologies to identify and eliminate toxins and understand bacterial evolution. To study the Hpt protein requirement, we deleted the *hpt* gene. We assayed growth of Δhpt and $\Delta flhR$ mutants and a wild-type strain on methylotrophic substrates. These assays demonstrated that the Δhpt grows at the same rate on methanol as the wild-type. Furthermore, we tested the activity of formaldehyde dehydrogenase in lysates of cells grown on various carbon sources. Enzyme activities in extracts of the Δhpt were comparable to wild type, whereas activity was greatly diminished in the $\Delta flhR$ mutant. The growth and enzyme activity suggest that Hpt is not required for methylotrophic growth and therefore uninvolved in the FlhSR-mediated signal transduction pathway. We generated *fbp* and *cbbR* promoter-lacZ reporter fusions and introduced the constructs into *P. denitrificans*. β -galactosidase enzyme activity assays will determine whether these promoters are activated during methylotrophic and autotrophic growth. We expect strong activation in wild type during growth on C1 substrates and it will be interesting to determine whether FlhSR regulates *fbp* transcription.

Abstract Name: Evaluating Murine Uterine Cell Viability on Polyacrylamide Hydrogel Models of Varied Stiffness

Aging has been shown to increase the risk of numerous uterine conditions, such as endometriosis, infertility, and endometrial cancer. Mechanical properties such as the stiffness of the uterus's extracellular matrix (ECM) can be significantly affected by age, contributing to the development of these disorders. Uterine cells interact with the components of the ECM, such as elastic fibers and collagen, to facilitate uterine remodeling. This process is crucial for menstruation, pregnancy, and endometrial homeostasis. There are documented changes to the stiffness of the uterine ECM and the decrease in cell mechanosensitivity in fibroblast-like cells with age. However, interactions between these factors are not fully understood. As the ECM stiffness changes with age, an in vitro study of uterine cell mechanosensitivity requires an environment that reflects these modifications. We hypothesize that aged uterine cells exhibit cell adhesion and growth on polyacrylamide hydrogels of varied stiffness. To investigate the impact of age on cell mechanosensitivity during future studies, we aimed to develop and optimize a protocol for the isolation, culture, and quantification of aged murine uterine cells on soft and stiff polyacrylamide hydrogel models. Uterine tissue was collected from four aged non-pregnant female mice. Endometrial cells were isolated using an enzymatic digestion mix consisting of collagenase and trypsin-EDTA. The cells were seeded on polyacrylamide hydrogels with stiffnesses of 1 kPa and 10 kPa. Brightfield imaging capturing preliminary experiments depicted cell growth and adhesion on both cell culture flasks and soft (1 kPa) and stiff (10 kPa) polyacrylamide hydrogels. The successful isolation and culture of endometrial murine cells indicate that this optimized protocol can serve as a reproducible

framework for future biomechanical studies exploring uterine cell mechanosensitivity in aging. Understanding cellular responses to variations in ECM stiffness with age may advance knowledge of uterine remodeling and the mechanisms of reproductive aging and related disorders.

Abstract Name: Faces Around Us: A Photographic Study of Community

Faces Around Us is a photographic series documenting the people of Truman State University through analog large format film portraits paired with short personal stories. My goal is to highlight the familiar faces we pass every day, students, faculty, and staff, and create a sense of connection by showing not just how they look, but who they are. This project is inspired by Philippe Halsman's "Jump" series, where he photographed well known figures in moments of openness. I want to create a similar sense of honesty, but through conversation rather than movement. Large format film is a slow and deliberate process that gives me time to talk with each person as I set up the camera. I will ask open ended questions such as "What is your best silly memory?" or "What is something most people do not know about you?" to help them relax and share something personal before I take their portrait. As one of the few students still using the university darkroom, I am committed to preserving traditional analog practices. I often work with older materials, including damaged cameras and expired photo paper that others have thrown away. This appreciation for film shaped my earlier project for the Student Research Conference, where I printed archived negatives onto old photo paper that had turned gray. The imperfections created a nostalgic atmosphere, and I invited viewers to take home any photograph they connected with, giving new life to materials once considered waste. Faces Around Us continues that idea of connection. This time, I want to learn about the people in this community, their memories, their humor, and their stories, and pair their portraits with short written reflections. The project shows that people are more than faces we see in passing. They are stories waiting to be known.

Abstract Name: Developing Silkworm Pupae as a Biological Resource for Alzheimer's Pathway Research

Silkworm pupae (*Bombyx mori*), which are widely consumed as a traditional food in many silk-producing countries, contain high levels of proteins, lipids, and other bioactive nutrients known to support cellular and neural health. These properties suggest that pupae-derived compounds may influence oxidative stress, cholinergic function, and other pathways relevant to neurodegenerative diseases such as Alzheimer disease. Building on this foundation, the project aims to prepare pupae from various *Bombyx mori* strains as the initial step toward testing silkworm-derived media on Alzheimer's *Drosophila melanogaster* model flies to evaluate potential improvements in memory and other neural pathways, which will be assessed using behavioral,

molecular, and oxidative assays. Previous stages of the experiment focused on controlled nurturing of three silkworm strains to produce high-quality pupae for future extraction and experimental testing. Although developmental observations across instar stages were recorded, these data primarily served to verify reliable pupal production rather than to analyze strain-specific differences. The preserved pupae will be processed into media to be administered to genetically modified Alzheimer's model flies. Future work will assess whether pupae-derived compounds modulate memory performance, oxidative stress responses, and other neurobiological pathways associated with neurodegeneration. The next phase will center on behavioral assays, including negative geotaxis and olfactory learning tests, to evaluate whether pupae-derived compounds influence memory performance or mitigate Alzheimer-related functional decline. Upcoming studies will incorporate immunohistochemical staining of Alzheimer's fly brains to assess amyloid-beta plaque accumulation, as well as antioxidant assays examining potential effects on oxidative stress pathways. By combining a reliable pupae-production pipeline with a well-validated *Drosophila* AD model, this work lays out the groundwork for identifying biologically derived compounds that may influence Alzheimer's-related mechanisms. Attendees will gain insight into early preparation steps and the translational relevance of pupae-based functional testing for discovering accessible interventions targeting neurodegenerative pathways and functional food-based therapeutics.

Abstract Name: Stoichiometry Dependent Modifications in Synthetic Heme Peroxo Reactivity with Nitrosonium: A New Paradigm for Understanding Heme Mediated Nitration Chemistry

The nitric oxide dioxygenase (NOD) pathway, where heme-superoxo intermediates are proposed to mediate the oxidation of nitric oxide to regulate its levels in biological systems, represents a fundamental detoxification mechanism for reactive nitrogen oxide species. Recent work has demonstrated that synthetic heme-peroxo intermediates can stoichiometrically react with NO^+ in an isoelectronic approach to mimic NOD chemistry, leading to metastable heme peroxynitrite intermediates. This breakthrough highlights the critical importance of nitrogen oxide stoichiometry, and opens new avenues for gaining detailed understanding into heme peroxynitrite chemistry, an area poised for revolutionary advances given the challenges in direct observation of such highly reactive intermediates in biological contexts. Nonetheless, the fate of similar reactivities with excess NO^+ remains unexplored, leaving fundamental questions unanswered. Understanding these reactivities is essential because interactions of heme-oxygen intermediates with nitrogen oxides are known to be highly stoichiometry dependent, with paramount implications in human physiology and pathology. This study investigates the reactivity of synthetic heme-peroxo complexes with excess NO^+ equivalents, revealing a distinct reaction pathway that differs from the established NOD chemistry observed with stoichiometric amounts of NO^+ . When exposed to 4 equivalents of NO^+ , synthetic heme-peroxo adducts generate two stoichiometric equivalents of $\bullet\text{NO}_2$, yielding ferric heme products. Comprehensive computational and spectroscopic analyses support this transformation confirming the formation of $\bullet\text{NO}_2$, which competently drives the subsequent nitration and oxidation of biologically relevant organic substrates. These findings provide new mechanistic understanding into how excess NO^+ alters the outcome of NOD

reactivity of heme-peroxo intermediates, offering new insights into how the manifestation of nitrosative stress may vary with divergent concentrations of nitrogen oxides.

Abstract Name: Exploring the Impact of Adverse Childhood Experiences (ACEs) on Hair Cortisol Levels in Children Aged 3-12: A Biomarker Approach to Early Stress Assessment

Adverse Childhood Experiences (ACEs) are negative events that occur throughout a child's life. These events are associated with prolonged activation of biological stress-response systems: the hypothalamic-pituitary-adrenal (HPA) axis and the sympathetic nervous system. ACEs have been shown to increase negative health outcomes in adults from HPA axis dysregulation leading to a suppressed immune system which could increase illness. While the effects of ACEs on HPA-axis function in adults are well studied, much less is known about how ACEs affect HPA-axis function during childhood. Our primary hypothesis was that children aged 3–12 years old with higher ACEs scores would have lower hair cortisol concentrations than children with lower ACEs scores, reflecting HPA-axis dysregulation. We recruited children aged 3-12 years for this study. ACEs were measured via the ACEs-10 questionnaire which was given at a local Knoxville pediatric clinic. Cortisol levels were measured via hair sample using quantification by ELISA. The study was approved by the UTK IRB (UTK IRB-20-06025-XP). Our findings show that higher ACE scores are linked to lower hair cortisol levels, suggesting that HPA-axis regulation may already be altered in childhood. Because hair cortisol reflects only one aspect of HPA activity, further studies using additional measures of stress hormones are needed to clarify how ACEs affect HPA-axis function.

Abstract Name: Carbon Footprint: Decoding Greenhouse Gas Emissions' Impact on Investment

In March 2024, the U.S. Securities and Exchange Commission (SEC) finalized The Enhancement and Standardization of Climate-Related Disclosures for Investors (“the rule”). After finalizing the rule in 2024, the SEC delayed implementation and a year later stayed it following legal challenges and internal skepticism. This change in regulatory stance by the SEC leads to a critical question: does the absence of greenhouse gas (GHG) emissions disclosure in the US leave investors with an incomplete understanding of a company’s climate risk, and if so, to what extent does it influence their investment decisions? This is an important question, as in the European Union the Corporate Sustainability Reporting Directive (CSRD) mandates that all large companies disclose their emissions data. We use a two-by-three between-subjects design where investors (i.e., survey participants) choose between a high- or low-polluting hotel index fund or a 30-year bond to answer this question. Additionally, we examine whether herd behavior, which explains how individuals within groups tend to follow collective trends, is triggered among investors when index fund managers make statements in support of or against GHG disclosure impact investors’ decision making. Our study examines whether emissions data alters investment behavior, providing evidence that can either support the case for mandatory disclosure or affirm the SEC’s current stance on the rule.

Abstract Name: Beyond the Prescribed Music List: Female-Composed Music for the Modern Horn Student

In recent years, there have been much-needed conversations about expanding the repertoire that students perform and study to include more underrepresented composers. In the book *Analytical Essays on Music by Women Composers* edited by Laurel Parsons and Brenda Ravenscroft, they explain that in the same way women’s rights and representation are growing in most field of work, the growth of representation of women composers is constantly growing as well. With resources like Caiti Beth McKinney’s website that catalogs horn repertoire by underrepresented composers this makes everything more accessible to every instructor. Despite these efforts to inspire change, the prescribed music lists for high school level solo and ensemble horn competitions in Texas, Arkansas, Oklahoma, and Missouri feature predominantly male composers. If we want add representation in the secondary horn curriculum there needs to be change starting within these state level competitions. In this presentation I propose excerpts by women composers that fulfill the technicalities that fit the judging criteria. would I have examined the prescribed music lists for OSSA (Oklahoma Secondary School Activities Association), ASBOA (Arkansas School Band and Orchestra Association), UIL (University Interscholastic League), and MSHSAA (Missouri State High School Activities Association). I have explored why these technical passages are so crucial for young horn players and how we can incorporate more diverse examples. My recommendations will be drawn from the works from multiple composers, including Gina Gillie, Ruth Gipps, and Adrinne Albert.

Abstract Name: Pitch Changes and Harmonic Variations of Oboe Reeds through Material Reduction

The purpose of this research is to quantify the relationship between reed thickness and reed pitch. By taking new reeds and methodically reducing and measuring them, this research will analyze the effect of cane being taken out of specific sections of the reed. Most professional oboists spend just as long making reeds as they do playing their instrument. Because there are so many pieces, steps, and variables, every reedmaker develops their own superstitions about what makes a good and bad reed. The goal of this research is to demystify one aspect of the reedmaking process: changing the pitch. Unfortunately for current reedmakers, there are very few studies where the effects of scraping is tested across many reeds. Very few people possess the knowledge, skills, and resources to make reeds, and those people are focused on making them for their own use and for sale. It is generally accepted that any scraping done on the reed will lower the pitch and any clipping off the top of the reed will lower the pitch, however, there is no easily accessible data demonstrating this trend. I will start by making reeds of the same materials—cane from the same company, gouge, shape, and staple. I will record the number of scrapes on each section of the reed and document them along with when each session of scraping took place. I will then record notes into an audio software, scrape cane off the reed, and record again. I will continue this process to the deterioration of the reed. I will repeat this process with a variation of the reed and for each dataset, analyze the change in frequency and harmonic series over the progression of the material reduction.

Abstract Name: Humanity's Mother: Eve and Original Sin as the American Female Archetype

This research examines the biblical story of creation in Genesis 2-3 and the enduring influence of Eve—both the original sinner and humanity's mother—on American perceptions of motherhood. In the biblical narrative, Eve's consequence of pains during childbirth after yielding to the forbidden fruit's temptation has created a paradigm that frames motherhood as both a punishment and moral burden. This thesis argues that the cultural legacy of Eve's transgression positions American women as responsible for atonement through childbearing. It further analyzes how deeply embedded Evangelical narratives persist in both literary representations, including *The Awakening*, *The Handmaid's Tale*, and works by Sylvia Plath, and contemporary American political debates on reproductive rights. Through close readings of four biblical translations—the King James Version, New International Version, English Standard Version, and New Living Translation—I trace how Eve's fall and its consequences are characterized, particularly in contrast to the antithetical figure of the Virgin Mary. By connecting biblical archetypes with modern cultural discourse, this thesis shows how religious narratives are ingrained in the American consciousness and continue to constrain women's autonomy.

Abstract Name: Locating Exoplanets Using Lightkurve

Lightkurve software facilitates the analysis of data collected by the Kepler and TESS space telescopes. Through the use of this software, as well as Python analysis code, we can identify potential planetary transits from periodic dips in the brightness of stars. These periodic dips can be further refined and analyzed to determine other characteristics of the system such as the approximate size of the planet and parameters of its orbit. Data is accessed from the TESS space telescope using the MAST archive, and a variety of refinement techniques in Python are used to interpret and analyze this raw data. This research expands our understanding of distant solar systems and provides an efficient method of locating unidentified exoplanets. The specific star that I am analyzing is called TIC 283722336, which has about 0.8 times the mass of the Sun and is located about 6.5 parsecs from Earth. This star has multiple known exoplanets, but this project is the first to include the most recent data from the MAST archive. With this data, I have been able to rederive and refine transit times, orbital periods, and sizes of multiple planets orbiting this star.

Abstract Name: Structural Determination of Putative Lytic Transglycosylase Inhibitor IVY-P2 via X-Ray Crystallography

Pseudomonas aeruginosa is a pathogenic Gram-negative bacterium with the potential to cause serious illnesses, notably lung infections in cystic fibrosis patients and other infections in immunocompromised individuals. The formation of biofilms and pervasive multiple drug-resistant strains make treatment of *P. aeruginosa* with traditional antibiotics difficult. Therefore, research into potential drug targets and the development of novel treatment options are of paramount importance for controlling deadly infections. One potential drug target, IvyP2, is a homolog of lysozyme glycoside hydrolase inhibitor IvyP1 and is purported to be an inhibitor of *P. aeruginosa* lytic transglycosylases. While the structure of IvyP1 has been experimentally determined, the structure of IvyP2 has not, and there are conflicting observations about the mechanisms for molecular recognition in this family. To define the details of molecular recognition that govern specificity and potency, the structure of IvyP2 was studied to enable comparison to the structure of IvyP1. A structure of IvyP2 determined by X-ray crystallography revealed significant structural homology with notable divergence at the N-terminal alpha helix between IvyP1 and IvyP2. While prior structural work on IvyP1 suggests that the key inactivation loop is the predominant driver for molecular recognition of IvyP1 for its target, our data suggests that additional surface contacts are required. A thorough understanding of the specifics of molecular recognition within the IVY family may answer some of the persistent questions regarding peptidoglycan synthesis and remodeling.

Abstract Name: Modulation of $\alpha 7^*$ -nAChRs on Basal Forebrain Cholinergic Neurons by Amyloid- β Fragments in Alzheimer's Disease

Alzheimer's Disease (AD) is a progressive brain disorder that gradually destroys memory and cognition. One major contributor to early AD appears to be small soluble clusters of amyloid-beta 42 (oA β 42), which build up in the brain years before symptoms begin and are strongly linked to cognitive decline. Basal forebrain cholinergic neurons (BFCNs), which help regulate memory circuits, are especially sensitive to these toxic peptides. These neurons rely on $\alpha 7$ -containing nicotinic acetylcholine receptors ($\alpha 7^*$ -nAChRs), which oA β 42 can abnormally activate. Interestingly, shorter naturally occurring N-terminal A β fragments (A β 1–15/16) and their core sequence (A β 10–15) may instead have protective/regulatory effects on these same receptors. The purpose of the study was to determine the effects of oA β 42, the N-A β fragment, and the shorter N-A β core peptide on the activity of $\alpha 7^*$ -nAChR expressed by BFCNs, which are the cells known to degenerate early in the course of AD. To perform these studies, we prepared ex vivo acute brain slices from ChAT-eGFP transgenic mice and identified BFCNs in the medial septal diagonal band (MSDB). We then used cell-attached single-channel electrophysiology to measure the actions of the peptides on $\alpha 7^*$ -nAChR channel activity. The preliminary results in the current study indicate that both N-A β fragment and N-A β core peptide evoke single-channel openings of $\alpha 7^*$ -nAChRs on MSDB BFCNs. Importantly, distinct biophysical properties such as open-channel burst duration and single-channel open probability (P open) are enhanced when combined with PNU-120596, a selective positive allosteric modulator of $\alpha 7^*$ -nAChRs. These results suggest that the two naturally occurring A β -derived peptides directly interact with $\alpha 7^*$ -nAChRs on BFCNs. Determining how these naturally occurring fragments differentially affect the activity of vulnerable BFCNs may reveal new therapeutic targets to counteract the harmful influence of oA β 42 and ultimately help slow or even reverse cognitive decline in individuals with AD.

Abstract Name: Comparing the Effects of $\Delta 9$ -THC and $\Delta 8$ -THC in *C. elegans* Lifespan and Chemotaxis

The effect of cannabinoids on model-organism longevity is a rapidly emerging research area. In this study, we use *Caenorhabditis elegans*, a soil-dwelling nematode and cherished model organism, prized for its inexpensive husbandry and short life cycle, to test the effect of cannabinoid exposure on lifespan and sensory behavior. We expose adult worms to specific concentrations of water-soluble tetrahydrocannabinol-9 (THC-9), and a common analog tetrahydrocannabinol-8 (THC-8) environmentally in order to test each compound's effect on lifespan. Concurrently, we tested *C. elegans*' propensity to chemotactically favor environmental cannabinoids when presented a control option of pure water via a standard chemotaxis assay protocol with a Sodium azide reagent to paralyze the worms in defined experimental zones. A growing body of experimental data supports the idea that compounds like cannabidiol, a cannabinoid that is widely sold as an over-the-

counter supplement, has a measurable effect on lifespan in *C. elegans* worms. We expand the scope of this research by selecting a different set of phytocannabinoids produced by the cannabis plant in THC-9 and THC-8 and comparing the effects of each. While the data collection phase is complete, analysis and compiling is still a work in progress. We expect to see a few notable and quantifiable effects on *C. elegans* lifespan and chemotactic behavior once this process has finished. Our aim is to systematize the use of *C. elegans* as a low-cost, early-stage screening apparatus for testing compounds for their longevity promoting, or inhibiting effects.

Abstract Name: Comparative Performance of Li-Ion 4680 and LiFePO₄ Polymer Cell Batteries in Subzero Freezing Temperatures

Lithium-ion batteries are notorious for their performance degradation at subzero temperatures, where reduced ionic conductivity and increased internal resistance lead to a severe decline in capacity and power. In previous NASA-supported research, we proposed and validated a novel technique to overcome this limitation by encapsulating the battery in a vacuum chamber. This passive thermal management method significantly slows a battery's cooling rate by eliminating conductive and convective heat losses. Initial experiments were conducted on a LiFePO₄ polymer cell. Compared with atmospheric conditions, it took 25% longer to reach -15°C and 75% longer to reach -20°C when cooled from 20°C to -20°C in a vacuum. This thermal buffering was directly associated with lower performance loss in discharge capacity tests. This research is now being extended to a 4680 cylindrical lithium-ion battery, which presents an interesting comparison. The 4680 cell differs significantly from the more stable, flat LiFePO₄ cell in its cylindrical shape (46 x 80 mm), its smaller surface-area-to-volume ratio, and its high-nickel cathode chemistry. The working protocol involves placing the 4680 battery in a custom vacuum chamber and subjecting it to sub-zero environments by inserting it in a freezer along with its accessories like thermocouples, electrical cables, and vacuum pipes to set pressure inside the vacuum chamber. Key variables monitored include battery surface temperature, ambient temperature, vacuum cell pressure, and discharge IV characteristics. Work is still in progress, but preliminary results are promising and align with predictions. It is anticipated that the 4680 battery will demonstrate superior thermal retention due to its compact size and internal chemistry, resulting in even better performance in cold conditions. A full comparative analysis of the thermal and electrical performance for both battery types will be presented, concluding with insights into the practicality of this technique and outlining future work for real-world implementation.

Abstract Name: Analysis of Psychedelics and Sociopolitical Stigmas

Psychedelic-assisted psychotherapy (PAP) is under investigative research to determine whether the use of psychedelic drugs and psychotherapy, within a professional setting, results in improvements for those with mental health disorders like post-traumatic stress disorder (PTSD) or treatment-resistant depression. Current studies have shown promise in PAP; however, the negative sociocultural stigmatization of psychedelic drugs is also apparent. These views, which are reflected in historical analysis, have been shown to limit research potential and contribute negatively to the scientific inquiry of psychedelics. This study expands the current knowledge of the public's perceptions of PAP/psychedelics. Via an online survey, data from 139 respondents have been analyzed to determine how various perspectives and knowledge towards psychedelics impact one's own attitudes toward PAP. Some results concur with previous studies: college students generally accept PAP (82.8%); there is a statistically significant relationship between one's knowledge of identifying a psychedelic and having a more positive attitude towards PAP. These results suggest that more education on psychedelics with university students may work to decrease the stigmatization of PAP. Further data collection of various sample sizes to garner a greater understanding of the public's attitudes may aid in assisting the growing interest and possible assimilation of PAP for the treatment of mental health disorders. This study has contributed to that understanding by employing historical analysis to examine the underpinnings of the stigma itself.

Abstract Name: The Human Signature: Facial and Behavioral Biometrics in Cybersecurity

Trust in architecture remains questionable as all security systems have advanced significantly. Traditional popular authentication models, such as passwords and tokens, which are still in use in 2025, are increasingly vulnerable. This research introduces "The Human Signature," a multimodal mechanism in cybersecurity that bridges the gap between biological identity and digital verification. Additionally, the goal is to measure and analyze these mechanisms in this diverse world and explore their potential for future applications. Moreover, the prominent approaches include facial and behavioral biometrics; these two modalities combined can be called a human signature — a composite of innate and learned traits that are extremely difficult to counterfeit. However, it is a study about a mechanism that executes liveness detection, ensuring the user is not falsifying their information, and identifies anomalies that don't fit the normal pattern. In addition, the blend of two biometrics: facial recognition (micro-expressions, gaze tracking) with behavioral analytics (keystroke dynamics and interaction patterns) uses advanced image analysis and machine learning to develop adaptive user profiling that continuously verifies legitimacy rather than doing so instantaneously. Furthermore, the methodologies include capturing real-time footage to recognize liveliness and review subconscious human behavior traits that are difficult to imitate. According to the preliminary findings, hybrid biometric mechanisms outperform single-modality verification by reducing the False Acceptance Rate (FAR) and False Rejection Rate (FRR), while enabling an uninterrupted authentication process. The research concludes that the future of cybersecurity favors an adaptive system that perceives the evolving behavior of a user and can also identify them by facial features, moving away from rigid barriers.

Abstract Name: Perspectives of AI Analytics in Professional Sports: Contracts, In-Game Strategy, and Health

Since the first Olympic Games in 776 B.C.E., human judgment has guided athletic strategy and decision making. In today's sports world, however, artificial intelligence (AI) and data analytics are increasingly reshaping these processes. This shift places many viewers and decision-makers in a challenging position, uncertain whether AI will truly enhance team performance or if relying on human judgment remains the better path. This development led to questions about how AI impacts viewers' trust and opinions regarding sports decisions. This research addresses Americans' views on to what extent artificial intelligence should be integrated into decision-making processes within the sports industry. To this end, I designed a survey with questions pertaining to AI in making sports decisions related to contracts, in-game strategy, and athlete health. The results demonstrate that the decision to support the use of AI in decision making in sports differs with the age of the respondents. Specifically, the younger population highly supports the role of AI in decision making more than the older population. These findings suggest that, consistent with trends in other industries, AI integration in professional sports is likely to expand in the coming years, particularly as younger, more AI-supportive generations become a larger share of the fan base and workforce.

Abstract Name: Development of a Continuous Flow Synthesis of X-Ray Imaging Contrast Agent: Iohexol

Iohexol is a non-ionic, iodinated, contrast dye administered intravenously for medical diagnostics through X-Ray imaging and CT scanning. In 2024, the global market of iohexol was valued at \$1.344 billion. With this market being susceptible to production shortages, as evident during the COVID-19 pandemic, the diversification of production processes is advantageous. Traditional iohexol synthetic routes rely on batch processes. Batch chemistry production processes are often limited by lengthy production times, inconsistent yields, and the generation of undesired waste. Continuous flow synthetic approaches mitigate these limitations by allowing greater control over reaction parameters, such as temperature and mixing, leading to faster production times with more consistent products and efficient processes. Additionally, continuous flow chemistry allows for greater heat and mass transfer, enabling high temperature high-pressure chemistry with improved safety. Process analytical technology can also be easily implemented into continuous processes for automation control and quality by design pharmaceutical manufacturing. Iohexol can be afforded in a three-step process involving a one-pot Ullmann-type cross-coupling and transamination, followed by iodination and acylation. A continuous flow iohexol production process will be developed by screening batch conditions for each step to identify conditions for further screening in continuous flow chemistry. Thus far, screening of the one-pot Ullmann-type cross-coupling and transamination with excess copper catalysts to simulate a packed bed reactor has shown promise for the transition to a flow system. The process development of an iohexol continuous flow synthesis has the potential to provide a more scalable, efficient, and environmentally friendly pathway, leading to greater accessibility of the imaging agent in the clinic.

Abstract Name: The Effects of Genetics on the Bone's Response to Immobilization

Mechanical unloading from disuse decreases bone mass, increasing the risk of fracture. Our lab has shown that genetic variation influences the magnitude of bone loss from disuse in inbred male mice. To further elucidate the effects of genetic variation, we used male and female mice of the diversity outbred (DO) mouse population. DO mice were developed by cross-breeding eight highly genetically diverse inbred founder strains. We hypothesized that genetic variation would affect the magnitude of bone loss from disuse via single-limb immobilization. Ten female and ten male 16-week-old DO mice had the right hind limb immobilized in a cast for 3 weeks, and then the mice were sacrificed. Femurs were scanned by in vivo micro-CT at baseline on day 1 and three weeks later, on day 22. All data was analyzed as the percent change from baseline to final scans. There was a significant decrease of mid-diaphyseal cortical Periosteal Perimeter/Total Bone Perimeter (B.Pm/T.Pm) for both sexes. Male mice had significant decreases of metaphyseal Bone Volume (BV), Bone Volume/Total Volume (BV/TV), and Trabecular Number (Tb.N), while female mice experienced significant increases in Tissue Mineral Density (TMD). Both sexes experienced increases in metaphyseal Trabecular Separation (Tb.Sp). Distal femur epiphyseal bone was more negatively affected by immobilization: BV, BV/TV, Trabecular Thickness (Tb.Th), Tb.N, Tb.Sp, and TMD all had significant differences due to immobilization. Male mice experienced a greater increase in TMD and Tb.Sp, than the females; females experienced a greater decrease in BV, BV/TV, Tb.Th, and Tb.N than the males. All mice had bone loss due to immobilization, regardless of genetics. Disuse leads to an increased risk of knee injury due to bone loss in the distal femur epiphysis.

Abstract Name: Living Independently with Glaucoma

Designing a residential environment for individuals with visual impairments requires a clear understanding of their spatial, safety, and navigational needs. An estimated 39 million people are blind, and around 246 million have moderate to severe visual impairments. Glaucoma is a progressive condition that gradually reduces peripheral vision due to irreversible damage to the optic nerve. Glaucoma most commonly affects individuals over 60. Although treatment can slow the progression of glaucoma, lost vision cannot be restored. This project aims to design a single-family home that accommodates a resident living with glaucoma. The project incorporates insights from case studies, literature reviews, and established accessibility and low-vision design guidelines, including ADA standards, appropriate for aging residents who want to age in place. These findings guided the development of the project, a residence that prioritizes wayfinding, visual contrast, and spatial clarity. Wainscoting in the living room provides tactile guidance throughout the home, while contrasting cabinet colors in the kitchen enhance visual differentiation. Door frames were intentionally designed in darker shades than the doors themselves to improve depth perception and increase contrast for individuals with reduced peripheral vision. The home's primary corridor forms a U-shaped pathway that naturally guides residents through the space and reduces disorientation. Additional rooms also incorporate

distinct color schemes to promote independence and safe navigation. Passageways and corridors are kept open and unobstructed to enhance visibility and spatial awareness for users with limited peripheral vision, improving overall safety. As a result, the project demonstrates how evidence-based interior design strategies can improve safety, navigation, and quality of life for individuals with glaucoma and other visual impairments. By focusing on accessibility and user experience, the home meets the users specific needs while fostering independence and safety in daily life.

Abstract Name: The Crisis of Modern Sport; Toward a Phenomenology of the Athletic

What does it mean to be an athlete? Philosophers of sport have largely focused on either the formal structure of games or the aesthetic unity of the skilled body in action, yet the concept of athleticism has been underdeveloped, often used to denote any participant in sport. This work develops a phenomenological conception of athletics and the athlete, as such. I argue that athletic pursuit puts our body out of its everyday functionality, revealing what is normally lost in the mundane. In this sense, athletics serves as a horizon for the disclosure of the body. With this understanding, I consider the ways in which this path of self discovery is put at risk by contemporary sporting structures. The tendency for commercialized sport to engage in its own simulation (televised events, sports video games, and the promulgation of sports betting) have made sports leagues billions of dollars, but misunderstand the purpose of sport. By returning to its phenomenological essence we arrive at a deeper appreciation for sport, and also a framework for an ethics of athletic pursuit.

Abstract Name: Voting Choice as a Predictor in County Level Sexual Orientation and Gender Motivated Hate Crimes across the United States: A Latent Growth Modeling Approach

Animus towards LGBTQ (Lesbian, Gay, Bisexual, Transgender, and Queer) individuals remains high, exemplified through the growing incidence of hate crimes motivated by a victim's perceived LGBTQ identity. The increase in hate crime incidents may seem incongruous given recent polling data suggesting that attitudes towards the LGBTQ community are growing more positive year over year rather than negative. Recent work has proposed the importance of political factors influencing hate crime incidence in the United States, with jumps in occurrences loosely associated with major political events. Thus, my research seeks to clarify how one such event, the United States's 2016 presidential election, may relate to hate crime incidence for the following four years post-election. To answer my research question, I will assess whether hate crime incidence motivated by LGBTQ identities at a county level differs based on voting results in the 2016 election, such that Republican voting Republican counties have a higher incidence than Democratic counties over a four-year time span. My main analyses will consist of a mixed-effects ANOVA to quantify mean differences in incidence at a group level (Democratic county compared to Republican county) and in mean

differences over each time point. The second analysis will consist of a Latent Growth Model capturing intra-county changes in hate crime incidence across 16 timepoints from county election results.

Abstract Name: Perceptions of Therapists Identified as AI Generated or Human

As artificial intelligence (AI) continues to advance, its integration into mental healthcare offers both promise and uncertainty. Although digital therapists such as Woebot and Wysa have demonstrated effectiveness in reducing symptoms of anxiety and depression, skepticism remains regarding the ability of AI to replicate the empathy and authenticity of traditional human practitioners. Previous research has shown that text-based digital therapists are perceived as warmer and more trustworthy when the user is unaware that the therapist is AI generated. This study used a randomized controlled design to examine whether perceptions of empathy, credibility, and expected treatment outcome differ based on whether a therapist is described as AI generated or human. In the study, participants (N=300) obtained from an online recruitment platform listened to two therapist audio recordings identical in content and both from a human therapist. However, in one of these recordings the therapist was identified as AI generated; in the other recording the therapist was identified as human. Half the participants heard recordings of male therapists and the other half of female therapists. After listening to each recording, participants evaluated therapist empathy, perceived credibility of treatment, and expectations concerning the success of the treatment. Analysis using a therapist identity × therapist sex analysis of variance revealed that participants judged therapists labeled as human more positively across all measures. Although the results did not vary reliably as a function of therapist sex, prior therapy experiences moderated perceptions when considered alongside therapist sex. These findings suggest that the belief that a therapist is AI generated results in less favorable perceptions even when actual therapy content is identical, revealing ongoing challenges for the integration of artificial intelligence in the field of psychotherapy. The study also highlights the need for continued exploration of factors shaping acceptance and trust in AI-based mental healthcare tools.

Abstract Name: Spectral Warrior: Learning RF Through Gamification

Radio frequency (RF) concepts such as wireless transmission, antenna propagation, and propagation effects are ubiquitous in daily life but are inherently hard to conceptualize, due to their complexity and that they are invisible to the naked eye. The Spectral Warrior concept, built in partnership with the Naval Surface Warfare Center Dahlgren Division (NSWCDD), leverages state-of-the-art virtual reality hardware and software tools

in order to make the invisible, visible. Beyond simply visualizing RF concepts, Spectral Warrior also gamifies relevant concepts in order to engage users more effectively to learn how these concepts are applied in real-world applications. An exemplar of this concept is the developed electric warfare (EW) search and destroy game. Built in Unreal Engine 5.5.4, this scenario has the user interfacing with a dynamic linear phased array, which they must utilize to locate and terminate incoming missiles before impacting the vessel they are stationed on. Through learning to play the game effectively, the user sees the impact on the RF propagation based on the choices they make, and learns interactively how phased arrays work and are leveraged in mission critical applications.

Abstract Name: Let the Students Design: Building an AI Critical Literacy Course with and For Students

Note: The lead faculty mentor is proposing these presentations before students conduct research (Jan-May), due to the loss of funding in July 2026. Four student presenters and three faculty members in an English Department plan to attend NCUR. We propose a round-table or two presentations with two student presenters each. The students will show how collaborative, student-centered research and design can foster critical thinking, technological fluency, and equitable access to AI education while offering a model for integrating AI critical literacy into general education writing programs. The rapid spread of AI across communication and composing technologies has made it harder for faculty and students to maintain integrity and autonomy as writers. In response, faculty mentors and undergraduate researchers are collaborating to develop AI critical literacy. Student researchers will help formalize a relevant, accessible, evidence-based course and address our guiding question: How can collaboration between student research assistants and faculty mentors inform the design of an ethical AI critical literacy course that engages students while addressing evolving debates about machine learning and authorship? This project is grounded in work on digital ethics, critical information literacy, and student-centered curriculum design, particularly in HSIs where first-generation and Hispanic students often lack equitable access to emerging technologies. Students will present selections from their mixed-methods approach that incorporate the following: surveys and focus groups, analysis of existing AI literacy curricula, experimental piloting of assignments, and their evaluation of AI outputs for bias, accuracy, and rhetorical appropriateness. The presentations will demonstrate how student-centered design can foster critical thinking, technological fluency, and equitable access to AI education. Expected results include a modular course proposal with units on ethics, authorship, and algorithmic bias; a digital portfolio of adaptable materials; and recommendations for inclusive pedagogies that foreground student voices in course design.

Abstract Name: The Role of Blockchain in Finance: Enhancing Fraud Prevention and Data Integrity

Fraud and data manipulation in finance and accounting remain global challenges that cost organizations billions each year. As industries strive for transparency and trust, blockchain technology offers a

revolutionary approach to strengthening financial integrity. This research explores how blockchain's decentralized and tamper-proof ledger can prevent fraud and improve accuracy in financial reporting. By recording transactions across multiple nodes, blockchain eliminates the possibility of altering data without network consensus, making every financial record verifiable and permanent. The study examines how key features such as triple-entry accounting, smart contracts, and immutable transaction records can address weaknesses in traditional systems. Real-world examples, including implementations by JPMorgan Chase and Deloitte, demonstrate how blockchain enhances auditing, reduces intermediary costs, and enables real-time verification. Moreover, the integration of artificial intelligence with blockchain has the potential to detect irregularities and prevent financial crimes before they occur. While the technology faces regulatory and scalability challenges, its promise to create a transparent and fraud-resistant financial ecosystem positions blockchain as a transformative force in modern finance. This project invites readers and conference participants to envision a future where financial trust is built not on paper trails or intermediaries, but on secure, self-verifying digital systems designed to protect both institutions and individuals.

Abstract Name: A Longitudinal Study of Macroorganism Associations and Health Status of Demospongiae Species in Roatán, Honduras

Sponges are some of the most prevalent and vital members within coral reefs. Some poriferan species possess a spongocoel and large protuberances, which provide refuge for marine organisms. Species such as *Niphates digitalis*, *Callyspongia plicifera*, and *Xestospongia muta* are notable for these features. Associations between sponges and macroorganisms are generally incidental or opportunistic. However, interactions between brittle stars and poriferans can be mutualistic to parasitic. The association between macroorganisms and sponges and sponge health is unknown. This study examined macroorganism associations and health status for Demospongiae species in Roatán, Honduras between May 2024 and 2025. In 2024, *X. muta* displayed noteworthy macroorganism diversity, with one individual harboring ~130 fish (92.9%). Of note were seven juvenile threespot damselfish (*Stegastes planifrons*), a species typically associated with staghorn corals. Over 60% were algae fouled or diseased. *N. digitalis* were predominantly healthy (75%), but brittle star presence correlated with lesions in 61.9% of hosts. All *C. plicifera* were found healthy and unassociated with macroorganisms. In 2025, *X. muta* health status increased, with 51.8% being healthy. *N. digitalis* was consistent in health (90%), while *C. plicifera* showed increased stress with only 50% being healthy. Across both years, *X. muta* exhibited the greatest number of macroorganism associations (311 fish, 8 crustaceans). Five juvenile threespot damselfish were observed with *X. muta* in 2025. *N. digitalis* primarily hosted brittle stars (60%) and crustaceans (7%), and *C. plicifera* had minimal associations. This research serves as a foundation for future studies on sponge health and microorganism associations.

Abstract Name: BAG3 Modulates Clathrin-Mediated Endocytosis and Tau Uptake in Astrocytes

One of the major hallmarks of Alzheimer's disease (AD) is the abnormal accumulation of the protein tau. Tau becomes abnormal and dysfunctional when it is hyperphosphorylated, leading to the polymerization of its natively unfolded structure. In both healthy and pathological neurons, dysfunctional tau can be released to protect the neuron. In healthy individuals, pathological tau that is released by neurons and taken up by astrocytes is trafficked to the endosome-lysosome complex, where it is degraded and thus fully removed from the extracellular space. Previous studies have determined that cells affected by AD have lower levels of the protein quality control factor Bcl-2-associated anthanogene 3 (BAG3) in both neurons and astrocytes when compared to wild-type (WT) cells. Additionally, proteomic analyses of proteins co-precipitating with BAG3 showed numerous proteins involved in clathrin-mediated endocytosis (CME) and the endosome-lysosome pathway, including clathrin heavy chain, dynamin, and subunits of the AP2 complex. To extend these findings, we used a proximity ligation assay (PLA) to observe that there is an association between BAG3 and clathrin (<40nm) and that when BAG3 is depleted, there is also a decrease in the interactions between clathrin and AP2. Using flow cytometry, we demonstrated the importance of BAG3 in this endocytosis pathway, as BAG3-depleted astrocytes endocytose significantly less tau than control astrocytes. We have also identified trafficking differences between control and BAG3-depleted astrocytes. We hypothesize that with lower expression of BAG3, astrocytes are not able to protect neuronal health due to a compromised ability to take up and traffic tau that had been released by neurons. This would increase the likelihood of the uptake of pathological tau by other neurons, resulting in the propagation of tau pathology and progression of the neurodegenerative characteristics of the disease.

Abstract Name: Impact of Clothing on Perceiving Masculinity and Sexual Orientation

Extant research suggests that judgments of sexual orientation based on brief nonverbal interactions are more accurate than chance. Those who identify as heterosexual tend to dress in more gender-stereotypical attire than those who identify as a gay man or lesbian, and observers use this to infer sexual orientation. Research also shows that appearance can be used to infer personality characteristics. In this study, participants were randomly assigned to view one of four possible target photos in a 2(Target Gender: Man vs. Woman) X 2(Attire: Masculine vs. Feminine) design, and then they rated the target individual on perceived level of masculinity and sexual orientation. Participants were expected to perceive targets in gender-typical attire as more likely to be heterosexual compared to targets in gender-atypical attire, and rate targets in masculine attire as more masculine. Results indicated that targets dressed in masculine attire were perceived as more likely to be heterosexual. Male targets were perceived as more masculine, and this was moderated by the type of attire. The results were driven by the male targets, the perceived differences in the female targets were negligible. Results supported predictions, but highlighted the need for further research on perceived personality traits in females.

Abstract Name: Engineering Ferroelectric Field-Effect Transistors for Artificial Intelligence-Enhanced Edge Computing Systems

Given the importance of memory efficiency in Artificial Intelligence (AI), reducing the latency between computation and memory is imperative for the demands of reliable, high-performance non-volatile memories in AI. The current mainstream computing devices are built on the Von Neumann architecture, but other architecture can reduce delays and improve efficiency. Computer-in-memory architecture addresses these issues by enabling memory to be accessed closer to the source of computation. As the semiconductor industry pushes toward energy-constrained edge computing and embedded memory integration, ferroelectric field-effect transistors have emerged as a promising edge-computing candidate due to their scalability, fast switching, and low-power operation. To further improve device designs, using interface materials that can mediate trap states at the interface and bandgap engineering allows for a larger memory window for read operations. The memory window is crucial because it minimizes reading errors, thereby improving overall performance and reliability. I developed compact models using interface materials, including HfO₂, ZrO₂, Al₂O₃, and La₂O₃ to evaluate the impact of ferroelectric material parameters on remanent polarization (Pr) and coercive field (Ec) using Synopsys Technology Computer-Aided Design simulation and modeling tools. Based on physical parameters from experimental devices, I developed and calibrated physics-based models to capture ferroelectric hysteresis and nonlinear dielectric behavior. Additionally, I will use these models to investigate the mechanism of charge trapping kinetics and field-dependent polarization fatigue, enabling simulations of device behavior under various conditions. Ultimately, this research aims to deliver a set of experimentally validated ferroelectric devices capable of reliable low-voltage operation, suitable for integration into scalable, reliable embedded hardware platforms. Beyond device optimization, the work will contribute to a deeper understanding of interface-dependent ferroelectric switching, charge trapping dynamics, and voltage scaling. These findings will inform design strategies for next-generation embedded memory, compute-in-memory, and AI hardware platforms, where energy efficiency and integration density are paramount.

Abstract Name: Vulnerability Assessment of Smart-Grid SCADA Systems

Protecting U.S. critical infrastructure is a national security imperative. However, many operational

technology (OT) environments still run legacy, geographically dispersed SCADA systems. Catastrophic impacts could be realized if those systems' weaknesses were to be exploited. Therefore, there is an urgent need to provide the ability to test both hardware and software in realistic environments. The research team developed a SCADA smart-grid testbed prototype that mirrors real-world OT network configurations and equipment, enabling controlled analysis of high-value attack surfaces. This is the result of phase 1 in a larger effort to build next generation cyber-physical modeling simulating multi-domain exploitation, including integration with Large Language Models (LLM) and Extended Reality (XR) User Interfacing (UI). The system architecture consists of one SEL-2411 field-interface device and two SEL-3505 Real-Time Automation Controllers (RTAC) configured to represent Level 0–2 interactions within a power-system environment. This phase seeks to identify the operational attributes and communication behaviors—timing intervals, tag-state transitions, dependency relationships, and protocol-specific message structures—that will be most valuable for comprehensive evaluation in later stages. In addition to behavioral baselining, the research design team incorporates protocol-level analysis and ICS red-teaming methodologies. Planned protocol testing will examine the operational characteristics of common SEL and utility communication standards, such as DNP3, Modbus, and IEC 61850, with an emphasis on message timing, error handling, and field-device interaction patterns. The testbed will also be structured to support controlled red-team activities intended to evaluate the robustness of logic execution, field-device interactions, and supervisory dataflows against realistic adversarial techniques. A further component of the project involves integration with embedded Linux environments used for supervisory control and data aggregation. This includes designing mechanisms for logging, data extraction, and real-time monitoring using Linux-based hosts coexisting with the SEL hardware stack.

Abstract Name: Forecasting Future Foraging: Comparing Flowering Strategies of Related Species in a Changing Climate

Appalachia is a foraging hotspot home to many plants with culinary and medicinal uses, but climate change could cause range shifts that impact access to these native plants. Throughout history, Appalachian foragers have relied on over 170 native plant species, from winemaking with muscadine grapes to treating headaches with American ginseng. We will create Ecological Niche Models to study the impact of climate change on native plant accessibility. This will illustrate possible habitat range shifts of significant Appalachian plants by combining reported species occurrence data with predicted climate conditions based on future greenhouse gas emissions. We will use the Global Biodiversity Information Facility website to compile species occurrence data from iNaturalist, museums, and herbaria. Ecological Niche Models will be constructed using a R script that employs the dismo package to combine climate conditions with reported species occurrences and calculates suitable habitat in eastern North America. We will model habitat range shifts resulting from future climate conditions predicted in the Representative Concentration Pathways (RCPs), then map species occurrence probability using QGIS to illustrate shifts in habitat ranges across the eastern United States. Range shifts may hinder forager access to native plant species and cause a decrease in edible plant and folk medicine traditions. We found no correlation between flowering times and resistance to climate change with the eight species examined thus far. We will test species that are more closely related and have similar morphology to better understand impacts of shared lineage on resilience to a changing climate, allowing us to predict which native plants and foraging traditions are most at risk.

Abstract Name: Developing an enzymatic biomarker for cyanotoxin exposure in the round goby (*Neogobius melanostomus*)

The presence of harmful algal blooms (HABs) in the Lake Erie watershed has repercussions for humans and wildlife. Due to the negative health effects of HAB cyanotoxins, local waterbodies are frequently sampled to prevent human exposure, but this does not account for impacts on aquatic wildlife. One way to estimate this is by measuring a trait that is directly affected by exposure, also known as a biomarker. Because exposure to cyanotoxins is known to affect the liver, the quantification of detoxifying liver enzymes like glutathione S transferase (GST) could be a biomarker. The objective of this project is to determine if GST activity is a good biomarker for cyanotoxin exposure in the invasive round goby (*Neogobius melanostomus*). Round gobies will be collected from six different sites in Lake Erie and its tributaries as well as an additional site at an inland lake (LeBoeuf Lake). The activity of GST from homogenized liver tissue will be measured in vitro using a plate reader. If GST activity is a good biomarker for cyanotoxin exposure, then these measurements should correlate with the reported HAB levels across the sites. This research is an important step toward understanding the consequences of HABs in affected waterbodies.

Abstract Name: Nursing Shortage Affects Quality of Care

Abstract Background and Significance: For many years, the shortage of nurses has been a problem around the world. Most healthcare facilities are facing staff shortages which lead to higher patient-to-nurse ratios. This situation seriously affects the quality-of-care patients receive. **Aim:** The goal of this project is to emphasize how important it is to review nurse-to-patient ratio to determine interventions to help alleviate or minimize the impact of the problem. Dorothy Orem's Self-Care Deficit Theory provides the theoretical foundation for this research, highlighting the essential role nurses play when patients are unable to meet their own self-care needs. **Methods:** This cross-sectional study combines both qualitative and quantitative methodologies and to identify the relationship and patient outcomes. Quantitative data will be gathered through structured surveys measuring nurse workload, burnout, and perceived quality of care. In contrast, qualitative data from interviews will provide insight into nurses', patients', and administrators' lived experiences regarding staffing challenges. Ethical consideration, including confidentiality, anonymity, and informed consent, will guide all data collection processes. **Conclusion:** The findings of this project will contribute to policy development and workforce planning strategies to mitigate nursing shortages and enhance the quality of patient care. It will inform healthcare leaders, policymakers, and professional organizations about the urgent need to implement interventions that address staffing shortages, strengthen nurse retention, and enhance the overall quality of patient care. **Keywords:** 'Nursing Shortages', 'Patient Care', 'Patient Safety', 'Nurses burnout and stress', and 'Affecting Quality of Care'.

Abstract Name: Developments on the Local Convergence of Newton-Like Methods in Normed Linear Spaces with Applications to Motion Problems

Numerous problems from computational sciences are converted using mathematical modeling to solving an equation iteratively. Newton's method (NM) and its variants are the most popular methods for generating a sequence approximating a solution of a nonlinear equation defined on the real line or more abstract domains. However, the convergence conditions in the literature may not be satisfied. So, the convergence cannot be assured although the method converges. In this project, we extend the applicability of (NM) by providing weaker convergence conditions than before. Our approach allows for a wider choice of initial points and requires fewer iterations to reach a desired error tolerance. Applications are provided from diverse disciplines where the new results are compared favorably with earlier ones.

Abstract Name: A Closer Look at Substance Use: Understanding Abstinence in Social Gatherings

Abstract: Purpose: This study investigates the landscape of alcohol and drug use within social contexts, focusing on why many individuals choose abstinence. By exploring these dynamics, we aim to empower students to make informed decisions about substance use and understand the factors that influence their choices. **Methods:** Utilizing secondary data from participants involved in an outpatient treatment program with wrap-around services, we analyzed survey responses measuring substance use over the past month. This included assessing individual usage patterns and the impact of social interactions, with specific attention to questions about drug and alcohol use, social connectedness, as well as instances of concurrent use. **Results:** The findings reveal that a significant majority of respondents reported no recent substance use; specifically, 60.7% indicated abstaining from drugs, and 59.9% reported not consuming alcohol. Additionally, 64% of participants stated they had not used drugs and alcohol together. Notably, we examined how many participants selected "not applicable" in response to questions concerning combined use, despite undergoing treatment for substance use. **Conclusions:** The data indicate that many individuals surveyed do not regularly engage in substance use during social interactions, presenting a more nuanced perspective than typically captured in public health literature. These insights suggest that abstinence may be more common than previously recognized and highlight the need for further research. Analyzing contextual influences, motivational incentives, and demographic impacts will enhance our understanding of the choices made regarding substance use, ultimately fostering environments that promote healthier decision-making.

Abstract Name: Effects of Heat Wave and Geographic Origin on Ovary Development in *Osmia lignaria*

Climate change is a major driver of global species declines, and heatwaves are particularly concerning because they are becoming more frequent and intense and can suddenly push organisms beyond their thermal limits. Cavity-nesting solitary bees may be especially vulnerable, as they develop immobile within above-ground nests with limited protection from extreme heat. Many bee species also span broad geographic ranges, experiencing diverse local climates that may shape their thermal tolerances; yet, we still lack a clear understanding of how heatwaves impact bee fitness across life stages and populations. To address this gap, we exposed developing *Osmia lignaria* from three western U.S. populations to experimental heatwaves during larval development. We assessed survival and development during and after the heat wave, and the following spring, we evaluated adult outcomes, including emergence timing, ovary maturation, and thermal tolerance. Heat wave exposure during larval development reduced survival and altered developmental timing, with variation among populations in the magnitude of these effects. These findings provide insight into the vulnerability of solitary bees to heatwaves and highlight the importance of life stage and geographic origin in shaping thermal resilience. Understanding these patterns is crucial for predicting the impact of future climate extremes on bee persistence and pollination services in both natural and managed ecosystems.

Abstract Name: Examining Heart-Brain Connections: The Link Between HRV and Frontal Lobe Function in Older Adults

Heart Rate Variability (HRV) is the fluctuation in time between heart beats and is thought to reflect activity in the autonomic nervous system. HRV is useful for monitoring health status and predicting future health outcomes, with lower HRV associated with compromised health and lower morality. HRV also reflects vagus nerve functioning which influences the prefrontal cortex and neural circuits that support executive functions. Building on this, we wanted to test whether better scores on neuropsychological tasks that involve the frontal lobe are correlated with higher HRV and therefore better cognitive health in older adulthood. Older adult participants (age 60+) completed visits with two parts. First, we recorded resting physiological metrics such as heart rate and respiration rate to calculate standard HRV indices at rest. Second, participants complete a brief battery of frontal-lobe tasks: Digit Span, Mental Arithmetic, Mental Control, and Verbal Fluency. We then examine correlations between HRV, and the scores taken from these tasks. We predicted that higher HRV would be correlated with higher frontal lobe scores, but this was not supported potentially because of a small, and generally healthy sample.

Abstract Name: Utilizing AI/ML to Develop a 3D Printing Performance Predictive Framework

Recent advances in 3d printing have increased the need for data-driven tools capable of predicting how process parameters influence material behavior. In earlier work, we developed a machine learning model that utilized 3D printing parameters, including layer height, print speed, infill density, and temperature, to predict key mechanical properties of printed parts (surface roughness, tensile strength, and elongation) using a dataset from Kaggle. However, a key limitation of this initial model was that it required the material type (ABS/PLA) to be known beforehand. To address this constraint, a second model was developed that reframed the problem as a classification task. This model predicted the material type itself. By combining two datasets and applying a Random Forest Classifier, the system achieved an accuracy of approximately 85% in distinguishing ABS from PLA, demonstrating that material identity can also be inferred from process conditions. With the two fully developed models, we had the foundation needed to construct a unified predictive framework for 3d printing. The framework first identifies what material the part is made of, and then immediately predicts how that material will behave under a chosen set of printing conditions. This pipeline eliminates the main limitation of the first model, the inability to predict properties without knowing the material type, and transforms the two separate models into a coherent, end-to-end tool. This framework simulates the way engineers make decisions in practice. Experimental work was also conducted to generate our own data. 3D printed dogbones (~500 PLA/ABS) were tested for output parameters such as tensile strength, and the corresponding input parameters were recorded. In our future work, we will be using in-house-generated data to develop predictive models for various 3D materials.

Abstract Name: How Do Humans Experience Social Rejection and Acceptance From Artificial Intelligent (AI) Agents?

As artificial intelligence (AI) agents become increasingly integrated into everyday life, understanding how humans socially respond to them is essential in identifying potential psychological risks and ensuring that proper ethical safeguards can be placed in future models. By bridging the gap between social psychology and human-computer interaction, this study examines how humans experience social rejection and acceptance from AI agents. Current literature implies that within human-human interaction, conversational response time is an important signal of social rejection. Long response gaps, longer than four seconds, are associated with feelings of awkwardness and disconnection between strangers; however, close friends do not experience these negative effects. This project extends this idea into AI to see if humans will respond similarly to these temporal cues during their conversations with an AI agent. The methodology includes a mixed-methods design. Participants first complete a pre-task survey measuring weekly AI usage, rejection sensitivity (RSQ), attachment styles (ECR-12), anxiety (GAD-7), parasocial interaction, and intolerance for uncertainty (IUS-12). Afterwards, participants engage in a lab-based task involving three distinct conversational blocks with an AI bot: an 'acceptance condition' (1-2s response, warm personality), a 'rejection condition' (8-12s slow response, cold personality, simulated rejection by intermittent typing indicators), and a 'neutral condition' (4-5s response). The participants' emotional state, feelings of awkwardness, and willingness to re-engage with the bot will be assessed in between conversational blocks through self-report surveys. It is hypothesized that participants will show negative psychological responses (e.g., increased anxiety, awkwardness) to simulated AI rejection, and these effects will be moderated by pre-existing individual differences, such as rejection

sensitivity and attachment style. These findings would suggest that humans are beginning to apply complex social cues, typically reserved for human interaction, to their interactions with AI agents.

Abstract Name: Struggling in Silence: The Distrust of Doctors Among Southern Black Americans

This project explores the deep-rooted distrust of doctors and medicine among Southern Black Americans, a topic that carries personal significance within my own family. The central research question asks: How have historical injustices and generational experiences shaped the ongoing mistrust of healthcare systems within Southern Black communities? Growing up, I witnessed many older relatives choose to endure illness or pain rather than seek medical attention. This behavior reflects not only personal choice but a broader legacy of fear and skepticism built over generations. Drawing on historical events such as the Tuskegee Syphilis Study and ongoing racial bias in healthcare, this project aims to connect personal family narratives to larger social and historical forces that continue to affect health decisions today. The research employs a qualitative approach, incorporating family interviews, narrative reflection, and historical analysis to examine how stories passed down through generations shape health attitudes. Preliminary findings suggest that this distrust is not rooted in ignorance or stubbornness, but in generational trauma and self-protection. Understanding these experiences reveals how cultural memory influences modern healthcare relationships. The project seeks to emphasize the need for culturally responsive and empathetic medical care that acknowledges history while rebuilding trust between healthcare providers and Black patients.

Abstract Name: Overworked and Underpaid: A Study of Migration Intent in South Africa's Young Medical Professionals

Brain drain, or the loss of skilled laborers, causes South Africa to lose a significant number of medical professionals annually due to specific push and pull factors influencing migration to more developed countries. The proposed research analyzes how pre-established migration factors, such as working conditions and wages, encourage young medical professionals in Cape Town to consider migration from South Africa for work. Upon review of the current literature on the South African brain drain, few studies focus on young medical professionals, such as medical students and nursing students. Moreover, the current literature fails to consider how young medical professionals make migration decisions based on the push and pull factors perpetuating South African brain drain. Therefore, the proposed research uses current literature to develop a list of five push and pull factors medical professionals must consider when migrating. Through six semi-structured interviews of medical students and nursing students studying in Cape Town, interview data will be thematically coded to determine which factor most significantly contributes to the migration decisions of young medical professionals. Findings may reveal that poor working conditions are the most significant push factor causing medical students and nursing students to migrate from Cape Town for work. The proposed

research will confirm the significance of poor working conditions on healthcare worker migration and thus inform workplace-improving legislation that targets the source of brain drain in South Africa.

Abstract Name: Illuminating Human Drug Metabolizing Enzymes Through Structure–Activity Relationship Studies of Carbonate-Based Fluorogenic Chemical Tools

Human carboxylesterases (CESs) are key enzymes in drug metabolism that catalyze the hydrolysis of multiple classes of drugs and play a particularly key role in the activation of prodrugs. Responsible for over 80% of the total hydrolytic activity in the liver, CES1 plays a dominate role in the first-pass metabolism of drugs. To study CES1's role in drug metabolism our group has previously developed a carbonate-based fluorogenic chemical tool based on a fluorescein scaffold that is specific for CES1 over CES2 in a live cell model of CES-mediated drug metabolism. Here, we seek to optimize our tools by developing a structure–activity relationship (SAR) for the hydrolysis of carbonates by CES1. Fluorogenic carbonates were synthesized in a single step reaction with fluorescein and the corresponding chloroformate. After confirming the purity and structure, each tool was evaluated for suitability for use in live cells. In vitro results found several carbonates with improved specificity than carbonates used in our current generation chemical tools. The more specific CES1 substrates developed in this work will enable the development of better fluorogenic chemical tools capable of studying CES1 in live cells. Studies utilizing these tools will be used to illuminate the intricacies of CES1-mediated drug metabolism providing safer and more effective treatments for patients.

Abstract Name: Omnipresence: the UWG Journal in Psychology of Gender and Sexuality

Omnipresence aims to identify and fill a critical void in undergraduate publishing: the specific psychological study of gender and sexuality. Though there are numerous journals that concern either psychology or gender and sexuality studies, very few focus specifically on their intersection. We accept submissions from diverse disciplines—strictly contingent upon a dual focus on psychological inquiry and gender/sexuality frameworks—and invite contributions from institutions worldwide. To capture a large net of submissions, we intend to accept papers from institutions across the world. Beyond location, we also intend to accept submissions besides the typical paper. More specifically, creative nonfiction, fiction, poetry, and visual art. Creative projects must be coupled with a statement of intent, which explores the academic themes of their work, while allowing for unique approaches to the topics at hand. This decision allows for a much wider variety of eligible submitters, and makes submission more approachable for undergraduates of numerous disciplines. The purpose of the journal is to provide a specific outlet for spreading the research and content

related to our topics. As the title concepts researched are “omnipresent” in our lives. Prejudice, exclusivity, and blatant hostility against those of minority communities within the world make the outreach of such research more important than ever before. A new journal requires much research into the framework of similar journals as well as understanding what resources are needed for an editorial board made up of similar undergraduates. Once the journal process begins and peer review starts, there will be an opportunity to provide a much wider scope into this process. Making decisions within an undergraduate board and inventing solutions as situations arise is also important to the process. I will be able to explore this in-depth within my presentation of the journal.

Abstract Name: Answering the Call for End of Life Care for Our Aging Population: A Community Engaged Approach to Improving Community Outreach and Volunteer Recruitment

End of life care is becoming all the more crucial as our population ages. However, there is a lack of volunteers or specially trained professionals who are willing and able to do this work. Without people to serve in this role, nonprofit organizations like the Joan Nicole Prince Home, a nonprofit that provides compassionate, no-cost care for individuals at the end of their lives, are struggling to meet the needs of their patients. To address this gap, an interdisciplinary team of students from Siena University’s Nonprofit Excellence and Transformation Fellowship partnered with the Joan Nicole Prince Home to evaluate and modernize their outreach methods, analyze prior marketing performance, and redesign promotional materials to authentically represent the organization’s mission. By combining evidence-based analysis with community-based learning, this project enhanced the Joan Nicole Prince Home’s marketing strategy, increased awareness across the Capital Region of Upstate New York, and strengthened the link between academic research and nonprofit transformation. The resulting recommendations focused on increasing community awareness, improving storytelling in marketing content, and building stronger relationships with potential volunteers. For example, students created a new flyer and logo that accurately represents the organization’s mission and developed a sustainability document that provided evidence-based suggestions, such as to center specific audiences in all outreach materials. Through this partnership, students applied classroom concepts to a real-world setting, strengthening both their professional development and the Joan Nicole Prince Home’s capacity to serve the community. This project highlights how academic-community collaborations can foster meaningful social impact and sustainability in nonprofit work.

Abstract Name: How Digital Twin Models Support Public Access and Preservation: Analyzing User Behavior Within Immersive Virtual Spaces

By creating compelling and accessible digital twin models, we aim to integrate user-focused design methodology with immersive documentation. Using Matterport 3D capture technology, we’ve documented museums and historical locations to examine how spatially accurate virtual environments can function as

tools for public access and preservation. The models function similarly to Google Street-View, immersing users in freely navigable spaces, with the inclusion of interactive “tags” providing information and suggested guided paths or “tours”. The goal of such models is to provide users with high levels of agency while upholding high constraint in best-practice interactions. Our primary case study is of the Archeological Museum and Site of Isthmia, Greece. Here we created a comprehensive digital walkthrough of the museum galleries and active archeological site. The scale and layout of the site posed a unique challenge in that it lacks the traditional confines of a single building or exhibit, creating space for innovation in how the creation of the model is approached, and how users are guided through the final product. To assess how users interact with these environments, we’ve conducted iterative testing with students, educators, and non-academic user samples. By giving users a set task to achieve within the model, we are able to observe and measure both quantifiable interaction data, as well as qualitative user feedback to improve the balance between user agency and guided structure. Their responses informed design decisions related to interface layouts, point-to-point navigation, information layering, and visual guidance. This process treats 3D capture not only as a tool for documentation, but as an interactive design medium shaped by user needs with the goal of refining approachability and accessibility in immersive virtual spaces.

Abstract Name: Optimizing Mechanical Advantage in Climbing Rescue Systems: An Analysis of Rope Tension and Mechanical Advantage in Pulley-Based Systems

In rock climbing and rescue scenarios, multi-pulley systems are essential for creating mechanical advantage, dividing the weight of a load across multiple strands of rope to lift heavy climbers. The simplest mechanics theory suggests that adding pulleys linearly divides the load. However, real-world applications introduce counteracting forces, such as friction and the weight of the equipment being used. This project addresses a critical optimization question: At what point does adding more pulleys to a system become disadvantageous? By analyzing the difference between theoretical and actual mechanical advantage, this project identifies the optimal configuration where force reduction is maximized before counteracting forces overpower. Due to the practical limitations of using a full-scale system, a controlled, miniaturized model has been constructed using rigid fishing line and varying pulley configurations. A digital force gauge is used to measure the input tension required to lift varying calibrated masses. The input force required to overcome static friction and initiate movement in each configuration is recorded and compared against the theoretical value. The initial hypothesis is that while increasing the number of pulleys will initially reduce the required input force, the cumulative friction introduced by additional pulleys will cause the efficiency to drop non-linearly. This presentation will document the search for a pulley configuration in which the addition of another pulley results in negligible force reduction or increased resistance, making the addition of more pulleys counterproductive. This study will therefore quantify the difference between ideal and actual mechanical advantage and will pinpoint the threshold at which counteracting forces outweigh the force reduction achieved through mechanical advantage. The establishment of a pulley configuration of optimized efficiency could inform best practices for rescue scenarios and other situations that require moving heavy loads.

Abstract Name: Mood Disorders and Physical Health in Pediatric Populations: Correlations Across Pre- and Post-Adolescence

Even though the connection between the mind and the body is increasingly acknowledged, the current pediatric care is still very much in silos where mental and physical health are treated as separate clinical domains. This masks the fact that mood disorders have significant physiological effects and should be classified as multisystem illnesses that have aetiology in the psychological domain. This study highlights the strong and bidirectional relationship between pediatric mood disorders and long-term physical health and emphasizes that the associated psychosocial morbidity is a public health crisis which calls for integrated, holistic care. Mood disorders can deeply and biologically profoundly influence physical health by elevating stress on the Hypothalamic–Pituitary–Adrenal (HPA) axis and changing neuroendocrine signaling resulting in the accumulation of significant physiological costs. The period of Adolescence, which is already characterized by developmental vulnerability, magnifies these effects. Research shows that emotional dysregulation is the main driver of adverse trajectories which include substantial BMI variations and increased cardiometabolic risk (e.g., insulin resistance even at the same BMIs), particularly for adolescent girls with a family history of mood disorders. Additionally, these conditions interfere with pubertal timing as evidenced by the psychiatric risks linked to Central Precocious Puberty, thus, pointing to an important developmental mismatch. Moreover, the physiological load is also evident from the immune system perspective, where chronic, low-grade inflammation is detected in raised levels of C-reactive protein (CRP) that correspond to depression severity. As this morbidity affects multiple systems - metabolic, developmental, and immune pathways, often with sex-specific inflammatory signatures, the fragmented care model is far from being sufficient. A swift move towards holistic pediatric models that emphasize early, interprofessional screening—where psychological evaluation is done together with metabolic and hormonal monitoring—is important if the long-term health side-effects of youth mood disorders that are both severe and costly are to be averted.

Abstract Name: Open Source Modular Volumetric Additive Manufacturing

Volumetric additive manufacturing (VAM) is a method of 3D printing that creates entire geometries in one step, often through some kind of optically cured resin. Rotational VAM uses a vial of resin rotated under an optimized projected video to selectively cure resin to the desired geometry. Current models and methodology involving VAM require expensive and complex setups, which limit its actual application and development. Printers are in the thousands of dollars and require moderate software/scripting ability. Our model of VAM 3D printing is able to be constructed under \$200 and uses open source software for optimizing projections. The physical construction is built around modularity to allow the use of a variety of projectors, limiting the cost. This is made possible by the focus on traditionally 3D printed parts or consumer products. A consumer projector was also modified to allow the transmission of 405nm UV wavelength light, appropriate for the resin chosen. Due to the nonlinear nature of VAM resin, we attempt to use an ambient light source to reduce the required power output of the projection. A UV ambient light source assists the consumer projector by lowering the required projected power threshold for curing. This reduces the required dose given by the projector by having the entire volume sit right below the curing point. Ambient light also proves to speed up the curing process with weak projection, with moderate penalties to quality. Future steps are to improve open source software to allow fluid workflow within VAM manufacturing. Additional outreach is being done to trial printer and software capabilities. Our method hopes to spread the capabilities of VAM.

Abstract Name: Racial Governance and Affective Histories of Japanese Peruvian Detainees during World War II

This research explores the often-overlooked history of Japanese Peruvian internment during World War II. Over 2,200 Japanese Latin Americans were uprooted from their homes and relocated to U.S. detention centers operated by the Immigration and Naturalization Service (INS) following Pearl Harbor. Focusing on the experiences of Japanese Peruvians, who comprised approximately 80% of these deportees, this study delves into their everyday realities within United States detention camps and their postwar struggles for national belonging and legal recognition. Existing scholarship on Japanese internment predominantly focuses on Japanese Americans, while the few studies on Japanese Peruvians primarily address hemispheric diplomacy and the exchange of individuals among Latin American and U.S. governments. A significant gap remains in the historical record regarding their personal experiences within INS camps and the diasporic identity-making of Japanese Peruvians. Specifically, this paper highlights that despite the seemingly haphazard and improvisational managerial perspective of U.S. policy, the resulting displacement, fractured identities, and lasting psychological scars were profoundly impactful for detainees. Analysis is constructed through first-hand accounts from the Densho Digital Repository, mainly oral histories and autobiographical narratives conducted 50-60 years after the war. First, this research examines the interplay of diplomatic pressures and racial prejudices that led to the forced removal and detention of Japanese Peruvians, highlighting their living conditions in transit to the U.S. and in temporary Latin American detention centers. Mainly, it reveals the contradictory experiences of individuals who were stripped of their agency and forced to navigate survival and identity in the very country that confined them; detainees often grappled with ambivalence and sought to overcome this inexplicable tragedy by identifying as American, even as feelings of “otherness” persisted. This work integrates how these wartime internments served as a laboratory of racial governance, where inclusion was engineered without true empowerment.

Abstract Name: Role of Mxc Phosphorylation in Histone Locus Body Function and Structure

Histone proteins are essential to the mechanisms of chromatin: they provide structure and can be post-translationally modified to adjust the wrapping of DNA. Histone gene expression is cell cycle dependent, specifically being produced in S phase. Histone RNAs are made and regulated through a nuclear body called the histone locus body (HLB) and are unique because they have a stem loop structure instead of a poly A tail. The HLB is made up of several constituents, one of which is a key scaffolding protein called Mxc. Previous research has shown that Mxc is phosphorylated by CyclinE/Cdk2, and although we know the HLB is

phosphorylated during S-phase of the cell cycle, it is still unknown how this phosphorylation affects the structure and function of the HLB. We performed mass spectrometry to analyse HLB members, which revealed two putative phosphorylation sites on the protein Mxc within its N terminus. We obtained a plasmid that contained Venus-tagged Mxc. Using site-directed mutagenesis, we mutated these 2 sites from serines to alanines so that they could no longer be phosphorylated. We generated single mutants and a double mutant in which both serines were mutated to alanines. We are currently testing different protein lysis and western blotting conditions to show that these constructs are expressed in S2 cells. Our future experiments include: (1) determining if the mutants show a lack of signal from the MPM-2 antibody, which targets phosphorylated Mxc; and (2) determining if the phosphomutants have altered localisation in cells using immunofluorescence experiments. The results of these experiments will shed light on the effect of phosphorylation on Mxc as well as expand our knowledge of how the HLB functions.

Abstract Name: The Developmental Dance: How Genes and Environment Interact in Trait Expression

This study aimed to investigate the complex interplay between genetics and environment, and how resulting trait expression is affected by it. While previous scientific knowledge suggested genetics and environment act exclusively from one another, modern scholarly works have started to find an intricate relationship between the two factors. Existing literature has begun to uncover segments of a theory known as gene-environment interaction. This paper compiled multiple studies, and created a cohesive argument supporting gene-environment interaction theories. Furthermore, this study analyzed manifestations of gene-environment interactions, such as socioeconomic status. Additionally, this article examined differences of gene-environment interplay of various traits, including intelligence and personality. Over the course of several months, a wide array of sources were collected and examined. After consideration, works were synthesized and argumentation was developed. Following careful evaluation, this article found that genetics sets a palette of genetic potential that can be dynamically changed by surrounding environmental factors. A strong example of this phenomenon discovered was socioeconomic status. Moreover, epigenetic theories apply to the same interplay. In terms of specific traits, intelligence is affected from genetics more compared to personality; as such, personality is more susceptible to environmental changes. These results have many implications. Considering how traits have different sensitivities to environment, parents can allocate appropriate resources to produce an environment that benefits specific traits. Properly comprehending the interaction between genes and environment can help develop medications and other treatments, mitigating disease and suffering for many. Further research should investigate the same interaction to reproduce results, as well as develop methods to apply these theories to modern medicine.

Abstract Name: Investigation of Differences Between Perception of Cell Phone Usage and Actual Cell Phone Usage Among Adolescents in Senior and Freshman Grade Levels

This study investigated the difference between the perception of cell phone usage and actual cell phone usage among teenagers in the ninth and twelfth grade levels. Existing literature focuses largely on the effect of screen usage on different aspects of health, including mental health and developmental changes in children. However, the relationship between the perception of screen time and actual screen time use has not been extensively studied. Under the guidance of Dr. Jennifer Frank, 111 freshmen and seniors at the Woodbridge Academy Magnet School in Woodbridge, New Jersey completed two online surveys. The first asked for their estimation of daily screen time over the past ten days; the second instructed subjects to check their iPhones for their actual daily screen time average over the previous ten days. The difference between perception and actual use of cell phones was quantified using a 2-tailed matched-pairs t-test for means. Using an alpha level of $\alpha = 0.05$, the p-value calculated was 0.00001326345565, suggesting statistically significant results. The null hypothesis was rejected and in this sample there was a difference in a subject's perception of screen time usage and their actual screen time usage. This study brings into light the possible inaccuracies with public surveys that ask for self-reported data, especially health studies. Cognitive bias in teenagers can be studied further to see the effect it has on other aspects of teenagers' lives beyond screen time usage. Furthermore, this information can be used to create applications and other technologies that can assist teenagers struggling with mental health and a lack of self-control in their daily lives. Although these results are significant, studies with larger sample sizes and more diverse subject demographics should be conducted to observe if results can be replicated.

Abstract Name: Early Exposure to the Outdoors Results in Higher Levels of Adventurousness in High School Students

This study examines the relationship between early childhood exposure to the outdoors and a high school student's current sense of adventurousness, particularly in outdoor activities. While existing literature has proven the benefits of the outdoors and nature on emotional and cognitive development, there has been limited research conducted on whether childhood outdoor experiences affect a person's willingness to try unfamiliar activities later in life. To investigate this, an analytical cross-sectional study was done using two surveys given to freshmen and seniors at a competitive magnet school in central New Jersey. The first survey measured the level of outdoor exposure a student had before the age of eight, and the second survey measured the student's current sense of adventure through scenario-based questions on a Likert scale. Each student received a composite score from both surveys. An independent t-test was conducted to compare the average adventurousness composite scores between two groups: students with greater childhood outdoor exposure and students with lesser exposure. The p-value from the test was 0.003, which fell below the significance level of 0.05. This supports the hypothesis that more early exposure to the outdoors is associated with a stronger sense of adventure. Two more t-tests were conducted comparing gender and grade level against level of childhood outdoor exposure; only the gender comparison yielded significant results with a p-value of 0.03. These results have profound implications, as early interaction with unfamiliar outdoor environments may help individuals embrace uncertainty and risk-taking later in life. Although the study supports this relationship, it was limited by self-reported data, recall bias, and a homogenous sample population. Further research should include more heterogeneous populations and account for potential confounding variables such as socioeconomic status and parental influence.

Abstract Name: An Interactive Physical Model for Visualizing Fundamental Statics Principles

This project presents a physical prototype designed to improve the way students learn key concepts in a statics course. Many students see statics as only mathematical and abstract, which makes it difficult for them to connect the equations with real physical behavior. The goal of this project is to create a hands-on teaching aid that helps professors explain core statics topics through clear visual demonstrations. Additionally, it makes it easier for students to grasp and interpret the calculated values based on the physical model. The prototype includes four main learning modules: (1) Reaction forces in beams, where the system calculates the reaction forces at the support points based on loading scenario; (2) Tension in cables, which display the tension changes based on the cable angle; (3) A friction model, consists of an actuator and sensors to illustrate the resistance to motion and measure the coefficient of friction between different surfaces in real time; (4) A moments module, which shows how changing the lever arm length affects the resulting moment. The system uses an Arduino controller connected to infrared sensors, load cells, and an actuator to measure forces and motion accurately. All calculations are done automatically in the background. The user can switch between the four learning modules using simple push buttons. The measured values and results are displayed on an LCD screen in multiple formats, depending on the user's choice. This prototype allows students to directly observe how forces, friction, and moments behave, turning theory into something they can see and interact with. By connecting mathematical equations with real physical responses, the system helps students build stronger intuition and improves classroom engagement. The model gives professors a practical tool to demonstrate difficult statics concepts and makes students understand topics by creating a more interactive and meaningful learning experience.

Abstract Name: Role of an Ion Transporter in Temperature-Sensitive Behavior and Neurodegeneration in a Fruit Fly Model

Proper calcium (Ca^{2+}) regulation is fundamental for the function of neurons. Seizure disorders and age-related neurodegenerative diseases are associated with disruptions in ion transporters that maintain Ca^{2+} flow in cells. However, the mechanisms that control these disruptions are still not fully understood. The common fruit fly, *Drosophila melanogaster*, is a powerful genetic model for the studies of such neurological conditions. Flies have facilitated the discovery and characterization of mutants in displaying temperature-sensitive (TS) convulsions — a phenotype related to epileptic activity — along with progressive neurodegeneration similar to vertebrates, providing new insights into their underlying mechanisms. In a genetic screen, our lab identified the gene *Nckx30c* which encodes a potassium (K^{+})-dependent sodium/calcium ($\text{Na}^{2+}/\text{Ca}^{2+}$) ion transporter that is predominantly expressed in brain tissue. This gene also shares homology with the mammalian Solute Carrier Family 24 A2 (SLC24A2) gene. We found that flies carrying *Nckx30c* mutations exhibit TS convulsions, age-dependent neurodegeneration, and a shorter lifespan. Locomotor behavior was analyzed using an automated video tracking system equipped with a heated plate. Our findings revealed that in comparison to their wild-type controls, *Nckx30c* mutants displayed increased temperature sensitivity resulting in abnormal locomotion. As a result, *Nckx30c* mutants exhibited reduced velocity and lower percent active time. Such phenotypes worsened with age and also appeared when *Nckx30c* was specifically knocked down in neurons. Since the function of the mammalian ortholog of *Nckx30c*, SLC24A2, in the central nervous system remains poorly defined, our results in *Drosophila* could provide novel insights about how this gene contributes to calcium homeostasis, seizures, and age-dependent neurodegeneration in mammals, including humans.

Abstract Name: "Politics! Not My Thing!": The Misrepresentation of Anne Boleyn in 'SIX: The Musical'

With the rise of *Hamilton* and *Come From Away*, stage musicals have become the next hottest form of historical reenactment, and the six wives of Henry VIII are no exception. These modern spins on Tudor history are typically riddled with inaccuracies that leave audiences with a skewed idea of Tudor England. The wives of Henry VIII, in particular, are the victims of centuries of historically inaccurate fictional media. *Six: The Musical* is a modern musical spin on this centuries-old story, following the six wives of Henry VIII as

they reclaim their narratives in a pop concert competition on who had it worst. Anne Boleyn, Henry's second and most famous wife, is a prominent figure throughout SIX, beyond her own solo musical number. However, her characterization falls short of the modern feminist reclamation the musical claims to portray. Using surviving correspondence from King Henry VIII and other notable figures in the sixteenth century written to or about Anne, this paper compares primary texts to the lyricism and characterization of Anne Boleyn's on-stage persona. Additional biographical sources are used to comprehend Anne's upbringing, question the validity of primary accounts, and understand Anne through a more feminist lens. This research reveals that after nearly five centuries, Anne's story is still told through a biased, misrepresentative, and misogynistic lens. The stereotypes and misconceptions that characterize Anne Boleyn in SIX are an amalgamation of past perceptions of Anne that were shaped by the limited surviving documents detailing her life, most of which are littered with biases and defamatory statements that lack the evidence necessary to back them up. More attention and consideration by female Tudor historians to present Anne more accurately to her situation would help end harmful misconceptions about controversial women in history.

Abstract Name: "A Couple Days in the Life of What It's Like In Washington Heights:" The Representation of Latine Immigrants in Lin-Manuel Miranda's 'In the Heights'

The United States of America is a nation built by and made up of immigrants, being home to one-fifth of all migrants across the world. Anti-immigrant prejudice and xenophobia have long defined the American people and national policy, but the target demographic is constantly changing to reflect current narratives and fears. In recent years, Latine immigrants have been a prominent topic of concern in American politics. Lin-Manuel Miranda's 2021 movie musical *In The Heights* aims to celebrate the existence of immigrants in Washington Heights, a neighborhood in New York City. Using peer-reviewed scholarly sources and movie reviews, this comprehensive literature review analyzes the representation of the Latine community in *In The Heights*. This research paper also examines over a century of American government legislation on immigration in order to discover if the challenges faced by immigrants in the musical are based on historical accuracy. *In the Heights* shines as a musical representation of Latin American immigrant communities by avoiding harmful stereotypes, emphasizing the panethnic Latine identity, and normalizing issues faced by Latine populations in America. Despite the musical's positive contributions to Latine media, there are still some areas where the film falls short, including the sexualization of female characters, absence of Afro-Latine representation, and the lack of conversations surrounding accountability and consequences in terms of federal policy. *In The Heights* celebrates the beauty of Latine culture, normalizes a minority group that is historically stigmatized in America, and highlights many struggles that come with being an immigrant. While *In the Heights* reveals a detailed chronicling of the realities of being an immigrant in America, the musical falls short in representing the diversity that is the Latine community and the potentially devastating political immigration crisis that currently looms over America, when sensitivity and inclusion are imperative for representative media.

Abstract Name: Viscosity Solutions in the Martinet Space

In this project, I establish the existence-uniqueness of viscosity solutions to the infinite Laplace equation and the infinity(x)-Laplace equation in Martinet spaces, which are sub-Riemannian spaces that lack both the algebraic group law of Carnot groups and the triangular vector fields of Grushin-type spaces. In addition, existence-uniqueness of viscosity solutions to uniformly elliptic equations are proved.

Abstract Name: Roots of Origin: Geographic Imprints on Poplar Tree Microbiomes in the Popup Poplar Gardens

Soil microbes play an essential role in supporting plant health, influencing nutrient cycling, disease resistance, and resilience to environmental stressors. Poplar trees (*Populus* spp.) are especially valuable for studying plant-microbe interactions as they are fast-growing commonly used in ecological restoration, carbon sequestration studies, and bioenergy production. This project proposes a comparative study of soil microbiota associated with poplar trees planted in the Popup Poplar Gardens, a National Science Foundation-funded collaborative network spanning 18 sites across the United States. At Salisbury University (SU), 100 poplar trees have been planted from cuttings originally collected from 50 locations across Alaska, Canada, and the Northwest United States. My research group will analyze the root-associated microbiomes of 20 trees in five geographically distinct groups. Although all 20 trees are growing side by side at SU under shared conditions, we hypothesize that their root microbiomes may still reflect the trees' original geographic adaptations. By investigating whether the rhizosphere communities differ between trees derived from the five distinct locations, we aim to determine whether geographic origin leaves a lasting imprint on microbial associations. Ultimately, this project will generate foundational microbial profiles for the Popup Poplar Garden trees that can be used as a reference point for future research studies across different geographic sites and climates, advancing both ecological research and community science engagement.

Abstract Name: Shape Retention and Recovery In Shape Memory Polymer Foams: Implications for Aneurysm Treatment

A brain aneurysm is a bulging brain artery that can rupture, often causing severe debilitation or death. A potential patient-specific treatment involves using a polyurethane shape memory polymer (SMP)-based foam that can be compressed for endovascular surgical insertion and then expanded with heat to maximally fill the aneurysm space. By blocking blood flow into the aneurysm, our customizable SMPs reduce rupture risk and improve patient outcomes. However, their long-term durability and recovery capabilities must be well

understood before they can be safely implemented in medical applications. The goal of my project is to examine the durability, shape retention, and recovery time of SMPs through repeated compression tests, so this material can eventually be used to treat patients. In this project, I will fabricate eighteen (n=18) SMP foams with 10%, 15%, and 20% infill densities using fixed ratios of three monomers: (i) hexamethylene diisocyanate (HDI), (ii) N,N,N',N'-tetrakis (hydroxypropyl) ethylenediamine (HPED), and (iii) triethanolamine (TEA). Nine samples will undergo 15 compression tests at 60 °C to obtain stress-strain data, with recovery time recorded by a camera and microscope images taken every five cycles to assess any structural changes/damage. The remaining nine samples will undergo compression tests after recovering only 50%. The stress-strain results will be compared across infill densities and recovery levels using a two-way ANOVA test to determine how repeated compression influences the SMPs' thermo-mechanical properties. In a well-designed SMP, repeated compression should minimally affect shape retention and recovery time. The findings of this research will provide critical insights into the feasibility of SMPs for long-term medical use, ensuring their reliability in high-stakes biomedical applications. In addition, this project could expand SMP use beyond aneurysm treatment, enabling applications in other areas of the body, such as cardiovascular stents, tissue scaffolds, or minimally invasive orthopedic implants.

Abstract Name: "It's Monday Night:" Class From the Twentieth Century to Today

Over the course of American history various authors have written about the fractures of class in American society. From the turn of the nineteenth century, when Upton Sinclair wrote of Lithuanian immigrants working the meatpacking factories of Chicago, to the Great Depression, when John Steinbeck wrote of sharecroppers moving from Oklahoma to California for a chance at a better life, to the very end of the 1990s, when George Saunders wrote of the struggles of a male stripper trying to support his poverty-ridden family. Many of these works have also been explored by scholars like William Brevda, who explores how Tom Joad from *The Grapes of Wrath* becomes a ghost who represents the lower classes and the ghost of socialism, and Orm Øverland, who examines how Lithuanian immigrant communities in early 1900s Chicago were stripped of their identities by an aggressive capitalist society. Using these works of literature and their accompanying scholarly articles, I explore class in the modern era through my own short story, "It's Monday Night," following the character Thomas as he navigates a shift as a caterer on his college campus. The story is built upon the works of Sinclair, Steinbeck, and Saunders, as well as my own personal experience working a catering job. In the accompanying essay, I discuss "It's Monday Night," analyzing how Sinclair, Steinbeck, Saunders, and the scholarly articles written on their works, contributed to inspiring my short story and its themes regarding class: how divides still endure in the twenty-first century, how these divides are enforced and operated, and the various influences that keep people trapped in poverty.

Abstract Name: Creativity and Repetition in Contemporary Violinmaking

In this paper, I aim to understand how contemporary violinmakers experience creativity. Sociologists have studied the experience of creativity within other art fields, but violinmaking is a particularly useful lens through which to understand this question because of its fixed nature: a beautiful and well-functioning violin was defined 300 years ago, so violinmakers must work within a narrow set of parameters. To answer this question, I conducted in-depth interviews with eighteen full-time luthiers based in Europe and the US who attended the Oberlin Violin Makers Workshop, a prestigious two-week workshop that has been running for over 35 years. I found that some luthiers experience making as creative, even within these narrow parameters, and tend to think on the scale of the process involved in making a single instrument. Others do not experience it as creative, instead understanding it as repetitive. These luthiers tend to think on a larger scale of progress and improvement over the course of a career. I conclude that a violinmaker's experience of creativity and repetition is related to the level of abstraction at which they think about their work. This allows us to reimagine our understanding of repetitiveness as a goal oriented process without negative connotation. Repetition becomes a long-term complement to creativity that allows one to develop consistency and expertise, which is crucial in preserving artisanship in contemporary society.

Abstract Name: Developing of a Large-scale Teaching Assistant and Mentor Program to Foster Support and Community in Research Writing Courses

Because universities are hierarchical structures, it can be easy to lose sight of their central purpose: engaging students in the creation of knowledge, ideas, and relationships. Faculty often report up a chain rather than to students, which can create distance from daily student experiences. We have found that an effective way to stay student-centered is to give students real authority to share their expertise. My empathy-based pedagogy prompted me to reimagine a co-curricular teaching assistant (TA) program for a required research writing course from one TA per section to a large community of 25+ student mentors/TAs. The model distributes responsibility, reduces individual pressures, builds belonging and professionalism, and taps into the expertise of students across disciplines. Clear roles ensure each TA knows their purpose and how to collaborate effectively. TAs run breakout sections, record class notes, offer assignment feedback, and co-teach complex research concepts. The program retains 80% of mentors annually, with many students opting to serve as TAs until graduation. Incorporating student expertise yields meaningful payoffs for faculty and, more importantly, for students. Students in our research writing courses consistently describe the TA program as a course highlight. The expansion of this program gives TAs autonomy to co-create communal, high-demand study groups and breakout sessions. Each year, over a dozen new TAs join and about 25 return. Students want to be part of this community because they were supported, and now want to support others. Our proposed presentation highlights how we foster a healthy academic future by investing in students beyond traditional markers of excellence. A panel of TAs and I will discuss their roles and share what motivates them to remain engaged in the program. We will offer tips to others who wish to start their own, large-scale TA/mentor programs for research.

Abstract Name: Impact of VasX on Type-VI Secretion System-Dependent Interactions in *Vibrio fischeri*

The type VI secretion system (T6SS) is a toxin-release mechanism used by many Gram-negative bacteria to kill neighboring cells. In *Vibrio fischeri*, T6SS helps maintain its symbiotic relationship with the Hawaiian Bobtail squid (*Euprymna scolopes*) by releasing antibacterial toxins that destroy competing bacteria lacking key immunity factors. VasX, a T6SS toxin found in the related bacterium *Vibrio cholerae*, contributes to the virulence of cholera. A homolog of VasX exists in nearly all *V. fischeri* strains, such as FQA001. However, since *V. fischeri* is not a pathogenic bacterium, the specific role of this homolog in T6SS function and bacterial competition remains uncertain. Additionally, each strain contains a unique number of immunity factors, also varying in structure, making the mechanisms of neutralization unclear. To address these gaps, this research employs computational models in conjunction with cloning studies to explore these questions from multiple angles simultaneously. Our data suggests that the VasX homolog is highly conserved in two key regions. One is a putative Pleckstrin Homology domain, believed to interact with cell membrane lipids in eukaryotic cells, and the other is a colicin-like pore-forming domain targeting Gram-negative membranes. By developing a membrane modeling workflow, we were able to test the functions of each region more efficiently *in silico*, thereby guiding future research. Additionally, we found that all immunity factors are expressed within FQA001 in two polycistronic transcripts. Future work will be needed to determine whether both transcripts are necessary to neutralize VasX. Overall, our data support the idea that VasX acts as a trans-kingdom effector, designed to target both eukaryotic and prokaryotic membranes, and that several immunity factors help prevent autotoxicity and bacterial killing during inter-bacterial competition. Furthermore, future research is needed to evaluate the impact of the VasX homolog on interactions within the host system.

Abstract Name: Green Technological Innovation for the Utilization of Tropical Fruit Waste, Agglomerated as Sustainable Biocomposites for Aquaculture Applications in Rural Areas.

The Materials Science plays a fundamental role in the development of agro-industrial products for the aquaculture industry, among others. In this context, the need for the development of new agro-industrial biocomposites was addressed, taking the Panamanian context as a reference. On one hand, this responds to the local reality, and on the other, to the growing emphasis on sustainability, enabling students to research, develop, and propose new products that reduce the environmental impact of aquaculture. To preserve their antioxidant compounds, the mango peels underwent a freeze-drying process followed by pulverization and agglomeration using a binder based on banana peel starch, as previously mentioned. The pellets were used to feed juvenile Nile tilapia (*Oreochromis niloticus*) for over a month. Based on the results obtained during the manufacturing process and the potential of this alternative feed for aquaculture species—considering that the juveniles were exclusively fed with this material—it is necessary to continue this project, particularly in terms of scalability and funding. By the other hand, part of the work was presented at WEEF & GEDC 2025

(World Engineering Education Forum & Global Engineering Deans Council Annual Conference) in Daegu, South Korea, last September in the Education Track session: Real-World Connection through Engineering Education where we were able to share the main findings, opportunities, and challenges with the participating community. In short, Materials Science provides a solid foundation for addressing challenges and opportunities, such as the aquaculture industry, giving students opportunity to contribute to the development of new, more efficient and sustainable agro-industrial products. Given the results obtained in the manufacturing process of this potential alternative feed for aquaculture species, and considering the maintenance of fry fed exclusively with the same feed, it is necessary to continue this project from a scalability and funding perspective.

Abstract Name: Coping Mechanisms of Individuals on Death Row

Capital punishment in the United States has gone through numerous periods of opposition or support. The individuals on death row in the United States experience abhorrent physical conditions, including extreme solitary confinement, little privacy, and abuses from both other inmates and guards alike. These conditions can have severe repercussions on mental health, producing symptoms like a distinct loss of identity, which reduces the individual to something similar to an animal. These people must also deal with the deaths of the friends they make on death row, as well as their own impending executions. Death row phenomenon occurs as a result of three components: temporal, physical, and experiential. Death row syndrome comes from death row phenomenon, and refers to mental effects suffered by an inmate on death row. People on death row cope in a variety of ways. They may turn to educational pursuits, which include reading and writing. Escapist strategies are very popular, constituting methods like sleeping, drugs, suicidal ideation, and "tripping", or actively and vividly imagining oneself in the outside world. Religion is also very popular, and many people use their faith as a way to cultivate positive relationships with other parties. Many use exercise as a way to keep themselves busy as well, though this has seen limited success among individuals. The research into life on death row, and specifically the coping mechanisms of the individuals that live there, is far from complete, and much more needs to be done to fully understand how people in death row facilities live their lives.

Abstract Name: College Student Opinions and Moral Convictions related to Abortion Rights.

The right to abortion is a controversial issue. Understanding levels of moral conviction regarding abortion opinion is important for understanding potential political behaviors, given the association between moral conviction and intolerance, polarization, and inflexibility. The present study sought to describe opinions of a sample of college students on abortion and their levels of moral conviction. Students (n=480) at a Midwest university participated in a survey. Participants had an average age of 19 years (M=18.99), were majority Christian (64.6%), female (63.5%, 23.5% male), white (66% white/Caucasian), and represented a variety of

political preferences (47.2% democrat, 27.8% independent, 25% republican). Participants self-described abortion opinion using a six-point Likert scale. Moral conviction was reported using 2 items: “To what extent are your feelings about the legal right to abortion a reflection of your core moral values and convictions?” and “To what extent are your feelings about the legal right to abortion deeply connected to your beliefs about ‘right’ and ‘wrong’?” The two items were assessed with five-point Likert scales. Descriptive statistics were calculated on demographics, abortion opinion, and moral conviction. The right to abortion was supported by the majority of students (n=298; 69.1% support, n=133; 30.9% oppose). More than half (n=229; 53.2%) of students held “strong” opinions on the right to abortion, with 41.8% strongly supporting (n=180) and 11.4% strongly opposing (n=49); Students overall showed moderate moral conviction regarding their opinion about abortion (M=3.48, SD=1.06), and students with “strong” opinions showed greater moral conviction. The majority of college students supported abortion, and stronger opinions were associated with greater moral conviction. Given the relationship between moral conviction and political behaviors such as intolerance, the prevalence of strong opinions on a contentious issue and levels of moral conviction should be of interest to researchers studying these behaviors.

Abstract Name: Political Intolerance: Opinions and Moral Conviction in a College Sample

Political intolerance is widespread in the U.S, yet there is sparse literature regarding opinion on political intolerance. Further, moral conviction is important to understand in the context of intolerance given the known associations between moral conviction and polarization. The present study describes opinions of a sample of college students on political intolerance and corresponding moral conviction. Undergraduate students (n=480) at a Midwestern university participated in a survey. Participants had an average age of 19 years old (M=18.99), were majority Christian (64.6% Christian, 20.6% atheist/agnostic), female (63.5% female, 23.5% male), white (66% white, 12.5% Black/African American), and represented a variety of political preferences (47.2% democrat, 27.8% independent, 25% republican). Participants answered, "Is it okay to be intolerant of other's political beliefs and ideas?" using a four-point Likert scale. Moral conviction was reported using 2 items: “To what extent are your feelings about political intolerance a reflection of your core moral values and convictions?” and “To what extent are your feelings about political intolerance deeply connected to your beliefs about ‘right’ and ‘wrong’?” Participants responded using five-point Likert scales which were averaged to create a moral conviction scale. Descriptive statistics on demographics, intolerance opinion, and moral conviction were calculated. The majority of students stated political intolerance is “sometimes okay,” (n=222; 51.5%). 30.2% stated intolerance is “never okay” (n=130). Remaining students stated that intolerance was “often okay” (n=60; 13.9%) or “always okay” (n=19; 4.4%). Participants held moderate moral conviction regarding intolerance opinions (M=3.25, SD=1.01). The majority of participants stated political intolerance is “sometimes okay,” although a large portion stated intolerance is “never okay.” Moral conviction levels were moderate. Given the relationship between moral conviction and political phenomenon such as polarization, opinions on intolerance and corresponding moral conviction should be of interest to researchers studying these behaviors.

Abstract Name: Policy Implications for Relocating Socially Vulnerable People Out of Public Housing

The relocation of residents from public housing remains a central concern for policy analysis. Over the past several decades, federal initiatives such as Moving to Opportunity, HOPE VI, and Choice Neighborhoods have attempted to transform distressed public housing developments and expand access to greater opportunity. Yet these efforts have also produced substantial challenges for residents who are economically disadvantaged, people of color, and individuals who are socially vulnerable. Relocation frequently disrupts long-standing social networks, diminishes access to essential services, and creates uncertainty as families attempt to navigate unfamiliar environments. These consequences raise important questions about equity, justice, and the long-term well-being of affected communities. As cities continue to redevelop and adopt mixed-income housing strategies, it is essential to critically examine how displacement and relocation shape the everyday lives of the populations most directly impacted. Ensuring that redevelopment efforts promote social justice requires a comprehensive understanding of the lived experiences of relocated residents, as well as the structural barriers that shape their ability to adapt and thrive in new settings. This longitudinal study investigates the ongoing effects of a major relocation effort on a socially vulnerable urban community in Virginia. Drawing on data collected across multiple phases of the Choice Neighborhood relocation project, the research traces how residents' experiences, access to resources, community stability, and perceptions of neighborhood change evolve over time. By following participants throughout the relocation process, the study captures both immediate and enduring impacts, offering insight into how policy decisions reverberate through individuals' lives and within the broader community. Because the analysis is still in progress, the findings presented reflect emerging patterns rather than final conclusions. Nonetheless, the study contributes to ongoing discussions about equitable redevelopment, the unintended consequences of relocation, and the need for policy frameworks that prioritize the stability, dignity, and well-being of displaced residents.

Abstract Name: Mobile Manipulator Performance Under Dynamic End Effector Payloads

Mobile manipulators are poised to enhance automation of repetitive tasks in fields such as agriculture, construction, and manufacturing. Adoption of mobile manipulators for these tasks depends on achieving high position and orientation accuracy in unstructured environments with dynamic impairments. Examples of these impairments could include vibrations from connected tools or nearby machinery. To measure the effects of these disturbances, the National Institute of Standards and Technologies developed repeatable methods of testing a disturbance's impact on mobile manipulator functionality. For example, the Mobile Manipulator Workpiece Agitator applies repeatable disturbances to a workpiece to test the mobile manipulator's capability to correct for the applied disturbance. An extension of this work is to instead apply a disturbance to the manipulator itself. Therefore, the contribution of this project was the creation and validation of an apparatus that induces a repeatable and measurable disturbance on a mobile manipulator end effector. Such disturbances could be representative of vibrations caused by dynamic payloads such as power tools and robotic grippers. The repeatability of the induced disturbance was validated using data collected from an accelerometer and optical tracking system, considered a ground truth, to measure the g-force of the end effector during a 22 factorial experiment. While results of the experiment have yet to be analyzed, they are expected to show that the apparatus has created a repeatable disturbance that is able to be scaled by adjustments of speed and weight.

Abstract Name: Exploring Kinematics of Quadrapedal Locomotion in Captive and Wild Chimpanzees

Chimpanzee locomotion is often used in reconstructing the positional behavior of the last common ancestor of humans and chimpanzees. However, chimpanzee locomotor kinematics have been primarily studied in captivity with limited understanding of how locomotor performance of these individuals compares to those in the wild. As wild individuals are more active, and often moving quadrupedally on uneven terrain compared to their captive counterparts, we measured the forelimb and hindlimb kinematic performance of individuals in the wild and compared this to both published results from captivity and captive individuals from a local zoo. This study uses video capture of wild chimpanzees from Uganda and captive chimpanzees from Virginia. All sequences were filmed with individuals quadrupedally walking orthogonal to the camera. Shoulder, hip, and knee joint angles were measured at touchdown, midstance, and toe-off and trunk angle measured at midstance in 20 adult and adolescent individuals (15 males, 5 females) with 5 of these individuals representing averaged values from repeated sampling. We anticipate that most of our angle measurements will overlap between our wild and captive samples at each part of step. However, due to increased daily activity and therefore potentially longer strides in our wild sample, we anticipate finding larger shoulder angles at touch down and larger hip angles at toe off in wild individuals compared to their captive counterparts. If wild chimpanzees do move differently than their captive counterparts, this needs to be taken into consideration when using captive data in modeling “typical” chimpanzee locomotion and for further investigation to determine if this disparity is due to differences in subject demographics, methodology, or environmental factors.

Abstract Name: Custom Analog ASIC Prototyping with SKY130: An Open-Source VLSI Design Pathway for Undergraduates

Modern integrated circuits are usually designed with expensive, proprietary software, which limits hands-on chip design experience for many undergraduate students and smaller institutions. In this project, we investigate whether a complete, fabrication-ready custom analog application-specific integrated circuit (ASIC) can be designed, simulated, and verified using only open-source tools and an open-process design kit. We use the open SkyWater SKY130 nm CMOS process together with Xschem, Ngspice, Magic VLSI, and Netgen to implement a full custom design flow that is accessible to undergraduates. As a first step, we design a simple CMOS inverter at the schematic level in Xschem and run pre-layout simulations in Ngspice to verify correct operation, focusing on the voltage transfer curve and switching threshold. We then create the physical layout of the inverter in Magic VLSI, placing and routing the NMOS and PMOS transistors and interconnect to satisfy the foundry’s design rules. Design rule checking (DRC) and layout-versus-schematic (LVS) verification using Netgen confirm that the layout is both manufacturable and electrically equivalent to the schematic. Next, we extract parasitic capacitances from the layout and rerun post-layout simulations in

Ngspice, including process-corner analyses (typical, slow, and fast devices), to study how layout-dependent effects and fabrication variations modify delay and logic thresholds. To extend the study beyond a single cell, we plan to design and simulate a simple ring oscillator using the same open-source flow, allowing further analysis of timing behavior and the practicality of the toolchain for larger circuits. By completing this open-source design flow, we aim to document a detailed step-by-step procedure for custom layout design, highlight its advantages and limitations, and show that undergraduate students can carry out realistic integrated circuit projects without access to commercial electronic design automation tools.

Abstract Name: Exploring Coordination Between School Staff: Supporting Elementary School Students Experiencing Homelessness in North Carolina

Elementary school students experiencing homelessness are at a higher risk for lower learning outcomes in both math and reading, and for more behavioral struggles than their housed peers. With student homelessness having risen by over 40% in the past ten years in the state of North Carolina, we are seeing increasingly more elementary school students experiencing mental health challenges, including suicidal ideation, and lower rates of high school graduation long-term in this population. The McKinney-Vento Homeless Assistance Act provides a range of essential services for students to ensure their learning is not disrupted, but organizational barriers often prevent these supports from reaching students. Through sequential mixed-methods, this study will examine the experiences of collaborating MVA appointed liaisons, teachers, and principals in North Carolina elementary schools, in order to better understand the barriers and facilitators to implementing the Act. Phase 1 of the study consisted of a survey to MVA liaisons, teachers, administrators, which included an adapted version of the MVA Implementation Scale to assess perceptions of effective integration of the legislation. This scale consists of 26 close-ended questions and has been repeatedly verified as a reliable metric. Phase 1 results will inform a series of semi-structured interviews (Phase 2) conducted in Summer 2026 with teachers, in order to better explore the learning experiences of students experiencing homelessness, and how teachers support them in their classrooms. This data will be used to propose recommendations aimed at increasing the efficacy of staff partnerships in such a way that homeless students receive the support they are federally designated, and liaisons, teachers, and principals are better equipped to implement these supports. This presentation details the preliminary responses of Phase 1.

Abstract Name: The Great Work Begins: An Exploration of Sexuality and the Promise of Sexual Utopia Within Tony Kushner's Angels in America

I am combining my English major with my theater minor to make my thesis a psychoanalytical critic of Tony Kushner's Angels in America. I aim to explore how the show depicts sexuality within the plot, specifically how the show represents the endless battle within man's psyche between the forbidden desires of the

unconscious and the controlling superego that defends civilization as we know it. From there I will propose the question: “Is it possible for humanity to return to a state of nonrepression? Could we experience a sexual utopia where sexual desire can be acted upon without complicating factors like guilt and shame which aim to restrict us?”. The answer that I have come to is unfortunately no. Civilization has progressed too far and we can no longer separate ourselves from these structures. Just as Prior assures the Angels that God isn’t coming back, humanity must also try to accept the loss of a past age of sexual freedom. This conclusion however opens us up to exploring a new question: “In what ways can we closer to exercising freedom over our desires, if not all the time then under specific contexts?”. Outside of my primary source of Angels in America, my main theoretical source is Sigmund Freud. From there, my primary scholars that expand upon utopian thinking are Leo Bersani, Jose Estaban Muñoz, Micheal Warner, and Herbert Marcuse. I will be comparing the arguments of these scholars with the events of the play and analyzing how the struggles of the characters connect to what these critics observe about the nature of sexuality. My work has already been presented at the Georgia Undergraduate Research Conference but I would like to use this opportunity to present it on a larger scale and receive additional feedback.

Abstract Name: Evaluation of Antimicrobial Resistance in Pathogens Relevant to Long-Duration Space Missions

Antimicrobial resistance is a growing global concern that necessitates the development of effective strategies for selecting appropriate antibiotics, especially in the context of future long-duration space missions, where infection control and treatment options are limited. This study employs the Kirby–Bauer disk diffusion assay to evaluate the antimicrobial susceptibility of *Pseudomonas aeruginosa* and other clinically and spaceflight-relevant bacterial pathogens such as *Klebsiella pneumoniae*, *Staphylococcus aureus*, and *Streptococcus pneumoniae*. These pathogens will be tested with commonly used antibiotics and potential natural compounds. The pathogens will be cultured and isolated onto Mueller–Hinton agar plates. Antibiotic disks, along with various flavonoids disks, such as Quercetin, will be used to evaluate its potential antimicrobial activity against the pathogens. The bacteria and disk will be placed on the plates then incubated at 37 °C overnight. Zones of inhibition will be measured to determine susceptibility patterns and to assess the comparative effectiveness of conventional antibiotics versus natural compounds like Quercetin. Due to preliminary findings, it is anticipated that *P. aeruginosa* will exhibit low susceptibility to penicillin-streptomycin due to its resistance mechanisms, while showing greater sensitivity to gentamicin. Understanding the susceptibility patterns of these pathogens has both terrestrial and spaceflight implications. On Earth, multidrug-resistant infections are a major public health issue, especially in the hospital environment. In space, the risk is amplified by the immune dysregulation experienced by astronauts, the closed spacecraft environment, and the reduced availability of treatments. Characterizing resistance trends and researching alternative therapeutics such as Quercetin could help guide targeted treatment strategies and inform future countermeasure development for spaceflight-associated infections. Ultimately, these findings will help inform infection prevention and treatment strategies that are critical for safeguarding crew health during long-duration space missions.

Abstract Name: Leaf-Derived Vascular Scaffolds (LeaVS) Functionalized with Pro-Angiogenic Factors Support Endothelial Recruitment

More than 6.5 million Americans suffer from chronic wounds annually. To restore quality of life and reduce mortality, engineered skin substitutes are often necessary. However, currently available options have insufficient vascular networks, which can lead to graft failure. Previous work has shown that decellularized spinach leaves (leaf-derived vascular scaffolds, or LeaVS) are a promising alternative, as their vascular structures are retained and similar to that of human skin. With the novel contribution of pro-angiogenic factor functionalization, we hypothesize that neovascular network formation in LeaVS can be enhanced. Toward this goal, this work evaluates the adsorption rate, release kinetics, and endothelial recruitment of passively functionalized LeaVS as well as a method of covalent functionalization. Using Transwell migration assays, we found that functionalizing LeaVS with sphingosine-1-phosphate (S1P) results in a 5-fold increase in endothelial migration, which is a crucial step towards vascularization. Additionally, 1-cyano-4-dimethylaminopyridinium tetrafluoroborate (CDAP) chemistry was used to covalently bind bovine serum albumin (BSA) to LeaVS, and results were verified with Fourier transform infrared (FTIR) spectroscopy. This conjugation method is applicable to molecules containing amino groups such as S1P and may promote sustained release as the scaffold degrades. Taken together, these results provide a promising methodology for enhancing neovascular network formation in LeaVS.

Abstract Name: Establishing an In Vivo Model of Leptomeningeal Disease Using Tamoxifen-Resistant MCF7 Cells

Leptomeningeal disease (LMD) is a devastating complication of solid tumors, affecting 5–15% of patients with metastatic breast cancer, particularly in the estrogen receptor–positive (ER+) subtype. Prognosis remains poor, and treatment is complicated by the frequent emergence of endocrine resistance after prolonged tamoxifen therapy. Imlunestrant (LY3484356), a next-generation, brain-penetrant oral selective estrogen receptor degrader (SERD), has shown potent ER α degradation in resistant models and is under clinical investigation. This study establishes a novel in vivo model of LMD using luciferase-expressing, tamoxifen-resistant MCF7 cells to evaluate imlunestrant's therapeutic potential. Cells (5,000–20,000) were stereotactically injected into the cisterna magna or lateral ventricle of immunodeficient SCID mice. Tumor growth was monitored with bioluminescent imaging, neurologic assessment, and weight tracking. Once engraftment was confirmed, mice were randomized to imlunestrant (10 mg/kg, oral, daily $\times$ 5/week) or control groups. Longitudinal imaging and histopathology will assess treatment efficacy. Preliminary findings demonstrate successful modeling of therapy-resistant LMD and support the feasibility of this system as a preclinical platform. Ongoing studies will determine whether imlunestrant reduces tumor burden and improves survival, offering insights into therapeutic vulnerabilities in this otherwise intractable disease setting.

Abstract Name: Examining the Link between Molecular Hardness and Binding Affinity for Rational Drug Design

Proteins are a primary target for developing drug therapies to address certain diseases. Understanding the link between ligand characteristics, such as molecular hardness, and binding affinity could provide a more effective way to design drugs for use in treating disease. Thus, this study involved the subset of diverse proteins (Acetylcholinesterase, AmpC Beta-Lactamase, Cytochrome P450 3A4, Glucocorticoid Receptor, HIV Reverse Transcriptase, and Serine/Threonine Kinase 1) from the Database of Useful Decoys: Enhanced (DUD-E), with a focus on ligand binding sites. The active site of was probed with computational docking of more than 50 molecules for each protein. Separately, electronic structure calculations were also carried out, and the molecular hardness values of these ligands were determined. The combined results are being used to generate a quantitative scale of active site hardness with greater predictability of ligand binding.

Abstract Name: Social Support and Resilience and Its Impact on Academic Self-Efficacy and Academic Performance

Social support and resiliency are important among college students, since these factors can impact their academic self-efficacy and overall academic performance. Social support can come from multiple different sources: institutional, familial, and peer. From these separate support facets, college students can have improved academic self-efficacy and increased academic performance. Resiliency has been seen as a need among college students, especially since 2/3 of students report experiencing moderate to high levels of stress due to strenuous conditions of college. This study takes a central focus on comparing the differences between first-generation college students and continuing-generation college students. First-generation college students are known to have lower retention rates as well as have lower academic self-efficacy. With increased social support, they can have an increased resiliency and higher self-efficacy, which is not just limited to academics. The overall purpose of this study is to explore the impact of social support from different groups and resiliency to stress to see how it affects self-efficacy and academic performance. The hypotheses of this study are that first-generation college students, specifically, will have higher resilience against stress if they have stronger social support systems. College students overall will have higher academic self-efficacy and performance if they have stronger social support. Finally, higher resilience among college students will correlate with higher academic self-efficacy and performance. The study will be conducted via self-reported

survey with relevant social support, academic self-efficacy, and resilience scales and open-ended questions. If these hypotheses are fulfilled, all students would benefit from resiliency building lessons and social support programs. It could also indicate the need for institutions to provide transition programs with support avenues for first-generation college students, while also providing educational programs about building resiliency to prevent negative reactions to high levels of stress.

Abstract Name: Linking Vegetation Structure and Composition to Food Resources for Declining Songbirds in the Virginia Appalachians

Non-native, invasive plants displace native species in human-altered landscapes, reducing biodiversity. Early successional habitats (ESH) are important, declining ecosystems that are susceptible to non-native plant invasion. Non-native plants cannot replace native plants as hosts for caterpillars, an important source of food for birds, including golden-winged warblers (*Vermivora chrysoptera*; GWWA) and chestnut-sided warblers (*Setophaga pensylvanica*; CSWA), two threatened early-successional songbirds. Associational effects occur when insect herbivore abundance increases or decreases due to the vegetation neighborhood surrounding a focal plant. To understand if neighborhood density, composition, and diversity affects food availability for songbirds, we collected clippings from three tree species preferred as foraging substrates by GWWA and CSWA and conducted vegetation surveys across private properties in Highland County and Bath County, Virginia. We found no relationship between the proportion of non-native vegetation in a neighborhood and caterpillar abundance or biomass. Overall, black locust trees had the most caterpillars. There is a negative relationship between caterpillar abundance and neighborhood diversity and density, as well as between caterpillar biomass and neighborhood diversity. These results show that dense, diverse vegetation neighborhoods provide trees with an associational resistance to herbivory by caterpillars. This could be because these neighborhoods block visual and chemical cues used by insects to locate their host species. Diverse vegetation may also reduce herbivory on the focal tree by generalist herbivores. This study emphasizes the importance of black locust as a foraging substrate for early-successional songbirds as well as the need to maintain patchy, open landscapes for insect herbivore and songbird populations.

Abstract Name: *Borrelia burgdorferi* (Lyme's Bacterial Spirochete) Means & Understanding of the Method of Entry into HEK (Human Embryonic Kidney) Cells through Confocal Microscopy.

The bacteria that causes Lyme's Disease is in the deer tick *Ixodes scapularis*, A single tick bite is capable of multiple systemic problems resulting from inflammation. Infection in the kidneys leads to Lyme Nephritis, a condition leading to hyponatremia. This condition is more prevalent in dogs and is the leading cause of death in dogs. The goal of this research is to determine if the spirochete directly interacts with isolated Human

Embryonic Kidney(HEK) cells. Recent research in the Clarke Lab has shown significance in understanding how this spirochete interacts with various types of culture cells to begin identifying the target tissues in Lyme Borreliosis Our experimental approach was to coinubate HEK cells (ATCC####) with *Borrelia burgdorferi* (strain B19) that constitutively expresses Green Fluorescent Protein (gfp-Bb) at 37oC for XX hours. HEK cells were seeded onto cover slips at XX x 10⁶ cells/ml, incubated overnight to form a lawn of HEK cells. Coinubate was initiated by adding gfp-Bb to different final ratios of HEK:gfp-Bb to assess an optimum MOI. Cells were sampled by aspirating the supernates, and washing the adherent cells with ice cold Phosphate Buffered Saline. These cells were fixed with Paraformaldehyde (PFA). The cover slips were treated with DAPI to label the nuclei then inspected by confocal microscopy to determine if the gfp-Bb could be identifiably associated with the HEK cells. The overall significance is to understand how the Bb is actively interacting with a kidney cell.

Abstract Name: Carotenoid Extraction from Spinach Using Deep Eutectic Solvents

Carotenoids are innate pigments located in algae, plants, and photosynthetic bacteria. Fruits and vegetables that are rich in carotenoids include spinach, watermelon, carrots, kale, oranges, and tomatoes. Carotenoids are widely used in the pharmaceutical and food industries worldwide due to their health benefits. For instance, carotenoids are used as antioxidants in the human body to help prevent chronic diseases. Due to their fat-soluble nature, carotenoids are contained within lipid molecules at the cellular level and are stored throughout the body, including in the skin, eyes, liver, and adipose connective tissue. Humans cannot naturally synthesize such pigments, so they must be consumed through fruits and vegetables. This research focuses on using green solvents, commonly known as deep eutectic solvents (DES) to successfully and efficiently extract carotenoids from spinach, which is a model plant widely used in scientific research. The advantages to using these “green friendly” DES include their inexpensive cost, biodegradability, contain non-toxic compounds, and straightforward preparation. Such DES prepared consist of choline chloride mixed with either glycerol, ethylene glycol, propanediol or urea, and betaine mixed with ethylene glycol or glycerol respectively. The carotenoid extracts were analyzed using a high-pressure liquid chromatography (HPLC) instrument with a C30 carotenoid column to determine the most efficient deep eutectic solvent for carotenoid extraction.

Abstract Name: Repurposing Anti-Cancer Drugs as Antiparasitics Against *Toxoplasma gondii*

Toxoplasma gondii is an obligate intracellular parasite and the causative agent of toxoplasmosis, an infection that damages the brain, eyes, and other organs. *T. gondii* lives asymptomatically in roughly thirty percent of the global population, except for immunodeficient individuals, who often experience substantial adverse

effects. The objective of this study is to develop novel treatments by evaluating anti-cancer drugs, a class of compounds that have previously exhibited anti-parasitic activity. *T. gondii* possesses several kinases critical for survival; therefore, current FDA-approved cyclin-dependent kinase (CDK) inhibitors targeting breast cancer, including Palbociclib HCl, Ribociclib HCl, and Abemaciclib, were examined. Experimental methods to test the efficacy of the CDK inhibitors as a potential treatment include doubling assays of the compounds at varying concentrations. Results indicate that two of these drugs show a significant reduction in parasitic growth and replication of *T. gondii* while preserving the viability of the host cells. To further assess inhibitory activity, derivatives of the effective inhibitors were tested in luciferase assays, with preliminary results indicating a potential effect on parasite growth and replication. This research contributes to the development of novel therapeutics by focusing on anti-cancer agents and provides evidence for the repurposing potential of CDK inhibitors.

Abstract Name: Investigating Neurotransmitter Packaging in Dual Neurotransmitter Neurons

The mechanism of communication between neurons is largely understood to begin with a presynaptic neuron packaging one type of small-molecule neurotransmitter (SMN) into synaptic vesicles for release at chemical synapses. These types of neurons are referred to as single neurotransmitter neurons (SNTs). Interestingly, there is a subset of neurons that signals using two types of SMNs, known as dual neurotransmitter neurons (DNTs). Despite being discovered several decades ago, how DNTs are functionally different from SNTs is not well understood but the mode of neurotransmitter packaging for neuronal signaling has profound implications for how DNTs signal to downstream neurons. When neurotransmitters are co-packaged in DNTs (co-release), release is spatiotemporally synchronized, while separate packaging (co-transmission) allows distinct transmitters to signal independently across time and space. Thus, understanding how DNTs signal requires knowledge of their mode of neurotransmitter packaging. We hypothesize that different DNTs will utilize distinct modes of neurotransmitter packaging that underlies the functional differences in their mechanisms of signaling to downstream neurons. We have been exploiting the genetic advantages of *Drosophila melanogaster* to investigate the mode of neurotransmitter packaging in DNTs in the brain. The challenge with studying synaptic vesicle co-localization is the miniscule size of the synaptic vesicle, which measures ~30nm across. Since the resolution of confocal microscopy is only ~250nm, individual synaptic vesicles cannot be distinguished using this standard method of imaging. To solve this, we use a technique known as expansion microscopy that isotropically expands tissues tenfold. This allows for visualization of separate vesicles within one synapse at a resolution of ~25nm, and thus a determination of whether a given DNT co-packages or independently packages its neurotransmitters. These studies will yield insight into understanding normal behavior in *Drosophila* and other species, as well as have potential implications for psychiatric and neurodegenerative diseases in humans.

Abstract Name: From Efficiency to Ecology: The Changing Definition of “Sustainability” through the Lenses of 20th-century Modernism and 21st-century “Material Ecology”

As the changing climate refocuses the architect's moral obligations, the idea of sustainability has evolved from efficiency and moderation towards stewardship and reciprocity. A comparison of the works of the modernist architect Frei Otto and the "material ecologist" designer Neri Oxman reveals how two, distinct forms of experimentation --- the structural and biological, respectively --- highlight the moral necessity of design through empirical inquiry. Modernist architects of the 20th century, such as Ludwig Mies van der Rohe, advanced "Less is More" as an aesthetic of ethical economy: efficiency equated to virtue, a refutation of past epochs. Rejecting the fascist aesthetics of Germany's Third Reich, Frei pursued a minimization of matter through exhaustive form finding, developing tensile structural systems and lightweight envelopes, with the goal of an egalitarian and democratic built form. Presently, twenty-first-century designer Neri Oxman advances matter to the position of collaborator. Through her theory of "material ecology," Oxman integrates biological and computational methodologies to produce forms and structures that grow, calcify, and decompose, highlighting the environmental and architectural needs of the new millennium. This paper examines this shifting definition of sustainability through a comparative analysis of Otto's and Oxman's respective works. Drawing on their writings and projects, including Otto's Munich Olympic Stadium and Oxman's Aguahojá I & II, an argument is formed that suggests Otto's ethic of efficiency and Oxman's framework of symbiosis exist within two distinct ecological paradigms. Ultimately, Otto's sustainability is quantitative; Oxman's is qualitative. Together, their work traces the disciplinary shift from a modernist efficiency to a posthuman ecology: from "less is more" to "what if the built environment lived with and beyond us?"

Discipline: Physical/Occupational Therapy and Speech Language Pathology

Authors:

Abstract Name: Prospective Study of Auditory Neuropathy Spectrum Disorder

ANSD presents unique diagnostic and intervention challenges that require coordinated management across audiology and speech-language pathology. However, limited research has examined speech-language pathologists' preparedness to assist this population. This prospective study investigates the perceptions of practicing SLPs regarding: the level of their current understanding of ANSD, the extent and quality of their preliminary and in-service education concerning ANSD, and their perceived positions in the assessment, treatment, and interprofessional collaboration. Research findings suggest considerable variability in training exposure, with many respondents describing minimal formal instruction related to ANSD despite serving children who presented with Auditory-Neuropathy Spectrum Disorder. Key responsibilities identified by participants included monitoring speech and language development, including individualized communication strategies, supporting family education, and collaborating closely with supplemental professionals regarding technology outcomes and intervention planning. The results of this study suggest the need for increased educational resources and targeted professional development to better equip SLPs to serve individuals with ANSD. This study attempts to explore the necessity of enhancing clinical preparation and interdisciplinary communication to optimize outcomes for affected children and families.

Abstract Name: Did the CIA win or are you a tool of Conservatism: The Rise of Conservatism in Black Youth

AbstractThe political climate of the United States has been cyclical since the inception of this country. We are now encroaching a period reminiscent of post reconstruction within the Black community. The rise of conservatism is experiencing a resurgence in black youth. My research seeks to explore this phase in our history through an Afro-pessimistic lens. The wonderful works of the talented tenth and scholars of literature written by 20th century scholars and theorists served its purpose to inspire formerly enslaved peoples and extricate the Black identity from enslavement. Although, the belief that co-opting the ideologies Anglo-Saxon Americans about what is expectable seemed like a good idea at the time, now, it has proven to do more harm than good. Today amongst the black youth the ideals are described as conservatism. Questions about lifestyle choices, child rearing, public spending are all leading us down a path of conservatism that is influenced by religion and white supremacist indoctrination. In this research I aim to explore and explain - the memefication and use of conservative social thought in casual interactions has led to the rise of conservatism in Black Youth. The use of an afro-pessimistic framework serves to highlight the ways that conservative doctrine is contradictory to black identity. Afro-pessimism, while flawed in explaining all the way the other races and identities are impacted by this viewpoint, explicates the perception of blackness. Simply put Blackness is subhuman because to be black is to be property. The origin of Blackness in this country has been enslavement and ownership, so to be black is to be owned. Through this lens conservatism by black youth is irrelevant. Adopting the thoughts of your owner will not buy you freedom. The only way to truly be free is to reject blackness as we know it.

Abstract Name: Genotyping Nuclear DNA From Rootless Human Hair

Human hair is one of the commonly found biological evidence at crime scenes. Genetic analysis of rootless hair is challenging due to extremely low nuclear DNA content and increased susceptibility to degradation from environmental factors and keratinization. This research examined the effectiveness of extracting and genotyping nuclear DNA from 10cm of rootless human hair samples. Recent reports suggests that advancements in chemical lysis and purification may improve recovery, though the reliability of rootless hair for STR genotyping remains a challenge. This research aims to contribute to this discussion by evaluating an extraction and amplification workflow optimized for rootless human hair. Twelve naturally shed, rootless human hairs were collected, trimmed, and washed with a 5% Terg-a-zyme solution to remove contaminants. DNA extraction followed a multiphase protocol including chemical lysis with Buffer ATL, Proteinase K, and DTT, prolonged incubation to encourage the release of DNA, and purification through a MinElute column following ethanol and buffer washes. Recovered DNA was dried, rehydrated with TE-4 buffer, quantified, and subjected to qPCR quantitation and STR amplification to assess the presence and quality of amplifiable nuclear DNA. Obtained results showed that autosomal STR profiles could be generated from four rootless hair shaft, but the overall success rates for generating informative STR profiles from more than 8 STR loci for eight hair samples was low. These results suggest that when DNA extraction procedure is optimized with right volume of proteinase K, addition of optimum amount of DTT, and extended incubation time for proteinase K, STR profiles can successfully be generated from rootless human hair.

Abstract Name: Investigating the Impact of Socioeconomic and Environmental Factors on Life Expectancy in 2023: Top 20 vs. Bottom 20 U.S. Counties

More than 30 years of discrepancy in life expectancy between the top and bottom 20 U.S. counties led us to investigate influential factors. This study compares 23 different socioeconomic and physical environmental variables on life expectancies in 2023. We conducted statistical analysis using RStudio, including descriptive statistics, two-sample t-tests and Wilcoxon Ranked-Sign tests, and correlation tests to identify which variables significantly distinguish the two groups. Visualizations such as box plots and correlation scatterplots were also used to support pattern recognition. The results show that the top 20 counties have clear socioeconomic advantages. Statistical tests revealed significantly lower poverty rates, higher rates of college graduation, and much higher median household incomes compared to the bottom 20 counties (p -value < 0.05 for each). In addition, correlation analysis further indicated strong positive relationships between life expectancy and both income and education, while poverty and unemployment showed strong negative correlations. Environmentally, high life-expectancy counties also tended to have a higher rate of people living near greenspaces and greater forest coverage, although these factors displayed weaker statistical relationships. The bottom 20 counties, many of which are located in rural South Dakota, North Dakota, and Appalachia, showed consistently higher poverty rates, lower graduation rates, and lower median incomes. Although some environmental factors such as air pollution were favorable, the statistical analysis suggested that these advantages do not counteract the impact of socioeconomic hardships. Overall, the statistical results highlight socioeconomic factors as the most influential predictors of life expectancy, as well as certain environmental factors. Thus, we conclude that a combination of socioeconomic and environmental inequalities drive much of the life expectancy gap across U.S. counties. Our results could be shared with policymakers to improve quality of life amongst vulnerable communities.

Abstract Name: The Personality Profile of Business Leader Elon Musk

This poster presents the results of an indirect personality assessment of business leader Elon Musk, from the conceptual perspective of personologist Theodore Millon. Psychodiagnostically relevant data about Musk were collected from biographical sources and media reports and synthesized into a personality profile using the Millon Inventory of Diagnostic Criteria (MIDC), which yields 34 normal and maladaptive personality classifications congruent with DSM-III-R, DSM-IV, and DSM-5. The personality profile yielded by the MIDC was analyzed on the basis of interpretive guidelines provided in the MIDC and Millon Index of Personality Styles manuals. Musk's primary personality patterns were found to be Ambitious/confident and Dominant/asserting, supplemented by secondary Dauntless/adventurous, Outgoing/congenial, and Contentious/resolute patterns and a subsidiary Conscientious/respectful tendency. An appropriate descriptive label for Musk's personality composite, given the prominence of the Ambitious and Dominant patterns in his

overall personality configuration, is “fearlessly ambitious innovator.” These individuals see themselves as extremely capable, talented, and deserving of success. They strive for achievement and recognition, prompting a surplus of arrogance and entitlement.

Abstract Name: Multimodal Learning and its Impact on Elementary Student’s Understandings of Scientific Inquiry.

Research in learning sciences suggests that sound and high-quality science education heightens students' achievement, yet many students have limited opportunities to engage in science at the elementary level. As a result, many students do not acquire the building blocks necessary to succeed in STEM learning later in their academic journey. In our local community, Guilford County, 42% of the elementary schools scored below the average proficiency for science during the 2022-2023 school year. Thus, creating high-quality elementary science education research benefits students nationally and in our local community. In this study, I focus on scaffolding inquiry, specifically guided inquiry approaches to learning. Guided inquiry allows students to build knowledge and comprehension while following a structured plan laid out by the teacher. While some research has investigated closing the gaps in understanding with guided inquiry, most fail to focus on its application for elementary school. Further, continuing the prevalence of low science proficiency rates by ignoring the communication of foundational science concepts. My research explores how multimodal learning, such as incorporating multimodal text and mixed reality, impacts guided inquiry. Taking three groups of fourth graders, we will look at their pre- and post-tests to see how the different modalities (worksheet, multimodal text, and mixed reality) affect their understanding of conceptual knowledge during guided inquiry. While the results are preliminary, they suggest that mixed reality during guided inquiry enhances student outcomes and understanding of scientific content knowledge.

Abstract Name: Infralimbic GABAergic Interneurons Show Opposing Activity During High and Low Fear States in Pavlovian Fear Model

In 2019, 4% of the world population reported experiencing an anxiety disorder, such as severe anxiety, phobias, or post-traumatic stress disorder (PTSD). The rodent medial prefrontal cortex (mPFC) is known for its role in regulating fear. Specifically, the infralimbic (IL) region of the mPFC is thought to be a key site for fear suppression. Aside from the glutamatergic principal neurons, GABAergic interneurons (INs), such as somatostatin (SST) and parvalbumin (PV) INs, are present within the IL, suggesting influence on the IL’s function. To determine the roles of PV-INs and SST-INs in both high and low fear states, we exposed transgenic reporter lines PV-Cre/Ai9 and SST-FlpO-Ai65F—which express the red fluorescent protein,

TdTomato, in either PV-INs or SST-INs—to a cued fear conditioning paradigm followed by fear retrieval or extinction retrieval. After this, we immunostained their brain slices for the immediate early-gene cFos, to mark neuronal activity. We found that PV-INs were more activated during high fear states, while SST-INs were more activated during low fear states. These results suggest that PV-INs and SST-INs play opposing roles in fear promotion and suppression within the IL region[UC1] . For further confirmation, we optogenetically activated PV-INs and silenced SST-INs in PV-Cre and SST-Cre mice during extinction retrieval. We hypothesized that this manipulation would drive high fear responses; however, we found no significant difference in behavior between control and light-manipulated groups. This suggests that the IL may not play an important role in extinction retrieval. By investigating the roles of PV-INs and SST-INs in the IL's function, we highlight their importance in regulating fear suppression and driving both high and low fear states. [UC1]It is important to highlight this because in other brain regions and even in other subregions of the mPFC, the interneurons have different roles than they have in the IL.

Abstract Name: Addressing the Declination of Interest in Conscious Hip-Hop

During the Golden Era of the Hip-Hop movement, which is defined as the time between the mid-1980s to the mid-1990s, culturally conscious songs led the rap music charts. Conscious rap songs talk about societal issues within the community and how they affect the people. Well-known conscious rap songs include the song “Brenda’s Got a Baby” by Tupac and the song “Daughters” by Nas. Much of the hip-hop produced during that time promoted positive, affirming stories about the Black experience. It can be argued that too much of modern rap music promotes violence, drug use, and hypersexuality, and there is a need for hip-hop to experience a second renaissance. As a songwriter, rap artist, and producer, I want to join conscious hip-hop artists like Kendrick Lamar as an example of how art can be used to positively impact the Black community. My fourth album, *Save The Game*, aims to provide social commentary and awareness, and answers the question of whether the impact of modern hip-hop music on society is primarily negative or positive, and asks why. My album includes songs that are about various cultural, political, and personal introspective issues. For example, my song “Fear” is about how exposure to violence can impact a child and cause them to feel paranoid and uneasy. It includes my experience of witnessing police brutality and school shootings on the news, and how the realization that the world can be a dangerous place affected me. My reason for making the album was to further develop my career as an artist and effect change in my community.

Abstract Name: Analysis and Measurement of Trebuchet Projectile Using Quaternions

The purpose of this project is to analyze the motion of a projectile launched by a floating arm trebuchet with the aid of quaternions. Quaternions have been studied and are traditionally used for graphic design, but not for tracking physical projectile motion. This project is unique in that it uses the quaternions to establish the

accelerometer's rotated input into a readable reference frame to measure position over time. To measure this, a gyroscope and an accelerometer are placed inside of the projectile additionally a camera setup, a more common methods of analysis, is used in order to compare the results. The results from the sensor were compared to the camera setup and demonstrated an accurate representation of the projectile's rotation. The positional results from the sensor have not yet been utilized.

Abstract Name: Sourcing Ancient Stone Tools from Parsons, TN.

The current study examines the source of prehistoric stone artifacts to determine if past humans utilized local rock resources at the archeological sites located on the Townsend property. The Townsend property has several prehistoric sites which provide evidence that this area was used and occupied for millennia. The Townsend property would likely have been an appealing landscape due to its location near the Tennessee River and the abundance of natural resources including duck/wild game and chert, a rock similar to flint used to make stone tools. Reflectance spectroscopy is the method used to source the chert artifacts, and the results show that past humans were predominantly using local chert resources, but from a different outcrop than expected. This method produces spectra based on the reflectance of stone artifacts. Those spectra were analyzed with R to produce two different statistical models that identify a source. The study provides insight into past human behavior and how ancient humans were using the resources in this area. The current study also contributes to a larger body of research into reflectance spectroscopy stone sourcing. This body of research could significantly improve insight that archeologists could obtain about past human interaction with their landscape.

Abstract Name: Exploring Freshwater Bacterial Communities: Culturing Challenging Isolates with Selective and Differential Media

Freshwater bacterial communities are influenced by environmental factors such as temperature, pH, organic matter, and pollutants. Because these ecosystems have direct ecological and public health relevance, systematic identification of microbial populations—including potential pathogens—is essential. Over the past decade, our team has collected water samples from the Rochester Lake Ontario Embayment, isolating more than 1,300 bacterial specimens. Of these, 1,023 isolates were sequenced using 16S rDNA, with approximately 200 showing contamination or mixed cultures. This project focused on isolates with poor sequencing results. Cultures were plated on selective and differential media (MacConkey and Mannitol Salt agar) and quality of resulting sequences assessed. DNA sequences from these samples were used to characterize bacterial diversity and assess genus-level prevalence; GIS mapping will be used to examine the

geographic distribution of key taxa. Particular attention is given to isolates from taxa with known pathogens. This work contributes to our long-term goal of developing a predictive model that integrates microbial data with satellite imagery to forecast the presence of specific bacterial taxa. By combining molecular analysis with geospatial tools, this study advances understanding of freshwater microbial ecology and provides a foundation for monitoring water quality and safeguarding public health.

Abstract Name: (Re)Framing Police Data: A Mixed Methods Study through the Lens of Black STEM Students on Policing, Safety, and Data Justice

Policing in communities of color, especially Black communities, remains a persistent civil rights and public health issue marked by racial bias, excessive force, and declining trust (Cooper & Fullilove, 2016; DeVolder et al., 2022). However, much policing research emphasizes administrative data over community perspectives. This study aims to shift that focus by centering the voices of Black undergraduate students in STEM fields at HBCUs and generating evidence based on their lived experiences. We employ an exploratory sequential mixed-methods design, beginning with a qualitative phase that includes a brief screening survey, in-depth interviews, and focus groups. This phase collects personal narratives about STEM identities and interactions with policing among those most affected. These insights guide the development of research questions for the quantitative phase, which uses open-records administrative data from the Chicago Police Department. The study demonstrates how counter-narratives influence research priorities and challenge dominant interpretations of policing data while highlighting gaps often overlooked by traditional approaches. Our work is based on the Phenomenological Variant of Ecological Systems Theory (PVEST) and QuantCrit. PVEST explores how young Black adults interpret and respond to racialized encounters and how environmental stressors affect identity, well-being, and academic paths. QuantCrit highlights that quantitative data are neither neutral nor objective and must be interpreted with attention to racial systems and lived experiences. These frameworks shift policing research from studying “on” communities to studying with them. They support a participatory co-researcher model where qualitative findings become measurable, context-aware analyses that directly address community concerns. We expect the qualitative phase to reveal patterns linking racialized stress, STEM identity, and daily navigation of policing encounters. Quantitative results will contextualize these experiences within broader enforcement trends and predictive policing systems. Together, the findings will support discussions on public safety, equity, and data justice, guiding safer, more inclusive environments for Black STEM students.

Abstract Name: Relations between children's skin tone and skin tone satisfaction and outcomes via children's peer victimization and competency

Colorism, or prejudice against darker skin tones, has been a systemic standard upheld in U.S. society since its inception (Abrams et al., 2020); however, few studies have explored the implications of colorism, especially in terms of skin color, among youth. It is possible that the ways in which youth think about their skin tone may impact how they interact with peers and/or how they are treated by their peers which may, in turn, predict their self-concept. Although the associations between the peer context predicting academic outcomes and self-esteem have been tested (e.g., Spyropoulou & Giovazolias), there is limited research on whether skin tone and skin tone attitudes inform the peer context. To address gaps, the current study tested the associations between skin tone and skin tone attitudes (i.e., skin tone, skin tone satisfaction, and desire to change skin tone) and self-esteem via the peer context (i.e., peer competence and peer victimization). Participants included 275 Black and Latine children ages 5 to 11 who participated in a larger study. Results indicated that none of the children's skin tone factors informed their self-efficacy or self-esteem when the peer context was taken into account, highlighting the importance of examining mediating variables. Several significant mediation pathways emerged. Skin tone was associated with greater peer victimization and lower peer competency. Lower peer competency was, in turn, associated with lower academic self-efficacy and self-esteem, while greater peer victimization was, in turn, associated with lower self-esteem. Another significant mediation pathway emerged, which indicated that children's increased desire to change their skin tone was associated with greater peer victimization, which was, in turn, associated with less self-esteem. Findings highlight the importance of focusing on children's racialized experiences early in development as they have implications for their peer interactions and outcomes.

Abstract Name: Modulating Cognitive Control Networks Using Frequency-Specific Transcranial Magnetic Stimulation

Hierarchical cognitive control involves managing multiple layers of rules and goals, enabling us to flexibly switch between and nest these rules to guide context-appropriate behavior. Distinct neural mechanisms have been identified in this process, particularly in the prefrontal cortex. Prior research has established that delta oscillatory activity is often implicated in contextual control, whereas theta oscillatory activity is associated with control demand - both of which are key components of hierarchical cognitive control. Given these findings, the present study seeks to examine the behavioral effects of modulating these distinct oscillatory dynamics through transcranial magnetic stimulation (TMS), a safe, non-invasive brain stimulation tool. Among a sample of young adult participants, we expect that delta frequency stimulation will enhance performance regarding rule contextual control while theta frequency stimulation will improve behavioral metrics related to control demand. Our future aims are to analyze neurophysiological data collected with high-density EEG to assess the causal role of delta and theta oscillations in underlying hierarchical cognitive control.

Abstract Name: Embedded Linux in SCADA Systems

Supervisory Control and Data Acquisition (SCADA) systems run much of the infrastructure and industrial equipment we rely on; from factory lines to networked controllers. Because many SCADA devices and appliances use lightweight or embedded Linux distributions, they can inherit software flaws that attackers could exploit. This project scanned several Linux distributions commonly found in embedded and SCADA contexts (OpenWrt, Yocto-built systems, Buildroot, RHEL, BusyBox-based systems, and Tiny Core) to measure how many known vulnerabilities appear in readily available images. We pulled container images for each distribution, deployed them on Virginia Tech's CS Launch/Kubernetes resources, and scanned them using automated tools (Trivy and Gype) plus targeted testing with Kali tools. The scans returned different results across distributions; some images produced many vulnerability hits, and others failed to scan cleanly; highlighting differences in packaging, available metadata, and how scanners enumerate software. We then cross-checked hits against public CVE records and examined example exploits to show realistic attack paths (e.g., buffer overflows, improper permissions, escape sequence issues). This work shows that embedded Linux images can carry significant risk unless images and packages are tracked and updated. For practitioners, we recommend: (1) include vulnerability scanning in the deployment pipeline, (2) pin image versions and record SBOMs, and (3) treat embedded images like any other system when it comes to patching and monitoring. We will continue follow-up testing and practical exploit validation on RHEL, BusyBox, and Tiny Core images based on security-professional recommendations.

Abstract Name: Narrative in the Anthropocene

We as a species have so immeasurably changed the face of our planet that it may be widely argued we are presently in the Anthropocene, a new age inaugurated by our species, and our extensive domination of the Earth. Despite this, many people continue to struggle to grapple with the effects and causes of climate change, as it exists today in the Anthropocene. Why then, do we struggle little when it comes to narrativizing events within our own history, inaugurating ages that come and go with the passage of time, yet struggle in narrativizing the stories of the Anthropocene? Ecological and literary critics such as Amitav Ghosh have referred to the emergence of "a failure of imagination" within society as a whole. Seeking to address this failure, there have emerged new schools of thought among those in the humanities, particularly within fields of ecological literature, which I believe is key to addressing the present crisis of narrativization. It is the lack of a holistic vision, I contend, which perpetuates our failure to adequately narrativize the climate crisis. In this study, I tie together varying threads from within these new fields, titled the "Blue Humanities" or "Ecological Humanities" as a whole, with writers such as Hester Blum and Steve Mentz, to provide a narrative that

explains the origins of our “failure of imagination”, its systemic origins, and how the humanities play a vital role in narrativizing the already extensive scientific and sociological research on climate change. The findings of the study, through a close reading of post-growth ecological works such as Abigail Larkin’s “A Séance in the Anthropocene”, provide a powerful vision for what narrativization of the Anthropocene could look like within the humanities as a whole, and how they play a vital role in the fight against climate change.

Abstract Name: Transparent Soy Protein Composite Films For Sustainable Food And Pharmaceutical Packaging

Transparent soy protein composite films are presented as a sustainable alternative to conventional plastic packaging. These protein-based films are intended for direct contact with food and pharmaceutical products and combine safety, optical clarity, and flexibility with mechanical strength that approaches common commodity plastics. At the NIU Bioplastics Lab we formulate composite films from soy protein isolate SPI and cellulose nanofibers CNF recovered from soy hulls using an alkaline extrusion process that upgrades low value agricultural residues. Glycerin is incorporated as a plasticizer to provide flexibility. Acetic acid is used as a food grade multifunctional acid that forms ester and amide linkages with SPI and CNF, while sodium hypophosphite monohydrate acts as a benign catalytic salt that promotes this crosslinking at moderate temperatures without loss of transparency or edibility. The resulting formulations are cast from aqueous solutions by tray casting and controlled drying. The transparent SPI CNF films produced in our lab reach tensile strengths of at least 25 MPa, comparable to petroleum plastics such as low density polyethylene about 24 MPa. Reinforcement with CNF and acetic acid mediated crosslinking assisted by sodium hypophosphite substantially improve toughness, reduce solubility, limit water driven swelling, and decrease moisture sensitivity while preserving optical clarity. These balanced mechanical and barrier properties, combined with the use of abundant soy processing coproducts, position this system as a promising platform for sustainable packaging, including fresh produce wraps, edible or dissolvable films, and protective packaging for food and pharmaceutical products.

Abstract Name: A Comparison of Industry Leaders’ Effective Tax Rates with Key Competitors Across Three Flagship Industries

Most common criticisms of the current corporate tax system suggest that large corporations do not pay their fair share. This project does not consider the possibility of direct increases in tax rates, rather it seeks to analyze manipulations of income of top-performing publicly traded firms against other large key competitors

in the same industry to benchmark the Effective Tax Rates (ETRs) in three major industries. This analysis allows us to make claims that leaders of industries may or may not have more tools for tax avoidance and comparatively identify their Effective Tax Rates. This project can test claims of excessive tax avoidance relative to other firms and highlight the strategies involved in the tax planning process, including tax havens. Previous research in this area has focused on firm differences such as large vs. small, public vs. private, and multinational vs. national. Other research highlights specific tax avoidance strategies of only one or two firms and has not specifically analyzed major firms in the same way as this study. Pulling competitors for the three industry leaders of Apple, Nike and Starbucks from expert-agreed sources—such as IBISWorld, Bloomberg Terminal and 10k documents—we can create a sample for which we will benchmark ETRs. Using the COMPUSTAT tool, we can begin our data collection of ETRs and related information. Our analysis might find that the industry leaders will have lower ETRs year after year due to various reasons such as economies of scale for tax planning, political influence, ability to offset income against failing segments, ability to hold foreign income abroad, ability to create subsidiaries and transfer income and expenses between themselves and more. If this is true, the country must strive to create a more equitable tax revenue collection system for the public good through policy change targeting these leaders.

Abstract Name: Covalent Immobilization of DNA Nanostructures on Surface Modified with Self-Assembled Monolayers (SAMs)

Understanding protein-protein interactions is crucial for unraveling cellular mechanisms, with broad implications in biomedical applications, evolutionary biology, and beyond. DNA nanotechnology enables the localization of biomolecules like proteins at tens to nanometer scale precision. In the field of surface modification techniques like patterning and lithography, DNA nanotechnology is being widely explored as an alternative approach. In this project, we have used DNA nanostructures due to their ease of modification, high biocompatibility, and ability to enable selective targeting. Previous work from our group has shown that stability of the nanostructures is influenced by surface wettability and mixed silane SAMs, one of the widely used surface modification techniques, with a higher concentration of polar amine-terminated silane, results in the maximum density of DNA nanostructures with maintained structural integrity once deposited onto it. Our project explores the covalent attachment of DNA nanostructures to silicon dioxide (SiO₂) surface via click chemistry. We have modified surfaces with alkyne terminating SAMs using 2-propyn-N-(triethoxysilylpropyl) carbamate (PTESC) silane. ssDNA modified with azide-terminating nucleobase has been used for simplifying the condition in the first place, to verify the covalent transfer. To investigate the successful attachment, we have extensively used surface-characterization techniques, including Atomic Force Microscopy (AFM), ellipsometry, video contact angle measurements, and X-ray Photoelectron Spectroscopy (XPS). Early data provides evidence suggesting covalent binding, and our ongoing experiments aim to quantify the binding efficiency as well as the localization of target proteins via covalently attaching DNA nanostructures modified with selective strands. These results contribute toward creating programmable bio-functional surfaces for applications in molecular evolution, construction of artificial cells, understanding cell-free signal transduction, and protein-interaction studies in the future.

Abstract Name: Evaluating the Effects of Urbanization on Meiofauna Biodiversity in Chattanooga's Lentic Ecosystems Through GIS Applications

Lentic ecosystems—such as ponds, lakes, and wetlands—differ from flowing systems like rivers due to their stagnant waters, which accumulate sediment and organic matter, creating nutrient-rich habitats. These ecosystems are crucial for biodiversity, providing homes for diverse species, regulating water quality, storing water, and supporting human activities like fishing and agriculture. However, they face growing challenges from pollution, invasive species, habitat destruction, and climate change. Meiofauna—microscopic animals that inhabit these ecosystems—are key players in nutrient cycling, sediment stabilization, and food web dynamics. Due to their diversity, abundance, and short generation times, meiofauna serve as effective bioindicators of environmental change and provide valuable insights into ecosystem health. Despite their ecological importance, meiofaunal communities remain understudied, particularly in freshwater ecosystems. This study focuses on meiofaunal biodiversity across 10 lentic water bodies in the Chattanooga area, with an emphasis on understanding the impact of human activities on their communities. Using environmental DNA (eDNA) techniques, we assess biodiversity, including richness, community composition, and phylogenetic diversity. Additionally, GIS models are employed and integrated to quantify human influences such as population density, traffic, and land use in these ecosystems. The goal is to evaluate how human activities shape meiofaunal communities and contribute to the overall health of lentic ecosystems. The results will inform strategies for mitigating the negative effects of human impacts, supporting the development of sustainable practices to preserve the health and functionality of these vital ecosystems for future generations.

Abstract Name: Playing with Chance: Tuning Artificial Probability to Affect Player Engagement

Games frequently rely on randomness to generate excitement, suspense, and replayability (Goodman et al., 2025). However, developers often weight or present probabilities in deliberately misleading ways, simultaneously enhancing players' perception of fairness while amplifying emotional tension and engagement (Game Developer Staff, 2016; Myers, 2010). This research aims to investigate how players perceive and respond to such manipulations. Players' interpretations of chance are shaped by predictable biases: the gambler's fallacy, the hot-hand effect, and the near-miss effect (Dixon et al., 2024; Polin, 2023). These phenomena help explain why games that deliberately misrepresent in-game probabilities remain compelling and why players often overestimate their sense of control. To examine these effects, the research utilizes an experimental game in which participants roll virtual dice to earn points. The control group completes 90 rolls with truly random probabilities. The experimental group completes 30 baseline rolls with fair dice, followed by 60 rolls with subtly manipulated probabilities (specifically, adaptive streak-breaking and enhanced near-miss frequency). Throughout gameplay, behavioral measures are collected, including response times,

voluntary continuation decisions, and betting patterns. Post-gameplay, participants complete structured questions assessing perceived fairness, enjoyment, frustration, and pattern detection, followed by open-ended questions about their strategies and surprising moments. Quantitative data will be analyzed using mixed-model ANOVA to examine both between-subjects effects (control vs. experimental group) and within-subjects effects (across gameplay phases), while qualitative responses will be coded for thematic patterns related to fairness, strategy, etc. It is hypothesized that players who are exposed to weighted or near-miss conditions will report greater active involvement, enjoyment, and control with an equivalent or greater perceived fairness than those rolling unweighted dice. These findings will illustrate how cognitive biases interact with game mechanics, providing insights into the perception of randomness and future guidance for game designers seeking to create engaging experiences.

Abstract Name: Assessing Self-efficacy, Mental Toughness, and Perceptions of Performance after Sport Injury

Prior research indicates sport injury impacts athletes physically and psychologically (Tamminen & Watson, 2022). However, those with higher mental toughness levels experience less pronounced consequences from sport injury (Levy et al., 2006). This study investigates how self-efficacy and mental toughness impact perceptions of performance after a sport injury. It is hypothesized that those with higher mental toughness levels will demonstrate higher self-efficacy during sport injury, thereby mitigating the adverse effects of injury on perceptions of performance. Data was collected from 49 student-athletes who had experienced at least one sport related injury at a small private university through an online survey assessing history of injuries, self-efficacy, mental toughness and perceived performance. Initial correlational analyses were performed. Surprisingly, the number of injuries and severity of injuries were unrelated to self-efficacy, mental toughness or perceived performance. To examine whether mental toughness is associated with self-efficacy, multiple regression analyses were performed. Consistent with the hypothesis, mental toughness was positively associated with self-efficacy ($F(4,45) = 30.31, p < .001$). Professional Thoughts ($t(49) = 2.80, p = .007$) and Psychological ($t(49) = 2.91, p = .006$) were the components of self-efficacy most related to mental toughness. Additional regression analyses found mental toughness was associated with athletes' perception of performance ($F(3,46) = 18.08, p < .001$). In these analyses, the following components of perception of performance were strongly associated to mental toughness: Guilt ($t(49) = 1.87, p = .069$), Shame ($t(49) = -2.70, p = .01$), and No Concern ($t(49) = 2.57, p = .013$). These analyses suggest that mental toughness is associated with self-efficacy as well as perceptions of performance. The results highlight a need for fostering mental toughness, specifically in times of recovery from injury. This could allow athletes to better maintain self-confidence and performance perceptions in the face of adversity.

Abstract Name: Effect of diet on functionality of anti-viral response in bats

Bats are unique among non-rodent mammals for their ability to host zoonotic viruses, such as influenza, Hendra, Nipah, SARS, MERS, and likely Ebola, without developing severe illness. Understanding how they achieve this homeostasis could reveal new insights into immune regulation and the factors that influence viral spillover to other species. Evidence from longitudinal studies conducted in Australia suggests that nutrition plays a role in controlling viral shedding by flying fox bats. In our studies, we found that Jamaican fruit bats fed diets supplemented with various compounds vary in their immune response and control of influenza A virus shedding. This project asks: How does the quality of bats' diet affect their control of anti-viral immune response and virus spread? Current research suggests that type I interferon (IFN-I) cytokines, proteins produced by cells as part of early anti-viral defense, play a central role in controlling viral shedding in bats. However, whether and how the IFN-I pathway is regulated in bats remains poorly understood. Here, we investigated how the IFN-I pathway induced in response to influenza virus infection is controlled in bats fed different diets. Specifically, we investigated whether inhibitory ISGs, specifically USP18 and SOCS1/3, increase in activity before the antiviral gene MX1 declines in expression. The existence of this trend would suggest that bats' immune system intentionally suppresses their anti-viral immune response to prevent overactivation while also suppressing viral expression. To test this hypothesis, gene expression was analyzed using quantitative PCR (qPCR) on rectal samples from bats collected under various experimental conditions. The project also examines whether diet influences immune regulation, potentially shaping patterns of viral shedding and environmental transmission. The expected results will provide evidence clarifying how bats fine-tune their antiviral responses. This research contributes to a broader understanding of bat immunology and offers insights into zoonotic disease spillover.

Abstract Name: Cross-Modality and Visual Impairment

When taking in sensory information, visual stimuli is often the most dominant within the hierarchy of senses. However, when visual input is unavailable, specifically in those who are visually impaired, evidence of cross-modal plasticity and reorganization is present. Cross-modal reorganization in visually impaired individuals has been linked to the rewiring of the occipital lobe and other visual cortical areas to further support the processing of tactile and auditory information in the brain. This has led to strengths reported in sound localization, spatial attention, sound categorization, and haptic imagery. However, these findings are also dependent on the time onset of visual impairment, as the presence of visual experience impacts the potential for cross-modal reorganization, exhibited through the differences noted between congenital and late-onset blindness. By examining existing research, we aim to clarify both the functional advantages and the constraints of cross-modal reorganization in individuals with visual impairment.

Abstract Name: Beyond Masses, Multitudes, and Interests: Escavating the Subjects of Contemporary Politics

This paper responds to the tactical and conceptual impasses faced during the student movements of May 2024. One such impasse was political disavowal—the gesture of declaring care for a cause in the register of “I would love to...” immediately undercut by “...but nevertheless.” Following Lisa Wedeen, this can be read as the mark of split attachments to order and change. Yet I suggest it may instead reflect a dissonance between organizers’ expectations of how politics ought to unfold and the unruly ways it actually does. The “expected” model assumes individuals, as members of groups, articulate interests and press them into social reality. Despite its seeming obviousness, this model is a contingent construction whose emergence is peculiar and whose persistence demands interrogation. To that end, the paper traces its genealogy, contemporary variants (from the World Social Forum to the World Bank), and the implications these hold for organizing today. It is at once a history of theorists and organizers, concepts and tactics, phantasmic movements and actually existing ones. Its critical grounding is in David Scott’s problem-space and Stuart Hall’s notion of conjuncture; its method draws from André Drainville’s *A History of Global Order and Resistance* and C.L.R. James’s *Notes on Dialectics*. By situating related fieldsites across four historical moments, the paper tracks organic transformations in the terms of order and change where “world ordering meets social forces.” Its merit lies not in adding any new concepts to the Left’s repertoire, but in recovering dormant ones and reanimating their relation to movements that have since lost them.

Abstract Name: An Evaluation of the Difference Between Déjà Vu and Déjà Rêvé in Comparison to the BFI Personality Test

Many people experience a phenomenon commonly known as “déjà vu,” where they feel they are experiencing something again, despite knowing it has never happened. Much of the research on this subject suggests this is likely due to a malfunction in memory recall. However, there is often a misunderstanding of what déjà vu is, as there are some people who experience a different phenomenon. This phenomenon is known as déjà rêvé and can be described as the distinct impression that you are experiencing something from a preceding dream in your waking life. Though there is not as much research on this phenomenon, there has been a large study that looks at the connection between personality type and ability to experience déjà rêvé. A similar study was conducted with déjà vu. However, they have competing results both suggesting people who are curious and open minded are more likely to experience one of these phenomena. The goal of this study is to see if a distinction can be made between the likely personality type of each phenomenon. A questionnaire was sent out to college students enrolled in psychology classes. There were 39 responses from these participants, 17 of which experienced déjà rêvé and 15 who experienced déjà vu, with some participants in both categories. Participants were asked if they had experienced either phenomenon and about the frequency of its occurrence. They were also given the BFI personality test and asked questions pertaining to their dreams. Preliminary results seem to show that there is unlikely any statistically significant correlation between the personality types, demonstrating no distinctive difference between a specific personality type for each phenomenon. However, there seems to be a significant negative correlations between ability to experience déjà vu and one’s ability to experience both dreams and déjà rêvé.

Abstract Name: Underbelly of a Beast: Joseph Leidy's Anthropodermic Bibliopeggy and Curious Donations to the Mütter Museum

This project explores how one of Philadelphia's most respected scientists also became linked to some of the most unusual and troubling objects in the history of American medicine. Joseph Leidy, who lived from 1823 to 1891, is well known for his major contributions to paleontology, anatomy, parasitology, and medical research. However, he also left behind a book that has been proven to be bound in human skin, as well as many questionable medical specimens that later became part of the Mütter Museum. These items raise important questions about how medical knowledge was created in the nineteenth century and how human remains were treated during that time. This study uses museum records, letters, and scientific information to understand how Leidy might have obtained or created these objects. It places his actions within the larger medical culture of the nineteenth century, when doctors often relied on human bodies for teaching and research, even when consent was unclear or completely absent. Practices that seemed ordinary to some scientists of the time now appear deeply unethical. Items that were once seen as scientific tools are now viewed as sensitive and sometimes disturbing artifacts. Museums like the Mütter must decide if and how to present them in a way that respects the people involved while still teaching the public about medical history. By studying Leidy's unusual donations, this work shows how museums carry the weight of past choices and how they can encourage more honest conversations about ethics, history, and the treatment of human remains. Moreover, this project aims to show how these findings deepen our understanding of the topic and point toward broader implications for future research and interpretation.

Abstract Name: Words & Warheads: Understanding Status vs. Security-Seeking Drivers of Chinese Nuclear Expansion

This paper examines why China is rapidly expanding and modernizing its nuclear arsenal and whether this growth is motivated more by external security threats or by a desire for international prestige and Great Power status. China's growing nuclear arsenal has been a persistent worry for many nations, especially the United States. The ambiguity surrounding the PRC's modernization efforts has led to a wide range of interpretations about its long-term strategic goals. Many scholars argue that security concerns drive China's nuclear developments, while others claim China is seeking to elevate its international status. This project contributes to that debate by systematically evaluating China's nuclear discourse across major government documents and speeches. Using both quantitative linguistic frequency analysis and qualitative discourse analysis, the study compares threat- and status-related terminology across PRC Defense White Papers (1995–2025) and key leadership speeches (1984–2025). The documents were categorized based on audience, domestic versus international, to assess whether rhetoric shifts depending on the target audience. This mixed-methods approach allows for capturing both broad linguistic trends and the contextual meaning behind China's nuclear language. The findings reveal an audience-based hybrid explanation: domestic-facing documents emphasize national prestige, while international communication places greater emphasis on deterrence and security. The data show that White Papers contain more status-driven language, whereas speeches directed at foreign audiences incorporate more threat and deterrence terminology. This suggests that the PRC simultaneously frames itself as a rising great power to domestic audiences and as a defensive,

stability-seeking actor to foreign observers. Understanding this audience-shifting rhetoric not only offers insight into the PRC's strategic behavior but also helps assess whether China's nuclear buildup is primarily reactive to U.S. actions or part of a broader effort to reshape the international system. These findings provide U.S. policymakers with a valuable tool for interpreting China's evolving nuclear intentions.

Abstract Name: On Page and On the Stage: Landscape in Shakespeare's *The Winter's Tale* at the 2025 Stratford Festival

This project examines the relationship between literature, place, and performance through the Stratford Festival's 2025 production of Shakespeare's *The Winter's Tale*. Beginning with a close analysis of the written play, it investigates how Shakespeare's contrasting landscapes—Sicilia's constricted court and Bohemia's expansive pastoral world—establish thematic tensions that later take shape in performance. The project then explores how these landscapes are interpreted onstage and how those interpretations are influenced by Stratford, Ontario's own cultural and geographic identity. As a town named for Shakespeare's birthplace, bordered by the Avon River and neighboring the village of Shakespeare, Stratford offers an environment uniquely attuned to themes of transformation, exile, and renewal at the heart of the play. Through analysis of directorial choices, set and costume design, and the spatial dynamics of the Tom Patterson Theatre, this research considers how the Festival reimagines Shakespeare's landscapes in performance. It also investigates how Stratford's physical environment influences the audience's experience of *The Winter's Tale*, creating resonances between the play's imagined worlds and the town in which they are staged. By tracing these connections, the project highlights how the Stratford Festival engages with and reshapes Shakespeare's settings, offering interpretations that speak meaningfully to contemporary audiences and illuminate the powerful role of place in both literature and performance.

Abstract Name: The Impacts of Funding Type on Telehealth Services Offered by School-Based Health Centers (SBHC)

School-Based Health Centers (SBHCs) have emerged as a health-promoting intervention by providing accessible primary and mental health care to address unmet health needs in school settings. Along with the growth in SBHC care, telehealth services have also increased after the COVID-19 era, ultimately furthering accessibility to care. Despite the evident growth in need for improved accessibility to care, few SBH programs offer developed and refined services via telehealth. SBHCs have a wide range of funding types including governmental, philanthropic, school system, and sponsor organization contributions. Funding type

may define operational flexibility, implementation capacity, and ultimately what services can be provided at specific SBHCs, such as telehealth provision. The purpose of the present study is to determine whether funding type impacts telehealth availability in SBHCs across South Carolina by analyzing needs assessment data. Data were collected utilizing an annual needs assessment developed by the Youth Access to Psychiatry Program. The survey was sent to School-Based Health (SBH) programs' administrators (N = 14) across South Carolina. Frequencies and counts assessed differences in telehealth availability across funding type and service type. Among 14 SBH programs, 3 reported having non-governmental funding while 8 had government funding. Of the government-funded programs, 100% provided services via telehealth, while 66.6% of programs who were not governmentally funded offered telehealth options. Results of the present study suggest that federal funding is not a barrier to telehealth service provision. Rather, a higher number of government-funded SBH programs had telehealth services in comparison to those with other funding types. By furthering an understanding of how funding type affects telehealth presence and quality, SBH program implementers can identify funding opportunities that have more potential in increasing sustainability and complexity of telehealth service provision.

Abstract Name: Assessing the Effects of Blast Traumatic Brain Injury on Olfactory Threshold Detection in Mice

Traumatic brain injury (TBI) is associated with numerous sensory and cognitive deficits, yet olfactory dysfunction remains one of its most overlooked consequences. Among individuals with moderate to severe TBI, approximately 15 to 30 percent develop post-traumatic olfactory dysfunction (PTOD), but the mechanisms responsible for this impairment remain poorly defined in preclinical models. PTOD is thought to arise from several pathways, including shearing of olfactory nerve fibers at the cribriform plate, disruption of olfactory bulb circuitry, and broader central nervous system damage. However, the relative contributions of these mechanisms, particularly following blast exposure, are not well understood. Because olfactory impairment is associated with TBI severity, odor detection measures may serve as a noninvasive indicator of blast-related neural injury and may provide a useful tool for identifying and monitoring TBI. The objective of this study is to examine how blast-related brain injury affects olfactory sensitivity in mice and seeks to establish a dependable paradigm for measuring olfactory thresholds using the KNOSYS olfactometer. C57BL/6 mice (N = 13; 9 females and 4 males) will be trained on an odor detection task using serial dilutions of ethyl acetate. Behavioral responses will be used to determine detection thresholds before and after exposure to a controlled blast. Following behavioral testing, brains will be collected for immunohistochemical analysis. Brains will then be analyzed for astrocyte and microglia coverage in the olfactory bulb, hippocampus, and cortex to evaluate TBI-related neuroinflammation. It is expected that blast-exposed mice will show reduced odor detection sensitivity accompanied by increased astrocyte and

microglial coverage, reflecting heightened neuroinflammation. By linking behavioral sensitivity with immunohistochemical markers, this study aims to evaluate olfactory threshold performance as a potential behavioral biomarker of TBI severity. These findings may deepen understanding of post-traumatic sensory dysfunction and support the development of translational tools for evaluating and diagnosing TBI-related olfactory deficits.

Abstract Name: Linking Human Development, Harmful Algal Blooms and Cyanotoxin Production in Lake Jesup, FL, USA over the last 150 years

The development of harmful algal blooms (HABs) in shallow lake ecosystems can cause dramatic decreases in ecosystem services such as anoxia, fish kills and the production of cyanotoxins. Whereas cyanotoxin production is generally linked to cyanobacteria abundance, the triggers of cyanotoxin production (nutrients, temperature, grazing, allelopathy) are still being determined. Here, we conducted a paleolimnological sediment core analysis to explore the onset and development of harmful cyanobacteria dominance and cyanotoxin production in Lake Jesup, FL, USA. Lake Jesup is a shallow (mean depth 1.2 m) and large (43.1 km²) lake with a history of harmful algal blooms and the cyanotoxin, cylindrospermopsin, located in central Florida. Lake Jesup has received excess nutrients from poor wastewater management and fertilizer runoff following the urbanization of central Florida during the 1960s. The primary objective of our project was to determine the temporal onset of cyanotoxin production in Lake Jesup and to identify the drivers of cyanotoxin production over the last 150 years. Our sediment core was dated using ²¹⁰Pb and each core section was analyzed for nutrients, cylindrospermopsin, and algal pigments. Results show that, while urbanization contributed to a cyanotoxin spike, cyanotoxin concentrations reached harmful levels prior to the development of Seminole County. Comparing cyanotoxin concentrations with nutrient data, algal pigments, and various elements suggest that a combination of biogeochemical and lake characteristics trigger cyanotoxin production through time. These findings will be useful for the identification of human activities that have decreased water quality through time and benefit future management of Lake Jesup and other lakes in central Florida with comparable water quality concerns.

Built in Mexico: The Evolution of Mexican Architecture and Its Worldwide Impact
Susana Burgos Meza
1000 University Center Lane, Lawrenceville, GA, 30043 Architecture, Mexico, History

ABSTRACT:

This research explores the evolution and diversity of Mexican architecture across three major periods: pre-Hispanic, colonial, and modern. It also examines the global influence these traditions continue to have today. From the astronomical precision of Mayan observatories to the artistic fusion of Spanish colonial cathedrals and the rise of modernist works by architects such as Luis Barragán, each era has shaped Mexico's architectural identity. Pre-Hispanic civilizations, including the Maya and the Mexica (Aztecs), were pioneers in archaeoastronomy. Their structures were built to track celestial events that helped regulate agriculture and timekeeping. Their engineering achievements, such as the Mexica's hydraulic systems and aqueducts, demonstrate advanced craftsmanship still admired today. With the arrival of the Spanish and the establishment of Nueva España (New Spain), cultural blending became unavoidable. The forced and violent integration combined European and Indigenous styles, producing monumental structures like the Parroquia de San Miguel Arcángel and the Metropolitan Cathedral of Mexico City. These buildings reflect both fusion and conflict between two worlds. In modern times, Mexico's architecture continues to draw from its past. Architects such as Luis Barragán merged European Modernism with traditional Mexican aesthetics, creating emotional and spiritual spaces that have influenced architects worldwide. Through this research, the author aims to honor her Mexican heritage by sharing the richness, complexity, and global significance of Mexican architecture. By presenting this research and its lasting influence, the study seeks to spark curiosity, foster appreciation, and encourage others to recognize the profound impact Mexico has had, and continues to have, on the world of architecture.

Abstract Name: The Prematurity of Counter Small Unmanned Aerial Systems Legal Frameworks

Small unmanned aircraft systems (sUAS) have reshaped the modern threat landscape, yet the United States continues to develop legal and policy solutions that move faster than the technology required to support them. Although Congress, federal agencies, and the Department of Defense have proposed a wide range of counter-UAS (cUAS) frameworks, each of these efforts depends on a level of detection capability that the United States has not yet achieved. This paper surveys the major legal proposals currently under consideration, including the 2024 FAA Reauthorization Act's approach to low-altitude airspace, expanded federal mitigation authorities, and emerging state and local regulatory efforts. While these frameworks attempt to reduce risk and close jurisdictional gaps, they remain incomplete because none can function without consistent and accurate detection of sUAS activity. The analysis demonstrates that detection is the obstacle that shapes every other part of the cUAS mission. Existing sensors struggle to identify drones with enough accuracy to distinguish them from environmental noise or civilian objects. These shortcomings also create legal barriers, since unreliable detection data cannot meet constitutional or statutory evidentiary standards. As a result, policymakers lack the information they need to determine what authorities are necessary or how those authorities can be applied in a way that protects both national security and civil liberties. This paper concludes that meaningful cUAS governance is not possible until the United States first establishes reliable detection capabilities. Once detection is dependable, lawmakers can build legal processes that are enforceable and proportionate. In effect, detection is the foundation that determines whether any legal or policy framework can succeed.

Abstract Name: Rheological Effects of Microplastics on Biological Tissues

Microplastic contamination is becoming an increasingly important issue, but there is still little known about how they affect the mechanical properties of tissues. Blood, in particular, relies heavily on its rheological behavior to flow properly and deliver oxygen efficiently, so any disruption to its viscosity could have significant biological impacts. In this project, we measured how polyethylene terephthalate (PET) microplastics altered the viscoelasticity of biological tissues using rheological methods on the MCR 92 Anton Paar rheometer. Rheology provides a way to measure how biological materials respond to stress and strain, giving insight into how microplastics might physically interfere with the structure and function of soft tissues. Using controlled PET concentrations, we measured shifts in tissue mechanics such as viscosity under multiple types of stress. Across all samples, changes in viscosity indicated an interaction between microplastic presence and the microstructure of blood and cecum. These results show that microplastic contamination can be detected through quantifiable shifts in viscoelastic properties. For future endeavors, microscopic cell structure will be investigated before and after testing as well as in-vivo testing being used in hopes to measure a physiological effect of microplastics when introduced in a more dynamic system. This field is still vastly under-researched and the results of this project will be beneficial to future bio-materials research and microplastic research alike.

Discipline: Dance

Authors:

Abstract Name: Strangers

Strangers is a contemporary dance piece set to Celeste's "Strange," exploring the quiet ache of emotional distance that grows between two people once deeply connected. The work reflects on shared memories, honoring past closeness and beauty while finding the strength to accept, release, and move forward from what can no longer remain. The choreography builds upon Celeste's soulful, aching vocals to bring the story to life, using grounded movement and expressive gestures to communicate both longing and clarity. The piece incorporates soloist sections, duets, and full ensemble choreography to show how these emotions shift between the intimate and the universal. Group patterns form briefly and dissolve again, symbolizing the movement between confronting the present pain and drifting into the warmth of remembered moments. The first duet embodies the positive memories, times of deep connection, harmony, and comfort. In contrast, the second duet represents the harder, fractured moments that reveal the instability of the relationship. Together, they reflect the flow of grief, from denial to recognition. A break in the music marks a break in the story. The soloist that emerges symbolizes the internal process of piecing together memories, breaking through delusion, and reaching acceptance. By the end of the piece, two dancers cross paths without acknowledgment, as if they have never met. This moment signifies the completion of grief: the understanding that although the relationship has ended, both individuals continue forward, now as strangers. Overall, Strangers captures the pain, nostalgia, and bittersweet clarity of letting go. The performance offers a poignant portrait of separation not just its sorrow, but the strange familiarity of learning to move on.

Abstract Name: Harmful Algae Bloom (HABs) Dynamics in Mixing Zones of Lake Superior

Phytoplankton, commonly referred to as algae, are found in water and create the base of the food web in aquatic ecosystems. When an ecosystem becomes unbalanced from excessive nutrient inputs, phytoplankton can grow too much, resulting in an algal bloom. One species of phytoplankton, cyanobacteria (also known as blue-green algae), can produce and release harmful toxins into the water and concentrate into scum called a harmful algae bloom (HAB). This research was conducted to identify spatial and temporal patterns in phytoplankton species in the St. Louis River Estuary and southern shore of Lake Superior, with an emphasis on cyanobacteria. The results of this work help us understand the phenology of phytoplankton and what causes shifts in distribution and abundance. This project worked in collaboration with the United States Geological Survey (USGS) to analyze cyanobacteria peaks in mixing zones of Lake Superior, and to incorporate technology and develop an algorithm for the remote detection and automatic sampling of HABs. Preliminary results of this study show brown algae species (diatoms) as the most abundant species at all locations over the sampling season, but algae community composition varies considerably among sampling locations. When present, peaks in cyanobacteria species were found at one sampling location at a time and their occurrence often lasted one day. This demonstrates that seasonal influences do play a part in algae communities through variation of environmental factors.

Abstract Name: Synthesis of Human Cytomegalovirus Replication Inhibitors

With the high rates of infection of Human Cytomegalovirus (HCMV), specifically in transplant recipients, congenitally infected infants, and immunocompromised individuals, there is a great need for new treatment options. The effects of HCMV can be severe, causing organ rejection, intellectual disabilities, and vision and hearing loss. The contribution of our work conducted at the Medical College of Wisconsin and UWM is to synthesize new molecules that can then undergo further study to test for inhibition of HCMV. Specific molecules are targeted by taking the parent molecule, MLS000108969, and modifying parts of the structure. The molecules have then been analyzed to determine how the alteration in the structure of MLS000108969 changes its ability to inhibit HCMV replication to establish a structure-activity relationship. The synthesis of potential HCMV inhibitors requires methodically combining reactants to form the desired product. The impurity of this product is then removed using techniques such as column chromatography. After purification, the product can be analyzed using nuclear magnetic resonance (NMR) and mass spectrometry (MS). These methods are used to confirm the structure of the desired product and unknown compounds present in the sample. Following confirmation of identity, compounds are then sent to MCW to be tested against HCMV-infected Human Foreskin Fibroblast (HFF) cells to determine efficacy. It is anticipated that one of these compounds will be able to be used as a new treatment option for individuals affected by HCMV. All in all, while in normal and healthy adults HCMV infection is usually asymptomatic, certain populations as described before are vulnerable. The goal is to improve these individuals' outcomes and quality of life.

Abstract Name: Abortion Funds: An Unexplored Keystone of the Reproductive Justice Movement

Abortion funds, which have provided financial support to abortion seekers since the 1960s, have long been imperative to the accessibility of safe abortions. In the 1973 Supreme Court case, *Roe v. Wade*, the court ruled that abortion was protected by an individual's right to privacy. *Roe* lifted a significant legal barrier for abortion-seekers, but legality does not ensure accessibility. Financial and practical hurdles persisted, and these hurdles were exacerbated by laws that chipped away at the protections *Roe* provided. For example, the 1977 Hyde Amendment bans the use of federal funds (including Medicaid) to pay for abortions. Over the next several decades, abortion costs skyrocketed and barriers to access increased tremendously. There is extensive scholarship about the importance of abortion access within the Reproductive Justice movement. However, there is minimal literature (no book-length study) about abortion funds and how they promote accessibility in response to the skyrocketing costs of abortion (many of which arose as a result of increased legislative barriers in the decades after *Roe*). To understand how funds impact abortion accessibility, I am conducting archival research at Duke University and reviewing social media posts and newsletters from abortion funds, as well as local and national print periodicals. I am also gathering oral histories from employees of various funds to gain a realistic understanding of how they operate. I expect this project to deepen our understanding of the ways abortion funds have been crucial to maintaining access in the US. Pregnant people turn to funds when they have decided that termination is the right choice for them but they cannot afford to make that choice. By providing financial and practical support, abortion funds have provided access to life-altering and even life-saving healthcare for thousands of people.

Abstract Name: Isolation and Characterization of Anaerobic Microbes from Queen's Laundry

Thermal springs are believed to mimic the environment on early Earth when evolution of the earliest life forms was underway. Queen's Laundry is an alkali-silica spring and possesses significant microbial activity. Distinctive biomat sample were collected and served as inoculum to determine the metabolic capabilities of each biomat. These samples were then sequenced, revealing that a new species of bacteria was present in one of the samples. Phylogenetic mapping indicates that the organism is most similar to the *Anaerovirgula* and *Natronincola* genera. Attempts to recover this organism are ongoing with multiple enrichments established. DNA extraction will be performed to isolate DNA from each sample, followed by PCR using primers matching a unique segment of the species' DNA. Gel electrophoresis will then be used to separate the DNA segments with the goal of locating the species in one of the samples. Once the organism has been located, anaerobic roll tubes will be used to culture the bacteria within the sample(s). Unique colonies will then be

isolated until a pure culture of the new species has been obtained. A pure culture will be confirmed by DNA sequencing. Standard characterization tests will determine the growth requirements and characteristics of the species. The current scope of the study focuses on isolating and characterizing the organism of interest. We endeavor to isolate the organism using anaerobic cultivation techniques in order to determine its growth requirements, a process that will both reveal the nature of the organism and the biomat, or group of mutualistic bacteria, that it originates from. Understanding the biochemical characteristics of the isolate will provide insight into the community dynamics within the hot spring and potentially Earth's first species. The expected result is a profile of the new species of bacteria and an analysis of its ecological niche within the Queen's Laundry ecosystem.

Abstract Name: Ernest Charles Jones and the Fate of Children and the Helpless in Unregulated Capitalism

Ernest Jones' "The Factory Town" remains a seminal piece of workers' advocacy in the period of Victorian hyper-industrialism. His depictions of the crampedness, the aching noise, the quivering toil of bodies in industrial environments are by-in-large bone chilling; to relegate this suffering to children is a horror without words, and a crime unparalleled in its detachment from reality. Jones posits that it isn't just that these working conditions delay, dampen, or stunt a child's physical and intellectual growth, but it is a system that calls for the elimination of childhood altogether, in exchange for a fresh, capable body to be added to the pile. By milling away a child's natural inclinations toward discovery and learning, the consequences of this stunting supersede trauma, toward something of an emotional hollowing, in many ways an incurable, hereditary disease. We can get a further sense of the peril and subsequent activism of Jones' period by joining it with that of Charles Dickens' *Bleak House*. The novel, whether in its deprecation of bureaucracy or deification of orphanhood, calls into question both the quality of life of working class Londoners as well as the mechanisms slowing down the rate of social progress. In conversation, these texts illuminate the crumbling of human dignity in the midst of "modernity"-- the promise of philosophical-political movements centered around notions of individual liberty, reason, and truth. In his almost sermonic poetical voice, Jones describes not just the quality of suffering for industrial workers, but why there is a systemic hold on the spirits of the people that prevent them from rising up for the sake of children. His mission-- as a force in the working-class Chartist movement-- is to emphasize a consideration of the less fortunate, and that reform can only be achieved with the conscious effort of the many.

Abstract Name: Simulation-Based Reinforcement Learning for Autonomous Rocket Landing Control

This project explores the integration of simulated reinforcement learning (RL) and mechatronic design to achieve complex physical tasks. Specifically, the team aims to perform an autonomous landing of a rocket-like device, inspired by the SpaceX Falcon 9 booster landings. The RL agent is first trained within a physics-based simulation environment using a subset of RL called Proximal Policy Optimization (PPO), allowing the agent to learn how to stabilize and execute a controlled descent by managing four motors and four aerodynamic fins. The trained agent is then deployed to a custom-built rocket prototype designed to emulate the dynamics of a rocket using brushless motors and onboard sensors. By bridging simulation-based learning with real-world implementation, this project evaluates the effectiveness of RL for autonomous control compared to traditional methods. In the current state of this project, the researchers observed a ~32% successful landing rate with another 35% in “soft impact” failed attempts over 350,000+ simulations. We plan to improve these numbers throughout the year by moving to a different simulation method that will allow us to have more processing power available to go towards larger training sets at a quicker rate. The team also plans to refine our physical design to improve stability and efficiency. These results contribute to the growing field of autonomy in aerospace and robotics, highlighting both the potential benefits and the challenges of applying reinforcement learning to complex dynamic systems.

Abstract Name: Effects of Internal and External Verbal Attention cues on Concentric Barbell Velocity in the Bench Press

This research examines how focused verbal cueing can affect barbell velocity in the bench press. Verbal cues are employed by coaches to focus the athlete's attention in workouts; changing the cueing word slightly from internal to external focus may change an athlete's performance due to attentional-focus theoretical frameworks. This research study compares barbell velocity using internal cues (which direct attention to movements of the body) and external cues (which direct attention to the result or effect of body movements) while utilizing the attentional-focus framework. A randomized within-subject repeated measures crossover design will be utilized with resistance-trained adults (ages: 18-30) attending William Peace University. Participants will perform each cueing test condition in a counterbalanced order after completing a separate familiarization and one-repetition maximum (1-RM) session. During testing participants will complete two sets of three repetitions at 70 percent of their respective 1-RM for each cue type (internal and external). An internal cue would be "Drive through your chest and push elbows to lockout fast" and an example of an external cue would be "Punch the bar explosively toward the ceiling" cited verbatim (as scripted). Mean concentric and peak concentric barbell velocity will be measured using a GymAware FLEX device, with rep-to-rep variability and RPE deemed secondary outcomes. All variables in testing (grip width (1.5× biacromial distance), lifting cadence, and pre-testing routine) will be pre-standardized to control external variables. At this stage, it is anticipated that external cuing will produce faster barbell velocities, along with reduced rep-to-rep variability, in comparison to internal cuing. Overall findings in the study will clarify the understanding of how cue phrasing may impact an individual's movement efficiency and performance. The findings will translate into practical applications for strength and conditioning professionals to enhance the ability to verbalize instruction and increase athletes' overall power output.

Abstract Name: The U.S. Campaign Finance System and Youth Underrepresentation

This research investigates why young people remain underrepresented in elected U.S. offices and why youth voter turnout has historically remained low. Motivated by persistent shortcomings in U.S. youth turnout, the dominance of older elected officials, and recent high-profile victories by young mayoral candidates, this study asks whether young candidates (<40) increase youth voter turnout in U.S. elections—and, if so, whether structural factors prevent these candidates from winning. Existing literature on descriptive representation and electoral inequality suggests that young candidates may energize youth voters yet face systemic disadvantages that hinder their success. This research contributes to the literature by exploring how the U.S. campaign finance system shapes young candidates' electoral viability. Using a qualitative comparative case study design, we analyzed four large U.S. mayoral elections: two with victorious young candidates (Boston 2021; New York City 2025) and two where no candidate under 40 appeared on recent ballots (Los Angeles and Columbus). For each city, candidate eligibility rules, ballot requirements, party bylaws, primary election methods, and campaign finance laws were examined using publicly available legal and institutional documents. This approach allowed us to identify structural barriers while remaining open to unanticipated patterns across cases. Our findings reveal no explicit legal or party rules that impede young candidates. Instead, obstacles lie implicitly in the U.S. campaign finance system's lack of limits on contributions, candidate spending, and the normalization of high-cost campaigning. These conditions allow older candidates—who are more likely to possess greater financial resources—to outcompete younger challengers, limiting youth descriptive representation and alienating youth from electoral politics. We conclude that youth underrepresentation is sustained less by overt legal barriers than by embedded systemic inequalities in campaign finance, an issue with broader implications for electoral integrity, representative democracy, and youth voter turnout in the United States.

Abstract Name: Monster Grrrls: Visualizing the Monstrous-Feminine and Abjected Bodies Using Zinemaking

Femininity, long associated with "otherness," has been critically examined for decades. Barbara Creed, for example, described how the feminine is cast as abject, monstrous, or in need of suppression. Such ideas originate in the ways people societally defined as women are represented in film, literature, and other media. Therein, a cultural tendency to divide bodies into human, nonhuman, desired, and rejected parts has been shown. In *Monster Grrrls*, I use collage to explore these themes, presenting each collage as a separate page within a "zine." Zines, a term derived from "magazine," are handmade, self-published books that share art or information and often give voice to marginalized communities. Originating in the 1930s science-fiction scene, zines regained popularity through third-wave feminism and the Riot Grrrl movement. Publications like *GUNK*, *Girl Germs*, and *Candy Ass* became prominent in the 1990s. These zines acted as a medium to discuss the patriarchy, female objectification, or sexual abuse. The monstrous-feminine, comparatively, highlights the realities of the underrepresented. With the creation of a zine as a physical "body" for my work, viewers are enabled to engage with my art through touch. Literature and dialogue possess both function and vitality, similar to the human body. My collages draw inspiration from artists who explore the idea of female bodies, such as Rosa Verloop, Jessica Ledwich, and Alexandra Montclair, as well as from my personal experiences. The work of female "art monsters" and the concept of the monstrous-feminine empowers me to express my identity and experiences through art, even in a culture where censorship is normalized and those marked as "other" are deemed obscene. Art can transcribe our bodies, the abject, and force us to confront

what we reject. Through artmaking, I carve space for myself and am heard in a world that has labeled my existence "monstrous."

Abstract Name: Affordable Screw Based Modular Sports Prosthesis

Individuals with forearm disabilities often face barriers and limitations that prevent them from participating in common recreational and fitness activities, including but not limited to weightlifting and ball games. Existing prosthetic devices are often niche, expensive, unadaptable, or unavailable for a common population. This leads those with no connection to a possible manufacturer or those below the poverty line to have little success in finding and producing a prosthetic device for their situation and preference. Our research looks to introduce a modular forearm prosthesis designed to serve numerous functions through interchangeable wrist mounted attachments. The base of the design is a forearm mount with a secure screw mechanism on top, that allows users to attach and remove modular components with ease. This mechanism ensures that the attachment is firm and does not buckle under dynamic forces. A few prototype attachments include a curved bench-press hook that can encase a bar and dumbbells, and a scoop-shaped attachment optimized for tossing and receiving balls. Our design aims to reduce costs, increase accessibility, and give users freedom and adaptability over their equipment choice. Ultimately, the project addresses physical barriers faced by individuals with forearm differences, promoting participation and engagement in activity while offering a practical and low-cost solution for those facing these disabilities.

Abstract Name: The Future and Health of Coral Reef Species located along the Florida Keys Reef Tract

According to Zeng, K., et al. 2025, the coral reefs world-wide are predicted to experience major losses over the next few decades. The study indicates that one of the major influences leading to these losses includes the increased stress from climate change. The increased stress from climate change has led to warmer ocean temperatures and an increase in ocean acidification. An increase in human activities including the overfishing of the reefs and ecotourism has also contributed to reef stress. Other parameters that impact coral performance include the physiochemical conditions of changes in pH, salinity, and sedimentation. An increase in algae that is not part of the normal coral endosymbionts also has an effect on healthy coral. The purpose of this study is to combine historical geological and climate data, coral fossil records from the Florida Keys along with current coral studies being investigated by the Mote Laboratory to make a prediction on the future success of the growth and health of the Florida Keys Reef Tract. Five, 10 meter transects were

used to study and record fossil assemblages found at the Windley Key Fossil Reef Geological State Park. Data was gathered on all identifiable coral found both crossing and below the transect lines to the genus level including *Montastraea*, *Diploria*, *Colpophyllia*, *Porites*, *Acropora*, and *Orbicella*. Data was also recorded on Mollusk, Bryozoan, and Echinoid fossils but not to the level of genus or species. Observational reef data was collected while snorkeling at Cheeca Rocks, Bahia Honda State Park, and Key West. Information on current reef restoration was observed as well as participation in reef microfragmentation practices at Mote Marine Lab in Summerland Key. All experiences were combined to make a prediction about the future and health of both current and future reef species located along the Florida Keys Reef Tract.

Abstract Name: Feasibility and Acceptability of Brief Behavioral Treatment for Insomnia Via Telephone in People Living with HIV and Chronic Pain and Insomnia

People living with HIV (PLWH) experience high rates of insomnia and chronic pain. Insomnia strongly predicts pain outcomes; targeting insomnia in PWH is important and outcomes and targeting it may yield downstream benefits to pain outcomes. Traditional non-pharmaceutical insomnia interventions like Cognitive Behavioral Therapy for Insomnia (CBT-I) often have high barriers to access, especially for patients with high medical burden. Brief Behavioral Treatment for Insomnia (BBTI) via telephone may be a feasible alternative. BBTI utilizes behavioral strategies like stimulus control and sleep restriction to improve sleep outcomes. This pilot study is evaluating the feasibility and acceptability of BBTI among PLWH experiencing insomnia and chronic pain. Thirteen adults have been recruited from a community-care HIV clinic and randomized to BBTI or a control group receiving mindfulness. Feasibility and acceptability is assessed by closely tracking participant matriculation and attrition. Additionally, participants will complete a feasibility and acceptability questionnaire collecting quantitative and qualitative data. One hundred percent of completed participants report “strongly agree” to being satisfied with the interventions and that participation was easy, convenient, and helpful. Among BBTI completers, 100% agree or strongly agree that the intervention improved their sleep, pain, and overall quality of life. Of the 13 recruited participants, only 2 participants did not complete all sessions of the intervention and were lost to follow-up after the first intervention. The non-completers were randomized to both BBTI and mindfulness groups equally. One participant requested to drop out of follow-up following the final intervention due to an unrelated medical emergency. These results provide support that a brief, behaviorally focused sleep intervention may be feasible and beneficial for PLWH experiencing chronic pain and insomnia. Participants report strong feasibility, satisfaction, and benefits with both interventions which highlights the benefit and importance of non-pharmacological interventions focused on improving quality of life and symptom management.

Abstract Name: Industry-Specific Effects of Job Lock

The notion of job lock refers primarily to the phenomenon in which an individual forgoes the opportunity for more productive employment due to the high opportunity cost of losing their current job, which offers some non-wage benefit that may be difficult to obtain elsewhere. In the United States, health insurance is a common fringe benefit provided by employers to employees. Previous studies examining whether job lock is prevalent in the United States have yielded varying results, but few, if any, question whether the phenomenon may have heterogeneous effects across industries; in other words, industry-specific factors may influence labor market mobility among individuals who receive health insurance benefits from their employer. In this paper, I will introduce a new model for understanding the role of job amenities in producing job lock. Then, using data from the Current Population Survey's Annual Social and Economic Supplement (CPS ASEC) and the Survey of Income and Program Participation (SIPP), I will assess the impacts of job lock following the natural experiment of the Affordable Care Act's Medicaid Expansion, which extended Medicaid access to those with incomes within 138 percent of the Federal Poverty Level in 25 states on January 1st, 2014. Using triple and quadruple differences regressions, I will determine the effects of the expanded Medicaid policy on job mobility for people within the eligible income bracket who were obtaining health insurance from their employer prior to the enactment of the policy. Furthermore, I will separate individuals by occupation to test the hypothesis that those in occupations with fewer amenities experience job lock at higher rates than those in more amenable occupations, and therefore should show higher levels of mobility due to the Medicaid Expansion's augmentation of non-employer sponsored health insurance options.

Corinne Schob

Abstract Name: Qing & Nazca Pottery

Storrie: The surface paintings are specifically why I was drawn to the Qing dynasty for my recreation. The paintings on the pieces were so interesting and truly show such a range of images and symbolism. Some common things portrayed were dragons and phoenixes, representing imperial power. Landscapes and flowers such as peonies were commonly painted symbolising prosperity and feminine power. Then there were also human figures painted as well. Guanyin, a Buddhist goddess, is depicted on many different ceramics from this dynasty. When creating my piece, I have incorporated elements from three images. I adore the painting style of the white porcelain with the birds and flowers, especially knowing the significance of the images now. I have also used the structurally sound form of the dragon piece to ensure my piece will stand strong and hold its space well. Corinne: I decided to base my 12 inch vessel after the Nazca pottery style featuring literal imagery in a cartoonish approach while utilizing earth toned underglaze for a painterly effect typically with wide and flat walls in order to properly display the image. The Nazca people were a mainly nomadic group that took much creative inspiration from the Paracas who utilized complex tiles as well as similarly styled and decorated ceramic pieces. They typically lived on the southern coasts of Peru in river valleys of the Rio Grande de Nazca and Ica Valley though they did live a nomadic lifestyle giving us the Nazca or Inca lines they made, by stomping in uniform lines in order to make large shapes seen from a birds eye view, while they travelled. Overall, they are very creative people.

Abstract Name: Exploring Optimization Strategies As Stochastic Processes: A Case Study on a Block Game Using Genetic Algorithms and Stochastic Gradient Descent

This paper investigates the behavior of optimization algorithms under uncertainty by modeling them as stochastic processes. Specifically, we examine Genetic Algorithms (GAs) and Stochastic Gradient Descent (SGD). Initially, GAs are conceptualized as discrete-time Markov chains, where each population of candidate optimization parameters (strategies) constitutes a state. The transition from one generation to the next is governed solely by the current population and the application of genetic operators like selection, crossover, and mutation, without dependence on prior generations. This memoryless property aligns with the Markovian assumption and enables a probabilistic analysis of GA dynamics. Subsequently, we extend the Markovian framework to analyze SGD, a widely used optimization method in machine learning. Despite its foundation in calculus-based optimization, SGD shares the Markov property with the GAs, as its updates depend only on the current parameter values and the stochastic gradient estimate. Furthermore, we explore the stochastic nature of SGD by modeling its noise component as Brownian motion in the continuous case, and as discrete approximations to Stochastic Differential Equations (SDEs) in practical implementations. This dual perspective allows for a richer understanding of SGD's convergence behavior and its capacity to escape local minima. To ground these theoretical insights, we conduct numerical experiments using a simplified block game as a toy problem. In this setting, both GAs and SGD are employed to search for the optimal playing parameters aimed at maximizing the game score. The experimental results are analyzed to assess the degree to which each algorithm adheres to its theoretical stochastic model, and to compare their relative performance in navigating uncertain environments. The paper concludes with a discussion of the implications of these findings and proposes directions for future research, including the exploration of more complex games with varying constraints to further test the robustness and adaptability of these optimization strategies.

Abstract Name: Understanding the Dialectics of AI Integration among Business Executives

AI is now in every industry with its use proliferating daily in organizations. The purpose of this project is to use Baxter and Montgomery's (1996) relational dialectics to investigate the AI-related dialectical tensions experienced among executives across multiple industries as these executives navigate implementation of AI into their organizations. Relational dialectics has been used extensively as a framework including for examining end of life communication (Amati & Hannawa, 2013), African American entrepreneurial experiences (Anderson, Sims, Shuff, Neese, & Sims, 2015), and inter-professional relationships (Mikkola, Peltola, & Apker, 2025). While these investigations are within professional and business contexts, no research has yet probed relational dialectics through an examination of AI within the experiences of executives. Through 24 personal interviews with executives and comparative analysis, the research methods yield themes that contribute to the body of progressive technological AI research. The themes gleaned from preliminary research findings reveal key tensions negotiated in the areas of AI's impact on jobs, AI's optimization of workflow processes, and AI educational gaps. Preliminary research results can help business executives avoid the detrimental effects of being AI stragglers, improve their AI implementation, and enhance AI decision-making processes through cross-sectional perspectives. This ongoing research provides insightful information for business professionals looking to advance their AI endeavors.

Abstract Name: Simultaneous Approximation for Cryptography

Cryptography protects digital information by relying on mathematical problems that are difficult to solve. Many modern cryptographic schemes use lattices, geometric structures whose underlying problems are believed to be secure against classical and quantum computers. However, practical lattice-based schemes often require very large public keys, creating challenges for efficiency. Recent theoretical work suggests that a special class of lattices called simultaneous approximation lattices may offer a path toward reducing key sizes without sacrificing security. These lattices are compactly described by a single vector and one additional parameter and are proven to be as secure as general lattices. Our project explores how these objects can be implemented and used in real cryptographic schemes. This talk will outline the background of the project as well as projected paths forward.

Abstract Name: The Invisible Patients: Visual and Textual Representation of Human Diversity in Anatomy and Physiology Textbooks

This study seeks to identify how representation of the human body in the healthcare curriculum may impact students' understanding and perceptions of what constitutes a healthy, typical body. With many different textbook sources and AI resources available, undergraduates can study through a variety of methods with varying quality of representation. Focusing on the reproductive and integument systems, this study analyzes popular anatomy and physiology textbooks to assess the visual and textual coverage of normal anatomical variation by gender, race, age, and other physical characteristics. The textbook analysis quantifies: 1) the number and types of images and words representing diverse demographics, 2) compares coverage of male versus female reproductive anatomy and physiology, and 3) the total coverage of light skin tones and darker skin tones in integument chapters. Google Notebook LM was used in addition to self-analysis for comparison of word quantity. Findings reveal in the reproductive chapters a pronounced bias toward coverage of young, white, western-stylized individuals, often male, and frequently reflecting trends such as depilation and circumcision. The analysis of the integument chapters shows a substantial imbalance: images of light-skinned individuals outnumber those of dark-skinned individuals by roughly 9:1, meaning that fewer than 10% of visual examples depict darker skin tones. These conclusions identified problematic coverage, and this study

can advocate for improvements with both educators and publishers. Such representational gaps and biases risk narrowing undergraduates' understanding of human diversity and may affect the quality of care they provide to a broad patient population as future healthcare professionals. The goal is to help broaden the understanding of anatomy and physiology of undergraduates and enable them to become more informed and inclusive health care professionals who can provide care to all individuals.

Abstract Name: PURE-STEM: Expanding Research Pathways for Community College STEM Majors

The Preparation for Undergraduate Research Experiences in STEM (PURE-STEM) program is a pilot initiative designed to broaden access to STEM research opportunities for low-income, and first-generation students at Los Angeles Valley College (LAVC), a Hispanic-Serving Institution (HSI). Building on the success of the NSF-funded PaCES program, PURE-STEM addresses barriers that prevent community college students from participating in research experiences, which are critical for persistence and transfer in STEM disciplines. PURE-STEM leverages partnerships with R1 institutions to provide funded internships and scaffolded programming that introduces students to research culture, soft skills, and STEM identity development. Over three years, the program will engage Biology majors through a structured learning community, academic coaching, and exposure to diverse research environments. Key objectives include: (1) increasing the number of students with research experience; (2) boosting confidence and preparedness for Research Experiences for Undergraduates (REUs); (3) improving STEM transfer rates; and (4) fostering graduate school aspirations. The program employs evidence-based strategies such as mentorship, resume workshops, and symposia, complemented by immersive experiences in partnered research labs. Success will be assessed through mixed-methods evaluation, including pre/post surveys and qualitative focus groups, generating data to inform best practices for supporting marginalized students in STEM. Broader impacts include creating a replicable model for other two-year institutions, expanding internship pathways, and strengthening networks between academia and industry. By increasing opportunities in STEM and cultivating future scientists at the community college level, PURE-STEM contributes to a more experienced scientific workforce that enriches the innovative ecosystem.

Abstract Name: Broader Autism Phenotype Traits and Alcohol Motivations in College Students

The Broader Autism Phenotype (BAP) consists of subclinical, autistic-like traits in individuals who do not meet the diagnostic criteria for autism (Bolton et al., 1994). BAP comprises three traits: aloofness, rigidity, and pragmatic language difficulties. Individuals with elevated BAP traits often experience challenges in social communication, adaptability, and emotion regulation, affecting relationship quality and social connectedness. Such difficulties may be particularly relevant during college, where social integration is

crucial for well-being and alcohol may serve as a social lubricant or maladaptive coping mechanism. The present study examines how BAP traits relate to alcohol use patterns in a cross-sectional survey of 618 college students (76% female; Mage = 19.4). Guided by the Incentive Motivational Model of substance use (Cooper et al., 2016), we hypothesized that higher aloofness and rigidity would be associated with greater coping motives, while pragmatic language difficulties would relate to social or conformity motives. Our hypotheses were partially supported. Higher rigidity was associated with drinking to cope with anxiety ($r = 0.093$, $p = .03$) and depression ($r = 0.10$, $p = .02$), supporting our prediction that people with more rigid personalities are motivated to drink by psychological distress. Similarly, higher pragmatic language challenges were associated with drinking to cope with anxiety ($r = 0.116$, $p = .007$) and depression ($r = 0.153$, $p < .001$). Though we expected pragmatic language difficulties to be linked to conformity and social motivations, results suggest that individuals drink to cope with distress from communication difficulties in social settings. In contrast, higher aloofness was negatively associated with drinking for enhancement ($r = -0.138$, $p = .001$) and social reasons ($r = -0.133$, $p = .002$), suggesting that aloof individuals avoid social drinking settings. Our findings indicate that BAP traits associate with distinct drinking motivations, highlighting the importance of considering individual differences when examining substance use in college populations.

Abstract Name: An Equine-Assisted Environment Supporting Developmental, Sensory, and Emotional Well-Being in Neurodivergent and Special-Needs Children (Ages 8–15)

The project is grounded in research demonstrating that equine-assisted interventions can improve emotional regulation, communication, and sensory processing for neurodivergent children. However, most existing facilities are not designed to support these therapeutic needs. In addition to this research, an in-person interview with a parent of a child on the spectrum provided further insight into real-world sensory challenges, therapeutic barriers, and user priorities. Many studies indicate that structured interaction with horses can promote emotional stability, confidence, communication, and self-regulation, providing a supportive alternative to therapeutic settings. This project addresses that gap by proposing a neuro-inclusive, evidence-based facility that creates an approach to emotional safety, supports sensory regulation, and strengthens the overall therapeutic experience for children ages 8–15. This project translates these findings into spatial form through a carefully curated environment that promotes predictability, safety, and adaptive engagement. The design addresses the gap between social, emotional, and physical challenges faced by these users through evidence-based strategies that integrate equine therapy, sensory regulation, and environmental psychology. Through design, each space is shaped to reduce sensory barriers and support individualized comfort. The facility is designed to support ongoing growth, strength, and resilience, expressed through symbolic and functional upward movement. The design incorporates sustainable and wellness principles, emphasizing healthy air quality, lighting strategies, opportunities for movement, responsible material choices, and benefits for mental well-being. Key design features include sensory-friendly color schemes, acoustically supportive materials, biophilic elements, and flexible spatial layouts that accommodate a range of sensory needs. Spaces such as the therapy arena, observation lounges, sensory rooms, and reading zones provide varied ways to participate, observe, or engage hands-on. Wayfinding, privacy features, and controlled environmental conditions further enhance emotional safety and spatial understanding. These design strategies create a therapeutic environment where research-driven interiors support neurodivergent children by encouraging connection, empowerment, and meaningful growth.

Abstract Name: The Art of International Fashion

This research consists of exploring different aspects of fashion and cultures across the world through the ages. Divided into three themes “Ancestry, Timeless Eras, and Modern Day.” Ancestry showcases the origins, the roots of our identity. A period of time when fashion started to develop across the world’s differences and deep cultural heritage. Timeless Eras showcases where cultures started to get more refined. Reflecting elegance, structure, and social status. Creating a balance of sophistication and cultural identity. Modern Day showcases the celebration of individuality, creativity, and broad access to global influence. Blending aesthetics from the early 2000’s, combining bold colors, metallic fabrics, and eye-catching accessories like chunky sneakers, crop tops, low-rise jeans, and mini handbags. Along with today’s minimalistic layering, innovative materials that give it a contemporary edge. The purpose of this research is to create a space where people can express their art and culture, sharing their stories through the way they dress. Promoting cultural appreciation, expanding representation, and encouraging a deeper understanding of universal fashion. Through digital platforms, exhibitions, and collaborations, this research has the potential to reach audiences well beyond a local level, spreading awareness about the significance of cultural preservation in a rapidly globalizing world. It also inspires younger generations to take pride in their heritage and use creative expression as a tool for social change. In this way, the project not only showcases fashion but also sparks meaningful conversations about identity, inclusion, and the importance of celebrating your culture and heritage in every corner of society.

Abstract Name: How Widespread is the Fungus that Causes White-Nose Syndrome in Various Non-Karst Bat Habitats?

North American bats are threatened by white-nose syndrome (WNS), a disease caused by the fungus *Pseudogymnoascus destructans* (Pd). WNS primarily affects hibernating bats in caves and mines, where conditions are highly suitable for fungal growth. Pd is presumed to spread to bats in a variety of situations, but few studies have assessed the potential for transmission in places other than caves and mines. In our observational study, we assessed the prevalence of Pd DNA in bat feces collected from several habitat types and seasons. Guano samples were collected from bats captured in mist nets, roosts in bridges, and rock-crevice roosts on talus slopes in Virginia, Pennsylvania, Ohio, West Virginia, and Arkansas, between May 2012 and April 2025. We tested the presence of Pd DNA with PCR followed by gel electrophoresis, using positive and negative controls. Out of 169 guano samples, 97% were negative for Pd. We detected Pd in 3% of guano samples from Eastern Small-footed Bats (*Myotis leibii*) and Big Brown Bats (*Eptesicus fuscus*) on talus slopes in Virginia that served as roost sites throughout much of the year. It has yet to be determined whether Pd positive samples represented viable fungal spores, but our results preliminarily suggest there may be potential for bats to spread Pd at rocky landscape features, which are biologically important as roost sites across North America. Additional research needs to be conducted to determine the role that talus slopes and perhaps other rocky outcrops play in the spread of WNS. This question is especially relevant for understanding how WNS may spread in western North America, where bats tend to overwinter in rocky landscape features instead of caves and mines.

Abstract Name: Exploring Whole-Body Center of Mass Dynamics During Narrow Beam Walking to Guide Hip Exoskeleton Control

Mediolateral (ML) balance is crucial for stable walking but is harder to control, especially in tight spaces where body movement is limited. Improving ML stability with wearable devices can help prevent falls and make walking easier for both patients and healthy people. To evaluate how a wearable device can improve ML balance, we tested our hip exoskeleton, which provides assistance in the frontal plane during a narrow beam walking task. Normally, the body uses step width, arm, ankle, and hip movements to keep balance and control the center of mass (CoM), but to focus on the hip's role and the exoskeleton's effect, participants walked heel-to-toe with arms crossed and knees straight, limiting other movements and increasing reliance on ML control and the exoskeleton, which aims to reduce whole body CoM motion. The flexible controller lets participants override the exoskeleton and use their own balance reactions, so the body's movement is a mix of both, which helps improve overall balance during the task. It is hypothesized that smoother whole body CoM velocity in the sagittal plane and less CoM deviation in the frontal plane help improve performance on the narrow beam, so we analyzed CoM motion in both planes to understand its effect on successful distance traveled during the task. Therefore, in this study, we analyze the kinematics of the CoM in both sagittal and frontal planes to investigate the correlation between CoM behavior and walking performance outcomes.

Abstract Name: Targeting the lncRNA THBS1-AS1 Attenuates Biliary Fibrosis in PSC Models

Primary sclerosing cholangitis (PSC) is a biliary disorder characterized by progressive inflammation and fibrosis of the bile ducts, driven in part by the release of a profibrotic secretome. Our previous data revealed long non-coding RNAs (lncRNAs), including THBS1-AS1 regulate the expression of profibrotic genes through their interaction with epigenetic regulators within cholangiocytes. We hypothesize that inhibiting THBS1-AS1 would be a therapeutic strategy to mitigate inflammation and fibrosis in PSC. Antisense

oligonucleotide (ASO)–mediated knockdown of THBS1-AS1 was performed in vivo using the Mdr2-/- mouse model of chronic biliary fibrosis. Gene expression analysis was performed on liver tissue using RT-qPCR analysis. Fibrosis was evaluated by histological staining, and serum biochemistry was used to assess liver injury. In vivo ASO administration in Mdr2-/- mice led to decreased expression of multiple fibrogenic genes. RT-qPCR analysis confirmed significant reductions in THBS1-AS1 (~58%, $p < 0.01$), FN1 (~41%, $p < 0.01$), Serpine1 (~61%, $p < 0.05$), CTGF (~66%, $p < 0.001$), and Colla1 (~53%, $p < 0.05$). ASO treatment also led to an improvement in liver disease as assessed by serum biochemistry, ALT ($p < 0.01$), AST ($p < 0.01$), ALP ($p < 0.05$). Sirius red staining also showed reduced fibrosis with ASO treatment compared to controls ($p < 0.0001$). THBS1-AS1 regulates profibrogenic signaling in cholangiocytes. ASO-based RNA therapeutics silencing THBS1-AS1 blunt the fibrogenic gene expression and improve liver injury in the Mdr2-/- mouse model. These results in murine cholangiopathy models illustrate the translational promise of targeting lncRNAs and help set the stage for future clinical trials.

Abstract Name: Discipline and Protest: A History of the Freedom of Expression and Dissent Policy at Dartmouth College

The purpose of this project is to investigate the historical relationship between Dartmouth College's Freedom of Expression and Dissent (FED) policy and its campus dissent from the 1960s to 1980s. While recent scholarship has investigated how universities have entered a new, unprecedented era of authoritarian crackdown, this project nuances this era by revealing the slow, planned evolution of institutional policy that laid its groundwork. The analytical framework of policy history enriches existing understandings of university violence by interrogating the legal infrastructures that have materially and discursively enabled it. Further, this project offers a uniquely place-based study of Dartmouth College, an institution with a deep yet concealed complicity in racial segregation, the Vietnam War, and South African apartheid. I historicize how Dartmouth "prizes, defends, and upholds" the freedom of expression and dissent, though the "right to this freedom is not unfettered," through the College's Special Collections Library, the student newspaper, oral histories of student activists, archives of The Chronicle of Higher Education; and secondary sources regarding student movements and the politics of higher education during the late twentieth century. I find that Dartmouth's FED policy was first developed to regulate protests against pro-segregationist visiting speaker George Wallace in 1967, then reactively revised and expanded throughout the next two decades of antiwar and anti-apartheid protest. Through analyzing the historical causes, revisions, and applications of the FED policy, I argue that the FED policy was developed not to protect free expression and dissent, but to prevent such expression from disrupting the college administration's desired social order. While the FED policy offers Dartmouth the symbolic credibility of prizing free expression, its concomitant restrictions on permissible activity dampen such dissent's impactfulness.

Abstract Name: Construction of a custom insect classifier through BirdNET to create a synthetic acoustic

community

Agricultural fields across the world are experiencing massive biodiversity loss due to conventional agricultural practices. The use of chemical fertilizers and pesticides are negatively influencing insect populations. There has been a recent push towards regenerative agriculture in order to reduce the consequences of repeated use of these practices on farms. However, one of the main problems at hand that researchers face is the lack of automated technology to detect vocalizing insect presence. Recent developments involving artificial intelligence models in bioacoustic detection have proved to be effective with birds (BirdNET). We hypothesize the convolutional neural network model utilized by BirdNET can be translated to insect species. Previous work on BirdNET has shown that it was marginally successful at recognizing a sample of insect species. Here, we aim to improve accuracy metrics for acoustic insect identification. To do this, we will test three common vocalizing species found in regenerative agricultural fields; *Allonemobius allardi*, *Eunemobius carolinus* and *Scudderella curvicauda*. We predict that the expanded training model will recognize insect calls that overlap in acoustic space over other vocalizing species such as birds. The end goal is to create an insect classifier that is ground-truthed using a synthetic acoustic community for rapid assessment of insect species in agricultural fields.

Abstract Name: A Formulation of the Union-Closed Sets Conjecture Using the Hamming Metric

A family of sets is union-closed if the union of any two sets in the family is also contained in the family. The Union-Closed Sets Conjecture, also known as Frankl's Conjecture, posits that for any finite union-closed family of sets containing at least one nonempty set, there exists an element which belongs to at least half of the sets in the family. Although deceptively simple in its statement, the Conjecture has defied a definitive proof, despite extensive study through various approaches and equivalent formulations, which have thus far yielded only partial results. We approach the Conjecture from yet another angle, introducing a new formulation of the conjecture based on the Hamming distance (metric) between sets, which is defined as the number of elements in one or the other, but not both (the size of their symmetric difference). Using this framework, we derive multiple equivalent formulations of the conjecture and provide a complete characterization of the set of all elements that satisfy the conjecture. Furthermore, we demonstrate that our approach enhances the averaging method, a widely used approach that has led to numerous partial results. Finally, we obtain a criterion that relaxes the requirement of the averaging method for verifying the validity of the conjecture. Our findings suggest that the Hamming metric provides a powerful perspective on the Union-Closed Sets Conjecture. The connection between structural properties of union-closed families to Hamming distances offers promising avenues for further exploration, bringing a more algebraic outlook to this combinatorics problem. Future research will focus on extending this framework to continue improving existing partial results and analyze larger families of sets, identifying additional equivalences, and hopefully progressing toward a complete proof of the Conjecture.

Abstract Name: My Grandfathers' Hometowns

My Grandfathers are both from small towns in the south, and funnily enough, both of them are still there. I decided to interview both of them, asking them to tell me about their childhoods and favorite memories. My dad's dad, who is from a small town in rural Alabama along Lake Martin told me about his large family, from his older sisters to his cousins. He told me about his love of sports and how he played basketball on a scholarship in college. He told me about the time he set a couple of acres of forest on fire by accident while playing with his cousins. He told me about how he met my grandmother while teaching at a university and that he decided to move back to his hometown to raise my dad and aunt. My mom's dad was from another small town, but this time in North Carolina. He told me about his father's shop and all the characters in his hometown. He told me about his experience at military school, where he went to manage his dyslexia. He did leave his hometown for a job in Maryland, where he raised my mom and aunt, but after giving my aunt the house thirty years later, he and my grandma moved back to North Carolina. Both my Grandfathers are still in their hometowns today, where they both expressed nothing but love for where they live. Illustrating their stories through this zine has also been very rewarding, as I have been able to record and share their stories in a beautiful way. I am extremely grateful for having the opportunity to interview my grandfathers and learn more about their stories and childhood as they mean so much to me.

Abstract Name: Staged Multi-Modality Information Fusion to Improve the Diagnosis of Alzheimer's Disease

Alzheimer's disease (AD) is a progressive neurodegenerative disorder that requires early and accurate diagnosis for effective intervention. This study develops a machine learning framework to enhance AD staging by integrating multi-modal data—including clinical, magnetic resonance imaging (MRI), and positron emission tomography (PET) features—to classify patients as Cognitively Normal (CN), Mild Cognitive Impairment (MCI), or Alzheimer's Disease (AD). The research utilizes Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset, Australian Imaging, Biomarkers and Lifestyle (AIBL), and OASIS-3, importing patients' clinical data along with their MRI and PET scans. Image features were extracted from both modalities using eight brain templates processed through SPM12 and CAT12 pipelines, generating and combining imaging features per patient. To ensure dataset consistency only subjects with both MRI and PET scans and numerical clinical data were included, while non-numerical variables were removed or converted to numerical values. A neural network classifier was trained on this integrated dataset to improve classification accuracy across disease stages. This research contributes a staged, graph-based diagnostic framework that begins with the least expensive clinical assessments and progressively incorporates more advanced and costly modalities based on uncertainty quantification, thereby optimizing diagnostic accuracy while reducing medical costs. Future work will validate the model for real life clinical applicability.

Abstract Name: Computationally Predicting Important Amino Acids in Ferritin Nanocage Structure

Ferritin is a naturally occurring protein that many different organisms have which oxidizes iron in the body to be stored for later use. Its structure has become an area of interest in the nanomedicine community due to its ability to hold the precipitated ferric oxide due to the 24-mer hollow spherical shape. Researchers in the nanomedical field are trying to harness this ability of the protein to possibly be a use for chemotherapies in cancer treatment. Computational modeling in biochemistry has become prominent in the scientific field and has been found to be useful in studying structures of proteins. In this research it is being used to help predict the important amino acids for ferritin's structure. The program PDBePISA was used to determine the energetic change in the structure between the native strand and the mutations made around the 3-fold interface, made computationally via ChimeraX. Using the predictions, those mutations were made in lab through site-directed mutagenesis. After purification, the mutated proteins were run through gels to determine their molecular weights. Then multiple iron incorporation assays were run to determine the functionality of the mutations. It was found that mutations made at the 3-fold axis, specifically phenylalanine-117, affects the structure of the 24-mer. The mutated protein was broken down into the monomer or dimer as the molecular weights found after running gels was 17.07kDa compared to the wild type, 24-mer of 148.161 kDa. Although, the structure did not form correctly, the protein was still able to oxidize iron and at a faster than the wild type. From these results, it was found that the mutation at the 3-fold interface, F117, breaks down the structure of the protein, but its functionality of oxidizing iron is faster, although it cannot store the precipitate, because the structure fell apart.

Abstract Name: Investigating the Role of HIF-1 Induced Glycolytic Shift in Modulating Macrophage Anticryptococcal Activity

Cryptococcosis is a severe systemic fungal infection caused by *Cryptococcus neoformans* (Cn), a facultative intracellular pathogen that disproportionately impacts immunocompromised populations. Within the lungs, Cn encounters alveolar macrophages (AMs), innate phagocytes that ingest and eliminate the pathogen. Although AMs typically rely on mitochondrial respiration under resting conditions, Cn infection induces a metabolic shift towards glycolysis and activates hypoxia-inducible factor 1 (HIF-1), a central regulator of glycolytic gene expression, allowing the pathogen to avoid destruction and disseminate from the lung, resulting in life-threatening fungal meningitis. Recent findings from our lab demonstrate that stabilizing HIF-1 α with DMOG increases glycolytic gene expression, while inhibition with echinomycin partially reverses this effect. These observations suggest that Cn may exploit HIF-1-dependent metabolic remodeling to promote its intracellular persistence. Therefore, we hypothesize that inhibiting HIF-1 activity with echinomycin will reduce the intracellular replication of Cn. However, an optimal, non-toxic dose of echinomycin has not been defined, and its impact on antifungal defense has not been evaluated. Addressing these gaps is the central focus of this study. We first established an effective dose of echinomycin using J774 macrophage-like cells treated with DMOG, a HIF-1 α stabilizer. Quantitative real-time PCR (qRT-PCR) of canonical HIF-1 target genes was used to identify concentrations that suppressed HIF-1 activity while maintaining cell viability. These optimized conditions were then applied to fetal liver-derived alveolar-like macrophages (FLAMs), a physiologically relevant model that recapitulates key metabolic and transcriptional features of primary AMs. To directly assess the impact of blocking the HIF-1 activity on antifungal defense, live-cell imaging will be used to measure intracellular replication of Cn. We anticipate that blocking HIF-1-mediated glycolysis with an optimal echinomycin dose will reduce intracellular Cn replication and alter macrophage antifungal activity. These findings will advance our understanding of pathogen-driven metabolic remodeling and may identify new therapeutic strategies for combating cryptococcosis.

Abstract Name: Adapting Public Health Implementation Science Frameworks to Inform the Evidence-Based Adaptations of a Longitudinal Undergraduate Research Education and Training Program: A Case Study

Undergraduate research training programs have been highlighted as formative high-impact practices (HIPs) that complement classroom learning. Research in higher education interventions demonstrates that undergraduate research training programs are a key component shaping students' critical thinking, technical writing, and project management; these skills are critical to hone if a student aspires to enroll in a research-intensive postgraduate degree program, especially in STEM and health sciences fields. In a rapidly changing higher-education environment, especially over the past six years, colleges have struggled to produce evidence as quickly as staff and faculty have had to adapt. This has made it difficult to understand and respond to unexpected challenges affecting students' participation in high-impact practices (HIPs). In health sciences intervention research, researchers and interventionists have to quickly adapt the intervention based on preliminary data if intervention uptake is low or the intervention is prolonging or exacerbating a health issue. We present a case study of the ASEMS STARS program: a 16-month, undergraduate research training and preparation for advanced degrees. We will examine the novel ways in which researchers and programmers applied public health implementation science frameworks to a higher education intervention. Utilizing a mixed-methods approach, data on how the students' and mentors' acceptability of the intervention changed over time as the intervention itself evolved. We will also demonstrate longitudinal patterns in post-graduation outcomes and their associations with the shifts in the intervention programming. Finally, we will offer best practices and lessons learned for adapting implementation science to higher education HIPs in order to more efficiently respond to changing training and preparation needs of undergraduate participants.

Abstract Name: Advancing Sustainable Construction: Evaluating Portland-Limestone Cement Using a Non-Destructive Maturity Approach

The objective of this study is to evaluate the performance of Portland–Limestone Cement (PLC) containing 15% limestone powder using a robust, non-destructive maturity method. Traditionally applied to Ordinary Portland Cement (OPC) and mixtures incorporating fly ash, slag, and silica fume, the maturity method relates concrete temperature and time to in-place strength development. As a non-destructive technique, it offers advantages such as continuous monitoring of strength gain, reduced reliance on destructive sampling, lower testing costs, and improved construction efficiency through real-time strength prediction. With PLC gaining prominence as a more sustainable alternative to OPC, this research seeks to validate its performance while identifying opportunities to enhance its strength characteristics. The study will examine fifteen binary and ternary concrete mixtures containing newly acquired PLC combined with various supplementary cementitious materials (SCMs). The goal is to determine optimized mixture designs that support both mechanical performance and environmental benefits. Approximately eight mixtures will be tested per academic term, with about sixteen cylinders produced for each mixture. These specimens will be exposed to three controlled curing temperature conditions to assess the influence of thermal environments on strength development. Maturity meters will continuously record temperature histories, enabling the computation of temperature–time factors and equivalent-age functions for predicting compressive strength over a 28-day period. In parallel, two cylinders from each mixture will undergo destructive compressive strength testing at 1, 3, 7, 14, and 28 days to establish strength benchmarks. The primary goal is to compare experimentally measured compressive strengths with maturity-based predictions using a calibrated maturity curve. Because literature on PLC—particularly regarding temperature-dependent behavior—is limited, this research aims to advance knowledge of PLC’s strength development under varying curing conditions. Ultimately, the study seeks to validate the maturity method as a reliable, non-destructive approach for predicting the performance of PLC concrete in practical construction settings.

Abstract Name: Role of Levodopa in Murine Aortic Valve Elastogenesis

The aortic valve (AoV) endures billions of cycles of opening and closing over a lifetime, a mechanical challenge met by its specialized extracellular matrix (ECM), primarily composed of elastin (Eln) and collagen. These structural components are produced and maintained by valvular interstitial cells (VICs), a heterogeneous cell population that includes melanocytic cells similar to those that develop pigment in skin. Although the diversity of VICs is well recognized, the contribution of melanocytes to AoV development and pathology remains unclear. Recent studies from our group demonstrated that hypopigmented mice exhibit

reduced and disorganized elastic fibers in the AoV leaflets compared to the pigmented groups, suggesting a link between pigmentation and elastogenesis. Interestingly, previous studies have shown that treatment of albino mice with levodopa (L-DOPA), a precursor of melanin and a known neuromodulator, can restore visual function without altering pigmentation patterning. Building on this, we hypothesized that L-DOPA may influence elastin formation independently of its effects on pigmentation. To better understand the role of L-DOPA in elastogenesis, we treated pregnant albino mice with L-DOPA dissolved in water ad libitum and examined elastic fiber organization in the AoV leaflets of 3 days post-natal (P3) mice. Our preliminary data indicate that L-DOPA treatment rescues the elastin phenotype in postnatal day 3 (P3) albino mice, as evidenced by immunofluorescence analysis. Ongoing studies aim to elucidate the molecular mechanisms by which L-DOPA influences elastogenesis. These findings offer new insights into ECM regulation within the aortic valve leaflets and highlight the potential of repurposing clinically approved pharmacological agents to modulate elastin synthesis as a novel therapeutic strategy.

Abstract Name: Harnessing Community Voices: Empowering Richmond's Carver District Against Gentrification

Purpose: Gentrification and displacement are reshaping the cultural landscape of Richmond, Virginia, particularly in the Carver District, a historically significant neighborhood with a diverse identity. This poster highlights the pressing need for inclusive urban planning that empowers residents, particularly students, to advocate for their community and preserve its heritage. The central research question guiding this investigation is: "How can community engagement strategies effectively empower residents, particularly students, to influence urban planning decisions and mitigate the impacts of gentrification in Richmond's Carver District?" **Methods:** To address this question, the study employs qualitative methods, including community meetings with residents and students. These meetings serve as key platforms for gathering insights on local challenges and priorities. Students are encouraged to participate actively, voicing their perspectives on issues that matter most to them and their peers. This involvement not only enriches discussions but also fosters a sense of agency and responsibility, empowering them to advocate effectively for their neighborhoods. **Results:** Preliminary findings indicate that rising housing costs and community transformation have led to frustration among residents, with many facing eviction or relocation. Student engagement in these meetings has enhanced their understanding of civic responsibility and sparked interest in community advocacy. Their contributions highlight the specific needs of younger residents, reflecting a collective desire for planning processes that consider perspectives from all age groups. **Conclusions:** The Carver District exemplifies the vital role of community engagement in urban planning. By prioritizing the voices of residents—including students—we can go beyond rigid frameworks like Blueprint Urbanism, which often overlook specific community contexts. This research emphasizes the necessity of empowering students and community members as key stakeholders in shaping their environments, ultimately fostering advocacy for equitable urban development and cultural preservation.

Abstract Name: Analyzing Steroid Abundance in the Lyuberetskiy Wastewater Treatment Complex

The water running into wastewater treatment plants (WWTPs) is full of microorganisms such as bacteria and viruses. This water can also contain steroid estrogens like estrone, estradiol, and estriol. Previous research has shown that prolonged exposure to natural estrogen in water has adverse effects on humans and animals such as interfering with their sexual development, normal homeostasis, and behavior. The goal of the current research is to investigate and compare the amount of steroid estrogens removed by two independent wastewater treatments at the Lyuberetskiy WWTP complex in Moscow. Current technologies for removing steroid hormones from wastewater are very complex and costly, and because of this they are not implemented in WWTPs. The two treatments at the Lyuberetskiy complex have not been evaluated on their ability to remove steroids from wastewater, only their ability to remove antibiotic resistant genes (ARGs). For this research the raw metagenome sequences of the influent water, the two activated sludge samples, and the two effluent waters from the WWTP complex were acquired to look for homologous genes that might correlate to the presence of steroid estrogens. A gene catalog was created for protein-level homologs of estrogen-degrading genes, and those genes were then detected and quantified using bioinformatic analysis in R Studio. The findings of this research will shed some light onto the amount of steroid contamination removal in the Lyuberetskiy wastewater by the two different treatments.

Abstract Name: From Social Media to Campus Streets: The Impact of Online Police Misconduct on Student Perceived Legitimacy of Campus Police

Since 2020, the visibility of police misconduct on social media has increased dramatically. While these specific instances have led to national conversations about law enforcement, little continues to be known specifically about how this online presence shapes college students' perceptions of their campus police specifically. In this study, we explore how viewing internet-based, and specifically social media content, depicting police misconduct influences university students' views of campus police. By examining perceived legitimacy of campus police in a university setting, it allows researchers to examine an environment where police serve distinct roles and interact with their constituency in a unique way. This study was conducted at a large urban public university using an online survey that included close-ended and open-ended questions. Using qualitative student data, we identify major themes related to the impact of viewing police misconduct on students' perceptions of campus police. Preliminary findings indicate that exposure to police misconduct via online content eroded students' trust in campus police, heightened awareness of racial bias, and increased skepticism of the justice system. Further, student narratives emphasized a weakened willingness to cooperate with campus police. We discuss how these qualitative results compliment or differ with existing quantitative results on student perceptions of campus policing and highlight the need for campus police departments to engage in transparent communication, community-based trust building, and equity-centered policy development.

Abstract Name: Flavor with a Function: Targeting Colon Cancer with Cinnamon Extract

Cancer remains one of the leading causes of death worldwide, with colon cancer ranking as the third most prevalent form. Traditional treatments such as chemotherapy and radiation often come with significant side effects due to their inability to selectively target cancer cells, leading to widespread interest in natural alternatives. Cinnamon, a widely available and inexpensive household spice, has been shown in previous studies to have anti-inflammatory, antioxidant, and growth-inhibiting properties. In addition, previous studies have shown cinnamon to inhibit colon cancer cell proliferation. By analyzing dose-dependent responses, this research aimed to assess whether aqueous cinnamon extract has negative effects on the metabolic activity of the DLD-1 human colon cancer cell line, and explore its potential as a natural treatment. The effect of aqueous cinnamon extract on DLD-1 cells has not been tested previously. A stock solution of the extract was prepared by boiling cinnamon in water for 30 minutes, followed by centrifugation to spin down and pellet the components of cinnamon that did not go into solution, and filtering the remaining liquid to make it sterile. A total of five experiments were performed using the same treatment concentrations and each experiment showed a dose-dependent decline in the metabolic activity of DLD-1 cells in the presence of cinnamon. This study further demonstrates that cinnamon possesses anti-tumor properties, and should be assessed further as a potential treatment option in addition to more traditional cancer therapies.

Abstract Name: Design and Implementation of CTRE: An Infrastructure-as-Code Framework for Cyberwarfare Training Ranges at the United States Air Force Academy

The United States Air Force Academy (USAFA) provides a unique cyber education curriculum that goes beyond a traditional cybersecurity program. The institution's goal of including an operational cyberwarfare focus into its education relies on special training environments called cyber ranges, simulated platforms that provide a medium for learning and practicing technical skills that students will use as cyberwarfare operators. Existing methods for deploying cyber ranges at USAFA are manual, inconsistent, and unreliable, creating a limitation on the institution's ability to effectively provide a range ecosystem for local use. This research project aims to fix this limitation by developing the Cyber Training Range Ecosystem (CTRE), a standardized framework that leverages Infrastructure as Code (IaC) for the rapid, reliable, and reusable deployment of cyber ranges. This study combines industry standards for virtualization with the unique needs of USAFA as a military training program to identify optimal design aspects for a scalable and effective range ecosystem. These design aspects materialized into the CTRE proof-of-concept, utilizing Proxmox, Terraform, Ansible, and Docker technologies to automate the deployment of high-fidelity ranges including realistic network representations and target configurations. The use of CTRE drastically improves deployment speed, reducing deployment time for the proof-of-concept range from over a dozen hours to approximately 13 minutes. Building upon the foundations of CTRE, USAFA will continue to rely on IaC to provide an effective range ecosystem, ensuring that the next generation of warfighters are prepared to succeed in the cyber domain.

Abstract Name: Using Generative Artificial Intelligence as an Assistant in Hospital Emergency Rooms

The central research question of this project is to determine the extent to which Generative Artificial Intelligence (GenAI) can act as an assistant within hospital emergency rooms (ERs) to help reduce treatment errors and hasten accurate diagnosis. Other research has looked at the state of AI within medical settings for tasks such as note taking, recommended treatment paths, and solving overcrowding problems; however, this research focuses on listening to and interpreting patient/doctor or patient/nurse conversations in ER situations in real time with the goal of immediately suggesting diagnoses, treatments, and/or further tests that the medical professionals might have missed, i.e. to assist doctors and nurses in decision-making. A prototype will include voice technology combined with GenAI reasoning based on prior case studies that focus on details of a patient's story or medical status, e.g. something as simple as ChatGPT in listening mode integrated with a database holding a patient's medical records. The research methodology includes (i) a review and evaluation of similar prototypes or products in the medical field, (ii) a study of typical ER patient/examiner scenarios, (iii) a review of the Health Insurance Portability and Accountability Act on patient rights, and (iv) consultations with several professional ER workers for feedback. The testing of the prototype includes a series of simple scenarios and unusual scenarios to determine the degree to which GenAI assistance is perceived and appreciated by both ER workers and patients. The conclusions of the research will inform ER workers, patients, and other medical stakeholders with respect to the effectiveness, trust, accuracy, and pros/cons of GenAI-based assistance in hospital ERs.

Abstract Name: Database Security Auditing

Databases are central to how organizations manage and protect sensitive information, including student records, financial data, and operational systems. As threats to data security continue to grow, it's essential to understand how vulnerabilities can be identified and addressed before they are exploited. This research introduces a student-led initiative focused on auditing database systems to evaluate their security posture. The goal is to create a practical framework that students can use to assess access controls, encryption methods, user permissions, and logging practices. Through hands-on experience, students will learn how to conduct security audits, interpret system logs, and identify potential risks in both simulated and real database environments. The research project also emphasizes the importance of ethical data handling and compliance with privacy regulations such as FERPA and GDPR. By working directly with sandbox systems and student-developed databases, participants will generate meaningful data that can be used to improve institutional practices and support future funding proposals. This not only strengthens technical skills in cybersecurity and database management but also encourages civic responsibility and awareness of data privacy. Attendees will gain insight into how engaged learning in the field of database information systems can lead to impactful contributions within and beyond the university.

Abstract Name: Risk-Taking Under Scarcity The Mindset Factor

Poverty has been consistently linked to cognitive strain and reduced executive functioning, often conceptualized through the Conservation of Resources Theory (Hobfoll, 1998), which posits that resource-related stress arises from both actual and threatened losses. Empirical studies demonstrate that financial stress impairs working memory (Mani et al., 2013; Dang et al., 2016), limits mental bandwidth (Nugroho et al., 2023), and mediates the relationship between poverty and cognitive performance (Mullainathan & Shafir, 2013). These deficits can influence decision-making tendencies such as risk, loss, and ambiguity aversion (Haushofer & Fehr, 2014), potentially shaping behavioral outcomes in individuals from lower socioeconomic status (SES) backgrounds. The present study proposes to examine the potential mediating role of growth mindset, the belief that traits and abilities can be developed, on the relationship between SES and cognitive measures of risk-taking and inhibitory control. Previous research suggests that a growth mindset can improve cognitive performance and adaptability across populations (Plaks & Chasten, 2013; Hu et al., 2025), yet its interaction with resource-related stress and economic decision-making remains unexplored. This cross-sectional, correlational study will recruit a college student sample. Participants will complete demographic and SES measures (subjective SES scale; Adler 2000, parental education, government assistance indicators), growth mindset measures (ITEB-Q; Schleider & Weisz, 2016; Growth Mindset Scale; Sigmundsson & Haga, 2024; Implicit Theory Scale; Dweck, 1999), and cognitive decision-making tasks, including the Balloon Analog Risk Task and the Go/No Go Task. The independent variable will be growth mindset, and the dependent variable will be behavioral indicators of risk-taking and inhibition performance. Findings are expected to clarify whether a growth mindset moderates cognitive and decision-making biases often associated with low SES, offering insight into psychological resilience among populations facing resource scarcity.

Abstract Name: Lost in Translation: A Grounded Theory Exploration of Cross-Cultural Pain Communication and Epistemic Injustice among Spanish-Speaking Patients

Pain remains the leading cause of healthcare visits, yet it is an inherently subjective experience profoundly influenced by language, gesture, and culture. In cross-cultural settings, the "language of pain" is frequently misinterpreted, resulting in poorer health outcomes for linguistic minorities. Using Constructivist Grounded Theory, this study explores pain communication among 30 Spanish-speaking individuals living with chronic pain, divided evenly between residents of Spain and the United States. Analysis reveals four themes regarding the negotiation of suffering. First, linguistic reductionism occurs when culturally bound terms to describe pain, like "pupa," are used as a psychological tool by adults to "automatically diminish the perception of pain" in the listener. In clinical settings, cultural nuances of pain are stripped of meaning to fit rigid clinical metrics. Second, patients navigate the performativity of pain as they balance the need to perform symptoms for validation against cultural pressures for social harmony. Third, a gender paradox emerged particularly within the Spanish cohort, where men reported adhering to scripts of stoic endurance, or *aguantar*, to maintain

respect and social dignity. This highlights the conflict between cultural modesty and the clinical necessity of advocacy. Finally, participants described epistemic injustice fueled by clinical fatalism, a dynamic where providers dismissed pain as a natural consequence of aging based on cultural assumptions. These findings illustrate that the "pain gap" is not merely linguistic but structural. Addressing these disparities requires the healthcare field to move beyond translation services toward equitable practices that validate culturally distinct narratives of pain.

Abstract Name: Synthetic Route Optimization of Herdmanine-K and Analogues for PPAR γ Agonistic Activity

Type 2 diabetes is listed among the top 10 leading causes of death worldwide. Activation of the peroxisome proliferator activated receptor (PPAR) with synthetic agonist has shown much promise in the treatment of type 2 diabetes. Current FDA approved PPAR agonists known as TZD's, while effective, are associated with severe cardiovascular risks. Thus, the identification of novel PPAR ligands with reduced side effects is needed. The natural product Herdmanine-K was recently demonstrated to possess a binding affinity to PPAR comparable to the FDA approved TZD, Rosiglitazone, but its functional activity has not been determined. This poster outlines our work to optimize a synthetic route allowing access to Herdmanine-K and non-natural analogues. The Optimized route afforded Herdmanine-K in 27% over 4 steps. Yields of non natural-analogues using this route varied from 7 to 48%. Current efforts seek to execute an SAR study on the synthesized compounds at PPAR.

Abstract Name: The Effects of Distal and Proximal Acute Stressors on False Memory Creation

Past research indicates that stress has an impact on memory encoding and retrieval processes. The magnitude, timing, controllability, and duration of a stressor all impact differing aspects of the information processing model. The magnitude of a stressor can create a stage of fight-or-flight that resembles shock and can obstruct memory creation as a whole. One may observe that the impairment of memory by a stressor theoretically relates to the necessary situation needed in order to create a false memory. A participant's emotional state, physiology, and proximity to misinformation have been cited as influential in the creation of false memories. The study of false memories gained prominence in 1995, when Roediger and McDermott revitalized Deese's memory task, now known as the DRM paradigm. This task attempts to instill false memories through the usage of critical lures, words that are related to the gist of a list of words but not originally presented. This study will attempt to discern whether proximal versus distal stressors have more of an effect, if any, on false memory creation through the usage of the DRM paradigm and psychosocial measures of lab-induced, proximal stress. A DRM-task, Perceived Stress Scale, and Acute Stress Disorder Scale will be administered in a lab setting to 100 undergraduate students to measure distal and proximal stressors before and after

completion of a false memory task paired with a psychosocial stressor. A positive correlation between increased situational and personal stress and false memory is expected to be shown in data, as well as a difference in proximal and distal stressors on the amount of false memories created.

Abstract Name: The Galactic Neutrino Atom: The Success of the Classical Gas Model and Rejection of Quantum Modeling

The elucidation of the nature of dark matter represents one of the most significant challenges in modern cosmology, particularly in reconciling the success of the Λ CDM model on large scales with the structural anomalies observed on galactic scales. While massive sterile neutrinos offer a compelling candidate within Standard Model extensions, their dynamical behavior in galactic halos remains a subject of debate. This work presents a rigorous numerical analysis of Milky Way rotation curve data to evaluate the validity of two distinct theoretical frameworks: a Classical Fluid model in hydrostatic equilibrium and a Macroscopic Quantum Bound State (the “Neutrino Atom”). Contrary to recent proposals suggesting a need for quantum degeneracy or coherent field solutions, we demonstrate that the Classical Gas model successfully reproduces the galactic rotation curve. Our analysis reveals that the neutrino halo behaves as a self-gravitating isothermal fluid. Furthermore, we address potential thermodynamic concerns by showing that the negative effective energy states derived from this model are physically necessary to maintain a stable, gravitationally bound system over cosmological timescales. Conversely, we reject the quantum modeling approach. We demonstrate that the “Neutrino Atom” model, treating the halo as a macroscopic quantum bound state, fails to naturally reproduce the observed Keplerian decline and is fundamentally limited by the short interaction range of the weak force ($\sim 10\text{--}18\text{ m}$), which is insufficient to support galactic structures. Consequently, we argue that the galactic halo is best described not as a macroscopic quantum object, but as a classical fluid of massive neutrinos.

Abstract Name: Sorry, Not Sorry: Exploring Communication Patterns and Perceived Authenticity of Influencer Apologies on Social Media

This project poses the following overarching question to investigate the emerging apology aesthetic on social media: How do digital platforms shape the way influencers use image repair strategies? As public apologies increasingly unfold in algorithmic, highly mediated environments, a recognizable set of visual and rhetorical conventions has developed—often marked by subdued lighting, minimal editing, direct-to-camera delivery, and emotionally coded, self-reflective language (Mitchell and Choi, 2022). Although widely circulated in

digital culture, these aesthetic patterns remain understudied in communication research, and influencer crises remain undertheorized in the scholarly literature. To address this gap, the study utilizes a mixed-methods design. The first phase will employ a content analysis of high-engagement influencer apology videos posted on TikTok and YouTube between 2016 and 2025. The content will be analyzed inductively and deductively using a coding scheme that identifies recurring stylistic and narrative features associated with the apology aesthetic and academic literature on crisis communication and image repair theory. In phase two, a focus group will be used to collect qualitative data exploring how users perceive sincerity, emotional labor, responsibility-taking, and reputational motives in digital apologies. This research draws on insights from image repair theory and attribution and framing in mediated communication to examine how influencer apologies navigate the complex intersections of sincere self-expression, reputational management, and audience perception. By analyzing structural, stylistic, and relational cues in these videos, the study synthesizes previous research into a guiding Authenticity and Strategic Impression Management (ASIM) framework, offering a novel lens to understand how social media influencers balance authentic personal identity with strategic brand performance. It demonstrates that the apology aesthetic is not merely a stylistic trend but a culturally meaningful script through which trust, responsibility, and public identity are negotiated in contemporary online environments.

Abstract Name: Improving Seizure Prediction through Analysis of Interictal and Preictal Intracranial EEG

Epilepsy is a brain disorder characterized by abnormal brain activity that causes recurrent, unprovoked seizures that can disrupt daily life and potentially lead to life-threatening harm. One way to manage epilepsy is with preemptive intervention, administering medicine or neuromodulation therapies to prevent the onset of a seizure. Because seizures are variable and sudden, it can be difficult to predict and prepare for an oncoming seizure. To optimize this preemptive intervention, seizure prediction can be performed via analysis of neural data and activity patterns. Seizure prediction is often done by analyzing electroencephalography (EEG) data, a recording of the brain's electrical activity, to capture features and patterns occurring directly before seizure, the preictal period. Then, these patterns can be used as indicators for upcoming seizures. However, identifying these patterns can be challenging as EEG data varies significantly across individuals, brain regions, and seizure types. We aim to improve identification of these significant features using intracranial electroencephalography (iEEG) data and MATLAB to compare defined interictal (non-seizure) and preictal phases in a cohort of three epilepsy patients recorded at UAB Hospital. The iEEG data were filtered, preprocessed and assessed with a linelength spike detector, which computed spike rates at each electrode in both the interictal and preictal periods. We found that the interictal to preictal spike rate increased, indicating increased spiking activity as the seizure approached. We also found that contacts with a higher spike rate change were strongly correlated with the seizure onset zone and this correlation was stronger in specific frequency bands which were individualized to each patient. These findings suggest focusing seizure prediction analysis methods on contacts surrounding the epileptogenic zone and in specific frequency bands could improve seizure prediction efficiency by narrowing the data scope and creating a more personalized prediction process.

Abstract Name: Emotional Labor and Academic Pressure in Pre-Nursing Programs: An Autoethnographic Study

Pre-nursing programs are known for their rigorous academic demands. It is framed as a necessary “proving ground” for those who wish to enter the nursing profession, yet the emotional toll involved in preparing for nursing school is often overlooked. Through an autoethnographic approach, this study examines the emotional and academic strain involved in preparing for competitive nursing programs. I reflect on my own experiences of navigating heavy coursework, long study hours, and continual pressure to excel, while also engaging with other pre-nursing students to grasp a better understanding of these experiences beyond my own challenges. Drawing from the literature on stress and resilience, I consider how institutional expectations shape feelings of burnout, self-doubt, and inadequacy, even among highly motivated students. This study argues that the emotional labor required before entering nursing school plays a crucial role in forming professional identity, highlighting a need for pre-nursing environments to recognize and better support the well-being of their students.

Abstract Name: Understanding the Regulation of the Mitochondrial ESRE Pathway by Lipid Metabolism

The mitochondria is the organelle found in eukaryotic cells responsible for energy production and regulating apoptosis, or cell death. Research has shown that mitochondrial dysfunction leads to many pathologies like cancer, neurodegeneration, cardiovascular disease, and lessened immunity. Understanding the mechanisms driving mitochondrial homeostasis is imperative for the maintenance of cellular and organismal health. Preliminary data using model nematode *Caenorhabditis elegans* has shown that many lipid metabolism genes are upregulated following activation of the evolutionarily conserved mitochondrial surveillance Ethanol and Stress Response Element pathway (ESRE). ESRE can be activated by mitochondrial damage resulting from reactive oxygen species (ROS), acute iron removal, and liquid-based *Pseudomonas aeruginosa* pathogenesis (LK-Pa). Because ESRE is evolutionarily conserved, the decrease in mortality in *C. elegans* following ESRE activation has implications for cancer and Alzheimer's remediation in humans, if the ESRE pathway can be artificially probed into being activated without causing mitochondrial damage. After previous gene ontology performed identified a large number of lipid metabolism genes upregulated upon ESRE activation, a primary screen on 22 of these genes identified 5 hits (*acdh-1*, *acdh-9*, *ddo-2*, *mmaa-1*, *Y71F9B.9*) as required for ESRE activation and host defense in LK-Pa. We tested the hypothesis that these genes are required for ESRE activation in a ROS dependent manner by measuring ROS levels in RNA interference (RNAi) knockdowns of these genes. *C. elegans* strain *glp-4* was reared on transformed *E. coli* to knock down the genes of interest, then treated with combinations of ROS generating compound CCCP, ROS absorbing compound DMSO, and ROS dependent fluorescent compound DCFDA. After the worms were imaged over 8 hours, ROS levels were quantified via worm fluorescence. However, we did not observe significant changes in ROS levels, indicating that these hits activate ESRE via other means (e.g., signal transduction).

Abstract Name: Using spectrophotometry to quantify bacteriolysis efficiency in phage

An increasing global concern is the rise of “superbugs”, or antibiotic resistant bacteria (ARB), which cause the deaths of 10 million people every year. Bacterial pathogens that develop immunity upon repeated exposure to antibiotic treatment make exploration of new bacteriolysis vectors such as phage therapy an imperative. Phage therapy is the treatment of ARB with modified or engineered bacteriophages to eliminate bacterial infection while leaving human hosts and their microbiomes unharmed. Bacteriophages are the most abundant biological entities on Earth, with nearly every environmental biological sample containing a range of both lytic and lysogenic phages. Partnering with a local lab, we collect environmental samples from avian feces, bat feces, and pond water that we test for the presence of bacteriolytic phages. Once our bacteriophages are identified as viable candidates for phage therapy, they are sent to our partner lab for further analysis and testing. Previous research used spot assays to identify 8 hits, tested against *Staphylococcus aureus*, *Klebsiella pneumoniae*, and *Escherichia coli*. Previous research has shown that spectrophotometry allows for quantification of cell growth and lysis following the introduction of bacteriophages. We aim to further increase our knowledge of previously identified and new samples by developing a protocol to evaluate their bacteriolytic efficiency. We did this by measuring OD600 over time in cultures of *E. coli* strain DH5 α with different multiplicities of infection (MOI) of bacteriophage samples to first identify an MOI range that would result in consistent four-hour lysis curves. Following this, all the hits were tested and had their percent inhibition of cell growth compared against positive control bacteriophage sample ψ 6925. Past this, we plan on having their genome sequenced to identify and compare bacteriolytic efficiency correlated genes, exposing new targets for phage engineering.

Abstract Name: A Soil-Based qPCR Assay for Rapid Detection of *Rotylenchulus Reniformis*

The reniform nematode (*Rotylenchulus reniformis*) is a major plant-parasitic nematode limiting cotton production across the southern United States. Conventional detection requires labor-intensive extraction and microscopic identification, which can delay diagnosis and requires specialized expertise. This project aims to develop a quantitative real-time PCR (qPCR) assay for rapid and sensitive detection of reniform nematodes directly from soil. Five primer sets targeting *R. reniformis* were first evaluated in silico and then tested using conventional PCR with DNA extracted from single handpicked nematodes obtained from a greenhouse-maintained stock population on Phy 340 W3FE cotton. DNA extractions were performed using an in-house lysis buffer. Among the primer sets, Ren240F/Ren240R produced the strongest and most consistent amplification and was selected for SYBR Green-based qPCR assay development. Specificity testing was conducted using DNA from reniform nematodes and from 12 non-target nematode species representing eight genera. Ren240F/Ren240R exclusively amplified reniform nematode DNA, showing no cross-reactivity with

other nematodes commonly found in Alabama soils. Sensitivity and amplification efficiency were assessed using serial half-dilutions of DNA extracted from ten reniform nematodes. The resulting standard curve ($y = -3.2491x + 20.365$; $R^2 = 0.9994$) demonstrated a strong linear relationship between Cq values and log-transformed DNA dilutions. The slope corresponds to an amplification efficiency of approximately 103%, and the high R^2 value confirms excellent reproducibility across dilutions. The assay detected as little as 1/4096 of the DNA from ten nematodes, equivalent to approximately 0.002 of a single nematode, indicating high analytical sensitivity. The next phase of this research will evaluate assay performance using soil DNA inoculated with known nematode densities, followed by validation with field samples. Once optimized, this qPCR-based diagnostic tool has the potential to streamline reniform nematode detection, reduce dependence on specialized taxonomic expertise, and improve precision management strategies in cotton production systems.

Abstract Name: Paper Soldiers: The Role of the Parliamentary Recruiting Committee and Scottish War Savings Committee in World War I

British propaganda during World War I mobilized Scottish identity through two distinct but interconnected approaches that reveal broader tensions within "Britishness." This paper examines propaganda posters produced by the Parliamentary Recruiting Committee (PRC) and the Scottish War Savings Committee (SWSC) between 1914 and 1918 to analyze how these organizations deployed Scottish cultural symbols for British war objectives. The PRC, operating from London, frequently misunderstood or awkwardly appropriated Scottish identity, relying on stereotypes like kilts and accents and depicting Scottish soldiers defending distinctly English landscapes. Their geographic and cultural appeals evolved from emphasizing shared territory to incorporating symbols like the Union Jack and English saints, yet they often failed to authentically integrate Scottish distinctiveness. In contrast, the SWSC, based in Edinburgh after 1916, demonstrated internal co-optation by transforming Scotland's historical heroes, Robert the Bruce and William Wallace, into advocates for British war bonds. By analyzing these poster collections at the Imperial War Museum, chronologically and comparatively, this paper argues that the most effective subsumption of Scottish identity into a shared British identity came from both external stereotyping and internal collaboration. The PRC's limitations exposed the fragility of top-down imperial identity construction, while the SWSC revealed how Scottish agents themselves operationalized their own cultural memory for British purposes. This research contributes to existing scholarship on World War I propaganda by directly examining visual materials largely overlooked by historians and by providing the first historical analysis of the previously unexamined Scottish War Savings Committee.

Abstract Name: Feeding the Mind: How College Shapes our Relationship with Food

Feeding the Mind: How College Shapes Our Relationship with Food Submission by Valentina CaroAbstract
For many college students, there are significant challenges to maintain consistent and healthy eating behaviors amidst balancing academic demands, work schedules, financial constraints, and overall stress. The purpose of this project is to review these everyday barriers and demonstrate how they impact the choices students make, regarding nutrition and total well-being. Applying current research on college eating behaviors and student wellness, I created a short video-podcast intended to translate these findings into a format that is accessible, engaging, and easy for students to relate to. This video-podcast covers common factors shaping eating habits. This includes time constraints on preparing a meal, reliance on convenient foods, irregular schedules, and the difficulty of finding culturally familiar foods for international students. Through the use of visual and conversational elements, the project presents academic research in an easily digestible format for a generalized student population. The multimodal format will allow for easier explanations of key concepts through a guided discussion to help viewers understand not only what these issues are, but why they matter. The project aims to raise awareness of the everyday struggles students face with food and to discuss the support that they may need. Rather than prescriptive advice, the video-podcast focuses on understanding and connection, revealing the role of structural factors-not personal failure-in shaping student eating behaviors. This is a submission on the use of digital media for communicating health-related research in an informative, yet accessible manner. The audience will get an insight into the complexity of student nutrition and ways in which multimodal communication strategies make research more understandable and relevant to larger audiences.

Abstract Name: Why Did Ancestral Statue (moai) Construction End on Rapa Nui?

Why Did Ancestral Statue (moai) Construction End on Rapa Nui?Kharyn Carrasco, School of World Studies, Virginia Commonwealth UniversityThe massive anthropomorphic stylized statues (moai)erected on Rapa Nui (Easter Island) religious platforms (ahu)represents one of the most notable cultural achievements in Polynesia. This project poses a central question: When did large-scale moai construction end, and what environmental, societal, or colonial pressures best explain the timing of decline and cessation? Past archaeological work has shown that Rapa Nui experienced rapid deforestation, environmental degradation, a drought-prone climate, and nutrient-poor soils while also undergoing significant social and demographic shifts following European colonization. The chronology of moai construction remains unclear but the timing is central to understanding why construction ceased. The purpose of this study is to re-analyze existing obsidian hydration dates from the platforms and rampsof religious structures (ahu) to refine the construction chronology. The dates from each ahu are used to generate summed probabilities distributions (SPD) of peaks and troughs in ahu construction between AD 1200 and AD 1850. SPD plots graphically illustrate the phases of construction over this time range. By comparing the chronological patterns generated by SPD plots with the island environmental and colonial history, the study will attempt to identify if the cessation of ahu construction aligns with ecological stress, agricultural decline, or post-contact population decrease due to the introduction of diseases.

Abstract Name: Tracking Invasive Mystery Snail Movement and Growth at Presque Isle State Park

Chinese mystery snails (*Cipangopaludina chinensis*) are an aquatic invasive species introduced to Lake Erie. Identified by its operculum, spherical shell, and large size, these snails jeopardize local biodiversity by disrupting nutrient cycling, altering the food web, and outcompeting native species. However, little is known about their movement, growth, and dispersal patterns. Leveraging an ongoing transect-based mark-recapture study at Presque Isle State Park, snails were captured, marked with a unique identification code, measured, and returned to their original location. Sampling occurred for three one-week sampling periods in July and August 2025. Of the transects with recaptured snails, 8 of 14 showed a 100% recapture rate, indicating limited snail movement (<5-10 meters). The most movement occurred in Thompson Bay, with 50-67% of snails moving between transects. One snail moved from Leo's Landing to Graveyard Pond between 2024 and 2025. Average snail size also showed significant variation between locations. Snails at Thompson Bay ($46.8\text{mm} \pm 4.25\text{mm}$) were significantly larger than those in Graveyard ($42.5\text{mm} \pm 3.60\text{mm}$) and Lily Pond ($41.0\text{mm} \pm 1.26\text{mm}$), and snails at Feather Platform ($47.2\text{mm} \pm 3.60\text{mm}$) were significantly larger than those in Lily Pond. Due to the limited number of recaptures, robust statistical comparisons of growth between locations could not be performed. These findings suggest that, in general, Chinese mystery snails exhibit minimal movement. However, variation in movement and size across locations suggests that small-scale environmental factors, such as sediment type or vegetation, may influence the life history of Chinese mystery snails. These factors could be further investigated to develop more effective removal strategies, mitigate spread, and predict snail dispersal, thereby facilitating effective management.

Abstract Name: Developing a Non-Western Culture Aware AI Application

Most artificial intelligence models are trained predominantly on Western datasets, resulting in responses that often miss cultural nuances, misinterpret context, or provide inappropriate recommendations for non-Western users. Also, the language models are trained on English-heavy web data, resulting in weaker performance for many non-Western languages and cultures. Multilingual benchmarks show strong English scores but clear drops in other languages, indicating a systemic imbalance rather than isolated bugs. Research in massively multilingual MT shows these gaps can shrink when models and data prioritize low-resource languages. Recent research acknowledges cultural bias in AI systems. However, most solutions focus on post-hoc bias detection. They are not focused on incorporating cultural knowledge when building the AI application. Our goal is to build an open-source production application that centers non-Western languages by developing a Retrieval-Augmented Generation (RAG) based web application that would be made freely available for everyone. RAG systems have demonstrated effectiveness in domain-specific applications. However, less work has been done on building RAG applications trained on non-Western cultural data.

Abstract Name: Does habitat occupancy correlate with prey availability for a declining raptor? Insights from a novel acoustics and road-survey monitoring method

The American Kestrel (*Falco sparverius*), a threatened bird of prey, is found throughout North America. Kestrels are a generalist species which are able to exploit different prey types, including small birds, small mammals, insects, reptiles, and amphibians. In turn, this allows kestrels to occupy several different habitat types, although they are typically associated with open-country habitats. However, this species is experiencing idiosyncratic declines across its range, with one of the potential causes being loss of quality habitat. Thus, a study was conducted in Richmond and Highland County, Virginia during summer 2025 to assess kestrel habitat occupancy and prey abundance, which is correlated with habitat quality. Our team conducted road surveys to assess kestrel habitat occupancy and utilized acoustic monitoring to determine the abundance of singing prey types (i.e. songbirds, orthopterans) across the two ecoregions. A total of 25 kestrels were detected, all of which were found in the agricultural pastures of Highland County. Additionally, acoustic monitoring detected 85 songbird species and 18 orthopteran species between the two ecoregions. These data were used to explore the relationships between habitat type, singing prey abundance, and kestrel occupancy across the two ecoregions, providing insight into habitat selection and territory quality for this declining species in Virginia.

Abstract Name: How Round Goby Affect Native Fish Communities in Pennsylvania Tributaries to Lake Erie

Lake Erie and its tributaries are home to an abundance of native species that maintain aquatic ecosystem health. Invasive species can cause irreversible ecological damage to these same aquatic communities, with the round goby (*Neogobius melanostomus*) being a prevalent example in the Great Lake region, especially in Lake Erie. Beyond the presence of round goby in the main lake, little is currently known about their effect on connecting tributary systems and the delicate ecosystems they contain. Analysis of four major Pennsylvania tributaries to Lake Erie (Raccoon Creek, Elk Creek, Walnut Creek, and Cascade Creek) has revealed the effect round gobies have on native fish species in a tributary setting. Indexes of Biotic Integrity and redundancy analysis tests show trends that the presence of round goby negatively affects native fish community assemblages, but not at a statistically significant level as of now. This is shown through native species of similar ecological niche and diet to the round goby being outcompeted and displaced in turn. This negative influence is more profound with higher round goby densities in certain sampling sites. This baseline survey of Lake Erie tributaries presents novel data, underscoring the potential significant ecological threat round goby could pose to tributary ecosystems in the near future.

Abstract Name: The Hidden Gap: Exploring Barriers in the Oncology Transition for Black Childhood Cancer Survivors

Black childhood cancer survivors face persistent inequities as they transition from pediatric oncology to adult-centered care, a period already recognized as one of the most vulnerable points in the survivorship journey. Despite major advances in survivorship care, Black survivors continue to experience higher rates of treatment-related complications, lower follow-up adherence, and greater barriers to long-term support. Emerging evidence suggests that family perceptions, structural racism, medical mistrust, and limited culturally responsive communication significantly influence the quality and success of this transition. The purpose of this project is to examine the family-identified barriers, psychosocial challenges, and systemic factors affecting Black childhood cancer survivors as they move from pediatric to adult oncology care. This research was developed during an 8-week Summer Research Fellowship at the University of California-Irvine under the mentorship of Dr. Michelle Fortier and Dr. Dawn Bounds. Using a qualitative, equity-centered lens, peer-reviewed literature was reviewed, coded, and synthesized to identify themes related to mistrust, fragmented communication, loss of the pediatric support system, disparities in health literacy, and underrepresentation in survivorship planning. Evidence tables were constructed to map existing knowledge, identify gaps, and inform future research questions. Preliminary findings show that Black families frequently report feeling underprepared for transition discussions, uncertain about expectations in adult oncology settings, and disconnected from providers due to cultural and relational discontinuity. System-level obstacles, including insurance challenges, inconsistent follow-up coordination, and implicit bias, further compound these issues. These findings highlight an urgent need for culturally tailored transition models that support family engagement, strengthen trust, and improve continuity of care. By centering the experiences of Black childhood cancer survivors and their families, this work contributes to a deeper understanding of the disparities embedded within oncology transitions and offers direction for interventions that promote equity and long-term survivorship success.

Abstract Name: Tracking Chlamydomonas Cell Motility towards Development of a Hybrid Drug Delivery System

Drug delivery systems play a crucial role in patient care by ensuring that therapeutic compounds reach specific target areas within the body. Chlamydomonas cells have emerged as a promising candidate for use as biological drug-delivery vessels due to their natural motility and responsiveness to environmental cues. These unicellular algae possess two flagella that enable them to propel through fluid environments with measurable strength and speed. Understanding the mechanics of their movement is essential for developing engineered cells capable of navigating toward tumor sites. Tracking the motility of untreated Chlamydomonas cells provides baseline information about their natural behavior, which can later be compared to drug-loaded or light-guided cells to assess how modifications influence their movement and targeting efficiency. The goal of this study is to create a baseline for how Chlamydomonas cells move by culturing cells, capturing images of cells, using tracking algorithms to collect data on the velocity and direction of the cell, and produce a readable and comparable data visual for future research.

Abstract Name: A Narrative Review of Outcomes Involving Ethnic-Racial Identity in Early Childhood

Ethnic-racial identity (ERI), which involves awareness, affiliation, attitudes, behaviors, and knowledge about one's ethnicity/race(s), is a vital factor in children's development, as it may determine how they navigate through various life experiences (Williams et al., 2020). Research has shown that ERI is a protective factor against negative experiences that may be present in individuals' lives, however, limited work has examined these processes among young children. A recent review focused on how parents talk about race during early childhood (i.e., ethnic-racial socialization; Hall et al., 2025), but few recent reviews have been conducted on ERI during this developmental period. Thus, the goal of the current review was to explore literature examining the impacts of ERI development on outcomes, specifically in early childhood. Inclusion criteria for the search was that articles had to include a sample of children in early childhood (i.e., 2 to 7 years of age) and at least one component of ERI. The search yielded limited articles on this topic, but across the articles results indicated that the components of ERI that have been studied have positive effects for children. For example, children with greater ERI private regard (i.e., how one feels about their race and identity) demonstrated higher levels of self-esteem and perceived social support (Tyrell, 2019), and ERI centrality (i.e., the importance of one's race is to their self-image), predicted better mental health (Tyrell, 2019). Other work found that ERI positive attitudes, negative attitudes, and centrality predicted children's improved social functioning (Williams et al., 2022). ERI has also had protective effects against behavior issues (Marcelo, 2019). Overall, findings can be useful for educating parents and caregivers about the importance of having open racial conversations with their children and encouraging ERI development in early childhood.

Abstract Name: Dietary Patterns and Adolescent Well-Being in Rural North Carolina

Research on the relationship between dietary patterns and well-being has expanded rapidly in recent years. This study contributes to previous work by examining how diet relates to well-being among rural middle school students in North Carolina, with an average age of 12. Two indicators are used to measure youth well-being at an individual level: self-reported academic performance and perceived stress levels. Students' diets are categorized as healthy, unhealthy, or neutral, and we construct a health index to capture differences across these dietary patterns. Our analysis draws on cross-sectional data from the Motivating Adolescents with Technology to Choose Health (MATCH) program, a school-based wellness initiative implemented during the 2022–2023 academic year in rural North Carolina. Using a mixed-effects model, we assess the association between diet and well-being in this rural adolescent population. Results show that both healthy and unhealthy diets are significantly associated with adolescent well-being, though the magnitude of these associations varies. We also examine potential mediating pathways and find that sleep and body weight mediate the relationship between diet and well-being. Finally, we explore whether participation in MATCH moderates the

effects of dietary patterns. Although the findings suggest that school-based wellness programs may help buffer the negative influence of a poor diet, the moderating effect is not statistically significant. By focusing on a rural youth population and evaluating a real-world intervention, this study addresses an important gap in the literature. It provides actionable insights for policies that promote adolescent well-being and academic success in underserved communities.

Abstract Name: Exploring The Role Of Zfp189-Mediated Transcription On Microglial Activity In The Prefrontal Cortex

Rationale: Microglia are brain phagocytic cells that are increasingly recognized as cellular mediators of brain and behavioral adaptations. Previous research identified ZFP189 as a transcription factor (TF) linked to stress resilience, with its overexpression in the prefrontal cortex (PFC) protecting against social deficits. Delivering synthetic TF variants to PFC, our lab demonstrated that altering ZFP189 transcriptional control impacts immune gene expression, dendritic spine morphology, and social behavior. This study aims to investigate how ZFP189-driven transcription within PFC pyramidal neurons influences microglial activity and synaptic pruning. This work may provide insight into the molecular mechanisms underlying neuroplasticity and social behaviors. Objectives: We hypothesize ZFP189-mediated transcriptional control within the PFC regulates neuronally expressed markers, which can be detected by microglia to facilitate spine pruning at manipulated neurons. Methods: Male and female C57BL/6J mice (8-10 wks old) from JAX Labs were used. Stereotaxic surgery was employed to virally deliver synthetic transcription factor variants to the PFC. Three days following surgery, mice were perfused and brains were removed and postfixed in 4% paraformaldehyde. Following postfix, whole brains were cryoprotected, flash frozen, and 20µm slices of the PFC were obtained for each brain. Tissues underwent immunohistochemistry to stain for IBA-1, a microglia-specific ionized calcium binding adaptor protein, and GFP; co-expressed with our synthetic transcription factors. Tissues were mounted and imaged using a Keyence BZ-X810 microscope. Microglia were analyzed both proximal and distal to transduced pyramidal neurons using ImageJ software for Sholl analysis. Results: Preliminary results from Sholl analysis suggest differences in microglial morphology based on both ZFP189 TF variant and animal sex. Continuing analysis of data using Sholl and statistical analysis using one-way ANOVA or area under the curve may provide a deeper insight into the activity of microglia in relation to ZFP189 transcriptional modulation in the PFC.

Abstract Name: Efficacy of Presaturation for Controlling the Effects of Expansive Soil Below Slab-On-Grade in Southern California

Expansive soils containing clay minerals are highly prevalent worldwide across diverse geological and climatic environments. The presence of these clay minerals gives rise to the physical properties of expansive soils, which undergo expansion when wet and shrinkage when dry. These volume changes can be highly problematic for lightly loaded foundations, such as concrete slab-on-grade systems. In California, the effects of expansive soils can be further exacerbated by prolonged drought followed by excessive wetting from irrigation or intense rainfall. Mitigation of expansive soils requires low-cost treatment methods due to the relatively low construction cost of slab-on-grade foundations. One cost-effective technique used to reduce swelling is presaturation, which involves wetting expansive soils to induce heave prior to construction. However, the practice of presaturation in California has evolved largely from empirical evidence of successful site applications, and therefore lacks a rational, standardized methodology that extends beyond local practice. This study aims to evaluate the efficacy of presaturation beneath slab-on-grade foundations in two parts. The first part evaluated professional opinions on presaturation to gather a consensus on the California state of practice through local interviews and a statewide online questionnaire. The surveys identified key topics such as identification of expansive soils, presaturation recommendations, literary resources, construction techniques, measurement and verification, and cases of success and/or failures. California professionals were in agreement that presaturation offers a successful treatment of expansive soils, while a minority disagreed. The second part of the study tested a hypothesis for a rational approach to presaturation based on degree of saturation, expansion pressure, and the wetting process. Data from other studies were evaluated to determine the increase in in-situ moisture content and depth of saturation required to minimize volume change. This information supported the design of a step-by-step procedure for determining the effectiveness of presaturation for slab-on-grade.

Abstract Name: Public Infrastructure and Sustainable Development: Evidence from the Padma Bridge in Bangladesh

Public infrastructure plays a central role in shaping development outcomes, especially in emerging economies where improvements in mobility can transform economic and social conditions. This study examines the Padma Bridge in Bangladesh through the Sustainable Livelihoods Framework (SLF), which evaluates change across five forms of capital: human, social, natural, financial, and physical. In this context, the bridge represents a major expansion of physical capital with the potential to influence livelihoods across the region. The analysis uses two World Bank datasets from 2013 and 2022 to compare conditions before and after the bridge's construction. A difference-in-differences approach will help identify how the project may have affected trade activity, regional investment, mobility patterns, and access to essential services, isolating changes that coincide with the bridge rather than broader national trends. The goal is to offer a grounded, case-based understanding of how a large infrastructure project can affect multiple livelihood dimensions and to provide evidence that supports more informed planning in developing economies.

Abstract Name: Glucosylceramide Transferase and Cyst Wall Biogenesis in *Giardia lamblia*

Giardia lamblia is a waterborne protozoan that survives outside the host by forming environmentally resistant cysts that are essential for transmission of Giardiasis. Encystation is a tightly regulated differentiation process characterized by diverse molecular dynamics in gene expression, including changes driven by glucosylceramide transferase (GlcT1), an enzyme central to lipid metabolism. Giardial GlcT1 (gGlcT1) contains two catalytic domains, i.e. Ceramide glucosyltransferase (CGlcT) and ceramide galactosyltransferase (CGalT) that mediate the synthesis of glucosylceramide (GlcCer) and galactosylceramide (GalCer), respectively. This study investigates the role of gGlcT1 in *Giardia* encystation by examining its potential regulatory influence on five key interacting partners involved in encystation and chromatin-related processes: *cwp1*, *cwp2*, *cwp3*, *myb2*, and *hcmp*—a high-cysteine-rich membrane protein implicated in chromatin remodeling. We studied the expression of *cwp* genes and monitored cyst development following gGlcT1 silencing, targeted mutation, or enzymatic inhibition to assess how lipid metabolic pathways contribute to the encystation program. Disrupting gGlcT1 activity led to a verified reduction in CWP synthesis and resulted in defective cyst formation. These defects included irregular cyst wall morphology, decreased wall thickness, and compromised structural integrity, indicating that proper glycosphingolipid metabolism is essential for cyst wall biogenesis. While *cwp1–3*, *myb2*, and *hcmp* were included as interacting partners of interest, only CWP expression changes were experimentally confirmed in this study. The involvement of the additional genes remains a focus for future investigation. Overall, the findings identify gGlcT1 as a critical regulator of *G. lamblia* encystation, linking lipid metabolic processes to the structural pathways that drive cyst formation. This study provides new insights into protozoan differentiation and environmental survival while highlighting lipid metabolism as a potential therapeutic focus.

Abstract Name: The β -catenin/Liver X Receptor Axis Regulates Cholesterol Metabolism and Inflammation in Murine Cholestasis

Introduction: Primary sclerosing cholangitis (PSC) can result in retention of toxic bile acids (BA) within hepatocytes leading to cell death, inflammation, and fibrosis. Lithocholic acid (LCA) is a BA associated with adverse clinical outcomes in PSC; however, studies focusing on therapeutic interventions that target this toxic

BA are lacking. We hypothesize that β -catenin, which has been shown to regulate BA homeostasis, may reduce LCA-induced cholestasis. Methods and Results: Liver-specific β -catenin knockout mice (KO) and wild-type littermates were fed 0.6% LCA supplemented diet for 7 days. KO had a remarkable reduction in bile infarcts and hepatobiliary injury, as shown by histology and serum biochemistry. In the absence of β -catenin, xenobiotic metabolic pathways including pregnane X receptor (PXR) were activated, resulting in decreased serum hydrophobicity in KO. Additionally, loss of β -catenin increased HNF4 α occupancy of the oxysterol-activated liver X receptor (LXR) promoter in KO, resulting in the upregulation of downstream targets that regulate cholesterol metabolism and transport in hepatocytes. Conversely, LXR activation also repressed expression of inflammatory genes, such as IL-33 and ST2, which in turn decreased recruitment of disease-exacerbating type 2 innate lymphoid cells (ILC2). Conclusions: PXR- and LXR-mediated processes such as regulation of BA composition and cholesterol metabolism are enhanced by loss of β -catenin during LCA-induced cholestasis. Additionally, inhibiting β -catenin suppresses the inflammatory response by downregulating the LXR/IL-33/ST2/ILC2 axis. Taken together, these data demonstrate a newly-identified β -catenin-dependent mechanism for attenuating hepatic injury in patients with cholestasis.

Abstract Name: Evaluation of a Modular Raspberry Pi–Based Weather Station for Real-Time Environmental Monitoring

Pollution driven by industrial activity and urbanization poses a significant and often unnoticed threat to public health through the gradual accumulation of pollutants. Miami Dade College's Wolfson Campus is currently located at the center of a major construction zone, where constant development increases the likelihood of hidden environmental impacts. As a result, individuals in the area may experience negative health effects over time without realizing that everyday exposure is contributing to these issues. These conditions highlight the need for active environmental monitoring and greater awareness of how urban pollution affects surrounding communities. This study investigates the feasibility of using a modular Raspberry Pi platform to conduct real-time environmental monitoring and to evaluate whether such a system can serve as a low-cost complement to commercial weather stations. The research will evaluate the utilization of several compatible sensors, including temperature, humidity, pressure, and particulate matter sensors, controlled through customized Python code. The Raspberry Pi–based monitoring system will be strategically deployed at different locations around the Wolfson Campus for environmental relevance, collecting data across multiple time intervals. Sensor readings will be compared with publicly available environmental databases to assess the effectiveness of real-time monitoring and remote data access using open-source software tools. Ultimately, this study will help identify which sensor configurations offer the most reliable performance and provide insight into the practical trade-offs between affordability, accuracy, and long-term stability. The results of this research will be discussed in relation to the system's practicality for campus-based environmental monitoring and its potential use as a low-cost tool in broader urban settings.

Abstract Name: The Impact of Polyamine Depletion on Macrophage Polarization and Phagocytic Ability

Ovarian cancer remains difficult to treat, in part due to the immunosuppressive tumor microenvironment that impairs the immune system's ability to eliminate cancer cells. Macrophages within this environment often adopt an M2-like phenotype, characterized by reduced pro-inflammatory activity and altered phagocytic function allowing for tumor escape. Phagocytosis, the process by which macrophages engulf and eliminate cellular debris, pathogens, or tumor cells is a key mechanism of immune surveillance that can be compromised in the tumor setting. Previous work from our group has shown that polyamines, essential molecules involved in cell growth and immune regulation, are elevated in the tumor microenvironment and their depletion leads to an increase in M1 macrophage markers and a decrease in M2 macrophage markers in the ascites fluid of a murine ovarian cancer model. Current experiments are evaluating if this is a polarization switch or a change in immune recruitment in vivo. In this study, we investigated if polyamines are capable of influencing macrophage behavior in vivo, including their phagocytic ability. To investigate how polyamine depletion affects macrophage phagocytosis, THP-1-derived macrophages and mouse RAW264.7 macrophages were treated with polyamine depleting drugs, DFMO and ivospemin, and then challenged with FITC-positive IgG beads and analyzed by flow cytometry. Polyamine depletion increased the phagocytic capacity of both cell lines and supports the broader hypothesis that polyamine depletion supports an M1-like phenotype. Ongoing experiments are evaluating changes in M1/M2 related genes in these cell lines following polyamine depletion. My results provide insight into the potential of polyamine depletion to restore or enhance macrophage phagocytic function in the context of ovarian cancer and other difficult to treat cancers.

Abstract Name: Functional and Microbial Analysis of *Candida albicans* Colonization in Women from Stockholm, Sweden

Candida albicans is a common yeast species found in the human gastrointestinal and genitourinary tracts. Under certain conditions, it may become pathogenic, leading to long-term complications and heightened vulnerability to other infections. Chief among these are vulvovaginal candidiasis (VVC) and recurrent vulvovaginal candidiasis (RVVC). These infections affect millions worldwide, causing chronic pain, stigma and lost productivity. An estimated 75% of women globally will experience VVC in their lifetime, and 5-8% will experience RVVC, defined as three or more episodes within a year. Treatment is lengthy and often unsuccessful, as guidelines dictate more than six months of antifungal therapy, yet over half relapse. To better understand the mechanisms by which *Candida albicans* disrupts mucosal homeostasis and predisposes individuals to secondary infections, we looked at immunohistological analysis of vaginal biopsies from a cohort of Swedish women and profiled epithelial junction proteins and immune cell infiltration to compare two treatments: fluconazole, the gold standard oral azole, and chlorhexidine, an emerging novel compound used in antiseptics. We hypothesize that *C. albicans* may alter mucosal integrity and immune responses, and these treatments may reduce *C. albicans* presence, leading to an overall healthier vaginal microbiome and recovery of mucosal integrity and immune balance. Using metagenomic and shotgun sequencing, we aim to identify functional and microbial pathways and determine which specific species perform these functions. By integrating host and microbial datasets, we seek to reveal key molecular signatures associated with treatment response and mucosal health. This will allow us to identify how antifungal treatments modulate host-microbe interactions and guide the development of more effective, targeted therapies for VVC and RVVC.

Abstract Name: TRANSATLANTIC MARRIAGES IN THE GILDED AGE: CONSUELO VANDERBILT'S TRANSFORMATION FROM DEBUTANTE TO DUCHESS

Between 1865 and the onset of World War I, wealthy American women increasingly married titled European men, creating a stereotype of the glittering American heiress marrying into British high society. These marriages played a critical role for both parties: the newly moneyed elite asserted its claim to social status, and depleted European nobility regained the funds so essential to their longevity. By 1915, 454 American heiresses had married into the European aristocracy. In one famous example, Consuelo Vanderbilt was forcibly wed to the ninth Duke of Marlborough. As the Vanderbilt family labored to assimilate themselves into old-money New York society, the opportunity to tie their family name to English nobility could catapult the ambitious clan to the social ladder's apex. Alva Vanderbilt invited Charles Richard John Spencer-Churchill, the ninth Duke of Marlborough, to visit her summer home in Newport, Rhode Island. There, he met her daughter Consuelo, his unwilling bride-to-be who was already happily engaged to the man she truly loved, Winthrop Rutherford. Consuelo, through her mother's insistence, married the Duke at St. Thomas' church in New York City. She was immediately relocated to the Blenheim Palace in England, a historic home in desperate need of repairs that Alva's millions were to supply. Their unhappy marriage ended with divorce in 1920. Consuelo's tragic story mirrors that of dozens of others: a young American heiress becoming a bargaining chip between a wealthy American family and a struggling European aristocrat.

Abstract Name: Civil Engagement and Health in American Indians: Frequency of Different Factors in Relation to Civic Engagement.

This presentation explores the relationship between Native Americans and civic engagement. Native Americans are notoriously underresearched in regard to mental health and preventative measures. Civic engagement has been shown to have a positive bidirectional relationship with mental health and shows a potential focus area for the indigenous community. Creating relationships and forming a community is an important step to further build the indigenous culture. Thus, survey responses of the barriers, motivations, and the impact on well-being of Native people when they engage in civic engagement were collected and explored to develop new interventions or support for indigenous people and to improve the rate at which civic engagement is performed. Participants were surveyed on the challenges or barriers to civic engagement, and we discuss why time constraints were the most prevalent response. Additionally, we look at the motivations for civic engagement and discuss why family and community were indicated most frequently. Native people face many modern-day challenges, and a multi-faceted response is critical. Civic engagement is one avenue that appears beneficial and is an important component in the conversation about improving mental and physical health in indigenous people.

Abstract Name: Histological Assessment of Neuropathic Pain in Murine Nervous Tissue

Neuropathic pain is a symptom that occurs often in people with diabetes, multiple sclerosis, and HIV/AIDS. It is difficult to treat however, since the pain results from damage to the central nervous system. Gliosis and demyelination are the two most prominently seen changes to central nervous tissue. Current models of neuropathic pain in mice make studying difficult, since the methods are very invasive and require extensive training; ligation of the sciatic nerve and the T4 and T5 spinal nerves are the most common procedures in modern medicine. However, it has been shown that formalin can potentially induce chronic pain (pain lasting over two weeks from one injury) in mice, as it has been successfully induced in rats. Therefore, our experimental goal was to establish a formalin-induced model of neuropathic pain in mice for an easier and quicker alternative to the standard surgical methods. To do this, mice were injected with 5% formalin subcutaneously into the dorsal side of the hind paw and observed for a two-week period with mechanical and thermal tests. After 14 days, the mice were euthanized. Brains and lumbar spinal cords were collected, and tissue was prepared for histological processing to be cut with a cryostat. The slides created were stained with Hematoxylin & Eosin and were observed for any visible changes in the tissue between the control mice and injected mice. Gliosis and demyelination were observed in only the experimental mice, indicating that neuropathic pain was present due to the formalin injection. The results of this study open new means to research neuropathic pain without invasive surgeries. This will allow more research to be easily done to aid patients who suffer and have little to no treatment available. With this research, it is possible to get closer to the cure for chronic pain.

Abstract Name: Platinum-Decorated Carbon Nitride as a Mott-Schottky Photocatalyst for Efficient CO_x-free Hydrogen Production from Methanol

As the global demand for sustainable and efficient energy sources increases, hydrogen has emerged as a promising energy carrier due to its high energy density and clean conversion in fuel cells, producing only water as a byproduct. However, challenges in hydrogen storage and transportation hinder its widespread adoption. Methanol represents a practical hydrogen carrier because it can be readily integrated into existing fuel infrastructures. The efficient release of hydrogen from methanol relies on an active and stable methanol dehydrogenation catalyst. Molten-salt carbon nitride (MCN) has shown potential as a photocatalyst, yet its

limited interaction with methanol molecules constrains its catalytic performance. To enhance these interactions and improve photocatalytic activity, in this work, a Pt₁₃ cluster is incorporated into MCN to generate a Pt₁₃@MCN Mott-Schottky photocatalyst. We use Density Functional Theory (DFT) in VASP to optimize the structures of MCN, Pt₁₃, and methanol-based molecules including CH₃OH and CH₂O, along with composite systems including Pt₁₃@MCN-CH₃OH and Pt₁₃@MCN-CH₂O. We examine how charge distribution changes before and after adsorption to better understand the catalytic mechanism. Through computational comparison of Pt₁₃@MCN and pure MCN, this work offers a theoretical understanding of how Pt incorporation on MCN influences adsorption, charge transfer, and the reaction energy in methanol dehydrogenation.

Abstract Name: The Fight For Sex Ed: Battles Over Sexual Morality During the HIV/AIDS Epidemic

As one of the paramount health crises of the century, the HIV/AIDS epidemic in the United States provoked a multitude of conflicting responses from government officials and activist citizens alike. This produced rapidly increasing tensions between sexual abstinence education pushed by the Religious Right and the urgent need for HIV prevention education. Dialogue surrounding sex education throughout the 1980s shows the extreme diversity in ideas about what should be taught, how, and by whom. This research examines how and the extent to which debates sparked between key groups and figures transformed sex education during the HIV/AIDS crisis. As standards of sex education are still under scrutiny today, this research is impactful because it gives the basis for understanding why comprehensive programs face opposition and stigma. Methods include mixed-media research conducted through the lens of historical analysis, utilizing primary and secondary sources such as newspaper articles, advertisements, and peer-reviewed journals. The debates over safe sex led to community activist efforts and new conversations over condom usage, inextricably intertwining the pivotal ways in which key players and groups set the parameters of promoting sex education. I argue that through these means, the various discourses between scientists, activists, and the government created a paradox that often contradicted not only the “opposition,” but notions within their own groups.

Abstract Name: Reintegrating the River: Sope Creek Mill as the Site for Reviving the Connection to the Chattahoochee River

What environmental feature does San Antonio, Chicago, and Atlanta have in common? Despite their radically different urban cultures, these cities are all built around rivers! As anthropologists have shown, rivers are foundational to the creation of human settlement, and many cities design their urban fabric to interact with their respective rivers. Despite the scale of the Chattahoochee River, a visitor of Atlanta might not see the river as it is covered with highways and other infrastructures. Since the inception of colonial Atlanta as a

railroad town in the nineteenth century, the urban design deviated from having the rivers be central to the city's evolution, as scholarship shows. There was still an existing relationship with its rivers when waterways played essential roles in the economy as power sources for industrial mills. Once the economic use of mills declined, the relationship with rivers also fizzled out. This broken ecological relationship can be seen through the rise and fall of mills as a once-important part of Atlantean landscape. One such mill was Marietta Paper Mill on the Chattahoochee River that was once a booming economic source that lays abandoned today. These ruins symbolize the current relationship that the people of Atlanta have with rivers. This research design project brings into light the fraught relationship between Atlanta and its rivers. How can architectural interventions transform Sope Creek Paper Mill ruins to reconnect the broken ecological relationship between the Chattahoochee River and people into the urban fabric of Atlanta? This design research explores adaptive reuse of the Sope Creek Paper Mill as a technique to revive the connection between people and the Chattahoochee River. By reprogramming the Sope Creek Paper Mill and restoring the space, people who are not just hikers would interact with the space and establish their connection to the Chattahoochee River.

Abstract Name: Shifting Grounds: The Influence of Political Environments on Refugee Resettlement Policies in Germany and the United States (1975-2025)

This research project investigates the evolving impact of political environments on refugee resettlement policies in Germany and the United States (U.S.) over the past five decades. By tracing policy developments from the mid-1970s to the present, the study examines how domestic political dynamics—such as party ideologies, public opinion, and institutional structures—have shaped national responses to global refugee movements. The comparison of the two countries' approaches offers insights into how liberal democracies balance humanitarian obligations with political constraints. The study explores the Germany's post-World War II refugee reception policies, the influences of European Union directives, and political ramifications of the 2015 refugee crisis. It examines the influence of shifting coalitions, rising populism, and debates over national identity on asylum procedures, integration programs, and border enforcement. The research also focuses on the interplay between U.S.' federal and state-level policies, roles of presidential administrations, and impact of security concerns—particularly post-9/11—on refugee admissions and resettlement infrastructure. It also considers the influence of advocacy networks and religious organizations in shaping outcomes. The project draws on archival research, legislative records, policy documents, and interviews with policymakers and practitioners. It incorporates quantitative data on refugee admissions and qualitative analysis of political discourse to assess how narratives around refugees have evolved. The study identifies key inflection points—such as the end of the Cold War—that prompted significant policy shifts and public debate. The research contributes to deeper understandings of political environments mediating the implementations of refugee resettlement policies. It argues that while both Germany and the U.S. have institutional commitments to refugee protection, their policy trajectories are shaped by domestic political pressures and strategic interests. The findings have implications for current debates on refugee governance, democratic accountability, and the resilience of humanitarian norms in an era of rising nationalism and geopolitical uncertainty.

Abstract Name: Free Enterprise under Two Regimes: Tribal vs Commercial Casino Regulations

This project explores how different rules and regulations shape the performance of casinos in the United States by comparing tribal casinos (built on reservations) with commercial casinos. Both kinds of casinos compete for the same customers, but they often face different tax rates, regulatory requirements, and agreements with government agencies. These differences provide a useful setting to ask a central question in free enterprise: when the rules of the game change, does the market behave differently? To answer this, I plan to collect data on casino revenue, employment, and size (such as number of slot machines and table games) for tribal and commercial casinos that operate in the same or similar regions. I will then compare how well these casinos perform after accounting for local factors such as population, income, and tourism. If casinos operating under lighter tax or regulatory burdens consistently earn more per casino or per game, this would support the argument that less restrictive rules encourage investment, expansion, and competition. On the other hand, if performance is similar across regimes, it may suggest that market forces and consumer demand matter more than regulation in this industry. The goal of this project is to provide evidence that can inform discussions about the proper role of government in markets like gaming, and to offer a concrete case study of how different institutional frameworks can affect businesses, workers, and consumers.

Abstract Name: Discussing Barriers for Undergraduate Students to Participate in Research Experiences

The Office of Undergraduate Research (UgR) at West Virginia University (WVU) connects undergraduates with research opportunities. Every semester, hundreds of students express their interest in these opportunities through a widely publicized Interest Form (IF). However, only a fraction of these students proceed with the process of being matched with a faculty research mentor and participating in a structured research experience. Research experiences are known to positively impact students' persistence in college and the advancement of their careers. Therefore, we aim to identify and address potential barriers that prevent undergraduate students from following through with the process of getting involved in research. We collected data from IFs over four consecutive semesters to identify specific stages in which students stop the enrollment process in the UgR program. Additionally, we wanted to identify specific groups of students by major who were more likely to discontinue the process to develop targeted recruitment strategies for these groups.

Abstract Name: Perceived Unfair Treatment and Access to Dental Care Among Latin* Adults in Rural Southwest Virginia

Latin* people face significant oral health disparities across the life course as evidenced in higher oral disease rates and lower dental utilization rates than their counterparts. While the majority of studies have focused on the role of acculturation in driving these oral health disparities, less attention has been placed on the role of structural drivers such as discrimination. To address this gap, this study determined the distribution of perceived unfair treatment towards the self and observed towards others due to ethnicity, across dental care utilization status among Latin* adults residing in rural Southwest Virginia. Adults were invited to participate in an online survey administered via REDCap in either English or Spanish, consisting of 80 questions. This substudy focused on questions related to sociodemographics, dental care utilization, and unfair treatment, to self or towards others, attributable to ethnicity. Data analysis was limited to descriptive statistics generated for sociodemographic characteristics overall and perceived unfair treatment by dental care utilization status. Ninety-one Latin* adults enrolled in the study, of which the majority were female (70.3%%), over the age of 30 (63.7%), with more than a high school level of education (42.9%). Almost three-quarters of participants reported not having dental insurance (71.4%) and only 40.7% reported having utilized dental care in the past year. The majority of participants reported having experienced unfair treatment towards the self (73.6%) or observed towards others (73.5%). Among those that reported not attending dental care in the past year, 79.4% experienced unfair treatment and 75.9% witnessed unfair treatment towards others. Findings reveal a large proportion of Latin* individuals in rural Southwest Virginia have experienced unfair treatment towards the self or observed towards others due to ethnicity. Further research should explore how psychosocial stressors influence access to dental care and oral health status for minoritized ethnoracial groups.

Abstract Name: Analyzing The Regional Depository of Nasal Spray Medication in Adults vs. Children

Nasal sprays are a common form of medication that are prescribed to patients of all ages, children included. While general nasal sprays are considered effective, they lack specific dosage amounts specified for adults and for children. Apart from that, the nasal structure of adults differs from children. There have been studies done to explore the regional deposition of locally acting nasal sprays in adult nasal geometries. Other studies have revealed that medications administered intranasally to children are not as effective. The question that is left unanswered is whether the effectiveness of nasal sprays differs between adults and children, who have different nasal structures. Anatomically realistic in vitro nasal models of adults and children, three children and three adult, were used to analyze how different spray models perform in delivering their intended product through the nasal passage into five areas of interest. Three distinct nasal spray products were used on the in vitro nasal models under repetitive controlled experiments that carefully measured the angle at which the nasal spray is applied and the depth of insertion of the nasal spray. The experiments aim to shed light on specifically how much of the drug is delivered during a single spray into each of the five areas of interest. Doing so will reveal key information on the difference in drug delivery between the nasal models of children and those of adults as well as highlight other factors that tend to have an effect on the regional deposition of the drug through the nasal geometries.

Abstract Name: Archiving Black Madness: Race and Psychiatry in the Asylum Era

American psychiatry has a long history of racializing its subjects. From Samuel Cartwright's coining of drapetomania, Negritude and Dysarthria aethiopica, to the overdiagnosis of schizophrenia in Black communities exacerbated during the civil rights movement, psychological sciences have cultivated Black distrust. While contemporary research has established disproportionately poor treatment of Black patients across several metrics, we lack a complete historical perspective on the development of these racializing systems. This project explores the varied archival access to asylum histories in the United States, and how archival silences impact the history of Black mental health. I employ a mixed-methods approach to address this gap. First, locating and mapping Black-serving asylums to illustrate the ways they worked in larger hospital systems rather than as individual institutions as previous research suggests, and to quantify the impact of the asylum era on Black populations. Secondly, I will survey contemporary archival stakeholders (including researchers, descendants, former patients and archivists themselves) on what archival access issues they've encountered, and what policy changes they would like to implement. Lastly I will engage in a case study of the Texas State Hospital system, leveraging local resources to document the experience of performing historical research on Black patients. In doing so, I hope to create a macro history of the Black patients in the asylum era, contextualizing previous research and offering the foundation for further work into the development of racial-psychological rhetorics.

Abstract Name: miRNA Inhibition as a Universal Therapeutic Strategy for Treating Cystic Fibrosis

Cystic Fibrosis (CF) is a devastating genetic disease that affects over 100,000 people worldwide. The disease is caused by mutations in the CFTR gene, which encodes a chloride channel important for normal pulmonary function. Recent treatments benefit approximately 90% of CF patients but leave 10% without options, and even treated patients experience persistent symptoms. Thus, a need for novel therapeutic approaches for treating people with CF. To address this challenge, we are developing a CF therapy that revolves around microRNAs (miRNAs). These small regulatory molecules suppress gene expression by binding to specific mRNAs and eliciting their destabilization and inhibiting their ability to translate their protein product. Past studies have suggested that the CFTR gene transcribes an mRNA that is targeted by several miRNAs. We hypothesized that selective inhibition of these CFTR-targeting miRNAs would increase CFTR protein expression and hence provide a therapeutic strategy for all individuals with CF regardless of the nature of the mutation(s) in their CFTR gene. This approach is feasible because miRNA-binding sites typically occur outside of the mutation-prone coding region of genes, making it a broadly applicable approach. Using algorithms for computational prediction, we identified several candidate miRNAs with high probability of targeting CFTR. Using chemically-synthesized, sequence-specific miRNA inhibitors (anti-miRs) coupled

with a CFTR reporter assay in human bronchial epithelial cell lines, we found that seven of the anti-miRs we tested significantly increased CFTR expression (by >3-fold). Further investigation revealed that some of the CFTR-regulatory miRNAs work predominantly by destabilizing CFTR messenger RNA while others suppress CFTR protein translation. We are currently examining whether a combination of anti-miRs elicits stronger CFTR upregulation than single anti-miRs. Our results show that miRNA-suppression therapy is a promising, potentially universally-applicable approach that could benefit a wide spectrum of CF patients, including those for whom treatment options are currently unavailable.

Abstract Name: Design and Fabrication of a High-Pressure Chamber for the Combustion of Synthetic Aviation Fuel Droplets

Synthetic aviation fuels (SAFs), such as farnesane (C₁₅H₃₂), offer reduced life-cycle emissions; however, their fundamental combustion behavior at elevated pressures has yet to be explored. Farnesane has significance because it can be used in diesel engines and as a certified component in jet fuel blends. This study reports the design and commissioning of a high-pressure combustion chamber (HPCC) for generating and igniting farnesane droplets and diagnosing their combustion. This apparatus will enable quantification of flame structure, burning rate, and soot formation under controlled atmospheres up to 40 atm. The study aims to examine how burning rate, flame distance from the droplet, and soot behavior change with pressure and gas composition to inform models and the practical use of SAFs. Measuring how a single droplet burns provides the key parameters used to predict spray and engine behavior, guiding the design of cleaner injectors and combustors. The HPCC is a pressure-rated chamber with optical windows for imaging diagnostics, allowing for control of pressure and gas composition. Uniform droplets are suspended on a fine fiber and ignited by a retractable heated wire to allow for robust experimentation with minimal disturbance. High-speed imaging is performed in both the color spectrum for flame observations and in backlit black and white imaging for soot formation diagnostics. Overall, this setup enables the analysis of droplet sizing, flame shape, and soot characteristics over time. This work reports the apparatus, test procedure, and preliminary results on how pressure affects burn rate, flame, and sooting dynamics. Higher pressure is expected to increase the burning rate and the intensity of soot formation. Trends are interpreted using classical droplet combustion theory and thermophysical properties of the fuel. Overall, the HPCC provides an optically accessible platform for high-pressure SAF combustion studies and reference data to improve models and guide lower-emission injector/combustor design.

Abstract Name: From Scat to Sustainability - Analyzing the Effects of River Otter Scat on Soil Properties

The North American river otters (*Lontra canadensis*) are an important environmental indicator species as they can accurately reflect the overall ecosystem's health. In addition to their role as bioindicators, river otters can positively influence soil enrichment through scat deposits. Understanding this relationship is important for

evaluating and analyzing the health at Big Break Regional Park, and other biologically diverse sites with varying levels of river otter activity. This study examined the impact of river otter scat on soil quality by comparing nutrient levels in soil collection from areas with visible river otter scat, and from control areas with a lack of river otter activity. The research question guiding this study was: How does river otter scat affect soil quality at Big Break Regional Park? Soil samples were collected from four total sites, two with confirmed river otter presence and two environmentally matched control sites. Soil was sampled at a depth of 0-10 cm, and scat samples were collected using contamination-free methods (e.g. gloves, plastic bags, and trowels). All soil samples were brought to the lab, where they were tested for nitrogen (N), phosphorus (P), potassium (K), and pH using soil nutrient testing kits. The nutrient levels from both sites were compared using visual and statistical graphs and charts. Results showed a statistically significant difference in nitrogen concentrations between the scat and non-scat sites. Soil from scat sites exhibited a nitrogen deficiency level of 1.75, whereas soils from non-scat sites showed a depletion level of 0. These findings show that river otters can contribute nitrogen level to soil, ultimately enhancing soil fertility. This study highlights the ecological importance of river otters as contributors to nutrient enrichment and soil health. The addition of organic nitrogen from the river otters is seen to support plant growth and promote biodiversity.

Abstract Name: Association Between Water Exchange Rate Across the Blood-Brain Barrier and Blood Pressure in Older Adults

It is well known that high blood pressure is a risk factor for Alzheimer's Disease (AD) and dementia. Recently, it was found that the function of the blood-brain barrier is compromised in early AD and other dementias. As adults age, the blood-brain barrier begins to dysregulate, which has contributed to neurodegenerative and cerebrovascular diseases. However, it is not clear in the literature whether the decline of the blood-brain barrier is associated with high blood pressure. The goal of this study is to assess the integrity of the blood-brain barrier in healthy older adults using non-invasive neuroimaging methods and to investigate its associations with blood pressure and its variability. We use diffusion-prepared pseudo-continuous arterial spin labeling (dp-pcASL) to measure water exchange rate across the blood-brain barrier. This new technique quantifies the water diffusion across the capillaries in the brain and has shown that decreased water exchange rate is associated with declined cognitive ability in older adults. With the current study, we hypothesize that increases in blood pressure are associated with decreases in the water exchange rate across the blood-brain barrier. Based on the dataset that is being actively compiled, we collected dp-pcASL data from 29 older adults (ages from 60 to 80). We ran partial correlation analyses between blood pressure measures and water exchange rates when controlling for age. We observed that elevated mean arterial pressure in the supine posture was associated with reduced water exchange rate. The findings of this study can contribute to the current understanding of the pathways through which high blood pressure affects neurodegenerative diseases or symptoms.

Abstract Name: Architectural Appraisal of 3D-Printed Building Models: The Ingestion of Calculus for Design Optimization Using Surface Area and Volume Analysis

In recent years, 3D printing has become an exciting tool for creating building designs that are efficient and creative. This research explores how calculus, especially concepts like surface area, volume, and moment of inertia, can improve the design and structure of 3D-printed architectural models. Using CAD software and 3D printing technology, the study will analyze how mathematical principles help optimize material use, balance, and stability in building designs. The project also aims to show how hands-on tools, such as 3D-printed models, can make complex math concepts easier to understand and more practical. Overall, this study emphasizes the strong connection between mathematics, 3D printing, and architecture, showing how calculus bridges abstract theory and real-world design innovation.

Abstract Name: Artificial Intelligence Meets Special Education: Harnessing GenAI to Improve Communication with Autistic Students

This research presents the MVP design and development process of TillyTime © 2025, an innovative GenAI-powered communication prototype aimed at supporting non-verbal and semi-verbal autistic students. Utilizing a Design Science Research Methodology (DSRM), the researchers addressed the pressing need for personalized, intuitive communication tools in special education settings, specifically for autistic students. The TillyTime prototype was designed using features to facilitate expressive language through customizable visuals, emotion recognition, and context-based interactions. The MVP prototype frontend was developed using Thunkable. Later, GenAI and a 3D interface will be integrated, employing Firebase for backend user authentication and data management. Key user interface components of the present prototype include a splash screen, a login screen, and tab navigators featuring "Feelings," "Needs," "Accommodations," "Websites," and "Settings." TillyTime holds promise as a scalable and inclusive educational tool that leverages GenAI to transform communication support for autistic learners.

Abstract Name: Beyond the Athlete: How Racialized Expectations Influence the Mental Health of Black Female Athletes

Black female collegiate athletes navigate a unique intersection of racialized and gendered expectations that profoundly affect their mental health. Central to this study is the question: How do racialized narratives about

Black women impact the mental health experiences of Black female collegiate athletes? This inquiry explores how stereotypes, particularly the “strong Black woman” trope, contribute to stress, anxiety, and isolation, while also examining the coping strategies athletes employ including reliance on support systems, self advocacy, and acts of resistance. Guided by phenomenology, this qualitative study centers the lived experiences of current and former Black female collegiate athletes across diverse institutions. Data collection included a demographic questionnaire and one time semi structured Zoom interviews lasting 25 to 55 minutes with participants self identifying as Black women aged 18 or older who competed in collegiate athletics within the United States. This study employed a thematic analysis to examine how racialized narratives affect the mental health of Black female athletes. Data were drawn from seven semi structured interview transcripts conducted via Zoom. An a priori codebook guided the analysis, and AI assisted tools supported organization and pattern recognition while interpretive framing remained grounded in qualitative expertise. Grounded in Beauboeuf Lafontant’s critique of the “strong Black woman” schema and Bailey’s concept of misogynoir, this study situates Black women’s mental health within overlapping systems of oppression. Prior research, including Abrams and Lewis, emphasizes how these narratives pressure women to suppress vulnerability and discourage help seeking. Findings reveal that stereotypes such as sexualization and the “angry” label function as chronic stressors, contributing to exhaustion and guardedness. Yet community, sisterhood, and faith emerged as sources of resilience. Results inform recommendations for culturally responsive support in athletics and education, guiding institutions to foster inclusion and advance scholarship on race, gender, sport, and mental health.

Abstract Name: Electric Ducted Fan MAV Implementation Using Fused Deposition Manufacturing and Post-Processing Methods

The increased accessibility of Fused Deposition Manufacturing (FDM), also known as 3D printing, has enabled labs to research novel propulsion methods for Micro Aerial Vehicles (MAVs), also known as drones. Common alternatives to conventional open rotors, such as toroidal propellers and Electric Ducted Fans (EDFs), can minimize the vortices that contribute to significant noise pollution, an environmental concern, and cause efficiency loss in propulsion, a problem for hobbyists or research groups. EDFs can minimize wing-tip vortices by placing a wall, but unlike toroidal propellers, they can also reduce wake contraction and induce the Coanda effect, thereby increasing the system's efficiency. All of these issues can be mitigated with EDFs, but remain largely unexplored in the literature for MAVs due to the difficulty of implementation and the production of appropriate blades. With the rapid expansion of MAV use, labs, students, and hobbyists can benefit financially from manufacturing EDFs, both fans and ducts, in-house rather than purchasing MAVs fully assembled with standard propellers. This study aims to assess the efficiency gains, wake noise reduction, feasibility, and practicality of producing FDM-manufactured EDF for MAVs made in-house, while also investigating novel post-processing smoothing techniques to enhance the airflow parameters of plastic components produced via FDM, as the surface quality of 3D-printed plastics, such as Polycarbonate (PC), a plastic commonly used in regular drone fans, can be improved with acetone vapor smoothing. Ultimately, this work aims to provide a low-cost, accessible pathway to developing quieter, more efficient MAV platforms, thereby supporting students, autonomous control research, and mitigating environmental concerns associated with drone noise.

Abstract Name: The Role of Glial Cyp1 in Drosophila Larval Crawling Behavior

Drosophila larvae crawl through peristaltic waves of bodywall contractions that propel the animal forward or backward. Periodically, larvae pause, swing their head, and change their crawling direction in a behavior called a search. The Cyp1 gene encodes a putative chaperone that folds proteins. Mutations affecting Cyp1 increase searching behavior and backward crawling during larval locomotion. Glia are CNS cells that assist in neural circuit formation during development and modulate neural circuit function in mature animals. These phenotypes were also present when Cyp1 was knocked down in all glia. I aim to determine whether glial Cyp1 is required during neural circuit formation in the embryo or circuit function in mature larvae. To reduce Cyp1 expression in glia, I used RNA interference (RNAi) controlled by the GeneSwitch bipartite expression system. RNAi is produced only in the presence of RU486, and GeneSwitch enables the RNAi to be expressed exclusively in glia. By administering RU486 during embryogenesis or in third instar larvae, Cyp1 RNAi should be expressed either during circuit development or during circuit function. Larvae crawled on agar plates for 2 minutes, and their behavior was analyzed using impressions in the agarose and from video recordings. Cyp1 RNAi expression using the GeneSwitch system replicated the phenotypes observed with traditional GAL4-UAS knockdown, and RU486 feeding did not alter crawling behavior. Uninduced controls with no RU486 also showed increased backward crawling and searching, which was unexpected and likely due to background genetic effects. The glial-specific driver line that expresses Cyp1 RNAi in glia under RU486 control was located within MSP-300, a gene essential for neuromuscular function. Therefore, current work focuses on using a new inducible glial driver strain to determine whether it affects crawling on its own. If it does not, work with the Cyp1 RNAi in embryos or mature larvae will be presented.

Abstract Name: Beyond Personal Attitudes: The Critical Role of Subjective Norms in Shaping Medical Students' Willingness to Work With Older Adults

As the older adult population ages, there is a growing gap in appropriately trained healthcare professionals willing and competent to work with older adults. This study is part of a larger cross-cultural project examining healthcare students' perspectives on aging across multiple countries, including the United States. Ageism, the prejudice or discrimination based on age, has been identified as a significant factor impeding healthcare students' intention to work with older adults. Using the Theory of Planned Behavior (TPB), this research investigates how attitudes, subjective norms, and perceived behavioral control (PBC) impact career aspirations for those in China. A total of 1,081 undergraduate health sciences students at a large medical university in China were surveyed using the Working with Older Adults Scale (WOAS) and the Ageism Attitude Scale (AAS). A subsequent qualitative survey was conducted with 50 participants to better understand students' rationales. Attitude ($B=0.17$, $p<.001$), subjective norm ($B=0.73$, $p<.001$), and PBC ($B=0.12$, $p<.001$) all emerged as significant predictors, but the primary driver of students' intention to work with older adults was subjective norms, suggesting students' beliefs on what others expect of them have a

greater influence than their own beliefs or sense of capability. These results underscore the need to incorporate social interventions in education to reshape perceptions of geriatrics. Rather than focusing only on improving knowledge and attitudes, curricula should engage geriatricians as role models, highlight the social value of the field, and reframe careers in geriatrics to better attract students.

Abstract Name: Determining the function of gene YPR013C in *Saccharomyces cerevisiae*.

The *Saccharomyces cerevisiae* genome contains approximately 6000 open reading frames; nearly 1,300 of these are unknown and are categorized as Genes of Unknown Function (GUFs). The gene YPR013C is a non-essential gene that likely contains a tandem C2H2 zinc finger motif. The C2H2 zinc fingers are among the most abundant and conserved proteins in eukaryotic organisms, and most function as transcription factors that bind DNA in a sequence-specific manner. Deletion of YPR013C leads to misregulation of several genes, further supporting this hypothesis. To confirm that YPR013C is a transcription factor, we wanted to determine subcellular localization of the protein. To do this, we used a strain in which YPR013C was tagged with the GFP protein. In addition, we used cellular fractionation to isolate the nucleus from other organelles and used Western blot analysis to confirm that YPR013C localized to the nucleus. These assays indicate that YPR013C is distributed throughout the nucleus, supported by the co-localization of GFP-tagged YPR013C with DAPI staining. The localization of YPR013C strengthens the hypothesis that the gene product participates in gene-regulatory processes. Additionally, we were interested in determining novel functions of the gene product. To that end, we exposed strain in which YPR013C has been deleted to a variety of genotoxic stressors by performing a spotting assay. Interestingly, we find that deletion of the gene leads to sensitivity to the antifungal drug rapamycin, indicating a potential role in cell cycle progression. We tested this hypothesis by doing a bud index assay. We find that deletion of YPR013C leads to a delay in the G1/S transition, further supporting a role in cell cycle progression. Taken together, these data indicate a potential role of YPR013C as a transcription factor as well as a role in cell cycle progression.

Abstract Name: Fusion Ignition: A Net Energy Gain in Nuclear Reaction

Nuclear fusion offers a pathway toward a clean and nearly limitless source of energy by combining light atomic nuclei under highly specific, high-temperature and high-density conditions. This paper examines the physics required to achieve fusion ignition, where the energy produced by the reaction exceeds the total energy invested in initiating and confining the plasma ($Q \geq 1$). Central to this analysis are the Lawson criterion and the triple product ($nT\tau$), which define the minimum plasma density, temperature, and confinement time needed for ignition. The study compares deuterium–tritium (D–T) fusion, which currently has the most favorable reaction cross-section, with proton–proton fusion, whose low cross-section poses

significant confinement and temperature challenges. A major reference point is the December 2022 ignition event at the Lawrence Livermore National Ignition Facility (NIF), where a laser-driven inertial confinement experiment produced more fusion energy than the laser energy delivered to the target. This milestone highlights both the potential and the limitations of inertial confinement fusion, particularly the need for precise symmetry, high compression ratios, and minimal energy losses during implosion. The paper also discusses magnetic confinement approaches, with emphasis on the International Thermonuclear Experimental Reactor (ITER), which aims to sustain high-temperature plasmas long enough to demonstrate continuous net energy gain. Loss mechanisms such as bremsstrahlung radiation, conductive heat loss, and particle escape are evaluated to understand how they restrict achievable temperatures and confinement times. Overall, the paper aims to clarify the physical limits of net-positive fusion energy and assess the viability of developing stable, self-sustaining fusion reactions across different confinement methods.

Abstract Name: Characterizing the effects of rotor diameter on thrust for a small-scale dual rotor helicopter

In recent years, there has been a growing interest in improving the efficiency for drones and helicopters that have been increasingly used in both recreational and military applications, from forest fire evaluation to surveillance. We hypothesize that, for a dual rotor helicopter, thrust is impacted by various parameters, such as distance between rotors, camber, thickness, and rotor diameters. In order to test this, thrust stands are required. Commercial thrust stands suffer from limitations like price and design complexity. For this experiment, a simple thrust stand was designed and developed at SJSU to combat these problems. A dual rotor helicopter (SREJNGL-31.5"×3.5"×9.4") was mounted on an S-Type 20kg Load Cell attached to a HX711 load amplifier. A tachometer was used for measuring rotational speed. A calibration curve was obtained by using known weights and measuring the load cell response. Previous investigations have shown that thrust was maximized at 4.0 cm separation and with an airfoil with 18% thickness and 4% camber (NACA 4418). To determine the effects of rotor diameter on thrust production, current work involves altering the diameter of the top rotor, holding the bottom rotor diameter constant, and vice versa. For this purpose, new blades were designed and 3D printed. For this investigation NACA 4418 blade was selected (4%-camber/18%-thickness). The length of the rotor blade (NACA 4418) was selected to vary the rotor diameter from 35 cm to 39 cm. The separation between the rotors was kept at 4.0 cm, a separation distance that provided maximum thrust in our previous study. Preliminary results are being obtained. In addition, attempts are being made to visualize the vortex interaction between the two rotors by using a laser sheet, high speed camera, and a fog machine. Complete results will be presented at the conference.

Abstract Name: Identifying Early Hormonal and Physical Markers of Klinefelter Syndrome to Improve

Diagnostic Accuracy in Primary Care

This study investigates two questions: Which early hormonal and physical markers can reliably support diagnosis and prediction of Klinefelter Syndrome (47, XXY)? How can these indicators be used to ensure timely diagnosis in primary care? Klinefelter Syndrome is one of the most common chromosomal disorders in males, yet 70–75% of affected individuals remain undiagnosed during childhood and adolescence. Research consistently identifies hallmark symptoms: elevated LH and FSH, low testosterone, and reduced inhibin B, along with tall stature, delayed or absent puberty, and small testicular volume. Despite strong documentation, these findings are not being translated into a practical screening process for family medicine physicians, who are often the first to observe developmental concerns. As a result, many patients experience delayed treatment, limited fertility planning, and preventable psychological and metabolic complications. This project will synthesize endocrine and developmental findings into an accessible early screening approach tailored to primary care. Methods include a targeted review of cohort studies, endocrine profiles, clinical guidelines, and available datasets. Hormonal and physical markers will be categorized by age of onset, frequency, and predictive reliability. The study will then assess whether consistent symptom patterns can support the creation of a screening checklist that triggers early karyotype testing when clinical concern is present. The expected outcome is a concise set of high-yield markers—such as elevated FSH and LH, low testosterone, delayed puberty, and small testes—that consistently warrant further evaluation. The ultimate goal is to promote earlier diagnosis, guide timely hormone therapy, support fertility counseling, and reduce associated physical and mental health risks. By translating existing scientific evidence into a clear, practical tool, this study aims to strengthen early identification of Klinefelter Syndrome within primary care settings.

Abstract Name: The Skin Microbiome as a Modulator of Wrinkle Formation: Mechanisms Linking Microbial Shifts to Aging Skin

Skin aging leads to visible structural changes such as wrinkle formation, yet the biological factors driving this process remain partially understood. The purpose of this project is to clarify how the skin microbiome contributes to wrinkle development and to evaluate whether microbial interventions may slow or reverse these changes. Aging skin undergoes well-documented shifts in hydration, barrier integrity, and extracellular matrix stability, but emerging research indicates that parallel shifts occur within the skin's microbial community. These microbial alterations may influence inflammation, oxidative stress, and collagen degradation, positioning the microbiome as a potential regulator of skin aging. To address this question, I conducted a comprehensive review of peer-reviewed studies indexed in PubMed, focusing on literature describing topics such as age-associated microbial changes, matrix metalloproteinase activity, barrier dysfunction, and the effects of probiotics and postbiotics on skin structure. As part of the project, I developed three original graphical abstracts to illustrate key mechanisms linking microbial imbalance to extracellular matrix deterioration and to visualize clinical findings on microbiome-based interventions. The review revealed consistent evidence that aging is accompanied by a shift toward more pro-inflammatory microbial communities, which amplifies oxidative stress and accelerates collagen breakdown. In contrast, several probiotic and postbiotic treatments—such as strains of *Lactobacillus plantarum* HY7714 and *Bifidobacterium breve*—have been shown to improve elasticity, hydration, and wrinkle depth in clinical studies. These findings support the conclusion that targeted modulation of the skin microbiome may offer a viable strategy for reducing wrinkle formation. This project contributes to current dermatologic research by integrating microbiome science with established aging mechanisms and by identifying promising avenues for future clinical exploration of microbiome-based skincare therapies.

Abstract Name: Assessing Convolutional Neural Network Performance on Balanced and Imbalanced Image Datasets

Convolutional Neural Networks (CNNs) have driven major advances in AI-based image classification across applications such as autonomous vehicle perception, medical diagnostics, and planetary science. Despite these successes, real-world datasets are often imbalanced, and large disparities in class representation can lead to biased learning, reduced generalization, and poor performance on minority categories. This research examines how four widely used CNN architectures including DenseNet, InceptionResNetV2, MobileNetV2, and ResNet152V2 perform when trained on balanced and imbalanced image datasets. The goal is to understand how class distribution influences accuracy, precision, recall, and F1 scores. Particular attention is given to DenseNet, whose densely connected structure promotes feature reuse and efficient gradient flow, which raises the question of whether these advantages remain when the data contain significant class imbalance. Multiple image datasets of varying complexity and domain, including medical diagnosis, planetary surface imagery, and general object recognition, were evaluated using five-fold cross-validation and statistical analysis to compare model performance under different imbalance conditions. By examining the extent to which dataset imbalance affects classification outcomes, this study aims to inform model selection and training strategies for researchers and practitioners who rely on AI-based technologies in situations where obtaining balanced datasets is difficult or impossible. The findings aim to clarify whether some deep learning architectures show greater resilience to real-world data imbalance and how model performance can be improved under such constraints.

Abstract Name: The Holistic Study of the Neurological Effects of Breast Augmentation Surgeries on Breast Cancer Patients and Non-Carriers within the United States

With the advancement of neuroscience, body modification surgery, and mass spectroscopy, we intend to analyze the neurological and psychological benefits of breast augmentation surgery (BAS) on two groups, individuals in remission from breast cancer and non-carriers. Both groups of women experience varying levels of Body Dysmorphia, and we hypothesize that BAS is an alternative way to treat an individual's mental health as an alternative to pharmaceutical medication. Monitoring the dopamine levels produced in the Ventral Tegmental Area (VTA) by the Substantia Nigra, received by neurons in the prefrontal cortex, we can deduce if the groups are responding positively to the treatment. Using DaTscan, fMRI, and EEG, we can monitor the brain's functionality. Additionally, with the guidance of initial mental health screenings, the individuals will be given a survey before and after receiving the treatment to observe an increase (or lack thereof) in dopamine levels in the brain. This experiment will take approximately two years to evaluate the individuals, conduct the test, for recovery time and lifestyle adjustments. We expect to see an increase in the well-being of both populations.

Abstract Name: Evaluating Minnesota Hardwoods as Biochar Precursors for Supercapacitors

Supercapacitors are increasingly used as energy storage devices because they can deliver high power. Unlike batteries, supercapacitors are able to uptake electric charge and dispel them in a short amount of time. They are particularly important in applications such as electric vehicles, buses, and light rail systems, where they take advantage of their large energy uptake and quick energy discharges. One promising material for supercapacitor electrodes is biochar, a carbon-rich product derived from plant biomass. When the biochar is activated to increase its porosity, the biochar exhibits high surface area and good electrical conductivity, making it well-suited for energy storage applications. In this study, the biochar is prepared using self-activation, a process in which calcium oxalate (CaOx) naturally present in biomass decomposes upon heating to form pores in the carbon structure. To explore locally available resources, there were five different Minnesota hardwoods selected that contained varying amounts of CaOx. In the production of supercapacitors, the biochar is first produced and self-activated using a top-lit updraft gasifier, next mixed with a PVDF/NMP solution to be rolled out on copper and aluminium foils, then put in a vacuum oven to remove impurities, and subsequently fabricated into coin-cell supercapacitors. After the supercapacitors are produced, the coins are put in a LAND battery testing for capacitance, or the measure of how much charge a capacitor is able to hold. Among the tested samples, black walnut showed the highest capacitance, reaching 19.51 F g^{-1} at 0.1 mA . These findings suggest that locally sourced biomass, particularly black walnut, holds strong potential for sustainable supercapacitor electrode materials.

Abstract Name: Enzyme Activity in Crowded Colloidal Media

Tissue engineering aims to support the formation and healing of tissues that lack self-healing capabilities or to enhance their regeneration speed (Lin et al., 2019). Biomaterials can help bridge the gap between external treatment and the body's natural healing mechanisms, restoring native tissue function (Lin et al., 2019). Within this context, microgels are being utilized in a variety of bioengineering applications. The ability to control their size (from tens of nanometers to hundreds of microns), their colloidal stability, and their high solvent content make them ideal building blocks for engineered biomaterials (Bachman et al., 2015). Furthermore, microgels can be made stimuli-sensitive, allowing for the creation of materials that respond rapidly to their local environment, such as changes in temperature, pH, ionic strength, and protein binding (Clarke et al., 2013). The Lyon Lab has pioneered the fabrication of poly(N-isopropyl acrylamide)-based microgels for bioengineering applications. In the work presented here, highly crowded microgel assemblies called microgel pastes were investigated to determine how factors such as microgel concentration and pH

affect enzymatic reactivity within the paste. Given the high degree of macromolecular crowding associated with microgel pastes, we sought to understand whether that crowding would impact macromolecular activity. To determine enzyme activity within the pastes, colorimetric reactions were used to directly visualize the conversion of substrate to product in a model horseradish peroxidase enzyme assay. Our results show that enzyme activity is largely unperturbed by microgel crowding, and that substrate diffusion within the paste represents the rate limiting steps in enzyme activity. These results illustrate the promise of using crowded synthetic tissue scaffolds in biotechnology applications, where macromolecular activity must be maintained to produce biologically relevant outcomes.

Abstract Name: The United States of America's Constitutional Aristocracy

Since the birth of the United States of America, the resentment of elites has driven the desire for democracy for its citizens. Promptly after the revolution, the Anti-Federalists and Federalists engaged in discourse concerning the possibility of an aristocratic reign under the U.S. Constitution. While Anti-Federalists adamantly argued that the document was an aristocratic ploy, many of America's Founders, particularly Thomas Jefferson, argued that the unique characteristics of this new nation would mark a successful democracy with elected "natural" aristocrats, men of high caliber, character, and intellect. Jefferson predicted the merit-based aristocracy would emerge from accessible public education and flexible social mobility. John Adams disagreed with Jefferson, writing that it would be impossible to raise up a truly merit-based aristocracy without creating an artificial one, corrupted with family ties, accumulated generational wealth, and individuals with unearned influence and power. This study evaluates these predictions' accuracy of a possible aristocracy through the analysis of historical documents as well as current economic patterns, public education, and public opinion. This study determines that Jefferson inaccurately characterized the United States of America's ability to be the exception of developing a corrupted aristocracy due to the inequality of public education and the inability for citizens to climb the social ladder. This study examines the effects of this artificial aristocracy on the relationship between the "common man" and intellectual elites, and the following fractured sense of truth and reality. The study determines that the distrust and resentment built towards these elites have created a culture of anti-intellectualism and rejection of political bodies, thus fostering the current hyper-populism culture of politics today.

Abstract Name: Effect of Extracellular ATP on Growth and Toxin Expression in *Sneathia vaginalis*

Sneathia vaginalis (*S. vaginalis*) is a component of the human vaginal microbiome that is significantly associated with preterm birth. The lab had discovered, previously, that *S. vaginalis* triggers vaginal epithelial cells to release ATP through a mechanism that is dependent upon its pore-forming toxin, the cytopathogenic

toxin A (CptA). Extracellular ATP, or eATP, is a “damage-associated molecular pattern”, or DAMP, that induces an inflammatory response in the human host, and it has been shown to alter growth and the transcriptome in *E. coli*, suggesting that bacteria may also recognize it as a signal. We hypothesized that eATP would likewise affect growth of *S. vaginalis*, as well as affect the expression of CptA. We ran quantitatively assessed the growth of *S. vaginalis* with and without the addition of ATP. Because ATP is rapidly hydrolyzed by secreted enzymes, we kept the assay relatively brief and assessed *S. vaginalis* growth at three different time points: 1 hour, 2 hours, and 3 hours. Growth was quantified by counting colony forming units (CFU). We found no difference in the growth of *S. vaginalis* in the presence of eATP vs no eATP. This suggests that eATP release by the vaginal epithelial cells does not provide an advantage to the growth of *S. vaginalis*. We also investigated the effect of eATP on the expression of CptA in *S. vaginalis* by western blot and found evidence that eATP suppresses CptA expression. We will further examine this finding by measuring expression of the *cptA* gene by realtime RT-PCR. These results suggest that eATP, released from epithelial cells by the CptA toxin, may function in a negative feedback manner to downregulate CptA expression by the bacteria. Thus, ATP could play a role in the cytotoxicity of *S. vaginalis*.

Abstract Name: Collective Building Behavior Revealed: Internal Densities in Army Ant Bivouacs

Army ants (genus *Eciton*) live a nomadic lifestyle – moving on a daily basis and hunting food to feed their colonies. In order to support this lifestyle, these ants form temporary shelters, known as bivouacs, from the living bodies of workers and can also build other structures such as bridges to help support movement as they travel. This lifestyle requires an efficient construction process and the ability to modify collective architecture in an organized manner to adapt to various environments. To examine this process, live *Eciton* bivouacs were scanned using a custom computed tomography scanner at regular time intervals during the construction process. Three-dimensional scans were split into horizontal slices. These slices were then analyzed for density in concentric ring-shaped selections from the outside to the inside, highlighting the development of hollow internal pockets in larger and more mature bivouacs. Studying bivouacs – particularly their development over time – provides an opportunity to gain insights on how ants choose to distribute themselves in a structure to accomplish their goals while also maintaining the flexibility to adapt. Such construction rules have potential applications in city planning, social network analysis, swarm drones, and supply chain logistics.

Abstract Name: Low-Dose Atropine as a Therapeutic Intervention for Myopia Progression

The prevalence of myopia (nearsightedness) is growing at an increasingly alarming rate throughout the world. In 2010, the presence of myopia in the world's population was measured to be 27% yet is predicted to reach 52% by 2050. There is currently a variety of interventions in place to help slow the progression of myopia, with one of the most common being low dose atropine (0.01-0.05%) which acts upon the muscarinic

receptors in the back of the eye to slow the elongation of the eyeball, thus slowing myopia progression. The objective of this experiment is to examine the effectiveness of low dose atropine on slowing myopia progression in children by monitoring refractive error and axial length. It was hypothesized that low dose atropine will produce a measurable decrease in spherical equivalent change and axial elongation in pediatric patients over at least one year of treatment. This systematic literature review consisted of thirteen studies selected based on relevance to pediatric atropine treatment for myopia, while exclusion criteria included eliminating research that was outdated, not directly pertinent, or duplicates. Data extracted from included studies were placed in a cross-study analysis to compare outcomes and treatment methods. Analysis of the included studies reveal that low dose atropine effectively reduced myopia progression over at least one year of treatment. Results show variation in correlation of the effectiveness of higher concentrations and greater reductions where some studies suggest that there is a positive dose response and rebound effects occasionally observed at higher dosages. These findings support low dose atropine as an effective intervention to slow pediatric myopia progression and provide the foundation necessary for upcoming clinical trials. Further research is needed to solidify the effectiveness in atropine, as it has the potential to slow the increase of this ocular disease.

Abstract Name: End Animal Captivity: The Impact of Captivity on Orcas

This project investigates the ethical implications of animal captivity, with a focus on orcas, and presents its findings through a research-informed visual poster titled End Animal Captivity. The poster spotlights the consequences of keeping wild animals in confinement for entertainment, display, or financial gain. Drawing on research in animal welfare and studies conducted regarding captive orcas, the piece highlights how captivity places wild animals at serious risk for psychological harm, physical harm, and the loss of natural behaviors. The poster foregrounds orcas as a case study, referencing documented effects such as reproductive exploitation, reduced lifespan, and self-harming behaviors. By pairing these findings with a visual representation of the cruelty inherent to these conditions, the piece aims to create an accessible and personal entry point into a larger ethical issue. Many people view captivity as harmless entertainment, and some even assume animals are better off in human care. These attitudes can reinforce speciesism and limit public engagement on behalf of confined animals. The familiar symbolism of a fish in a plastic bag facilitates emotional connection with the audience by referencing a practice that is recognized as inhumane. Silhouettes of onlookers, incorporated chains, metal bars in the background, and a reserved color palette work together to convey the emotional weight of the situation. The integration of data and visualized statistics supports the argument that captivity is largely harmful. Research findings, such as orca mortality rates being approximately 2.5 times higher in captivity and the largest existing tank equating to only 0.0001% of the distance an orca would naturally traverse in a single day, highlight the profound deprivation inherent in captive environments. While orcas serve as a focal example, they represent just one of many species suffering under captive systems, emphasizing the urgent need to rethink how humans interact with wildlife.

Abstract Name: Mimetic Reactionary Thought: Propaganda in the Digital Age and a New Epistemology of Fragmented Incoherence

Although the media landscape has changed dramatically since the era of “keep calm and carry on” slogans, Nazi agitprop, and Red Scare McCarthy trials, the public conception of propaganda has remained largely the same: propaganda is overt, ideological agitation through false information, disseminated by the state. In the 1980s, Noam Chomsky and Edward S. Herman sought to analyze and outline how propaganda operated through “news filters” in the new media environment they found themselves in – i.e., one characterized by the dominance of television, concentrated ownership in massive media conglomerates, and a globalized world now driven by the profit motive. In *Manufacturing Consent*, they concluded that this profit motive and embedded capitalist logic in the media system were the primary directors of propaganda and the modern determinants of ideological production. In essence, propaganda became baked into the media we consume, covertly shaping public consciousness and discourse through sitcoms, flashy advertisements, and “objective” news from the mouths of well-manicured television personalities. While the Herman-Chomsky thesis detailed the media environment that propaganda operated within, Neal Postman theorized on the epistemological landscape created by such media, which in turn ripened the conditions for ideological reproduction. Through the injection of triviality and the mixing of decontextualized information with entertainment, our television-culture created a new epistemology characterized by fragmented thought and discourse. This essay explores how the propaganda model and Postman’s media-metaphor framework have evolved with the emergence of the internet and social media, where the meme – Richard Dawkins’ “unit of cultural transmission” – is the dominant medium of communication. The new epistemology of this digital era, which I have termed “mimetic reactionary thought,” has constructed the conditions for the widespread prevalence of disinformation and conspiratorial thinking, ideological incoherence, and cultural shift to the far-right that we are now experiencing.

Abstract Name: Fate of A Surrogate Organic Contaminant of Phenol under Conventional and Emerging Ultraviolet (UV) Irradiation in the Presence of Inorganic Nitrogen Species during Semiconductor Wastewater Treatment Processes

Introduction: Semiconductors are integral parts of biomanufacturing from specialized medical equipment to wearable devices and monitors. Semiconductor manufacturing involves many processes that use water. The wastewater from these processes contains pollutants such as nitrate, nitrite, phenolic compounds, heavy metals, and acids. These substances pose an ecological and public health risk if not treated properly. Ultraviolet (UV) based Advanced Oxidation Processes (AOPs) have been implemented in wastewater reclamation processes. However, it has not been tested in semiconductor wastewater. This project focuses on evaluating the photochemical fate of a surrogate wastewater contaminant of phenol under UV irradiation using both conventional (254 nm) and emerging (222 nm) UV light technologies in the presence of nitrate and nitrite at different pH values. Materials and Methods: Samples of the Nitrate solution were placed under the 222 nm UV light or the 254 nm UV light for 30 minutes, taking samples at 0, 5, 10, 20, and 30 minutes. This process was repeated for a solution of pH 7 and pH 11. Samples of phenol with nitrate were also placed under the two UV lamps at pH 7 and pH 11 respectively, but the 222 nm light sample was exposed for 10 minutes, while the solution under the 254 nm light was run for 60 minutes. Results: In the results, Phenol underwent more efficient degradation at pH 7, particularly under 222 nm UV light and when nitrate was present in the solution, phenol degradation was further enhanced. This highlights that phenol removal at neutral pH can be accelerated through reactive nitrogen species (RNS) formed from nitrate photolysis, rather than relying solely on direct UV absorption by phenol. These results demonstrate the potential of far-UVC

(222 nm) treatment for targeting phenolic pollutants through both direct and indirect pathways, making it a strong candidate for advanced semiconductor wastewater treatment systems.

Abstract Name: The Enduring Power of Racial Covenants: Links between Income and Racial Demographics of Today

During the time period of 1930 to 1948 racial covenants were used to maintain residential segregation. A racial covenant is a neighborhood-level agreement that includes a racial clause that restricts non-caucasian people from owning or living on the property unless they work on the property. Questions have been raised on how this practice has affected current socioeconomic factors. This analysis looks at the impact of these racial covenants on income and racial demographics within Weber County, Ogden more specifically. I run a multiple linear regression, to look at correlations between the density of racial covenants within a block group, the current median income, and percentage of non-white population, to determine if that correlation is statistically significant. Results of this analysis show two separate findings. Related to income, the data reveals a positive correlation between median income and the density of covenanted blocks. Related to non-white racial demographics, we also see a positive correlation between non-white demographic density and density of covenanted blocks. Both results are insignificant. These findings suggest that while there is still minimal diversity within Weber county, racial covenants alone were not the deciding factor of that restricted diversification. Other policies and/or practices of residential segregation may have a bigger impact or complement the impact of racial covenants, these other policies should be taken into account.

Abstract Name: Stressed and Hungry: How Does Oxidative Stress Alter Nutrient Choices and Investment Decisions?

Many aspects of environmental change—heat waves, droughts, and pollution—induce oxidative stress (OS), which is a physiological stress that can influence survival, reproduction, and dispersal. The costs of OS may be mediated by nutritional decisions, such as resource acquisition (feeding choices) and resource allocation (how ingested nutrients are invested into different tissues). Here, we investigated how OS influences these resource-related decisions in adult female variable field crickets (*Gryllus lineaticeps*). In the first week of adulthood, long-winged females received three injections of either saline (control) or OS-inducing paraquat (PQ, an herbicide that promotes oxidative damage). Throughout the experiment, crickets chose between high-carbohydrate and high-protein diets. The following were then measured: (1) consumption of calories, protein, and carbohydrate, (2) somatic mass gained as an indicator of self-maintenance, (3) ovary mass gained as an indicator of reproductive investment, and (4) functional status of flight muscle as an indicator of investment into dispersal capacity. We tested competing hypotheses regarding resource (food) acquisition that OS increases preference for consumption of (a) proteins to support antioxidant defenses, or (b) carbohydrates to

support energy use (given energetic costs of antioxidant defenses) and/or energy storage (fat). We also tested competing hypotheses regarding resource allocation– specifically, (c) whether resources were invested into current reproduction (ovaries) at an expense to self-maintenance (somatic tissue mass and flight musculature); i.e., ‘terminal reproductive investment’ or (d) vice versa where investment into current reproduction is deprioritized in favor of investment into self-maintenance; i.e., ‘reproductive restraint’. By examining how nutritional choices and OS influence investment strategies, our study helps us understand the mechanisms determining physiological resistance in changing environments.

Abstract Name: Investigating Para-phenylenediamine Levels in Hair Dyes, Henna, and Tattoo Inks

Para-phenylenediamine (PPD) is a common aromatic compound used in permanent and semi-permanent hair dyes. Crucially, it is also frequently found in henna and occasionally in tattoo inks, despite being unapproved by the FDA for use in these products. The presence of PPD in these widely used products poses a significant public health concern, as it is a potent sensitizer linked to an increased risk of severe allergic reactions and dermatitis. Furthermore, cases of acute hair dye poisoning associated with PPD have led to severe systemic effects, including renal failure, respiratory failure, and rhabdomyolysis. Given these potential risks, the continuous monitoring of PPD concentrations in these consumer products is essential. The objective of this study was to determine the concentration of PPD in commercially available hair dyes, henna, and tattoo inks using High-Performance Liquid Chromatography (HPLC). A total of seven brands of henna, three brands of tattoo ink, and three brands of hair dye were selected for analysis. Preliminary results showed no detectable PPD in the three brands of tattoo ink analyzed. However, PPD was quantifiable in both hair dyes and henna. Notably, the levels of PPD detected in henna were significantly higher than those found in hair dyes. In henna, PPD concentrations ranged from 34.8 ppm to 3180 ppm. In hair dyes the concentrations ranged from 33.7 ppm to 40.1 ppm. While all detected concentrations fall within the maximum allowed concentration specified by the current European Cosmetics Regulation, the extremely high variability and maximum concentration (3180 ppm) observed in henna products warrant further investigation into safety practices and regulatory compliance, particularly considering the unauthorized use of PPD in these products.

Abstract Name: Cytokine-Mediated Suppression of Caspase-1 by Astrocytic NLRC5

Astrocytes, a major CNS glial cell with immune-responsive properties, play a vital role in the innate immune response against inherent cell stressors and invading pathogens. A key mechanism underlying this response is the inflammasome complex, which mediates caspase-1 (CASP1) activation and the subsequent release of downstream pro-inflammatory cytokines through gasdermin D (GSDMD)-mediated pore formation.

Transcriptional upregulation of inflammasome sensors, such as NLRPs and NLRCs, within astrocytes can be achieved by agonists of toll-like receptors and cytokines such as interferon (IFN) γ and tumor necrosis factor (TNF) α . It is well known that the cytokines IFN γ and TNF α contribute to neuroinflammation, but their role in astrocytic inflammasome assembly is currently unknown. Bulk RNA sequencing of primary human spinal cord astrocytes indicates a high upregulation of a novel inflammasome sensor, NLRC5, specifically by IFN γ stimulation. We therefore sought to determine the role of NLRC5 within the inflammasome activation pathway in response to IFN γ and TNF α . Inflammasome activity was assessed in vivo using a model of neuroinflammation, experimental autoimmune encephalomyelitis (EAE), through immunohistochemical staining for NLRC5 and activated CASP1, where NLRC5 was identified to be upregulated in acute stages of EAE. In a knockdown model of IFN γ receptor 1 in astrocytes, immunocytochemistry revealed increases in CASP1 activity. However, in an NLRC5 overexpression model, CASP1 activity was reduced, while a siRNA-mediated NLRC5 knockdown reversed these effects. These findings suggest that IFN γ signaling mediates a direct interaction between NLRC5 and CASP1 to suppress inflammasome activation. Overall, the collected data indicate that IFN γ upregulates NLRC5 and other inflammasome components, repressing activation of CASP1, and suggesting an immunomodulatory role for astrocytic NLRC5.

Abstract Name: Epigenetic Regulation of Brain Aging GWAS Variants within Transposable Element Sequences

Genome-wide association studies (GWAS) have identified many loci associated with brain aging, yet most lie in noncoding regions, complicating functional interpretation because their effects must be inferred through regulatory mechanisms. In the brain, where long-lived cells rely on stable epigenetic regulation to maintain transcriptional homeostasis, transposable elements (TEs) represent a major component of the regulatory DNA landscape and a potential substrate through which noncoding variation may be interpreted. However, it remains unclear whether brain-aging GWAS variants are preferentially localized within specific TE sequences, whether these variants are linked to biological pathways relevant to brain aging, and through which regulatory mechanisms and cell-type-specific chromatin contexts they may act. Here, we applied an integrative genomic framework combining RepeatMasker TE annotations, single-nucleus ATAC-seq chromatin accessibility maps across major brain cell types, ENCODE candidate cis-regulatory elements (cCREs), and partitioned LD Score Regression. We found that GWAS variants frequently overlap transposable element sequences, but this overlap does not indicate global enrichment relative to genomic background. Instead, enrichment is non-random and specific to TE families: SINE elements, especially Alu, show the strongest genomic enrichment, whereas enrichment within cell-type-specific accessible chromatin is driven by other repeat families. Simple repeat elements exhibit consistent enrichment across multiple brain cell types, while TcMar-Tigger DNA transposons show strong, oligodendrocyte-specific enrichment. Brain-aging GWAS variants overlapping TE sequences are preferentially localized within transcription factor-associated cCREs and depleted from promoter-like regions, indicating bias toward transcription factor-mediated regulatory contexts. Functional enrichment analyses revealed limited and context-specific pathway associations. Partitioned heritability analyses showed no independent enrichment of TE annotations after conditioning on baseline functional features, indicating that TE-overlapping GWAS signals are largely explained by shared regulatory architecture. Together, these results support a model in which TE-localized GWAS variants reflect underlying epigenetic regulatory architecture rather than independent TE-specific genetic effects.

Abstract Name: Human Development Index (HDI) and Employment Diversification in GCC Economies: A Panel Analysis (1995–2023)

Gulf Cooperation Council (GCC) economies have long relied on hydrocarbon revenues and public-sector employment, creating labor markets characterized by limited sectoral diversity and strong dependence on government jobs. As these states pursue economic transformation agendas—such as Saudi Vision 2030, UAE Centennial 2071, and Oman Vision 2040—employment diversification has become a central policy objective. Simultaneously, GCC countries have invested heavily in improving human development outcomes through expanded education systems, enhanced healthcare access, and rising income levels. This study examines whether improvements in the Human Development Index (HDI) have contributed to employment diversification across GCC economies from 1995 to 2023. Using a balanced panel dataset covering Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates, this research employs fixed-effects panel regression to analyze the relationship between HDI and shifts in employment composition. HDI, sourced from UNDP, captures long-run improvements in education, health, and income. Preliminary trends suggest that GCC states with higher HDI levels—particularly the UAE, Qatar, and Bahrain—exhibit greater movement toward diversified employment structures, including growth in tourism, finance, logistics, healthcare, and technology sectors. Improvements in educational attainment appear especially influential, supporting the emergence of skill-intensive and private-sector employment. The analysis also indicates that the relationship between HDI and employment diversification strengthens after 2010, coinciding with intensified national development strategies. These findings underscore the importance of human development as a foundation for labor market transformation in resource-dependent economies. Enhancing education quality, supporting lifelong skill development, and promoting workforce health may be critical to accelerating diversification efforts. This study contributes to the understanding of how human development shapes structural economic change in the GCC and highlights policy pathways for achieving sustainable, post-oil employment growth.

Abstract Name: Investigating Preterm Birth and Smoking Patterns using Electronic Health Records

Preterm birth is defined as a baby delivered prior to the 37th week of pregnancy. Preterm is incredibly prevalent and affects around 1 in 10 mothers. Prior literature review, show that low cigarette use is associated with a increased risk of preterm birth. This study, we used logistic regression and random forest models to predict preterm birth among mothers who smoke, using data from the Analytics and Machine-learning for Maternal-health Interventions (AMMI) Datamart project (2019–2024), which includes clinical records from the Wake Forest/Advocate healthcare system. Key variables included race, maternal age, insurance status, smoking behavior, BMI, and hypertension. This study excluded non-singleton births. This study used the AMMI which included birth information on women in North Carolina. The study included 8,152 participants, with 12.7% experiencing preterm birth. Among them, 52% had never smoked, 17% were light smokers, and 15% were former smokers. Both models had a mean AUC of 0.69, indicating fair discriminative ability to

predict preterm birth. With the current dataset, we found that the logistic regression outperformed random forest overall in identifying preterm births. Both models found that higher maternal age and higher systolic blood pressure were associated with an increased risk of preterm birth. Limitations include low explanatory power and potential bias from missing data. Future work should explore data balancing techniques (e.g., SMOTE) and ensemble methods to improve model performance. In the future, this dataset can be used to examine blood tests and see how it may relate to preterm birth.

Abstract Name: Interpreting “Vampire” Burials in Medieval Eastern Europe

Since the early twentieth century, various atypical or deviant graves have been excavated across Eastern Europe, particularly in Poland. These discoveries have prompted much speculation, as the individuals were interred with items such as sickles placed over their necks or abdomens, along with other mortuary artifacts not considered normative compared to those found in typical community burials. Such practices suggest that these individuals were regarded as deviant or pariahs within their social contexts. Consequently, many have been quick to label these as “vampire burials,” interpreting them as measures intended to keep the dead from rising. However, this definition is problematic, as the medieval concept of vampires in Eastern Europe differs greatly from modern interpretations of vampirism. The reasons behind these atypical burials are far more nuanced and require an understanding of the religious and folkloric beliefs surrounding vampirism, as well as how medieval Eastern European societies perceived death and the afterlife. This research aims to explore how deeply folklore and religion permeated medieval Polish society, and how these beliefs shaped the living’s relationship with the dead and the beyond.

Abstract Name: Plant-Derived Flavonoids as Promising Inhibitors of *Candida albicans* Biofilms

Candida albicans is an opportunistic fungal pathogen capable of causing disease in immunocompromised individuals. During infections, *C. albicans* forms robust biofilms on both biotic and abiotic surfaces, including mucosal tissues and implanted medical devices. Biofilm formation significantly enhances resistance to host immune responses and conventional antifungal therapies, contributing to persistent infections and high relapse rates. As antifungal resistance continues to rise, the discovery of alternative or adjunctive therapies is urgently needed. Flavonoids, a diverse group of plant-derived polyphenolic compounds, have emerged as promising candidates due to their broad biological activities and low toxicity profiles. In this study, we explored the potential of flavonoids as antibiofilm agents by screening a library of structurally distinct flavonoids against *C. albicans* biofilms. To date, we have screen 240 compounds using a 96-well microtiter plate model for biofilm growth and identified 23 flavonoids (initial hits) that inhibit *C. albicans* biofilm formation by more than 50 percent at 20 micromolar (μM) concentration. Of these initial hits, the flavonoids with the greatest inhibitory effect on *C. albicans* biofilms are lycorine and 7-methoxyflavon. Lycroine inhibits

82 percent of biofilm formation at 20 μ m, and 7-methoxyflavon inhibits 78 percent at the same concentration. Current studies are focused on determining the effect of the hit compounds on various stages of biofilm development, including early adhesion and proliferation. Research has shown that certain flavonoids have increased the susceptibility of *Candida* species and other fungal pathogens to the antifungal drug, fluconazole. Thus, future studies will look for synergistic effects between the flavonoids and fluconazole. Overall, this work underscores the promise of plant-derived flavonoids as an innovative strategy to combat *C. albicans* biofilm-associated infections.

Abstract Name: The Impact of Transfer From 2-Year to 4-Year Campuses

This paper presents findings from an ongoing research study examining the experiences and outcomes of students who transfer from two-year branch campuses to the main campus of a large Hispanic-Serving Research University. Building on earlier stages of this project, the study further investigates how environmental factors such as campus climate, community support, cultural ecologies, and geographic context influence students' decisions to persist toward graduation with a four-year degree. These factors are particularly important at institutions that serve diverse and often first-generation student populations, where the transition from a smaller campus to a larger research environment can introduce new academic and social challenges. Using a mixed-methods approach that incorporates institutional data and student interviews, this study compares graduation, drop-out, and bounce-back rates with qualitative narratives gathered through semi-structured interviews with transfer students, returning students, and main-campus students. The goal is to understand how individual experiences align with, or diverge from, broader institutional trends. The central emphasis is placed on how the transfer process influences students' happiness, confidence, and sense of belonging, and how these emotional and social dimensions shape their decisions to continue or discontinue their academic pathways. Preliminary results suggest that feelings of isolation, unfamiliarity with campus resources, and limited cultural or community connection can negatively affect persistence, while mentorship, peer networks, and culturally responsive support systems significantly improve student outcomes. By analyzing these trends alongside the lived experiences of transfer students, this paper highlights the structural and cultural barriers that shape transfer-student persistence and identifies practical opportunities for institutions to strengthen support systems that promote degree completion.

Abstract Name: The Effects of Medicaid Expansion on Adult Mortality Rates.

The purpose of this research is to examine the effects of Medicaid on mortality rates across the United States. Specifically, this study investigates whether the Affordable Care Act (ACA) expansion is associated with lower mortality rates in expansion states compared to non-expansion states. Over time, Medicaid has become one of the largest healthcare providers in the nation, helping many low-income families and individuals with disabilities gain access to essential medical services. Understanding the relationship between healthcare

access and population health outcomes is critical for evaluating the effectiveness of public health programs. Mortality serves as a key indicator of population health, as higher mortality rates often reflect poorer health outcomes. In this study, mortality is used as the primary measure to assess the effectiveness of Medicaid and the ACA expansion in improving health outcomes. Previous research supports the positive impact of Medicaid expansions. Romero and Ponomariov (2023) found that expansion states experienced improved healthcare access and preventive behaviors, highlighting the ACA's effectiveness in reducing coverage gaps. Similarly, Miller et al. (2021) suggest that ACA Medicaid expansions substantially reduced mortality rates among beneficiaries. To estimate the causal impact of Medicaid on mortality rates, this study employs a difference-in-differences (DiD) approach using publicly available data from CDC-WONDER and state-level mortality rates, combined with linear regression analysis. Preliminary findings indicate a significant negative relationship between ACA Medicaid expansions and mortality rates among adults with diabetes.

Abstract Name: Bridging the Confidence Gap: ELL Mentorships and Narrative Exploration of the Mexican-American Student Experience

How should American rural school districts bridge the gap for immigrant student literacy needs for a growing population of second-language learners? How can other authors' personal narratives help inspire Mexican-American youth to further their educational journey? Over the last five years, the college town of Rockbridge County, VA has seen a 40% increase in Spanish-speaking students, leaving local schools and teachers racing to find inclusive, scaffolded ELL (English Language Learner) strategies despite VA Dept of Education's English immersion policies. Rural VA communities lack resources and bi-lingual support staff, affecting student growth in English and Spanish. Because Virginia Standards of Learning (SOLS) restrict alternative literacy instruction, Rockbridge County teachers are often unequipped to bridge language barrier gaps. Without adequate and consistent resources, ELL students lose confidence because they are not reaching the same level as their peers in basic reading skills and content learning. This creative research presentation weaves an autobiographical literacy narrative alongside grounded, qualitative analysis from a semester-long ELL Fieldwork Project mentoring 5th grade, second language learners. During her mentorship, Chavez developed a supportive program for rural bilingual students by designing guided language think-alouds and organizing an Inclusive Reading Bookshelf to validate student confidence, motivation and prior knowledge within regulated classroom routines. This mentorship inspired Chavez to reconsider her own bilingual literacy landscape in a rural Arizona border town. She explores her own emotional themes and experiences of learning as an "outsider," and draws on Mexican-American author Sandra Cisneros's memoir *A House of My Own – Stories of My Life* (2015) and *Ay Tu! Critical Essays on the Life and Work of Sandra Cisneros*. As a bilingual student that grew up in a failing education system, Chavez considers Cisneros's journey as conversation for the obstacles faced by current ELL students.

Abstract Name: Re-Engineering Student Success: A Habit-Driven System for Career Clarity in STEM and Higher Education Aspiring Students.

Students in the STEM and Healthcare field lack structures, personalized career guidance since there is limited access to mentorship, progress trackers, and planning systems. For this reason students pursuing long term goals such as MD, Engineers, and Lawyers need a platform that can guide them with tools that will focus on breaking down their long term goals into micro-milestones and habits, implement academic and professional planning, providing tracking dashboards, and linkage to mentorship and interest-based resources. Thus, supporting students who yearn for clarity in their career standpoints, to reduce burnout, confusions, and wasted semesters. Importantly, guiding students who are first generation gain access to structured systems of tracking and guidance into their dream careers. This research will be oriented on user research & needs analysis by interviewing College students that are in STEM, pursuing grad school, Pre-med, Pre-law, transfer, honors, and engineering. Conducting surveys on barriers in career planning & skill development and analyzing patterns in motivation and burnout cycles/ causes, positive and negative academic habits, resources for experiences challenges, and access to mentorship/ advising. Secondly this research will review literature that focuses on habit formation models like ABA reinforcement, cognitive science behind learning & goal-setting, theories of career-development, and behavioral psychology and motivation frameworks. Lastly, benchmarking and competitively analyzing existing platforms such as LinkedIn, career pathways websites and apps. Then applying this research into the app, first creating a prototype and system design by defining user journey, creating wireframes, building map of habit to career milestone structure, and building priority list. Secondly, creating a behavioral and Data model design by developing a competency tracking framework, habit reinforcement loops, and milestone algorithms. Finally Testing by running pilots with students and collecting feedback on motivation impact, clarity of their roadmap, and their level of ease of app consistency, measuring effectiveness.

Abstract Name: Locomotor motif deficits in Down Syndrome mouse models

This research project explores potential locomotor motif deficits in Down Syndrome mouse models. Within current research conducted in the field of neuroscience of Down Syndrome, there is not much attention given to early behavioral development. The project aims to identify the effect of trisomy on early postnatal locomotor development using AI-enabled tools. We used high-speed video recordings of mouse pups belonging to an established Down syndrome model (Ts65Dn) at different developmental stages including P5-P10 and P30-P60. We recorded video of selected pups from below a transparent box to capture whole body locomotion. We are currently using our preliminary dataset of videos to train a DeepLabCut model. After DeepLabCut pose-estimation we will run kinematic data through an unsupervised learning algorithm - B-SoID - to perform behavioral segmentation of locomotor data. By following these mice across development, this project aims to uncover the evolution of early locomotor motifs in typically developing pups and identify how trisomy alters these developmental trajectories.

Abstract Name: Impact of Nitrogen and Oxygen Additives in DBD Argon Plasma on E.coli Bacteria Mitigation

Dielectric Barrier Discharge (DBD) plasma is being used to sterilize wounds that can accelerate wound healing. This is due to the presence of oxygen and nitrogen reactive species (RONS) that are generated as the ambient air is entrained in the plasma. This study is investigating the techniques to enhance RONS by adding small amounts of nitrogen and oxygen in the plasma gas. The impacts of additive gases are being monitored by exposing the plasma on E Coli bacterial colonies. In addition, this study investigates the effect of varying experimental conditions (N₂ and O₂ percentage addition, plasma power and argon gas flow rates) on the interactions between plasma and bacteria. Through our research, various doses of nitrogen and oxygen (0.015, 0.03, 0.05, 0.07, 0.1 slpm) are introduced at a fixed argon flow rate (~16 slpm). Argon plasma jets were generated by applying 5-10kV at frequencies between 30-50 kHz. Emission spectroscopy was used to monitor emission lines from various radicals (Nitrogen 2nd positive lines, OH lines, argon lines, oxygen lines). The intensity of these lines provide information on RONS in a qualitative manner. E Coli bacterial colonies were grown in a sequential manner where a serial dilution was conducted to get the samples on ten petri dishes. Five of them were used as the control whereas five of them were exposed to plasma jets at various operating conditions. Petri dishes were kept in an incubator at 37 degrees centigrade for 24 hours to grow bacterial colonies that were counted using a software called Promega Colony Counting. Our preliminary results show that bacterial mitigation strongly depends on the plasma power and the percentage addition of oxygen. Nitrogen addition had marginal impacts. More results are being analyzed that will be presented in the conference.

Abstract Name: Barriers to Higher Education in the Carceral State: How the University of Chicago's Involvements with the Stateville Correctional Center Shaped Its Prison Programming, 1920s–1960s

The University of Chicago's collaborations with Stateville Correctional Center reveal the deep interdependence between higher education and the carceral state in the mid-twentieth century, yet scholarship has not yet accounted for how these partnerships generated enduring barriers to educational access in prisons. This project establishes how UChicago's involvement in prison education, scientific research, and rehabilitative initiatives at Stateville from the 1920s to the 1960s decisively shaped both the development and the structural limits of prison programming in Illinois. Drawing on archival collections, institutional correspondence, newspaper accounts, and historical analyses, the research delineates how funding constraints, institutional design, administrative prerogatives, and dependence on individual champions configured the possibilities and failures of early prison education. The findings demonstrate that although university-prison collaborations created programs such as the Stateville Correspondence School and facilitated scientific and pedagogical initiatives, they simultaneously entrenched inequities by situating educational access within systems of surveillance, institutional self-interest, and discretionary gatekeeping. This historical analysis asserts that reckoning with these entanglements is imperative for constructing contemporary university-prison partnerships that do not replicate past harms but instead cultivate durable, equitable, and ethically grounded models of higher education in carceral settings.

Abstract Name: Developing a Co-Culture Liver Organoid Model for High-Throughput Prodrug Screening

Patients with rare tumors have a lower 5-year survival rate (52.6 percent) compared to other cancer patients (70.1 percent). Our lab uses high-throughput drug screening on patient-derived tumor organoids to recommend promising drugs. However, prodrugs remain incompatible with our automated liquid handling protocol. To screen these drugs, they must first be metabolized. This project aims to develop a protocol using 3D bioprinted miniature liver inserts (MLIs), enabling the lab to include prodrugs in patient drug screening. Irinotecan, which converts into SN-38, is the focus. Before testing a co-culture model, we identified a concentration of irinotecan that minimizes cytotoxicity and assessed enzymatic activity in potential hepatocytes. HT1080 cells stood in for patient-derived cells, seeded in mini-rings in 96-well plates. Cell viability was measured via ATP assays, and enzyme activity with CYP3A4 cell-based assays and CES1 ELISAs. Staurosporine and DMSO were used as positive and negative controls. We found 1 and 10 μM irinotecan balances viability and conversion to SN-38. We also compared CYP and CES1 enzymatic activities between commercially available primary hepatocytes and clinical hepatocytes that we isolated from liver samples in our lab. In the future, we will test the co-culture model together. This system will allow patients to benefit from a wider range of drug recommendations, ultimately increasing their chances of receiving effective, personalized therapy.

Abstract Name: JWST Reveals High-Velocity Gas Jets in Baby Stars During Their Formation

In astronomy, one of the central open questions is how stars and planets form. Current theories suggest that planets form in protoplanetary disks around baby stars (protostars), but one unknown is how the materials in the disk conserve angular momentum as they fall toward the protostar. The proposed physical mechanism to conserve angular momentum is the launching of bipolar protostellar jets. Protostellar jets launch hot atomic and molecular gas at more than 100 km/s, which can be detected using the James Webb Space Telescope (JWST) by observing [Fe II] and H₂ emissions. Moreover, as matter is launched from the protostar, the ambient medium becomes excited by shocks and creates emissions that can be detected as well. Using emission line data collected from JWST, we characterize and perform analyses on the outflow of the protostar TMC1A. We found that the jets consisting of hot atomic and molecular gas show a collimated structure, and analysis of the brightness along the jet axis reveal a series of knots consistent with ejection events that occur in episodes. The shocked molecular gas is broader and displays a ring-like structure with brightness asymmetry around the ring. In addition, the redshifted and blueshifted sides of the jet exhibit a significant velocity asymmetry, providing insights into the launching conditions of the jet. Notably, our analysis shows no detectable transverse velocity gradients across the jet axis that would indicate rotation, contrary to theoretical expectations. Together, our findings indicate that mass ejection may not be a steady, rotationally driven process, but instead occurs in bursts and interacts asymmetrically with the surrounding medium. This suggests that the mechanisms responsible for conserving angular momentum during star formation are more

complex than a simple rotating jet, and these results provide new constraints on models for the evolution of young stars.

Abstract Name: A Deep-Learning based Self-supervised Denoising Method for Kinetic Plasma Simulations

Accurate kinetic plasma simulations are important for advancing fusion energy and, electric propulsion. However, the Particle-in-Cell (PIC) method, the dominant approach for fully kinetic modeling, suffers from inherent statistical noise that grows over time with computational cost. Traditional denoising techniques such as Proper Orthogonal Decomposition (POD) and Kernel Density Estimation (KDE) often require problem-specific tuning and may distort the physical quantities. To address this challenge, we develop a Deep Learning (DL) -based denoising framework that blends modern computer-vision (CV) architectures (Noise2Noise) to recover high-fidelity plasma features from noisy PIC simulations. The approach treats PIC outputs as image-like and employs DL to learn structured spatial-temporal patterns underlying plasma dynamics, integrated physical laws and boundary conditions. We use the PIC simulation with varying Nppc (number of particles per cell) to prepare the noisy data and use the noise-free grid-based Vlasov method to prepare the benchmark data. We vary Nppc across a wide range ($N_{ppc} \in \{10^1, 2 \times 10^1, 5 \times 10^1, \dots, 8 \times 10^6, 10^7\}$). Multiple initial-seed realizations are created at each Nppc for training. Outputs are reformulated into space-time tiles to learn spatial-temporal correlations. Our results show for a 1D Landau damping problem, using a trained 2D U-Net Noise2Noise model using two independent, low-fidelity PIC realizations (target Nppc = 1000, reference Nppc = 5000). The network learned the physical signal, making the noisy data show clearer wave structures. Quantitatively, this yielded a global Δ SNR gain of 21.672 dB, a 147x noise power reduction (99.3% removal). By comparison, POD achieved 18.677 dB (a 74x reduction). This suggests a CV-inspired DL method can achieve 2x greater noise power reduction, even with a low-resolution reference and on a problem dominated by one low-frequency signal mode easy for POD. Overall, this research establishes a promising pathway to achieving high-fidelity kinetic plasma modeling without prohibitive computational cost.

Abstract Name: Temperature and Relative Humidity Effects on Water Absorption and Dissolution of Urea Fertilizer

The critical relative humidity (CRH) of a fertilizer is the ambient humidity at which the fertilizer starts to absorb water from the air. For urea, the CRH varies from 83% at 50°C to 72% at 35°C. Thus, when urea is surface-applied to pastures or no-till fields, it usually absorbs water from the air during late night and early

morning hours. If the period of water absorption is sufficiently long, the whole urea granule will dissolve to form a saturated urea solution, which will further dilute as water absorption continues. Later in the day, when the air temperature increases and the relative humidity decreases, the urea solution may lose water to the atmosphere and therefore its concentration will increase. These changes in urea concentration can affect the rate of urea hydrolysis. This study was conducted to evaluate the rate of water absorption by urea when it is exposed to two relative humidities (88% and 100%) and three temperatures (10, 20, and 30oC). The results showed that the rate of water absorption at a given relative humidity increased as the temperature increased. These results were used to develop a simulation model in Stella Architect to estimate water absorption by granular urea when exposed to changing temperature and relative humidity under field conditions. Model results indicated that complete urea dissolution in a pasture or no-till field may take one to five days depending on environmental conditions.

Abstract Name: Which Comes First? The Temporal Order of Reward Sensitivity and Inflammation following Childhood Abuse

Childhood abuse is linked with increased cardiovascular disease risk, prompting the question of underlying mechanisms. Theories proposed two key mechanisms: (1) reduced reward sensitivity – experiencing less enjoyment or positive emotion from typically rewarding activities and (2) elevated low-grade inflammation – a prolonged and systemic state of unresolved inflammation. This is because both reward sensitivity and inflammation are sensitive to childhood adversities and predictive of cardiovascular disease. However, whether abuse first impacts reward sensitivity or inflammation is unclear. Moreover, prior studies relied on behavioral tasks, limiting ecological validity and real-world implications. To address these gaps, we analyze longitudinal data from the Midlife in the United States (MIDUS) study (N=780, 3 waves over 18 years) which included self-reported childhood abuse and biomarkers of inflammation. Using self-reported positive events and positive emotions from its 8-day telephone interview data, we ecologically operationalize reward sensitivity as within-person difference in positive emotion experienced on positive event vs. non-event days. We expect that people will generally experience more positive emotion on positive event days, but that there will be individual differences captured by within-person difference scores. Covariates include age, race, gender, socioeconomic status, and adulthood life stress. We will test two competing hypotheses: (a) childhood abuse measured at Time 1 (T1) will predict decreased reward sensitivity at Time 2 (T2), which in turn will predict increased inflammation at Time 3 (T3); (b) abuse at T1 will predict increased inflammation at T2, which in turn will predict decreased reward sensitivity at T3. Through testing indirect effect models, findings will clarify the temporal sequence of childhood abuse's impacts on reward sensitivity and inflammation. Clarifying reward-inflammation's directionality refines theories to a specific mechanistic pathway for how abuse heightens disease risk, can inform interventions, and may challenge the perception that health-compromising behaviors are merely lifestyle choices.

Abstract Name: Experimental Study on the Effect of Hydraulic Jumps on Bridge Pier Scour

Scour at bridge foundations is the leading cause of bridge failure, necessitating methods for determining scour impacts in various flow scenarios. While foundations are primarily located in rivers with low velocity, high depth subcritical flow, rainfall events can cause changes in flow regime through high intensity rainfall (raising critical depth above current water depth) or obstructions. The transition between gradually varied flow regimes, coupled with contractions at bridge foundations, may introduce hydraulic jumps, leading to scenarios where rapidly varied turbulent flow directly interacts with foundation elements. Previous studies have analyzed pier scour in subcritical and supercritical flow, noting that supercritical flow typically results in lower pier scour; however, studies have not yet determined the impacts of hydraulic jumps on pier scour. From inspection, the effect on scour depth is unclear, as turbulent flow increases erosion and pier scour, while eddy currents reduce scour by returning eroded soil to the pier. This study uses experimental methods to determine the effects of hydraulic jumps on pier scours. Identical piers are placed in a soil bed of fine beach sand at various distances along the channel and subjected to a hydraulic jump within a wave flume. Scour effects at the pier are measured as a ratio of pile diameter at set time intervals, providing implications into the need for further protective measures such as corrugated aprons or buried plates. Investigation of impacts of hydraulic jumps on bridge pier scour depth will assist in determining the effectiveness of protective measures or the effectiveness of modifying pier geometry in mitigating hydraulic jump effects and reducing scour related instability.

Abstract Name: Production Networks and Volatility Transmission in U.S. Industries: Insights from BEA Input–Output Linkages

This research proposes a network-augmented econometric model to investigate how production interdependencies shape volatility propagation across U.S. industries. With tightly connected domestic supply chains, shocks originating in one industry rarely remain isolated. This study addresses the question: How do inter-industry input-output linkages amplify or attenuate volatility transmission across the U.S. economy? Beyond traditional multivariate volatility models such as DCC-GARCH, our approach explicitly incorporates the network structure into conditional volatility modeling using time-series data from the BEA Input-Output accounts. The methodology augments a GJR-GARCH(1,1) specification for sector-level ETF returns with a network spillover term, allowing an industry's conditional variance to depend on a weighted average of its neighbors' lagged volatility. This captures the sector-specific spillover coefficients δ_i that measure the time-varying sensitivity of an industry's volatility to shocks within its supply network. Subsequently, we regress these coefficients on network centrality measures—degree, betweenness, and eigenvector centrality—derived from the weighted adjacent matrix, testing whether an industry's network position systematically determines its role as a volatility transmitter or receiver. Potential research findings are threefold: first, the identification of structurally critical industries whose network positions make them potent amplifiers of financial instability; second, an empirical characterization of how specific centrality features moderate the magnitude of cross-sectoral spillovers; and third, an analysis of how major recessions (2008 Financial Crisis, COVID-19 pandemic) have reconfigured these risk channels. These results aim to characterize systemic risk channels rooted in production, with implications for macroprudential policy, industrial resilience planning, and targeted risk management by highlighting sectors most susceptible to contagious shocks.

Abstract Name: A WISE Look at Variability of Maser Galaxies

Current cosmological models for the fate of the universe and its geometry lack constraints that can be found with observations of powerful laser-like microwave emission (maser) from galaxy centers. These so called megamasers are however very rare, with detections in only about 3% of all surveyed galaxies. We explore here ways of efficiently detecting megamasers via a possible connection between this type of emission and accreting matter on supermassive black holes at galaxy centers, known as Active Galactic Nuclei (AGNs). An important feature of AGNs is light variability, which can now be exploited with multi-epoch observations in mid-infrared from the Wide-field Infrared Survey Explorer (WISE). We present here results from our calculations and parameterization of the Structure Function for galaxies with and without maser emission, as a tool to identify and compare the most prominent variability features, and therefore AGN emission, associated with maser activity.

Abstract Name: Data-Driven Prediction of Hydrogen Storage Performance in Metal-Organic Frameworks

Fossil fuels are a finite resource that contribute to global warming through carbon emissions and cause ecological harm during extraction. These sustainability challenges have increased interest in hydrogen as a cleaner energy carrier for applications such as transportation and power generation. Its low density, however, poses a major challenge for effective storage. Traditional storage approaches, including compression and liquefaction, require extremely high pressures or very low temperatures and still face safety and efficiency limitations. Metal-Organic Frameworks (MOFs) offer a promising alternative because of their high surface area and tunable structural properties. However, the vast chemical and structural diversity of MOFs makes it impractical to experimentally evaluate every candidate, necessitating computational tools to screen and predict their hydrogen storage performance. To address this challenge, molecular simulations using RASPA are conducted to obtain hydrogen adsorption data for a range of MOFs under different pressure conditions. Two machine learning models: Decision Tree and Extra Trees are implemented to predict storage capacity. Model performance is evaluated using the coefficient of determination (R^2) and mean absolute error (MAE), with hyperparameters optimized to improve accuracy. The trained models are then applied to new datasets to predict hydrogen uptake and to analyze relationships between structural features and storage capacity. Results show that MOFs with high uptakes exhibit large surface areas, high pore volumes, and high void fraction, along with low densities. These findings illustrate the potential of machine learning to guide the design and evaluation of MOFs for improved hydrogen storage and to support the development of next-generation storage materials.

Abstract Name: Poems as Tour Guides: Uncovering Place During the Late 20th Century through Poetry

Charles Semones established himself as one of the great 20th century Kentucky poets by dedicating his work to capturing and preserving the history of Harrodsburg, Kentucky. His writing serves as an eloquent tour guide to the time and terra firma of central Kentucky. Each line of poetry retraces his footsteps across the rural landscape and reveals the captivating stories contained within its sprawling lakes and fields. He pulls the curtain back to reveal the secrets each home contains. This unique window into the community enables the reader to fully grasp the struggles, values, and shared experiences that bind its inhabitants together. Semones' poetry also explores a wide range of topics, such as grief and loss, religion, and the formative experiences that defined his childhood. While Semones spent most of his life living in a secluded area, he remained in constant conversation with other Kentucky poets. His peers, Robert Penn Warren and Joy Bale Boone, inspired and invigorated Semones through their correspondence. This research will qualitatively examine poetry and the correspondence in the Charles Semones Papers, 1950s-1980s, at the University of Kentucky Special Collections Research Center to explore connections among poets who explored similar themes and supported each other's work. By studying Semones work in conversation with Warren and Boone, this research will provide intricate portraits of the individuals, locations, and literary traditions that defined Central Kentucky during the late 20th century.

Abstract Name: Repurposing Metastatic Breast Cancer Drugs in a Mouse Model of Alzheimer's Disease

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by the buildup of amyloid-beta plaques and neurofibrillary tangles in the brain, leading to memory loss and cognitive decline. A potential contributor to this buildup is the disruption of protein folding mechanisms. In particular, the chaperone protein GRP78 has been found to be highly expressed in AD, possibly causing disruption in damaged protein clearing within the brain. In this ongoing preclinical study, we investigate whether a combinatorial approach of AR12 and neratinib could strengthen protein clearance leading to memory deficit prevention. AR12, an anti-viral/anti-cancer drug, improves autophagy, a natural cellular recycling process, while neratinib, an FDA-approved breast cancer therapeutic, reduces GRP78 levels and targets amyloid precursor proteins for degradation. Beginning at approximately three months of age (i.e., prior to accumulation of amyloid-beta) mixed sex APP/PS1 mice, a transgenic mouse model of AD, received daily injections of AR12 and neratinib or vehicle for five months. All mice were evaluated for memory deficits using novel object recognition and object location learning and memory tasks, prior to experimentation and after chronic treatment. All APP/PS1 mice did not significantly differ from wild-type controls in either task, which precludes interpretation of potential drug-related effects. Nevertheless, the drug combination treatment was well tolerated, with no observed differences in weight gain. Further analysis of brain tissue via

immunohistochemistry will determine whether the chronic combinatorial treatment prevented amyloid-beta plaque accumulation in the APP/PS1 mice. Future studies should consider using other learning and memory assays known to undergo age-related performance deficits in APP/PS1 mice (e.g., Morris water maze). Ultimately this work will establish whether a combination of two repurposed drugs possess the potential for preventing age-related memory deficits or the accumulation of amyloid-beta in the brain using an established mouse model AD.

Abstract Name: Optical Phantom Mimicking Cerebral Blood Flow for Validation of Speckle Contrast Optical Spectroscopy

Monitoring cerebral blood flow (CBF) is essential for understanding and maintaining brain health. Non-invasive optical techniques such as Speckle Contrast Optical Spectroscopy (SCOS) offer a method for assessing CBF. However, evaluating SCOS depth sensitivity is limited by the lack of suitable tissue phantoms. Many existing phantoms use bulk liquids or single-layer solids and model a uniform tissue type. To address this, we propose a multi-layer tissue phantom designed to better reflect optical properties and flow patterns of skin and skull. A two-layer phantom was fabricated using polydimethylsiloxane (PDMS) with embedded silicone tubing at 4 mm and 10 mm below the surface to simulate superficial blood vessels. Titanium dioxide (TiO₂) and India Ink were added to match brain-like scattering and absorption properties. The experimental setup used an 852 nm long-coherence laser (200 mW, coherence length >50 m) and a 2M-pixel, 8-bit CMOS camera at 160 fps with 1920 × 1200 resolution. The detection optics consisted of a two-lens assembly (aspheric and plano-convex) providing ~4× magnification, ensuring a speckle-to-pixel ratio >2. Light was delivered through a 600 μm multimode source fiber, and detection used multimode fiber bundles with 90° molded tips. Source–detector separations (SDS) were varied between 1.0 and 1.5 cm to evaluate depth sensitivity. An intralipid solution circulated through tubing using a syringe pump to produce flow. Speckle contrast (κ) was calculated from recorded videos. A rectangular ROI was selected from each frame, and $1/\kappa^2$ increased as flow rate increased, demonstrating sensitivity to flow. While promising, these results demonstrate feasibility. Validation experiments are in their final stages to refine depth-dependent sensitivity by optimizing source–detector separations and adjusting optical properties. The finalized two-layer phantom will serve as a standardized benchtop platform for calibration, benchmarking, and performance evaluation of optical flow measurement technologies, supporting broader applications in cerebral blood flow measurements.

Abstract Name: Mentorship at HBCUs: How Black STEM Mentors Shape Identity, Belonging, and Career Aspirations

Historically Black Colleges and Universities (HBCUs) play a critical role in shaping the academic and career pathways of Black students in science, technology, engineering, and mathematics (STEM). While mentorship is known to strengthen persistence and identity development in STEM, little research has examined how these processes operate specifically within HBCU environments. This qualitative study investigates how Black STEM mentors influence Black undergraduates' STEM identity formation, career aspirations, and coping with race-related challenges. Guided by Social Cognitive Career Theory (SCCT) and the Phenomenological Variant of Ecological Systems Theory (PVEST), this project explores how self-efficacy, outcome expectations, and identity development emerge through mentoring relationships. Participants include eight mentor-mentee dyads across four HBCUs, consisting of graduate student and faculty mentors and junior/senior STEM majors. Data collection involves a prescreening survey and two semi-structured interviews per dyad—an individual interview followed by a joint interview. Transcripts are analyzed using a two-cycle coding process that incorporates a priori codes from SCCT and PVEST as well as inductive codes reflecting students' lived experiences. Hermeneutic phenomenology and counter-storytelling approaches support interpretation and challenge deficit narratives surrounding Black STEM achievement. Preliminary findings suggest that mentorship at HBCUs operates on multiple levels: mentors build students' confidence through modeling and shared identity; expand career expectations by normalizing Black success in STEM; provide culturally informed guidance on navigating academic and professional spaces; and buffer racialized stressors by affirming belonging and identity. This study advances understanding of how HBCU ecosystems uniquely support STEM persistence and offers implications for designing culturally responsive mentorship models across higher education.

Abstract Name: The role of Hippo pathway kinases LATS1 and LATS2 in ovarian cancer

High-grade serous ovarian cancer is often diagnosed at an advanced stage and has poor long-term survival, highlighting the need to better understand pathways that restrain tumor cell proliferation. The RB family and the DREAM complex enforce a G0/G1 checkpoint by repressing cell-cycle genes, whereas the Hippo kinases LATS1 and LATS2 inhibit the pro-growth transcriptional co-activator YAP. Clinical data link low LATS1/2 expression in ovarian tumors to poorer overall survival and earlier onset, suggesting that Hippo pathway disruption is clinically relevant. Previous work in our laboratory shows that shRNA-mediated loss of both LATS1 and LATS2 in human ovarian cancer cell lines results in increased proliferation, anchorage-independent growth, migration, and tumor growth in vivo. These changes were mediated in part by reduced activity of DYRK1A protein kinase that promotes the phosphorylation of LIN52 protein, required for DREAM complex assembly, as well as increased nuclear YAP and cyclin D1 upregulation. To validate these findings and gain a mechanistic understanding of these effects, this project aims to establish additional human and mouse ovarian cancer models with simultaneous knockdown of LATS1 and LATS2. Using lentiviral infection, we generated shControl and shLATS1/2 SKOV3 and Kuramochi human cell lines, as well as ID8 mouse ovarian cancer cells. The targeted cell populations were enriched using GFP-based sorting, and knockdown validation was performed by Western blotting. Gene expression changes of the Hippo and DREAM targets were assessed by RT-qPCR, and the DREAM complex assembly and DYRK1A activity were measured by immunoprecipitation and Western blotting. These models are amenable to in vitro and in vivo preclinical studies to determine how the loss of LATS kinases can rewire the Hippo and DREAM pathways and influence the CDK4/6 inhibitor sensitivity in ovarian cancer.

Abstract Name: Evaluating Recruitment Methods for the NOSES Study: Insights and effectiveness at Student Health

Acute rhinosinusitis (ARS) affects ~15% of adults annually, yet despite most cases being viral, antibiotics are prescribed in nearly 70% of ARS-related encounters. The Nasal Irrigation, Oral Antibiotics, and Subgroup Targeting for Effective Management of Acute Sinusitis trial is a four-arm, double-blind RCT evaluating alternatives to routine antibiotic use. The trial aims to determine how treatment efficacy varies across patient subgroups to inform more personalized ARS management. Across Virginia, recruitment occurs in urgent care, primary care, and student health clinics. Research assistants (RAs) play a central role, introducing the study, screening for eligibility, reviewing procedures, and guiding the informed consent process, including enrollment procedures. Recruitment is generally consistent across sites, though workflows differ. In urgent care and primary care clinics, RAs rely on clinician referral. Clinicians identify patients presenting with sinus symptoms and notify the RA, who then approaches the patient after the clinical assessment. This model limits RA–patient interaction to encounters initiated by clinical staff. At VCU Student Health Services, RAs employ a proactive outreach model, remaining in the waiting area, discreetly approaching patients upon check-in. RAs introduce themselves, share a study flyer, and ask patients if they are interested in learning more. Those interested are escorted to a private room following their visit for the consent discussions. This approach reduces clinician burden, avoids using exam rooms, and enables efficient patient engagement. These strategies have increased enrollment at Student Health. Notably, the Student Health population is younger than the urgent care and primary care populations, highlighting the need to tailor recruitment approaches to different age groups. Overall, these findings emphasize the value of adapting recruitment workflows to clinic settings and patient demographics to maximize engagement and enrollment in clinical trials.

Abstract Name: Longitudinal Analysis of TWU/AFA CyberCamp Impact: A Decade of STEM Education Outcomes

This study examines the educational impact of the TWU/AFA CyberCamp by analyzing a decade of pre and post survey data that measure student knowledge, confidence, and skill development in cybersecurity and STEM domains. CyberCamp is a week-long intensive program designed to introduce middle and high school students to core cybersecurity concepts, hands-on technical training, and professional pathways. As cybersecurity threats and workforce needs have expanded significantly over the past ten years, understanding

how early interventions influence student learning and career interest has become increasingly important. The dataset underlying this project includes S-STEM survey responses, cybersecurity knowledge assessments, and demographic information collected annually from participants. These data provide a unique opportunity to investigate how short-term instructional experiences shape student self-efficacy, knowledge gains, and interest in STEM fields over time. The study evaluates changes in participants' cybersecurity knowledge and confidence by comparing matched pre and post responses across four survey instruments. Analysis of data focuses on examining patterns of growth in skill areas such as network security, password management, virtual machines, and online safety. Additionally, this will explore broader STEM constructs including confidence in math and science, 21st-century learning skills, and career readiness perception. Because CyberCamp participants represent a diverse population from multiple school districts, this project also considers how educational background and demographic factors relate to learning outcomes. The findings will contribute to national discussions on cybersecurity workforce development by identifying which instructional components most effectively improve student understanding and engagement. Results will also inform program design for institutions seeking to broaden participation in cybersecurity and strengthen early STEM pipelines. This work supports the broader need for evidence-based approaches to cybersecurity education as organizations and communities face an increasingly complex digital threat landscape.

Abstract Name: Adverse Childhood Experiences, Family Resilience, and Mental Health in Latinx Children

Adverse Childhood Experiences (ACEs) are associated with poor mental and physical health outcomes (Loria & Caughy, 2018; Zetino et al., 2020), but limited research has examined what might help buffer the negative impact of ACEs on mental health in this population. The current study is a secondary data analysis of the 2022-2023 National Survey of Children's Health (NSCH) that aims to examine the relationship between ACEs and mental health in Latinx children (N= 12,333) and to explore whether family resilience buffers this relationship. Most children were third generation or higher (48.5%), 39.1% had a parent born outside the US, and 3.7% of the children were born outside the US. Logistic regression, which included categorical ACE levels (0, 1-2, 4+), family resilience, controlling for nativity, generational status, sex and age, tested the relationship between ACEs, family resilience and mental health. Children with 1 ACE had higher odds of mental health problems versus no ACEs (OR= 1.54, $p < .001$; 2-3 ACEs had higher odds (OR=2.67, $p < .001$); 4+ ACEs had higher odds (OR=5.56, $p < .001$). The ACE x family resilience interaction was significant for 2-3 ACEs ($p = .022$) and marginally significant for 4+ ACEs ($p = .069$), indicating diminished buffering at higher adversity. This pattern remained consistent across nativity ($p = .104$) and generational status ($p = .340$). Latinx children who experience more ACEs face progressively higher risks of mental health problems. Family resilience was protective factor, however, the buffering effect diminished as ACEs increased. Migrant status does not seem to impact this interaction. This suggests that some families of Latinx children may need more support, and more research is needed to understand how family resilience helps kids do better in stressful situations.

Discipline: Dance

Authors:

Abstract Name: Bridging the Gap Abstract - Elizabeth Delcid

My research explores the evolution of choreographic identity through immersive participation in the Bates Dance Festival (BDF), a nationally recognized hub for dance innovation and collaboration. Motivated by a personal inquiry into artistic growth, my project studies how choreographers develop and express meaning through dance, storytelling, and cultural observation. My research explores various choreographic techniques and the influence of rigorous training environments on the development of creative voices, drawing on journalistic, performative, and ethnic methodologies. My research looks at rehearsal procedures, thought-provoking discussions, and contemplative performances through close collaboration with well-known artists like David Dorfman and The Bill T. Jones/Arnie Zane Dance Company. I research how technique, emotion, and interpretation interact. MK Abadoo's mentoring offers a structure for goal-setting, critical evaluation, and ongoing reflection, highlighting the value of self-awareness, flexibility, and involvement in artistic practice. The research highlights the significance of community, vulnerability, and cultural dialogue in choreographic development. It also discusses issues like perfectionism and imposter syndrome, providing insight into how emotional experiences can be turned into artistic creations. Ultimately, my work strengthens the fields of choreography, and arts-based research by emphasizing the potential of movement as an outlet for research, connection, and leadership. As a result of this project, I will be able to share my voice in the dance community, which will direct future work in instruction, performance, and collaborative creation.

Abstract Name: Bridging the Gap: How Under-Resourced High Schools Compensate for Limited AP Access

Educational inequality in the United States is a problem that still shapes students' access to quality academic opportunities, more precisely at low-resourced high schools. Many lower-resourced schools often have no Advanced Placement courses, which allow students to develop college-level skills, earn early college credit, and strengthen their college or university application. Without access to AP coursework, students in under-resourced schools typically face significant barriers to college readiness and long-term academic success. Some low-income schools have responded by creating alternative programs to keep high-performing high-school students adequately challenged: dual-enrollment or early-college relationships that give students college credits, as well as honors courses with a more rigorous level of academic challenge and CTE pathways with added practical learning to regular academic learning. Many offer similar benefits to AP coursework, these varying in effectiveness for differing reasons that include partnerships, teacher preparation, and funding. The study investigates the ways in which under-resourced schools compensate for a lack of AP courses, as well as assorted impacts of their alternative programs on college readiness. This study aims to inform whether and how these programs successfully bridge the gap in access to academically rigorous or challenging instruction by closely analyzing how the programs function and the range of outcomes they produce. The final goal should be to point out ways to guarantee equal opportunities for college preparation irrespective of students' socioeconomic status and background.

Abstract Name: Chronic Pain, School Absenteeism, and Suicidal Behaviors in a Nationally Representative Sample of US Adolescents.

Youth suicidality is a critical public health issue, reflected by suicide being the third leading cause of death among 13-18 year olds in 2023. An increasingly studied factor that contributes to worsened mental health in youth populations is chronic pain status. National data suggest that chronic pain among youth is prevalent, having been reported by over 20% of US adolescents. An additional dimension of chronic pain that can contribute to decreased youth mental health is its impact on school absenteeism. The purpose of our study is to add to this body of literature by investigating the mediating role of school absenteeism in the relationship between chronic pain and youth suicidality. We used nationally representative data from Waves 1-2 of the National Longitudinal Study of Adolescent and Adult Health to determine if chronic pain prospectively increased the risk for suicide ideation and attempts, and if school absenteeism partially accounted for this association. Chronic pain was measured at Wave 1 across four separate pain sites including: joint, headache, body aches, and stomach pain. School absenteeism and suicide ideation and attempts were measured at Wave 2. Logistic regression models, controlling for gender and race, indicated that both the presence and extent of chronic pain significantly increased the likelihood of both missing school and suicidality. As hypothesized, the frequency of missing school mediated (accounted for) the increased risk of suicidal behaviors due to chronic pain. Results will suggest future research directions as well as implications for intervening with health care providers, parents, and school personnel to educate them about the potential ramifications of chronic pain among youth.

Abstract Name: Systematic Optimization of Prime Editing to Correct JAK2 V617F

Prime editing is a next-generation CRISPR-Cas9 genome-editing system that enables precise, versatile DNA editing without generating double-stranded breaks or requiring donor DNA templates. While it holds great promise for correcting pathogenic mutations, limited efficiency remains a significant barrier to its therapeutic application. One such therapeutic application is for the correction of a particularly pathogenic mutation in the JAK2 gene. JAK2, or janus kinase 2, is a key protein involved in the JAK/STAT signaling pathway, which controls the cell growth and differentiation of hematopoietic stem cells in the bone marrow. Mutations in this gene are implicated in several myeloproliferative neoplasms (MPNs), a group of blood cancers characterized by uncontrolled cell differentiation. Of these, the V617F mutation, caused by a G·C to T·A transversion in Exon 14, is most common and thus offers a therapeutic opportunity. Due to the nature of the mutation, it can only be corrected using prime editing. Therefore, optimization of a prime editing strategy to correct this mutation would be an invaluable contribution to therapeutic efforts to treat MPNs caused by the JAK2 V617F mutation. Efficiency screens using plasmid transfection and next-generation sequencing analysis are conducted in two mammalian cell lines: HEK293T cells, a commonly used workhorse line, and leukemia-derived K562-s cells that closely mimic the disease environment. By optimizing editing conditions across both model and disease-relevant cell types, this project aims to provide researchers with the foundation to develop therapies that correct the JAK2 V617F mutation using prime editing, while also improving the applicability of prime editing for correcting other pathogenic single-nucleotide variants.

Abstract Name: Dual Inhibition of PDE5 and mTOR Attenuated Chemotherapy and Immunotherapy Induced Cardiotoxicity

Combining HER2 (human epidermal growth factor receptor 2, ErbB2)-targeted immunotherapy with anthracycline-based chemotherapy (Doxorubicin, DOX) improves progression-free survival in HER2-positive breast cancer, but increases the risk of heart failure. We previously showed that Sildenafil (Sild, a phosphodiesterase inhibitor) prevents DOX-induced cardiotoxicity while potentiating antitumor efficacy. As mTOR (mammalian target of rapamycin) signaling is over-activated in multiple cancers, Rapamycin (Rapa) attenuates tumor growth. In this study, we investigated whether novel therapy combining Sild and Rapa could reduce the cardiotoxicity associated with DOX and the HER2 inhibitor. Female C57BL/6J mice were treated with DOX (6 mg/kg/twice/week, i.p. 5 times). After a one-week interval, Afatinib (AFA, a selective ErbB inhibitor, 10 mg/kg, p.o.) was further administered to mice for 2 weeks. Mice were co-treated with Rapa (0.25 mg/kg/twice/week, i.p.) and Sild (0.4 mg/ml in drinking water) throughout the experimental period (12 weeks) and body weight and survival were monitored. After 6 weeks following completion of DOX±AFA treatment, cardiac function was examined by Echocardiography, then hearts were collected to isolate proteins for Western blot analysis. Body weight and survival were decreased following treatment with DOX alone and DOX+AFA, which were improved with co-treatment of Sild+Rapa. Left ventricular ejection fraction (LVEF) was reduced in DOX+AFA-treated mice, while co-treatment of Sild+Rapa restored the cardiac function. Western blot analysis revealed DOX alone and DOX+AFA induced phosphorylation of mTOR and S6 (marker of mTOR complex 1, mTORC1), which were attenuated with the cotreatment of Sild+Rapa in mice hearts. The expression of a proapoptotic marker, Bax was induced in mice hearts after DOX+AFA treatment, which was also repressed by Sild+Rapa co-treatment. Cotreatment with Sild+Rapa may represent a novel strategy to reduce cardiotoxicity associated with chemoimmunotherapy by inhibiting mTOR, specifically mTORC1 activity and proapoptotic protein Bax.

Abstract Name: The Role of Law in Addressing Climate Change: Shaping Public Perceptions of Climate Change through Educational Policy in Spain

Spain offers a uniquely compelling context for examining the relationship between legally-mandated climate

education and public perceptions of climate change. The country ranks among the EU's leading nations with high citizen support for climate reform and has enacted comprehensive national climate education laws. Additionally, Spain exhibits remarkably high public climate engagement with 95% of Spaniards supporting urgent climate action. This study investigates Spain's climate education laws, including Law 7/2021 (Climate and Energy Transition Law), LOMLOE educational reforms, and Royal Decree 217/2022, to understand how these legal mandates may relate to Spain's strong public commitment to climate action. The methodology for this research also included a systematic literature review of legal documents, policy analyses, and public perception studies. Interdisciplinary perspectives from law, cognitive science, and community psychology were utilized to examine how climate education laws relate to the public's perceptions on addressing climate change. Findings reveal significant outcomes that demonstrate these policy-perception relationships. Spain shows exceptionally high public awareness with 80% of Spaniards believing they can personally make a difference in the climate crisis (eight points above the EU average). Spain's action-oriented, transversal approach also fosters cross-sector sustainability awareness with 83% of young Spaniards prioritizing the employer's sustainability strategies during job searches. These findings emphasize that legal frameworks often relate to the reinforcement of environmental values in Spain. In fact, 79% of Spaniards under 30 support stricter government behavioral measures in the future. This creates a feedback loop where the climate education laws enhance the public's understanding of climate change's threats, which subsequently generates support for policies and candidates advocating for stricter environmental legislation. By analyzing Spain's distinctive integration of law, education, and civic attitudes, this research highlights the importance of policy-driven climate education as an effective component in addressing the climate crisis.

Abstract Name: Investigating Synesthetic Adjectives with Diachronic Word Embeddings

While historical linguistics has enjoyed great success in discovering laws governing many aspects of linguistic change, this has proven difficult for semantic change. In the past decade, diachronic word embeddings have shown promise to ameliorate this. Using diachronic word embeddings, I evaluate the proposal that sensory adjectives ("bright", "loud", etc.) are governed by a systematic and unidirectional law of semantic change in their metaphorical extensions to other sensory modalities, as put forth in Joseph Williams' 1976 paper "Synaesthetic Adjectives: A Possible Law of Semantic Change". Diachronic word embeddings are vector representations of words, with values determined by the frequency with which a given word appears adjacent to context words in a large text corpus, organized by the time period of the sources in which these appearances are found. By analyzing their relative values, prior work has demonstrated a method for identifying interpretable semantic dimensions. Using this method to identify dimensions representing sensory modalities, I track the metaphorical extensions of the sensory adjectives attested in Williams (1976). I use cosine similarity to measure semantic relatedness between each sensory dimension and a given adjective for its embeddings over several time periods from the 1800s to present, and compare the direction of change to Williams (1976)'s hypothesis, which is informed by data from c. 1000 to his time of writing. Diachronic word embeddings afford finer granularity, but also impose a shorter temporal window of analysis, due to the sparsity of corpus data from before 1800. Analysis is still ongoing. Results in line with Williams (1976)'s hypothesis would support his proposal, establishing that his proposed law is ongoing and steady over shorter time periods. Results contradicting Williams (1976)'s hypothesis or inconclusive results would indicate that his proposed law is no longer in effect, or is too noisy to be observed over shorter time periods.

Abstract Name: Adults with Congenital Anosmia: Lifelong Absence of Smell in Relation to Creating Autobiographical Memory and Personality

Congenital anosmia, the lifelong absence of smell, has connections to autobiographical memory and personality development, which allows for examination into the shaping of cognition and the construction of self in adults with congenital anosmia. In normosmic individuals, olfactory cues are closely tied to emotional learning, vivid memory recall, and the retrieval of autobiographical memories through direct connections between primary olfactory regions and limbic structures. Individuals with congenital anosmia lack these sensory-emotional pathways and show distinctive structural and functional brain differences compared to normosmic adults, including reductions in primary olfactory cortex volume and altered connectivity in regions supporting memory and emotion. Evidence indicates reliance on conceptual, semantic strategies during remembering, resulting in autobiographical memories that are less perceptually detailed, less emotionally intense, and more effortful in retrieval compared to cue-driven recall typical in normosmic adults. Most of these discoveries were found from individual studies about imaging methods, odor processing instead of memory and personality outcomes, and neural changes unrelated to the lived cognitive experience. These findings leave the psychological consequences of congenital anosmia underexplored, with gaps in the understanding of how these neural differences translate into lived cognitive experience. Combining behavioral, cognitive, and neurobiological findings may clarify how individuals with congenital anosmia construct autobiographical memories through conceptual and linguistic mechanisms rather than sensory cues, and how these alternative processes shape personality development. Together, these observations highlight how the absence of a sensory modality can influence both memory systems and personality formation, demonstrating the importance of olfaction in shaping emotional development.

Abstract Name: Exploring the Frequency of Community Service in the School of Health Professions

Community engagement is essential for student development, fostering leadership, social responsibility, and hands-on experience. In the School of Health Professions (SHP), service is embedded in both education and research, enhancing students' ability to address health disparities and contribute to community well-being. This study explores the extent of community service involvement within SHP through surveys and interviews with faculty, student organization, and staff. Participants engage in 30-minute sessions, with a goal of collecting responses from at least 20% of each department and one student organization per department. The survey investigates the prevalence of service activities, affiliated organizations, and whether these efforts align with research and educational goals. Preliminary findings suggest that most groups within SHP actively engage in service, partnering with organizations such as Firehouse Ministries, Live Health Smart, and United Ability. These partnerships focus on healthcare access, disability advocacy, and wellness initiatives. While results indicate a strong commitment to service, data collection is ongoing. Community service is a vital component of SHP's mission, equipping students with essential skills such as cultural competence, interdisciplinary collaboration, and problem-solving. By integrating service into academic training, SHP prepares students to become well-rounded healthcare professionals who are not only clinically competent but also dedicated to improving public health and addressing community needs.

Abstract Name: Molded Plywood Movement

The goal of this research project is to investigate the characteristics of molded plywood to better understand how various factors influence its movement. Plywood is a versatile material that can be used to build furniture, wooden structures, and much more. It is made by laminating thin sheets of wood (i.e. veneer) perpendicularly across each other, resulting in a piece of wood that has great structural integrity compared to its mass. They typically come in flat sheets, but the process of making plywood also allows them to be formed in organic curves, which are referred to as “molded plywood” or “bent laminations”. However, wood is an organic material, and is prone to shrinking and expanding depending on external factors. Though the crisscrossing layers of plywood minimize this effect, molded plywood reflect this warping, also referred to as “movement”, more distinctly than flat plywood. To minimize plywood movement, industry facilities use special drying chambers once molding their pieces. However, in an educational institution, such special facilities are unavailable. Due to this, many student molded plywood projects face unexpected shrinkage, resulting in final products that do not match their original design. Particularly for furniture projects, this shrinkage can compromise the usability of the piece, undermining the efforts behind perfecting the designs. To aid student facilities to achieve desired bending angles reliably, I conducted experiments on a few factors that could affect the movement of molded plywood; specifically the characteristics of the mold, including its initial angle and corner radius. Other variables, like veneer thickness, plywood thickness, or wood species, were kept constant, to keep results consistent. This investigation results in quantitative findings that define an estimated formulaic relationship between the mold angle and resulting plywood angle. With this information, students will be able achieve desired bending angles more reliably by creating the appropriate molds.

Abstract Name: Understanding Psychological Mechanisms of Rain Ceremonies and Modern Coping Responses to Environmental Uncertainty

This study is a cross-cultural content analysis of archival data that investigates the psychological mechanisms underlying rain ceremonies worldwide. Rain ceremonies are human attempts to influence weather patterns, which have been observed throughout human history, gaining prominence as agriculture developed. The researchers explore how cultural beliefs about nature shape rain ceremonies and their connection to psychological and scientific explanations of human behavior. Data collection is ongoing, sourced from archaeological, anthropological, historical, and contemporary empirical literature. Through qualitative analysis of rain ceremonies, ten primary themes have emerged, though these may evolve as data collection progresses. The study examines cultures (N=101) across all six historically inhabited continents, spanning ancient history to the present day. Once data collection is complete, a frequency analysis will be conducted to identify the most frequently recurring themes and subthemes within the dataset. The findings suggest that rain ceremonies reflect the universal psychological impulses to regain a sense of control, reduce anxiety, and create meaning and connection in times of stress. These same impulses are similar in modern behaviors observed during natural weather disasters, where individuals collectively participate to prepare and cope with uncertainties. Whether through emergency readiness practices or shared cultural behaviors and gatherings, people continue to rely on ritual-like behaviors found in rain ceremonies to cope with environmental distress.

By comparing the responses observed in rain ceremonies with the modern coping behaviors found during extreme weather events, this study reveals how humans continue to use ritualistic and collective actions as coping mechanisms in order to seek stability and control in environmental unpredictability.

Abstract Name: How Does Parental Exposure to Plastics Affect Offspring?

Microplastics (MPs; plastic particles <5 mm) have become ubiquitous in Earth's ecosystems, even reaching the most isolated environments and human tissues. In addition to their toxicity, MPs release harmful phthalate esters (PAEs), which are plasticizers that give plastics their unique characteristics of flexibility and durability. Unfortunately, PAEs are also problematic to animal health because they act as endocrine disruptors and interfere with steroid hormone regulation. Yet, we lack a comprehensive understanding of the combined effects of MPs and PAEs, which may entail additive or synergistic costs to important traits, such as reproduction and offspring fitness. Since environments exhibit long-term contamination by MPs and PAEs, it is also essential to characterize their transgenerational effects— that is, how parental exposure to MPs and/or PAEs have carryover effects that influence their offspring. Here, we used a factorial experimental design and fed four different diets (control [no additives], MPs added, PAEs added, and both MPs + PAEs added) to breeding pairs of the variable field cricket (*Gryllus lineaticeps*). We then determined within-generation effects on reproduction (mating success and egg production) and transgenerational effects on offspring (hatching success, hatchling starvation resistance, and hatchling development rate). Our study will be the first to test for the sex-specific effects of MPs and PAEs on fitness-related traits within and across generations.

Abstract Name: The Effect of Bisphenol A on The Neurodevelopment of *Drosophila melanogaster*

Bisphenol A (BPA), a common endocrine-disrupting chemical (EDC), whose worldwide presence in the environment is responsible for chronic exposure during vulnerable periods. BPA, whose contamination can occur via food, water, air, dust, and soil, has been proven to have adverse effects on the development of organs and tissues, but specifics are largely under-researched. BPA has been suspected to cause neurodevelopmental disruptions, though its specific effects remain poorly understood. This study investigates the impact of BPA on the neurodevelopment of *Drosophila melanogaster*, commonly known as fruit flies, a widely used model organism for studying neurological processes. Fruit flies were exposed to 4 μ L, 10 μ L, and 100 μ L concentrations of BPA during critical developmental stages. Behavioral assays will be conducted to assess locomotion and sleep patterns as indicators of neurodevelopmental changes. Results are being gathered, but trends show a concentration-dependent effect, with higher BPA levels correlating with reduced

locomotor activity. These findings suggest that BPA exposure negatively affects neurodevelopment by impairing essential neural functions. Further research is needed to explore the underlying mechanisms and potential long-term consequences of these disruptions.

Abstract Name: Investigating intracellular/extracellular Tau dynamics post-injury in a 3D Neuron-on-Chip platform

Traumatic brain injury (TBI) is known to be a high risk factor for the development of Alzheimer's disease and related dementia (ADRD). The progressive prion-like propagation of neurodegenerative Tau aggregates is a key contributing factor for the development of ADRD in TBI patients. It is commonly acknowledged that pathological tau aggregates escape from neurons into extracellular space and internalized by adjacent neurons in AD. However, it remains unclear the mode of transition of Tau and its intracellular/extracellular dynamics after TBI. To bridge this gap, we conducted a study on intracellular/extracellular tau dynamics to explore the behavior of pathological tau post-TBI. Our study used the Neuron-on-Chip platform, a microfluidic platform previously developed by our lab, culturing hPSC-derived prefrontal cortex neurons (PFCs). PFCs were subjected to a weight drop injury using a focal impactor. Tau pathology was evaluated using western blot for Tau46, pTau181, pTau231 and pT396, Immunocytochemistry for AT8 and neurofibrillary tangles (NFT), and secretome analysis for total Tau, pTau. Data was collected at days 0, 1, 3, 5, and 8, providing a comprehensive characterization of Tau dynamics. Western blot analysis showed a marked reduction in total Tau in injury groups across all time periods, elevations in pTau181 and pTau396, with no difference in levels of pTau231 across control and injury groups. Immunocytochemistry showed significantly elevated levels of AT8 and NFT on day-5 and -8, and day-8 respectively, indicating an acute increase in levels of intracellular pathological Tau. Secretome analysis showed increased levels of pTau181 and total tau from day 1-5, revealing progressive release of extracellular Tau. These results advance the understanding of the acute progression of tau pathology following TBI, further clarifying the role of TBI in the development of neurodegenerative diseases such as AD.

Abstract Name: Neuron-Enriched Extracellular Vesicle microRNAs Reflect Hormonal Suppression Associated with Oral Contraceptive Use in Young Women

Hormonal contraceptives alter hypothalamic–pituitary–ovarian (HPO) feedback, but their impact on brain-associated molecular communication remains poorly understood. Neuron-enriched extracellular vesicle

(nEV) microRNAs (miRNAs), isolated from plasma, provide a minimally invasive window into brain molecular activity. This pilot study examined nEV miRNA expression in young women (ages 18–22) who were either naturally cycling or using a combined monophasic oral contraceptive (OC) pill. To identify hormonally responsive miRNAs, we calculated effect sizes (Cohen's d) between the two groups and selected those showing large between-group differences ($|d| \geq 0.8$). These miRNAs were entered into a principal component analysis (PCA) to reduce dimensionality, and the resulting components were correlated with measured hormone levels (FSH, LH, estradiol, and progesterone) to determine biological relevance. Principal Component 1 (PC1), explaining the largest variance, correlated positively with log-transformed estradiol ($r = .64$, $p = .003$) and progesterone ($r = .70$, $p = .001$), representing an ovarian steroid axis consistent with endogenous hormonal activity suppressed by OC use. Principal Component 2 (PC2) correlated positively with FSH ($r = .59$, $p = .006$) and LH ($r = .46$, $p = .041$), reflecting pituitary feedback mechanisms characteristic of exogenous hormone regulation. Scatterplots showed clear group-level separation along these components, highlighting distinct endocrine profiles between OC users and naturally cycling participants. Together, these findings reveal that nEV miRNA expression patterns align with hormonal regulation at multiple levels of the HPO axis—from pituitary gonadotropin signaling to ovarian steroid output. These data suggest that nEV miRNAs provide a molecular window into neuroendocrine adaptations to exogenous hormonal modulation.

Abstract Name: A Look at Japan's Sartorial History: The Identity of the Kimono

A person's clothing is both among the most overt and most malleable aspect of their identity. By exploring material culture such as the formal dress kimono/wedding kimono (kurotomesode) housed at the Illinois State Museum, we can reveal an intimate look at how kimono embody the idea of self-fashioning. In particular, this research included reading works published both about kimono and material culture, conducting a personal interview, and attempting to uncover this object's personal history. Serving as the dominant wear of Japan for centuries, kimono were an integral part of Japanese everyday life. Not tied to a specific gender, class, or lifestyle, the robes changed with those who wore them, becoming an outward-facing and explicit message of identity. Every aspect—fabric, color, sleeve length, symbols, motifs—was chosen with intent to communicate something about the wearer. Through clothing alone, intimate details could be revealed, status hierarchies enforced, and art could be woven into a person's day-to-day life. This kimono specifically was created following the introduction of Western influence in the Meiji period of Japan, a time period that caused the solidifying of two distinct categories of being: Japanese clothing (wafuku) and Western clothing (yōfuku). The kimono, though eventually phased out of everyday wear, transitioned into a symbol of Japanese national identity, along with the idea of wearing the robe as a signifier of being Japanese. This kurotomesode stands as both a personal canvas for self-expression and a view into the extensive history of the garment at large, and its transformation throughout time.

Abstract Name: State Legislature Demographics and Anti-Transgender Legislation

Starting in 2015, anti-transgender bills have been introduced in state legislatures in exponentially increasing numbers, with a sharp uptick in 2020 and numbers that nearly doubled every year since then. These bills concern a wide variety of issues, from sports participation for transgender adolescents to drag bans to restrictions on bathroom usage. This paper finds that only a small percentage of the bills are passed into law, indicating that passing laws is less important to legislators than introducing bills. Given these intentions, this paper seeks to analyze the demographic makeup of chambers that introduce and pass these bills to understand who is supporting these bills and whether descriptive representation has a positive effect on transgender policy priorities. Data was gathered from various websites, including the ACLU's anti-LGBTQ+ bills databases, Out for America's list of LGBTQ+ legislators, and Center for American Women in Politics' databases. Linear regressions were run for continuous variables, such as bill percentages and the proportion that were signed into law, and logit models were run for binary variables, such as whether a bill was introduced or passed by a chamber. The results indicate that in tightly controlled chambers, more LGBTQ+ legislators indicate more anti-transgender legislation. Additionally, in Republican controlled chambers, having more women indicates a higher percentage of anti-transgender legislation. These findings have important implications for the causes of anti-transgender legislation and the effects of descriptive representation.

Abstract Name: Characterization of the barley microbiome through the malting process

Barley malt is a critical ingredient in brewing and distilling. Malt impacts the taste and aroma of beverages and contributes important enzymatic potential. The microbiome of any grain impacts the flavor it will contribute, the microbial load being added to mash or wort, and may be indicative of potential spoilage in both grain supply and ferments. One area where the microbiome on barley could contribute to these factors in beverage production is during the malting process. To determine if the microbiome of barley is altered through the malting process, the microbiomes of the grain surface and vessel surface will be analyzed through the three steps of malting: steeping, germination, and kilning. To determine whether the microbiome changes from step to step in the malting process or if it is affected by the vessels used, sterile flocked swabs dipped in a sterile wash solution will be used to sample both grains and vessels in each of the steps. The malting steps sampled will include raw grains, soaked grains at the end of steeping and the steeping tank, germinated grains at the end of germination and the germination tank, and grains after kilning as well as the two kilns used. Swabs will be transferred to Dr. Harmonie Bettenhausen at the James B. Beam Institute and will undergo DNA extraction in Dr. Kendall Corbin's lab in UK's Department of Horticulture. The extracted DNA will be sequenced for both 16s and ITS sequencing and analyzed for changes in the microbiome through the malting process using QIIME. Results from this project will reveal critical information on the barley microbiome as it progresses through the malting process. These shifts in the microbiome will benefit research on barley grain, the flavors associated with microbial changes, and overall microbial load issues for malt.

Abstract Name: Is There a Significant Difference in Sway Index (SI) as a Function of Rock-Climbing Status and Testing Conditions?

Background. The BIODEX Balance System SD is often used to determine multiple variables when it comes to postural stability. Unlike Thiele et al., who observed temporary balance impairments from acute fatigue, our study examines whether long-term climbing participation produces sustained improvements in postural stability. This supports the use of the BIODEX SI as our primary outcome measure. Purpose. The purpose of this project is to understand whether continued participation in rock climbing is associated with improvements in postural stability, as measured by the Sway Index (SI), in novice rock climbers. Specifically, the study aims to investigate whether SI becomes better (lower score) as participants gain more rock climbing experience over the course of the study. Both eyes-open and eyes-closed balance conditions will be assessed to determine whether visual input restricts this relationship. Method. This study will be conducted over the course of a 12 month period where Participants will complete two custom postural stability assessments using the Biodex Balance Systems under two conditions: Eyes Open and Eyes Closed. Each condition will be assessed separately. During these assessments participants will be instructed to maintain their center of gravity for three trials. They will be instructed to place their hands on their hips, while the surface changes dynamically for 20 seconds. There will be a minimum of 5 seconds rest between each trial. A higher Stability Index score reflects greater instability. The participants' amount of time spent rock climbing over the study period will be recorded (frequency and duration of climbing sessions). This variable will be examined in relation to SI scores to determine whether increased climbing exposure corresponds to improved postural stability.

Abstract Name: The Commercialization of Seasons and The Cyclic Nature of Health

The advancement of agricultural technologies has allowed for a new modern era of globalized food production and a global food marketplace. The definition of food seasonality has been divided in recent literature into food that is grown in season in the country that it is produced, and food that is grown and consumed in season in the country that it is produced. Western countries and other regions with connection to global food markets have access to seasonal foods on a year-round basis. Despite this ability to eat foods from any season year round, there is a tendency for people to reach for more seasonal foods. As well, the implementation of mass consumerism has produced marketable products for seasons. This explicit replacement of seasonal foods for commercialized products follows the same seasons, but through profit-rearing marketization. Continually, the literature presents findings that eating seasonally improves health. The literature also presents questions of why Body Mass Index and ability to exercise have not leveled out within seasonal differences because of the global food marketplace and having access to produce all year-round. This research claims to reframe these differences within seasonal contexts. With the review and analysis of literature, this research claims that the commercialization of seasonal products is a replacement for seasonal food and cultural affairs. Furthermore, this research attempts to connect health with the cyclic nature of seasons and their variation.

Abstract Name: Traditional Healing Methods, Witchcraft, and History of Conventional Medicine: How Conventional Medicine Has Excluded Ancient Knowledge, and How It Denotes Credibility Problems Within Western Science

Similar healing methods are found in documented indigenous cultures from around the world. Furthermore, the belief systems attached to Indigenous cultures, societies, and healing are similar—that everything in the world has a spiritual interconnectedness. These methods and beliefs parallel ideas within witchcraft, another group that has been stigmatized by Western society. The stigmatization of witchcraft as a religion due to widespread Christian movements (along with enlightenment principles) indicates that traditional healing may have been ostracized because of racism and xenophobia. Because these healing methods (massages, herbal remedies, music/chanting, warming, rituals, etc.) and beliefs (spiritual interconnectedness) are globally widespread, there is little reason for Western societies to not have further researched it except for that their own belief systems stem from opposing Western philosophy/enlightenment principles. In this way, Western medicine is based on the same cultural properties that other traditional healing methods draw from, designating it more cultural than inherently credible. This designation is a source of concern for medical knowledge within the reasoning that traditional healing methods are not accepted by Western medicine because they're not clinically proven or have controlled trials, as traditional healing methods are more culturally credible within their own societies (Zhang). Western medicine is more widely accepted, however, because Western society dominates the global culture and has implemented a credibility basis solely within the rules of Western conventional medicine. Because the traditional healing methods, beliefs, and culture have been ostracized from Western medicine, science, and society, conventional medicine has left behind knowledge that could further healing methods. Through literature reviews, this research attempts to connect research surrounding the historic stigmatization of non-Western cultures/religions, traditional indigenous healing methods, and gaps in conventional medicine. Additionally, it presents a question of if conventional medicine is credible due to its purposeful exclusion of non-Western/non-Christian knowledge.

Abstract Name: Examining 17β -Estradiol's Regulation of Ubiquitin-Proteasome System Activity and CA1 Spine Structure Following Object Training in Ovariectomized Female Mice

17β -estradiol (E2) enhances long-term memory formation and the function of the dorsal hippocampus (DH) by activating cell-signaling cascades in the DH that regulate synaptic structure. Although protein synthesis is essential for these effects, protein degradation via the ubiquitin proteasome system (UPS) is also required for memory function. This study examined how E2 influences proteasome activity following object learning and whether manipulating proteasomal degradation alters dendritic spine density on CA1 basal dendrites. In the first experiment, adult female mice were trained in a novel object recognition task and given 20 min to

accumulate 30 s of exploration time with two identical objects in an open field. Immediately after training, mice received an intrahippocampal infusion of vehicle or E2, and DH tissue was collected 5 min, 1 h, and 4 h later. Vehicle-treated trained mice showed reduced proteasome activity at 1 h later that returned to baseline by 4 h. In contrast, E2 prevents the training-induced reinstatement of proteasome activity 4 h later, suggesting that E2 suppresses proteasomal degradation at synapses during memory consolidation. To relate these molecular effects to spine structure, a second cohort of mice received intracerebroventricular (ICV) infusions of vehicle or E2 and simultaneous DH infusions of vehicle or the proteasome inhibitor β -lactone 2 h prior to whole brain collection. CA1 basal dendrites were traced, and spine density was quantified. E2+Veh treated mice had increased spine number on secondary basal dendrites, whereas E2+ β -lactone treated mice did not, suggesting proteasome activity is necessary for E2 to enhance spine density. Together, these experiments test the idea that E2 coordinates protein degradation dynamics and dendritic spine remodeling in the DH to support memory consolidation. Understanding these mechanisms may provide insight into age-related cognitive decline and neurodegenerative diseases such as Alzheimer's, in which synaptic plasticity is impaired.

Abstract Name: Anxiety and Depression Symptoms in Youth with vs. without Chronic Illness: Exploring Demographic Differences

A chronic illness is a long-lasting health condition (i.e., lasting 3 months or longer) that requires continuous or ongoing medical attention and/or limits daily activities. While these conditions tend to be more prevalent in older populations, many children are also affected, with pediatric-onset conditions rising over 30% from 1999 to 2018. Currently, nearly 1-in-3 young people live with a pediatric-onset condition that significantly affects their lives. Children with chronic illnesses often experience emotional distress, including higher levels of anxiety and depressive symptoms due to factors surrounding pain, medical procedures, and social limitations. This study sought to examine whether the internalizing symptoms among 250 youth (32.9% female; ages 6-17 years) with chronic illness differed based on various demographic factors (age, biological sex, socioeconomic status [SES]). Families (family income = \$0-\$450,000) were recruited from a Child Assessment Clinic where youth received a comprehensive psychoeducational or autism evaluation. Parents reported on children's medical history as part of the intake process, with 57 children being reported to have a chronic illness (e.g., asthma, seizures). Youth reported their anxiety and depression symptoms using the Beck Youth Inventory. Regression main effects indicated that chronic illness did not significantly predict internalizing symptoms overall; however, interaction effects indicated that this association was significantly moderated by age. Specifically, for children, having a chronic illness was unrelated to anxiety and depression symptoms; whereas, for adolescents, having a chronic illness was linked to significantly more depression and anxiety symptoms. A main effect was found for SES such that families with higher annual income had children who reported fewer internalizing symptoms. Sex assigned at birth did not significantly predict internalizing symptoms or moderate the association between chronic illness and internalizing symptoms. The psychological impact of chronic illness is not uniform across development; interventions are needed supporting well-being in adolescents with chronic illnesses.

Abstract Name: The Interactive Effects of Sleep and Physical Activity on Cognition

Inadequate sleep is known to be associated with impairments in memory, executive function, and processing speed, and physical activity is associated with preservation of cognitive function in these domains. This study's objective is to determine whether sleep interacts with activity levels in relation to cognitive outcomes. Data were analyzed from the CHAMP Lab's Fitbit study at the University of Pittsburgh's Alzheimer's Disease Research Center (ADRC) from February 2024 - June 2025. Participants ($n = 139$, 74.+7 years, 63.3% women) were eligible if they had a non-demented, eligible for PET imaging, and had completed an ADRC clinical visit in the past year. Participants wore a Fitbit Inspire 3 for one consecutive week, and the average sleep duration, efficiency, standard deviation (SD) of sleep midpoint, and physical activity measures were calculated. Interactions in linear regressions were used to examine the interactions between sleep duration, efficiency, regularity, and physical activity on cognitive domains, adjusting for age, sex, race, and education. There was a significant interaction between moderate to intense physical activity (MIPA) and SD of midpoint with the vegetable fluency cognitive outcome ($p = 0.036$, $\beta = -.332$) and the language composite ($p = 0.019$, $\beta = -.413$). In this sample, we found that the interaction between sedentary time and efficiency is significant with cognitive measures. Evidence suggests that sleep and physical activity depend on each other, rather than acting independently on cognition. Future research could include analyzing a multidimensional sleep score and its association with cognition.

Abstract Name: Framing Generative AI's Impact on Public Relations: A Content Analysis of Public Discourse on X

The rise of generative artificial intelligence (AI) is rapidly changing the public relations (PR) industry. While existing scholarship has examined AI's implications for PR from professional and theoretical perspectives, limited research explores how the general public discusses these transformations on social media. This study uses quantitative content analysis to investigate how the impact of AI on PR is framed in public discourse on X (formerly Twitter). Using Brandwatch, all posts containing keywords related to both AI and PR published on X between May 13, 2024, and May 12, 2025, one year following the release of ChatGPT 4o, were collected. From this dataset, 5,000 posts were randomly sampled for manual content coding. Each post is analyzed for overall tone, framing types (e.g., risks/benefits, individual/societal, ethical, temporal, and other thematic emphases), references to PR functions and tasks, mentions of specific AI tools, anticipated roles of AI in PR, call-to-actions, and user engagement metrics (e.g., likes, reposts, and comments). Findings show that benefit-oriented and technological optimism frames dominate the discourse, particularly among PR practitioners and AI-focused companies. Most posts highlight efficiency and data-driven insights as key advantages of AI integration in media monitoring and audience engagement. At the same time, concerns about misinformation, loss of authenticity, and ethical transparency reveal a parallel narrative of caution. Societal frames appear more prevalent than individual perspectives, reflecting institutional efforts to negotiate technological change. By analyzing the evolving narratives that shape perceptions of AI in PR, this study contributes to an understanding of how new technologies are socially constructed and legitimized through

public communication. The findings underscore AI's dual role as both a strategic enabler and a reputational risk, emphasizing the importance of ethical accountability as PR adapts to an increasingly automated communication landscape.

Abstract Name: Growing Native Plants in Urban Green Spaces to Contribute to Local Biodiversity and Bolster a Local Gene Bank

Flying insects, many of whom are pollinators, have experienced marked declines since the industrial revolution. Intensifying agricultural outputs associated with widespread herbicide use may be driving factors, because declines in the native plants that support these insects confer a positive feedback loop. Monarch butterflies (*Danaus plexippus*) who rely exclusively on Milkweed plants (*Asclepias syriaca* and others) as hosts for their larvae are a key example. The goal of this project is to develop and document effective methods for propagating native species in the hope of bolstering the local pollinator ecosystem, specifically in the Richmond, Virginia area. By increasing the density of native plants in urban spaces, we will create more opportunities for pollinators to thrive on native species. *Asclepias syriaca* was grown from seeds using two different approaches: winter sowing outdoors and greenhouse starts that were later transplanted outdoors to a pollinator garden. Additionally, two different treatments during seed preparation were used as hormone treatments: cold stratification and application of gibberellic acid (GA3). Cold stratification was done in controlled greenhouse conditions and compared to outdoor winter sowing conditions. Each group was monitored and measured for its germination success rate. We expected to find that after germination is complete, the gibberellin treated seeds will have a higher rate of germination. Once established, seedlings were transplanted to a local Richmond pollinator garden for further observation. Plant health was monitored into the spring to ensure survival, as well as ecosystem impact measured in pollinator visits. We expect to find that the surviving plants will serve as a catalyst in a growing pollinator ecosystem. Phenotyping for plant identification and future seed collection are the methods employed by our team with the hope to preserve.

Abstract Name: Sense of belonging and mental health outcomes among immigrants in British Columbia

Rates of mental illnesses, such as depression and anxiety, have continued to increase in recent years, especially among vulnerable populations such as immigrants. Immigrants comprise close to a quarter of the total Canadian population, many of whom face significant challenges regarding their health and well-being not only upon arrival to Canada but also throughout their lifetime. Mental health challenges and inequalities in the use and access of mental health services are felt by the immigrant population across the country, which can influence their overall quality of life. Sense of belonging, a key indicator that captures social connections

as valuable resources, is associated with mental health among Canadian adults. Where a strong sense of belonging has been connected to positive mental health, a weak sense of belonging has been linked to poor mental health outcomes and an increased risk of experiencing mental health challenges. Investigating the relationship between immigrants' sense of belonging and mental health outcomes will provide new insights into this growing body of research. Therefore, the main objectives are to: (a) assess whether sense of belonging is associated with experiencing symptoms of depression and anxiety, and (b) determine whether sense of belonging is associated with the likelihood of accessing mental health services. This study will focus on immigrants in British Columbia, utilizing data from the 2019-2020 Canadian Community Health Survey (CCHS), a two-year cross-sectional survey that collects information about the health status and health determinants of populations aged 18 and over across the country. Descriptive and inferential analyses will be performed using the Statistical Package for Social Sciences (SPSS) version 29 software. Study findings will add to the existing literature about sense of belonging and mental health and will support the development of programs and policies aimed at improving belonging among the immigrant population.

Abstract Name: Negative Schemas and Relationships: How do Sexual and Romantic Relationships Affect Second Year College Students Mental Health and Academic Achievement?

In college, many adolescents enter into their first sexual and/or romantic relationship (Tillman et al., 2019). Prior research suggests that young adults experience positive outcomes in long term healthy relationships, but negative outcomes among their counterparts in unhealthy relationships (Ritter et. al., 2022). Unhealthy relationships can be attributed to many factors, but one's beliefs about relationship norms can affect individuals' relationship schemas (Sakaluk et. al., 2019). In this study, we proposed to explore whether college students with negative relationship schemas have reduced relationship satisfaction, worse mental health, and less academic success relative to peers with more positive relationship schemas. Importantly, in contrast to prior work, we define relationships broadly to include a variety of more casual and more serious sexual and romantic relationships (Claxton & Dulmen, 2013). To test our hypotheses, we will collect survey data from second year college students at a large public university who self-identify as having a romantic and/or sexual partner. We plan to examine correlations between relationship schemas, relationship satisfaction, mental health (defined as anxiety and depression scores), engagement in risky behaviors, and perceived academic success. We expect that students whose relationship schemas reflect atypical and unhealthy norms (e.g., strict unspoken rules governing one partner's behavior) will be more likely to report engaging in risky behavior as well as a greater degree of anxiety and depression symptoms. We expect that, in turn, these students' academic success will be lower than peers with healthier beliefs about relationship norms. Additionally, we will explore possible moderating effects of relationship type and length. The long-term goal of this research is to inform novel interventions for supporting interpersonal development among college students.

Abstract Name: Schubert's "Themes of Death": the Denial and Eventual Acceptance of Mortality

Schubert's String Quartet no. 14 "Death and the Maiden" is an effective piece that conveys the nature of death through Schubert's own "themes of death" and avoidance of resolution. Schubert, despite clearly beginning in D minor, never confirms the opening key with a cadence in tonic until the last section. Instead however, Schubert cadences in a variety of different major keys without actualizing the tonic key in minor. This delay of resolution is unusual; however would Schubert really cadence in the incorrect key and never resolve his phrases without clear intention or is there some reasoning behind his suspension of resolution until the end? Is there some personal connection to this narrative and artistic decision? I firmly believe the choices are intentional and why Schubert would choose to disobey the formal structure and harmonic progressions standard of his time in favor of a calculated delay of resolution is the question I will answer in this paper. To support this claim, I will examine each thematic idea and motif to convey why Schubert delays harmonic resolution and modifies formal structure to encapsulate the idea of death being kept at bay, but always looming. While not uncommon to delay resolutions for short periods of time, it is quite an ingenious task to write a near 40 minute piece delaying resolution nearly the entire time yet still composing a hallmark of the String Quartet world. Schubert continually avoids the finality of death by delaying true resolution in the original key of D minor by utilizing his themes of death he expertly conveys the narrative of death lulling the maiden with his sweet melodies and the maiden's ever-growing fear until at last, death claims her. A tug of war between death and the maiden as she tries not to succumb to rest.

Abstract Name: Exploring Racial Disparities in College Expectations Among Female High School Students

This study examines racial differences in higher education expectations among Black and White female high school students through an intersectional theoretical lens. Using nationally representative data from the High School Longitudinal Study of 2009 (HSLs:09), the analysis focuses on female respondents identifying as Black/African American or White. A chi-square test of independence assessed the relationship between race and educational aspirations. Results indicate a statistically significant association between race and expected educational attainment, with Black female students more likely to aspire to professional or doctoral degrees, while White female students more often anticipated completing a master's degree. These findings highlight the importance of intersectional perspectives in understanding how race and gender jointly shape students' educational pathways and future planning.

Abstract Name: Institutional Influences on Emotional Suppression and Gendered Racial Identity in Black Women

Black women have historically been excluded from dominant Eurocentric constructions of femininity, leading to stereotypes such as the Strong Black Woman (SBW) and Angry Black Woman that frame emotional resilience as required for survival. These racialized and gendered expectations continue to shape how Black

women navigate emotional expression, particularly within academic environments. This study explores how undergraduate institutional context influences emotional suppression, gender role performance, and responses to racial stress among Black women. It examines whether attending a Predominantly White Institution (PWI) or a Historically Black College and University (HBCU) affects the adoption of coping strategies rooted in the SBW schema. Sixteen Black women enrolled in graduate programs at an HBCU completed an anonymous online survey adapted from validated instruments measuring emotional suppression, perceived discrimination, and gender role beliefs. Quantitative items used Likert-type scales to assess frequency of discrimination, identity expectations, and emotional regulation across undergraduate and graduate contexts. Qualitative open-ended questions provided narrative insight into shifts in emotional expression, comfort, and femininity across institutions. Results showed that participants who attended PWIs reported substantially higher emotional suppression, perceived discrimination, and SBW identity endorsement than those who attended HBCUs. Large effect sizes supported these differences. Qualitative themes reinforced the quantitative patterns: PWI attendees described masking emotions and heightened vigilance, while many HBCU attendees reported greater emotional openness and institutional safety. However, participants also noted that respectability politics and narrow expectations of femininity persisted even in culturally affirming environments. These findings suggest that institutional environment meaningfully shapes how Black women regulate emotions and perform gendered racial identity. While HBCUs reduced reported discrimination, both contexts involved pressures that limited emotional freedom. This study highlights the complex psychological costs of navigating Black womanhood in academic spaces and underscores the need for environments that support vulnerability, belonging, and authentic self-expression.

Abstract Name: Golden Years, Rapid Strides: Kinematics of the Senior Sprint

Aging is commonly associated with gradual declines in physical performance, yet many older adults continue to participate in competitive athletic events, including sprinting. Understanding the mechanical factors that contribute to sprint ability in later life can help clarify how aging affects movement and performance. This study investigates the kinematic variables that influence sprint performance in elderly athletes during a 60-meter dash. A previously recorded race involving senior competitors was analyzed using the Tracker Video Analysis and Modeling Tool. The winner of the race was selected for detailed examination, and key kinematic parameters included displacement, velocity, acceleration, kinetic energy, and force. During the analytical process, it became evident that the curved geometry of the track created challenges for accurate coordinate mapping within the software. As a result, several numerical outputs were distorted or inconsistent with expected physical values. The displacement was 0.233 meters, with an average velocity of -0.0714 m/s, acceleration of 0.9896 m/s², a kinetic energy of -2.831 J, and the force exerted was 78.479 N. These limitations highlight the difficulty of applying two-dimensional motion-tracking tools to curved sprint paths without calibration adjustments or additional reference points. Even with these constraints, the analysis provides valuable insight into the significant physical capabilities maintained by older adults who engage in regular training and competitive activity. The study illustrates the potential of kinematic assessment to deepen our understanding of age-related changes in human movement and performance. Furthermore, the findings emphasize the importance of promoting physical activity across the lifespan and suggest that tailored training and wellness programs may support improved functional capacity and overall health outcomes in aging populations.

Bryson Clarson

Abstract Name: Abstract Title: Long-Term Impacts of Childhood Emotional Maltreatment on Male Emotional Intelligence in Adulthood

This research will examine how childhood emotional maltreatment (CEM) affects the emotional intelligence (EI) of males in adulthood through a systematic review of existing literature. CEM refers to behaviors from parents or others that harm a child's emotional well-being, making them feel unloved or unwanted. CEM is broken into two categories: childhood emotional abuse and childhood emotional neglect. EI is the ability to recognize, control, and regulate one's own emotions and the emotions of others. EI impacts every relationship within our lives, and a person with lower EI may encounter more obstacles in their lifetime. However, the male population faces significant barriers in emotional development, ranging from societal factors to stigmas that surround manhood. Males are not always allowed to healthily express their emotions. This is reflected in statistics: men die by suicide nearly four times more often than women, and only 37% of men seek help for mental health struggles compared to 52% of women. Suicide is too late, and these statistics speak to the need within the male population. CEM is often underresearched because it is hard to measure, but the emotional scars can impact a person for a lifetime. The systematic review methodology will analyze peer-reviewed literature published between 2000 and 2025 from databases including PsycINFO and Google Scholar, applying strict inclusion and exclusion criteria to ensure quality and consistency. The review will explore key themes, concepts, and effective intervention strategies. Expected findings include a statistically significant relationship between CEM and reduced EI in adulthood. This research will illuminate how childhood experiences shape emotional development. It will be used to equip men emotionally and break generational cycles.

Abstract Name: An Analysis of Emission Control Technologies for Wood-fired Biomass Boilers: A Case Study of the Ripley Plant at Northern Michigan University

The heating and cooling system at Northern Michigan University (NMU) has the potential to transition from natural gas to woodchips in one of its boilers at the Ripley Plant. Northern Michigan University's administration has established goals of reducing greenhouse gas emissions on campus, and according to a 2023 Energy Master Plan Report, switching to wood as a fuel source could reduce emissions by about 27%. Although wood is renewable energy, combustion of biomass results in the release of harmful air pollutants including particulate matter (PM), sulfur dioxide (SO_x), nitrogen oxide (NO_x), and carbon dioxide (CO₂). Numerous studies have examined the efficiency of different emission control technologies used in industrial biomass boilers. However, little research exists on what pollution control technologies are best suited for an industrial biomass boiler firing northern hardwood chips, and how varying fuel characteristics between northern hardwood, soft woods or agricultural residues impact technology efficiency and selection. This study combines a systematic review of scientific articles on fuel characteristics and emission technologies with ten semi-structured interviews. The interviews provide information on how other facilities located in northern hardwood forests have managed emission levels through technology selection and operational strategies. We investigate the optimal pollution control technologies for a biomass boiler using northern hardwoods, and how different characteristics of woodchips affect emissions control technologies. Specifically, we will

examine how the operation of electrostatic precipitators, fluidized bed systems, wet scrubbers, fuel feeding systems, and fuel injection ratios are affected by the utilization of hardwood chips. The results of this study will not only provide understanding of how different feedstock types might impact the efficiency of emission control technologies at Northern Michigan University, but will also provide insight for other institutions located within northern hardwood forests that are interested in investing in renewable energy technologies.

Abstract Name: Reimagining Biology Labs: An Interdisciplinary Aquaponics Lab for Experiential Biology Education

Traditional biology labs often follow predetermined outcomes, limiting opportunities for authentic research and problem-solving. In contrast, our aquaponics lab at Miami Dade College engages students in building and maintaining integrated systems that combine aquaculture (raising fish) and hydroponics (growing plants without soil). These systems create a symbiotic loop where fish waste fertilizes plants, and plants purify water for the fish. Aquaponics offers a sustainable alternative to wild-caught fisheries, reducing ecological impact while supporting food production. Students gain hands-on experience with biological, chemical, and engineering principles while managing ornamental fish and edible plants. They explore microbial roles in the nitrogen cycle, monitor water quality, and troubleshoot system challenges. To deepen engagement, students breed fish and auction offspring at local fish clubs, introducing entrepreneurial aspects of ornamental aquaculture. This interdisciplinary, experiential approach fosters critical thinking and exposes students to potential career paths in biology and related fields. Conference attendees will receive a detailed lab handout, rubric, and a highlight video showcasing student projects.

Abstract Name: Low Retention from Lack of Attention: Transgender Students in STEM

Within the fields of science, technology, engineering, and mathematics (STEM), transgender people are a very underrepresented portion of the workforce. I believe that many of the reasons transgender people are not going into STEM is because of their time studying STEM as high school and university students. These students have negative experiences, or face a lack of positive experiences and do not receive the resources they need to feel like they will be accepted in a STEM field. This results in a lack of retention of transgender people in STEM programs in universities. Though, very little research has been done about this topic, and few solutions have been offered to either the students, or the educational institutions who seek to give these students a more inclusive environment. With my research, I aim to investigate what struggles transgender students in STEM go through, to what degree those struggles contribute to the lack of retention of these students, and what high schools and universities can do to ensure that transgender people feel accepted and included in their STEM programs. To do this, I will be interviewing transgender students, staff, and faculty at my university, the University of Central Oklahoma, and compare their experiences in their different STEM

fields to what research has been done previously. My research will bring a light to the lives of transgender high school and university students in STEM, reflecting on the problems they have, and propose solutions towards these issues.

Miguel Clemente

Abstract Name: Institutional Strength, Commodity Shocks, and Exchange Rate Volatility in Argentina

Argentina's economic history offers a distinct case study on the interaction between monetary regimes, institutional frameworks, and external shocks. This paper investigates the evolution of exchange rate volatility in Argentina, specifically analyzing how policy decisions and commodity cycles influence stability. Existing literature predominantly analyzes specific economic episodes in isolation. For instance, Gay & Pellegrini (2003) and Wang et al. (1995) focus on misalignments and stabilization under the Convertibility Plan. Conversely, Grigsby & Arnade (1986) and Campos (2019) examine the sectoral impacts of commodity markets and exchange-rate distortions. However, few long-run analyses apply a consistent volatility measure across these contrasting eras. This research addresses that gap by connecting institutional analysis with the study of commodity shocks, comparing volatility across the high-inflation 1980s, the Convertibility peg, and the post-2000s managed float. We utilize bilateral nominal ARS/USD exchange rate data at a monthly frequency, sourced from the Central Bank of the Argentine Republic (BCRA) and the IMF. Instability is quantified by generating a single annualized volatility metric per year based on the standard deviation of monthly logarithmic returns. Our results indicate that while Convertibility successfully suppressed short-term volatility, its rigid framework amplified the transmission of global commodity shocks. By contrast, the post-2000s managed float exhibits greater resilience, with institutional adaptability and countercyclical policies mitigating volatility despite persistent exposure to external terms-of-trade movements. These findings highlight the importance of institutional strength in shaping how economies absorb commodity-driven pressures and maintain exchange-rate stability over time.

Abstract Name: The Effectiveness of Planned Exercise in Reducing ADHD Symptoms in Children

Attention deficit hyperactivity disorder is one of the most common neurodevelopmental disorders in children and is characterized by various developmentally inappropriate symptoms including inattention, impulsivity, motor restlessness, and poor executive function. Medication is first line treatment, however this can come with adverse effects and high monetary costs. Research indicates that 70% of children diagnosed with ADHD have symptoms that continue into adolescence, with 50% suffering from lifelong effects. In addition, research indicates both overtreatment in individuals diagnosed with ADHD and misuse of medication in individuals without a diagnosis, demonstrating a need for non-pharmacological alternative treatments for ADHD. Studies

have shown that exercise and physical activity cause natural physiological and psychological processes which promote physiological and cognitive function. This literature review investigated the impacts of a plan of exercise compared to no plan of exercise in the reduction of ADHD symptoms. Executive functioning, hyperactivity, inattention, and impulsivity were all shown to be improved when interventions of physical exercise were implemented for children with ADHD. Regular, aerobic exercise that was cognitively-engaging and fun were the most effective interventions. Implications for practice include the use of physical exercise interventions as an effective way to manage ADHD symptoms and improve executive functioning in children diagnosed with ADHD. This literature review revealed that plans of exercise should be considered for incorporation into treatment plans for children with ADHD.

Abstract Name: Microspeckle Stamping for using Digital Image Correlation on Carbon Fiber Reinforced Composites

The increasing push to understand material behavior at a micromechanical level requires evolving experimental techniques. Digital image correlation (DIC) is an experimental technique for measuring surface deformation of a specimen with no inherent length scale. DIC requires the application of a speckle pattern onto the specimen's surface, commonly created with spray paint at the meso- and macroscales. At higher magnifications, to understand behavior at smaller length scales, the speckles from spray paint are too large for DIC to correlate properly. Thus, microspeckle stamps have been invented to produce micron scale patterns. Existing stamping methods, however, have been optimized for black speckle patterns, particularly on metals. Therefore, applying current techniques to the black substrate of carbon fiber reinforced composites (CFRP) results in an unidentifiable speckle pattern. To solve this issue, microspeckle stamps coated with non-black inks were investigated as an alternative method for generating micron scale speckle patterns on black specimens such as CFRP. The features of these microspeckle stamps are on the order of microns, and thus ink chemistry, pigment size, and application conditions become relevant for successful application. Several ink sources, such as fluorescents, acrylic paints, and metallic Sharpies were investigated. The final choice, metallic Sharpies, had their ink applied directly to the microspeckle stamps, then the stamp was applied to the CFRP specimen to transfer the microspeckle pattern. Preliminary testing on smooth CFRP samples demonstrated that this method could produce distinguishable, high contrast, micron scale patterns that can correlate properly. The ability to produce a visible microspeckle pattern on CFRP enables DIC techniques to be used to obtain high resolution measurements of a specimen's strain under mechanical loading.

Abstract Name: A Preventable Tragedy: Taking a Look at the Great Molasses Flood in Boston, 1919 and its Effect on the United States

On January 15, 1919, Boston's North End was struck with a tragedy unlike anything its residents could have

imagined. A wave of molasses ranging from 15 to 40 feet high washed across several blocks, destroying everything in its path. This Great Molasses Flood, caused by the collapse of a molasses tank made three years earlier by United States Industrial Alcohol, had devastating consequences. In its wake, it left twenty-one people dead and many more injured. Yet strangely enough, very few people know about it today. This project aims to introduce the event to those who are unfamiliar with it and draw together the scattered pieces of information that exist on the topic. It makes use of primary sources such as newspapers, death certificates, and quotes from the ensuing trial, as well as research from Stephen Puleo's *Dark Tide* (the only non-fiction book written entirely on this subject to date) and other sources. Through this research, it is made clear that the Great Molasses Flood was a tragic, avoidable event with far-reaching consequences. The failure of a company to prioritize safety over profit led to twenty-one deaths, several city blocks destroyed, and families all around Boston devastated. The court case afterwards, however, eventually helped spur the institution of safety codes and regulations that still affect construction and engineering today, such as licenses for engineers and stricter requirements for building plans.

Abstract Name: Freudian Analysis of the Relationship Between Religion and Politics Within Christian Nationalism

The cultural formation referred to as Christian Nationalism is a rising social phenomenon in American society, gathering support throughout the past decade in the election of right-trending politicians. Grounded in a narrative of a “power-devaluation crisis,” Christian Nationalism exhibits a reconfiguration of historically conventional relations between spheres of religion and politics that sees these spheres as inherently connected and syncretized, creating a seemingly odd and sometimes paradoxical combination of its beliefs, interests, and values among its adherents. In a September 2025 New York Times opinion column, David Brooks suggests that the phenomenon of Christian Nationalism raises several questions regarding the relationship between politics and religion, as well as issues stemming from groups that lack a coherent theory of that relationship. The presentation I am proposing here draws on Freud’s Group Psychology and the Analysis of the Ego to elucidate the relationship between religious and political spheres in Christian Nationalism as manifested in the memorial service of political activist Charlie Kirk. This analysis addresses aspects of Christian Nationalism such as the leader’s role within the group, the group’s love for conservatism and traditionality, and the group’s contradictory perspective on truth as these apply to the intersection of political ideas and religious belief. Within Freudian analysis the emergence of this phenomenon is referred to as idealization, in which the loved object within the group--in this case President Donald Trump--takes the place of the idealized version of oneself in the mind of its followers. This form of identification results in unwavering reverence of the idolized object as well as further identification procedures aligning the group with the leader’s character and will. This Freudian analysis explains the mechanisms behind Brooks’ concern that Christian Nationalism results in a degradation of religion and a totalization of politics.

Abstract Name: Behavioral Responses of *Tenebrio molitor* to Volatile Cues Linked to Parasite Transmission

Chemical cues play an important role in how intermediate hosts interact with parasite-contaminated environments, particularly in systems where transmission depends on host foraging behavior. The tapeworm *Hymenolepis diminuta* infects rats as its definitive host, and its eggs are shed in rat feces that beetles encounter while foraging. Previous studies with *Tribolium confusum* and *Tenebrio molitor* have shown that beetles may prefer feces from infected rats, likely due to volatile chemicals associated with infection. These findings suggest that odor cues, along with hunger state and social interactions, can influence beetle behavior in ways that increase the parasite’s chances of completing its life cycle. This project expands on earlier work by testing whether specific fecal-associated volatile compounds can independently attract *T. molitor*. To investigate this question, adult beetles were fasted for 24 hours and tested in a two-choice circular arena similar to designs used in previous behavioral assays. Each trial presented beetles with a choice between cover slips treated with different odor solutions: deionized water, limonene, or a four-acid mixture consisting of butanoic acid, methyl butanoate, 2-methyl butanoate, and pentanoic acid. Thirty beetles were released into

the arena for each run, and their positions were recorded once per minute for ten minutes to determine whether they aggregated preferentially toward a particular odor. Preliminary patterns indicate that beetles distinguish between odor treatments and tend to move toward the area containing the four-acid mixture. These acids are known components of volatile profiles associated with infected feces, suggesting they may serve as cues guiding beetles toward parasite-containing substrates. This study helps clarify the role of individual volatile chemicals in *T. molitor* host-seeking behavior and contributes to broader understanding of how *H. diminuta* may influence intermediate host activity to enhance transmission.

Abstract Name: Creating High Fidelity Data Sets Using Student and Community Involvement

Urban trees, both street trees and trees on other public lands, provide numerous ecosystem services, including stormwater regulation, carbon sequestration, and air quality improvement; however, the public is often unaware of the services that they provide. This project aims to partner with municipalities to increase awareness of the value of street and public land trees by utilizing i-Tree and scannable QR codes. Each tagged tree will link to a website that provides tree-specific ecosystem service valuations, while also providing educational materials on Municipal Separate Stormwater Systems (MS4s) and the broader role of urban forests in overall community health. By pairing economic valuation with accessible digital resources, the project aims to increase public engagement and municipal support. This project is also working to develop a Standardized Data Collection Protocol (SDCP) that enables biology students to contribute field data collected as part of biology courses at Gaston College directly to the municipal tree inventories. This will help build a large, long-term dataset for participating communities while integrating online with in-person, hands-on learning into biology courses. This SDCP will produce a replicable model that combines community outreach, municipal planning support, and student-driven research. By making the ecological benefits of trees tangible and assigning them economic value, the project will foster stronger connections between residents, local governments, and their urban forests, while arming them with additional knowledge to inform decision-making.

Abstract Name: Elastohydrodynamic Theory of Wet Particles

The dynamics of small, solid particles coated by thin layers of viscous fluid has many applications in the chemical industry space such as particle agglomeration, spray coating and fluidized-bed drying. In our work, we investigate the close contact, head-on collisions of two wet spheres in three regimes: (i) when the surface roughness of the particles dominates the collision, (ii) when the elastic deformation of the solids dominates and, (iii) when both length scales of roughness and elasticity are of the same order of magnitude. Much existing research focuses on hard and soft particle interaction in the fully immersed case, where the particles

travel through a large expanse of fluid. In our case, when the particle surfaces have sufficiently large roughness elements, the distance between the nominal surfaces decreases until physical contact, prior to any solid deformation. A nearly instantaneous, hard-sphere-like collision follows. In the other limit, we combine lubrication theory and Hertz contact theory of linear elasticity to model elastohydrodynamic deformation during a collision of two wet spheres. It is observed that as the particles approach each other, very high pressure develops, which both slows their relative motion and deforms their surfaces near the axis of symmetry even before physical contact occurs. When the stored elastic deformation energy is released, the particles rebound. The collision dynamics are governed by the interplay among the Stokes number, the elasticity parameter, and the dimensionless film thickness. No rebound occurs below a critical Stokes number, but above this threshold the coefficient of restitution increases with Stokes number and eventually plateaus at sufficiently large Stokes number. As the elasticity parameters increases, the critical Stokes number for separation decreases, whereas the deformation and separation times increase.

Abstract Name: Tuning and Fabricating PEDOT:PSS Films

PEDOT:PSS is a cost-efficient organic polymer that can be fabricated into conductive films with greatly tunable degrees of mechanical stability, thickness, carrier concentration, and carrier mobility. Mechanical stability and thickness are generally inversely proportional, likewise for carrier concentration and carrier mobility. Doping PEDOT:PSS with ethylene glycol would result in consistently thicker and more stable films. During the annealing process, films tend to shrink along the edges, resulting in a pinched shape to the film or, in some cases, tearing. This can be mitigated by heating the solutions in a vacuum oven and allowing for a much longer and slower heating process. With only PEDOT:PSS films, this results in high-quality, even films; and, for ethylene glycol-doped films, this prevents tearing and adds a noticeable increase to the evenness of the film while still being thicker. Another significant change as a result of ethylene glycol doping is a large increase in the conductivity of the film. The films produced by said solution are capable of being further bathed in ethylene glycol or DMSO for an even greater increase in conductivity. This bathing process significantly increases the carrier concentration of the film, but at the cost of carrier mobility. This inversely proportional relationship allows for more customization of the films depending on what is necessitated, though it is important to note that at the cost of an increase in carrier concentration, the film will be lifted off the substrate that which it was fabricated. For thin films, the method of spray-coating a heated substrate with a PEDOT:PSS solution produces uniform thin films regardless of the size of the film. These results depict the vastly varying parameters of PEDOT:PSS films depending on the specific planned usage of the film.

Abstract Name: Process of Fabricating Iodide Ion Gels

Ion gel films have the capacity to be finely tuned electrochemically and mechanically, all the while maintaining the ion conductivity of the used ionic liquid. The function of the solid-state ion gel can be tailored based on the polymer of choice, the ionic liquid composition, and dopants. Out of the various possible solutions, halide/iodide ion gels stand out as a result of their having a rich redox chemistry and strong ionic interactions. The research we did focused on fabricating a mechanically viable and functional iodide ion gel for application on solar cells. Our research followed an iterative process, thoroughly exploring the various avenues of fabrication and the quality that the ion gels yielded. Some of the major obstacles include the fact that the quality of the ion gels varied significantly and seemingly are inversely proportional to the presence of iodide ionic liquid in the initial solution. Alongside this, spincoating would consistently yield gels that are too thin and thus lacking the necessary mechanical stability to be freestanding. Dropcasting allowed for much greater quality control; however, it inherently has the capacity for a greater margin of error. Subliming iodine shows promising potential as a workaround for incorporating iodide in the ion gel without the presence of an iodide ionic liquid; rather, a ‘placeholder’ ionic liquid to absorb the gaseous iodine after the gel is formed. The mechanical limitations of iodide ionic gels can be mitigated to a degree by diluting the presence of the iodide ionic liquid with the aforementioned ‘placeholder’, resulting in a clear quality and ionic conductivity tradeoff. This tradeoff seems inherent to the nature of these iodide ion gels, though via dilution and sublimation, a functional middleground does exist.

Abstract Name: Butterflies and You: Considerations of Human Relationships with the Natural World

Science communication only accounts for approximately 2% of the entire scientific output of 2017-2022 (Parejo-Cuellar et. al, 2024). It is an under-researched and under-valued field, especially in an age that has devalued science as a whole. The delicate art of explaining complicated ideas to people who are unfamiliar with scientific jargon is vital to humans’ understanding of the world. Butterflies & You is a documentary film exploring the relationship between humans and the many different butterfly species that call Illinois home. Video-based science communication is important to research and practice because of its impact on environmental advocacy and the growing popularity of video content. By making informative videos that appeal to a wide range of audiences, science communication can raise awareness for important environmental issues. Butterflies & You was informed by texts such as Ryan Vachon’s Science Videos: a User’s Manual for Scientific Communication, and Bill Nichols’s Introduction to Documentary. This project applies documentary film theory and industry standard practices. Impactful communication can only be achieved by identifying the intended audience and learning how to reach them (Vachon, 2018). These ideas were the guiding principles of my research, and the documentaries that inspired Butterflies & You are great examples of how to reach an audience. Many films influenced my work, including Dancing With the Birds. This film uses the strategies and visual language of expository and observational modes of documentary filmmaking (Nichols, 2017). The field footage of Butterflies & You includes uncommon butterfly species from around the state of Illinois, many of which are limited to very specific locations in Illinois, and have not been heavily documented on film. The results of my activity will contribute to the growing video science communication landscape, and raise awareness about butterfly conservation.

Abstract Name: Early Childhood Exposure to Maternal Depression: Health & Cognitive Development in India

This study explores the impact of early childhood exposure (6-18 months) to maternal depression on children's health and cognitive development in India. Focusing on the younger cohort of the Young Lives Study (YLS), which tracks 8,062 children over 15 years, I use propensity score matching to assess the effects on a composite health indicator (combining perceived health status and growth metrics including weight-for-age, height-for-age, BMI-for-age z scores), as well as cognitive outcomes, including vocabulary, math, and Peabody Picture Vocabulary Test (PPVT) scores. Preliminary findings indicate that early exposure to maternal depression has significant negative effects on health across all five rounds of the 15-year tracking period. Affected children have poorer health, with reduced PPVT and math scores in later tracking periods, though vocabulary scores were not significantly affected. While further research is needed to fully understand the underlying mechanisms, I hope to find that early exposure significantly worsens parent-child relationships, highlighting a critical area for intervention. Importantly, health impacts not only represent a direct effect of maternal depression but also potentially mediate the adverse effects on cognitive development, amplifying negative outcomes.

Abstract Name: Rat Foraging Decisions in a Virtual Floor Patch Task

Foraging decisions require balancing patch quality and travel costs to maximize food intake. Typically, laboratory paradigms use spatially discrete patches with declining reward rates. Here, we developed a virtual foraging task with declining opportunity rates, where rats control reward timing. This design probes rats to actively take rewarding opportunities during virtual patch navigation. Behavioral sessions were conducted in a square, opaque-walled environment with flexible control over the environment floor (n = four Long-Evans rats). Each session began with a travel period, after which rats chose between two stimuli (patches). Each patch was associated with a distinct floor pattern. Within a patch, individual stimuli (opportunities) were presented at a random location, and rats earned a reward for each opportunity they selected. Rats could leave the patch by selecting a distinct "leave" stimulus, returning them to the travel period. Sessions were randomly assigned a long or short travel time. Patches within a session were randomly assigned a slow, medium, or fast declining opportunity rate. Across all sessions, rats selected 50-70% of the opportunities presented, and stimulus selection increased with decreasing patch quality. Speed profiles showed that rats could differentiate between the opportunity and leave stimuli. Latency between pellet deliveries increased as rats stayed longer in a patch, with separation between patch qualities emerging after the fourth pellet. These findings suggest that while rats distinguish travel and opportunity stimuli, they behave differently in the virtual foraging task compared to spatial foraging tasks. Future work will apply modeling and protocol adjustments to improve task engagement.

Abstract Name: Pueblo Pottery: Early Existence, Colonization, Rebellion and Resilience

Pottery by the Pueblo peoples transformed over time, based on many factors, including access to raw materials and colonization. While scholars mostly focus on technical aspects of pottery, this study emphasizes how Pueblo peoples used the traditional methods of pottery production maintain their identity under colonial power. To demonstrate the continuation of these Ancestral practices, this comparative study focuses on pre-colonial Pueblo pottery and the colonial period of the early twentieth and twenty-first centuries. First, I will discuss the Ancestral Pueblo pottery designs. Next, I will briefly discuss the colonization of the Pueblo peoples by Spain and its impact on the pottery production, followed by the Pueblo Revolt of 1680 that led to the expulsion of the Spaniards and the revitalization of the Ancestral Pueblo pottery methods. Following, I will discuss how Pueblo pottery transformed from utilitarian use to commercialized art following the establishment of the railroad in the late 19th century. I will focus on monochrome pottery created by early twentieth-century San Ildefonso Pueblo artist Maria Martinez and contemporary biochrome pottery about the Pueblo Revolt by Pueblo artist Virgil Ortiz, demonstrating the resilience of traditional methods. This study is based on historical, archaeological and scholarly research about Ancestral Pueblo and the website of artist Virgil Ortiz. This study is important because it demonstrates how traditional practices of pre-colonial Pueblo pottery have survived colonization and are still prevalent in the current work of Pueblo artists.

Abstract Name: Identity Labels and Aesthetics of Native American Art

This research project focuses on the adverse social meaning of the concept of “Native American” art in the 21st century based on examinations of artwork by four well-known contemporary artists. The research demonstrates that while many previous artists chose to be identified as an American artist, the artists in this study embrace their Native American identity to reclaim their heritage and ancestral identity, as reflected in their work. I will examine four contemporary artists who are descendants of First Americans, but with different life experiences. I will examine “Neufs for Oklahoma Autumn” by Edgar Heap of Birds, “Lexicon” by Rose B. Simpson, “The Animal That Therefore I Am” by Jeffery Gibson and “Singing Everything (Refrain)” by Marie Watt. First, the introduction to contemporary notion of “Native Americans” will be provided, including the historical changes in nomenclature. Second, a formal examination of each of the artworks with historical context will be provided. Third, conduct and/or review interviews with each artist to gain perspective on their art in relation to their identity through their lens as well as their experience as a contemporary artist and how identity labels have impacted each of them. Lastly, the comparative conclusion will demonstrate the influence that identity labels have on contemporary artists that are First American descendants.

Abstract Name: Reexamining the Alignment of STEM General Education Learning Outcomes in the 21st Century

General education curricula in the United States have long aimed to cultivate critical thinking skills, civic engagement, and democratic responsibility. Foundational reforms—such as Columbia University’s 1919 Peace Studies course and Harvard University’s 1945 General Education in a Free Society—helped define these aims. More recently, questions have arisen about whether general education still meets these goals, especially in science, technology, engineering, and mathematics (STEM), where scientific literacy and critical reasoning are increasingly vital. This project aims to determine whether the course-level learning objectives of STEM general education courses are consistent with both their institutions’ stated student learning outcomes (SLOs) and the historical mission of general education in the United States. Specifically, we address two preliminary questions: Which SLOs are most common in STEM general education courses, and do these differ by Carnegie Classification or regional accreditor? In the current phase, we examine how these course objectives align with institutional expectations and assess whether they continue to fulfill the foundational aims of general education. To address these questions, we used a qualitative codebook developed through iterative refinement to analyze general education SLOs from more than 60 institutions. Continuing this approach, we coded five syllabi per institution for the courses that fulfilled these requirements. Early results indicate that problem-solving, content knowledge, and mathematical reasoning dominate the course objectives, while gathering information, communication, and technical proficiency appear far less frequently; as coding progresses—with completion of R1 institutions anticipated in January—we expect to determine whether these trends persist across the full dataset. These findings will reveal how closely STEM general education courses align with institutional goals, historical intentions, and the broader purpose of preparing college graduates for scientific literacy and civic engagement.

Abstract Name: Queer Distortion: Analyzing the effects of Greer Lankton’s misrepresented “Lonely Dolls” during the AIDS epidemic

In this research project, I analyze artist Greer Lankton’s exhibit *Doll Party*, an installation of various dolls created throughout the AIDS epidemic that offer satirized, grotesque visages of trans and queer women as inherently effeminate or feminized by their proximity to AIDS. Using a queer studies and medical humanities approach that deploys Jack Halberstam’s concept of female masculinity and Priscilla Wald’s examination of outbreak narratives, I highlight how Lankton’s work problematizes cultural narratives of binary gender that feminize AIDS and its predominantly gay male victims, leading to the medical industry’s stigmatization and neglect of queer-folk and AIDS carriers during 1980s America. This hostile relationship between (presumably cis) practitioners and queer patients continues into the twenty-first century. I firmly argue that Lankton’s over-usage of horror elements and grotesqueness in her work satirizes this hostile relationship and the media narratives that pathologize queer victims of AIDS to create a cognitive dissonance—which I call queer dissonance—between her audience and the media narratives themselves, intending to correct this hostile

relationship. I suggest that in over-satirizing the misrepresentation of queer-folk during the AIDS epidemic, Lankton's work fails to appeal to twenty-first-century audiences and ironically contributes to the stigmatizing narratives of queer-folk that she aimed to prevent.

Abstract Name: Building up Arts in a Small Community

Cultural awareness is so important in today's society. This is something I have been hearing a lot in my art education classes. Coming from a small predominantly white community, cultural awareness is something that wasn't talked about while I was growing up. Art is the universal language of shared human experiences. It has the ability to cross cultural bridges and overcome barriers, such as language, dialect, and time. Art has the ability to create a common meeting space where people of all cultures and identities can be expressed and understood. Through this research project I have had the privilege of learning about the different cultural facets within my small community. The art pieces that have been created, represent each of the different cultures by celebrating our differences and unifying a small town in a common meeting space. These works of art are displayed on the outside of the Cultures, Humanities and Arts center in Virginia, Minnesota. My goal for this project was not only to pay tribute to each of our unique cultures. It is also meant to educate the next generation about the beauty and uniqueness that is inside each and every one of us. In order to move forward as a society it is important for all peoples to celebrate and embrace their differences, their beauty and different ways of life. I believe that art is a key component to understand one another. Art is transcendent and has the ability to reach us beyond our minds and into our souls. Art speaks to all people's no matter who you are or where you come from. I believe that art should be at the forefront of education. I am beyond grateful for this project and it's opportunities in educating the next generation.

Abstract Name: European-Islamic Ceramics from the Eighteenth Century Onward

Expanding upon prior research on the stylistic ceramics of the Safavid, Mughal, and Ottoman Empires (fifteenth and sixteenth centuries), this study illuminates a crucial moment in time; Islamic ceramic traditions providing an indispensable foundational catalyst for European ceramic modernity, profoundly shaping both aesthetic form and critical technical practice. Historically, Islamic ceramic traditions were an origin point for monumental technical advancements, including lusterware, cuerda seca, and underglaze painting. These techniques were transmitted through conquest and trade, leading to precursors like Spanish Lusterware or Hispano-Moresque, and Italian Maiolica. The technical legacy of tin-glazing continued to influence century production, such as Dutch Delftware. By the eighteenth century, Islamic aesthetics manifested as Orientalism and Turquerie, making Islamic forms desirable for elite consumption, as seen in Meissen porcelain. This foundational interest intensifies dramatically in the nineteenth century, sparking a technical resurgence where European manufacturers address their debt by rediscovering and adapting Islamic glazing chemistry to industrially refine luster and tin glazing. This technological boom presented opportunities for the Arts and

Crafts movement and figures like William de Morgan, who directly emulated Persian Lusterwares and employed palettes inspired by Iznik ceramics. Crucially, European manufacturers simultaneously leveraged industrial methods such as transfer printing to customize and export mass-produced earthenware featuring Islamic motifs back to the Islamic world, demonstrating a complex, transactional, and commercial dynamic based on the Islamic foundational aesthetics they appropriated. This paper validates profound historical debt, showcasing how the migration of Islamic ideas led directly to the developmental shifts extending into the Art Nouveau and Art Deco styles, and discovering its presence as far west as North American museums, private estates, and auction houses.

Abstract Name: Altered Entorhinal–CA2 Circuit Dynamics Underlying Social Memory Dysfunction in Schizophrenia

Schizophrenia is a severe neuropsychiatric disorder characterized by profound deficits in social cognition and social memory, yet the circuit mechanisms that drive these symptoms are yet to be fully understood. The CA2 hippocampal region and its inputs from the lateral entorhinal cortex (LEC) have emerged as a key pathway for encoding social identity and shaping social behavior, raising the possibility that dysfunction within this circuit directly contributes to the social impairments observed in schizophrenia. The goal of this project is to determine how LEC-CA2 communication supports normal social memory and to identify the specific ways in which disruption of this pathway leads to schizophrenia-related social deficits. Using an animal model with strong behavioral and circuit-level relevance, we combined targeted manipulation of entorhinal inputs, measurements of neural activity, and quantitative behavioral assays of social recognition memory to probe how this pathway transforms social information into hippocampal representations that guide behavior. Focusing on the LEC projections to the CA2 as a circuit, this work seeks to reveal how alterations in synaptic drive and population coding at the circuit level translate into changes in social decision-making and memory performance. Ultimately, finding how LEC-CA2 dysfunction contributes to social symptoms has the potential to identify mechanistic targets for future circuit-based interventions aimed at improving social functions and quality of life in individuals living with schizophrenia.

Abstract Name: Anti-Cancer Properties of the *Acacia raddiana* Acacia Tree Extracts

Cancer treatments are rapidly becoming more expensive, with the average cost of chemotherapy being around \$12,000 per month. The continuous time commitment required for treatment also reduces accessibility for many patients. Therefore, osteopathic treatments are often the only options for many people, including those in economically disadvantaged countries. The use of Acacia tree extracts is a popular cancer treatment in many nations with savannas, such as Africa and South America. However, there are over 1,300 acacia species and not all of their anti-cancer properties have been fully evaluated. The aim of this research was to determine the anti-cancer efficacy of leaf, seed, and gum extracts from *Acacia raddiana*, an acacia species that grows in

Morocco and nearby countries. Activity against many cancer types, including breast, colon, cervical and lung cancers, was determined. In addition, anti-cancer properties of water and ethanol-based acacia extractions were compared. The acacia extracts were incubated with the cancer cells and cell proliferation was measured using the MTT assay. All acacia extracts significantly decreased proliferation with the ethanol-based extractions having the largest effect on decreasing proliferation. Cellular death was measured using the Lactate Dehydrogenase release assay. Similar to the proliferation data, all acacia extracts induced significant levels of cell death. To calculate antioxidant levels, a Trolox equivalent activity capacity analysis was completed. All extracts contained compounds with anti-oxidant activity with the seed ethanol extract showing the highest antioxidant levels. These data demonstrate that extracts from the *Acacia raddiana* tree could possibly be developed as cheaper and more accessible cancer drugs.

Abstract Name: Comparison of One-Step Methyl Ester and Microwave-Assisted Fatty Acid Extraction using *Synodus foetens*

Fatty acid (FA) profiles are essential biomarkers for assessing food web structure, fish health, and environmental changes in marine ecosystems. Effective FA extraction is essential to ensuring efficient and accurate FA analysis. This study compared two extraction methods, one-step methyl ester (OSME) and microwave-assisted extraction (MAE), using dorsal muscle tissue samples from inshore lizardfish (*Synodus foetens*, $n = 11$) collected from five sites off the coast of New Orleans in the summer of 2023. Fatty acid methyl esters were extracted from muscle tissue using both methods, and FA concentrations were quantified using gas chromatography–mass spectrometry. Extractions were performed in duplicate to test the efficacy and consistency of the FA extraction methods. Statistical comparisons were performed using Friedman’s test followed by Wilcoxon signed-rank tests for pairwise analysis in R. OSME yielded 30 of the 33 fatty acids detected and consistently yielded the highest concentrations across all compounds it identified. Three fatty acids, heptadecanoic acid, eicosanoic acid, and methyl stearate, were only detected in MAE samples. Hexanoic and tridecanoic acids were not detected by either method, likely due to low concentration or degradation. Out of the 33 fatty acids quantified, 29 showed statistically significant differences between methods, with OSME yielding higher FA concentrations than MAE ($p < 0.05$). Concentrations of 9-octadecenoic acid, methyl ester, E differed significantly between OSME duplicate trials. ($p=0.905$). These findings indicate that OSME is the most efficient and reliable method for broad FA quantification, offering higher yields compared to MAE. However, MAE contributes complementary detection of certain minor or thermally sensitive compounds.

Abstract Name: The Effects of Thinning on Wood Density Among Different Loblolly Pine Genotypes

Loblolly pine (*Pinus taeda* L.) is the most valuable timber species for the southeast US forest products sector. Over the decades of managing this species, growth of the trees have continued to accelerate but effects on wood quality must constantly be reassessed to meet current practices. A common practice is thinning in which initially planted trees are removed to decrease the overall stand density and increase future growth capabilities of the remaining trees. The presented research is to compare the difference in density of the earlywood and latewood of three different families of loblolly pine, before and after a thinning treatment. The three loblolly families were the LA (Louisiana Family), a common North Carolina coastal family, and the 93 family which is a clone selected from the North Carolina coastal family. Multiple trees from each family were harvested, and tree cookies were taken three feet above the stump. These samples were dried to a moisture content of 12%. Small squares that are roughly 1 ½ x 1 ½ inch were cut from all tree cookies. A Laboratory Density Profile Analyzer DENSE-LAB X-light , was used to measure the density of each sample, focusing on the last five years of the tree before harvest. Samples are put into the machine in the orientation of pith to sapwood. The DENSE-LAB uses x-ray technology to measure the density of the entire sample and outputs all measurements in a detailed graph. The first two years, (pre-thinning treatment) and the last two years (post-thinning treatment), were compared across the three families. This research allows for effects on wood density to be explored under the very common thinning silvicultural practice.

Abstract Name: Relations Between Personal Identifiers and Outlook on Existential Futures

The central research question I would like to tackle with my research is how personal identifiers and life events can predict or inform general outlook on various existential futures, to give a general understanding of our common purpose and shared experiences and with which further research could be built upon to better our society in some way. A study by Alrofi et. al. in 2020 forms a large part of the basis for my interest in pursuing existential psychology, and outlines a concept of “authentic temporalizing”, the culmination of our moments. There are several limitations to this study though and the authors encouraged further research in light of modest results. An article in 2025 by Riker, professor of philosophy, discusses how we typically seek meaning in our lives and significance in death. Another relevant study in 2020 by Tomaszek & Muchacka-Cymerman investigated existential awareness of mortality during Covid and identified a similarity between the pandemic and negative or traumatic experiences resulting in loss of life satisfaction. I will be using a questionnaire and different methods of comparison to evaluate trends and correlations with the intention of finding any surprising or valuable results in regard to the states of mind of respondents and how they might be based on their individual qualities or characteristics. I will then compile the results of these analyses onto a poster to present my findings. I expect to find some common trends and associations such as religiousness and positive outlook, which I would then discuss in the appropriate context from which the link may arise. My hope is that this research would provide some basis or association to other works that may benefit the humanities and add to the body of research on the psychology of long-term outlooks on life for use by other works.

Discipline: Anthropology and Archaeology

Authors:

Abstract Name: The Theoretical Framework of North American Indigenous Archaeology and its Influence on the Field

The field of archaeology continues to adapt as anthropologists work to expand the theoretical framework that it operates from. As time progresses, archaeologists understand and critique the political and biased nature that is subconsciously present in their research. The foundation of the field centered on profits and exoticizing other cultures which meant that there was a limitation of ethically studying and respecting other cultures. In my research I will argue how those who work in the field of archaeology have ethical obligations to foster relationships and promote stewardship to respect the rights and beliefs of Indigenous peoples. "Indigenous archaeology" is a relatively new theoretical framework that prioritizes strong relationships and collaboration with Indigenous communities. I have gathered through reading generally in this field and analyzing academic scholarship that both Indigenous and non-Indigenous people collaborate intimately to recover the traditional knowledge and heritage of Indigenous communities. This in turn ensures that their cultural heritage, agency, and dignity are preserved in their own terms. North American Indigenous archaeology and its theoretical framework will lead to the evolution of the field of archaeology as researchers will ethically and responsibly research and collaborate with other cultures. With this research I will ultimately be creating my own definition of what Indigenous archaeology is based on previous theoretical framework and academic literature to form one uniform definition. This idea will be furthered as this is applied to the concept of repatriation in relation to Indigenous archaeology theoretical framework.

Abstract Name: Spatiotemporal Patterns of Meteorological Hazards and Climate Change in Pennsylvania (1960–2023)

Human-driven climate change is reshaping natural systems, including the frequency and characteristics of natural hazards. Meteorological hazards, while often perceived as less severe than other natural hazards, consistently remain among the most frequent and damaging events in the United States from 1960 to the present. Pennsylvania, with its mix of densely populated cities and extensive rural communities, provides an ideal setting to examine how climate-related hazard patterns and impacts vary across geographic contexts. This study analyzes meteorological hazard frequency and associated monetary and human losses across Pennsylvania's 67 counties from 1960 to 2023 using data from the Spatial Hazard Events and Losses Database for the United States (SHELDUS). State temperature records from the Pennsylvania State Climatologist were utilized to quantify warming trends in Pennsylvania. Meteorological hazards were identified as severe storms, thunderstorms, hail, lightning, wind, and tornadoes. Results indicate a statistically significant increase in average annual temperature over the study period. This increase was significantly correlated with rising meteorological hazard frequency, suggesting a climatic influence on storm occurrence. However, no clear relationship was found between warming and changes in economic or human losses, indicating that mean annual temperature alone does not capture the complexity of hazard severity or impacts. Monetary and human losses showed no consistent upward trend but remained substantial each year. Geographic disparities were evident in the way meteorological hazard damages presented across Pennsylvania. Rural counties experienced a greater total number of events and cumulative losses due to their larger area, while urban counties exhibited higher losses per event, on average, likely due to greater infrastructure density. These findings emphasize the need for hazard mitigation and climate adaptation strategies that consider both climatic trends and geographically distinct vulnerabilities across urban and rural Pennsylvania.

Abstract Name: A Comparison of the Work-Life Balance of American, British, and Germany women in the Second World War

The Second World War has long been regarded as a watershed moment for women and their role in the work force. Historians such as Becky Aikam and Tilar J. Mazzeo have primarily focused on women's military and espionage service, noting how it helped the war effort. As important as these stories are, the efforts of women on the home front were just as vital to winning the war. My research aims to highlight those women in Germany, Britain, and the United States who worked to support the war, their families, and their nation. By looking at propaganda posters, letters, and oral histories, I have pieced together how women supported their nation while maintaining a work-life balance. I have also drawn comparisons between the roles of women in German, British, and American wartime societies and how they were treated by their respective governments. The working world they were entering was crafted by and for men. The women entering it were not only mothers, but students fresh out of high school. They had their own money, they had new freedoms. They bought themselves new watches, navigated rationed food and materials, and maintained contact with their brothers, spouses, loved ones. In some cases, they were by themselves for the first time, learning how to carve out a space in society. By revisiting oral histories, government documents, and propaganda, my research aims to answer the following questions: How were women mobilized by their governments? What types of jobs were they called into? How did the war change their day-to-day routine? How did working mothers care for their families? What were the main differences between the experiences of German, British, and American women?

Abstract Name: Through the Lenses of DEI and Personal Confidence: The Impact of Culturally Responsive Teaching on Students' Sense of Belonging in STEM Environments and on Campus

Culturally Responsive Teaching is a practice that emphasizes the students' experiences and diverse cultural backgrounds and has been shown to increase a sense of belonging. Students in a microbiology class participated in an Indigenized laboratory experiment, one form of culturally responsive teaching, where we measured their sense of belonging in STEM and on campus before and after the experiment. This study observed how participation in this Indigenized laboratory impacted how students' viewed Diversity, Equity, and Inclusivity, (DEI) in these spaces and their personal confidence. Data was gathered using pre- and post-surveys collected through Google Forms where students responded to open-ended and Likert scale questions related to their sense of belonging in STEM environments and on campus. Qualitative coding of the student responses were sorted using NVivo 14. Based on preliminary results from the quantitative data, students' sense of belonging across the pre- and post-surveys at a STEM level slightly increased. There was an increase in the qualitative data with more positive responses regarding DEI and personal confidence. This is likely because the students created personal connections through the culturally responsive teaching activity. In contrast, there was no change observed at the campus level, possibly because the activity did not impact their feelings with the DEI on campus and their personal confidence. Evaluating student responses will determine

if Indigenizing this laboratory experiment affects a students' sense of belonging in both STEM environments and on campus. With a positive impact from this lab, we seek to encourage students to continue pursuing STEM.

Abstract Name: Echinoderm Diversity in Roatán, Honduras

Echinoderms are marine invertebrates that function as predators, prey, filter feeders, and detritivores, filling diverse ecological roles supporting habitat structure, nutrient cycling, and biodiversity across marine ecosystems. Sea urchins regulate macroalgal growth, sea cucumbers enhance sediment oxygenation through bioturbation, and brittle stars and crinoids contribute to habitat complexity and energy transfer. Echinoderms are considered sentinels of reef health as sea urchin immune responses to environmental stresses, including changes in pH, temperature, and conventional and emerging pollutants. There has been a lack of data on echinoderm diversity, which limits the ability to detect ecological shifts. This study was conducted to document echinoderm diversity in Roatán, Honduras. Data was collected from 27 - 30 May 2025, using the Randell Robertson Marine Survey Technique (RRMST) for shore and reef surveys. A total of 645 echinoderms were recorded with substrate preference across six sites. The most abundant classes were Echinoidea (74.9%), Crinoidea (14%), Ophiuroidea (9.9%), and Holothuroidea (1.2%). Overall, substrate preference by class was Rock for Echinoidea (85.9%), Coral for Crinoidea (93.3%), Rock for Ophiuroidea (42.2%), and Sand for Holothuroidea (100.0%). The most dominant species by class were *Echinometra lucunter* (80.8%) for Echinoidea, *Davidaster rubiginosus* (58.9%) for Crinoidea, *Ophiocoma echinata* (48.4%) for Ophiuroidea, and *Holothuria mexicana* (62.5%) for Holothuroidea. Chi-square tests revealed significant associations between echinoderm species and sampling method. Shore snorkeling surveys had the highest species richness and abundance. Significant relationships were found between class and substrate type, and within classes, Echinoidea and Ophiuroidea exhibited significant substrate associations, while Crinoidea did not. Sea urchin species with shorter lifespans, such as *Echinometra lucunter* should be monitored for population declines since they serve as bioindicators for ecosystem stability. Given the ecological significance of echinoderms and growing environmental pressure, this study establishes a baseline for future reef health assessments and conservation efforts in Roatán, Honduras.

Abstract Name: Water Conservation in Rural West Texas

Texas faces an escalating water crisis driven by prolonged droughts, population growth, and aging infrastructure. Projections by the Texas Water Development Board indicate a shortfall of up to 5.74 million acre-feet annually by 2050, with even greater deficits expected by 2070 if current trends persist. This research examines water conservation policy in rural West Texas through the lens of institutionalism theory, emphasizing the role of state and local institutions in shaping policy responses. Historically, Texas has implemented significant measures, such as the Water Planning Act of 1957 and the creation of the Texas Water Development Board, yet gaps remain in funding and research. Recent legislative efforts, including Proposition 4 and the establishment of the Texas Water Fund, signal progress but rely heavily on surplus revenue, creating uncertainty in long-term sustainability. This policy brief analyzes three potential policy solutions: (1) guaranteeing annual funding regardless of surplus, (2) requiring oil and gas industries to contribute a portion of revenue to water management, and (3) increasing allocations for scientific research on groundwater and climate impacts. Implementation strategies include tax adjustments, community outreach, and transparent fund management to ensure equity across regions. By analyzing institutional frameworks and proposing actionable solutions, this research contributes to ongoing discussions on sustainable water policy and highlights the urgency of addressing resource scarcity in rural West Texas communities.

Abstract Name: Water Quality Monitoring and Analysis

Urbanization surrounding Richland Creek, including expansion of nearby residential areas and the development of a large global technology complex, has increased concern about the impacts of growing impervious surfaces on local water quality. Richland Creek flows through the 245-acre Carl Alwin Schenck Memorial Forest in western Wake County, an urban forest valued for education, recreation, and long-term research opportunities. Because the forest lies within eight miles of downtown Raleigh, it provides an important natural area within a rapidly developing region. To assess potential environmental shifts, researchers have conducted continuous weekly monitoring over several years to establish a baseline for comparison. At each site, a YSI Professional Plus multiparameter instrument is used to measure dissolved oxygen (mg/L), specific conductivity ($\mu\text{S}/\text{cm}$), and pH, while a portable turbidimeter records turbidity (NTU). When compared with earlier datasets, seasonal dissolved oxygen trends follow expected patterns typical of Piedmont streams. However, specific conductivity values show notable irregularities. In particular, readings from Spring 2025 were significantly elevated relative to other seasons and previous years. These increases may be associated with intensified runoff and sediment mobilization linked to greater rainfall and expanding impervious surfaces surrounding the watershed. Currently, chemical analysis has begun, with the data of each site monitoring heavy metal content. Monitoring of conductivity and other parameters, including chemical analysis, will continue, and updated Fall 2026 results will be incorporated, as preliminary observations indicate meaningful changes that require additional interpretation.

Abstract Name: Carrying What Isn't Spoken: A Young Black Woman's Autoethnography on Family Mental Health and Loss

This autoethnography examines how, as a young Black woman in college, witnessing mental-health challenges within my family and losing loved ones to these struggles shapes my daily life, communication patterns, and emotional expression. Rather than focusing on my own mental health, this project explores the perspective of navigating school, family expectations, and early adulthood while carrying the emotional impact of others' battles with depression, anxiety, and trauma. By reflecting on personal memories, family conversations, and cultural norms within Black communities, I analyze how ideas of strength, silence, and resilience influence the way I respond to conflict, offer support, and manage emotional boundaries. These experiences shape how I interpret others' behaviors, how openly I communicate, and how I balance empathy with self-protection. Connecting my story to broader conversations about mental health in Black families, this autoethnography highlights the often-invisible labor young Black women perform as supporters, observers, and survivors of generational emotional struggle. It demonstrates how loss and mental-health challenges around me continue to shape my identity, my communication style, and my understanding of healing.

Abstract Name: Evaluation of Floral Hairs for Species Identification of Wild Gingers (*Hexastylis*)

Hexastylis is a genus commonly called wild gingers or heartleaves containing eighteen species that are endemic to eastern North America. Wild gingers are characterized by evergreen, variegated leaves and tubular flowers that can be found under the leaf litter. Recognition of the genus is a subject of taxonomic debate. While it is morphologically distinct from the closely related *Asarum*, phylogenetic studies hypothesize that *Hexastylis* is contained within *Asarum*. The genus is not well understood, as species identification is heavily reliant on the three-dimensional shape of the floral tubes and this character is lost in pressed herbarium specimens. There are a number of characters in wild gingers that have not been explored as identification characters but may be useful. One of these characters is the hairs found within the flowers as some species can be identified by their distinctive hairs. We combined field collecting with herbarium specimens of Virginia populations to evaluate the hairs for differences among species. We sectioned the flowers at the base of a lobe of the floral tube and treated them with a bleach solution to increase visibility of the hairs. The sections were viewed under a light microscope and photographed. The hairs were scored for the presence of distinct basal cells, hair length, and hair density to determine differences in hair structure among different species. We found that hair traits varied among individuals in the same species and these traits overlapped among species. This makes the character not useful for species identification, but other characters such as the bracts at the base of the flower stalk may be useful in this group. We will continue examining these potential characters to determine other useful tools for *Hexastylis* identification.

Abstract Name: The Impact of Vocal Health on Burnout Levels in Choral Music Educators

Vocal disorders, stress-related injuries, and vocal health are increasingly relevant topics among choral music educators. According to Vimala Venugopal Muthuswamy, educators, particularly those in the field of music, are susceptible to voice-related disorders due to their reliance on vocal delivery in their professional duties (Muthuswamy et al. 2024). Research shows that a majority of music educators that do feel burnout, vocal fatigue, and have vocal health issues are choral music educators in jobs that have the potential to strain and damage vocal cords. “Voice disorders, such as vocal nodules or cysts can be complicated and attributed to various factors, including voice use, sleep, or illness” (Grady et al. 2022, p. 142). The purpose of this study was to shed light on what truly causes vocal fatigue, burnout, and other vocal health related issues in choral music educators in today’s classrooms. An anonymous survey was created using Qualtrics Software that included questions regarding vocal health issues, burnout commonalities, and overall self-care of choral music educators. This survey was open to all choral music educators throughout the United States. Open-ended questions were asked at the end of the survey, so educators could share how their personal experiences have impacted their lives within the education field. The results of this survey will inform choral music educators how to avoid burnout, vocal fatigue, and how to take care of personal vocal health, while also being a full-time educator. By analyzing data collected from the survey, results will inform choral music educators, administrators, and future music educators on how to create preventative habits to avoid poor vocal health and fatigue. This will impact both educators and students by creating an overall healthier environment in the classroom, while also improving mental health and vocal health in the process.

Abstract Name: Gendered Narratives and Institutional Power in the Integration of Displaced Women in Austria

Forced displacement disproportionately affects women and girls, who experience compounded risks of violence due to legal precarity, economic instability and gender inequality. As of 2024, over 110 million people are forcibly displaced worldwide, with females making up half of the population, yet research on how they develop the personal, cultural, spiritual and social resilience to navigate the complexities of healthy integration remains limited. Popular discourse often frames displaced women as powerless, overlooking the strength and redefinition needed for them to adapt their faith, culture and often their families to new host contexts. Europe, and particularly Vienna, Austria, is a key hub for displaced communities and peacebuilding initiatives that often shape public discourse about integration. This research situates Vienna as a case study site for examining how narratives of and about displaced women are framed, iterated, resisted and/or reinterpreted within cultural and religious contexts. It investigates the patterns in shaping both representation and agency within often patriarchally-gendered integration processes. Adopting a mixed methods approach from a feminist and decolonial perspective, I draw from institutional reports, field observations and discourse analysis of gendered integration strategies to examine how institutions in Vienna translate women’s lived realities and trauma, both within policy and practice. Preliminary findings suggest that while many European institutions adopt feminist language, they often reinforce Western-centric narratives positioning displaced women as passive recipients of aid. On the other hand, the study found that grassroots organizations and women-led initiatives in Vienna actively reinterpret religious and cultural narratives as tools of empowerment, fostering spaces of solidarity, agency and self-representation. This research underscores the

need to reimagine integration and peacebuilding through intersectional, religious and culturally grounded perspectives. By centering patriarchal narrative reinterpretation and institutional reflexivity, it contributes to broader debates on women's empowerment, resilience building, host city integration, and gender inclusive policy design.

Abstract Name: A New AI Crisis in Mental Healthcare

Technology companies are bringing LLM tools to healthcare, e.g., Wysa's AI mental healthcare chatbot was recently designated as a 'breakthrough device' by the FDA. We argue that the principles of medical ethics need to be treated as obligatory rather than as mere guidelines in the development of these technologies. This not only safeguards end-users from potential harms but the companies as well, helping align stakeholder interests in bringing these technologies to the market in beneficial ways. We review Wysa's chatbot through the lens of the four principles of biomedical ethics: autonomy, beneficence, non-maleficence, and justice. Wysa's breakthrough designation was, in part, thanks to the expansion of access to mental healthcare by introducing a novel stratification of care. However, this newly tiered service of care is, by definition, suboptimal. Even where it is beneficial, it still introduces the risk of what we call the re-entrenchment of vulnerability: a cyclical pattern of harm faced by marginalized populations when they consistently receive suboptimal care, further embedding their pre-existing vulnerabilities. Wysa's device designation was for patients suffering from chronic pain and experiencing associated anxiety and depression. Their current messaging goes beyond that, claiming the chatbot is useful for patients struggling with low mood, stress, and anxiety, despite no clinical data supporting this utility. Another potential harm is the issue of data storage and encryption. Wysa is not transparent about how their LLM is learning from end users; patients are susceptible to being unwilling participants in the training and development of this program, in violation of standards of privacy for medical information. These are symptoms of an underlying problem: treating the principles of biomedical ethics as mere guidelines. That leaves patients more vulnerable to these and other harms. Those risks can be mitigated by treating ethical principles as obligatory.

Abstract Name: Join The Herd: A Processual View of Viruses

Connecting herd immunity gained through vaccination to the life cycle of an individual virus can feel a bit abstract. A conventional way to do this is by adopting a reductionist framework. Herd immunity is achieved when immune systems are trained to respond effectively to viral strains that cause disease, often through natural recovery or vaccination. But this view is too constrained. It promotes a naïve causal explanation and fails to capture the dynamic features of how these systems are connected. Instead, I argue that we ought to regard all these systems as processes. Adopting a process ontology has several advantages. It treats processes as being part of a "hierarchy of processes, stabilized and actively maintained at different timescales" (Nicholson & Dupré 2018). This reframes how we think about and research herd immunity. In this

project I will examine the connection of viral life cycles and herd immunity with a case study of measles. Measles undermines herd immunity through immunological amnesia. The processual stance allows us to examine in depth this connection to public health and individual viruses. This context adds another layer of complexity that can be difficult to interpret in the constantly evolving scientific space. I believe that adopting a process approach here will help scientists effectively communicate complex empirical data and systems in a way that is digestible and understandable.

Abstract Name: Navigating Through Compassion and Psychological Distress

Compassion can be a powerful balm against despair, especially for college students facing loss and uncertainty (Allen et al., 2012). Compassion is a crucial psychological and spiritual construct in emerging adulthood, yet little is known about how it emerges. Strauss's (2016) compassion theory consists of five elements: recognizing suffering, understanding its universality, feeling empathy for the sufferer, tolerating uncomfortable emotions, and being motivated to alleviate the suffering. This study investigated how individual and relational factors predict compassion and psychological distress among first-semester college students. Predictor variables included demographics (age, gender), community connection (student and faculty belonging), and spiritual traits (exhibiting Acts of Mercy and Acts of Piety) (Knight, 1992). First-time freshman participants from a private liberal arts university in the south central United States were asked to complete self-report measures, including the compassion scale, Kessler Psychological Distress Scale (K-10), Mercy and Piety Practices Inventory (MAPPI), and the Duke University Religion Index (DUREL). Results revealed that psychological distress did not significantly predict compassion. Older students reported higher compassion and greater psychological distress. Female students reported higher levels of both compassion and distress. Both student and faculty belonging significantly predicted compassion; however, only student belonging predicted lower psychological distress. Interestingly, practicing past piety predicted greater compassion, while present mercy was associated with higher distress. Present piety also predicted lower distress. Intrinsic religiosity consistently predicted higher compassion and lower distress. These findings offer a nuanced understanding of how belonging, spirituality, and personal factors interact in shaping compassion and distress during college.

Abstract Name: Pleasure or Pressure: Social Stigma in the Representation of Prostitutes in the Eighteenth Century

Prostitutes in eighteenth-century works, such as *Memoirs of Margaret Leeson* (Peg Plunkett) (1795) and Mary Wollstonecraft's *The Wrongs of Woman* (1792) endured many persecutions throughout their lives. Specifically examining Margaret Leeson and Jemima led to findings of extreme poverty, shame from societal stereotypes, violence endured from gangs, trauma in many forms, and various sexual double standards. When reviewing *The Old Bailey Proceedings* (1674), it is clear that bigotry and power dynamics played a key role

in the perception and mistreatment of prostitutes. This work builds on other studies regarding the representation of prostitutes in eighteenth-century fiction, non-fiction, historical documents, and the intersection of societal intentions throughout the different genres. I recognize the work of eighteenth-century scholars who have analyzed Wollstonecraft's language and politics to show how they ultimately affected her attitude towards sex workers. I argue that the illusion of progress and many other contributing factors affected the negative depictions of prostitutes in multiple genres of literature. Leeson and Jemima comparatively had different mindsets about their profession as well as different reasons for entering into this lifestyle, adding to the importance of examining the two women concurrently. In exploring the gendered language in The Old Bailey Proceedings, major evidence has shown society's, more specifically men's, demeanor towards prostitutes. This evaluation of sex workers will highlight their portrayal in literature, while spotlighting the neglected research about the reasoning behind different women becoming prostitutes.

Abstract Name: Framing Abortion: A Content Analysis of the Pro-Choice Movement's Social Footprint Post-Roe

This project explores how advocacy organizations in the US vested in the abortion debate strategically shape public opinion about the debate through social media, a shift from the traditional focus of news media. Existing research has examined how organizations use traditional public relations tactics to frame abortion and sway public opinion. In recent years, social media platforms such as TikTok have become critical outlets for abortion discussion, particularly after the overturning of Roe v. Wade in 2022. There is little research, however, that explores how abortion is being framed by organizations when they are using social media to connect with audiences. The central purpose of this project is to conduct a qualitative content analysis to answer two research questions around the rhetorical frames and strategic communication techniques employed by pro-choice advocacy organizations in their TikTok messaging. This thematic content analysis uses an open coding procedure. Two reputable lists were used to identify prominent abortion advocacy organizations to include in the study. Using selection criteria, a total of 41 TikTok videos across 11 organizations were chosen for analysis. Atlas.ti, a popular qualitative data management tool, was used to transcribe the sample. An open coding process is underway to examine themes, frames, messages, and strategies of both visual and textual content within the TikTok videos. The research should uncover the strategies abortion advocacy groups use to share informative and persuasive content. Based on existing research, themes will likely center around reproductive justice and legislation, correcting misinformation, and educating on women's health. The findings will be discussed in the context of how digital advocacy is being used to shape today's abortion discussions. Ultimately, this study aims to fill the gap in the literature by exploring how pro-choice advocacy groups frame the abortion conversation to influence public opinion in the post-Roe landscape.

Abstract Name: Communalism Values and Centrality as Predictors of Negative Experiences in African American Students Across College Campuses

African American college students' experiences can be shaped by college environments, while cultural values and racial identity can simultaneously influence how they feel on campus. This project focuses on the role of Afro-cultural values (i.e., communalism) and their racial identity (i.e., centrality). In this study, we examined whether students with higher communalism values would report higher racial centrality and whether those higher levels of racial centrality would be linked to more negative college experiences. We also wanted to see if these associations looked similar or different across three types of institutions: a predominantly White institution (PWI), a minority-serving institution (MSI), and a historically Black college/university (HBCU). 170 African American students across the campuses completed self-report measures of communalism, racial centrality, and negative college experiences, and separate mediation models by institution were conducted using Model 4 of the PROCESS macro for SPSS. Across all three campuses, higher communalism values were associated with higher racial centrality (PWI: $\beta = .50$, $p = .001$; MSI: $\beta = .53$, $p < .001$; HBCU: $\beta = .38$, $p = .018$). At the PWI, higher racial centrality was significantly related to more negative college experiences ($\beta = .44$, $p = .014$), and the direct link between communalism and negative experiences was small and non-significant ($\beta = -.02$, $p = .89$), which is consistent with full mediation. At the MSI and HBCU, racial centrality showed small-to-moderate positive, but non-significant, associations with negative college experiences (MSI: $\beta = .21$, $p = .088$; HBCU: $\beta = .24$, $p = .18$), and direct effects of communalism were also non-significant (MSI: $\beta = -.09$, $p = .46$; HBCU: $\beta = -.19$, $p = .29$). Overall, communalism predicts stronger racial centrality among African American college students, but how central one's race is to their identity and how it shapes their negative college experiences depends on the campus.

Abstract Name: Empowering Dame La Mano: Fostering Self-Efficacy and Emotional Well-Being Among Women in Transitional Shelters

Women residing in transitional shelters frequently experience complex emotional, psychological, and environmental stressors that can undermine personal stability, limit autonomy, and impede long-term wellbeing. Self-efficacy, the confidence in one's ability to navigate challenges, is a well-established protective factor associated with resilience, reduced stress, and improved health outcomes. The purpose of this project was to examine changes in self-efficacy and perceived stress among women living at the Dame La Mano Transitional Shelter after participating in a six-week, empowerment-focused, service-learning intervention designed to strengthen agency and problem-solving skills. Seven adult participants engaged in twice-weekly, student-led sessions that incorporated collaborative activities, reflective discussions, and presentations from community guest speakers. Topics were selected by participants and centered on priority concerns such as food access, transportation challenges, and navigating healthcare services. Outcomes were measured using the General Self-Efficacy Scale (GSE-10), the Health Self-Efficacy Scale (HSS), and the Perceived Stress Scale (PSS-10). Pre- and post-project scores were analyzed using paired-samples t-tests and Wilcoxon Signed-Rank Tests due to the small sample size. Quantitative analyses revealed no statistically

significant changes in general or health-related self-efficacy, $t(6) = -1.83$, $p = .118$, nor in perceived stress, $t(6) = 1.56$, $p = .168$. While preliminary, these patterns align with existing literature indicating that confidence in personal capability may buffer the psychological impact of adversity. Although statistical significance was not reached, the project demonstrated the value of participant-directed, sustainable engagement as a mechanism to promote emotional wellbeing, autonomy, and community connection among women in shelter environments. These findings highlight the need for continued research with larger samples and longer intervention periods to better understand how empowerment-focused initiatives can strengthen resilience and support long-term stability in vulnerable populations.

Abstract Name: The Infernal Schism: Analyzing the Causes and Events behind the Departure of Congregations from The Satanic Temple

Research surrounding organizational splits has typically operated under the assumption that schisms occur due to some type of change within the organization, which members view as undermining the fundamental values of the group. During the summer of 2024, The Satanic Temple (TST) underwent its own schism in which ministers either left or were removed from their positions following the firing of a Canadian minister. Drawing on interviews with twenty individuals - some who left TST and others who stayed - this paper explores the factors that led to this schism. What distinguishes this schism from those previously examined by scholars is that there was no organizational change that preceded these events. Rather, many ex-members cited the firing of this minister as the tipping point, arguing that this was an abuse of power by the highest level of leadership in the organization. Other factors, including political activism and differences in perceived organizational goals, also played an important role in the dismissal and departure of many of the organization's members.

Abstract Name: In Pursuit of Novel Bacteriophages

Bacteriophages are viruses that infect and kill bacteria. They are among the most abundant biological entities on Earth, with an estimated 10³¹ present. However, only a small portion have been discovered (only 13,571 genomic sequences have been deposited in NCBI as of December 2025). The goal of our project, part of the Science Education Alliance-Phage Hunters Advancing Genomics and Evolutionary Science (SEA-PHAGES) discovery program, was to isolate and characterize bacteriophages from the soil that target the bacterium *Arthrobacter globiformis*, an important member of many soil microbiomes. Isolating and characterizing such bacteriophages not only contributes to our general understanding of biodiversity and bacteriophage biology

but to our understanding of the soil ecosystem. Furthermore, though the clinical significance of *Arthrobacter* infection is limited, the occurrence of infection with members of the *Arthrobacter* genus in immunocompromised individuals has been reported. Thus, bacteriophage capable of killing *Arthrobacter* species have potential as alternatives to conventional antimicrobials. To date, four unique bacteriophages have been isolated and added to PhagesDB: Elsanna, Moseby, Tipton, and WileyJr. Elsanna was harvested from the soil of the Charlotte Codo Prairie in Frankfort, Illinois. Moseby, Tipton, and WileyJr were isolated from the soil of a retired urban garden plot in Joliet, IL. Biologically, all four bacteriophages produce clear plaques, indicating a lytic life cycle. All four phage display siphovirus morphologies, with two (Elsanna and WileyJr) having a prolate capsid and two (Moseby and Tipton) having an icosahedral capsid, as evidenced by electron microscopy. Genetic characterization (restriction enzyme analysis and genome sequencing, and annotation) of the bacteriophages is underway. Once completed, these phages will be added to NCBI for comparative analysis of novelty, gene content, and evolutionary relationships. Supported by NSF Grant 2516066.

Abstract Name: Enzymatic Hydrolysis of Soybean Hull Without Pretreatment and Its Enhancement of Bioethanol Production Using Xylose-Fermenting *Escherichia coli* (FBR5)

Agricultural residues represent an abundant and renewable feedstock for sustainable bioproduct and biofuel production. Among these materials, soybean hulls, generated as a low-value byproduct during soybean oil and meal processing, offer significant potential due to their high carbohydrate content. However, the complex architecture of lignocellulosic biomass typically requires pretreatment to enhance enzymatic accessibility. Conventional pretreatment methods can generate inhibitory compounds such as furfural, hydroxymethylfurfural (HMF), phenolics, and lignin-derived degradation products, which reduce enzymatic activity and elevate processing costs. This study investigates the feasibility of direct enzymatic hydrolysis of untreated soybean hulls as a strategy to bypass pretreatment, improve process efficiency, and reduce production barriers for industrial biorefineries. Soybean hulls (5%, w/v) were hydrolyzed at 50 °C for 72 h using a dual-impeller mixing system operated at 250 rpm. Enzymatic saccharification was performed with two commercial enzyme preparations, Cellulase Blend and Multifect Pectinase, applied at 45 mg enzyme protein/g solids. A reduced enzyme loading of 10 mg/g solids was also evaluated to assess cost-effectiveness. Conversion of glucan, xylan, and arabinan into fermentable sugars was quantified, and hydrolysates were subsequently fermented with the xylose-utilizing *Escherichia coli* FBR5 strain to assess bioethanol production. High conversion efficiencies were achieved without any chemical pretreatment, yielding 94.4% glucan-to-glucose, 72.6% xylan-to-xylose, and 69.3% arabinan-to-arabinose. In contrast, control reactions lacking cellulolytic enzymes produced only 14.2–20.1% conversion. Notably, the moderate enzyme loading (10 mg/g solids) achieved 90.6% cellulose conversion, nearly equivalent to the higher loading, indicating strong potential for enzyme cost reduction. Fermentation of the resulting hydrolysate by *E. coli* FBR5 achieved 94% theoretical ethanol yield, with a production rate of 0.33 g/L/h and an overall productivity of 0.48 g ethanol/g sugar. These findings demonstrate that soybean hulls can be efficiently hydrolyzed and fermented without pretreatment, offering a cost-effective and scalable pathway for bioethanol production.

Abstract Name: Poder y Democracia: Una Mirada Desde los Sofistas

Questions about power and democracy are as old as the Greek polis. Democracy is founded on the idea of a people whose citizens are both the holders of political power and the source of its legitimacy, while its institutions seek to rationalize the ever-present threat of violence through deliberation and collective judgment. Within this context, the sophistic movement argued that rhetoric is the central instrument of political action, since discourse and *lógos* make it possible to transform force into persuasion and to rationalize the exercise of power. This project aims to clarify the conceptual relationship between power, rhetoric, and democracy by examining key sophistic contributions and their relevance for interpreting contemporary political dynamics. In sophistic thought, *krátos*—or power—operates in both military and civic spheres. For thinkers such as Gorgias, the strength of the warrior shifts into the potency of speech: a form of “symbolic violence” capable of influencing collective decisions without physical coercion. Jacqueline de Romilly notes that the transition from warrior *krátos* to rhetorical power does not eliminate conflict but interiorizes it, relocating struggle into language itself. Recognizing this shift reveals that power does not disappear under democracy; it changes form and often hides beneath apparent consensus. Democracy, meanwhile, places authority in the *demos*, enabling citizen participation in institutions such as the Assembly and the Agora. Yet this openness also produces internal *stásis*—tensions that can lead to institutional crises or the concentration of power. This conceptual analysis argues that defending democracy requires maintaining a balance between force and speech—between *krátos* and *lógos*—and that this tension remains crucial for understanding contemporary political discourse and the challenges facing democratic societies today. This presentation will be delivered in Spanish, with English explanations available upon request.

Abstract Name: Image clustering and analysis using K-Means for analysis of membrane damage in C2C12 cells

Image clustering and analysis using K-Means for analysis of membrane damage in C2C12 cells Authors: Lizbeth Cortez Paz, Daniel Pintard, Shama Iyer, Susan Agolini Microscope images of biological structures contain complex visual information that researchers manually analyze, a process that is time-consuming and prone to human error. This project aims to develop a tool for identifying, counting, and analyzing regions of interest in biological images, specifically measuring membrane damage in C2C12 cells, using the K-Means clustering algorithm. The methodology involves preprocessing microscope images using OpenCV to split color channels (red, blue, and gray) and applying techniques to isolate biological features. K-means clustering then groups similar regions, such as nuclei and myo strings, based on color and structural characteristics. The results are visualized using Jupyter Notebook, providing qualitative and quantitative insights for

researchers. Plasma membranes of C2C12 cells grown on coverslips were damaged using Streptolysin O, treated with and without calcium for 2 minutes, and labeled with membrane-impermeable dye, propidium iodide (PI), to assess membrane repair. Coverslips were mounted on slides with mounting media containing DAPI and imaged to assess the performance of the image analysis tool developed. Currently, the tool can identify the number of nuclei, the number of myotubes and/or myoblasts, and, using images of cells labeled with PI, detect which myonuclei are healthy or damaged. While the current version focuses on structural segmentation rather than disease diagnosis, future advancements could enable automated classification, more detailed measurements, and integration with medical applications. Its adaptability across various biological image types makes it a valuable resource for researchers in cell biology, pathology, and related fields.

Abstract Name: Creating a Successful STEM Pipeline: The Journey of a First Generation Student

Alverno College is a four-year, undergraduate liberal arts college and Hispanic-Serving Institution (HSI) located in Milwaukee, Wisconsin with a strong history in providing college access and success for first-generation, low-income women. Alverno's Natural Science faculty strive to serve students through research-based programming aimed at creating a supportive STEM community and promoting student confidence, leadership, sense of belonging, and STEM identity. This presentation will explore how we have intentionally scaffolded a developmental pathway of co-curricular programming, academic support, research opportunities, and scholarship assistance, all while emphasizing cohort- and community-building in STEM. We will follow a student's journey, from high school participation in our Girls' Academy program to graduation. This exploration will take us through her experiences in early and advanced research, peer tutoring, peer mentoring, attending professional conferences, and even a presentation to the college Board of Trustees. We will travel through the pipeline Alverno has crafted that especially supports first generation and low income students, allowing us to address disparities in higher education and STEM degree attainment, promoting the success of individual students and contributing more broadly to the workforce needs of our community and our nation.

Abstract Name: Initial Explosive Contractions Influence Metabolic Responses Within Sets Of Resistance Exercise More Than Heavier Loads

Our laboratory previously found that concentric repetitions (reps) performed prior to eccentric within the same set increased energy cost during subsequent eccentric reps. It is unclear whether heavier or explosive reps performed first would influence energy expenditure more in subsequent reps. PURPOSE: Therefore, we tested whether heavier or explosive reps performed first would enhance energy expenditure to a greater extent in the latter part of sets. METHODS: We used two exercise protocols (4x8 reps of squat) from a larger study that tested 7 men (20 ± 0.9 yrs; 82 ± 12 kg; 181 ± 5 cm). One of the protocols included 3 explosive reps followed by 5 recreational using 50% of maximal strength (1-RM) (3EXPL/5REC-50%). The other protocol required subjects to perform all 8 reps recreationally using 57% of 1-RM (REC-57%). Subjects' 1-RM was determined on a squat machine, and peak power was determined using an accelerometer. Repetition speed, ROM, and rest intervals were standardized among protocols. Expired air was collected 15min before and during using a metabolic cart. Data were analyzed using a 2-way repeated measures ANOVA with Fisher's LSD post hoc. We hypothesized that metabolic rate would be similar during the first three reps, but greater during the last 5 reps of 3EXPL/5REC-50% compared to REC-57%. RESULTS: Rates of oxygen consumption ($\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) were significantly greater ($p \leq 0.05$) during the last 5 reps of each set of 3EXPL/5REC-50% (sets 1-4: 15.4 ± 1.5 , 16.3 ± 2.2 , 17.3 ± 2.4 , 17.4 ± 2.3 $\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, respectively) compared to REC-57% (sets 1-4: 13.5 ± 1.4 , 14.2 ± 1.2 , 14.8 ± 1.6 , 14.2 ± 1.3 $\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, respectively). There were no differences in metabolic rate during the first 3 reps between protocols. CONCLUSION: Explosive reps performed first within a larger set appear to influence the subsequent energy cost more than heavier loads, despite higher work.

Abstract Name: AI as a Substitute for Student Writing: Effects on Confidence, Perceived Quality, and Academic Integrity

This proposed research study aims to explore and define what impact AI work in replacement of original work has on students' perception of and confidence in their own writing. Specifically, this study will consist of interviews of students at a small high school in rural Nevada. The research will notably evaluate the complex effect that AI generated writing has on students' academic performance and confidence in their own writing, and whether this practice of academic dishonesty makes it difficult for students to return to finishing their own writing. This research topic emerged from my own experiences witnessing my peers use AI, specifically with essays, which oftentimes look to be mostly AI generated. Included in this research, I will base further questions around the ubiquitous research question: To what extent does AI use (specifically ChatGPT) among students as a substitution for their own writing impact their confidence as writers? Additionally, I propose the following research questions: 1. To what extent do students use AI to complete assignments? 2. To what extent does AI use alter students' perceptions of the quality of their writing? 3. To what extent does AI use impact students' ability to complete writing assignments without AI support? As a result of this study, I anticipate finding that students who use AI to complete their assignments feel insecure with their own writing. I also expect to find that using AI is a slippery slope that makes it harder to stop using it as a replacement for their own work. Likewise, I expect for there to be pushback on certain questions due to the sensitivity of the topic. This proposed study will use semi-structured interviews, which will allow students to provide in-depth explanations regarding their feelings and experiences about the connections between AI and students' confidence in writing.

Abstract Name: Continuous monitoring of fracture healing using wireless sensors

Bone fractures remain a significant clinical burden worldwide, affecting millions of individuals annually and leading to substantial economic costs. Despite advancements in imaging technology, accurately tracking the healing process of bone fractures in real time remains a challenge. This gap leads us to the research question: Can implantable bone strain gauges be used to continuously monitor bone healing in a sheep model? We hypothesized that for this study implantable bone strain (mechanical deformity) gauges can provide an accurate quantitative assessment of bone healing in sheep compared to radiographs. Sheep underwent sterile surgical preparation and implantation of calcium-coated strain gauge sensors onto femur fracture sites. Sensor function was verified with weekly strain data collection and compared against radiographic imaging. As healing progressed from the soft callus phase to the remodeling stage, a corresponding decrease in strain was observed. There was an overall decrease of 75 percent when comparing the averages from week 4 to week 11, this is correlated to the healing of the bone throughout the weeks. These results suggest that calcium-coated strain gauge sensors offer a promising solution to existing gaps in bone healing research. Ultimately, this work advances the development of continuous monitoring techniques that enhance our understanding of fracture repair and support more effective clinical interventions.

Abstract Name: The Comparative Analysis of Judicial Roles in Problem Solving Court Verses the Traditional Adversarial Model

This study compares the role of judges in problem-solving courts and traditional adversarial courts, focusing on how differing judicial functions influence case outcomes, courtroom culture, and concepts of justice. Problem-solving courts—including drug, mental health, and re-entry courts—operate as specialized forums emphasizing rehabilitation and reduced recidivism through collaborative, non-adversarial processes. Traditional courts, by contrast, follow an adversarial model centered on neutrality, procedural regularity, and resolving discrete legal disputes. The study examines how each model constructs the judge's role: an active, therapeutic decision-maker and case manager in problem-solving courts versus an impartial arbiter in adversarial settings. It analyzes how problem-solving judges directly engage with participants, motivate compliance, and function within multidisciplinary teams, compared with the more reactive, rule-focused work of adversarial judges who primarily safeguard due process. Methodologically, the study draws on empirical research evaluating both court types and theoretical work on therapeutic jurisprudence. It also considers critiques of problem-solving courts involving due process, coercion, and power imbalances. In addition, interviews with judges in local problem-solving courts provide insight into how they entered these roles, how the work differs from their prior adversarial experience, and what they view as essential for effectiveness. These interviews deepen understanding of judicial practice and support existing scholarship on

the problem-solving model. Findings indicate that problem-solving judges, through more active, relational, and therapeutic engagement, tend to promote stronger perceptions of fairness, collaboration, and compliance, and often achieve improved rehabilitative outcomes. However, these benefits come with risks, including judicial role strain, inconsistency, and due process concerns. The study concludes by identifying conditions under which problem-solving practices can be integrated into, or carefully limited within, adversarial systems to balance innovation with procedural safeguards

Abstract Name: THE ROLE OF GAD67/65 AND PARVALBUMIN IN THE THERAPEUTIC EFFECTS OF KETAMINE AND FLUOXETINE IN FEAR-CONDITIONED MICE.

Post-traumatic stress disorder (PTSD) is a chronic psychiatric disorder and the most common disorder following exposure to a traumatic event. The most commonly used drugs in PTSD treatment are selective serotonin reuptake inhibitors (SSRIs), though only about 50% of patients respond to this treatment. Previous work in our lab demonstrated the combination of chronic fluoxetine (FLX) and acute ketamine treatment decreased fear response in a contextual fear paradigm in male C57/BL mice. In rodents, fear conditioning (FC) is commonly used in the literature to induce behaviors related to PTSD. The central fear memory circuit in mammals involves a dynamic interplay between excitatory projection neurons and inhibitory parvalbumin-positive (PV+) interneurons within the prefrontal cortex, hippocampus, and amygdala. Fear-related disorders, such as PTSD, are driven by dysregulation in GABAergic and glutamatergic function. Numerous studies have reported altered levels of GABA release, GABA receptor expression, and the rate limited enzyme: GAD67/65. Parvalbumin-positive (PV+) interneurons function as essential regulators of fear memory through their direct inhibitory influence on excitatory pyramidal cells (PCs) throughout the amygdala, hippocampus, and PFC. Limited research has been conducted on the combined effects of FLX and ketamine on inhibitory circuitry in the adaptation of fear memory. This study will quantify the expression of PV and GAD67/65 in brains harvested from mice that underwent FC and treatment from a previous study conducted in our laboratory. Specifically, this research aims to assess the expression and function of inhibitory neuronal populations in the infralimbic prefrontal cortex (IL-PFC), the CA1 region of the hippocampus, and the bed striatum terminalis of the amygdala (BNST).

Abstract Name: Adapting Outreach Strategies for Violence Prevention and Relationship Education for Students with Disabilities

My project is to research a way to deliver content developed by the Sexual Violence Advocacy and Support Center to students with disabilities in EXCEL, which stands for "extraordinary expectations for career, education and life". The purpose is for neurodivergent and differently abled students to understand and apply

these concepts. I will also be developing support materials and resources for EXCEL faculty and mentors. During my time working at the SVASC on campus I have had the privilege of learning about what can be done to combat the prevalent issues of relationship violence, sexual violence, stalking and harassment. We must ensure that all students are aware of their resources on campus and have access to information that can help if a dangerous situation arises. The EXCEL program offers a secondary education to young adults with intellectual or developmental disabilities, providing them with the same college experience as their peers. For many, this is an educational opportunity to continue studying in an adaptive learning environment. However, with university life comes the healthy and normal desire to socialize. Topics such as dating, online safety, or violence may not be at the forefront of their or their caregivers' minds. There is a lot to learn about consent, healthy relationships and boundaries when beginning university. Young adults naturally create friendships, professional and personal relationships. Unfortunately, students with disabilities are at a higher risk of victimization. To protect and include this statistically vulnerable population, I will recommend delivery modifications of the safety and violence prevention content that the EXCEL program receives. The product of this research is a modified series of workshops that can be presented to the EXCEL program or other students with disabilities, along with evidence-based strategies for implementing these changes.

Abstract Name: A note on a key inequality in a 2D Smoluchowski Equation

Recently, the two-dimensional Smoluchowski equation, which models the behavior of nematic liquid crystalline polymers, was reevaluated. A novel proof was subsequently established for determining the number of steady-state solutions. The original proof was when the intensity constant was less than 4, which made the derivation somewhat complex. To address this, I focused on the isotropic-nematic phase transition using the 2D Smoluchowski equation for specific cases when the intensity constant ranges from 0 to 4. An alternative proof of the key inequality was developed using elementary calculus, which gave a more transparent approach to understanding the steady-state behavior of the system. By simplifying the original argument, it improves the clarity of the mathematical reasoning, which makes the results more accessible to researchers outside of the field of liquid crystalline polymers. This work shows that classical mathematical techniques can still be applied to modern problems in statistical mechanics.

Abstract Name: Designing an Innovative Adoption Center and Temporary Housing for Homeless Dogs and Cats

Dogs and cats have long been faithful companions to humans, yet many continue to experience abandonment, neglect, and abuse in communities around the world. For every dog or cat who enjoys a safe home and consistent care, countless others struggle to survive on the streets or inside overcrowded shelters. Even with the dedication of shelter staff, many animals endure stressful environments, and some ultimately face euthanasia. The purpose of this project is to design an adoption center that fosters a positive, supportive environment for dogs, cats, and the people who interact with them and to shift perceptions of homeless animals to increase and sustain adoption. This project uses a multi-method research approach, incorporating case studies of existing adoption centers, a literature review, and interviews with animal shelter staff. The proposed design prioritizes spaces that promote meaningful interaction between animals and people, ensuring that every dog and cat receives sustained human engagement that supports physical and emotional well-being. The center provides safe temporary housing, medical care, and behavioral rehabilitation delivered by trained professionals. Public areas are warm, welcoming, and educational, encouraging visitors to connect with animals and learn about responsible pet ownership. Animal housing emphasizes well-being, enrichment, comfort, and dignity, while staff and volunteers benefit from durable, flexible, and efficient workspaces. Dedicated areas allow adopters to meet animals in a calm, supportive setting and participate in structured educational programs. A media production space enables the creation of content that features animals seeking homes and encourages adoption rather than pet purchases. Sustainable finishes, natural daylight, and access to natural environments help enhance the health and well-being of both animals and people. Ultimately, the center will serve as a compassionate, sustainable community hub that supports strong human-animal connections and lasting adoptions.

Abstract Name: From Custody to Care: Understanding Mental Health and Recidivism in the Criminal Justice System

Previous studies on genetic influences in mental health disorders have been shown to correlate with incarceration rates in families. Consequently, there are individuals within the criminal justice system under the clinical threshold of a mental health diagnosis; it has been found that almost half of the incarcerated population was arrested due to acting upon their mental health disorder, while 27 to 38 percent developed PTSD while imprisoned. Furthermore, the serious and exhausting cycle of recidivism within the criminal justice system highlights the failure to provide the necessary mental health treatment required to support rehabilitation while incarcerated and prevent reoffending upon social reintegration. At this time, few studies exist on restorative intervention methods and the impact of community engagement in criminal justice reform. To understand the effect of mental health rehabilitation programs in prison systems, research was extended to explore the quality of mental health treatment and identify factors influencing re-offense rates. This study uses a cross-case analysis to compare perceptions of care within the criminal justice system and recidivism data to present initiatives for prison reform and reentry support. Findings contribute to a holistic understanding of criminal offense by highlighting the complex role mental health plays in the legal system and broader aspects of society. Ultimately, addressing recidivism and rehabilitation efforts through intentional program development and evaluation strengthens community wellness, increases public safety, and improves local funding stability over time.

Abstract Name: Evaluating the Abuse Potential of Gabapentin in Combination with Buprenorphine Using Conditioned Place Preference in Female Mice

Medication-assisted therapy is common in opiate addiction treatment, often including suboxone, a combination of buprenorphine (BUP) and naltrexone (NAL). Recently, gabapentin (GBP) has been added to further reduce relapse risk. Though previously considered non-addictive, current studies suggest GBP may have abuse potential. Our lab has previously reported evidence to the rewarding effects of GBP in male mice using conditioned place preference (CPP). This study aims to replicate these findings in female mice to examine sex differences and the effects of additional doses. Treatment groups will include saline, GBP, BUP, NAL, and combination treatment groups will consist of BUP + NAL, GBP + BUP, and GBP + BUP + NAL. We will also assess subthreshold rewarding doses of BUP and GBP in combination with all other treatment variations. Mice will undergo standard CPP using a three-compartment apparatus. Drugs and saline are alternatively administered over eight consecutive days. We hypothesize that GBP and BUP, when administered alone and in combination, will induce CPP. We predict that NAL will attenuate the rewarding effects of GBP and BUP. Additionally, we hypothesize that proestrus and estrus phases of the estrous cycle will positively correlate with induced CPP, and the diestrus and metestrus will positively correlate with

attenuated CPP. These findings raise important concerns about the abuse potential of GBP and the effect of the female hormonal cycle on CPP. Results from these studies underscore the need for cautious clinical application and further investigation into GBP's non-opioid mechanisms of reward.

Abstract Name: The Magnus Archives: Cross Examination Between The Panopticon, Implied Author, Prosopopeia, and Metonymy

The processing of information, communication of concept, and modern story telling have come to depend largely on sight as a direct route of information sharing, arguably a more alluring approach to the horror genre. The Magnus Archives is a fictional horror narrative based in supernatural exploration through a framework of academic institutions. The importance is the medium the production company Rusty Quill chose to tell the story through, as The Magnus Archives is an audio-only podcast with a vivid soundscape. As a personal interest of mine, I have found ways to incorporate my studies through analysis of creative works, such as The Magnus Archives. This interdisciplinary overlap pertains largely toward Foucault's Panopticism and Booth's rhetorical theory of the implied author. The "found-footage" narrative lends heavy implication to the implied author, while the role of the protagonist within his academic institution implements a dynamic that beckons theories from Panopticism. The address of the audience within the narrative as implied listeners to the protagonists recorded tape statements suggests an intimacy, pulling the audience closer to the events within the plot. The main applicable rhetorical devices through which The Magnus Archives will be analyzed are Metonymy, synecdoche, and Prosopopeia. Synecdoche applies to the presence of watchers within the narrative as "The Eye", both the implied audience, the institution, and larger entities at work. The use of prosopopeia in the protagonist is in direct relation back to the figure of "The Eye". At the crux of these theories and devices, The Magnus Archives presents a unique focus on the relevant academic fields of this essay, but provides an enriching listening experience with a substantial foundation.

Abstract Name: Managing Negative Thoughts and Emotions in Times of Personal Stress and Crises Among Adult Black Women in Detroit, Michigan

This research was inspired by my own experiences growing up in a family where women were expected to stay strong and never show emotion. I often wondered if I was the only one struggling with heavy thoughts and overwhelming feelings. This project became a way to explore whether other Black women shared similar experiences and to create space for the stories that are rarely spoken aloud. It focuses on how adult Black women in Detroit cope with their thoughts and emotions during times of personal stress and crisis. The main question guiding this study is: How do Black women cope with emotional pain, and what helps them stay strong when life becomes overwhelming? Many studies show that Black women face high levels of stress due to financial challenges, caregiving responsibilities, social pressure, and the ongoing effects of racism. Yet

much of the existing research does not examine the deeper emotional side of their experiences. This project aims to fill that gap by using a storytelling and podcast-style approach that allows women to share openly, honestly, and in their own voices what they go through and how they heal. This study uses qualitative methods, including open-ended, conversation-style interviews. Participants describe how they manage stress, navigate negative thoughts, and cope with emotions such as fear, sadness, anger, and burnout. These conversations are recorded, transcribed, and analyzed to identify common themes related to resilience, faith, support systems, and emotional balance. Early findings show that many Black women rely on faith, close relationships, personal reflection, and intentional solitude to stay grounded. Participants also talk about the pressure to “be strong” even when they feel tired or unseen. Final results will highlight the importance of mental health equity, culturally responsive emotional support, and safe spaces where Black women can express their feelings without judgment.

Abstract Name: Depicting Multitudes: Juan de Pareja and Biracial Representation in Portraiture

For millennia, portraiture has been a vessel for expressing oneself without words. It's also a means for an artist to express their perception of their subject. Representations of ethnic minorities in art history are not unheard of, but in many Western narratives they're typically less flattering than their Caucasian counterparts and don't acknowledge people of multiple backgrounds. As a biracial woman, much of my research is dedicated to the legacies of biracial historical figures; I believe that Baroque painter Juan de Pareja exemplifies biracial representation succinctly. Pareja was born in 1606 in Seville, Spain, was a revolutionary painter of mixed African and Spanish descent. He spent the first 20 years of his life in captivity to baroque painter Diego Velasquez. After being freed, Pareja would lead his own life as a painter and depicted himself in his most famous painting, “The Calling of Saint Matthew.” Pareja's portrait differs greatly from Velasquez's, which toned down Pareja's appearance. This is frequent in depictions of biracial people, where their heritage would be visually erased by whitewashing or blackwashing their features. Using Velasquez's and Pareja's paintings as examples, I will explore portraiture of biracial figures and the general erasure of biracial people throughout history.

Abstract Name: The Preservation of the Past and Present in Contemporary Tibetan Artwork

Contemporary Tibetan artwork serves as a living archive, one that follows the traditions of the past, documents events of the present, and looks forward to the future. History inspires many contemporary Tibetan artists, as many include references to Tibet's harsh oppression from China in their artwork. Pop iconography often appears in juxtaposition with traditional themes, such as in the work of Gade's Mahākāla (2013), which depicts the god bursting through a pattern of Chinese soldiers, looking similar to a traditional thangka, or scroll painting. The soldiers stand on lotuses with haloes around their heads, and Mahākāla holds a sickle and little red book alongside various weapons, while wearing a gas mask. Shrek and Ronald

McDonald sprout from this protective gear, while Mahākāla wears a garland of Mickey Mouse heads. Western pop culture characters have long been used to mock Chinese political figures, such as comparing Mao Zedong to Mickey Mouse and Xi Jinping to Winnie the Pooh. This piece both documents the Chinese oppression of Tibet while referencing the repeated attempts at controlling Tibetan Buddhism. Similarly, Jhamsang's piece, *Mr. XXX* (2010), shows a passport alluding to the quiet erasure of Tibet through China's new name for the region into the name Xizang. Tibetan script and depictions of the Buddha run in the background, a grim reminder of a past that is being slowly and systematically washed away, while the rest of the passport is in Chinese and English. Through the interdisciplinary methods and study of art history, anthropology, and religion, this research aims to show how contemporary Tibetan artwork records the atrocities of the past and present while still holding onto traditions, and therefore becomes a form of historical documentation.

Abstract Name: Design and Implementation of Customized Instrumentation System to Measure Mountain Bike Trail Profiles

With rising mountain biking participation, both recreationally and professionally, precision development techniques are beginning to leverage trail topology analytics to enhance mechanical performance and rider-specific configurations. Mountain bike trail modeling and surface profiling remain underexplored areas in terrain analysis. To address this gap, a distance sensor-based system was developed which is capable of capturing detailed surface profiles using a dual-suspension mountain bike. The present approach utilizes two distance sensor arrays mounted on both the front and rear hubs, with three sensors per hub. Additionally, an inclinometer/gyroscope is included at each wheel hub to determine angular position/motion information at each location. Data from these sensors are collected and fed into an algorithm to calculate the vertical displacement of the front tire relative to the ground. To ensure durability and accuracy, custom mounting brackets were designed for both hubs. The front sensors are secured via a fabricated bracket connected to a rod extending from the bike's front axle, fixed to the rigid part of the fork. The rear bracket follows similar principles but is adapted to avoid interference with the brake rotor and gear system. This configuration protects the sensors from environmental and terrain-related damage while maintaining precise alignment. The collected data enables the creation of high-resolution surface models of mountain bike trails, which can be used for trail assessment, rider training, and performance optimization. This project presents a novel terrain profiling methodology utilizing a custom sensor array and integrated real-time data capture framework.

Abstract Name: Isolation and identification of fungal endophytes from *Euphorbia bicolor*

Endophytic fungi are organisms that inhabit plant tissues without being pathogenic. *Euphorbia* species are known to synthesize bioactive chemicals and have symbiotic relationships with endophytic fungi. We discovered the presence of endophytic fungi in *E. dentata* and *E. bicolor*, two native species not studied before. Our research goal is to identify the symbiotic endophytic fungi and determine the secondary metabolites they produce, since pharmacological studies are finding plant endophytic fungi as potential sources for bioactive metabolites. Isolation of the endophytic fungi from *E. bicolor* stem, leaf, and bract pieces was performed on V8 agar medium. The isolates were continuously cultured on the same medium until pure fungal cultures were obtained. Microscopic studies identified *Alternaria*, *Fusarium*, *Cladosporium*, *Phoma*, and *Nigrospora* as endophytic fungal species of *E. bicolor*. *Alternaria* has ovoid, pale brown, smooth walled conidia, with spores that have a clubbed tail. *Fusarium* presents filamentous and septate hyphae with a sickle shaped macroconidial spore. *Cladosporium* possesses olive-colored, branched conidiophores, with numerous branched conidia in chains. *Phoma* has unicellular, colorless spores with black, depressed pycnidia. *Nigrospora* showed short, clustered conidiophores, having single-celled, spheroid conidia. Genetic testing using ITS1 and ITS4 primers confirmed the species of fungal endophytes. Further research will focus on the identification of medicinal chemicals synthesized by fungal endophytes. These chemicals will be compared with secondary metabolites identified in the plant tissues, thus establishing the origin of the bioactive chemicals and get deeper insight into the symbiotic relationship between *Euphorbia* species and their endophytes. This study has both scientific and practical applications and could lead to the discovery of new pharmacologically active chemicals to treat pain and cancer.

Abstract Name: Monitoring Water Quality Within the Walnut Creek Watershed in Southeast Raleigh, North Carolina

This study focuses on evaluating the impact of sewer infrastructure improvements, particularly those in downtown Raleigh, on the water quality of Little Rock Creek. Previous work in the training program examined water quality conditions before and during the infrastructure project. The current phase of the study aims to assess post-construction impacts and determine how water quality has changed since the project's completion. To achieve this, several water quality parameters, including dissolved oxygen (DO), specific conductivity (SPC), pH, nitrates and nitrites, and turbidity, were measured via YSI probes weekly. Additionally, biological parameters are performed once a month using Colilert for coliform and *E. coli* testing. This data will be compared across the three time periods: before, during, and after construction. The findings will provide insight into the current water quality status within the greater Walnut Creek Watershed and help evaluate the effectiveness of sewer infrastructure improvements in Southeast Raleigh. Ultimately, these results can inform future City of Raleigh initiatives related to sustainable sewer management and water quality protection.

Abstract Name: Reimagining the Renaissance: Analyzing Langston Hughes' poetry in the context of Florence Price's musical settings from the 1920s to the 1940s, in conjunction with the Chicago Black Renaissance

This paper explores pro-Civil Rights rhetoric spread during the Chicago Black Renaissance, particularly through Langston Hughes' poetry and Florence Price's settings of his poems. Moving between the critical analysis of Hughes' poetry and Price's compositions, this study shows how different interpretations of Hughes' poetic works could be utilized in spreading his anti-discriminatory message to larger audiences. Utilizing five different musical settings of five distinct poems, the research shows how Florence Price's music served as a unifying catalyst and call-to-action in Chicago from the 1920s to the 1940s. By examining the specific metaphors, personal responses, text painting, and intentional theoretical choices by Price, this paper explains how her music made Hughes' message more relatable to the middle-class Black community in order to set up a unified front as more specific political and social action was made for equality in the United States. This paper will contextualize how classical music aided movements such as the Chicago Black Renaissance and will build upon the limited research conducted regarding Florence Price's classical pieces with political and social undertones. The study ultimately argues for the consideration of Florence Price in the discussion of the Chicago Black Renaissance, as her works demonstrate how art can be reshaped through different interpretations in order to engage audiences of varying religious and socio-economic statuses in supporting a common cause for racial equality.

Abstract Name: Nomadic Herding as a Catalyst for the Expansion of The Great Green Wall

The Great Green Wall (GGW) initiative is an Africa lead project that aims to restore degraded landscape and enhance food security stretching across the Sahel region of Africa through a large-scale vegetation project. This project is projected to transform arid lands into fertile ecosystems that will be capable of sustaining both people and wildlife. Despite substantial progress, challenges remain ensuring the projects long-term sustainability and natural expansion. The traditional practice of nomadic herding may play an important role in this ambitious endeavor. This research explores how nomadic herding can serve as a catalyst for the expansion and sustainability of the GGW. The study compares the relationship between livestock mobility, seed germination rates and soil fertility, and how these factors reinforce vegetation growth. A mixed methods approach is being used to further explore this relationship. Satellite imagery is used to track vegetation changes along herding routes and monitor the greening trends among them. Case studies provide detailed insights into areas where herding practices have contributed to vegetation recovery. Community Engagement helps gather insights from herding communities regarding routes, seasonal movements, and traditional practices. Data will be analyzed using GIS mapping and qualitative analysis to identify patterns and relationships. Preliminary findings suggest that manure acts as both a fertilizer and protection for the young seedlings from the harsh environmental conditions. The movement of herds across the landscape unintentionally track seedlings and plant product to support wide-range growth. These patterns suggest that traditional herding routes could play a crucial role in the natural expansion of the GGW which will create both ecological and communal sustainability. Ultimately, this study envisions a future where indigenous practices and modern restoration efforts can coexist and thrive together.

Abstract Name: Analyzing a Simple Mechanical Representation of ACL Injuries

The purpose of this project was to create an easily repeatable, mechanical representation of an ACL tear with soccer cleats. ACL tears are most common among female college soccer players and are often linked to the types of cleats worn. When determining which cleat style to purchase, athletes have to decide whether to prioritize performance or safety. Soccer cleats are designed to provide grip strength, but too much grip strength can result in an ACL tear. By simulating an external force in this mechanical model, this project investigated the primary causes of ACL tears to identify the cleat style and other parameters that best prevents these injuries.

Abstract Name: Gender-Responsive Asylum in France: An Analysis of OFPRA Reports Over the Last Decade (2014-2024)

The number of asylum-seekers is increasing in France. By 2024, female asylum-seekers made up 43.39% of total asylum-seekers, whereas in 2019, female asylum-seekers made up 32.55% of total asylum-seekers. Therefore, understanding the issues that female asylum-seekers face in France is increasingly important. Historically, asylum procedures in France have been gender-neutral or gender-blind, thus not taking into account gender-based discrimination in the asylum process. This study builds on existing literature about asylum in France, answering the question, "To what extent has the French government responded to trends among female asylum-seekers between 2014 and 2024?" Previous studies on the topic were either conducted before more recent refugee crises or did not focus on the information published in government reports. Therefore, through a gender analysis of 11 annual reports published by the French Office for the Protection of Refugees and Stateless Persons (OFPRA) between 2014 and 2024, I found that there are diverse trends among female asylum-seekers. Many women seek asylum due to gender-based violence in their home countries, and these female asylum-seekers have varied demographics. Additionally, through this analysis, I found that the French government has responded to these trends through changes to internal procedures and guidelines, as well as interactions with other government entities and nonprofits. However, there is still room for improvement in gender-responsive design and implementation in the French asylum process. Thus, I identified three policy recommendations focused on implementation, prioritization, and communication. Ultimately, this research has broad implications for not only improving gender-responsive asylum practices in France, but also implementing gender-responsive asylum practices worldwide.

Abstract Name: Factors Affecting Microbial Diversity in the Navel of Gen Z College Students: An Investigation of the Navel Microbiome in the Post-COVID Generation

The human skin microbiome plays a vital role in protecting against pathogens, supporting immunity, and maintaining overall skin health. The navel is a particularly informative site for assessing microbial diversity because of differing individual hygiene habits and its environmental exposure. Although several studies conducted before COVID-19 examine skin microbiota composition, little is known about how the microbiomes of the post-COVID Generation Z population may differ. This research aims to investigate the factors shaping microbial diversity within the navels of Gen Z college students. Participants (n=15) collected samples using a moist sterile swab inserted into their navels. De-identified samples were then struck on two blood agar plates: one incubated aerobically and the other anaerobically at 35 degrees Celsius. Swabs were also placed in cooked meat broth to screen for anaerobic bacteria. All plates were evaluated for growth after 48 hours. Abundance was assessed semi-quantitatively by examining colony distribution across the streak quadrants, recorded as rare, few, moderate, or many. Bacteria that could not be presumptively identified using morphology, hemolysis, bench-top biochemicals, and gram stains were identified using the Vitek 2 system. Cooked meat broth was subbed on day 14 to screen for slow-growing anaerobes. Participants also completed a correspondingly de-identified, IRB-approved survey that evaluated their navel shape and personal hygiene habits. Preliminary results demonstrated robust growth and microbial diversity however quantity varied widely among participants. Results will be analyzed alongside the corresponding survey data evaluating personal hygiene behaviors and individual characteristics of the navel.

Abstract Name: Modernizing Technologies of Cultural Conservation for Tangible Heritage

Cultural heritage is best defined as the tangible and intangible heritage assets of a certain society which are inherited from previous generations. Where tangible heritage defines the scope of physical cultural property (ex. statues, clothing, paintings), intangible heritage defines nonmaterial heritage (ex. oral history, dance, song). The growth of heritage conservation as a field has led to a number of sustainability concerns, exacerbated by factors such as climate disasters, cultural tourism, vandalism and looting, leaving tangible heritage vulnerable to severe physical deterioration. Large gaps in conservation technology are only recently being addressed and innovated - from outdated digitization processes and inadequate copyright security, to labor-intensive inefficient strategies. Addressing technological limitations demands the development of advanced tools and restructuring how they are applied in order to effectively protect tangible heritage. Focusing specifically on tangible heritage is purposeful; the importance of physical cultural history has been lost on us in the modern digital age. Through a comparative case study analysis of the conservation flaws found in the tangible heritage fields of manuscripts and textiles, an alternative methodology based on an

interdisciplinary approach and advanced digital tools will address existing gaps in conservation efforts which suffer from gaps in innovation. This research's goal is twofold: First, it shines light on the shortcomings of current conservation technologies. Second, it offers an applicable innovative alternative for preservation of tangible heritage.

Abstract Name: Photoactivation analysis studies at the Madison Accelerator Laboratory to investigate the copper origin of artifacts excavated in the vicinity of the "lost" Roanoke colony

In this presentation we will be discussing our summer research project related to the irradiation at MAL of copper artifacts from James River Institute for Archaeology. The goal of this investigation was driven by a key question about the provenance of the copper, that is, whether it was of European or Native Indian origin. Out of the 8 artifacts that we investigated, a band excavated from the Elizabeth Gardens, a site located within Fort Raleigh National Historic Site, was of particular interest to the team of archaeologists from James River Institute. Based on their previous work, there were qualitative differences in the chemical compositions of European and Native copper artifacts. For example, some elements like Zinc or Tin were present only in the composition of European copper. Qualitative Photoactivation Analysis (PAA) was applied to determine the chemical composition of the irradiated artifacts by the MAL's linac. The γ -rays following the β -decays of these activated artifacts via (γ, n) or (n, γ) reactions were subsequently detected with a 45% relative efficiency High Purity Germanium detector. The γ -ray emission energy peaks were recorded by the Genie 2000 data acquisition software and analyzed with a dedicated γ -ray spectroscopy data analysis tool. Our findings regarding the copper origin of the Elizabethan Garden band, based on qualitative PAA only, may be significant. The site where the band was found contains only Native American artifacts and therefore a European origin would be evidence of contact between Raleigh's colonists and the Roanoke Indians.

Abstract Name: Surrogate Endpoints in Oncology: Reassessing PFS, Patient-Centered Outcomes, and Policy Implications

Oncology research is making a dangerous shift away from patient-centered care. Blinded by shortened trials and sped up drug approvals, surrogate endpoints have greatly overcome the use of overall survival and quality of life as the primary goals of oncology drug trials, A figure decreasing from 49% to 36% by 2004. My study examines how reliance on surrogate endpoints, like PFS, reflects a growing ignorance of patient wellbeing at the center of treatment, ultimately putting patients at risk for far too modest strides in the field. This analysis uses case review and policy evaluation to compare surrogate-based approvals with outcomes in confirmatory trials, utilizing Avastin's trial timeline to highlight modern regulatory gaps that have caused

direct harm. I compare existing FDA guidelines and international standards (ex., IQWiG) are compared to assess surrogate validation strength, transparency, and consistency. Through research in current policy, trial design, and consent documents, this study exposes structural weaknesses and areas for reform. Regulatory language and the widely accepted “gold standard” of PFS have proven to allow poorly made drugs with limited effect on mortality and quality of life to flood the market, adding incentive to insufficient patient care. Alongside this, misinformation surrounding the correlation of overall survival and surrogates has created a gash in fully informed consent in clinical trial participation and drug use. The current use of surrogate endpoints requires a significant overhaul of regulations, function, and application to refocus cancer drug development on patient well-being, mortality reduction, and quality of life. My study aims to break down how the overuse of surrogate endpoints in cancer research harms patients, alongside suggestions for reform, in the hope that cancer patients will better understand the ethical and practical concerns surrounding prescribed drugs and clinical trial involvement.

Abstract Name: “Doomscrolling” on Instagram and Tik Tok: Positive Intermittent Reinforcement May Lead to Higher Risk of Developing Cross-addiction of Alcohol, Nicotine, and Marijuana in Adolescent American Females aged 12-15

The social connectivity that video-sharing social media platforms provide has allowed many benefits, such as increased access to information, enhanced communication, and community building. Unfortunately, this same social connectivity has given rise to the social media addiction phenomenon, “doomscrolling,” a consequence unconsidered by early developers. The “doomscrolling” phenomenon’s potential association with increased depressive symptoms, PTSD, anxiety, and addictive qualities, such as positive intermittent reinforcement and personalized feeds, may alter neurological pathways, including Resting State Functional Connectivity, the Fronto-Striatal Circuit, and the Amygdala. Altered reward-circuit pathways have been known to make the mind more vulnerable to cross-addiction, increasing susceptibility to alcohol, marijuana, and nicotine abuse. This susceptibility may be intensified by similarities in the neurological alterations resulting from behavioral addictions and chemical addictions present in social media addiction and substance abuse. Cross-addiction from problematic social media usage may be a factor in the increasing substance usage and addiction rates among American adolescents since 2016, with current adolescents having the highest rates of marijuana usage compared to previous generations. The adolescent female American population is especially vulnerable, stemming from heightened Instagram usage compared to their male counterparts. The potential neurological alteration caused by “doomscrolling” and the increased depressive symptoms, PTSD, and anxiety associated with “doomscrolling” may heighten substance usage and addiction within female American adolescents.

Abstract Name: Shifts in Menstrual Hormones and Their Impact on Joint Enzymes in College Athletes

Despite the growing participation of women in sports, research shows that female athletes are at a

significantly higher risk of injuries, such as anterior cruciate ligament (ACL) tears, compared to their male counterparts. However, studies addressing the origins of these complications remain limited, leaving female athletes at a disadvantage in how to prevent and treat injuries effectively. Relaxin-2 impacts cartilage and tendon function by enhancing collagenase activity directed at Type I and Type III collagen through Matrix Metalloproteinases (MMPs) involved in extracellular matrix degradation. It is presumed that Relaxin-2 similarly modulates Lysyl Oxidase (LOX) enzymes through similar receptor-mediated pathways. The purpose of this research is to see how Relaxin-2 and estrogen influence Matrix Metalloproteinase (MMP) and Lysyl Oxidase (LOX) enzyme production throughout the menstrual cycle, contributing to our understanding of tissue remodeling in women's reproductive health. Using repeated plasma and serum sampling from sixteen female athletes, Relaxin-2 and estrogen levels were correlated with MMP1, MMP2, and LOX1 enzyme concentrations. Prior to analysis, all samples were maintained at -20°C. It is anticipated that Relaxin-2 acts synergistically with estrogen to elevate MMP expression and suppress LOX activity during the luteal phase. Data collection is currently underway in the form of various ELISA tests to determine enzyme concentrations. Statistical analysis of the data obtained from the Relaxin-2 ELISA, Human MMP Panel 2 ELISA, Human MMP3 ELISA, and Human LOX-1 ELISA will be performed using one-way analysis of variance (ANOVA). It is expected, based on prior research on hormone expression in female athletes and joint laxity, that Relaxin-2 will act synergistically with estrogen to elevate MMP expression and suppress LOX activity during the luteal phase.

Abstract Name: Rain in the (Education) Desert: The Importance of Community Colleges in Rural Areas

This study examines areas that qualify, or have qualified, as “education deserts” -- areas with no more than one public broad-access postsecondary institution -- and measures how new access to higher education affects long-term outcomes. In this research, I focus on areas in Oklahoma that due to the openings of community college campuses no longer qualify as education deserts and assess how employment and earnings have changed for both men and women. A quasi-experimental differences-in-differences regression analysis model is used to measure the change in economic stability according to census data from before and after the openings of campuses using areas that have not had new community college campuses as a control group. Additionally, I take an ethnographic focus using surveys and interviews of graduates surrounding the opening of the Northern Oklahoma College campus in Enid, with specific attention to educational outcomes of graduates from Medford High School and Tonkawa High School.

Abstract Name: Locomotor Ecology Shapes Pelvic Evolution in Rodents

Rodents are the most evolutionarily and ecologically successful mammalian clades, with over 2,200 extant species distributed across all continents except Antarctica. This study investigates the influence of locomotor

ecology on pelvic morphology across 44 phylogenetically diverse rodent species. Whole-body micro-CT scans were used to segment the pelvis, which was analyzed using 3D geometric morphometrics. Landmark data were processed through generalized Procrustes analysis to quantify shape variation. A phylogenetically generalized least squares (PGLS) analysis revealed that locomotor mode, categorized as arboreal, terrestrial, fossorial, semifossorial, and ricochet, is a significant predictor of pelvic shape. In contrast, a test for phylogenetic signal indicated no significant effect of phylogeny on pelvic morphology. Our findings suggest that rodents exhibit a high degree of morphological plasticity in the pelvis in response to ecological demands. This evolutionary lability may help explain the group's remarkable adaptability and diversification across habitats, contributing to their global success.

Abstract Name: Using the Oral Health Impact Profile-5 (OHIP-5) to examine oral health-related quality of life in a sample of Latin* adults

Oral health is a multidimensional construct that impacts overall health. Understanding how patients perceive their oral health is essential to designing effective interventions to promote positive outcomes for overall well-being. Oral health related quality of life (OHRQoL) provides a framework for evaluating individuals' perceptions of their oral health using validated instruments such as the Oral Health Impact Profile-5 (OHIP-5). Although the OHIP-5 has been applied across diverse populations, its use among Latin* adults remains limited, despite this group experiencing disproportionately high rates of periodontal disease compared with other populations. To address this gap, the present study examined OHRQoL among Latin* adults. Participants (N = 189) were recruited from an academic dental center in the Greater Richmond area and completed a phone survey on sociodemographic characteristics and oral health. OHRQoL was assessed using the Oral Health Impact Profile-5 (OHIP-5), which includes five questions rated on a Likert scale (never, hardly ever, occasionally, fairly often, and very often). OHIP-5 item and summary scores were analyzed using Chi-squared tests of independence to compare both overall and domain-specific categories: oral function, orofacial pain, orofacial appearance, and psychosocial impact. Means and standard deviations were also calculated. Additionally, OHIP-5 total and domain-level scores were compared across sociodemographic variables (age, sex, marital status), socioeconomic factors (educational attainment, household income), and health-related variables (insurance status). The total average OHIP-5 score among participants was 4.01 (SD = 3.7). The highest subdomain scores were observed for orofacial appearance (mean = 1.34, SD = 1.42) and oral function (mean = 1.35, SD = 1.68). Findings highlight the importance of implementing culturally and linguistically tailored strategies to improve the oral health-related quality of life of Latin* adults, with particular emphasis on oral aesthetics and function.

Abstract Name: Parenting Aspirations among Young Adults of Diverse Sexual Identities and Racial/Ethnic Identities

Our study investigated the parenting aspirations among heterosexual and sexual minority young adults of diverse racial/ethnic identities. We recruited 1024 participants who were 18-35 years old in the United States (549 identified as heterosexual, Mean age = 28.00 years old, and 461 as members of sexual minority groups, Mean age = 27.38; 507 identified as female, Mean age = 27.20, and 503 as male, Mean age = 28.23; 540 identified as non-Hispanic white, Mean age = 27.98, and 470 as Hispanic or other groups of people of color, Mean age = 27.41). Participants completed a questionnaire survey via Qualtrics. Results of the ANCOVA analyses showed that parenting desire, with sexual orientation, race/ethnicity, and gender as the independent variables, demonstrated that participants' desires for becoming parents differed as a function of their sexual orientation ($F(1, 862) = 26.93, p < .001, \eta^2 = .030$) and the interaction of sexual orientation and gender ($F(1, 862) = 4.03, p = .045, \eta^2 = .005$). Overall, heterosexual participants expressed stronger parenting desires compared to their sexual minority peers. Female and male heterosexual participants reported similar levels of parenting desires. Although there was no significant effect of race/ethnicity, sexual minority non-Hispanic white male participants reported the lowest level of parenting desires compared to participants of other groups. Regarding parenting intentions, the ANCOVA analysis showed that intentions for becoming parents differed as a function of sexual orientation ($F(1, 861) = 33.77, p < .001, \eta^2 = .038$). Heterosexual participants expressed stronger parenting intentions than their sexual minority peers. Our study highlights the role of sexual orientation in how young adults envision their future parenthood and calls for the public and policymakers' attention in supporting sexual minority young adults in achieving their life goals in family formations.

Abstract Name: Changes in Uniaxial Contractility of the Murine Cervix with Age

Due to various societal and socioeconomic factors, women are having children later in life. Advanced maternal age increases the risk of birth complications such as preterm birth (PTB). Reported PTB rates are the lowest for women aged 30-34 years old, with an increase for women aged 40 and older. While the exact mechanisms of PTB are not understood, improper cervical function may contribute, as the cervix aids in keeping the fetus inside the uterus during development. These functions are influenced by both the cervix's contractile and extracellular matrix properties. Understanding remodeling with age in the nonpregnant cervix may give insight into age's effect on these properties, which may then correlate with risk of adverse outcomes. Past research in the murine vagina has shown that stiffness increases with age while contractility decreases. However, the murine cervix's stiffness decreases with age, and changes in contractility are unknown. Therefore, this study aims to quantify contractile behavior with age in the nonpregnant murine cervix by utilizing an organ bath with potassium chloride (KCl) as an agonist. We hypothesize that contractility will decrease with age. Testing with 50mM KCl resulted in an average maximum contractile force of 550.96 ± 383.50 mN/g ($n=8$) for mice 1-3 months of age, 991.92 ± 433.09 mN/g ($n=8$) for 4-6 months, 759.99 ± 478.00 mN/g ($n=8$) for 7-9 months, and 363.27 ± 146.72 mN/g ($n=8$) for 11-14 months, and 517.36 ± 231.36 mN/g ($n=8$) for 16 month or older mice. Maximum cervical contractility decreased with age ($p < 0.0001$). This decreased contractility of the cervix may indicate impaired or reduced cervical function

for older mothers, which may contribute to the observed increased PTB risk. Understanding the changes in baseline cervical behavior with age will inform future studies on PTB etiology and prevention.

Abstract Name: Mentorship in Action: Guiding Students in Developing Low-Cost Technologies for Wildlife Research and Environmental Sensing

This mentor-led initiative highlights how hands-on guidance enables undergraduate students to engage with authentic environmental challenges through the development and refinement of low-cost technology tools. The work is grounded in real community needs, including rising pollution levels around the Miami Dade College Wolfson Campus, as well as ecological concerns presented by faculty collaborators (i.e., biology) whose observations of predation affecting endangered butterfly species helped shape the direction of this research. Through these experiences, students engage in applied STEM investigation using Raspberry Pi-based systems that support both wildlife observation and environmental sensing. Students often require structured support to connect foundational STEM concepts to real-world applications, particularly in fields such as physics where theory can feel abstract without practical context. Through guided experience, students learn to apply scientific reasoning, programming skills, engineering judgment, and analytical thinking to tangible environmental questions. Applying fundamental principles through low-cost, accessible technologies gives them a strong foundation for designing more complex systems and prepares them for future STEM workforce challenges. Together, these experiences demonstrate how guided research opportunities enable students to transform classroom knowledge into practical contributions, strengthening their scientific identity and deepening their engagement with real-world environmental challenges.

Abstract Name: Influence of Nest Box Characteristics on Box Temperature and Prothonotary Warbler (*Protonotaria citrea*) Nestling Fitness

Man-made nest boxes are commonly used by researchers to study cavity-nesting birds with the benefit of offsetting natural cavity losses due to habitat destruction. However, few studies address how nest box construction and placement may impact internal box temperatures and consequently nestling fitness. This study investigated the relationships between box characteristics, temperature, and nestling growth rate within an existing Prothonotary Warbler (*Protonotaria citrea*) nest box system located at Deep Bottom Park along the lower James River in Henrico, Virginia. During the 2025 breeding season, nest box characteristics (e.g. size, entrance diameter, % canopy cover) were collected and hourly temperature loggers were deployed at 44 of the 65 nest boxes to capture internal box temperatures. We also deployed two loggers in nearby vegetation to capture ambient environmental temperature. Nestling mass was recorded twice throughout the developmental

period to determine growth rate. We found a significant negative relationship between canopy cover and box temperature. We also found a significant negative relationship between nestling growth rate and both minimum and average box temperature during the early breeding season, with nestlings growing faster in cooler conditions. These results demonstrate that box placement influences internal box temperature which has an effect on nestling growth rate and therefore should be considered when deploying nest boxes. We plan to assess if nestling growth is associated with nestling condition and the mechanisms that may link cooler temperatures with faster growth rates.

Abstract Name: Polarized Persuasion: Socioeconomic Divides and the Mechanics of Propaganda from Chávez to Putin

Propaganda often functions as a catalyst and driving force behind the rise of authoritarian regimes. Venezuela's late president, Hugo R. Chávez, made himself a brand associated with underserved communities through his policies and speeches. One of his main tactics was polarization, dividing politics between *el pueblo* versus *los oligarcas*. Similarly, Vladimir Putin has applied such tools in his presidency, demonizing any opposition to the Russia-Ukraine war. This documentary implements a literature review on the limits of polarizing propaganda and how it is influenced by class division, exploring whether citizens can recognize or resist messages that conflict with their reality. The film also uses a comparative approach, analyzing both dystopian literature and interviews with Venezuelan and Ukrainian citizens, to examine propaganda tactics under Chávez and Putin. Socioeconomic status influences responses to propaganda, and those with lived experiences that contradict political messaging will demonstrate greater resistance. Understanding the effects of propaganda is imperative for democracy; this film will equip societies with the tools to defend themselves against new manipulation and division and lay the foundation for new policymakers to promote public accountability.

Abstract Name: The Reversed Recapitulation of Schubert's Piano Sonata in A minor, D.845

Franz Schubert's Piano Sonata in A minor, D. 845, is an interesting piece that deviates from the expectations of classical sonata form. This sonata is the first of a set of three composed during a brighter period of Schubert's life. It bears the title of *Premiere Grand Sonata* and showcases the development of Schubert's mature style for piano sonatas. It was composed in May of 1825, and the other sonatas of its set are *Piano Sonata in D major, Gasteiner*, and *Piano Sonata in G major, Fantasie*. As Schubert's music is a considerable part of Western repertoire, and has been for centuries, examining the form of his work offers opportunities for novel interpretation. The first movement of this particular work was analyzed with Hepokoski and Darcy sonata theory as well as theorized variations of those forms. Key areas and cadences were found in order to

assist in assigning formal names to sections of the music. These sections were compared to typical sonata form based off of their place in the work and key centers. Much of this work follows the expectations for the genre; however, there are deviations, most notably in the recapitulation. There is a delayed statement of the primary theme in tonic after the secondary theme. This is unexpected as the primary theme typically resolves at the beginning of the recapitulation and does not come back later on for its final resolution. This unusual reversal can be analyzed as a reversed recapitulation and further suggests ambiguity as a central theme of this piece.

Abstract Name: The Adjustment of Autistic First-Generation Students to Higher Education

First-generation students and students on the autism spectrum each have a unique set of challenges as they navigate higher education, but little research has explored how these identities intersect. Seeing the rise in autism diagnoses in recent years and given the large population of first-generation students in college, it is important to understand how these students adjust to higher education and the additional barriers they may face through the lens of intersectionality. The purpose of this study is to examine the adjustment and sense of belonging of autistic first-generation college students compared to autistic continuing-generation students, neurotypical first-generation students, and neurotypical continuing-generation students. To address this research question, a sample of undergraduate students will be recruited to complete an anonymous virtual survey assessing multiple dimensions of college adjustment and sense of belonging, including self-efficacy and academic motivation. It is hypothesized that autistic first-generation students will report lower levels of adjustment and higher levels of autistic masking than their peers. Findings aim to highlight the experiences of this underrepresented population, identify unmet needs, and inform future efforts to create a more supportive and accessible college environment.

Abstract Name: Creating A Sense of Belonging for Black Students in the High School Classroom

High school is an important time for all students because it is the point where they are moving through adolescence and looking for a space to belong. For Black students in a high school classroom, feeling a sense of belonging is especially important. However, during my time in school I noticed that many classrooms struggled to create environments where Black students felt both seen and heard. This research aims to explore what makes Black students feel a sense of belonging in the classroom. This research also aims to explore relational factors that contribute to creating a sense of belonging for Black high school students. The research design is qualitative. Data will be collected through structured interviews and observations, in order to get a firsthand understanding of what students believe belonging looks and feels like in the classroom. The goal of this study is two-pronged. First, I aim to discover what makes Black students feel a sense of belonging in the classroom. Second, to share that data with teachers in order to strengthen their level of sociocultural knowledge toward supporting Black students in the classroom. The implications of centering this research

around the experiences of Black students could encourage culturally inclusive environments and intentional relationship building that support academic and socioemotional success.

Abstract Name: ApoE4-R251G Corrects Dynamical and Conformational Features of ApoE4

APOE-ε4 is the most studied risk factor associated with development of late onset Alzheimer's disease (AD). R251G, a rare APOE variant, was discovered to neutralize the risk associated with apoE4 and potentially even decrease overall risk of developing AD. Examining how the R251G substitution protects against AD would also provide insight into the key pathogenic features of apoE4 and possibly reveal novel therapeutic strategies to mitigate the risk associated with apoE4. ApoE is synthesized as nonlipidated monomers but is largely lipidated in vivo, which induces distinct structural changes. Therefore, to understand the effects of R251G on apoE4, it is important to evaluate both nonlipidated and lipidated states. We used molecular dynamics (MD) simulations to determine how apoE4-R251G alters apoE4 by comparing closed/open non-lipidated and lipidated apoE structures. The starting closed nonlipidated apoE structure (PDBID: 2L7B), was run through a coarse-grain molecular dynamics simulation in the presence of dipalmitoylphosphatidylcholine (DPPC) lipids by Prakashchand et al. (PMID: 33979165), to generate a starting structure for lipidated apoE. The open nonlipidated apoE structure derived from Stuchell-Brereton et al. (PMID: 36749730). Using the equilibrated trajectories, we generated four representative structures for each apoE3 rep which were then used to generate four structures each for apoE2 and apoE4. The representative apoE4 structures were then converted to apoE4-R251G to run the final simulations. Subsequent analysis was performed on the equilibrated trajectories of four simulations for each apoE isoform. Analysis included examining changes in apoE structure, conformation, dynamics, and molecular interactions. ApoE4-R251G appeared distinct from apoE4 in secondary structure, conformational stability, and dynamics in both the nonlipidated and lipidated simulations. Structural analysis of apoE4-R251G provides insight into unique and shared characteristics with apoE4 and highlights potentially targetable regions for future therapeutics. This work was supported by the NIH R01AG068395 and Alzheimer's Drug Discovery Foundation.

Abstract Name: The Spectral and Sherlock Holmes: How Spiritualism Influenced Sir Arthur Conan Doyle's "The Adventure of the Sussex Vampire"

Authors write in the context of spiritual movements that occur during their lives. My overall project shows how the fluctuating beliefs of Sir Arthur Conan Doyle affected the short stories he wrote. In his autobiography *Memoirs and Adventures*, a timeline of his morphing faith is apparent. Though born Roman Catholic, he proceeded to dabble in Unitarianism, materialism, and Theosophy before devoting his life to Spiritualism. Doyle's religious and philosophical development paralleled his short story output. By reading these short stories through the lenses of biographical, psychoanalytic, and cultural criticism, religion's impact

on the author and his works becomes apparent. My proposed presentation focuses on a story from later in Doyle's life. In 1886, Doyle was first attracted to Spiritualism. By 1894, he had dedicated himself to the religion, and soon became a leading figure in it. In early 1924, *The Strand* and Hearst's *International* magazines published his short story "The Adventure of the Sussex Vampire," which contrasts Spiritualism and Psychology. In this story, Sherlock Holmes and Dr. Watson investigate an injury to Robert Ferguson's infant son. Ferguson has Spiritualist tendencies and therefore assumes a supernatural cause: he claims his wife is a vampire who has harmed her own baby. However, Holmes is skeptical of the supernatural, and seeks an alternative explanation. He discovers that her violent behavior is psychological in nature. Holmes concludes that Ferguson's wife's allegedly vampiric behavior is actually motivated by her obsessive love of her family. This story and others during this period reflect Doyle's deep, and even somewhat obsessive, commitment to Spiritualism.

Abstract Name: Evaluation of binding and intermolecular forces of Chloramphenicol across *S. aureus*, *D. radiodurans*, and *L. monocytogenes* Ribosomal Peptidyl Transferase Centers

Antimicrobial resistance is a growing concern as antibiotics become less effective in treating infectious diseases, posing a potential global health crisis. To address this growing concern, a comparative study of the peptidyl transferase center (PTC) of three different gram-positive bacterial ribosomes, *Staphylococcus aureus*, *Listeria monocytogenes*, and *Deinococcus radiodurans*, was performed using computational methodologies. This analysis focused on how the broad-spectrum antibiotic chloramphenicol interacted within the PTC, using molecular docking to characterize the types of intermolecular interactions formed and to determine whether interactions bind to similar nucleotides across all three ribosomes, which may influence antibiotic efficacy. As chloramphenicol inhibits bacterial protein synthesis through A-site binding in the 50S ribosomal subunit, this is well-documented in *D. Radiodurans*, but not in *L. monocytogenes* and *S. aureus*, as visualizing the interaction between the A-site and chloramphenicol could display antibiotic efficacy. After molecular docking, a fingerprint analysis was performed, which revealed a consistent nucleotide interaction between chloramphenicol and nucleotides U-2483 through U-2485, highlighting conservation in the PTC of the studied species. Nucleotide U-2485 demonstrated hydrogen bonding with chloramphenicol throughout all three ribosomes, which displays the validity of the chloramphenicol binding pocket. This highlights U-2485 as an essential residue that aids in the binding of chloramphenicol. A CavitOmiX analysis was performed and showed an overlay of the three individual ribosomes displaying highly conserved structural alignment. Therefore, conservation of the chloramphenicol binding pocket in the PTC across the three ribosomes, along with detailed characterization of residue-level interactions, provides a structural basis for the rational design of next-generation antibiotics targeting Gram-positive pathogens.

Abstract Name: Cataclysm within the Court: The Bosnian Genocide Case and its Implications on Historical Understanding of Calamity

The Bosnian Genocide remains one of the most challenging cases within the history of modern conflict and calamity. As the first occurrence in which the International Court of Justice applied the Convention on the Prevention and Punishment of the Crime of Genocide to a state, the International Court of Justice's legal proceedings on the Bosnian Genocide set a new standard for the obligations of the international community to act in the occurrence of genocide. This research aims to clarify the nature of the 1992-1995 conflict between the nations of Serbia-Montenegro and Bosnia-Herzegovina using primary source documentation, modern commentary, and the codification of genocide prevention under the United Nations arbitration between Bosnia and Serbia. It also serves to identify how the understanding of the Bosnian Genocide has changed over time within both the legal discipline and the historicization of violence as a whole.

Abstract Name: The Death of Isolationism: U.S. Foreign Policy and Afghanistan

The September 11th attacks ignited a new era of American foreign policy—the Global War on Terror. As the United States sought out punishment for those responsible, it facilitated the creation of a new narrative in which the U.S. played a more centralized role within the deterrence of globalized terrorism. Academic literature published after 9/11 has maintained that the United States became aware of threats from Afghanistan as a result of the 1998 Kenyan and Tanzanian embassy bombings; however, this study argues that the United States government was aware of terrorism from the nation of Afghanistan earlier than 1998 and ignored it in a larger effort to absolve the U.S. from participation in international affairs. While this study does not explain the events of modern political discourse between Afghanistan and the United States, it serves to analyze the pre-existing history between the two nations up to and including 2011 and contribute to existing scholarship about U.S.-Afghan relations.

Abstract Name: Understanding Advanced Lab Methods in Polymer Chemistry

Anion exchange membranes (AEMs) are a part of fuel cells and other electrochemical devices. Anion exchange membranes (AEMs) move hydroxide ions that are needed for energy reactions. The long term performance of Anion exchange membranes (AEMs) depends on whether the chemical structure of Anion exchange membranes (AEMs) stays stable in alkaline environments. During my internship I tried lab methods to test Anion exchange membranes (AEMs) materials. I also got hands on experience, with the techniques that polymer chemistry researchers use. I was curious, about how ion exchange capacity (IEC) works. I learned how to measure ion exchange capacity (IEC). When I measured (IEC) with titration I could see directly how many active sites were present and how that number affected the membrane ability to transport

ions. I used H NMR spectroscopy to examine the chemical structure of the AEM samples. I examined the AEM samples before the alkaline exposure and, after the alkaline exposure. I watched the hydrogen peaks. The appearance of hydrogen peaks or the disappearance of hydrogen peaks gave clues, about the polymer backbone. The polymer backbone broke down when the hydrogen peaks disappeared. The stable spectra stayed the same. The stable spectra indicated that the material stayed whole. I also did conductivity testing to see how well hydroxide ions move through the membrane. Changes, in conductivity showed breakdown or bad membrane shape. The measurements and the conductivity testing gave a picture of how the membrane works under operating conditions. I learned to read chemical data to use instruments and to solve problems, in the lab. The experience showed me how polymer chemistry can help improve energy technologies. By linking chemical ideas to real world uses the project provided an understanding of how advanced materials are tested, refined and used to support cleaner and more efficient energy systems.

Abstract Name: PERK/FGFR4 Dual Inhibition with AMG PERK 44 and BLU-554 in proliferation and survival of colorectal cancer

Cancer is one of the leading causes of death across the world. Although recent advances in medicine have allowed for novel and effective treatments to develop, there are still many cases in which these novel therapies are not effective. FGFR4 upregulation has been linked to drug resistance, along with the survival and proliferation of cancer cells. PERK has also been linked as one of the proteins that helps cancer survive different therapies by managing cellular stress. The link between these two proteins and potential novel therapies that target FGFR4/PERK resistance pathways that fight against chemotherapeutic treatment are still unknown. We plan to evaluate the potential of a dual inhibitor therapy that uses AMG PERK 44 to target PERK and BLU-554 to target FGFR4 in colorectal cancer cells. A cell viability assay and a scratch assay will determine the effects on cancer survival and proliferation. We also aim through Western blotting to evaluate the signaling pathways affected by this dual therapy. This will provide a reflection of what is going on inside the cell upon dual inhibition. Altogether, we expect to find effectiveness with this dual inhibition treatment to target cancers that upregulate FGFR4 and PERK for drug resistance to other therapies.

Abstract Name: Pushing Artificial Intelligence (AI) to Its Limits: Developing Red Teaming and Adversarial Prompting Methods

Background: Red teaming is a structured attempt to test generative artificial intelligence (genAI) models to uncover weaknesses, pushing models beyond their expected behaviors. Adversarial prompting, a specific red teaming technique, is defined as inputting prompts to expose vulnerabilities in genAI, leading to unexpected or misinformative outputs. Together, these techniques help identify and differentiate AI-generated content from human-generated content. Purpose: The goal was to develop and evaluate successful red teaming adversarial prompting methods with multimodal genAI using single-request prompt engineering techniques to

assess their consistency and effectiveness. Methods: Seven genAI models (ChatGPT, Grok, Gemini, DeepSeek, Copilot, Llama, Claude) were evaluated using diverse linguistic, unicode and special characters, programmatic simulations, visual recognition tasks, and multimodal prompts, to discover unexpected outputs when exposed to adversarial conditions. Successful methods were compared across all models using identical prompting techniques to assess cross-model consistency, with reassessment utilizing most up-to-date genAI models nine months later. Results: Red teaming adversarial prompts produced consistent patterns across models including incorrect translations, non-sustained repetitions, unreliable interpretation of visuals, error-terminated outputs, issues counting, and unreliable performance with compound single-step prompts, though not all models failed in every approach. However, all seven models (100%) consistently failed Ishihara color vision tests (Pass/Fail) and incorrectly interpreted images when modified, reformatted, or hand-drawn. All models (100%) correctly interpreted factual requests within compound single-step prompts and saw improved repetition-based output consistency up to each model's repetition tolerance limits. Conclusions: Red teaming adversarial prompt performance was mixed, with some methods maintaining consistency, while others' effectiveness declined as new models versions were released during the study. As genAI continues to evolve, our methods must be regularly reassessed and refined. Successful prompting approaches can be applied to distinguish AI-generated content from human-generated content. Our findings support researchers, educators, and everyday users to effectively assess genAI content authenticity and reliability.

Abstract Name: The 'Candide' Role of Voltarianism at the American Opera: On Bernstein's Cross-Centuries' Channelling of Voltaire

From the curious jungles of Paraguay & El Dorado, to warzones of Westphalia & Dutch Colonial Surinam, to beautiful cosmopoleis Venice & Constantinople, the whirlwind adventure of his namesake takes Candide on a manic globetrot about Voltaire's world, real & imagined. Enduring perilous pursuit of his lost love, Cunégonde, Candide encounters several companions of differing socio-philosophical dispositions. Written in just 3 days—Upon reading, it's obvious why this hilarious novella has been enjoyed in high esteem across centuries; satisfyingly electrifying, yet a succinct read. Voltaire's just as brilliant, witty, & packing of political resonance as the orchestral showpiece written in honour. Encoded into the cultural climate of 1950s America, composer Leonard Bernstein became an FBI target during the infamous Red Scare—censored & considered “too controversial” to appear publicly; placed on the Security Index; denied a Passport. It's highly coincidental, then, for Voltaire himself, exiled for critiques of authority, was denied a Passport, too, but 200 years before; in the 1750s—which may play into why, not physically traveling as other intellectuals, he could inscribe mental & hearsaid travels into the theme of exploration throughout his novella. This personal, overarching historical, & artistic alignment created a spectacle, a musical rendition mirroring absurdities of Voltaire's era to ideological absurdities of their own. Bernstein saw a kindred spirit in Voltaire's use of satire to challenge present dogma & hypocrisy. The 1956 operetta, likewise, mocks blind optimism, religious hypocrisy, & authoritarianism; defending intellectual freedom, laughing in the face of tyranny. Accompanying historical & political significance of this operetta's circumstances, its musical motifs aren't just sonic elements; we pinpoint where & how recurring motifs trace across Bernstein's operetta, establishing linkage to particular narrative elements, revealing their role in articulating cultural memory between these two figures. Beyond musical function, semiotics encode references to real history & philosophical disposition. Finally, archival methods bring new understanding to the works' cultural, historical contexts.

Abstract Name: Sleep Duration and Mental Health in College Students

College students experience substantial academic and social pressures that frequently disrupt sleep. Insufficient sleep has been consistently associated with higher symptoms of anxiety and depression, yet large, nationally representative samples of college students remain understudied, and few analyses distinguish between weekday and weekend sleep patterns. The purpose of this project is to examine whether sleep duration is associated with symptoms of anxiety and depression among college students using secondary data from the 2023–2024 Healthy Minds Study. By analyzing sleep hours alongside validated mental health measures, this project aims to contribute to ongoing research by evaluating these relationships in a diverse college population and by identifying behavioral trends that may influence student well-being. The study uses self-reported weekday and weekend sleep durations, along with anxiety and depression scores, to assess whether shorter sleep corresponds with higher emotional distress. Because this project involves secondary analysis, no new data were collected. Instead, existing survey responses were analyzed using descriptive and correlational methods appropriate for large datasets. Results are currently in progress, but it is expected that students reporting fewer hours of sleep will also report higher symptoms of anxiety and depression, consistent with previous behavioral and stress-related research. These findings will be discussed in the context of student wellness, behavioral stress indicators, and potential implications for campus mental health practices. The presentation will also address limitations of self-reported and cross-sectional data, as well as future research directions that may incorporate sleep quality, longitudinal designs, or physiological measures to better understand mechanisms linking sleep and emotional well-being.

Abstract Name: Analysis of Pituitary-Regulated Hormones in the Serum of Healthy Individuals and in Epilepsy Patients

Alterations in hormone levels have been reported in some individuals with epilepsy, potentially arising from chronic seizure activity, long-term antiseizure medication use, or interactions between the nervous and endocrine systems. Therefore, we analyzed serum levels of key pituitary-regulated hormones in a well-characterized large cohort of adults with epilepsy and age- and sex-matched healthy controls. Serum samples were collected from patients with epilepsy and healthy controls ($n = 80$ per group; 40 male and 40 female), with informed consent under approved IRB protocols, and obtained from the Indiana University Health ECRO Biorepository. Hormone levels, including follicle-stimulating hormone (FSH), growth hormone (GH), luteinizing hormone (LH), prolactin (PRL), and thyroid-stimulating hormone (TSH), were quantified using multiplex enzyme-linked immunosorbent assays (ELISAs). Group differences between epilepsy and control cohorts were assessed using Student's t -tests. Sex-based comparisons were conducted using one-way ANOVA. Pearson correlation coefficients were calculated to evaluate associations between hormone levels,

age, and epilepsy duration. Serum levels of FSH, GH, LH, and PRL were higher in all females compared to males. No differences were observed between the groups. TSH levels were similar across groups. FSH levels increased with age in both female groups and in the male epilepsy group. LH levels increased with age and epilepsy duration, but only in females with epilepsy. Higher TSH levels correlated with longer epilepsy duration only in males with epilepsy. Comparable hormone levels between the epilepsy and healthy groups indicate normal pituitary function. Females showing expected higher levels of FSH, GH, LH, and PRL than males confirm the internal validity of our measurements. These findings suggest that although overall hormone profiles are similar between epilepsy and control populations, subtle age- and sex-dependent endocrine variations may emerge with longer disease duration. Further work is needed to clarify whether these correlations reflect physiological adaptation, medication effects, or epilepsy-related neuroendocrine modulation.

Abstract Name: Dragons, Starships, and Mental Health: How Speculative Fiction Uniquely and Effectively Explores Mental Health Through Worldbuilding.

This paper explores how speculative fiction is an effective genre for exploring mental health in unique and compelling ways. Although these genres are often ignored for their entertainment value, science fiction and fantasy use worldbuilding, magic systems, and technology to explore the struggles of their characters in ways that traditional fiction cannot. Through an analysis of *The Poppy War*, *The Stormlight Archives*, *The Magicians*, *The Murderbot Diaries*, and *The Lord of the Rings*, this study examines how characters experiencing a variety of mental health issues are portrayed within their fantastical worlds, thereby highlighting their respective struggles. In addition, this study examines how the authors of these novels utilize these settings to explore various aspects of the human condition, incorporating their own personal experiences and research to make these portrayals more authentic. These novels help readers gain a deeper understanding of mental health, both in others and in their own lives, by transporting readers outside their own context and engaging with these issues in a new way.

Abstract Name: From Silos to Synergy: Improving Healthcare and Disaster Relief Coordination After Hurricanes Helene and Milton

In 2024, Hurricanes Helene and Milton devastated the Tampa Bay area, forcing 53 healthcare facilities to evacuate and triggering the deployment of almost 3,000 rescue personnel. Local disaster relief organizations (DRO) provided shelter, meals, and emotional support to almost 20,000 residents. Post-hurricane reports cite a need for enhanced horizontal collaboration and coordination among DROs to improve community resilience. This study investigates strategies to strengthen coordination between healthcare facilities and

DROs in Hillsborough County to provide lifesaving and life-sustaining services to those affected by disasters. In particular, the United Nations' Sustainable Development Goals (SDGs) serve as a framework to categorize these organizations. Representatives of disaster relief organizations gathered for a World Cafe-style round table event to gain a variety of perspectives on improving resiliency. Both oral and written data were collected and coded to perform a qualitative thematic analysis. Additional interviews were conducted with health-focused organization representatives. Research found that most frustration stemmed from organizational objectives overlapping without shared communication of each organization's needs. This lends to a lack of knowledge and regard about what resources can be shared. Results found little connection between local healthcare facilities and other DROs, with healthcare being mentioned the fewest times among the three SDGs coded. Findings suggest that disaster relief networks would benefit from more integrated collaboration between healthcare facilities and other DROs. This could include exchanging staff, resources, and training in order to understand and work towards the common mission of saving and sustaining life during disasters.

Abstract Name: Timeline and Systematic Implementation of Bitcoin's Post-Quantum Security

The current global market cap of cryptocurrencies is 2.5 trillion dollars, predicted to be 6.3 trillion dollars by 2033, indicative of the immense and growing popularity of cryptocurrencies. However, with the emergence of quantum computing and Google's demonstration of quantum superiority in 2019, the security of cryptocurrencies has been called into question. Specifically, the public and private key cryptography, such as Bitcoin's use of Schnorr encryption in securing an individual's wallet, was proven to be decryptable by a quantum computation method known as Shor's Algorithm. This paper analyzes that a reasonable timeline for when quantum computers would be strong enough to crack Bitcoin's Schnorr encryption is from 2 to 8 years in the future, meaning that 2 to 8 years into the future, quantum computers can potentially rewrite transaction information before the transactions are confirmed by Bitcoin. Furthermore, this paper builds a two-phase roadmap following the estimated timeline so that by the time Schnorr keys are easily decryptable, Bitcoin would have replaced all instances of Schnorr encryption with the quantum-safe CRYSTALS-Dilithium signature scheme. Ultimately, we implement a post-quantum signature scheme for Bitcoin while retaining all of Bitcoin's current attributes, functionalities, and systems, complete with Python code modeling the changes on a Bitcoin test chain.

Abstract Name: A Comparative Analysis of Women Entrepreneurs in the United States and Europe

Entrepreneurship is an evolving field dedicated to increasing understanding of the factors that influence venture creation. This study focuses on an understudied area of entrepreneurship, a lack of literature examining the entrepreneurial experience of women in the United States and Europe. Guided by institutional theory and social capital theory, it examines how institutional frameworks and social relations influence an

entrepreneur's outcomes. Institutional theory investigates the effects of formal, such as laws, and informal, like societal expectations, systems on venture activity. Social capital theory examines how connections and networks influence entrepreneurs' access to capital and other resources. Drawing on existing literature, it suggests that women entrepreneurs in the U.S. benefit from larger markets and comparatively better access to monetary resources. However, they continue to encounter struggles with cultural norms and lack of support. In comparison, women entrepreneurs in Europe enjoy better work life balance but struggle to gain access to funding for growth. By integrating both theories, this research seeks to uncover the institutional forces and interpersonal dynamics that shape women's entrepreneurial experiences across these regions. Through a thorough examination of how cultural norms, formal structures, and network relationships intersect, this study seeks to provide a more comprehensive understanding of both the opportunities and constraints women entrepreneurs encounter when starting and scaling their ventures. The findings of the research can serve as a valuable resource for scholars and governmental figures to improve inclusivity within entrepreneurial environments.

Abstract Name: Mapping Seizure-Driving Inputs in a Mouse Model of Focal Cortical Dysplasia

Focal cortical dysplasia type II (FCD-II) is a leading cause of drug-resistant epilepsy in children, yet the neural circuits that initiate and sustain seizures remain poorly understood. While FCD is defined by a localized cortical malformation, clinical and experimental evidence indicates that seizures often engage brain regions beyond the dysplastic site, suggesting that epileptogenesis depends on a distributed network rather than isolated pathology. Understanding these network-level interactions is critical for developing targeted therapies, as current treatments for FCD-related epilepsy are limited and often insufficient. This project aims to identify and map cortical and subcortical inputs that interact with dysplastic cortex and contribute to seizure activity. Using in utero electroporation, the mTOR pathway will be hyperactivated in layer 2/3 progenitors of the embryonic mouse prefrontal cortex, generating focal dysplastic regions that recapitulate key features of human FCD. Retrograde and anterograde tracing with CTB-Alexa488 will label incoming and outgoing projections connected to the dysplastic area. Following perfusion and sectioning, confocal microscopy will quantify labeled neurons and projection patterns across multiple brain regions, enabling the construction of high-resolution maps of connectivity in FCD mice compared with controls. By pinpointing regions that provide seizure-relevant inputs or receive aberrant outputs, this study will elucidate how local cortical malformations interact with broader neural circuits to sustain epileptic activity. These findings are expected to advance fundamental understanding of seizure network dynamics and may guide the development of network-targeted interventions. Ultimately, this work has the potential to reduce seizure burden and improve long-term outcomes for individuals with FCD-related epilepsy, providing a foundation for more precise, circuit-based therapies.

Abstract Name: Non-Thermal Plasma-Mediated Irreversible Electroporation for Targeted Elimination of Residual Breast Cancer Cells at Surgical Margins

Residual tumor cells left behind at the surgical margin are a major cause of local recurrence in solid tumors. The Canady Helios Cold Plasma (CHCP) system is a non-thermal, non-contact cold atmospheric plasma technology that generates brief electric fields and reactive species capable of disrupting cancer cell membranes. This study investigated whether CHCP produces voltage-dependent irreversible electroporation across biologically distinct breast cancer subtypes. Four breast cancer cell lines were tested: two triple-negative lines (MDA-MB-231 and Hs578T), one ER+/PR+/HER2- line (MCF-7), and one ER+/PR+/HER2+ line (BT-474). Cultures were exposed to cold plasma for five minutes at either 25 V or 30 V, and membrane permeabilization was assessed through propidium iodide uptake over 120 minutes. Additional analyses evaluated morphological changes, functional pore formation via delivery of BCL2A1-targeting siRNA, and clonogenic survival. Tumor margin samples from a Phase I clinical trial (NCT04267575) were examined ex vivo to assess tissue-level responses. CHCP exposure produced clear voltage- and time-dependent membrane permeabilization in all four breast cancer lines. Treatment at 30 V resulted in strong and sustained dye uptake, whereas 25 V generated a shorter, less intense response. Cells displayed structural changes consistent with membrane disruption, and CHCP enabled intracellular siRNA delivery and significantly reduced colony formation, confirming effective electroporation. Ex vivo analyses demonstrated selective injury to malignant cells while preserving adjacent non-cancerous tissue. Overall, CHCP functions as a non-thermal, non-contact plasma-based electroporation platform capable of controlled membrane permeabilization and selective cancer cell death. These findings support its potential intraoperative use to eliminate residual tumor cells at the surgical margin and reduce the risk of local recurrence.

Abstract Name: Automating the Security Verification of 5G Networks Using AI and Logic-Based Tools

The 5G Authentication and Key Agreement (5G-AKA) protocol helps protect users in modern cellular networks by confirming identities and securing communication. However, the official protocol description is written mostly in natural language, which makes it difficult to analyze and increases the chance of human error during security review. This project introduces an automated system that transforms these text-based protocol descriptions into precise logical statements that can be checked by computer programs. The system uses a large language model (LLM) to break the 5G-AKA procedure into small steps and translate each step into logical rules. These rules are then tested with verification tools to examine important security properties, such as whether both parties can trust each other and whether secret keys remain protected. Early results show that the system can correctly represent key parts of the protocol and match known behaviors. The long-term goal is to create a reusable tool that reduces the manual effort of analyzing communication protocols and makes formal security verification more accessible to both researchers and engineers.

Abstract Name: Exploring Volume Emission Rate asymmetries for the ICON-MIGHTI observations

The Ionospheric Connection Explorer (ICON) satellite mission, launched in 2019 by NASA, investigated the relationship between Earth's upper atmosphere and space. One of the instruments onboard, the Michelson Interferometer for Global High-resolution Thermospheric Imaging (MIGHTI), was designed and operated by the U.S. Naval Research Laboratory (NRL). MIGHTI's primary goal is to measure neutral wind velocity and temperature in the thermosphere (~90–300 km) by observing Doppler shifts and spectral line broadening in two key atomic oxygen (OI) airglow emissions: the red-line at 630.0 nm and the green-line at 557.7 nm. From these same observations, the Volume Emission Rate (VER), a measure of excited or ionized oxygen density, can also be derived through analysis of the interferometer's fringe amplitude and phase. MIGHTI retrieval algorithms assume that wind and emission rates vary only with altitude and are horizontally uniform along each viewing altitude shell. While this assumption simplifies data processing, it is inaccurate in regions where large horizontal gradients occur, such as near the solar terminator, or within the Equatorial Ionization Anomaly (EIA). These regions produce large electric field variations that alter the VER and drive larger than expected vertical components in the neutral wind. Currently, data in these regions is often flagged as low-quality or invalid, since the assumption of horizontal uniformity no longer holds and as such the retrieval algorithm can no longer return a reliable profile. This research examines how horizontal density and emission variations affect MIGHTI's wind and VER retrievals. By quantifying the influence of these gradients on measured fringe patterns, we aim to improve the interpretation of MIGHTI data under non-uniform atmospheric conditions. Ultimately, this work enhances the reliability of ICON's observations and advances our understanding of thermospheric dynamics, ion-neutral coupling, and space weather variability in Earth's upper atmosphere.

Abstract Name: Nutrient-Dependent Transport of Run-and-Tumble Escherichia coli in Micropillar Arrays

The ability of motile bacteria to navigate structured environments is central to processes ranging from colonization to infection. In this study, we investigate how run-and-tumble Escherichia coli move through arrays of micron-scale pillars when suspended in two chemically distinct nutrient-rich fluids: Motility Buffer (MB) and Tryptone Broth (TB). Using high-resolution 4D (3D + time) tracking microscopy, we reconstruct full bacterial trajectories within the structured domain. Surprisingly, the micropillar lattice enhances bacterial dispersal rather than hindering it. This enhancement is medium-dependent: in MB, where cells exhibit longer runs and fewer tumbles, transport becomes more persistent and super-diffusive; in TB, cells show more frequent directional changes and slower spreading. Spatial variations in swimming behavior suggest that hydrodynamic interactions with pillar surfaces and local run-tumble dynamics jointly shape escape rates and long-term transport. Our findings highlight how nutrient conditions and geometric confinement together

modulate bacterial motility, with implications for microbiome engineering, antifouling strategies, and the design of structured microbial habitats.

Abstract Name: Probing Stability and Hydrogen Bonding in Heteroatom-Containing Cyclopentadiene Carbaldehyde oximes: Dual AICD & GIMIC Approach

Hydrogen bonds are a physical phenomenon that arises from the distribution of electrons in chemical species; most commonly, how they are shared between a directly bonded pair and a nearby species ($\text{OH}\cdots\text{X}$). This atomic triad is inner system hydrogen bonding. If present in a molecule within a certain distance and orientation, they lower its energy and make it less reactive. As reactivity is the heart of chemistry, this is important knowledge to assess for. Electrons can be delocalized over several atoms, a behavior known as resonance. Such behavior is amenable to computation, a discipline within chemistry that involves the use of computers to simulate physical phenomena. It is a common method used to validate experimental data. We want to see if computation can then be used to model or describe this behavior in hydrogen bonds. To test this, we used two main methods: Anisotropy of the Induced Current Density (AICD) and Gauge-Inducing Magnetically Induced Currents (GIMIC) along with Density Functional Theory (DFT). These computational methods have been widely used to simulate and visualize electron delocalization in chemical systems, particularly in the study of aromaticity. In this work, their potential for identifying hydrogen bonding is investigated using a series of cyclopentadiene carbaldehyde oximes, in which the sp^3 carbon is systematically replaced by chalcogen atoms, from Oxygen down to Tellurium, (1-4). Through this analysis, the combined usefulness of AICD and GIMIC for characterizing hydrogen bonding in 1-4 is assessed, as well as insights into the factors contributing to stability. Our work so far rejects AICD due to indistinct values, and literature favors GIMIC for characterization.

Abstract Name: Behavioral Responses of *Tenebrio molitor* to Volatile Cues Linked to Parasite Transmission

Chemical cues play an important role in how intermediate hosts interact with parasite-contaminated environments, particularly in systems where transmission depends on host foraging behavior. The tapeworm *Hymenolepis diminuta* infects rats as its definitive host, and its eggs are shed in rat feces that beetles encounter while foraging. Previous studies with *Tribolium confusum* and *Tenebrio molitor* have shown that beetles may prefer feces from infected rats, likely due to volatile chemicals associated with infection. These findings suggest that odor cues, along with hunger state and social interactions, can influence beetle behavior in ways that increase the parasite's chances of completing its life cycle. This project expands on earlier work by testing whether specific fecal-associated volatile compounds can independently attract *T. molitor*. To

investigate this question, adult beetles were fasted for 24 hours and tested in a two-choice circular arena similar to designs used in previous behavioral assays. Each trial presented beetles with a choice between coverslips treated with different odor solutions: deionized water, limonene, or a four-acid mixture consisting of butanoic acid, methyl butanoate, 2-methyl butanoate, and pentanoic acid. Thirty beetles were released into the arena for each run, and their positions were recorded once per minute for ten minutes to determine whether they aggregated preferentially toward a particular odor. Preliminary patterns indicate that beetles distinguish between odor treatments and tend to move toward the area containing the four-acid mixture. These acids are known components of volatile profiles associated with infected feces, suggesting they may serve as cues guiding beetles toward parasite-containing substrates. This study helps clarify the role of individual volatile chemicals in *T. molitor* host-seeking behavior and contributes to broader understanding of how *H. diminuta* may influence intermediate host activity to enhance transmission.

Abstract Name: Serotonin Dysfunction in the Anterior Thalamus may be Implicated in Dravet Syndrome

Dravet Syndrome (DS) is a severe, genetic epilepsy starting during infancy, leading to long-term intellectual and developmental disability. Serotonin is thought to play a critical role in regulating brain excitability, as prior research links enhanced serotonin signaling to reduced seizure activity. In the last five years, serotonin-based therapies such as fenfluramine have been approved to treat DS. Despite recent advancements, there is still little scientific understanding of how serotonin suppresses seizures in DS. Previously, we showed that serotonin is involved in feed-forward inhibition in the thalamocortical circuits, with serotonin reducing excitatory neuron spike firing in the anterior thalamus and increasing inhibitory neuron spiking in the reticular thalamus. A DS mouse model displayed decreased feed-forward inhibition to the anterior thalamus, suggesting that this circuit may be impaired in DS, leading to increased thalamocortical excitability. Moreover, the impact of serotonin on this circuit is reduced in DS mice, but it remains unclear if this results from a decreased response of thalamus neurons to serotonin, or if there is less serotonergic input in the thalamus circuitry. To assess this, we imaged fluorescently labeled serotonin neurons and measured the quantity of serotonin cell bodies in the raphe nuclei as well as axons in the anterior thalamus region of wild type (WT) and DS mice. If serotonin cell count and axon innervation in DS versus WT mice are similar, it would indicate that serotonin connectivity is normal. Alternatively, a difference would suggest an impairment in serotonin innervation that potentially disrupts thalamocortical circuit function and contributes to the disease state. Investigating the means by which serotonin suppresses seizure activity in DS will elucidate mechanisms underlying hyperexcitability in seizure circuits and advance therapeutic treatments targeted towards areas of dysfunction.

Abstract Name: Not a picky eater: Re-documenting the feeding habits of the grape berry moth, *Paralobesia*

viteana (Lepidoptera: Tortricidae).

The grape berry moth (GBM), *Paralobesia viteana* (Lepidoptera: Tortricidae), is one of the most important pests of grapes in Eastern North America. The insect is native to this region and established its association with wild grapes well before grape cultivation. For over a century, GBM have only been documented feeding and developing exclusively on grape berries. However, GBM larvae were found on galled wild grape (*Vitis riparia*) leaves infested with phylloxera (*Daktulosphaira vitifoliae*) in field conditions in Erie, Pennsylvania. This study tested GBM larval development on alternative diets consisting of ungalled leaves, galled leaves, and fruit from commercial and wild grape species. GBM neonates from a laboratory colony were individualized in cups and reared on each of the following treatments: phylloxera galls from *V. riparia* leaves (with and without phylloxera eggs) ungalled *V. riparia* leaves, phylloxera eggs only, Concord (*Vitis x Labruscana*) leaves, Riesling (*Vitis vinifera*) leaves, and grapes from *V. riparia* and Concord (control). Larval mortality and development, pupae development, pupae weight, and adult emergence were monitored daily. GBM larvae successfully developed into adults when fed on all diet treatments, except for those provided with Concord leaves and phylloxera eggs only. GBM larvae developed faster when fed on all diet treatments compared with those fed on Concord grapes. Larvae fed on galled *V. riparia* leaves developed faster than those fed on any other treatment, but there were no differences in pupa development or pupa weight. Viable eggs were produced from adults reared on both gall diets, *V. riparia* leaves, Riesling leaves, and grapes. These results demonstrate that GBM can develop and reproduce when feeding on phylloxera galls and leaves from wild and cultivated grapevines, broadening our understanding of GBM ecology with potential vineyard management implications.

Abstract Name: Prenatal High-Fat Diet Accelerates Neuroblastoma Progression via Increased Tumor Burden and CD4⁺ T Cell Exhaustion in Offspring

Maternal nutrition during pregnancy is a key determinant of offspring health, influencing susceptibility to cancer. Neuroblastoma, a pediatric malignancy arising from neural crest cells, is highly sensitive to genetic and environmental factors. While oncogenic drivers like MYCN amplification are well-characterized, in utero environmental exposures, particularly maternal diet, remain underexplored. This study investigates how a prenatal high-fat diet (HFD) influences neuroblastoma progression and anti-tumor immunity in predisposed offspring. Using the TH-MYCN transgenic mouse model, which develops spontaneous neuroblastoma, pregnant dams were fed either a control diet or an HFD. Offspring were assessed for tumor onset, progression rate, tumor burden, and survival. Immune profiling of the tumor microenvironment helped evaluate T cell function and exhaustion status. Offspring exposed to HFD in utero exhibited significantly earlier tumor onset, accelerated progression, and increased tumor burden compared to controls. These changes were accompanied by reduced overall survival, indicating a more aggressive tumor phenotype and enlarged spleen in HFD mice. Flow cytometric analysis of spleen immune composition revealed a suppressed anti-tumor immune response, particularly among CD4⁺ T cells. These cells displayed elevated expression of exhaustion markers, including PD-1, TIM-3, and LAG-3, alongside reduced proliferation and diminished cytokine production (IL-2, IFN- γ). A notable increase in CD4⁺CD44⁻CD62L⁻ cells was also observed, suggesting abnormal T cell differentiation or functional impairment. The HFD-exposed mice showed increased immunosuppressive signaling and altered antigen presentation, further supporting a state of immune dysfunction. These results suggest that prenatal HFD exposure induces long-lasting immune alterations that compromise anti-tumor immunity and

promote neuroblastoma progression. In summary, prenatal exposure to HFD accelerates neuroblastoma development and impairs adaptive immunity through the exhaustion and dysfunction of CD4⁺ T cells. These findings underscore the importance of maternal nutrition in shaping offspring's cancer susceptibility and immune competence. Targeting maternal diet may offer a novel approach to reducing childhood cancer risk.

Abstract Name: Multimodal Imaging System for Diabetic Retinopathy using DL-alpha-aminoadipic Acid Rabbit Model

Known as one of the leading causes of blindness, diabetic retinopathy (DR) can lead to permanent vision loss due to the late detection of pathological angiogenesis. Current imaging systems lack adequate diagnostic capabilities to detect DR in rabbit models which increases the risk of significant structural damage to the eye. To address this challenge, we propose a longitudinal multimodal imaging system that's composed of spectral-domain optical coherence tomography (SD-OCT), fluorescein angiography (FA), and color fundus photography to detect the DL-AAA induced retinopathy model. The DL-AAA induced retinopathy model is used to selectively target Müller glial cells which triggers sustained blood-retinal barrier breakdown via a single intravitreal injection of DL-AAA. In contrast to acute models, studies have found that this imaging system could detect and quantify specific biomarkers of chronic diabetic retinopathy that are generally missed by successfully visualizing the progression of vascular incompetence. SD-OCT with its depth-resolved capabilities can accurately identify structural pathologies such as acute retinoschisis, internal limiting membrane thickening, and the protrusion of neovascular tufts into the vitreous cavity while FA can distinguish trends of persistent leakage and vessel tortuosity for up to 52 weeks. The high-contrast resolution enables automatic quantification of the Mean Leakage Area (MLA), validating that the model achieves 100% reproducibility in generating a sustained angiogenic phenotype like DR. In conclusion, this multimodal imaging system has the capability to become the new standard for evaluating diabetic retinopathy. Its integration of advanced imaging modalities with the DL-AAA induced retinopathy model addresses the diagnostic limitations of the outdated imaging systems by allowing us to detect early signs of diabetic retinopathy.

Abstract Name: Stimulating Myofibrillar Hypertrophy for Optimal Volume Ranges, Rest Times, and Training Loads: Mechanical Tension, Metabolic Stress, and Muscle Damage on Myofibrillar Hypertrophy

Resistance training (RT) is a widely practiced exercise modality for inducing skeletal muscle hypertrophy, primarily through two mechanisms: myofibrillar hypertrophy, which involves growth in myofibril size and number, and sarcoplasmic hypertrophy, characterized by volumetric expansion of non-contractile elements such as the sarcolemma, mitochondria, sarcoplasmic reticulum, and enzymatic content. Mechanical tension, driven by actin-myosin cross-bridging; metabolic stress, marked by metabolite accumulation; and muscle

damage, characterized by inflammatory responses, are physiological byproducts of RT that are widely believed to promote skeletal muscle hypertrophy. However, their relationship with myofibrillar hypertrophy remains unclear in the literature. These physiological byproducts are thought to be influenced by the manipulation of RT variables, including set volume, inter-set rest intervals, and training loads. This study investigates the mechanisms behind myofibrillar hypertrophy, excluding increases in the size of non-contractile elements within the muscle. The research consists of two parts: (1) investigating the direct effects of metabolic stress, muscle damage, and mechanical tension on myofibrillar hypertrophy using animal and human muscle biopsies, and (2) examining the interactions among key RT variables—set volume, inter-set rest intervals, and training loads—and their influence on metabolic stress, muscle damage, mechanical tension, and myofibrillar hypertrophy. The study aims to determine the effects of these factors on myofibrillar hypertrophy and to propose practical RT programming recommendations.

Abstract Name: The Influence of Biological Sex, Relationship Status, and Adult Attachment Styles in Features of Histrionic Personality Disorder

Background: Considerable research has focused on sexual attitudes/behaviors of Cluster B personality disorders (PDs), including borderline PD, yet few studies have focused on sexual attitudes/behaviors of individuals with histrionic PD (HPD) features—inclusive of males and females. Further, maladaptive personality traits underlying PDs have been clearly linked to insecure attachment. The purpose of this study was to assess features of HPD and attachment patterns. Method: The sample comprised 627 undergraduate students ($n = 481$ females and $n = 146$ males); mean age = 19.49 years ($SD = 1.21$). Along with demographics, HPD features were assessed using the Brief Histrionic Personality Scale (BHPS); communication of sexual needs was assessed using the Hurlbert Index of Sexual Assertiveness (HISA); adult attachment styles were assessed with a four-group model. Results: Three-way (2 [biological sex] $\times$ 2 [relationship status] $\times$ 4 [adult attachment style]) factorial ANOVAs were performed for the following: Seductiveness and Attention Seeking subscales of the BHPS and HISA total scores. For the BHPS Seductiveness subscale, there were significant main effects for biological sex, ($F[1, 610] = 5.46, p < .05$) and for relationship status ($F[1, 610] = 6.35, p < .05$). For the BHPS Attention Seeking subscale, there were significant main effects for biological sex ($F[1, 611] = 5.84, p < .05$) and for attachment style ($F[3, 611] = 9.23, p < .001$). For HISA total scores, there significant main effects for biological sex, ($F[1, 540] = 8.82, p < .05$) and for attachment style ($F[3, 540] = 4.39, p < .01$). Discussion: Addressing biological sex differences in the presentation of HPD features and associated sexual attitudes/behaviors provides additional insight to this topic area. Similar to other studies of HPD and attachment, this study highlights how attachment disturbance may play a key role in development of core personality traits underlying PDs.

Abstract Name: Are You Looking for A Research Project for the First Time Student Researcher?

The purpose of my mentee's project was two-fold: to satisfy honor's coursework in the form of "something different" and to support the mentor's research on portfolios in capstone public relations courses. The mentee agreed to develop an annotated bibliography of 10 peer-reviewed journal articles that discuss experiential learning and public relations portfolio assignments in capstone courses at the college/university level in the United States. The student received honor's credit for the project, and the bibliography sources will be added to other journal articles to be collected for the mentor's research. A comprehensive collection of articles will help the mentor researcher to understand what the literature says about the topic, to formulate a thesis, and to understand how to build on the existing research. The annotated bibliography summarizes each article, which includes the purpose of the research, teaching methods, findings and conclusions. This type of annotated bibliography contrasts with those that provide an evaluation of an article and may discuss how the research fits in one's own research. Mentors and mentees may find that annotated bibliographies can serve as a valuable research project for novice undergraduate researchers and student-faculty collaboration. It enhances student learning and research skills and faculty teaching and mentoring skills. In the case of this research, the annotated bibliography was the first research project for the student researcher. Due to the time limitations of the project, the student researcher found it challenging to find articles that focused only on public relations portfolio assignments. A few articles focused on other communications courses including journalism and mass communication, magazine writing, and advertising.

Abstract Name: When the School Split: Students on the Front Lines of New Orleans' Education Reform

This study examined the long-term educational and social impacts of New Orleans' post-Hurricane Katrina shift to a charter-based school system through a focused case study of George Washington Carver High School. While charter schools were often praised for academic improvement and operational flexibility, critics argued that they operated as business-driven institutions prioritizing funding, efficiency, and test performance over student well-being and equitable access. Carver High School's unusual transition, splitting its student body so that 9th and 10th graders remained under charter management while 11th and 12th graders were displaced due to funding constraints, revealed how financial interests shaped policy decisions at the expense of student stability. Despite the profound disruption students experienced, most existing discourse centered on administrative perspectives, leaving student narratives largely undocumented. To address this gap, the project collected interviews from 20 former students and additional staff members to understand how the split transition affected academic trajectories, emotional well-being, and perceptions of the charter system. Archival data, including school demographics, funding sources, and operational records, supplemented these firsthand accounts and provided broader policy context. The final outcome was a long-form, journalistic feature that foregrounded student voices while critically examining the influence of privatization on public education. Drawing on both personal experience within New Orleans charter schools and academic training in race, journalism, and educational policy, this study illuminated how business-oriented reforms continued to shape the lives of students nearly two decades after Katrina.

Abstract Name: Maternal positional behavior and energetics during infant carrying in Coquerel's sifaka

Infant carrying has evolved multiple times in primates and is hypothesized to be energetically expensive. Lemurs either carry or park their infants. Infant parking leaves them vulnerable to predation while carrying protects the infant at the potential expense of increased maternal energy expenditure. Coquerel's sifaka (*Propithecus coquereli*) are strepsirrhine primates who use dynamic locomotor modes such as leaping, yet they still carry their infants for more than 6 months and at over 30% of maternal body weight. We hypothesized sifaka mothers will experience higher energy expenditure and/or modify their locomotor behavior in response to infant growth. We fit two sifaka mothers at the Duke Lemur Center with Technosmart Axy-5 accelerometer collars and collected simultaneous video and acceleration data for 3 1-week intervals from 2 mothers carrying infants 3-6 months old. We quantified positional behavior, overall dynamic body acceleration (ODBA, a proxy for energy expenditure due to movement), and peak acceleration relative to age and weight of the infant using Chi-square and generalized linear models. Overall frequency of infant carrying did not change significantly as the infant grew in weight, however carrying frequency during leaping decreased when the infant was in the heaviest weight class ($>1500\text{g}$). The frequency of resting increased and traveling frequency decreased as the infants grew in weight. Between infant ages of 3-5 months the mother's ODBA increased, however, ODBA decreased around 6 months when the mother's carrying frequency was reduced. Infant carrying in sifakas is energetically expensive, it is associated with behavior modifications in mothers, and it is likely related to the relatively slow somatic growth observed in sifakas. Examination of the energetics of infant carrying in additional strepsirrhine primates can help us better understand the evolution and implications of this infant care strategy in primates.

Abstract Name: Isolation of Iron-Oxidizing Bacteria from Environmental Sampling

Iron-oxidizing bacteria (IOB) are nonpathogenic microorganisms that convert soluble ferrous iron (Fe^{2+}) into insoluble ferric iron (Fe^{3+}). This metabolic process generates the reddish-brown deposits that often appear in well-water systems and are frequently misinterpreted as chemical corrosion. In Southside Virginia, these stains are common due to naturally acidic groundwater, yet the biological source of the problem is not widely understood. This project investigated which IOB species are present in local private wells and household plumbing and how they contribute to visible iron staining. Samples of well water and biofilms were collected from multiple residences across the region. They were cultured on three iron-enriched media under microaerophilic and slightly acidic conditions to promote IOB growth. Resulting isolates were examined through Gram staining, light microscopy, and PCR for preliminary identification. Scanning electron microscopy paired with energy dispersive X-ray spectroscopy was used to verify iron deposition on bacterial structures and to characterize cell morphology. Preliminary work identified several distinct IOB morphotypes across sampling sites. Final results are expected to provide a localized profile of IOB species in Southside Virginia and clarify which taxa are most strongly associated with visible staining. These findings will help

refine isolation and identification methods, supply baseline data for future genomic analysis, and support community education aimed at improving understanding and management of rural well-water systems.

Abstract Name: Investigating the Effects of Bile Acids on B-Cell Function and Immunity

Bile acids, key factors in lipid digestion, are critical signaling molecules influencing metabolic and immune responses. Studies suggest that bile acids interact with immune cells, such as T cells and macrophages, via receptors like the G protein-coupled bile acid receptor (TGR5), Sphingosine-1-phosphate (S1P) receptor 2 (S1PR2) and the farnesoid X receptor (FXR). However, their impact on B cells—key players in adaptive immunity responsible for antibody production—remains unclear. B cells are essential for humoral immunity, and their dysfunction is implicated in autoimmune diseases, infections, and metabolic disorders. More than 98% of the human genome consists of non-protein-coding sequences, including long non-coding RNAs (lncRNAs), and microRNA (miRNAs). MiRNAs have been recognized as crucial regulators of numerous physiological and pathological processes by acting as activator or suppressor for RNA translation. By pinpointing the specific sequences of miRNAs associated with FXR and TGR5, it is possible to explore how different bile acids control gene expression by regulating the expression of those receptors. Bile acids modulate B-cell function by activating TGR5 and/or FXR, leading to generating more miRNAs that alter cell proliferation and cytokines production. Therefore, applying any change on bile acid structure and concentration has potential implications for immune regulation and metabolic-immune crosstalk. Bile acids may enhance or suppress B-cell proliferation depending on concentration and receptor activation, and subsequent activation of FXR/TGR5 could upregulate anti-inflammatory pathways. Discovering the impact of bile acids on B-cell biology may uncover new therapeutic possibilities for immune-related disorders.

Abstract Name: Are Hostile Traits Associated with Health Behaviors and Outcomes in Emerging Adults?

The goal of this study is to better understand predictors of positive vs. negative health behaviors in emerging adults. Specifically, this study examines the role of hostility, anger, and aggression (physical, and verbal) on physical, social, and mental health behaviors in emerging adults (ages 18-29). Personality plays a role in decision making, meaning that certain traits (e.g., hostility) may have specific associations with health behaviors, leading to potential future health outcomes throughout the lifespan. Factors during emerging adulthood may contribute to health disparities later in life, making it important to understand health during this time. This project has been approved by the Salisbury University IRB, and the data will be collected and analyzed in January. Survey materials have been entered into Qualtrics, and participants will be gathered using the online platform Prolific to create a sample that is well representative of the population of emerging adults. Data will be downloaded from the Qualtrics website into SPSS where it will be analyzed using correlation, regression, and ANOVA. I hypothesize that emerging adults who show greater hostility will

experience a greater frequency of negative health behaviors. Since emerging adulthood is a time of exploration, if hostile traits are found to lead to certain unhealthy behaviors, interventions may be implemented during this time to put a person on a path to prevent negative health outcomes later in life. If the results are consistent with hypotheses, a manuscript will be prepared and submitted to a peer-reviewed journal for publication. Overall, this research looks to broaden the literature involving how hostility, anger, and aggression relates to health during emerging adulthood.

Abstract Name: Social Motives and Leadership Preferences: How Views on Childcare are Associated with Preferred Traits in Political Leaders

Voter preferences in elections around the globe have suggested a recent trend toward dominant male political leaders, such as Donald Trump and Viktor Orbán. Prior research on leadership preferences has suggested that certain individual differences, such as a person's chronic concerns about safety, are associated with a greater preference for such dominant male leaders. The current project is interested in investigating the individual differences that are associated with people instead preferring more prestigious (or skill-based) female leaders over dominant male ones. Some of our pilot work using survey data and archival data from the 2016 American National Election Studies suggested that participants with more chronic concerns for their children's welfare were more likely to prefer prestigious female leaders over dominant male ones, including in terms of rating preferences of imaginary candidates, and in terms of a greater likelihood of voting for Hillary Clinton (a prestigious female candidate from the Democratic party) over Donald Trump (a dominant male candidate from the Republican), even when participants' political party was statistically controlled for. However, given that there is an association between childcare issues and specific political parties, we are currently following up on this study using an original, online survey study in which adult participants rate their congressional preferences for male dominant leaders (who are Democrats) and female prestigious leaders (who are Republicans) from recent congressional races. We will also measure participants' motives, including their childcare motivation, and expect that our regression analyses will show that participants with higher levels of childcare motives will significantly prefer prestigious female leaders over dominant male ones.

Abstract Name: The Effects of Heat Waves on Monarch Butterflies: Responses in Development, Reproduction, and Mate Selection

Insects are essential to ecosystems, however more frequent heat waves can threaten their survival. Thermally

sensitive species like the monarch butterfly (*Danaus plexippus*), whose migration relies on temperature and host plant condition, are especially vulnerable. Despite this, the transgenerational effects of repeated heat wave exposure remain poorly understood, especially how thermal stress during different life stages and plant exposure affect fitness in *D. plexippus*. This study investigates the effects of heat waves through two experiments: Legacy and Fertility. We hypothesize heat waves will negatively affect development, behavior, and reproductive output. For both experiments, control groups maintained at 30 ± 0.5 °C, heat wave treatment of 37 ± 1 °C for four hours/day over three consecutive days. In the Legacy Experiment, eight treatment groups of ($n = 100$) caterpillars were reared on either control or heat-stressed common milkweed (*Asclepias syriaca*) and were either exposed (or not) to heat during 1st, 3rd, or 5th instar. We measured development time, consumption, larval and adult morphology, survival, and reproductive output. The Fertility experiment assessed the effects of direct adult heat stress on reproduction and behavior in *D. plexippus*. All combinations of stressed and control pairings were tested ($n = 10$ per pair type) to measure heat and sex-specific stress impacts on egg production, hatching success, behavior, and survivorship. The subsequent Choice experiment tested mate preference by offering individuals a choice between heat-stressed and control partners. Heat-stressed milkweed significantly lowered survivorship ($p = 0.036$; $p = 0.0468$), host-plant stress had stronger negative impacts than direct larval heating. Early-instar heat exposure reduced adult wing size, and mate-choice trials showed a trend toward preferring control partners ($\chi^2 = 3.6$, $p = 0.058$), indicating behavioral sensitivity to prior stress. Our findings will inform predictions about insect responses to climate extremes and enhance our understanding of how thermal legacies shape population dynamics and migratory success.

Abstract Name: Addressing Perinatal Health Disparities for Immigrant and Refugee Populations in Baltimore

Immigrant and refugee women in Baltimore face persistent disparities in access to perinatal healthcare due to interacting structural, cultural, and policy-related barriers. This study examines the underlying drivers of these inequities and explores how financial strain, language barriers, limited health literacy, fear of deportation, and unfamiliarity with the United States medical system collectively undermine maternal and infant health outcomes. Using a qualitative, community-informed approach, the research draws on expert interviews with clinicians, policy analysts, and maternal health scholars, in addition to field observations from work with local refugee support organizations. Relevant policy documents and literature were also reviewed to contextualize current challenges in perinatal care access. The thematic analysis revealed that mistrust of healthcare institutions, cultural incongruence between patients and providers, and chronic stress related to immigration contribute to delayed or inconsistent engagement with essential perinatal services. Community organizations serve as critical support structures, yet their efforts are often hindered by unstable funding and restrictive policies. The findings highlight the need for interventions that prioritize the experiences and needs of immigrant communities. Potential strategies include the creation of culturally specific maternity hubs, improved multilingual access to Medicaid enrollment, expanded access to professional interpretation services, and comprehensive cultural competency training for healthcare providers. Additional solutions such as the expansion of telehealth prenatal visits, flexible clinic hours, and collaboration with trusted community institutions may further reduce logistical and cultural barriers to care. This study underscores the importance of community-centered and culturally responsive approaches to advancing equitable perinatal health outcomes in Baltimore.

Abstract Name: Reducing Hallucinations in Large Language Models Through Retrieval-Augmented Generation

Models with large language capabilities, such as GPT-3.5 and LLaMA-2, can create seamless and cohesive contextual text, but tend to create 'hallucinations', which are potentially damaging to the context of the text as they consist of potentially believable falsities. This severely impacts the realms of education, science, and medicine. This study attempts to answer the following questions. To what degree do large language models create fictional text, and does retrieval-augmented generation (RAG) have the potential to ground evidence and thereby reduce the hallucinations? This project uses the publicly available benchmarks SQuAD v2 with unanswerable questions and TruthfulQA, which assesses the limits of addressing the false. It assesses factual accuracy, precise match of response to the questions asked, and the hallucinations of the different models. The baseline analysis is to assess the regular generative performance and for the integration of the RAG system, which has a dense document retriever that is built on Wikipedia, which is used to augment contextualized evidence to be provided before responding to each of the questions. Before using the system, it has been reported that on a baseline of 20 to 30% hallucinations were present, especially for questions that were vague or misleading, but using retrieval-based grounding, the rate of hallucinations dropped significantly. In addition to the numerical figures, our qualitative analysis suggests that retrieval enhances the reasoning along with the transparency, while also lessening the overconfident language present in wrong answers. This study aims to create a reproducible structure to assess and lessen the factual inaccuracy of generative AI systems. This work shows, with some evidence, that combining retrieval and detection systems that external grounding improves the ability to stay on the truth.

Abstract Name: Synthesis of Potentially Selective 5-HT_{2A} Serotonin Receptor Agonists with a Forced Active Conformation

This proposal outlines work toward the synthesis of two potential serotonin 5-HT_{2A} receptor agonists based on the established molecule (2S,6S)-2-(4-bromo-2,5-dimethoxybenzyl)-6-(2-methoxyphenyl)piperidine (compound 3). A synthetic pathway has been developed based on work conducted in previous semesters for these molecules, which aim to improve the potency of their predecessor in the desired receptor while maintaining selectivity over the 5-HT_{2C} receptor. The addition of a methyl group to the central ring on compound 3 is hypothesized to favor the active conformation of the molecule, effectively increasing potency. This new agonist will give us a better understanding of the structure and function of the 5-HT_{2A} receptor and will give us further insight into its involvement in certain neurological conditions as well as its potential applications in the medicinal field. In the past, moderate amounts of tert-butyl (trans)-2-(2,5-dimethoxybenzyl)-6-(2-methoxyphenyl)-4-oxopiperidine-1-carboxylate (compound 10) were synthesized with great effort; thus, we have tested the proposed reactions on an analog of compound 10. By optimizing these reactions first, we will make it more likely that the reactions on the actual compound 10 will succeed, allowing us to ultimately synthesize desired compound 3.

Abstract Name: Using Nature-inspired Sustainable Design via Biomimicry of the Peregrine Falcon to Improve the Development of Japan's F-X Fighter Jet

Modern fighter jets face a persistent challenge when it comes to improving aerodynamic efficiency without having to sacrifice high-speed performance or long-term sustainability. These aircraft rely heavily on high thrust and agility, and in doing so, they consume large amounts of fuel due to aerodynamic drag and limited energy efficiency. As a result of these constraints, advanced military defense development projects, such as Japan's Mitsubishi F-X fighter jet program, have been delayed, highlighting the need for more sustainable solutions. Biologically inspired designs, also known as biomimicry, have emerged as a promising alternative. The peregrine falcon, the fastest bird in the world, exhibits extraordinary flight capabilities that include steep dives that exceed 320 km/h, precise maneuvering, and stability under harsh conditions. In this paper, a comprehensive literature review was conducted to explore how the peregrine falcon could inform next-generation fighter jet design and aerodynamics. By using a comparative analysis of both biological and engineering studies, this paper investigated the four key aspects of the falcon's morphology, which include tapered wing structures, microstructured feathers, joint flexibility, and dynamic tail control. This paper ultimately examines how these traits can be applied to aircraft systems. The findings suggested that these natural mechanisms exhibited by the peregrine falcon (*Falcon peregrinus*) may parallel emerging morphing-wing technologies that are aimed towards enhancing lift-to-drag ratios and conserving fuel. Incorporating these biomimetic adaptations into aircraft systems, such as the Mitsubishi F-X, could significantly reduce operational energy demands, improve fuel efficiency, and enhance maneuverability and stability at high speeds.

Abstract Name: Anticipated Barriers to Implementation of the Adapted Intervention: Participant Perspectives

Stimulant and opioid overdose rates are rising sharply in Black communities, yet culturally adapted harm-reduction resources remain limited. THRIVE (Culturally AdapTed Harm Reduction Intervention: Community Engaged InterVention for Black Adults that MisusE Opioids and Stimulants), a pilot mixed-methods study conducted by the University of Cincinnati and the University of Kentucky, aimed to expand awareness of harm-reduction tools such as naloxone and fentanyl test strips. The purpose of this analysis is to explore participants' perceptions of the potential challenges associated with implementing the adapted intervention. This study included two aims: Aim 1 refined the intervention manual, while Aim 2 piloted the adapted intervention with 57 Black adults aged 18–65 in Louisville and Cincinnati via in-person focus groups of 8–10

participants. Groups assessed feasibility, utility, barriers, and community needs, with data analyzed using thematic analysis. Preliminary analysis of focus group data revealed several perceived challenges to implementing the adapted intervention across Cincinnati communities. Preliminary findings showed that some of the key findings included ensuring cultural relevance, improving distribution of information, and overcoming individualized stigma and fear surrounding addiction disclosure. While some concerns were consistent across focus groups, others reflected unique concerns regarding neighborhood visibility and distribution, differing levels of trust from community members, relevance of the distributed information, and individualized barriers. Participants identified a range of potential challenges that could hinder the successful implementation of the adapted intervention. However, perceptions of challenges were not consistent across all focus groups; some expressed optimism about community receptiveness. Future work should investigate the extent to which prioritizing the community's perspectives regarding the intervention can impact community engagement with the intervention.

Abstract Name: From Surveillance Capitalism to the Surveillance Classroom: Artificial Intelligence, Oppressive Scaffolding, and the Crisis in Learning Today

This paper examines how Artificial Intelligence (AI) erodes trust and reproduces inequalities in education. Drawing on the notion of surveillance capitalism and hostile scaffolding, it argues that AI is reconstructing the modern classroom as a site of extraction, surveillance, and suspicion. Both students and teachers are reshaped into managed subjects instead of partners in learning. Zuboff (2019) uses the term surveillance capitalism to capture how technology companies collect and monetize user data to predict and shape consumer behavior. Such technologies have gradually crept into classrooms and, with the rise of AI, now seem a permanent fixture in today's learning environments. Scholars emphasize the resulting harms for students – from invading their privacy to robbing their attention spans. One harm that has been less well studied is the effect AI has on teacher-student relations. In this paper, I introduce the idea of oppressive scaffolding to explore this harmful effect. Broadly speaking, scaffolding describes how environments can support learning, allowing us to think in more efficient ways (Sterelny 2010). Timms and Spurrett (2023) introduce the idea of hostile scaffolding to show how environments can also be built to manipulate and control (e.g., casinos). Likewise, Spurrett (2025) refers to oppressive technologies (e.g., high-heeled shoes) that are produced by and contribute to some injustice. I introduce the term oppressive scaffolding to describe a learning environment structured by companies and managed by teachers in ways that are harmful for learning. In today's classroom, students are nudged to use AI and teachers are nudged to root it out. On the surface, AI detection is about maintaining the integrity of the educational institution. In practice, it is a form of surveillance that destroys the collaboration and trust so central to learning. Whether intentional or not, teachers end up controlling students rather than liberating minds.

Abstract Name: What is Inevitable and What is Malleable?: Fatalism and Pessimism in Protestors' Visions of the Future

Social mobilizations mirror the broader cultural and political shifts of their respective eras. Contemporary protest movements are fit to new ideological landscapes of increasingly pessimistic or catastrophic narratives about the future. Climate change, democratic backsliding, rising authoritarianism, and global disinformation have all contributed to an atmosphere where the future appears precarious, foreclosed, and removed from agency. Quantitative social-science scholarship tends to conceptualizes pessimism and fatalism as stable individual traits; in contrast, interpretive scholarship highlights the effect of environment, system, and collective on ideas of the future. This study draws on and extends this idea of "future visions", which reframes fatalism/pessimism as a cluster of both affective and practical orientations that define what kinds of futures protesters see as imaginable or possible. To investigate these questions, the project will form an analysis of protest materials drawn from three different contexts and temporalities: Vietnam-era antiwar mobilizations, contemporary Palestinian protests, and both historical/current climate movements. The research will analyze how imagined futures are present in protest discourse by collecting archives of signs, chants, manifestos, and posters. Through qualitative coding of narrative structure, temporal framing, and repeated symbols, the project will identify patterns and factors within future visions. The research clarifies the role of imagined futures in shaping protest cultures, ultimately arguing that they operate not simply as barriers to action but as meaningful components of collective resistance.

Abstract Name: Smart Eye Security: Real-Time AI-Powered Threat Detection for Enhanced Surveillance Systems

Traditional surveillance systems rely heavily on sustained human attention, yet maintaining vigilance over long monitoring periods is difficult and often leads to missed threats. This motivates our central research question: Can an affordable, real-time AI system reliably detect weapons and safety violations to improve situational awareness and response times? To address this challenge, we developed Smart Eye Security, an AI-enabled surveillance platform that combines computer vision, automated event processing, and real-time visualization. A major limitation in existing research is the lack of domain-specific datasets for realistic surveillance environments. To bridge this gap, we created a custom labeled dataset focused on pistols, knives, and PPE violations. This dataset enabled training a YOLOv8 object detection model tailored to indoor security scenarios. The model operates at 29.05 milliseconds per frame, supporting real-time analytics. Detected events are automatically clipped into short video segments, logged using a Python-Flask API with an average response time of 2.33 milliseconds, and displayed through a web-based dashboard. A tracking module also estimates occupancy and visualizes movement patterns. Evaluation results demonstrate strong performance, including a 98.4% confidence score for PPE detection under optimal conditions. Performance decreases at distances beyond 15 meters, in low-light environments, and in high-occlusion traffic, indicating areas for improvement. Future work includes expanding the custom dataset to capture diverse lighting and camera angles, integrating infrared imaging for low-visibility detection, and applying temporal smoothing to stabilize tracking. Overall, this project demonstrates the feasibility of deploying cost-effective, AI-driven surveillance tools in schools, businesses, and public spaces.

Abstract Name: High Energy X-ray Imaging and Machine Learning Based Image Segmentation of Basalt Minibar Reinforced Concrete

Fiber-reinforced concrete structures offer significant advantages for civil infrastructure applications by enhancing the mechanical properties of concrete, including increased strength and ductility, which enable structures to endure harsher environmental conditions. Basalt fiber minibars, a type of chopped bundled macrofiber reinforced polymer bar, have emerged as a promising environmentally friendly reinforcement material for concrete mix designs. These minibars improve mechanical behavior by transitioning failure modes in the cement based composite materials. Key parameters such as minibar orientation, volume fraction, and dispersion critically influence the mechanical performance of reinforced concrete. Additionally, factors like flowability, workability, porosity, and rheology of the concrete mix design further affect its mechanical properties. However, the structure-property relationships associated with higher volume loadings of basalt minibars, including their dispersion and orientation, remain insufficiently understood. This study employs high-resolution X-ray computed tomography (XCT), a state-of-the-art non-destructive evaluation technique, to investigate the spatial microstructural features of basalt minibar-reinforced concrete. Three cubic concrete samples were analyzed prior to mechanical testing: two samples containing different basalt minibar volume fractions and one neat concrete sample without reinforcement. Machine learning-based segmentation techniques were utilized to differentiate minibars, pores, and matrix materials within the complex geometries of the concrete samples. Quantitative analyses derived from image segmentation included measurements of minibar surface roughness, orientation, and Euler Characteristic parameters. Pore analysis encompassed evaluations of shape descriptors such as sphericity and pore diameter across the three samples. The findings provide critical insights into the structure-property relationships of basalt minibar-reinforced concrete mix designs, supporting the development of computational models aimed at optimizing durability and performance in structural applications.

Abstract Name: Quantum Oscillations Reveal Key Differences Between Scandium and Yttrium Based Bilayer Kagome Metals

Kagome-lattice materials exhibit novel electronic behaviors, including chiral magnetism, topological band structures, charge-density waves (CDWs), and superconductivity. A central question is how the presence or absence of a CDW affects the electronic structure. In this project, we investigate two isostructural bilayer Kagome compounds, ScV_6Sn_6 and YV_6Sn_6 , to understand these differences. Using quantum oscillation measurements in pulsed magnetic fields up to 91 T, we map the Fermi surface to examine how electrons move within each material. YV_6Sn_6 , which does not develop a CDW, shows a large electron pocket and a relatively heavy effective mass, suggesting a van Hove singularity near the Fermi level. In contrast, ScV_6Sn_6 exhibits clear signatures of zone folding, indicating that the CDW reconstructs its electronic bands. To further interpret these results, we compare our measurements with density functional theory (DFT) calculations. The calculated Fermi surface in the “unfolded” Brillouin zone for YV_6Sn_6 agrees well with our experimental observations, while the CDW in ScV_6Sn_6 generates a more complex, “folded” Fermi surface. Analysis of the Berry phase from the oscillation data reveals a signature of non-trivial electronic topology in these Kagome materials. These results will be discussed in the context of how CDWs and topology interact in Kagome-based quantum materials.

Abstract Name: Augustine's Methodological Inconsistency Against the Proportionality Objection to Hell

This paper argues that St. Augustine of Hippo provides an inadequate and methodologically inconsistent defense against the “proportionality objection” to the eternal, conscious torment (ECT) view of hell. The proportionality objection argues that since man’s crimes on earth are finite, eternal and infinite punishment in the afterlife would not be “proportional” and therefore not just. In Book XXI of his *City of God*, Augustine approaches this argument in two variants: the “duration” variant and the “effect” variant. The duration variant (DV) argues that a just punishment should be temporally proportional, or equal, to the time taken to commit a crime. The effect variant (EV) argues that a just punishment should be proportional, or equal, to a crime in its effect, or intensity. In his defense of ECT, Augustine successfully defeats the weaker, duration variant by developing a framework which utilizes moral intuition and normative justice to dispel with the claimed necessity of temporally proportional punishment. However, when Augustine turns to attack the effect variant, he abandons this intuition and normative justice framework in favor of theological dogmas, substantially weakening his argument structure and contradicting his methodology in the process. In the extension to this methodological shift, Augustine defends against the effect variant, perhaps successfully, by applying it to the case of Adam in Genesis as someone who does deserve infinite punishment, but he thereby is forced to use questionable dogmas to extrapolate Adam’s guilt onto the rest of mankind. Augustine’s dogmatic assertions leave the effect variant inadequately answered at best and dismantle his “moral intuition” methodology at worst.

Abstract Name: This study tests methods to reduce oxylipin loss in milk fat globules by increasing tracer amounts, aiming to match bovine serum albumin delivery for improved accuracy in animal studies.

Oxylipins are important lipid molecules made from polyunsaturated fatty acids (PUFAs). They play key roles in cell function and act as precursors for many lipid mediators. However, previous research has shown that when oxylipins are delivered using milk fat globules (MFGs), about 30% of them are lost, resulting in lower concentrations compared to bovine serum albumin (BSA). This loss limits how effectively oxylipins can be delivered during animal trials. The goal of this study was to increase oxylipin recovery in MFGs so that levels match those found in BSA. To do this, we tested several treatments using different tracer concentrations with both BSA and MFGs. We first confirmed that BSA delivers oxylipins more efficiently, with about 30% higher recovery than MFGs. We then increased tracer levels in the MFG samples by 30–50% to make up for the loss that occurs in the MFG membrane. A washing treatment was also added to help prevent oxylipins from dissolving or being lost from the surface of the MFGs. Overall, this research aims to optimize oxylipin encapsulation in both BSA and MFGs to improve delivery for future animal studies. Increasing the amount of tracer used in MFGs may help achieve similar oxylipin levels between the two delivery systems.

Abstract Name: Usability in the Nonprofit Sector: Improving the User Experience and Online Presence of a Rural Nonprofit

Usability of nonprofit websites is a growing problem for low-income communities. The American Community Survey (2019) reported that 14.5 million households are affected by a “digital divide” that restricts access to evolving technology. This divide harms Americans that rely on community support, as 89% of nonprofits, which offer food, clothing, shelter, and other essential services, rely on digital communication to achieve their mission (“Digital Engagement,” 2022). Nonprofits supported by grants and donations often cannot allocate funds to adequate website design, further dividing Americans who can access digital spaces. Incorporating user feedback through volunteer efforts and digital literacy could provide low-income communities relying on nonprofit services a functional layout that alleviates the digital divide. I conducted research on Circles of Jackson County, a nonprofit in western North Carolina, to identify the pain points users experienced on the website and how we can improve usability in the nonprofit sector. My presentation and research follows the Nielson Norman Group’s Design Thinking Process and includes: (1) Gathering user feedback on existing design through surveys and interviews, (2) Empathizing with users and defining user errors, (3) Performing comparative research of successful nonprofit websites, (4) Ideating solutions with user input with design applications, (5) Implementing prototypes into the website and testing with users, and (6) Reviewing user-centered design improvements. Identifying the issues with nonprofit websites lays the groundwork for what improvements must be made. Utilizing volunteers to implement a user-focused design may improve the online presence of nonprofits, expand their services to the broader community, and overcome an advancing social issue.

Abstract Name: Interconnected Signaling Loops: Growth Factor Signaling through ERK5 and ERK

Growth factor signaling in mammalian cells is initiated at the cell surface but the transduction pathway to the nucleus involves a series of intracellular molecules that relay information to one another through phosphorylation and dephosphorylation events that control interactions. These pathways are critical for cell proliferation and are the site of mutations that can lead to dysregulation in some cancers. One of the most well-studied signaling pathways is epidermal growth factor (EGF) mediated proliferation acting through a mitogen-activated kinase (MAPK) cascade with the final signaling molecule extracellular signal-regulated kinase 1/2 (ERK1/2), which can translocate into the nucleus when phosphorylated. A related but distinct alternative MAPK pathway leads to the phosphorylation of ERK5 which is also known as the BMK1 (Big Mitogen-activated Kinase 1) due to its large size. It is also able to move into the nucleus like ERK1/2 but the nuclear targets are distinct. Mathematical models of ERK1/2 based on differential equations have been previously developed but our focus was on how the presence of ERK5 and its pattern of phosphorylation would be distinct and act as a competitor or enhancer for ERK1/2. An in-depth model of the MEK5/ERK5 system has been created using ordinary differential equations which is distinct but has interdependence with the ERK1/2 pathway. Simulation testing has been completed using MATLAB with a focus on varying parameter values and specific activation and deactivation rates. Simulations suggest a unique phosphorylation profile for ERK5 that is dependent on both ERK and AKT with downstream molecule p90RSK serving as a key regulator for both MAPK pathways. Modeling and in silico studies of cell signaling pathways is one way to gain insight in how loss of regulation of cell proliferation might occur due to mutations and might suggest ways that investigators could introduce restorative measures.

Abstract Name: Broadening Representation in the Chemistry Classroom

Chemistry curriculum at all levels often lack diverse representation, with most scientists featured in the textbooks being white and male. This is problematic as scientists from many racial, ethnic and racial backgrounds have contributed to advancements in science. However modern chemistry textbooks continue to perpetuate the stereotype of the white male chemist. Recent analyses of US college chemistry textbooks published between 2016-2020 revealed severe imbalances in gender and ethnic representation. One study found that male names appeared every four pages of a textbook, compared to female names appearing every 250. Additionally, only 3% of the named scientists represented in textbooks were identified as being female. Furthermore other studies have also demonstrated that a student's sense of belonging and the ability to see themselves as a scientist influences resilience and success in STEM careers. To address some of these challenges this project focused on identifying excluded chemists and linking their contribution to specific topics taught in chemistry courses. Historical research was conducted to collect information on the scientist's background, and achievements. From this research 1-2 slides summarizing the scientists' work were formulated. These slides will be a part of an open-access Google site repository of teaching materials that highlight their contributions they relate to materials being taught in class. The goal of this repository is to provide chemistry instructors with a searchable database of downloadable slides and materials on hundreds of historically excluded figures in chemistry that align to their curriculum. As this repository continues to expand, it will continue to promote inclusivity within the chemistry classroom by educating students and faculty on all the contributions of scientists in underrepresented groups.

Abstract Name: Educating to Empower, or Educating to Exclude?: A Historical Analysis of the Minnesota Governor's Interracial Commission, 1943-1956

On April 27, 1943, in the midst of World War II, Minnesota Governor Harold Stassen resigned from office. The lieutenant governor at the time, Edward J. Thye, assumed his duties and became the twenty-sixth governor of Minnesota. In this position, Governor Thye advocated for preventative action (eliminating a problem before it happens) as preferable to remedial measures (addressing a problem after it has already occurred), especially when it came to violations of civil rights. He created the Minnesota Governor's Interracial Commission to act on this, tasking the Commission with educating the state's citizens on civil rights issues. From 1943 to 1956, the Commission researched and authored reports on how minority populations in Minnesota experienced work, housing, and education. The purpose of my research is to understand how successful the Minnesota Governor's Interracial Commission was at addressing racial inequities in the state. Through close reading and analysis of the Commission's archival and public report records, we identified some major themes. The Commission brought awareness to the systemic racism entrenched in Minnesota and became a model for communities to create their own local human rights organizations. However, the lack of diverse voices on the Commission led to inaccurate accounts, improper language usage, and a lack of accountability in the pamphlets. This led to the Commission offering ineffective, vague, and detrimental recommendations for supporting minority groups in Minnesota and negatively impacting how white people viewed people of color. These findings demonstrate how Minnesota grappled with bringing about greater equity in the 1940s and 1950s and provide insight into how current inequities might have come to be.

Abstract Name: Variations in Portrayals of Superman's Humanity in Modern Live-Action Films: An Ideological Critique

Superman has dominated popular American culture for nearly one hundred years, and live-action films have reflected this fascination by continuing to interpret his character in various ways. Modern films especially have differed widely in their depiction of the characteristics of Superman's humanity as society has developed a desire for more complex heroes. This rhetorical analysis uses ideological criticism to compare the differences in portrayals of Superman in the films *Superman Returns* (2006), *Man of Steel* (2013), and *Superman* (2025), focusing on the way each film depicts Superman's humanity, as shown through his love, his physical vulnerabilities, and his mistakes. These attributes are chosen because they can be generalized to humanity as a whole and are crucial to the narratives of the three films. The specific films are chosen for this analysis because they are the three most modern films that concern themselves solely with Superman. Over the last two decades, these depictions of this idealized protagonist reflect a growing effort to emphasize Superman's humanity—depicting a caring, vulnerable, and fallible hero. This increased focus on Superman's humanity provides insight into how these filmmakers have crafted a savior figure whose humanity deepens and broadens to increase the character's popular appeal and cultural relevance in America.

Abstract Name: Graphic Design as Cultural and Linguistic Activism

With more than half of the world's languages now extinct and many more disappearing every day, it is evident that traditional preservation strategies alone cannot sustain a language and its accompanying culture. This paper explores the historical connections between graphic design and language preservation. It argues that graphic design serves as both a cultural and linguistic form of activism by transforming linguistic content into engaging visual representations through infographics and typography. The role of design extends beyond mere aesthetics to influence the psychological and political aspects of representation, empowerment, and cultural pride. By making endangered languages visible, graphic design affirms their legitimacy and promotes cultural revival.

Abstract Name: Resolving Type 2-Polarized T Follicular Helper Cells in Human Peripheral Blood

CD4 T cells are an essential component of the immune system that coordinate protective responses during vaccination, infection, and other disease contexts. CD4 T cells can differentiate into subsets such as T Helper (Th) and T Follicular Helper (Tfh) with distinct functions. Th cells are grouped into Th1, Th2, and Th17 subsets based on expression of surface proteins and transcription factors. Compared to Th cells, Tfh more potently stimulates antibody production by B cells. However, recent studies demonstrate Tfh can ‘polarize’ toward Th1, Th2, and Th17, yielding Tfh1, Tfh2, and Tfh17 subsets. Tfh1 and Tfh17 surface proteins in humans are well characterized, but Tfh2 cells remain poorly defined. There is no standard set of surface markers to identify Tfh2, and their expression of common Th2 markers remains unclear. We therefore sought to evaluate whether Th2 markers such as CCR3, CCR4, CCR8, or CRTH2 are expressed in Tfh2 cells and how they correlate with GATA3, a transcription factor known to drive Th2 differentiation. By analyzing Th2 surface markers and GATA3 expression in human CD4 T cell populations using spectral flow cytometry, our goal is to better define Tfh2 identity. Defining the Tfh2 subset is critical, as targeting subsets like Tfh2 through vaccination may lead to stronger, longer-lasting protection against pathogens. Vaccine responses are one of the most effective ways we prevent infectious disease and protect vulnerable communities.

Abstract Name: Investigating the Possibility of Faster than the Speed of Light Travel

Can humans travel faster than light? This research explores the theoretical foundations and challenges associated with interstellar travel at speeds exceeding the speed of light. Current physical laws, particularly Einstein’s theory of general relativity, establish that nothing with mass can reach or exceed the speed of light. General relativity describes gravity as the curvature of spacetime caused by mass and energy, while quantum

mechanics explores phenomena at subatomic scales. Reconciling these two frameworks remains a major challenge in physics, yet theoretical models suggest possible avenues for faster-than-light travel. The study focuses on advanced concepts such as the Alcubierre warp drive, which proposes a “warp bubble” in which space in front of a spacecraft contracts and space behind expands, allowing effective faster-than-light travel without violating relativity. Key limitations include the need for enormous amounts of energy, exotic matter, and materials capable of withstanding extreme spacetime distortions. The work of Harold White and NASA’s Eagleworks laboratory has refined these models, proposing methods to reduce energy requirements and test spacetime curvature effects using sensitive instruments such as modified interferometers. Additional frameworks, such as the Chung-Freese metric, suggest that travel through extra dimensions may circumvent some relativistic limits. A 3D model of a warp bubble was designed and printed using TinkerCAD, providing a visual representation of the theoretical concept and aiding understanding of the associated physics. Although experimental confirmation is lacking, current research demonstrates that manipulating spacetime remains mathematically plausible and may inspire future technological innovations. While faster-than-light travel remains purely theoretical, this study highlights its potential to deepen understanding of general relativity, quantum mechanics, and their unification. It also emphasizes the importance of developing new materials, instruments, and experimental frameworks. Ultimately, studying warp drive concepts not only expands the frontiers of physics but inspire novel approaches to interstellar exploration and advanced space propulsion.

Abstract Name: Characterizing BATF3 Expression and its Impact on Human T-Cells

Basic leucine zipper transcription factor 3 (BATF3) is a member of the Activator Protein 1 (AP-1) family of transcription factors. Although first identified in human T-cells, most knowledge of BATF3 function derives from murine studies. In mice, BATF3 promotes T-cell survival, proliferation, and memory development, while its absence leads to impaired memory formation and increased apoptosis in CD8⁺ T-cells. Despite these findings, the role of BATF3 in human T-cells remains undefined. We hypothesize that BATF3 regulates proliferation and effector responses in human CD4⁺ and CD8⁺ T-cells. To test this, human T-cells were isolated from peripheral blood mononuclear cells (PBMCs) and divided into three groups: unstimulated, anti-CD3-stimulated, and anti-CD3+CD28-stimulated. Cells were stained with fluorescently conjugated anti-CD3, anti-CD4, anti-CD8, anti-BATF3, and anti-Ki-67 antibodies. Anti-CD27 and anti-CD45RO were used to assess BATF3 expression in differentiated human T-cell subpopulations. The data was acquired on CytoFLEX and analyzed using FloJo software. Our results show that BATF3 is upregulated in T-cells upon activation, with greater induction by anti-CD3+CD28 compared to anti-CD3 alone. BATF3 expression was higher in activated CD8⁺ T-cells than CD4⁺ T-cells. Interestingly, BATF3⁺ cells exhibited increased proliferation, suggesting its role in promoting T-cell proliferation. Further analysis revealed that BATF3 was predominantly upregulated in central memory (CM) CD8⁺ T-cells, indicating a functional role in memory T-cell subsets. Future studies will evaluate effector responses in BATF3⁺ vs. BATF3⁻ T-cells by measuring intracellular cytokines by flow cytometry. Our findings suggest that BATF3 expression is induced during human T-cell activation, preferentially in CD8⁺ T-cells, and is strongly associated with proliferative capacity. Enrichment of BATF3 in CM CD8⁺ T-cells highlights its potential role in memory transition and long-term immune competence. These observations extend murine findings into the human context and suggest BATF3 may act as a key regulator of proliferation and memory fate decisions in human T-cells.

Abstract Name: Preserving the past in spite of the Present: The Politics of Muslim and Jewish Heritage in Palermo

In April 2025, Palermo opened its first present-day synagogue, 533 years after the expulsion of Sicilian Jews. Similarly, since 1990, three mosques were inaugurated, marking the rebirth of Islam in Sicily since the 13th century. These events occurred in the context of a renewed interest in Sicily's multi-religious medieval past. Between street signs in Hebrew and Arabic and Arab-Norman UNESCO tours, this history faces an unprecedented memorialization. However, commemorating the past does not necessarily translate into multireligious coexistence in the present. During my ethnographic fieldwork in Palermo, I witnessed the city wrestling with the contradictory logics of memorialization: on one hand, the historical presence of Islam and Judaism in the city is acknowledged and capitalized on through tourism; on the other, present-day Muslim and Jewish communities struggle to negotiate their place in Palermo's urban space. How do these communities navigate living in a city that commemorates their past while disavowing their existence in the present? To explore this question, I conducted 13 semi-structured interviews with community members, and participant observation at cultural events. Additionally, I investigated built environment as a site where tensions concerning memorialization critically emerge. My investigation reveals that the conversion of former churches in mosques and a synagogue highlights a competing framework of memorialization. Bound to Italy's strict preservation laws, these architectural interventions must preserve the overall built environment. Therefore, in establishing new places of worship in former churches—and thus negotiating their place in Palermo's urban landscape—the Jewish and Muslim communities must compete with the memorialization of the pre-existing architectural forms. Consequently, Jewish and Muslim heritages fail to fully (re)establish a claim over Palermo's urban landscape in the present. In an religiously and politically fraught Mediterranean, Palermo's approach to memorialization highlights the challenges of dealing with cities' plural histories in a globalized and multi-religious present.

Abstract Name: From Data to Drug Design: Exploring the Molecular Hardness of G Protein-Coupled Receptors Active Sites

G protein-coupled receptors (GPCR) are a diverse group of cell surface receptors that bind ligands, undergo a conformational change, and initiate an intracellular signaling cascade through binding to a G-protein. The receptor group binds to molecules of a vast chemical space and is known to have regulatory role in functions ranging from growth sensation to hormone responses. This research investigates the chemical environment and hardness of GPCR active sites through protein visualization, electronic structure calculations, and

experimental docking analysis using molecules from chemical informatics database with known inhibitory potentials. Based on the hard-soft acid-base principle, it is hypothesized that the GPCR active site is predominately soft in nature due to its location within the cell membrane; however, several critical polar residues likely optimize ligand orientation. Characterization of this chemical environment will inform future drug design and research to optimize inhibition potential of GPCR receptors.

Abstract Name: Development and optimization of ex ovo culture methods for *Biomphalaria glabrata*

Schistosomiasis is a neglected tropical disease caused by parasitic flatworms of the genus *Schistosoma*, affecting over 250 million people worldwide each year. These parasites use freshwater snails, such as *Biomphalaria glabrata*, as intermediate hosts to complete their life cycle. There are potential gene candidates of interest that may play a role in the chemosensory attraction of the worms, allowing them to seek out the snail. Current methods for genome editing in *B. glabrata* are lacking. This research investigates the methodical development of an ex ovo culturing method for *B. glabrata* embryos and juveniles. Establishing this system is a key step toward future genome editing studies targeting candidate genes in the snail, enabling assessment of how disruption of these proteins may affect worm attraction. If transgenic snails with targeted gene knockdowns that prevent parasite-host recognition were introduced, a gene drive could spread these traits through wild populations, potentially reducing transmission and lowering the burden of schistosomiasis.

Abstract Name: Devouring as Creative Resistance in the Autobiographies of Artist Niki de Saint Phalle

This project investigates to what extent the metaphor of devouring functions as a mode of social resistance and self-construction in the autobiographical writings of Franco-American artist Niki de Saint Phalle (1930–2002). I examine how her three memoirs—*Mon Secret* (1994), *Traces* (1999), and *Harry and Me: The Family Years* (2006)—constitute a self-theorizing project in which literal and figurative devouring articulate how illness, sexism, and art-making frame and drive her work. Although de Saint Phalle has enjoyed international acclaim and been widely studied for her shooting paintings, *Nanas*, and monumental sculptures, her life writing has received virtually no scholarly attention, leaving the textual dimension of her self-construction as a contemporary woman artist as yet untheorized. In these texts, devouring takes on multiple meanings: de Saint Phalle's body is consumed by Graves' Disease and emphysema; incestual assault and patriarchal norms threaten to devour her autonomy; and she performs a counter-devouring through the violence of her shooting paintings and the scale and exuberance of her monumental sculptures. While limitations lie in conceptualizing devouring in terms of de Saint Phalle's physical and mental illnesses, it effectively functions as a metaphor for social resistance and self-formation across her writing and art. Her autobiographies are particularly heavily imbued with images of devouring, desire, revenge, and subsequent self-creation. Visual art, the epistolary form, and co-authorship often visually overtake written narratives, further disrupting traditional

autobiography. Methodologically, this project combines on-site research at her Tarot Garden in Tuscany, close textual analysis of her life writing, and visual analysis of artworks illustrative of devouring. Drawing on aesthetic theory, philosophies of sexuality—like Jean-Luc Nancy's chapter "Devouring" in *Sexistence*—and feminist life writing studies, I show how de Saint Phalle stages devouring as an act that simultaneously generates a new artistic self and practices intersectional feminist resistance.

Abstract Name: Structural Transitions in (CAG)_n DNA associated with Huntington's Disease

Trinucleotide repeats (TNRs) are repetitive three nucleotide sequences found in genes. TNRs are associated with the pathological effects of several genetic disorders such as Myotonic Dystrophy and Huntington's Disease. Expanded TNR DNA and RNA can form C-G mediated hairpins that affect structural stability. This research has explored (CAG)_n structure, a specific kind of TNR associated with Huntington's Disease, and examines environmentally induced structural changes using FRET and other spectroscopic techniques. The data has revealed that (CAG)_n DNA end-to-end distance increases with increasing temperature consistent with thermal denaturation of duplex structure. However, when the temperature is subsequently decreased, initial re-folding along the same path is then followed by a new conformational change to a state with increased end-to-end distance. The temperature at which this conformational change occurs is dependent on salt identities/concentrations. Notably, there is a release of Mg²⁺ ions from the (CAG)_n DNA at the temperature where significant structural changes occur. These results are highly suggestive of slippage, where base pairs in the DNA duplex become misaligned leading to an increased end to end distance. It has been demonstrated that (CAG)_n structure is highly sensitive to viscosity, and that the impact of viscosity is temperature dependent. Additionally, there seems to be a difference between the structure and stability of (CAG)_n with an even number of repeats and (CAG)_n with an odd number of repeats. A greater understanding of (CAG)_n structure, and the proposed slippage of base pairs within it, may offer insight into the mechanism of the disease.

Abstract Name: Rhythm and speech rate in Ventureño Spanish: A speech production study of Mexican American heritage speakers in Southern California

The present study examines the prosodic behavior (timing, rhythm, and pitch) of heritage Spanish-English bilinguals in Ventura County, California. It focuses on rhythm and speech rate in relation to bilingual identity, age of Spanish acquisition, and potential English-to-Spanish prosodic transfer. Building on a four-person pilot study, the current project has grown the sample size to seven heritage Spanish speakers (4 women, 3 men; ages 19-27), all fluent in both Spanish and English. Participants completed speech elicitation tasks (a reading

passage, semi-spontaneous scenarios, and monologues) that were audio-recorded for acoustic analysis. Praat software was used to segment recordings and extract rhythm and timing metrics, including percentage of vocalic time (%V), consonant-vowel (CV) rate, articulation rate, and variability indices (VarcoC, VarcoV) as well as the Pairwise Variability Index (PVI). Preliminary results from the semi-spontaneous scenario task indicate that heritage speakers' Spanish exhibits English-like prosodic features: higher consonantal timing variability, faster articulation rate, and a narrower pitch range relative to typical monolingual Spanish patterns. However, participants with stronger identification with Mexican culture exhibited more Spanish-like rhythmic properties. Overall, the spontaneous Spanish speech of these bilinguals displayed a blend of English and Spanish prosodic patterns. These results support the view that heritage bilingual prosody is shaped by both linguistic structure and sociocultural identity. While task type was not a strong predictor, some patterns suggest that controlled speech may elicit more English-like timing, whereas semi-spontaneous speech retains more Spanish-like rhythmic traits. Expanding the study to twenty participants will allow for stronger statistical modeling of how gender and ethnic orientation interact in shaping prosodic outcomes. This work contributes to the growing body of research on heritage Spanish and provides insights relevant to sociophonetics, bilingualism, and heritage-language pedagogy.

Abstract Name: El Lissitzky, the Man Who Abandoned His Culture for the Future

In the early 20th century, Russia was in a state of great change both politically and culturally. The Bolshevik Revolution brought down the Czar and instated a new communist regime focused on instilling a new cultural identity based on seeking the future. One of the focuses was on art, and few men exemplify this better than El Lissitzky. El Lissitzky was a founder of Suprematism and Russian avant garde, who was tasked with spreading the new Soviet ideals throughout Europe with his art. Lissitzky was raised Jewish but chose to forfeit his cultural identity for that of Russia; this paper will examine El Lissitzky's life and work, in an effort to deem the extent that the Soviet Union had on El Lissitzky as both a man and an artist. Keywords: El Lissitzky, Suprematism, Proun

Abstract Name: Behind Bars and Beside the Crib: Exploring Prison Nursery Programs in the U.S. and Their Impacts

This paper explores the impact of two models, prison nursery programs and community-based alternatives to incarceration, on the well-being of incarcerated mothers and their children. It aims to (1) examine how these models support maternal-child bonding and reduce recidivism, and (2) consider their potential as more humane, cost-effective alternatives to traditional incarceration. Drawing on feminist legal theories, carceral studies, psychology, and maternal health research, this paper engages in a theoretical and interdisciplinary analysis informed by feminist epistemology, which understands knowledge as partial, situated, and shaped by systems of power (Naples, 2014). The data for this paper come from a content analysis of peer-reviewed studies, policy reports, and documentary media focused on the lived experiences of currently and formerly

incarcerated mothers to illuminate the human impact of these models. Findings suggest that while both models offer measurable benefits, their effectiveness is shaped by eligibility restrictions, racial and systemic disparities, and underlying ideologies of punishment and care. Moreover, analyses demonstrate that centering the rights and needs of incarcerated mothers within rehabilitative frameworks is essential to building more equitable and restorative justice systems. By expanding access to prison nursery programs and community-based alternatives to incarceration, these models can preserve families and foster sustainable reintegration.

Abstract Name: Investigating a clade of pied harvesters (Opiliones: Cosmetidae) from Costa Rica

The order Opiliones, commonly known as harvesters or daddy long legs, is one of the most ancient and diverse lineages of arachnids, with over 6,500 identified species distributed across the world. The classification of taxa for Opiliones has been problematic when based on morphological data, and recent studies have now used effective genetic data. Opiliones play a major role in earthly habitats as both roles of predator and prey. Fossil evidence found all over the world has revealed that Opiliones have an ancient lineage that goes back 400 million years, demonstrating their remarkable stasis through evolutionary time. Despite their importance to the environment and forms of diversity, the evolutionary history of most groups of Opiliones has not been well studied. For example, the family Cosmetidae is the largest family of Opiliones with 723 species distributed throughout the Americas and the Caribbean Islands. There are hundreds of undescribed cosmetid species, but describing them will require a new approach to defining and delimiting the genera in this family. In this study, we apply a phylogenomic framework based on ultraconserved elements (UCE) to investigate the evolutionary relationships of a new species of Cosmetidae from Costa Rica. UCEs are a powerful genomic tool that provide detailed insights into the study of evolutionary history and have greatly advanced phylogenetic studies across diverse taxa. By generating and analyzing UCE data from a dense taxonomic sampling of Cosmetidae from Costa Rica, we aim to reconstruct a phylogenetic tree to clarify evolutionary relationships among lineages and investigate how cosmetid harvesters have diversified and adapted across multiple different habitats in the region. In addition, this project utilizes detailed morphological work including high-resolution images, digital illustrations, and precise morphological measurements, to produce a formal species description.

Abstract Name: Mental Health Disparities Among Hispanic Students in Horry County: A Policy and Public Health Perspective

Horry County's Hispanic families comprise a growing proportion of the total population, yet accessible, culturally competent pediatric health resources have remained stagnant. Hispanic children in this county face disproportionate barriers to care, including poverty, language differences, transportation challenges, limited insurance coverage, and stigma. 25.9% of Hispanic residents live below the poverty line. MRI studies show that children born into poverty have lower volumes of grey matter in frontal and parietal lobes, essential for processing information and execution, suggesting that socioeconomic disadvantage can impede cognitive development from early childhood. These social determinants of health contribute to adverse childhood experiences (ACEs) and poor health outcomes. If left unaddressed, these conditions will exacerbate gaps in health statistics, academic achievement, and behavioral health. Horry County presents a unique case study, as it contains densely populated and growing areas like Myrtle Beach and Carolina Forest, as well as smaller towns like Aynor and Loris. This geographic and socioeconomic variation contributes to uneven access to healthcare infrastructure, transportation, and school-based support. Schools are often the first point of contact for children experiencing mental or behavioral difficulties, yet a limited number of multicultural staff members can hinder effective support. This interdisciplinary project aims to analyze systemic and cultural barriers of mental health for Hispanic children in Horry County, identify available mental health resources, and propose policy- and community-based solutions to improve outcomes. This research will employ a mixed-methods approach. A literature review will be conducted with peer-reviewed studies and government data from PsycInfo, PubMed, and state health reports. Qualitative interviews will be conducted with key actors such as school counselors, local providers, policy officials, and families. The discussion will emphasize policy initiatives that expand bilingual counselor recruitment, rural mental health infrastructure, telehealth access, and school-community partnerships to promote culturally-responsive support for Hispanic children and families.

Abstract Name: The Asch Conformity Study Revisited: The Role of Gender

Gender inequality is pervasive in today's society. Stereotypes affect the way women are perceived by all genders, including women themselves. This study investigates gender differences in conformity to a unanimous majority, focusing on how gender influences behavior. Prior research suggests that women conform more often than men, due to internalized sexism and gender stereotypes. This study replicates Solomon Asch's classic line-judgment conformity study with the addition of participant and confederate gender as independent variables. Specifically, we examine whether men and women conform differently as a function of the gender of the confederates who provide social pressure by unanimously agreeing on an incorrect visual discrimination. Participants (24 men, 26 women), along with a group of five male or five female confederates, are directed to pick one of three lines they believe is the same length as a reference line for 18 trials, 12 of which are critical trials when the confederates give a unanimous incorrect answer. Participants' answers are observed on these critical trials. We predict that men will conform less to women than men, while women will conform more to men than to women. Preliminary results reveal an overall conformity percentage of 36%, which is not significantly different from the conformity percentage of 32% reported by Asch. Additionally, the overall conformity percentage for male participants was 29%, which is also not significantly different from what Asch found in his sample, which was exclusively male. In other words, conformity levels have remained relatively stable over time and were not significantly different from Asch's finding in his exclusively male sample. Our study is still ongoing, with no statistically significant results available regarding the impact of gender on conformity. The eventual results will provide insight into how gender influences conformity in various group decision-making situations—from the workplace to educational settings.

Abstract Name: What Are Gender Differences in Risk Aversion? Examining the Role of Gender in Final Jeopardy Wagers

This study will explore the differences in risk aversion between genders in the television show Jeopardy!. The literature suggests that men and women exhibit different behaviors toward risk aversion. Data for this study will be collected from a fan-made online source, J! Archive (<https://j-archive.com/index.php>). Using information from regular season episodes of Jeopardy! in 2024, statistical analyses will be conducted to evaluate relationships among variables such as gender, returning players, place in the competition, score before Final Jeopardy, and wager. The results will be interpreted to examine whether women are more risk averse in their wagers, if their risk aversion relates to their answer's correctness, and if more conservative bets correlate with lower overall winnings. The study will see if findings are shared by a similar study performed on Swedish Jeopardy! and explore which factors may affect risk aversion and self-confidence in wagering. The results of this study will contribute to the conversation about risk aversion in situations involving skill, and the pros and cons of risky versus conservative decisions. Additionally, it can explore how gender socialization contributes to behaviors in risk-taking and competitive environments. We hypothesize that women will bet a smaller proportion of their score on average compared to men, and women will bet a larger proportion when they are confident in their answer (when they answer correctly), than when they are not (when they answer incorrectly).

Abstract Name: Eigenvalue Bound Preservation: Numerical Experiments on the 2D Q-Tensor Flow

We study the evolution of nematic liquid crystals in two dimensions using the Q-tensor model, a continuum framework that describes the orientational order of rod-like molecules via symmetric, traceless matrices. Focusing on the Landau-de Gennes energy and its associated gradient flow, we consider a reduced two-dimensional formulation in which the Q-tensor is fully described by two scalar functions. This reduction simplifies the system to a nonlinear, coupled PDE for the scalars, while preserving essential physical features. A key question is whether the eigenvalues of the Q-tensor remain within the physically admissible range under this flow. Building on a theoretical result that establishes eigenvalue preservation for smooth solutions, we perform numerical simulations using a slightly modified version of the Crank-Nicolson method to verify this behavior. Our results confirm the robustness of the eigenvalue constraint across various initial configurations, providing computational support for the physical consistency of the model.

Abstract Name: A Qualitative Approach to Understanding Racial Identity Stability and Fluidity among Biracial Young Adults

Biracial individuals are one of the fastest growing populations in the United States, and while literature is growing, there are gaps in existing research regarding this population's ethnic-racial identity processes, including racial identity stability and fluidity. The current study examined whether racial identity was stable for Biracial individuals of African descent. Participants were young adults, ages 18 to 25, who had at least 1 parent of African descent, so it included monoracial and Biracial individuals. A survey was given that included a qualitative section, which asked about individuals' racial identity stability. Using the lifespan model of ethnic-racial identity as the framework, we developed a codebook based on participants' responses to questions on their racial identity stability and fluidity, and then understanding what the individual attributed their racial stability to, which are known as "influencers of racial identity". Our results aligned with various influencers posited in the lifespan model, and included local current context (e.g., neighborhood, school), individual characteristics (e.g., phenotype), identity-relevant experiences (e.g., family rejection, racial invalidation), and developmental considerations (e.g., racial identity evolution over time). Methodological reflections reveal challenges in writing a codebook, including identifying narratives and ensuring ambiguity, relationality, and variability in context. This work expands the literature by offering an application of the lifespan model, and evaluation of racial identity specifically in Biracial individuals of African descent, a population that is largely underrepresented in racial identity research. Results also indicated that Biracial participants experienced more fluidity in their identity compared to the monoracial participants. Findings highlight the importance of research and interventions that are inclusive of the diverse experiences of monoracial and Biracial Black individuals.

Abstract Name: Meeting the Needs of Women within the Tabletop Gaming Hobby through Furniture Design

The Elytra Chair is designed for women interested in tabletop game playing. Today, women make up 39% of the tabletop game player population who contribute millions of dollars to the gaming market. Tabletop gaming encapsulates a wide range of games such as fantasy roleplaying, board games, card games, and more. These games require a lot of space such as for appropriate playing surfaces and storage for game pieces which may not be available to all players. The space requirements for tabletop gaming hobbies has a tendency to create limits for players who are unable to procure an adequate space. Thus, the Elytra Chair offers a variety of solutions for the space demands of the hobby. This includes a small retractable table within the arm of the chair that can be moved and adjusted as needed as well as a small cup within the arm that can be used to hold dice and other pieces that may be used for a game. This will allow players in the chair to use the small table during gameplay as well as the cup for temporary storage of items. Additionally, the chair is a standard width and height which allows it to be used with dining tables and desks, widening the range of use of the chair. The aesthetic design of the Elytra Chair is informed by the hard shell, segmented legs, and wings of a Goliath beetle which connects to the fantastical nature of tabletop roleplaying games such as Dungeons and Dragons or Pathfinder. Considering that the chair was designed with women in mind, the components have a smaller scale to fit a woman's smaller frame and more feminine sensibilities. Overall, the Elytra Chair uses fantasy inspired imagery to create seating that resolves the space needs for a tabletop game player.

Abstract Name: Improving the Quality of Life in a Senior Assisted Living Environment through Biophilic Design

Assisted living facilities have a variety of issues that interfere with the quality of life of its elderly residents. This includes crowded and loud dining rooms, lack of storage in the bedrooms, and harsh lighting from overhead lights and east facing windows. This project focuses on celebrating the experiences and hard work of older adults, enhancing their overall well-being, and creating a welcoming environment that promotes connection and comfort. A functional solution was developed through a combination of literature review, interviews with assisted living facility staff and residents, and precedent study research. Research suggests that biophilic design provides a connection to nature that promotes good mental health, creates a calm atmosphere, and provides an aesthetic quality. For these reasons, biophilic design directly informs the decisions made throughout the design process of the assisted living facility. Additionally, wayfinding takes into consideration visual, physical, and memory impairments in creating a solution that improves navigation for elderly residents. Key design solutions include providing furniture with high seat and armrests, arranging furniture to promote social interaction, incorporating high contrast molding and handrails for improved wayfinding, and using strategically placed bright colors to create distinctive focal points. The overall design incorporates a biophilic aesthetic with landscape mural wallpapers featuring harvest-inspired imagery. A

complementary palette drawn from the bright colors of Glass Gem corn, such as deep yellows, blues, greens, and oranges, adds bold contrast throughout the space. The idea is carried into the furniture through tufting that reflects linear, kernel-like patterns, providing familiar, easy-to-read visual cues and tactile texture that support comfort and orientation for older adults. Overall, the design honors hard work, gratitude, and the simple joys of life, creating an environment where seniors can find comfort in their daily living experience.

Abstract Name: Title: Cognitive Biases in Jury Decision making and implications for Legal practice

This study explores how trial lawyers identify, manage, and mitigate juror biases during real trials, with a focus on cognitive biases and their influence on trial outcomes. The research aims to uncover the strategies attorneys use in jury selection, voir dire questioning, and bias mitigation techniques, as well as their perceptions of juror impartiality and the overall fairness of trials. Data will be gathered through interviews with experienced attorneys, who will share their insights on how cognitive biases such as confirmation bias, anchoring, and implicit racial biases affect juror decision-making. The study integrates concepts from psychology and law, examining how factors like the framing of evidence, the presentation style of attorneys, and juror social dynamics influence verdicts. It will address how attorneys assess potential jurors, manage challenges related to implicit biases, and adapt their strategies during trial to ensure fairer outcomes. Attorneys will also reflect on their experiences with bias reduction techniques, such as pre-trial jury instructions and the use of peremptory challenges. The research draws on existing literature, including studies by Ingriselli (2015) and Kang et al. (2012), which emphasize the importance of addressing biases early through debiasing instructions. Additionally, Kaplan and Miller (n.d.) explore how evidence reliability and courtroom behaviors shape juror verdicts, while Sommers and Norton (2008) and Curley et al. (2022) highlight how social pressures and cognitive overload during deliberations can influence decisions. Through interviews, the study will gather qualitative data on how attorneys perceive these factors and manage juror biases, ultimately offering insights into improving jury selection, trial strategies, and fairness in the courtroom.

Abstract Name: Effect of light variation conditions on the comparison of fired bullet evidence.

In recent years, ballistic evidence and examination has been heavily scrutinized in courts and have often been deemed inadmissible due to judges finding that the method of analysis isn't "scientific". This study examined how different light conditions, specifically light angle, affect the comparison of fired bullet evidence. The goal of this study is to find how different light angles affect ballistic identification features and whether the light angle under which fired bullet evidence is examined affects the conclusions drawn about the evidence". Using a comparison microscope, a scissor jack, and multiple different tripod heads, we were able to adjust

our light source to let us control what angle the light was shining on our samples. Digital images of our samples were then taken at different angles of light and transferred to a computer for analysis using a photo editing software that allowed us to compare images side-by-side. Preliminary results show that light angles significantly affect how examination of fired bullet evidence is conducted and how results vary because of it. Some results show that angle differences of just 3-6 degrees can completely change some of the features that would otherwise be used for an examiner to confidently give a positive result or a negative result. These results can drastically change the field of ballistic forensic science since changes of the light angle can be so minute, but still have huge impacts on an examiner's conclusion. One direction this could take in the future is to find how light angle might affect a confocal microscope and possibly find the degree of error adjusting light angles bring.

Abstract Name: Bedtime Procrastination, Doomscrolling, and Loneliness

Bedtime Procrastination (BP), purposefully delaying one's sleep, is a problem that many students struggle with. Prior research has shown possible correlations between BP, doomscrolling (i.e., flooding your social media with negative content for extended periods of time), and loneliness (i.e., a disconnect between one's desired amount of social connection and the actual amount of connection). Therefore, this study assessed both doomscrolling and loneliness to determine if they were predictors of BP. The data in this study were collected from five undergraduate classes: Behavior Science Statistics, Issues in Science, Concepts of Mathematics, Abnormal Psychology, and Investigating Terrorism, consisting of a total of 104 participants (75 women; 28 men; 1 "prefer not to say") of varying ages and college classification. The instruments used were the Reasons for Bedtime Procrastination Scale (RBPS), the Doomscrolling Scale (DS), and the Revised UCLA Loneliness Scale. The results of a multiple regression analysis revealed that doomscrolling scores significantly predicted bedtime procrastination scores. Loneliness scores and gender were not significant predictors of bedtime procrastination. Practical implications, limitations, and recommendations for future research were discussed.

Abstract Name: Determining Circulating Levels of NT-proBNP in Mice Using Sandwich ELISA

Cardiovascular disease is the leading cause of death in patients with chronic kidney disease (CKD), so identifying early biomarkers of cardiac stress is essential for improving diagnosis and treatment. This study aims to measure changes in a common cardiovascular disease marker within a CKD mouse model induced through adenine diet supplementation. Adult male and female mice were fed either a 0.2% Adenine diet to induce CKD or a standard chow diet to serve as the healthy control for up to 12 weeks. Plasma and serum

samples were collected every 3 weeks to measure N-terminal pro-Brain Natriuretic Peptide (NTpro-BNP), a circulating biomarker of left ventricular remodeling released by cardiomyocytes. NTpro-BNP concentrations were quantified using a sandwich Enzyme-Linked Immunosorbent Assay (ELISA). Adenine-fed male mice exhibited increased NTpro-BNP levels at week 6 ($203.13 \text{ pg/mL} \pm 0.489714$), much earlier than adenine-fed females ($90.26 \text{ pg/mL} \pm 0.489714$). Adenine-fed female mice had an increase in NTpro-BNP as the weeks progressed (Week 3: $75.67 \text{ pg/mL} \pm 0.489714$, Week 6: $93.72 \text{ pg/mL} \pm 0.489714$, Week 9: $166.84 \text{ pg/mL} \pm 0.489714$, Week 12: $173.84 \text{ pg/mL} \pm 0.489714$). There are not enough male mice at later timepoints to determine a pattern due to the lack of survivability of male mice at later timepoints using the CKD model. There were no significant changes in the control group as the weeks progressed. Consistent with the previous studies by our lab identified sex-specific differences in cardiac function and electrophysiology in adenine-induced CKD mice. These findings suggest that adenine-induced CKD promotes cardiac stress, and disease progression differs between sexes.

Abstract Name: Investigation of the Lewis Basicity of Small Organics Interacting with Uranium Hexafluoride

Utilizing computational chemistry, we aim to expand the understanding of how organic functional groups interact with uranium hexafluoride (UF₆). This fundamental knowledge may guide future strategies for repurposing the United States' surplus of 700,000 tons of depleted UF₆ created from uranium enrichment. By quantifying how functional groups distort and bind to UF₆, we seek to characterize which functional groups most effectively bind to UF₆ to form an adduct. A series of functional groups were screened to determine which led to the greatest disruption of the octahedral geometry of UF₆. Functional groups containing only nitrogen heteroatoms exhibited higher intermolecular binding energies (IBE) with UF₆ compared to groups containing nitrogen and oxygen, or oxygen alone. These results indicate that UF₆ has a stronger preference for coordination with nitrogen lone pairs than with oxygen lone pairs. Furthermore, increasing angular deviation of the UF₆ octahedral geometry correlated with higher IBE values, indicating the formation of stronger adducts. Additionally, early results reveal that IBE values for UF₆ adducts align with trends observed in the BF₃-affinity scale, a widely used proxy for the Lewis basicity of organic functional groups. This correlation suggests that UF₆ and BF₃ may exhibit similar binding behaviors despite the different molecular geometries of the two Lewis acids. Understanding these parallels can help establish predictive models for UF₆ adduct formation and guide the identification of functional groups for these strong interactions. Our ongoing work continues to probe these relationships to advance the understanding of Lewis basicity and potential reactivity within UF₆ chemistry, while further exploring the parallels between UF₆ and BF₃.

Abstract Name: Issues with Rental Housing Quality in Dunn County

In Dunn County, 33% of the population are renters. This study aims to look at what Dunn County renters' current issues are, if these issues are across the board or specific to certain landlords/rental companies, if safety is a concern of renters, and how renters feel about their landlords versus how landlords perceive themselves. To identify trends and potential persistent issues, a survey of University of Wisconsin Stout students (who make up a large percentage of renters in the county), interviews with landlords, and 10 years of previous housing quality complaints in Dunn County were leveraged. Surveys indicated that UW-Stout students' largest issue was landlords and rental companies not fixing things in a timely manner. 33% of students from the survey reported issues with landlords and rental companies not responding to complaints, and 54% reported that it takes "a few days" to fix an issue. However, 46% reported that it takes around "a few hours" to reply. Further, 52% of the respondents from the survey reported issues with mold, 42% reported utility issues, 33% reported issues with bugs, and 21% reported issues with the return of their security deposits. No matter the landlord/ rental company many renters faced similar issues and came to the same consensus that they believed their landlord or rental company just didn't care. In contrast, in the interviews with landlords, they perceived themselves as being very reliable, easy to communicate with, and respectable. This is a very different view than that held by student tenants, and the two different perspectives added to my understanding of how miscommunication and lack of knowledge can cause issues to get out of hand fast. If a community wants to better address rental conditions holistically, they will first need to get landlords and renters to agree on a singular experience.

Abstract Name: Effects of Estrogen and Acetylcholine Depletion on Spatial Memory: Assessing E/P Therapy in a Rat Model of Female Aging

Aging in women is often accompanied by decreases in circulating estrogen and acetylcholine levels caused by menopause and Alzheimer's disease respectively. Both of these declines have been linked to impairments in memory recall and decreased overall cognitive functioning. Previous research has investigated the memory impairments caused by estrogen and acetylcholine depletion, however little is known about whether hormone replacement therapy via estrogen and progesterone (E/P) injections is a viable treatment to overcome these impairments. This project investigates the effects of estrogen and acetylcholine loss on spatial memory, and evaluates the potential of E/P therapy as a treatment for spatial memory impairment. Sixteen female Long-Evans rats were trained on a radial arm maze (RAM) to establish baseline spatial memory performance. All rats then underwent ovariectomy surgery (Ovx) to induce estrogen depletion, followed by one week of recovery. The rats were then divided into four groups ($n = 4$): (1) OvX-only with no E/P treatment, (2) OvX-only with E/P treatment, (3) OvX + scopolamine-induced acetylcholine depletion with no E/P treatment, and (4) OvX + scopolamine-induced acetylcholine depletion with E/P treatment. Spatial memory recall was reassessed using the RAM, with the same arms baited as in the original pretest. Working and reference memory errors were recorded in a standardized format, allowing for the comparison of errors made between each of the four testing conditions; with more errors indicating further impaired spatial memory. By comparing performance across groups, this study examines how estrogen and acetylcholine depletion interact to influence spatial memory, and whether E/P therapy can reduce memory impairments associated with female neuroendocrine aging.

Abstract Name: Glial Expression of Neuronal Marker MAP2 in Vitro and in Vivo

Microtubule-associated protein 2 (MAP2) plays a role in neuronal microtubule assembly. Although MAP2 expression was reported in injured astrocytes decades ago, this protein is widely used today as a neuron-specific marker. Here we report MAP2 expression in rat primary astrocyte cultures, using two independent antibodies. We also confirmed prior reports of in vivo MAP2 expression in murine GFAP⁺ astrocytes. Astrocytes expressed a low-molecular mass isoform of MAP2 but not the neuron marker NeuN. Control primary cultures containing neurons expressed two isoforms of MAP2 and abundant NeuN. Treating astrocyte cultures with paraquat and hydrogen peroxide or increasing the passages number did not increase MAP2. The proteasome inhibitor MG132 affected neither MAP2 nor GFAP expression in primary astrocyte cultures. Thus, additional MAP2 may not be expressed in cultured astrocytes, as they have already undergone intense gliosis. These findings have significant implications for the common use of MAP2 as a marker of neurons.

Abstract Name: The Identification of a Safer Alternative to BPA using a Zebrafish Model

Bisphenol compounds, such as bisphenol-A (BPA), are linked to negative health outcomes like diabetes, obesity, and hormone-dependent cancers. BPA and BPA analogs like bisphenol-B (BPB) and bisphenol-C (BPC) are found in products such as plastics, thermal receipts, and food packaging. BPA, an endocrine disruptor, binds to and activates estrogen receptors. Previous studies have identified bisguaiacol-F (BGF) as a potential replacement for BPA due to lack of estrogenic activity. Our research uses a zebrafish model to determine the effects of BPA, BPB, BPC, and BGF on development and seeks to determine if BGF is a safer alternative. Our acute toxicity experiments have identified BPC as the most toxic with BGF being the least toxic at 96 hours post fertilization. The LC₅₀ values for the compounds are as follows: BPC ($16.0 \pm 1.1 \mu\text{M}^*$), BPB ($24.0 \pm 2.6 \mu\text{M}^*$), BPA ($35.3 \pm 1.3 \mu\text{M}^*$), and BGF ($82.3 \pm 0.8 \mu\text{M}^*$) (mean $\pm$ SEM, of at least three independent experiments, *p < 0.05). Ongoing studies include effect on expression levels of known estrogen-responsive genes such as vtg1, vtg3, and cyp19a1b and the expression levels of estrogen receptors ER α , ER β 1, and ER β 2. RNA-seq will establish a transcriptional profile of these of each compounds at 24, 48, and 72 hours post fertilization. Genes with altered expression levels identified from RNA-seq will be confirmed and quantified using real-time quantitative polymerase chain reaction (qPCR). Genes of interest will be classified according to their function. Our studies using a zebrafish model will further understanding of the health risks posed by potential environmental toxins.

Abstract Name: The Influence of Social Essentialism on Reader Identity Development and Comprehension

Reading comprehension is critical for college students' success, which can be influenced by their reader identity and reading motivation. Social contexts can shape reader identity, and social essentialism may predict it. Social essentialism relates to a belief system that maintains social groups have inherent, fixed properties. Although evidence exists that essentialist beliefs influence sociocultural identity, little is known about its effect on reader identity. Moreover, despite overwhelming evidence of the influence of social factors on motivation, the literature is scant about the role of social essentialism in college students' reading motivation. Given the impact of comprehension on postsecondary achievement, it is crucial for educators to identify the social predictors of reader identity and reading motivation and understand how reader identity and reading motivation influence comprehension. As such, the present study asked: (1) How do students' social essentialist beliefs influence students' reader identity and motivation? We also replicated prior studies to explore two additional questions: (2) How are students' reading motivation and reader identity predicted by other social factors (3) How are students' reader identity and reading motivation related to their reading comprehension? Undergraduate students (N = 132) attending a public university in the Southeastern USA completed a survey online and were assessed on their social essentialist beliefs, reader identity, and reading comprehension. We found that stronger essentialist beliefs on cohesiveness and naturalness were positively associated with reader self-efficacy and utility value. However, the naturalness dimension was positively correlated with reader identity, metacognitive self-regulation, and motivation. Cohesiveness beliefs were positively related to students only reading for academic purposes. Interestingly, a multiple linear regression revealed that family was the only significant predictor for reader identity and motivation. Finally, the students' reader identity and motivation were associated with greater reading comprehension. Implications include insight for educators and families to develop adaptive reader identity.

Abstract Name: Reframing Pre-Service Teachers' Beliefs: Investigating Post-Intervention Discussions on Implicit Biases

This study examines whether counter storytelling can reduce implicit racial bias among pre-service teachers. Prior research shows that implicit attitudes influence teachers' expectations, disciplinary decisions, and interpretations of student behavior. These patterns contribute to racial disparities in education. Because teachers play a central role in shaping students' academic and social outcomes, understanding whether bias can shift during teacher preparation is important. Guided by Critical Race Theory (CRT), this project investigates whether exposure to counter stories, which are narratives from people of color that challenge dominant racial assumptions, can influence subconscious beliefs. This project used a quasi experimental design. Ninety-five first-year education majors at a liberal arts university completed the Race Implicit Association Test (RA-IAT) before and after an instructional intervention based on the novel *Caste*. Fifty-nine

students participated in the counter storytelling intervention. Thirty-six students served as a control group. ANCOVA results showed that although both groups demonstrated implicit pro-White bias, students who engaged with counter stories showed a trend toward reduced bias after the intervention. Qualitative data from focus groups added depth to these findings. Participants described encountering perspectives they had never heard before and noticing how racial narratives become normalized in society. Many reflected on their own assumptions and explained that unlearning bias requires active work rather than a colorblind approach. Taken together, the quantitative and qualitative findings suggest that counter storytelling can help pre-service teachers begin to challenge biased thinking. Although these results are preliminary, they point to the value of including narrative-based racial equity coursework in teacher education programs. Future cycles of data collection will strengthen understanding of how counter stories shape implicit attitudes and how this learning might influence classroom practice. Overall, this study highlights the potential for teachers to reduce bias by listening to voices that are often overlooked.

Abstract Name: Social Pathways to Belonging: Investigating Involvement, Friendships, and Campus Connection

Despite research identifying sense of belonging as a key predictor of persistence, engagement, and well-being in higher education, less is known about how close friendships developed on campus shape belonging within institutional environments. While campus involvement is assumed to strengthen belonging, this outcome may vary based on the students' friendships, depth of involvement experiences, and the broader institutional context. Furthermore, the relationships among these variables may differ at larger universities, where students may struggle to build meaningful friendships despite high campus involvement. This raises the question: if involvement supports belonging, where does this relationship falter with actively involved students? To address this gap, this study asks: To what extent do extracurricular involvement, campus friendships, and leadership involvement predict students' sense of belonging, and do campus friendships mediate the relationship between involvement and belonging? This project uses secondary data from an institutional survey administered to a random sample of students at a large, public research institution in Spring 2025. In this study, involvement is defined as participation in campus events and student organizations; friendships are measured by the number of close friends on campus; and belonging is measured using a multiple-choice scale reflecting students' perceived connection to the institution and its community. Demographic characteristics (gender, race/ethnicity, first-generation status, student level, housing) and extraversion will serve as controls. To examine the research questions, hierarchical multiple regression will be used to analyze the predictive contributions of involvement, friendships, and leadership. A mediation analysis will then test whether the number of close friendships mediates the relationship between involvement and belonging. By investigating these relationships, the study aims to offer insights into how students' social networks may shape their sense of connection at the university, while also informing strategies to foster stronger community and support student well-being.

Abstract Name: Extending the Essentially Entropic Lattice Boltzmann Method to Three-Dimensional Turbulent Flows

The Essentially Entropic Lattice Boltzmann Method (EELBM) has demonstrated strong numerical stability and accuracy for two-dimensional simulations, particularly at higher resolutions where the entropic formulation introduces only minimal stabilizing turbulent viscosity and eventually converges to the Lattice Bhatnagar–Gross–Krook (LBGK) formulation. This built-in stabilization can be interpreted as an implicit large-eddy simulation (LES) model, allowing EELBM to capture complex turbulent behavior without requiring explicit subgrid-scale closures. While these advantages have been thoroughly validated in 2D, understanding how the entropic constraint regulates dissipation in three dimensions is essential for assessing EELBM's suitability for practical, turbulence-dominated applications. This work focuses on the development and evaluation of a three-dimensional EELBM solver based on the D3Q27 lattice and assesses its performance on representative turbulent flow configurations. The study considers flows in which inherently three-dimensional structures and vortex dynamics play a central role, including the cubic lid-driven cavity and flow over bluff-body geometries. Simulations will be conducted across a range of Reynolds numbers, Mach numbers, and grid resolutions to evaluate numerical stability, accuracy, and the effectiveness of the entropic stabilization mechanism. A central component of this investigation is quantifying the stabilizing viscosity produced by the entropic condition and determining how this effective turbulent viscosity scales with resolution and local flow gradients. Understanding this behavior is critical for predicting the degree of under-resolution the model can accommodate and for informing prospective users about the method's implicit turbulence-modeling characteristics. Successfully demonstrating stable and accurate performance in three dimensions would significantly expand the applicability of EELBM and establish it as a robust, entropy-driven alternative to traditional LES approaches for complex turbulent flows.

Abstract Name: Quantitative Assessment of Wellness Among Caregivers of Children with IDD's Using the Five Factor Wellness Inventory

An estimated 13.6 million children in the United States live with special health care needs, including intellectual and developmental disabilities (IDDs). IDDs can affect behavior and cognition, limiting children's ability to perform daily activities such as managing oral hygiene. Consequently, caregivers play a central role in supporting oral health for children with IDDs. However, little is known about how caregiver wellness shapes oral health caregiving. This study is part of a larger mixed-methods project examining how caregiver wellness influences oral health caregiving for children with IDDs. The present analysis reports the quantitative component, which assessed caregiver wellness using the Five Factor Wellness Inventory (FF-WEL). The FF-WEL is a strength-based, multidimensional instrument with 91 scored items covering five domains: creative self, coping self, social self, essential self, and physical self. Responses yielded overall and subdomain wellness scores, and descriptive analyses examined scores by sociodemographic and caregiving characteristics. Thirteen caregivers enrolled, all identifying as women. On average, participants had served as caregivers for 9.5 years (range: 2–17), and most (69%) cared for a child with Down syndrome. Total wellness scores ranged from 61.26 to 82.97 (median: 73.9). Social self had the highest subscale scores (range: 71.8–100; median: 87.5), while physical self scored lowest (range: 57.5–92.5; median: 67.5). These quantitative findings offer an initial snapshot of wellness among caregivers of children with IDDs, highlighting strengths in social well-being and potential needs in physical wellness. Results can inform targeted supports and interventions to bolster caregiver holistic wellness, which may in turn improve oral health caregiving and

child outcomes. These results may inform national practice and policy as outlined in the Blueprint for Change Framework.

Abstract Name: From Past Burdens to Finding Peace Through Spirituality

Regret is an emotion that arises when individuals reflect on past decisions and recognize that different choices could have led to better outcomes (Beike et al., 2009; Kahneman & Tversky, 1982; Roeser & Summerville, 2007). Although previous research has explored cognitive and emotional mechanisms underlying regret, less attention has been given to how spirituality influences the experience and interpretation of regret. Spiritual beliefs may serve as a framework for meaning-making and forgiveness or, conversely, heighten guilt and self-blame (Pargament et al., 2011; Yamada et al., 2020). The present study aims to examine how positive and negative religious coping styles relate to the intensity of regret experienced after decisions that fail either by action or inaction. Approximately forty undergraduate participants will complete the Brief RCOPE, read scenarios depicting regrettable action or inaction, and rate anticipated regret. This will allow us to examine how positive and negative spiritual coping influence regret using a 7-point scale. It is hypothesized that positive religious coping will be associated with lower levels of regret through self-forgiveness and meaning-making, whereas negative religious coping will be associated with higher regret intensity, particularly for decisions involving moral conflict. It is anticipated that participants with higher levels of religiosity will report stronger regret, consistent with heightened moral sensitivity. However, among those engaging in positive religious coping, this relationship is expected to weaken, reflecting the protective role of forgiveness and acceptance. Conversely, individuals high in negative religious coping (e.g., perceiving punishment from God) are expected to report greater regret intensity, particularly for moral violations stemming from action. These expected findings will extend research on the intersection of emotion and spirituality by clarifying how faith-based coping frameworks influence counterfactual reasoning and self-evaluation. Understanding these dynamics may guide interventions that incorporate spiritual coping to promote emotional resilience, self-compassion, and adaptive growth following regret.

Abstract Name: Finding Life Satisfaction Through a Week of Gratitude

Although many people dedicate time to achieving their goals, a deep sense of life satisfaction often remains elusive even after success. Gratitude journaling, the practice of noting things you are thankful for each day, is a simple and effective way one can try to enhance their well-being. Focusing on gratitude may help gently shift one's perspective, ease emotional burdens, and help life feel more fulfilling. The purpose of this

proposed study is to examine the impact of daily gratitude journaling on life satisfaction. Research has found that practicing gratitude promotes a positive outlook on life, further improving one's well-being (Chauhan et al., 2025). Therefore, we expect that practicing gratitude, even for just a week, can improve one's outlook on life and in turn, their perceived life satisfaction. To test this, participants will complete the Satisfaction with Life Scale (SWLS) (Diener et al., 1985) to measure their baseline of life satisfaction. Then, over a seven-day period, participants will practice gratitude journaling, writing down three things they are grateful for each day, and will conclude by completing the SWLS again to assess any changes in life satisfaction. It is hypothesized that participants will perceive higher life satisfaction after the gratitude journaling period than at baseline. These findings would be consistent with previous research showing that gratitude journaling can help reduce stress and negative emotions (Fekete & Deichert, 2022), and that practicing gratitude can elevate one's well-being by supporting better mental health (Chauhan et al., 2025). The proposed study aims to add to the growing evidence that gratitude journaling can help improve perceived life satisfaction. This could be especially beneficial for individuals looking to improve their life satisfaction through mindfulness-based practices like gratitude, as well as for those hoping to improve their well-being over a short period of time.

Abstract Name: Typing Patterns Never Lie: Robust Behavioral Biometrics with Hybrid Ensembles

Mobile devices have become indispensable; existing authentication methods such as PINs and passwords verify users only once at login, leaving devices exposed afterward. Continuous Authentication (CA) mitigates this risk by continuously verifying user identity during interaction. Among CA techniques, touch-based behavioral biometrics are particularly promising because they require no special hardware and can unobtrusively capture unique user patterns. This paper proposes a hybrid one-class ensemble framework for robust continuous authentication using large-scale mobile typing data from over 30,000 users. Our approach combines One-Class Support Vector Machine (OC-SVM) and Isolation Forest (IF) anomaly detectors through score-level fusion, reinforced with Hard Negative Mining (HNM) and cross-shard impostor simulation to ensure generalization against unseen attackers. Using a 12-feature standardized set capturing timing, rhythm, and error dynamics, our system achieves an average AUC of 0.97 and EER of 2.9%, with over 90% of users below 5% EER. These results demonstrate that ensemble-based one-class modeling with hard negative refinement can deliver exceptionally reliable continuous authentication without requiring labeled impostor data.

Abstract Name: Lewy Body Dementia in King Lear

Lewy Body Dementia involves cognitive impairment, irrational behavior, hysteria, and confusion. These

symptoms are clearly evident in King Lear through his behavior and others' responses to his actions. Although diagnosing a fictional character doesn't fully account for a disease's complexity, King Lear's diagnosis helps readers gain a deeper literary understanding and empathy for dementia patients overall. It examines the symptoms of cognitive decline, including delirium, psychosis, and depression, emphasizing the importance of distinguishing these symptoms from normal aging. Modern clinical descriptions of dementia, particularly Lewy Body Dementia, provide a framework for identifying key behavioral and cognitive characteristics, which can then be compared to King Lear's actions and interactions throughout the play. At the same time, this analysis acknowledges ethical and methodological concerns regarding the application of medical diagnoses to fictional characters, addressing counterarguments about the limitations of assigning clinical labels to literary figures. By combining textual evidence from the play with established medical knowledge, King Lear can be validly diagnosed with Lewy Body Dementia and his diagnosis can be used to improve understanding and empathy towards dementia patients overall.

Abstract Name: General Position Colorings and Graph Powers

In mathematics, a graph G (sometimes called a network in other fields) is a set of vertices (or nodes) that are connected by edges. When two vertices are connected by an edge, we say that these vertices are adjacent to one another. In mathematics and computer science, as well as in many other areas of inquiry, both practical and theoretical problems can often be modeled using graphs. In this project, we study a way of selecting special sets of vertices in a graph so that no shortest path of a given length in the graph contains more than a predetermined number of vertices. We also study how to color the vertices of a graph so that each color class satisfies this same restriction. These two ideas lead to two numerical measures of a graph: (1) the k -general d -position number, which records the largest possible size of such a restricted set, and (2) the k -general d -position chromatic number, which records the smallest number of colors needed to produce a coloring in which every color class satisfies the restriction. We establish several basic relationships between these two measures and explore how they change when we take powers of a graph, a standard operation that connects vertices that are within a fixed distance of each other. For graphs that come from powering a path, we give exact formulas for both measures. For cycle graphs, we obtain an exact formula for the k -general d -position chromatic number. We determine an upper bound for the k -general d -position number of any graph power in terms of the original graph, and a similar lower bound for the k -general d -position chromatic number.

Abstract Name: Occupational Teleworkability and Long-Term Post-Pandemic Labor Market Disruptions

Using National Longitudinal Survey of Youth 1997 (NLSY97) data, I study whether pre-pandemic occupational teleworkability is related to long-term post-pandemic labor market disruptions, as measured by changes in earnings, labor force participation, and hours worked. Past research has shown that those who had occupational teleworkability during the pandemic fared better than those who didn't, but has not looked at the long-term implications of occupational teleworkability on long-term labor market disruptions from the

pandemic. Past research has also used mostly cross-sectional studies; using longitudinal data on individuals to track changes over time for each individual allows me better control for individual heterogeneity than cross-sectional studies. Multiple models will regress teleworkability in 2019, sex, race, ethnicity, education level in 2019, census regions in 2019, industry in 2019, and marriage status in 2019 on the difference in income between 2018 and 2020/2022, the difference in hours worked between 2019 and 2020/2021/2022, whether a person who worked in 2019 stopped working in 2020/2021, and whether a person changed occupation between 2019 and 2020/2021. I expect to see that having an occupation with low teleworkability will lead to a decrease in income differences and an increase in the likelihood that participants drop out of the labor force. I expect to see no effect on the difference in hours worked and the likelihood that participants change occupations. Preliminary results show that pre-pandemic teleworkability has a negative effect on the income difference between 2018 and 2020, and whether a participant stopped working between 2019 and 2020.

Abstract Name: Downward Nominal Wage Rigidity: An Application Analysis

In Real Business Cycle models, there are sometimes different approaches to imposing constraints. Downward Nominal Wage Rigidity (DNWR) is a popular constraint used to amplify business cycle downturns, which has been introduced in an ad-hoc manner instead of being explicitly included in the household's wage-setting problem. In the ad-hoc model, the household solves its wage-setting problem, and then DNWR is ex-post imposed on the resulting equilibrium wage in a simple labor market. In this paper, we modify a simple New Keynesian model such that the household has wage-setting power and refuse to accept a wage below a certain threshold. We include the DNWR constraint in the formulation of the household's optimization problem, and they choose their current wage to be weakly greater than or equal to their previous wage. This naturally introduces the constraint into the model as the household's first-order equilibrium conditions account for the DNWR constraint. Using MATLAB, we obtain a global nonlinear solution nonlinear to both models. Then we will compare our model to the ad-hoc model by looking at business cycle moments, impulse response functions, and zero-lower bound episodes to determine if the ad-hoc model is consistent with the dynamics of our model. Our hypothesis is that our model may have meaningful differences from the ad-hoc model due to the underlying difference in how the DNWR constraint is imposed.

Abstract Name: Finding Access Through Silence: How Assistive Technologies Shape Learning for Deaf and Hard of Hearing Students

Deaf and hard-of-hearing students often face challenges in higher education due to communication barriers, especially in environments not designed to support their needs. Clear and direct communication is critical for processing and understanding content, and hearing loss complicates this. This study evaluates how accessible

accommodations and assistive technologies, such as captioning, Roger Pens, and word-dictation tools offered at Georgia State University Perimeter College (GSUPC), support or limit students' learning in classroom settings while considering both environmental and instructional factors. The primary assumption of this study is that the effectiveness of assistive technologies relies on their ability to support the cognitive processes critical for understanding and retaining educational material. These tools are intended to bridge the gap between spoken information and accessible content that students can engage with and use for learning. The study also assumes that academic success depends on the availability, usability, and implementation of these tools in classroom environments. Cognitivism serves as the theoretical framework, focusing on the mental processes involved in understanding and organizing information and providing a lens for interpreting how hearing-related assistive technologies support comprehension in academic settings. The purpose of this study is to evaluate how well assistive-technology accommodations at GSUPC support the academic participation and learning needs of students with hearing disabilities. Using a mixed-methods approach, the study analyzes institutional documents, counselor insights, and interviews with TRIO and Access and Accommodations Center counselors. A literature review is also included to compare GSUPC's practices with broader research on assistive technologies. Expected findings suggest that while these technologies provide meaningful support, their effectiveness is influenced by classroom variability, instructional choices, and environmental factors. Insights from this study may inform improvements to assistive-technology implementation at GSUPC and similar institutions.

Abstract Name: Principles of Undergraduate Laboratory Management within a Team-Science Model: The FishLab at CNU.

This project highlights the role of the undergraduate laboratory manager within a team-science research model and demonstrates how this largely under-researched position, fundamentally different from professional lab management in research-intensive settings, prepares students for future careers in research, healthcare, and scientific leadership. In this context, team science refers to a collaborative approach in which undergraduate researchers contribute to multiple concurrent projects, coordinate shared workflows, and participate in collective decision-making within an interdisciplinary research group. The FishLab at Christopher Newport University consists of students with diverse academic backgrounds who collectively work across several behavioral neuroscience projects, including studies on zebrafish choice behavior, fluoxetine-induced impulsivity in *Betta splendens*, the effects of a synthetic alarm substance on social preferences as well as shoaling responses in zebrafish, and the development of a remote-sensing, fish-operated land vehicle. This breadth of research underscores the need for structured and cohesive management. The undergraduate student serving as the laboratory manager supports this structure by organizing schedules, matching new researchers to teams, tracking attendance and training progress, and fulfilling responsibilities essential to lab operations. The manager meets weekly with the principal investigator to review project progress, identify growth opportunities, onboard new recruits, and recognize students demonstrating strong work ethic and emerging leadership potential. Weekly lab meetings led by the manager provide updates on active projects, manuscripts, presentations, and lab events, and include professional development instruction designed to prepare students for graduate and professional programs through training in interview preparation, presentation skills, academic development, and research writing. Unlike professional laboratory managers whose work centers on administrative oversight, technical operations, and maintaining continuity in large, highly-funded labs, undergraduate laboratory managers operate within a peer-based framework emphasizing collaborative coordination, communication bridging, and

mentorship. This model strengthens laboratory productivity while equipping student managers with transferable skills in teamwork, communication, and organizational leadership.

Abstract Name: Bold Flavor, Bolder Strategy: Were They Enough to Make Doritos' "Ultrasound" Super Bowl Advertisement Memorable?

Every year, the Super Bowl brings together more than a 100 million people: not just for the game, but for the commercials that've become just as famous as the touchdowns. If you can remember, one of the most unforgettable of these ads came from Doritos in 2016. Their "Ultrasound" commercial, a fan-made entry from the company's Crash the Super Bowl campaign, sparked laughter, debate, and millions of views. What made this 30 second ad so powerful and what does it reveal about how modern brands connect with audiences? From this presentation, we're going to explore how there's more to Doritos' success than just a combination of bold flavor and bolder strategy. Furthermore, we're going to take a close look at how Doritos' "Ultrasound" ad used market segmentation, targeting, and positioning strategies to reach its audience, and how humor and emotional storytelling played a key role in its success. By the end of this presentation, we'll realize how a simple, outrageous idea (an unborn baby reacting to Doritos) managed to blend shock value with relatability, reaching both young adults and parents in a way that felt fresh, bold, and completely unforgettable. What truly sets this ad apart is its origin. It wasn't created by a professional marketing agency but came from a fan. Doritos' decision to open its Super Bowl campaign to the public showed a new kind of marketing power: something that was authentic and driven by the audience's creativity. The ad quickly went viral and earned the top three spot in USA Today's Ad Meter for 2016. What this reveals is user-generated content being able to disrupt traditional marketing. This ad reveals that sometimes a simple looking idea that is both bold and funny is able to connect people to a brand more deeply than a polished studio production.

Abstract Name: Culture-Verified Functional Heterogeneity in Bloom-Associated Marine Bacteria

Marine algal blooms release significant quantities of β -glucans such as laminarin, creating carbon pools that are processed by heterotrophic bacteria. This study aimed to isolate, culture, and identify these polysaccharide-degrading bacteria from the 2025 Cocolithophore bloom near the Gulf of Maine. Seawater collected from 40°54.207' N, 65°56.711' at station 2 cast 42 with a depth of 50m was enriched in a laminarin-containing medium. After 4 days, a high turbidity in the culture media was observed, indicating successful microbial growth. Two distinct microbe colonies, 03VD25 and 04VD25, were isolated and streaked to obtain pure cultures. The isolates were identified using 16S rDNA gene amplification followed by sequencing. Through BLAST nucleotide analysis, 03VD25 and 04VD25 were identified as *Shewanella inventionis* and

Pseudoalteromonas sp., respectively. Growth assays demonstrated that *Pseudoalteromonas* grew in a medium containing laminarin as the sole carbon source, whereas *Shewanella* (03VD25) showed no detectable growth under the same conditions. These results suggest a potential “cheater dynamic” between the two microbes cultured in this study, where *Shewanella* *inventionis* is the non-degrader, cross-feeding on laminarin hydrolyzed into smaller oligosaccharides/monosaccharides by primary degraders such as *Pseudoalteromonas*. Additionally, EcoPlate metabolic profiling revealed *Pseudoalteromonas* is capable of processing pyruvic acid methyl ester, Tween 40, Tween 80, α -cyclodextrin, D-mannitol, and glycyl-L-glutamic acid, suggesting they have the genomic capacity to utilize a diverse set of substrates. Together, these findings highlight community-level interactions in bloom-associated bacteria,- reinforcing the need for culture-based verification when evaluating their traits.

Abstract Name: Joinery & Scale: Case Study of a Beginning Interior Design Studio

This project introduces the first version of an interior design studio course curriculum offered to second-year design students who are taking their first interior design-focused studio course. The interior design studio course curriculum consists of five project assignments of ever-increasing scale with the added element of mechanical joinery -- unusual for an interior design class. Coursework focuses on a single joinery-based design assignment where students are expected to work on a single type of mechanical joinery, such as nailing, stitching, pinning, lashing, etc., and use them in five different design projects with increasing spatial scales that range from a volleyball-sized artifact scale to a metropolitan scale. The focus of this inquiry is each student's commitment to one joinery typology of their choice throughout the entire 15-week semester. Students are expected to use a mechanical joinery method to study different possibilities that present themselves via the ever-increasing scale of each bi-weekly assignment. Through this study, we aim to understand how this project framework promotes design exploration via a required focus on joinery in different spatial scales; how this project's framework promotes design thinking via the required translation of the same joinery and design concepts from small-scale to large-scale design projects; how does this project's framework promote design thinking via the joinery method's influences, direction, and/or focus of the design thinking and/or spatial design decisions; how does this project's framework promote design thinking by compelling students to work beyond their familiar comfort zone while considering the different properties being considered for implementing mechanical joinery. So that we can develop a framework for interior design studios that focuses on joinery-based spatial innovation and structural reasoning, through a single joinery-based curriculum assignment.

Abstract Name: Implications on the Bending of Cyclopentadienyl Ligands in Half-Sandwich Complexes

Metallocenes and sandwich compounds in general are well-known structural motifs in organometallic chemistry. Over seven decades since the clarification of the structure of ferrocene, showing that the cyclopentadienyl rings are co-planar (a 'linear' sandwich structures), such systems and variants, including half-sandwich, ansa-sandwich, and bent sandwich structures, involving metals beyond the d-block continue to attract wide interest. We have investigated the bending in less or previously unstudied half-sandwich, C₅H₅-M-X, compounds of group 1, 2, and the cation of the group 3 lanthanide complex. We examine, at the MP2 and wB97X-D levels, the influence of methylation on the bending tendencies in these compounds and explore the evolution of bending from the simple binary and ternary metal dihalides to the corresponding half-sandwich to the metallocene systems going down those groups. A key goal of our work is to assess the relevance and application of competing theoretical frameworks for explaining the bending in the simple dihalides to the more complicated (half-)sandwich systems. We report structural and other features of the group 1 and 2 half-sandwich systems, which exhibit little to no bending while most complexes containing group 3 centers experienced significant bending. C₅H₅-Sc-F and C₅H₅-Y-F are found to be linear, but all of the other C₅H₅-M-X complexes show significant bending. Exploring more derivatives of these structures, and assessing the relevance of pseudo-Jahn teller arguments to bending in sandwich structures, is the next phase of our investigation.

Abstract Name: Six-Axis Robotic Automation for Optimizing Crystallization Processes

Chemical automation focuses predominantly on handling liquids, but many chemical processes involve solids, either added to solution or produced by reactions. Crystallization seeks to create high purity solids from a solution, and is critical to pharmaceutical, agrochemical, materials, and food manufacturing. This research focuses on a 6-axis robotic arm used to handle solids and optimize crystallization processes through a Python-based API. Crystallization is a nonlinear chemical unit operation as slight changes in temperature, concentration, or seeding can significantly alter experimental results. Seeding is used industrially to improve purity and yield by suppressing uncontrolled nucleation and promoting uniform crystal growth. This process eliminates the need for random molecular collisions for spontaneous nucleation and instead provides a controlled reaction, giving new crystals a pre-formed surface to grow on. Rapid precipitation and control of the process is key in crystallization laboratories, but this process cannot be automatically optimized using existing systems. The 6-axis robotic arm with a 600-gram payload and 0.5mm repeatability allows for an automated optimization process where testing different seeding variables is possible. Initial findings include integration of various crystallization apparatuses using Python, including automated weighing of solids. Future research aims at detecting and changing temperature, seed loading, and agitation, and filtering crystal slurries all through a Python API. This can streamline process optimization for food and pharmaceutical processes by eliminating routine tasks such as handling solids, preparing seed crystals, and monitoring cooling cycles, allowing researchers to concentrate on analyzing crystal morphology and other higher-level analytical work.

Abstract Name: Assessment of Heavy Metal and Black Carbon Concentration Change Before and After Congestion Pricing Implementation in Manhattan, New York

This study examines the impact of congestion pricing on air quality in Chinatown, Manhattan, by measuring changes in PM_{2.5}, black carbon, and heavy metals. Air samples were collected 10 days before and after the implementation of congestion pricing, using Teflon filters and an aethalometer. Heavy metals were quantified using ICP-MS following microwave acid digestion. Results indicate variations in pollutant concentrations correlating with reduced traffic. The study offers insights into how urban policy can influence environmental health.

Abstract Name: Where You Live, How You Learn: A Socioeconomic Analysis Across Kentucky Public High Schools

Debates over the future of public education increasingly position privatization as a remedy for perceived shortcomings in public schools. Proponents often highlight the advantages of private institutions, yet these schools frequently serve specialized, socially and financially advantaged populations already positioned for higher achievement. In contrast, public schools remain tightly bound to the socioeconomic and spatial conditions of the communities in which they operate. Even with strong teachers and supportive staff, school performance is shaped by broader structural forces, some communities are simply better resourced to produce positive educational outcomes than others. Using statewide data from Kentucky, this study evaluates how community-level socioeconomic, demographic, and structural characteristics influence public high school performance across the Commonwealth. Drawing on data from the Kentucky Department of Education (KDE), the National Center for Education Statistics (NCES), and the U.S. Census, we analyze all public schools offering a Grades 9–12 curriculum from 2021/2022 through 2023/2024. Measures of academic performance, school funding, and community characteristics serve as outcomes and predictors. Independent variables include racial composition, proportions of English learners and special education students, median household income, poverty rates, and rural–urban classification. Preliminary findings reveal significant disparities both across and within districts. By exploring the community-level factors that shape school quality, this project aims to provide policymakers, educators, and local leaders with actionable, data-driven insights into educational inequality.

Abstract Name: Evaluating the Influence of Soil Amendments on Soil Health Indicators in a Turfgrass Lawn.

Turfgrass systems cover over 40 million acres in the United States, presenting a substantial opportunity to enhance soil health and improve carbon sequestration through sustainable management practices. This study evaluates how three non-synthetic alternative soil amendments—biochar, spent coffee grounds, and basalt rock dust—influence soil organic carbon (SOC), pH, cation exchange capacity (CEC), and Humic Matter in turfgrass systems. Thirty-five one-square-meter plots were established, and five plots each were treated with each amendment at two application rates, with amendments reapplied quarterly to capture seasonal variability. The remaining five plots were reserved for a control condition. Soil samples were collected at each sampling period for loss-on-ignition analysis, along with repeated pH measurements. At the end of the study, soil samples were analyzed by the North Carolina Agricultural Extension Office for CEC and Humic Matter. One-way ANOVA revealed a significant amendment effect on SOC ($p = 0.0054$), with coffee grounds at the high rate producing the greatest SOC increase and significantly exceeding basalt at the high rate, which had the least impact. However, the overall effect size was small ($\omega^2 \approx 0.03$), consistent with modest treatment differences. A two-way ANOVA showed significant effects of amendment/rate ($p = 0.0037$) and sampling date ($p = 0.0057$), with SOC increasing from October to February before declining toward late summer, while treatment rankings remained stable (interaction $p = 0.516$). Biochar plots exhibited the highest humic matter and slightly elevated CEC, suggesting enhanced long-term carbon stabilization. Coffee grounds produced strong short-term carbon increases but may have the potential to decompose quickly, whereas basalt showed minimal immediate change but provided mild pH buffering. Across all treatments, pH remained near neutral (6.0–7.0), indicating that amendments did not disrupt soil acidity. This study demonstrates that alternative amendments can enhance turfgrass soil health, though their benefits vary with amendment type, rate, and seasonal conditions.

Abstract Name: CNOT gates in a linearly coupled multi-fluxonium chain

High-fidelity two-qubit gates have been demonstrated in systems of two fluxonium qubits, yet scalable quantum processors require maintaining low errors in substantially larger architectures. We investigate a linear chain of four inductively coupled fluxonium qubits and analyze how additional spectator qubits influence the performance of a CNOT gate. We find that spectator-induced errors are strongly suppressed when the spectator frequencies are sufficiently detuned from those of the gate qubits. We identify favorable frequency configurations for the four-qubit chain that yield CNOT gate errors below 10^{-4} for gate times under 100 ns. Exploiting the symmetry of the nearest-neighbor coupling, we further show how these favorable configurations can be extended to longer fluxonium chains, facilitating scalable low-error quantum processors.

Abstract Name: Ixodes scapularis Larval Tick Attachment to Different Fabric Types

Ticks are blood-sucking parasites that serve as vectors for several diseases, posing significant threats to human health and agriculture. Despite the threats posed by deer ticks (*Ixodes scapularis* Say, 1821), tactile factors influencing larval tick attachment behavior remain poorly understood. Tick adherence to different fabric types has important implications for both population estimates using drag field sampling and guidelines for clothing recommendations to reduce tick transfer during field exposure. Fabrics used in clothing manufacturing are made of weave patterns and compositions that are not well-represented by traditional drag-cloth materials but may lead to more accurate population estimates. On a damp soil substrate, we exposed groups of 20 larval *I. scapularis* to nine types of fabric (denim, canvas, white nylon-spandex knit, black nylon-spandex knit, twill, rayon-spandex knit, brushed polyester, fur, flannel) for 40 seconds to determine the average number of ticks recovered ($N=271$, $n=30$ per fabric, 5,400 ticks). We found that fabric type had a significant effect on the number of recovered larval deer ticks. Twill showed the lowest collection rates, with an average of 2.93 ± 1.76 SD ticks recovered per exposure. Fur collected significantly more ticks than each of the other fabrics with an average of 11.48 ± 2.93 SD ticks recovered per fabric exposure. Black nylon-spandex knit collected significantly fewer ticks than white nylon-spandex knit, suggesting that brightness or color contrast may mediate attachment choice. Our findings may better inform how clothing choices impact larval tick exposure risk and the role of fabric material in tick drag field surveys affects population estimates.

Abstract Name: Linking Social Care with Healthcare Systems to Address Social Determinants of Health

Approximately, 1 in 5 Arizona residents speak Spanish at home, language barriers contribute to persisting limitations in healthcare, which could be mitigated by integrating social care into patient care. The Biopsychosocial Model of Healthcare is a conceptual framework that explains how healthcare is influenced by biological, psychological, and social factors. With this encompassing the mechanisms by which patients develop health conditions and their broader implications for treatment outcomes. Physicians are trained to address biological and psychological components of health, while community health workers (CHWs) are professionals who are trained to directly engage with members of the community to connect them to healthcare services and resources. Many of the CHWs implemented in clinics are bilingual, which helps to reduce the prominent Social Determinant of Health (SDOH) in Arizona. Language Concordant Care refers to the delivery of healthcare in a patient's primary language to assure effective communication between the patient and clinician. Language Concordant Care has been shown to improve patient outcomes and reduce confusion when educating patients. Since CHWs are mostly bilingual, they aim to reduce the communication barrier that has been implemented. The Arizona Community Education Alliance (AZCEAL) study aims to reinforce the necessity of CHWs as a part of a healthcare team and to give implementation strategies for CHWs by providing a model for the necessary infrastructure to utilize CHWs in clinics. AZCEAL aims to understand how implementation of social care, through the use of CHWs, better addresses SDOHs in high-risk populations to improve patient outcomes within clinical practices. Preliminary research on language concordance from this study has shown that bilingual participants have primarily chosen to speak in English, when given the option for either English or Spanish. Further exploration is taking place to identify potential reasons this is the case in order to improve clinical practices and outcomes.

Abstract Name: Promoting Early Literacy: Engaging Communities to Empower Young Learners

Reading is a fundamental component of academic achievement, establishing a strong foundation for future learning outcomes. This poster examines the crucial relationship between early reading and student success, supported by a review of existing literature and firsthand studies. Research consistently shows that children who engage in reading before age five are more likely to excel in elementary and secondary education, demonstrating enhanced vocabulary, comprehension, and overall academic performance. A critical aspect of promoting early literacy lies in effective community engagement to bypass economic barriers. Collaborative partnerships between schools, libraries, and community organizations can play a transformative role by providing resources, such as reading programs, workshops, and access to diverse reading materials for families. Innovative initiatives, such as "Reading Buddies" programs and community literacy fairs, actively engage children and their families, helping to reduce barriers to reading access and fostering a culture of literacy within the community. The central research question guiding this investigation is: "How can community engagement strategies be used to enhance early literacy outcomes among young learners and their families?" Empowering families through targeted workshops focused on effective reading strategies and literacy development is essential for encouraging their involvement in their children's education. Additionally, involving families and community members in the planning and evaluation of literacy programs ensures that these initiatives are culturally relevant and responsive to community needs. Such collective efforts contribute to creating a literacy-rich environment that values reading, ultimately leading to increased school readiness and improved long-term educational outcomes. In summary, this research highlights the crucial role that community engagement and early literacy interventions play in shaping educational policies and practices that foster student success with an emphasis on the black community. Fostering community engagement in early literacy initiatives is crucial for inspiring young learners and creating equitable educational opportunities that contribute to lifelong success.

Abstract Name: Transforming Narratives: Empowering Students Through Stereotype Awareness in Children's Literature

Children's literature profoundly shapes young readers' understanding of societal norms, yet it often perpetuates biases, such as racial, disability, and gender stereotypes. This poster presentation aims to empower educators and students by fostering awareness of these biases and advocating for transformative narratives that promote inclusivity and authenticity. Through a critical examination of existing literature, we will explore how gender stereotypes are deeply embedded in children's stories and illustrations, reinforcing outdated notions of identity. We will showcase compelling examples that reveal the critical shortcomings in the representation of Black experiences (Vickery & Rodríguez, 2021) and the inadequate portrayal of individuals with disabilities (Kaplan et al., 2022). By shedding light on how these narratives influence young minds, we highlight the need for educational reform. The visual elements of this poster will present interactive components, facilitating dialogue among attendees. Participants will engage with thought-provoking questions and activities designed to highlight cultural and social influences that shape children's perceptions

of gender roles (Saygan & Uludagli, 2020). These interactions will illuminate the impact of peer influence during adolescence, as well as the ways societal expectations can limit emotional expression and leadership potential (Brendler, 2014). Additionally, we will address recent trends in the banning of literature that features nonconforming gender identities, emphasizing the importance of inclusive storytelling in fostering critical awareness. Attendees will leave equipped with practical strategies to integrate inclusive literature into their educational practices, advocating for narratives that empower all children. By transforming the narratives presented in children's literature, this presentation strives to inspire educators and scholars to challenge stereotypes, ultimately creating a richer, more equitable literary landscape that empowers students to embrace diversity and overcome bias.

Abstract Name: Synthesis of trans-4-Bromo-2-Heptene

trans-4-Bromo-2-heptene (1) is a simple compound that, despite two reports to the contrary, has never been synthesized in pure form. Nevertheless, it could be a useful starting material for organic synthesis. The compound presents a significant synthetic challenge due to a propensity to undergo allylic rearrangement to form a mixture of allylic bromides. Therefore, the goal of this research was to synthesize 1 with a multistep synthesis. Step 1 was to produce hept-2-yn-4-ol (2) via a Grignard synthesis by combining butanal and propynyl magnesium bromide with the triple bond acting as a masking group for the alkene. The alcohol was then converted to 4-bromo-2-heptyne (3) using triphenylphosphine, bromine, and imidazole. The most critical step of selectively reducing the triple bond to the desired double bond was attempted using both H₂ and palladium on polyethylene imine catalyst and a monohydroboration method via disiamylborane and protonolysis with acetic acid. Finally, because the reduction should produce the cis alkene, the last step will be isomerization, to produce 1.

Abstract Name: Assessing Gaps in Shelter-Based Services for Homeless Individuals in Multnomah County

This project examined the range of services offered across overnight homeless shelters within a single county and identified where gaps in service provision limit accessibility for people experiencing homelessness. While homelessness in the Portland metro area has been widely documented, less attention has been given to the consistency, scope, and distribution of services across individual shelters. Understanding this variation is essential for improving equitable access to resources and reducing the burden on individuals who must navigate multiple organizations to meet basic needs. Shelters were reviewed using organizational websites, resource databases, and supplementary public materials. Services were categorized according to ten core needs: housing, food access, clothing, hygiene care, education, advocacy, childcare, transportation, translation, and healthcare. Each shelter was assessed for the presence and type of support offered. The analysis consisted of descriptive comparisons of service availability and overall shelter formats, including

operators and populations served. Data was collected from 50 overnight shelters. Housing, food access, and hygiene care were offered by over 90% of shelters. Clothing, advocacy, and healthcare were each available at 70%. Education, childcare, transportation, and translation services were far less common, with availability ranging from 12% to 34%. Within each category, substantial variation emerged in service types, highlighting both commonly provided support and rare resources. Even in broadly covered areas, such as food access, advocacy, and healthcare, many specific services were uncommon, indicating gaps that limit overall efficacy. Multi-site organizations tended to offer more standardized and comprehensive service profiles, while independent shelters showed greater variability. These patterns suggest structural barriers within the local homeless services. While immediate needs were reliably met, specialized or resource-intensive services were offered at far fewer sites. Strengthening collaboration and expanding co-located, integrated services may improve accessibility and outcomes for people experiencing homelessness.

Abstract Name: Is the Enemy of my Enemy my Friend?: How 3 to 6 year old Children Learn Transitivity in Social Relationships

Second order correlation learning (SOCL) is the ability to infer the relationship of two objects, features, or events (A and C) based on previously learned first-order correlations (A and B, B and C). In this study, I will present social relationships as SOCs to examine if and when children can use transitivity to learn about these relationships. Only a small number of studies have been conducted to test whether children 7 years of age and older can understand transitivity in non-social contexts. This study will be an extension of a previous study done in 1999 except it will test considerably younger children- those between 3 and 6 years of age- to determine if they too can learn transitivity, particularly when it comes to negative relationships among first order correlations. Similar to the 1999 study method, children will be shown a series of cartoon vignettes that depict different social relationships, both positive and negative. In a series of test trials, participants will see different combinations of social relationships of friends, non-friends, and enemies (A-B and B-C). Part of the extension is the manipulation of directional orientation that children are facing in the vignettes. This involves children making eye contact with each other or looking at various things on the walls instead. Thus, on top of the social relationship combinations, there will also be manipulation with children facing toward or away from each other. Participants will be asked to determine the relationship between the various characters for each scenario. This research will provide us insight into whether or not preschool aged children can learn transitivity and, if they can, around what age they start to understand it.

Abstract Name: Comparison Of Macroinvertebrate Colonization In Different Types Of Leaf Packs Within Different Velocities To Determine Stream Quality

Stream quality can be determined through sampling of macroinvertebrates. For this study, leaf packs were

used to determine stream quality. Each of the leaf packs were split into pairs containing combinations of sycamore/pin oak/maple (*Plantanus occidentalis*/*Quercus palustris*/*Acer* sp.) and black oak/white oak/elm (*Quercus velutina*/ *Q.alba*/ *Ulmus* sp.) leaves. The hypothesis was differences in leaf type and velocities yield differences in macroinvertebrate diversity and stream quality determination. If the sycamore/pin oak/maple leaves were in high velocities, there would be a difference in macroinvertebrate colonization and stream quality determination compared to the other leaf packs and velocities. Three leaf pack pairs were made and placed at different rates of velocities (fast, slow, and 0). Analysis of the sycamore/pin oak/elm fast velocity combined with the white oak/black oak/elm 0 velocity leaf pack had significant differences, mainly in EPT/Non EPT, pollution intolerant/pollution tolerant, and Shannon Diversity Index values compared to other leaf pack combinations ($p < 0.001$). The Macroinvertebrate Biotic Index for stream quality determination of the sycamore/pin oak/maple fast velocity combination with the white oak/black oak/elm 0, sycamore/pin oak/maple slow, and sycamore/pin oak/elm 0 velocity leaf packs were rated to be “fair” (5.01-5.70) compared to the other leaf packs which were considered “poor” (5.71-6.25). The sycamore leaves had high levels of colonization compared to oak leaves, yielding dominance of Hydropsychid caddisflies. Velocity showed differences in colonization between the different leaf packs, and in combination comparisons between the leaf packs, particularly regarding abundance. Riparian tree species impact macroinvertebrate colonization and stream quality determinations.

Abstract Name: Unpacking the Influence: Parental Engagement and Social Studies Success for Black Students

This study examines the association between parental engagement and Social Studies GPA among Black high school students, drawing on Pierre Bourdieu’s concept of cultural capital as the guiding lens. Prior research consistently finds that parental involvement supports Black students’ academic success, yet these benefits and the challenges students face are shaped by gendered racial dynamics, including disproportionate disciplinary actions targeting Black male students. Using data from the High School Longitudinal Study of 2009 (HSL:09), this project focuses on African American respondents and investigates whether parental attendance at school events is linked to academic performance in Social Studies. An independent samples t-test compared GPAs between students whose parents attended school events and those whose parents did not. Results show that students with engaged parents earn significantly higher Social Studies GPAs than their peers without such engagement. These findings suggest that parental engagement may operate as a channel through which cultural capital is transmitted, underscoring the importance of family-school connections in addressing educational disparities among Black students.

Abstract Name: Benefits and Barriers of Pulmonary Rehabilitation in Rural COPD Patients: A Prospective Evaluation at a Hospital System in Southwest Virginia

Pulmonary rehabilitation (PR) improves exercise capacity, dyspnea, and quality of life for patients with

chronic respiratory disease, yet completion rates remain substantially lower than those observed in cardiac rehabilitation (CR). Rural populations may experience amplified barriers, particularly transportation limitations and exacerbation-related interruptions that diminish program adherence and attenuate functional gains. This study will evaluate outcomes and barriers among pulmonary rehabilitation participants at a hospital system located in southwest Virginia, with a specific focus on the effects of disease exacerbations and geographic access. We will enroll 50 adult PR patients who complete at least one billable session and follow them through an 8–12-week program. Functional and psychosocial outcomes including six-minute walk distance, dyspnea, health-related quality of life, and depressive symptoms (PHQ-9) will be assessed at baseline and program completion. Clinical covariates (FEV1, supplemental oxygen, comorbidity burden, and exacerbation events during the program) will be recorded. To contextualize relative benefit, a secondary analysis will compare completion rates and functional gains with a matched cardiac rehabilitation cohort. A geospatial analysis will quantify travel burden using road-network distance from patient residence to the rehabilitation facility. We will model the association between distance and completion using nonlinear regression to identify a potential threshold at which the probability of program noncompletion increases significantly. Qualitative surveys will further capture patient-reported barriers, including transportation, exacerbations, financial limitations, and scheduling constraints. We expect PR completers to demonstrate improvements in functional capacity and symptoms; however, exacerbations and greater travel distance are anticipated to be strong predictors of interrupted participation and noncompletion. Identifying a distance threshold and characterizing interruption patterns will provide actionable targets for program redesign, including tele-PR expansion, transportation support, and flexible scheduling to improve PR accessibility and outcomes in rural populations.

Abstract Name: The Relationships Between Young Adults' Bodily Pain, Distress, Protective Factors, and Life Satisfaction

Young adults' somatic symptoms may manifest as mental stress, headaches, or chronic pain (i.e., back or joint pain). Often these conditions lead to academic stress, anxiety, depression, and lower life satisfaction. Many studies suggest social support and sleep quality have a bidirectional link with negative psychological factors (i.e., anxiety and depression) and pain or somatic symptoms. However, little research examines these variables (along with hope and gratitude) as predictors of life satisfaction or somatic symptoms. Additionally, there is a lack of research and understanding of these factors within a young adult population. This study of 216 college students will analyze the associations between these variables via Pearson correlation analyses and hierarchical multiple regression analyses cross-sectionally and longitudinally. This study will contribute to the understanding of somatic symptoms and pain experiences within a college population when accounting for protective factors such as social support, hope, gratitude, and sleep satisfaction.

Abstract Name: Association Between Emotion and Afro-cultural Beliefs in African American College Students

Value emotion beliefs refer to attitudes about the value of experiencing certain emotions. Past research suggests that emotion beliefs are associated with important emotion-related skills (e.g., ability to regulate and cope with emotions). However, it has focused less on African American individuals, families, and culture, limiting our ability to apply emotion research to African Americans. This poster investigates the potential associations between three value emotion beliefs (emotions just are, negative emotions are good, and positive emotions are good), and Afro-cultural beliefs (nationalism, primacy of social existence-based communalism, and group duty-based communalism, as outlined by Boykin & Toms' Triple Quandary Theory) in African American college students ($N = 169$). I hypothesized that having greater Afro-cultural beliefs would be associated with greater beliefs that emotions just are (neutral) and greater belief that positive and negative emotions are good. Data was collected from participants ($M_{age} = 20.62$, $SD = 3.92$) who were enrolled in the African American Beliefs and Emotions Study. They completed a set of questionnaires including their demographics, emotion beliefs, and Afro-cultural beliefs through an online survey. We found positive, significant associations between the primacy of social existence-based communalism belief, and the beliefs that emotions just are (neutral; $\beta = 0.16$) and positive emotions are good ($\beta = 0.24$). Also, there was a positive, significant association between the group duty-based communalism belief and the beliefs that emotions just are (neutral; $\beta = 0.14$) and negative emotions are good ($\beta = 0.16$). Findings contribute to knowledge investigating the relationship between African American cultural values and the emotion beliefs of African American youth. This knowledge can help inform emotion interventions for African Americans, and could contribute to healthy development/maintenance of emotion-related skills.

Abstract Name: Mind Your Tone: Investigating How Prompt Politeness Affects LLM Accuracy

The wording of natural language prompts has been shown to influence the performance of large language models (LLMs), yet the role of politeness and tone remains underexplored. In this study, we investigate how varying levels of prompt politeness affect model accuracy on multiple-choice questions. We created a dataset of 50 base questions spanning mathematics, science, and history, each rewritten into five tone variants—Very Polite, Polite, Neutral, Rude, and Very Rude—yielding 250 unique prompts. Using ChatGPT-4o, we evaluated responses across these conditions and applied paired sample t-tests to assess statistical significance. Contrary to expectations, impolite prompts consistently outperformed polite ones, with accuracy ranging from 80.8% for Very Polite prompts to 84.8% for Very Rude prompts. These findings differ from earlier studies that associated rudeness with poorer outcomes, suggesting that newer LLMs may respond differently

to tonal variation. Our results highlight the importance of studying pragmatic aspects of prompting and raise broader questions about the social dimensions of human–AI interaction.

Abstract Name: Whose Abuse is More Influential?: A Longitudinal Analysis of Mothers' vs. Fathers' Psychological Maltreatment in Adolescence on Adult Externalizing Behavior

Introduction: Psychological maltreatment, defined as emotional neglect and emotional abuse, is often overlooked in research because of its lower report rate. However, studies show that abuse or neglect in childhood roughly doubles one's chance of engaging in crime (Tekin & Currie, 2006). Therefore, the present study examines parental psychological maltreatment in adolescence and externalizing behavior in early adulthood. More specifically, this research aims to compare gender specific links between same-gender and opposite-gender parent-child dyads, as well as the mediating effects of time spent with deviant peers. Method: Data were collected from a sample of 184 ethnically and socioeconomically diverse participants (86 males, 98 females; 58% Caucasian, 29% African American, 13% mixed or other; median income in 1999 = \$40,000-59,999). The study included participants at ages 15-17, 22, and 25-26. Participants' externalizing symptoms were assessed at baseline and outcome ages with a questionnaire completed by their close peer. At ages 15-17, individual parents' use of emotional abuse and neglect tactics was assessed. At age 22, participants' time spent with deviant peers was measured. Results: Data collection is complete, and analyses have begun. Correlation analyses will examine relationships between parental psychological maltreatment in adolescence and externalizing behavior in early adulthood. A series of hierarchical linear regressions with interactions will be run to test the relationships more rigorously, specifically regarding gender specific links between same-gender and opposite-gender parent-child dyads. Further, we will conduct a test for the mediation of effects by time spent with deviant peers. Discussion: Same-gender vs. opposite-gender parental influence data contribute to developmental research regarding when a parent's abuse may be more damaging. Further, understanding predictors of deviant friendships and the consequences that come from having deviant peers may help predict criminal behavior.

Abstract Name: Cognitive Risk Under Economic Pressure: A Comparative Simulation of Decision Decay, Stress Oscillation, and Financial Constraints in Repeated Blackjack Play

Abstract: This project builds BJ21, a simulation framework designed to study how cognitive limits and financial pressure interact during repeated decision-making. The model tracks three internal stress variables: (decision-unit decay (DU), mental-workload oscillation (MWU), and variance shifts tied to fatigue) and connects them with external constraints such as salary, living-cost burden, interest cycles, and borrowing limits. Two configurations were tested. Version 3.1 focuses only on cognitive behavior, running twelve monthly decision cycles across three agent types (Pilot, AP_Pro, AP_Rookie). Version 3.2 adds 2024 U.S. economic benchmarks: median rent, role-based income, average credit-card debt, and “comfortable-living” thresholds. This turns the system into a combined cognitive-economic environment. Across twenty Monte Carlo runs (ten per version), Version 3.1 showed stable patterns: steady bankroll growth, low borrowing, and mild variance. Version 3.2 produced a completely different profile. Large debt escalation (\$100k–\$164k by month twelve) even when expected value was positive. This shows that economic pressure amplifies cognitive decay more strongly than cognitive decay shapes financial outcomes. The main result is a “lose-while-winning” pattern: agents perform well in the decision process but still collapse financially due to compounding obligations. The model has applications in aviation human-factors research, gambling behavior, and stress-performance analysis. Future work includes extending the simulation to multi-agent competitive environments such as poker.

Abstract Name: Pain, Function, and Fracture Severity in Vertebral Compression Injuries: A Retrospective Chart Review

Background/Purpose Vertebral compression fractures (VCFs) from osteoporosis and minor trauma are increasing at alarming rates in elderly populations and are frequently underdiagnosed due to the commonality of back pain in this group. The study’s aim is to explore associations between vertebral fracture level and (1) pain scores at presentation, (2) functional impairment, and (3) improvement in function at one month and one year. Methods This retrospective chart review will include patients seen for VCFs at Bergen Mercy Medical Center from January 1, 2024, to December 31, 2024. Inclusion criteria will include patients with T5-L5 VCF with 15% or more height loss identified on radiographs, CT scans, or MRIs. Exclusion criteria include three or more acute compression fractures, and high velocity trauma. Key data abstracted will include patient demographics, fracture level, pain scores, function levels, and follow-up functional level at one month and one year. Descriptive statistics will be used to characterize the cohort, and ANOVA will be used to assess

the relationship between fracture level, pain severity, impact on function, and time points during recovery. Results Data collection and analysis are in progress. Results will be available and presented at the time of the conference. Conclusions The findings of this study will help us better understand if fracture level is associated with pain intensity, loss of function, and the recovery process providing valuable insight into the development of care protocols for patients with VCFs.

Abstract Name: Enhancing Electrochemical Active Surface Area Using Biodegradable Nanofibers For Sweat-Sensing Application

Single-use biosensors have long been researched and developed. Their design allows for portable, rapid medical testing in a small, cost-effective device. Many also utilize sweat-sensing for noninvasive monitoring of biomarkers. An issue, however, arises as the small structure of these biosensors is attributed to significantly decreased sensitivity and signal amplification. Enhancing the sensitivity and amplification of these sensors would enable wider development and distribution, improving access to medical monitoring equipment for underserved populations that lack access due to financial, geographical, social, or physical constraints. This project focuses on the development of biodegradable nanofibers to be used for increasing biosensor sensitivity in sweat-sensing applications. The fibers are formed through electrospraying, an electrical process involving the polarization of a spraying needle and a collector plate that spins the solution to form solid fibers, and will be composed of nanocellulose, chitosan, and polyvinyl alcohol. Nanocellulose and chitosan allow for increased sensor amplification, and PVA provides structure and stability to the fibers. The biodegradable nature of this sensor allows for environmentally conscious disposable of single-use sweat sensors, and the nanofiber matrix provides additional amplification and increased electrochemically reactive surface area for increased sensitivity. Initial research has produced visible fiber formations. Additional testing and process optimization is ongoing to produce consistent diameter fibers in the nano-scale leading to a significant increase in surface area.

Abstract Name: Rights of Nature: Examining Nature's Rights in Law and Literature to Promote Legal Representation of the Natural World

Rights of Nature play a key role in the legal systems that protect our present and future living world through their effect on the regulation of air, water, the climate, and the communities these impact. To show how Rights of Nature apply to future environmental policy, examining legal frameworks and environmental literature through an Indigenous lens is essential to navigate their role within society. Robin Wall Kimmerer's chapter "Grammar of Animacy" in her book *Braiding Sweetgrass* illustrates the central idea that nature is animate. The grammar of animacy is language that allows for the expression of something with feelings and

agency of its own, as Kimmerer shows by calling a tree a ‘who’ instead of an ‘it’. Some countries even think animate nature deserves legal recognition. The success of Rights of Nature in legal frameworks is contrasted between the United Nations “Global Pact for the Environment” and Ecuador’s constitution. Literature plays a vital role in shaping public perceptions and policy regarding nature’s rights. Analysis of the rich narratives in poetry from contemporary Indigenous author Joy Harjo alongside the Enclosure Movement author John Clare’s “Swordy Well”, exemplify a cultural foundation for these legal shifts. The implications of nature’s animacy are explored by combining comparative legal analysis and close literary reading. This research highlights the importance of integrating Indigenous voices and shaping future environmental policies to foster a deeper, more holistic connection with the natural world which challenges conventional Western views and emphasizes a kinship with nature.

Abstract Name: A Systematic Framework for Transcranial B-Mode Ultrasound in Axial and Coronal Neuroimaging

Ultrasonography (US) is a commonly used imaging technique due to its non-invasiveness, extensive range of applications, and low cost. Intracranial imaging is an emerging use of ultrasonography, particularly for patients with suspected brain injury, and is performed using different planes to create a detailed image of the brain anatomy. However, intracranial imaging has been largely limited to axial (horizontal) imaging in adults, restricting its exploration across different imaging planes and age groups. This limitation reduces the accessibility of intracranial ultrasounds in populations in which utilizing CT or MRI scans may be unsafe or infeasible. To expand the framework to span a broader patient population, we have utilized B-mode ultrasound, a type of 2D imaging, to incorporate coronal (vertical) planes, frontal windows, and pediatric patients. In our study, images were collected from three prospective studies, which enrolled both children and adults with intact skulls, to evaluate the accuracy of B-mode cranial ultrasound in diagnosing intracranial pathology. The images were analyzed by investigators and compared with CT and MRI scans to identify anatomical and pathological features. Based on our findings, we propose a systematic method for obtaining transcranial imaging from frontal and temporal windows in both axial and coronal planes, utilizing established anatomical landmarks as internal controls to evaluate the quality of the scans. Pathologies can be identified and analyzed at reference planes to demonstrate the reliability of this approach. This framework provides a reference for working with transcranial ultrasound in both children and adults, and may promote future studies investigating the use of cranial ultrasound in detecting intracranial pathology. By establishing standard procedures, we highlight the potential of B-mode ultrasound as a practical and accessible tool for neuroimaging in intensive and emergency care, pre-hospital diagnosis, and resource-limited settings.

Abstract Name: Increased Policy of Privatized Education in the U.S. and Public School Segregation

The modern school voucher system was introduced to the United States in response to *Brown V. Board of Education* and continues to grow today. Whereas school vouchers emerged in the 1950s to reallocate public school funding to all-white private schools, vouchers today have expanded this funding to many private institutions, including religious programs. This project seeks to analyze whether the school voucher system has impacted school segregation between public and private schools within the past twenty years considering the increased privatization of education and the rise of Christian nationalism. Past research has suggested that these vouchers may have prolonged school segregation into the twenty-first century as private schools maintain the jurisdiction to practice selective admissions processes, exempt from certain federal regulations and Title IX discrimination practices that are required of public institutions. However, this implication of school segregation must be re-examined under the lens of the unprecedented increase of these voucher policies, both in quantity and funding, in recent years. In addition to a literature review of the school voucher system, this research will be composed of an analysis of public surveys measuring American religious values and a data set compiling the racial composition of students in American public schools by grade level from 2008 to 2023. This research will then conduct a regression analysis to determine the effects of both Christian nationalism and school vouchers on racial segregation in private and public schools. I hypothesize that there will be an increased composition of students of color in the public school system as both the use of school vouchers and Christian nationalism rises over time, whereas private schools may simultaneously see a decline in the enrollment of students of color.

Abstract Name: Protective Factors and Ultimate Outcomes amongst Racial-Ethnic Minoritized Youth in Functional Family Therapy

Functional family therapy (FFT) is a short-term evidence-based family therapy program intended for youth ages 11 to 18 years old with clinically significant behavioral problems. FFT uses a family- and strengths-based approach to address these challenges and is culturally responsive because it is tailored to each family's needs. Previously, FFT has been effective in serving racial-ethnic minoritized populations, including Black and Latine families. Past literature has shown that familial protective factors play a crucial role in reducing at-risk behaviors and cultivating positive growth (i.e., community involvement). However, research has yet to examine changes in protective factors before and after completion of an evidence-based program such as FFT. The current study addresses this gap by examining changes in the number of protective factors and positive outcomes for racial-ethnic minoritized youth in FFT programming. Study hypotheses include: 1) Protective factors will increase from pre-intervention to post-intervention among racial-ethnic minoritized families in FFT programming. 2) As the number of protective factors increases, ultimate outcomes will improve for racial-ethnic minoritized youth. 3) Finally, there will be racial differences in protective factors and ultimate outcomes when comparing white and racial-ethnic families. Data from families ($N \approx 670$) were aggregated as part of a larger statewide evaluation of FFT in Virginia. A paired t-test will examine how protective factors change across treatment for racial-ethnic minoritized youth participating in FFT programming. A regression analysis will be conducted, predicting ultimate outcomes (e.g., youth remaining in the community) and protective factors (e.g., caregiver love and support) among racial-ethnic minoritized families. Additionally, youth racial identity will be included in the regression analysis to explore racial

differences. Findings from this study clarify the influence of protective factors on the promotion of positive outcomes for youth. Results may provide insight into how protective factors influence the outcomes of racial-ethnic minoritized families who received FFT.

Abstract Name: Dose-Dependent Viability Effects of an Heterocyclic Small Molecule CNS Probe in Murine Neuronal Cells

Heterocyclic small molecules (HSMs) are shown to enhance cell media. For example, B-27 is a common formulation in tissue culture experiments and includes several heterocyclic compounds. We evaluated the effects of an HSM on the viability of N18 murine neuronal cells under xeno-free conditions. Cells were treated with 10, 50, or 100 μ M of the HSM, and viability was measured at 24 h, 48 h, and 7 days using the XTT assay relative to untreated and serum-free controls. At 24 h, 10 μ M the HSM produced slightly higher viability than higher doses. By 48 h and 7 days, all concentrations reduced viability, with 50 and 100 μ M producing the greatest toxicity. These results suggest minimal short-term effects at low doses, but substantial dose- and time-dependent cytotoxicity with prolonged exposure. Ongoing work will assess lower concentration ranges, alternative culture conditions, and compound stability.

Abstract Name: The Resale Advantage: Assessing Fairness in Online Ticket Purchase

The ticket purchasing experience has evolved from a simple transaction into a high-stakes digital race. With demand for concert tickets, sporting events, and entertainment increasing, some ticket platforms have attempted to make purchases more accessible by adding exclusive access codes and pre-sale benefits. But, there still appears to be a gap between these efforts and the perception of fair access for the general public. Specifically, I suspected that the effectiveness of online ticketing systems at ensuring fair access for the general public varies depending on the purchase channel used. To formally test the hypothesis of an accessibility gap, I constructed a survey of 15 questions and collected the data through RepData, yielding 413 responses from US citizens 18 and over. My results indicate that secondary marketplaces (resale platforms such as StubHub, VividSeats, or SeatGeek) are most effective at ensuring fair access to tickets for the general public. Furthermore, my results showed that primary platforms (such as Ticketmaster) were most likely to limit consumer access. These results prompt further investigation into how the structures of primary and secondary systems differently shape accessibility and fairness in the ticketing market.

Abstract Name: Draft Genome Assembly of Antarctic Microbe *Nocardioides* spp.

Members of the genus *Nocardioides* are Gram-positive, aerobic actinobacteria characterized by high GC content and broad ecological distribution across soil, aquatic systems, and extreme environments. While most documented strains are reported from the U.S. and China, the Branchwater Metagenome Query data indicate that *Nocardioides* species also occur in additional global regions. The isolates in this study originated from seawater ice cores collected near McMurdo Sound, Antarctica. The enrichment culture was serially diluted, plated onto seawater complete media, and pure cultures were obtained from select colonies. Genomic DNA was extracted using the Zymo Quick-DNA (Fungal/Bacterial) Mini Prep Kit. Libraries were prepared using the Nextera XT kit (Illumina). Genome assemblies generated using the HU Genome Assembly Pipeline, consisting of the following programs: FASTQ, Trimmomatic, SPAdes, QUAST, and Prokka. Phylogenomic was conducted using GToTree and visualized using Interactive Tree of Life (iTOL). The phylogenomic tree placed our isolates in the same clade as *N. seonyuensis*. Anvi'o was used for comparative genomics. The results revealed 10 unique gene clusters present only in the isolates and absent from all reference genomes, although these clusters currently lack functional annotation. In addition to this, the CAZyme profile from dbCAN3 further supports ecological specialization: the genome encodes 76 glycosyl hydrolases and 8 carbohydrate esterases, along with 23 carbohydrate-binding modules, suggesting an expanded capacity to degrade complex polysaccharides present in marine Antarctic ecosystems. Average Nucleotide Identity (ANI) value comparisons generated by pyANI showed that the isolates are 100% identical to one another, but share <86% ANI with all other available *Nocardioides* genomes. Because the accepted species boundary is 95% ANI, the 3 draft isolates meet genomic criteria for classification as a novel species of *Nocardioides*.

Abstract Name: Cultivating Scholars: Mentorship Transforms Adult Learners into Researchers

Adult learners returning to higher education bring determination and resilience but face unique challenges balancing coursework with full-time jobs, families, and community responsibilities. Their academic journeys often unfold during late nights and weekends, demanding extraordinary persistence. Yet, when paired with dedicated mentorship, these learners can achieve transformative outcomes as researchers and scholars. This presentation highlights the story of three working adult learners in an organizational leadership program who exemplify this potential. Despite their demanding schedules, these students collaborated closely with their mentor to apply for and successfully receive grant funding to conduct a qualitative multi-case study examining effective leadership in promoting diversity, equity, inclusion, and accessibility (DEIA) in higher education. Their research synthesized interviews with faculty, staff, and administrators at a private university, producing actionable insights on inclusive leadership, authentic role modeling, and structural reforms that

advance equity. By completing this project before graduation, they not only met rigorous academic standards but also contributed meaningfully to the broader conversation on leadership and diversity in higher education. The success of this project underscores the vital role of mentorship in cultivating scholars across diverse student populations. Through encouragement, structure, and motivation, mentors help adult learners aim higher than coursework completion alone—guiding them toward ambitious scholarly goals. This case demonstrates how mentorship can elevate students beyond traditional expectations, positioning them to secure resources, engage in original research, and disseminate findings that shape practice. By sharing this experience, the presentation will illustrate how mentorship transforms adult learners into confident scholars who achieve academic excellence while addressing real-world challenges. It affirms that cultivating research success is not limited to traditional undergraduates: with the right guidance, adult learners, too, can flourish as researchers, contribute to their fields, and model resilience and leadership for future generations.

Abstract Name: Does modulation of the S1P-S1PR2 signaling axis confer cytoprotective effects in a cellular model of NPC1?

Niemann-Pick type C (NPC) disease is a progressive neurodegenerative disorder caused by defects in the lysosomal trafficking proteins NPC1 (95%) and NPC2 (5%), required for cholesterol and sphingolipid transport. Defective trafficking leads to the accumulation of cholesterol and sphingolipids in endosomes and lysosomes, disruption of endocytic transport, and impaired autophagy. While cholesterol trafficking has been extensively studied, dysregulated sphingolipid metabolism is also central to NPC pathogenesis. Sphingosine-1-phosphate (S1P) is a bioactive lipid that binds G protein–coupled S1P receptors (S1PRs) and functions as an extracellular and intracellular signaling molecule regulating vascular development, endothelial barrier function, and cell survival. Multiple NPC1 mutant cell models exhibit decreased S1P levels due to impaired sphingosine kinase 1 (Sphk1) activity in endocytic vesicles. S1PR1 and S1PR2 are members of a five-receptor S1PR family and function inversely: S1PR1 activates the proliferative ERK/AKT pathway, while S1PR2 activates the Rho/ROCK pathway to modulate diverse cellular outcomes. JTE-013, a selective S1PR2 antagonist, has been shown to reduce cell death in various disease states. We hypothesize that inhibiting S1PR2 with JTE-013 will reduce Rho/ROCK signaling and enhance S1PR1-mediated mitogenic responses to S1P, representing a potential therapeutic strategy for NPC. NPC-deficient cells will be treated with JTE-013 at varying concentrations with or without exogenous S1P for 24–48 hours. Activation of MAPK, Rho/ROCK, and apoptotic pathways will be assessed by immunoblotting, and cell survival will be measured using CCK-8. We expect decreased ROCK activation, increased MAPK activation (pERK/pAKT), and reduced cell death in JTE-013–treated NPC-deficient cells.

Abstract Name: Novel Deep-Sea Coral Imputation Technique: Filling in Missing Data to Further Coral Conservation

Missing data, i.e., data values that are not stored for a variable, occur in different forms in all fields of data, including ecological datasets. Missing data can lead to a lack of statistical power and produce biased results. Statistical and data science methods are heavily utilized to mitigate issues with missing data, with many of these methods falling with the classification of imputation techniques. This research investigates missing data issues with the National Oceanic and Atmospheric Administration's (NOAA) deep-sea coral and sponge dataset. Deep-sea corals are slow-growing, fragile, and stationary animals that are currently being destroyed due to increased amounts of bottom-trawling, oil drilling, and ocean acidification. With the prevalence of missing data in the dataset, we propose a novel imputation technique that incorporates biological information of the corals. This new imputation method could also be applied to other slow growing organisms. Because deep-sea corals are slow-growing and stationary animals, we can claim with a degree of certainty that they were present in years prior to observed records at their respective locations. The main idea of the imputation method is to take the average size of a coral species divided by its average growth rate to calculate a 'backfill range' for a recorded coral at a certain location and time. For example, a coral observation recorded in 2010, with a backfill amount of 10 years, would have imputed values for that location from 2000 to 2009. Using NOAA's data, we applied our method to *Desmophyllum* spp. corals. Our results show that approximately 9% of data values were original and 91% of values were backfilled for *Desmophyllum* spp. Our technique will create more robust data sets that will allow the scientific community to have an increased understanding of deep-sea coral biodiversity, thus furthering coral conservation tactics.

Abstract Name: Neuropharmacological and Regulatory Drivers of Tianeptine Misuse in the US: A Growing Public Health Concern

Tianeptine is an atypical antidepressant that houses a unique set of neuropharmacological aspects, most notably its mu-opioid receptor activity, which allows for both its positive therapeutic effects for treating patients with depression, but also its high potential for misuse and abuse. Although this drug is not approved by the FDA, Tianeptine has made itself accessible in the US through online and retail sales due to its marketing as a dietary supplement. Most recently we have seen an uptake in the reports of dependence, misuse, and even overdose of this drug; creating a growing public health concern. Our literature review aims to analyze the underlying unique neuropharmacological mechanisms, population patterns of use, and the regulatory influences that are contributing to the concerning usage. Through a systematic review utilizing Covidence software, we can analyze studies describing Tianeptine's mechanism of action and epidemiologic data encompassing poison control reports, surveillance data, and any existing regulatory frameworks. Our findings highlight how the intersection of neuropharmacological susceptibility and underwhelming regulatory oversight has contributed to and enabled the misuse of this substance. By integrating neuropharmacologic, epidemiologic, and differing policy perspectives, this review will strengthen evidence-based regulation and provide empowerment for pharmacists and healthcare providers to first recognize the growing misuse of Tianeptine. It will also support them in advocating on behalf of their patients and communities through

compassionate care while setting a precedent for regulatory authorities to take informed action in addressing this growing issue.

Abstract Name: Making Her Blush: The role of queer women's literature, fashion subcultures, and theatrical pastimes in the creation of François Boucher's erotic paintings.

Throughout the centuries François Boucher has been captured within a polarizing tension; characterized as an emasculated symbol of debauchery and women's immorality by his contemporaries like Diderot, then later portrayed as a voyeuristic pillar of traditional heteropatriarchy by scholars like Erica Rand. Only within recent years has this contradiction been examined, primarily through the gender focused work of Dr. Melissa Hyde. The nuanced nature of Boucher's intimate depictions of women requires the specific consideration of women's influence, particularly of those inclined to engage in homosexual relationships. Does the gendered depiction of intimacy between women serve as a reinforcement of hetero-supremacy or have queer women left traces of themselves betwixt the mutual gaze of Diana and Callisto? Close looking and research into French eighteenth-century women's pastimes illustrate the definite influence of queer women on the creation of Boucher's erotic paintings. Throughout the rococo homosexual women immortalized themselves not only as the subjects of the rococo but also as intended viewers. The coquette-reform literature and theater of eighteenth-century women as well as their coquette fashion and artistic patronage reveal an apparent consumer base. Those who are often relegated to invisibility beyond the margins of history enjoyed rich lives full of coquette-reform literature, cross-dressing theater, and visits to the Salon. This unusual historic moment was facilitated by the same increase in social mobility that birthed the aristocrat coquette, Madame de Pompadour. Through the application of queer, feminist, and social historical methodologies my work demonstrates the historical presence of queer women within the art of François Boucher.

Abstract Name: The Chase for Control in a Capitalist System that Distorts Moral Purpose: An Analysis of Ambition in Danielle Evans's The Office of Historical Corrections

A common Marxist criticism of capitalist society is that it conditions individuals to measure their worth based on where they stand in a social hierarchy rather than through real moral fulfillment. Within these systems, even pursuits such as understanding history, which should spread awareness about the corruption occurring within the hierarchy, can be commodified and used to reinforce the very structure it is meant to challenge. This dynamic is explored in Danielle Evans's The Office of Historical Corrections, a novella from 2020 that examines how institutions can shape our identity and purpose. The novella follows Cassie, a former history professor who now works for the Institute of Public History, a fictional government agency established in order to address growing concerns about pervasive misinformation about the historical record. Cassie's job leads her across the United States correcting historical inaccuracies in public displays. This mission initially seems to promote progressive goals regarding the pursuit of truth. Despite this, many details in the story

indicate that Cassie's intentions with IPH are not entirely selfless; Cassie's actions often feel like attempts to assert her own authority over others. The novella also introduces the Free Americans, a white supremacist group which heavily resists the work done by IPH. The leader of this group is Chase Hall. Despite his and Cassie's opposing moral views, the two mirror one major theme; they both transform their insecurities into power, Cassie through authority, and Chase through extremist ideals. Their parallels show how capitalist systems are capable of distorting moral purpose and turning ambition into a struggle for control.

Abstract Name: How a "Real Man" Feels: Identifying the Appeal of Conservative Rhetoric Based on Interviews with Gen Z Men

Gen Z is widely viewed as the most progressive generation, yet the 2024 election revealed a surprising divide: while most young voters supported Harris/Walz, white Gen Z men without college degrees backed Trump at strikingly high rates. Psychologists note these men are still forming masculine identities and are heavily influenced by media figures. Economic anxiety, pressure to fulfill traditional provider roles, and appeals to jobs and lower taxes made Conservatism especially compelling to them. Because of this relatively recent phenomenon, qualitative research on this population in either popular or scholarly media is scant. This project sought to understand young men who have aligned themselves with conservative tenets with the goal of offering preliminary conclusions about what may be driving its unprecedented rise among Gen Z men. This project presents findings from nine qualitative interviews with Gen Z men (ages 19-22) who identify as conservative in order to develop an enriched understanding of the meteoric rise in popularity of Trumpism and Conservatism within this group. The nine interviews—each lasting between 30 and 60 minutes and conducted by a male undergraduate peer—worked to create an open environment for participants to elicit the narrative of how their beliefs developed over time. Using grounded theory, we analyzed the transcripts to identify four emergent themes: (1) finding inspiration, where men discuss what drew them to conservatism, (2) zones of belonging, where men explain how they find their place in conservatism (3) evolving personas, where they describe the evolution of their conservative identity and (4) understanding current issues, where they apply their conservative identities to current events and political issues in their daily lives. Together, these data offer a richer, more nuanced picture of the forces shaping the popularity of Conservatism and Trumpism among Gen Z men.

Abstract Name: Free and Fare: How Commute Burdens Further Displacement and Reinforce Social Inequities

As gentrification and rising rents push low-income New Yorkers farther from job centers, the gap in commute time and distance has deepened. In a nation defined by widening wealth inequality, it is difficult to imagine how a public transportation system – especially in the country's economic epicenter – can meet needs while serving as both a public benefit corporation and a for-profit. Understanding who funds and orchestrates the city's transit system reveals what political interests are embedded in its design. While public transportation

should bridge economic and social mobility gaps for New Yorkers, decades of underfunding and misguided priorities have left the system increasingly inaccessible. This paper challenges the political claim that the systemic pushout of New Yorkers is unrelated to transit policy. Using IPUMS USA data on commute burdens by class, gender, race, and immigration status, alongside transit budget allocation between 2014 and 2023, it identifies four central trends; (1) commute times increased for black and brown commuters across the board; (2) non-white and immigrant commuters in poverty consistently face longer commute times; (3) transit spending prioritizes large capital projects and policing over accessibility and material needs; (4) these patterns persist across two democratic mayoral administrations, revealing how the logic of capital prevails over nominally progressive governance. An increasingly mismanaged transportation system reinforces racialized and class-based displacement. The paper concludes by defining the need for free public transportation while also considering the potential economic and housing implications of this shift in a system designed to displace in the name of profit.

Abstract Name: Assessing Current Heavy Metal Concentration in Surface Sediments of Three Lakes in Northeastern Illinois

Heavy metal pollution in Midwestern lake surface sediments presents a threat to human and ecosystem health. The concentrations of heavy metals in many lakes, in particular smaller lakes, are often unmonitored in surface sediments. Unknown concentrations of heavy metals in surface sediments can make it difficult to assess human exposure to these toxic chemicals which lead to various cancers, organ damage, impaired reproductive systems, and/or worsened development. Our goal is to assess how concentrations of lead, zinc, and arsenic vary across Banana Lake, Willow Lake, and Lucy Lake surface sediments in Lake County, Illinois due to differing sources of pollution in each watershed. The concentrations of lead, zinc, and arsenic in lake surface sediments are dependent on the variable land covers and management practices, so Banana Lake, Willow Lake, and Lucy Lake in Lake County, Illinois were chosen for their varying types of watershed land cover, differing management, and contrasting exposure to heavy metals. The sediment samples were collected in the field using an Ekman dredge and dried in an oven at 105°C for 28 hours. To extract zinc, lead, and arsenic, we added nitric acid and hydrogen peroxide to the samples, and placed them in a microwave digester for 15 minutes at 200°C. We then used ICP-OES to quickly assess quantities of heavy metals in the samples. We hypothesize that each site will yield different quantities of zinc, lead, and arsenic because of differing point and non-point sources of heavy metal pollution in their watersheds. Depending on our findings, we'll be able to evaluate the need for further data collection and specific lake management plans. Quantifying heavy metal pollution in lake sediments can inform better prevention and recovery efforts that can minimize threats to human and ecosystem health.

Abstract Name: Differences in Acculturative Stress Between Larger Population and Smaller Population Asian-American Subgroups

Much of the research examining acculturative stress among Asian-Americans focuses on subgroups with the largest representation in the United States (e.g. Chinese, Vietnamese, Filipino). This means that smaller subgroups may be underrepresented in the data and therefore, underrepresented in findings and discussions of this type of stress. It is important to gather data on these smaller subgroups because they may not have the same access to peers of similar ethnic backgrounds through sources of culture, such as ethnic communities and enclaves. The current study will use the National Latino and Asian American Study (NLAAS) to test for differences in stress across subgroups within the “Asian-American” category, focusing on differences by country of origin and the relative size of peer group subpopulations. The study will also control for other individual characteristics and mental health conditions. Results are expected to describe differences between country of origin subgroups of Asian Americans and provide insight into how social support and access to different levels of social connections of a similar background and country of origin impact mental health outcomes.

Abstract Name: Non-Powered Dams Conversion for Electricity Generation

Energy generation infrastructure cannot scale as rapidly as global power demand increases due to artificial intelligence and data centers. There exists untapped hydropower potential of an estimated 80,000 non-powered dams (NPD, dams without electricity generation) in the United States. Through the 2026 Hydropower Collegiate Competition (HCC), the project aims to explore conversion techniques for existing non-powered dams for electricity generation while minimizing environmental impacts and benefiting the local community. The retrofit would non-destructively add to existing infrastructure and create additional opportunities for local communities, such as controlled irrigation. Timed water releases for downstream irrigation canals while simultaneously generating power will enhance agricultural productivity and drought resilience. Based on an in-depth study of a chosen site, the project intends to create a framework for future conversion of NPDs. The site selection will factor in risk mitigation, sustainability goals, economic projections, and co-development opportunities, such as controlled irrigation release and tourism. Based on prior explorations of multistorey reservoirs and turbine designs, the project will build and test a scaled prototype to operate in conditions found at the selected site. The built model aims to reduce transition costs, minimize environmental repercussions, and benefit surrounding communities. The findings should inform future decisions on upgrading existing non-powered dam infrastructure rather than creating new reservoirs to sustainably address growing energy needs.

Abstract Name: The effects of propylparaben on limb regeneration and digit formation in *Ambystoma mexicanum*

Developmental biology and the ability to regenerate limbs has interested the scientific community for years. Studying developmental capabilities in mammals, fish, and amphibians has become a high priority in biological research and the medical community. The purpose of this project is to observe the effects of an antimicrobial/antifungal chemical called propylparaben (PPB) on the stages of wound healing and limb regeneration in the model organism *Ambystoma mexicanum* (Mexican axolotl). The wound healing and limb regeneration process of the Mexican axolotl relies heavily on hormonal, cell, and nerve signaling to regenerate a fully functional limb. Prior studies with PPB in mammals have shown a correlation between increase concentrations and a reduced rate of development due to its ability to reduce hormonal signaling. High and low concentrations of PPB dissolved in ethanol were subcutaneously injected into axolotls following amputation of the right hind limb distal to the body and before the joint. Photographs were taken every 4 days for a total of 48 days to observe wound healing, limb regeneration, and digit formation processes. We hypothesized that a higher concentration of PPB would produce a more significant decrease in the rate of limb regeneration and digit formation. We did observe a significant decrease in the rate of limb regeneration and length following exposure to high concentrations of PPB, but only during the period between 16-24 days. We also observed the formation of extra digits in groups that were exposed to both high and low concentrations of PPB.

Abstract Name: Expression and Purification of Hsp40 Homolog Ydj1 to Explore Non-Canonical Protein Prenylation

Ydj1 is a heat-shock protein present in yeast that aids in allowing yeast to grow under high temperatures. To perform its job as a co-chaperone to Type I Hsp40, it must undergo the process of prenylation at its "CaaX" box sequence. However, Ydj1 does not follow the traditional prenylation pathway and instead undergoes a shunt pathway. Studies have shown that any post translational modifications past this shunt pathway inhibit the ability of Ydj1 to function. However, there is still a lot of mystery surrounding Ydj1 and what exactly its boundaries are for prenylation and the ability to function. This project worked to express the Ydj1 protein in bacteria as well as began work to purify the protein. Samples from each attempt were analyzed using Coomassie Blue stain gels and western blots. At the end of the project, it was found that Ydj1 is better expressed when grown in IPTG, under a low IPTG concentration and a low temperature, rather than auto-induction media. Only one attempt of purification was able to be completed and presented issues with being able to have the protein stable and soluble enough to be worked with.

Abstract Name: Remember Their Names: Media Coverage of Serial Murders from Jack the Ripper to the 21st Century

This paper analyzes the sensationalism of the infamous Jack the Ripper case in 1888 in Whitechapel, England, and how aspects of it have carried on to affect societal interest in killers over their victims in cases today. It argues for the realization and recognition of victims over their killers and aims to bring more attention to how the development of media has made it easier to warp information and influence public opinion while burying important stories and testimonies. Utilizing primary sources including recorded evidence and reports from the case, newspapers, and political cartoons, and secondary sources on the sociocultural environment of Victorian England from Martha Vicinus' edited work *Suffer and be Still* and Cameron A. Mitchell's *The Language of Murder*, the research reveals many similarities to modern events in regards to how many killers and their cases are treated by the public. These resources combine various different perspectives of the case including class, gender, and racial views based on the emerging working-poor women and high levels of immigration at the time. The paper brings in famous contemporary cases as well, noting comparable social attitudes towards them and the emerging pop-culture references that appear as a result. This paper points out the blatant sensationalism of real killers in media and urges readers to be mindful of the stories and families of victims. It discusses the differences in portrayals of the same cases throughout news sources and reminds readers that sensationalism is not always appropriate, but can always be taken too far.

Abstract Name: Improving Forensic Identification of Cathinone Isomers Using Multi-Energy Ionization.

Structural isomers of cathinone related compounds are difficult to differentiate using traditional analytical methods such as gas chromatography–mass spectrometry (GC-MS) because their mass spectra show only subtle differences. This research aims to enhance GC-MS discrimination by utilizing the data collected at varying ionization energies used in the electron impact ionization (EI). Preliminary studies conducted using Direct Analysis in Real-Time (DART) mass spectrometry (MS) database available freely (NIST) to compare the spectral differences between spectra collected with orifice 1 voltages of +30 V, +60 V, and +90 V. Our hypothesis is that fragmentation patterns correlate with ionization energy and these differences can be used to distinguish positional isomers effectively. DART mass spectral data were obtained and interpreted through NIST software for positional isomers of cathinones including chloromethcathinone (CMC), chloroethcathinone (CEC), and methylethcathinone (MEC). Mass spectral data of three isomers from each cathinone representing isomers differ by the chlorine atom's position on the phenyl ring (e.g.: 2-CMC, 3-CMC, and 4-CMC) were selected for analysis. Three dimensional visualizations of fragmentation patterns across different energies revealed clear fragmentation differences between isomers, for example: 2-CMC displayed major distinctions from the other two isomers, while 3-CMC and 4-CMC showed subtle but reproducible differences in both abundance patterns and energetics. These findings demonstrate that expanding GC-MS data into three dimensions can enhance the discrimination between closely related isomers. The next phase of this research will involve collecting a complete energy profile for all three cathinone isomers using smaller EI energy increments (10, 20, 30 eV, etc.). The long-term goal is to develop a

searchable database of 3D GC-MS models, enabling analysts to compare unknown samples against a robust spectral library.

Abstract Name: Organizing for Safe Water Services

Over two decades after E. coli contamination in Walkerton caused seven deaths and spurred comprehensive regulatory reform, Ontario water utilities continue navigating complex risk management challenges. The province implemented strict water quality testing requirements and mandated a 21-element drinking water quality management standard for proactive risk management. Still, we do not know which combinations of factors, including regulatory compliance, organizational culture, resource availability, or operational processes, actually drive effective risk management. This study examines risk management performance across five Ontario drinking water utilities operating under the province's unique regulatory framework. We analyzed annual water quality data including chlorine residuals, turbidity measurements, microbiological test results, trihalomethane levels, and reported incidents from 2019 to 2024, along with in-depth interviews with utility operators. To examine past isolated factors, we employed fuzzy-set Qualitative Comparative Analysis (QCA) to understand how multiple conditions interact to produce effective risk management. Our analysis explores the interplay of government regulations, utility resources, organizational culture and norms, existing infrastructure and technology, and utility processes within Ontario's regulatory context. Through thorough double-coding of interview transcripts in NVivo and fuzzy-set calibration, we identify which combinations of these factors consistently contribute to effective risk management. We measure effectiveness through sustained water quality performance and incident prevention. This research provides Ontario drinking water utilities with insights into risk management practices tailored to their specific regulatory environment. By uncovering how various factors combine to support or hinder risk management effectiveness, our findings offer pathways for utilities to strengthen their practices while working within Ontario's regulatory framework and their environmental constraints.

Abstract Name: The Effect of Carrier Tone Frequency on Sensorimotor Synchronization to Binaural Beats: A Behavioral Measure of Perception

The perception of binaural beats (BB) has been shown to be heavily influenced by the frequency of both the carrier tone and beat itself; however, no prior research has examined how carrier tone frequency influences the perceptibility of BB in a sensorimotor task. Studies on sensorimotor synchronization have demonstrated that individuals are capable of synchronizing their motor activity to a variety of different rhythms, with the greatest accuracy occurring at low frequency auditory rhythms between 1 and 2 Hz. This accuracy suggests that sensorimotor synchronization to BB can serve as an accurate reflection of active perception. The present

study investigates how carrier tone frequency influences sensorimotor synchronization to BB, employing synchronization performance as an index of BB perception. Participants were randomly assigned to one of four carrier tone conditions (100, 200, 300, or 400 Hz) and presented with 11 different delta-range BB (0.5 Hz - 3Hz), each repeated once. Across 22 trials, participants performed a sensorimotor synchronization finger-tapping task in which each 90-second trial consisted of three phases: a listening phase, a tapping-with-audio phase, and a continuation phase without audio. We expect to observe that the synchronization error rate to delta BB is lowest in lower frequency carrier tone conditions, and error rate increases as carrier tone frequency increases. Because BB have been shown to influence different cognitive tasks, such as sleep and relaxation through entrainment, and these findings are dependent upon the frequency of the BB, understanding the carrier tone conditions at which delta wave BB are best perceived may be helpful in ascertaining the conditions at which entrainment is most effective.

Abstract Name: Clean Curriculum: Menstrual Hygiene Education in Bangladesh's Secondary Schools

Current Bangladeshi efforts include policies and curriculum for secondary schools regarding menstrual hygiene management education. This project will research the impact of menstrual hygiene management education on teenage girls in Bangladesh from 2005 to 2025. The project will expand on research arguing the importance of educating girls to reduce absenteeism rates and on the effectiveness of government policies. Thematic coding will draw on selected codes inspired by the United Nations' guidance on menstrual health education. Coding will analyze Bangladesh's National Education Policies from 2005 to 2025 in five-year increments. Findings may reveal that Bangladesh's education policies do not provide adequate support to teenage girls. The project will provide the water, sanitation, and hygiene (WASH) organization with the resources to advise the Ministry of Education on developing a menstrual hygiene management curriculum tailored to Bangladeshi girls.

Abstract Name: What Forms of Inferential Language Characterize Teacher and EL Student Language Produced During One-on-One Instructional Conversations During Synchronous Remote Instruction?

Understanding inferential language is a critical component of English Learners' academic language development and overall school success. This study aims to describe the forms of inferential language that characterize teacher and student talk during one-on-one instructional conversations. Transcripts were drawn from synchronous remote lessons with ten 4th-grade Spanish-speaking English Learners and their bilingual instructors. Using meaning codes from the Systematic Assessment of Book Reading (Pentimonti et al., 2012, 2021), we will analyze six episodes of unscripted conversation embedded within each scripted lesson. Teachers were trained to sustain back-and-forth exchanges and to use questions strategically to provide upward and downward scaffolding. Each teacher and student utterance (approximately 106 per transcript)

will be coded for utterance type, including comment, question, directive, and cloze prompt. All questions will be categorized by question type, including wh-basic, why, how, auxiliary-fronted, and yes/no. Utterances will also be coded for the presence of inferential language features such as sequence or temporal markers, comparison and contrast, cognitive terms, feelings and emotions terms, desires/preferences, judgment/perspective, cause-and-effect relationships, and predictions or forecasts. We will generate descriptive data quantifying and characterizing the inferential language produced by teachers and students, and we will examine how teachers' inferential language use varies by question type. These analyses will serve as a pilot for a larger study designed to model how teachers' deployment of inferential language and scaffolding strategies predicts students' production of inferential language during instructional conversations.

Abstract Name: Obstacle Negotiation is affected by Poor Stereopsis in Amblyopia - Case Study

Amblyopia is the most common cause of vision impairment in a single eye, affecting over 100 million people worldwide. Because of the condition's impact on overall binocular vision, untreated cases of amblyopia can result in decreased stereopsis and reduced visual acuity in the affected eye. A previous study found that participants with reduced stereopsis due to amblyopia exhibited similar gait changes to visually normal participants when crossing an obstacle, though those with reduced stereopsis were more cautious for taller obstacles. However, this study examined younger adults, and analyses of gait behaviors in older adults with amblyopia have yet to be studied. Vision and gait were compared between 15 controls (67-88 yr) and one older adult with amblyopia (81 yr). Adults walked along a 6-meter walkway stepping over a single obstacle approximately 4 meters from the start. Gait was measured using motion capture (13 cameras sampling at 120 Hz, Oqus 3-Series, Qualisys AB, Inc., Göthenberg, Sweden). Mean and 95% confidence intervals for vision and gait factors were calculated for the control group using RStudio (RStudio, Boston, MA), and the amblyopia patient's data was compared to the confidence intervals. The amblyopia patient differed from the controls in the following demographic features and visual functions: height, binocular and monocular visual acuity, binocular contrast sensitivity, and stereopsis. Gait analyses of the amblyopia patient showed faster obstacle crossing speed, shorter step and stride lengths, and farther trail foot positioning just prior to crossing the obstacle. These findings indicate that amblyopia in the older participant may lead to inaccurate obstacle distance perception due to impaired stereopsis and altered gait, thereby increasing their susceptibility to falls and injury. Characterizing gait behaviors in people with amblyopia of all ages highlight the need for further investigations into mobility consequences of reduced stereopsis to inform fall-prevention strategies.

Abstract Name: Evaluating Navigational Patterns of Individuals with Reduced Central Visual Acuity during Gait

Age-related macular degeneration (AMD) is the leading cause of visual impairment in older adults, affecting 1 out of 10 people aged 80 and older with an expected increase in these numbers in future generations. AMD targets the central 15-20 degrees of the visual field (frequently in both eyes), creating a central scotoma that afflicts the fovea. With tasks including walking, running and other mobile activities, individuals with central/peripheral field loss experience a multitude of challenges and hesitations in daily occurrences. Visual information is a vital asset in determining future foot placements, as there is a minimal time span between established fixation points and determined footholds for support. Although many walking trials and gaze experiments have been conducted on patients with peripheral visual hindrances, gaze patterns for walking/moving/mobility/gait of those with central scotomas are yet to be understood. In this research, we investigate gaze patterns of those with normal vision and central vision loss with the use of a wireless eye tracking device as they complete walking trials with varying obstacles. Results from the eye tracking heat maps in both conditions of participants that individuals with central vision loss (CVL) focus their gaze more on the unfamiliar obstacle on the path rather than the end of the walkway. We also observed that individuals with CVL or peripheral vision loss (PVL) fixated on a larger area of the environment than those with normal visual acuity. This form of navigational strategizing may pose an increased risk of falls and injuries as those with CVL already experience mobility and depth-perception issues.

Abstract Name: What Makes a Home: Transgender Youth and Young Adult Perceptions of Housing Models

Despite increased research literature regarding the overrepresentation of transgender and gender non-conforming (TGNC) youth and young adults (YYA) within the homeless population, studies on tailored housing models to address this disparity remain limited. And within existing literature, even scarcer consideration is given to perspectives from TGNC YYA themselves on what housing and supports that fit their needs should look like. Meanwhile, outside of the scope of academia, grassroots housing initiatives led by and for TGNC folks are finding innovative ways to tackle homelessness in their communities. The goal of this exploratory study is to bridge the gap between literature, community, and young people by investigating what a “home” truly means for TGNC YYA who have experienced homelessness, and whether elements of community-led housing models resonate with that vision. Data will be collected through a focus group with six TGNC YYA, ages 18 to 25, who have experienced housing instability. Participants will be asked questions related to their firsthand accounts, visions of “home”, and thoughts on presented community-based housing models. The transcripts of the focus group dialogue will then be analyzed using thematic analysis, in order to interpret overarching themes between participant perspectives. These themes will inform a case study analysis of the community-based programs, conducted by the researcher using key informant interviews and document analysis. Findings will provide valuable input on how TGNC YYA conceptualize their housing needs and what factors from existing models would best align with them, informing future researchers’ ability to establish affirming, effective housing interventions that build on community designed models.

Abstract Name: Why Some May Not “Just Believe Science”: A Rhetorical Examination of Disparities in Public Health Distrust within the Framework of Health Equity

Contemporary outbreaks of previously eradicated disease have left American health officials in the predicament of convincing distrusting communities to opt in to vaccination programs responsible for reducing the prevalence of these diseases. Though distrusters are frequently written off as outlandish conspiracy theorists, there are nuances that confound this belief, especially when considering groups long disenfranchised by the United States. Historical medical abuses including Tuskegee Syphilis Experiment and the research conducted on women such as Henrietta Lacks have set the tone for an impeding of trust that is further supported by modern-day neglect reflected by infant mortality and cancer morbidity rates. To address this neglect, communication from health officials is an important strategy to repair broken trust. Effective communication begins with listening; therefore, this project employs a content analysis to examine rhetoric used by the Black community to better understand which pressure points health officials must address to regain trust. Historical African-American newspapers are examined alongside mainstream-media publications, utilizing both perspective coding and a keyword occurrence analysis. A statistically significant difference is found between each sample's mean number of negatively, but not positively coded articles. Statistically significant correlations between keywords include the relationship between references to Tuskegee with distrust and healthcare experimentation that is unique to the conversations occurring in African-American newspapers. These results suggest that public health communicators can seek to build transparency and trust by addressing concerns of constituents continually in their practice, rather than shutting critique out of their dialogue.

Abstract Name: Video-Based Micro-Assessments for Early Detection of Cognitive Changes Using Automated Question Generation

Early identification of cognitive decline is often limited by clinic-based assessments that occur infrequently and capture only brief snapshots of a person's cognitive functioning. In contrast, digital environments allow continuous, low-burden measurement of everyday behavior. This project explores whether short-form video interactions—paired with automatically generated comprehension tasks—can serve as noninvasive indicators of cognitive states in adults. As undergraduate researchers, we developed an automated pipeline that extracts transcripts from online videos, generates multiple-choice comprehension questions at different points in the video (approximately 30%, 70%, and 100%), and synchronises the timing of these questions with participants' viewing behavior. We also implemented logging tools that record passive engagement signals such as watch duration, pausing, skipping, replaying, and the time required to complete each question set. These data streams allow us to study how attentional patterns and working-memory processes unfold in real time. Linguistic features from each transcript guide the difficulty and structure of the comprehension items, while participant performance on timed questions provides a lightweight measure of attention and information retention. Based on prior findings in digital-behaviour research, we hypothesise that individuals with early cognitive vulnerabilities may exhibit slower completion times, less consistent accuracy, and more erratic viewing behaviour. We also expect that analyzing repeated sessions over time will offer more reliable insight into cognitive patterns than single-session measurements. This project aims to evaluate the feasibility of using short, automated, and ecologically valid video-based micro-assessments to monitor cognitive functioning outside laboratory settings. Our goal is to determine whether these digital traces can support scalable, continuous tracking of cognitive states while reducing participant burden. The tools and datasets

developed in this work also lay the foundation for future, more detailed investigations into digital markers of cognitive health.

Abstract Name: Modern Day Marketing: Marketing Experts' Choices on the Over Sexualization of Women

It was in the early 1900s that businesses used creativity in their targeting marketing communications en masse, as they discovered that brands could command higher prices than unmarked commodities as long as consumers perceived the brand to solve problems that they were either already aware of or were generated by these marketing communications. Women in sexualized contexts comprised a notable proportion of the creativity in these ads, and while it has changed forms across the decades, these images are still just as present in the marketing communications that reach consumers today. Although experts acknowledge that women are routinely subjugated in and by these images, the underlying question remains: why do sexualized images of women to sell products persist? This study examines the intersection between the over sexualization of women in advertising and the ethical or moral decision making of marketing professionals who continue to uphold these industry traditions. Building on existing multi-disciplinary research, individual interviews with marketing experts were collected and analyzed to understand why marketing teams veer away from their moral compass on this issue. The findings in this study point to insufficient education in university marketing departments perpetuate a cycle of anti-intellectual business demand and hypernormalization of the sexual objectification of women among consumers. These results are discussed, including implications for and guidance on more socially responsible marketing strategies. Keywords: women, media, marketing strategies, sexual imagery, mental health effects, ethical marketing strategies

Abstract Name: Chronic and Acute Academic Stress as Predictors of Anxiety and Depression: The Mediating Role of Academic Rumination

This research explores how chronic and acute academic stress contribute to anxiety and depression among college students, and whether academic rumination helps explain these relationships. Many students experience ongoing academic pressure as well as short, intense stressors like exams or deadlines. However, few studies examine both types of stress together or consider how repetitive negative thinking about schoolwork might worsen their effects. Understanding these connections is especially important as more students report struggling with stress-related mental health concerns. Many of these individuals are also seeking clearer explanations for why certain academic environments feel more overwhelming than others. The study will use validated surveys to measure chronic stress, acute academic stress, academic rumination, and symptoms of anxiety and depression among undergraduate students at a small liberal arts college. Students will also provide basic demographic information so that any group differences can be explored. These differences will then be interpreted within the context of the campus environment. Data will be collected from 100 undergraduate students through an online survey and analyzed using correlations and

mediation analyses to see whether rumination helps explain how stress leads to mental health symptoms. It is expected that both chronic and acute academic stress will be linked to higher levels of anxiety and depression. Students who ruminate more about academic problems are also expected to show stronger associations between stress and these outcomes. These findings will be discussed in the context of understanding why some students struggle more than others. They will also highlight how cognitive factors like rumination may shape emotional well-being and academic functioning across different stages of the college experience.

Abstract Name: The Impact of Hurricane Helene on Southwestern Virginia and North Carolina's Coldwater Fisheries

In the fall of 2024, Hurricane Helene brought record rainfall and flooding to southwestern Virginia and western North Carolina, raising immediate questions about how extreme hydrological events affected the cold-water fisheries of the Southern Appalachians. Salmonid species such as brook, brown, and rainbow trout are highly sensitive to disturbance, and previous literature indicates that storm impacts are often system-specific. However, little research has examined the effects of major flooding events on cold-water fisheries in this region. This project investigates Hurricane Helene's role in altering stream morphology, habitat availability, and salmonid population dynamics across three major river basins: the Holston, Watauga, and French Broad systems. Utilizing pre-storm ecological and hydrological data, the study combines USGS hydrographs, fisheries survey records, and GIS spatial analysis to compare conditions and population trends before and after Hurricane Helene's flooding. GIS analysis includes changes in floodplain disturbance across cold-water fisheries and watersheds, the flood susceptibility of hydrological regions, and the extent of disturbance along the storm's projected path. Outputs will be paired with fisheries population metrics to identify watersheds experiencing the greatest habitat disruption and shifts in density, distribution, biomass, and stocking influence. Statistical analyses, including paired comparisons and correlation models, will be used to determine the significance of change among salmonid populations. Preliminary expectations include substantial shifts in stream morphology, riparian damage, and reduced habitat suitability in heavily affected areas. These effects will likely cause short-term population declines, particularly in brook trout, due to their high environmental sensitivity. Results will be discussed in terms of ecological resilience, regional management implications, climate-driven hydrological extremes, and the broader consequences of mass disturbance events on Southern Appalachian cold-water fisheries. Ultimately, this project aims to provide a system-specific assessment of Hurricane Helene's ecological impacts and generate feasible strategies to support sensitive salmonid populations in southwestern Virginia and North Carolina.

Abstract Name: Skewed Sex Ratios in a Maryland Population of Painted Turtle

Male-skewed sex ratios reduce population-level reproductive capacity and can therefore pose a threat to animal populations. In freshwater turtles, male-skewed sex ratios are relatively common and can potentially be driven by female-biased road mortality during the nesting season. However, sexes can also differ in their season-specific activity levels, obscuring true patterns in turtle population sex ratios. Here, we conducted a study to determine the influence of road activity and season on measured sex ratios of painted turtles (*Chrysemys picta picta*) at the Patuxent Research Refuge and Bowie State University. We predicted that the male bias in sex ratio would increase with road density and in the summer. To test our predictions, we examined variation in sex ratio using historical as well as contemporary data over several sites, seasons (spring, summer, fall), and years (2000-2025). Surprisingly, we found no clear association between sex ratios and road usage or season. We also found remarkable consistency in the male-skewed sex ratio through two decades. We conclude that other mechanisms, such as predation of females during nesting, may drive the male bias of local painted turtles. We suggest continued study and monitoring to further understand the sex ratio bias and its consequences for long-term stability in freshwater turtles populations.

Abstract Name: The Integration of Artificial Intelligence in Healthcare: Opportunities and Concerns

Introduction: Artificial Intelligence (AI) is a rapidly evolving technology being used across myriad industries. As its capabilities expand, AI continues to reshape the way information is processed, decisions are supported, and services are delivered. Methods: Using a review of 14 scholarly articles, this paper examines the research of AI thus far within the healthcare field by addressing two questions: (1) How is the implementation of Artificial Intelligence in the healthcare field perceived by both professionals and consumers? and (2) How is Artificial Intelligence already being used in the healthcare field by professionals? Results: Findings show that the overall perception of AI's emerging role in healthcare has been more optimistic, as it is viewed as a tool that will enhance the field. However, concerns remain—especially during early stages of implementation—regarding algorithmic bias, privacy vulnerabilities, overreliance by professionals, and the loss of a “human touch” in care. AI implementation thus far is being used more as a support tool rather than an independent decision-maker. Its applications include administrative and operational tasks such as scheduling and resource management, diagnostic support, and clinical decision support systems (CDSS). Conclusion: Together, these findings highlight the potential impact that AI can have on the healthcare field, as well as important considerations that must be continuously evaluated as this technology becomes more prevalent in the industry.

Abstract Name: DEVELOPMENT OF ENVIRONMENTAL DNA TOOLKIT FOR DETECTION OF FRESHWATER MUSSELS (BIVALVIA:UNIONIDA) IN APPOMATTOX RIVER BASIN

Freshwater mussels are a keystone species providing crucial ecosystem services and river composition resiliency. Despite this, they remain one of the most imperiled groups globally. Traditional field sampling can often be laborious and ineffective in surveying rare species' distributions. Anecdotal evidence suggests the presence of freshwater mussels within the Appomattox river; the specifics of population sizes and suitable habitat remains an open question. Environmental DNA (eDNA) usage in conservation ecology has exploded in use within the past two decades, being far less invasive and cost-demanding than traditional methods. In an effort to detect presence of mussels in the Appomattox River basin and narrow the search space for traditional field sampling and thus the associated cost, an eDNA barcoding pipeline of the 16S mitochondrial ribosomal subunit was developed to target 16 extant mussel species in the Appomattox, but broadly the James River watershed. In collaboration with the U.S. Fish and Wildlife Service, we graciously received 130 freshwater mussel mitochondrial genomes to assist in the development of a 16S mitochondrial barcode. We will continue this work to procure the necessary consensus primers of the 16S mitochondrial genome and bioinformatic pipeline to assess the Appomattox River basin for presence of freshwater mussels. From our current understanding, this is the first usage of eDNA in the Appomattox River basin to detect freshwater mussel species presence.

Abstract Name: Sports Betting Legalization in the US: Substitution and Market Expansion Effects

My research reexamines the common assumption in the literature that the legalization of sports betting causes a strong substitution away from state lottery revenues. Using a staggered Difference-in-Difference (DiD) model with Callaway and Sant'Anna's estimator, I analyze panel data from US states between 2012 and 2024. I find that while lottery revenues initially decline following legalization, a result consistent with previous substitution effect research, the magnitude of such effect weakens significantly once broader gambling market dynamics are considered. Models that control for gambling market indicators, such as sectoral employment and real GDP, reveal that sports betting also contributes to overall industry expansion, meaning that the resulting losses in other gambling forms are considerably smaller than previously suggested. Overall, these results challenge the conventional static market view that overstates substitution effects and portrays sports betting as detrimental to other gambling activities, particularly state lotteries.

Abstract Name: Alpha Neurofeedback Training to Improve Visual Attention and Processing Speed in Younger Adults

Alpha neurofeedback training has been proposed as a method to enhance cognitive performance by increasing brain inhibition. While our long-term goal is to apply this technique to older adults, this study first examines whether younger adults can learn to modulate alpha power and whether such modulation influences visual attention and processing speed. Twenty younger adults were assigned to either an alpha neurofeedback training group (n = 10) or a control group (n = 10). During training sessions, participants in the neurofeedback group received real-time visual feedback of their EEG activity. All participants completed a cognitive test battery before and after the training period, including the Useful Field of View (UFOV), Digit Span, Symbol Digit Substitution Test (SDMT), Benton Judgment of Line Orientation, and selected conditions from the DKEFS Trails and Color Word Interference (CWI) tests. No significant differences were found in scores for UFOV, Digit Span, and Benton Judgement of Line Orientation assessments. Both groups showed significant pre-to-post improvements on the SDMT, DKEFS CWI, and DKEFS Trails assessments ($p < .05$). However, Group x Time interactions did not reach significance for any measures, suggesting both the neurofeedback and control groups improved at similar rates. Overall, changes in cognitive performance did not differ significantly between groups. Comparable improvements across groups suggest ceiling effects typical of younger adults. These findings provide a foundation for future research investigating whether alpha neurofeedback can enhance cognitive outcomes in older adults, where greater benefits may be observed.

Abstract Name: Synthesis and Characterization of L-asparaginase and glucose oxidase encapsulated PLL-g-PEG Nanoparticles for Therapeutic Delivery.

Smart drug delivery systems (SDDS) have emerged as a promising strategy for cancer therapy. In SDDS, advanced methods are used to deliver active drug molecules to selectively accumulate in the disease tissue for a prolonged time. These methods utilize highly controllable drug release mechanisms to enhance their therapeutic effects and to reduce related side effects. Furthermore, these drug delivery systems allow for the simultaneous delivery of drugs and/or genes (co-delivery), allowing for synergistic effects and enhanced anti-tumor activity. Nanoparticles (NPs) have broad applications in drug delivery. Their potential to shield healthy tissues from cytotoxic chemotherapies represents a significant advancement in targeted payload delivery. Our research focuses on co-encapsulating L-asparaginase (L-ASNase) and glucose oxidase (GOx) in poly(L-lysine)-graft-poly(ethylene glycol) (PLL-g-PEG) NPs. L-ASNase is a therapeutic enzyme which can destroy asparagine-dependent tumors by degrading circulating L-asparagine and destroying malignant cells. GOx is considered an attractive glucose depletion strategy and has been extensively used in cancer starvation therapy. In addition, GOx catalyzed glucose oxidation exerts a variety of effects on the tumor environment, such as enhancing hypoxia and increasing acidity. Protein immobilization was achieved using various crosslinkers (DTSSP and DSS), enabling controlled release under specific conditions. Dynamic light scattering (DLS) analysis of NPs revealed a hydrodynamic diameter of ~80 nm and a polydispersity index (PDI) of 0.153. SDS-PAGE data confirmed the successful encapsulation of both L-ASNase and GOx within NP complexes, although encapsulation was partial. In vitro protein release studies were conducted by exposing the NPs to dithiothreitol (DTT) for 2, 5, and 9 days, followed by SDS-PAGE gel electrophoresis. Electron microscopy imaging showed spherical NP morphologies. Our ongoing studies focus on obtaining quantitative protein release data from NPs by encapsulating fluorescently labeled proteins.

Abstract Name: Bridging the Gap: Evaluating the Integration of Mobile Health Units into Healthcare Networks for Referral and Follow-Up After Health Screenings

Introduction: In many low-income, or otherwise underserved areas, basic healthcare needs go unmet partially due to limited access to clinics, transportation barriers, and provider shortages. As preventive care is crucial for promoting long-term wellness and reducing disease incidence, effective strategies to reach these populations are essential. Mobile health units (MHUs) have emerged as valuable tools for improving access to preventive care by bringing services directly to communities. Previous studies demonstrate that MHUs, such as mobile eye units, improve disease detection rates by reaching populations that may otherwise go undiagnosed- thus serving as a bridge for accessible healthcare. However, challenges remain, such as lack of patient retention, incomplete follow-up after abnormal results, and limited integration with broader healthcare networks. Furthermore, disruption of medical services provided during the COVID-19 pandemic amplified the need to increase equitable access to preventive and diagnostic care. Thus, this study reviews existing evidence on the integration of mobile health units within established healthcare networks to provide patient care.**Method:** This literature review examines peer-reviewed studies on mobile health screening programs for conditions such as eye disease, breast cancer, and chronic diseases. Key outcome measures include disease detection rates, treatment compliance, and service delivery efficiency (e.g. cost per attendance and treatment duration). Both quantitative and qualitative analyses from prior studies are reviewed to assess impact and identify contextual factors influencing success.**Results:** Anticipated results of the analysis will help identify strategies for effective healthcare delivery. We expect to compare the effectiveness of various MHU providers to determine possible methods of increasing referral rates and efficient follow-up care.**Conclusions:** Mobile health units are a promising option for expanding screening access and early disease detection. The results of this research will identify methods to strengthen MHU integration, improve continuity of care, and support sustainable health equity

Abstract Name: GC-MS Analysis of Commercial and Non-Commercial Herbal Tinctures

Herbal medicines are regulated as health supplements; however, they are treated by many as alternatives to medicines. This can lead to unfortunate consequences with people that do not inform their doctors that they are using traditional medicines, as some compounds in them can inhibit or increase the metabolism of certain drugs. Herbal tinctures are a common form of herbal medicines which have become a popular alternative to modern medicines, as they are typically portrayed as more natural. This may not be as true as portrayed, as while they come from natural herbs, some sources have documented several different additives or contaminants that have been found in herbal medicines throughout the world. In this study, ten commercial herbal tinctures were analyzed by GC-MS and compared to corresponding non-commercial tinctures prepared in the laboratory. The selected tinctures represent several cultural traditions to provide a broader view of current manufacturing practices. GC-MS analysis enables comparison of chemical profiles related to plant origin, processing methods, additives, and natural contaminants. While some variation is expected due to inherent differences in plant composition, any notable discrepancies between commercial and non-commercial samples will be documented and further investigated using LC-MS to quantify key compounds. More experimental conditions and results will be presented at the conference.

Abstract Name: Does Age and Reading Activity Predict Children's Engagement in Grandparent-Grandchild Zoom Sessions?

Prior studies show the quality of young children's connections with grandparents is vital, as feelings of closeness are linked to both parties' well-being. Because many families live far apart, understanding Zoom activities that promote meaningful interaction may help create more engaging virtual experiences that strengthen emotional closeness despite distance. This secondary analysis examines how structured book reading during video chat supports joint visual attention (JVA; sharing attention with another person on an object) between young children and their remote grandparents. 181 families with children aged 18–72 months completed the larger study. Each family completed a baseline video chat, three sets of three randomized experimental chats (structured play, structured reading, or control), and a final uninstructed chat. Surveys assessed grandparent enjoyment and closeness, and all recordings were coded for child engagement and joint attention. For this sub-study, 59 families who completed the structured reading condition were analyzed. The first five-minute segment of each interaction was coded. Each individual request for JVA was coded for who was the initiator, who was the recipient, whether the recipient responded within five seconds, and if so, the type of response (e.g., verbal response, gaze, or gesture). Successful bids initiated by the grandparent will be analyzed from three sessions per family: the baseline session, the second grandparent-led reading session (grandparents read a copy of the book, showing the child the pictures using their camera), and the second matching book session (the grandparent and the child read matching copies of the book, so both could reference the book in both environments). Four ANCOVAs will test whether session type and child age predict successful JVA responses and whether the frequency of verbal, gaze, or gesture-based responses differs by age or session type. Findings will show how video-chat reading formats facilitate shared attention in early childhood and promote long-distance relationships.

Abstract Name: Of Women and Wolves: Hybridity, Gender and Colonialism in Medieval Lycanthrope Literature

Gerald of Wales's *Topographia Hibernica* contains an early example of a werewolf narrative which form connections between gender, early Irish subjugation, and lycanthropy that are similarly reflected in the unattributed *Melion*, estimated to be written shortly after the *Topographia*. *Melion* follows one of Arthur's knights—the eponymous *Melion*—and his marriage to an Irish princess, who abandons him for her native shores by tricking him into transforming into a wolf. In order to prevent him from returning to humanity, she takes with her the magical ring which allows him to change between human and animal. This point is notably similar to Marie de France's *Bisclavret*, wherein the wife of the titular character steals his clothing while he is in wolf-form, trapping him in his beastly shape. Though *Bisclavret* does not directly mention Ireland as the other two do, it navigates a complex relationship between women, monstrosity, and the law, perhaps due to influences from the previous two works. My research examines these three medieval werewolf texts—*Melion*, *Bisclavret*, and the *Topographia Hibernica*—and explores the relationship between wolves and subaltern identities, specifically intersecting the texts' treatment of both womanhood and Irishness. I argue that hybridity in the three works functions to place these identities within a liminal space that ultimately dehumanizes and subjugates them under the law, thus embodying Giorgio Agamben's definition of the bandit-outlaw posited in *Homo Sacer* (1998). The work takes a transnational approach by exploring the historical connections between French Normandy and Ireland which draw together French works—*Bisclavret* and *Melion*—with Irish progenitors such as the *Topographia Hibernica*. Alongside the use of Agamben as a theoretical cornerstone, I draw from a variety of feminist and postcolonial medievalist scholars such as Victoria Blud, Rhonda Knight, and Noah Guyunn.

Abstract Name: Peer Undergraduate Research Leaders: Advocating for Research Opportunities Through Student-Led Organizations

This project is about integrating undergraduate research into student culture. At Pace University, faculty and students collaborate on research projects for class assignments and grant-funded work. However, as endowments and funding for research across disciplines continues to be cut, a group of students have come together to realize new ways for research to thrive in spite of attempts to remove academic opportunity. With the support of faculty at the university, we created the idea for a student organization: the Peer Undergraduate Research Leaders (PURLs). We aim to empower students to explore personal inquiry, collaboration between peers and faculty, and pursue innovative academic and creative projects. The PURLs' mission aligns with undergraduate research values of fostering opportunities, dynamic interdisciplinary exploration, and

experimental learning. Our organization creates a roadmap for how students at any institution can advocate for themselves and their academic pursuits. Our aim was to build an association that is for students, and led by students, with the goal of making research enjoyable, collaborative, and an unfaltering part of our community through peer mentoring and collective engagement. As we have built the foundations for this project, we have uncovered an untapped interest within the student body to make research a more accessible feature of their academic journey, and to bring it from the classroom into campus life. We achieve this by centering principles of connection, advocacy, mentorship, and awareness. By pioneering this student research organization on our campus, we have created a space that is interdisciplinary and supportive of undergraduates with any level of experience. As universities across the United States continue to experience funding cuts, we propose our organisation as an example of how students can work with faculty and their institutions to champion themselves and their futures.

Abstract Name: "Passing through the garden door": Subversive Spaces in Jane Austen's Novels

This study contributes to the ongoing discussion of Jane Austen as a proto-feminist author and focuses on the relationship between place and space in her novels. Many argue that Austen's devotion to marriage plots prevents her work from realising its potential feminist messages. However, this research interacts with the idea posed by critical feminist Judith Butler in *Gender Trouble* to deny that claim. Butler notes that, "To operate within the matrix of power is not the same as to replicate uncritically relations of domination." I argue that this is the case for Austen; the physical places of her novels represent the power matrix of the 18th-century marriage system that she then subverts from within via the spaces she crafts. This work explores how space is tied to hegemonic notions of femininity and its role in providing an avenue for women in oppressive social networks to understand themselves and their potential. By combining settings with narrative techniques such as dialogue, free indirect discourse, and what I call "non-disclosure," Austen extends beyond tangible locations into malleable spaces in which female exploration of mind and body can occur. Through close readings of key passages in Austen's novels—including *Pride & Prejudice*, *Emma*, *Northanger Abbey*, and *Persuasion*—I define her work as critically operative within oppressive social networks. I propose that Austen navigates the marriage system of her time by queering space. In her work, space is not singular, rather it is a concept that can take many forms, such as distance, potential, or emptiness. Through this flexibility, space also transgresses the dominant social order that the rigid boundaries of place represent. I argue that it is through the discourse between place and these queer spaces that Austen weaves her social critiques based on the ideas of proto-feminist writers such as Mary Wollstonecraft and Mary Astell.

Abstract Name: Enhancing Intranasal Aerosol Delivery of Antiretroviral Nanoparticles to the Olfactory Region via a Gas-Propelled Vibrating Mesh Nebulizer

Intranasal drug delivery has gained increasing attention as a noninvasive route for transporting therapeutics directly to the brain, emerging as an appealing alternative for treating central nervous system (CNS) disorders such as NeuroAIDS. This study addresses the challenge of effectively targeting the olfactory region, which is a small anatomical area high within the nasal cavity and the primary deposition site for nose-to-brain delivery. Despite its importance, existing delivery devices deposit large proportions of aerosolized drugs in the anterior nasal region, limiting the ability of therapeutics to reach the olfactory area. This study utilizes a gas-propelled vibrating mesh nebulizer to enhance targeted delivery to the olfactory region. We first evaluated the impact of vibrating mesh nebulization on the physicochemical properties of our optimized drug formulation—PEGylated combination antiretroviral therapy solid lipid nanoparticles (cART-SLNs). Nebulization resulted in negligible changes in nanoparticle size and polydispersity, indicating suitability for intranasal administration. Using three 3D-printed nasal models to account for anatomical variability, we examined how auxiliary flow rate (10–40 L/min), insertion tip geometry (wide vs. narrow), and head (or sagittal) angle influenced regional deposition. To monitor the deposition throughout the segmented model, fluorescein sodium salt replaced the cART-SLNs and was quantified by separating and rinsing the model segments. The results showed that greater airflow rates, narrower insertion tips, and higher sagittal angles increased deposition in the olfactory region—recovering up to 10%—while reducing deposition in the anterior nasal region. This work demonstrates a promising strategy for overcoming key barriers to nose-to-brain drug delivery. By combining PEGylated SLNs with a gas-propelled vibrating mesh nebulizer optimized for olfactory targeting, we highlight how nanocarrier design and device engineering work synergistically to enhance intranasal delivery of HIV therapies. These findings lay important groundwork for future in vivo studies and support the possibility of treating NeuroAIDS via the intranasal route.

Abstract Name: Synthesis of Potentially Selective 5-HT_{2A} Serotonin Receptor Agonists with A Forced Active Conformation

This proposal outlines work toward the synthesis of two potential serotonin 5-HT_{2A} receptor agonists based on the established molecule (2S,6S)-2-(4-bromo-2,5-dimethoxybenzyl)-6-(2-methoxyphenyl)piperidine (compound 3). A synthetic pathway has been developed based on work conducted in previous semesters for these molecules, which aim to improve the potency of their predecessor in the desired receptor while maintaining selectivity over the 5-HT_{2C} receptor. The addition of a methyl group to the central ring on compound 3 is hypothesized to favor the active conformation of the molecule, effectively increasing potency. This new agonist will give us a better understanding of the structure and function of the 5-HT_{2A} receptor and will give us further insight into its involvement in certain neurological conditions as well as its potential applications in the medicinal field. In the past, moderate amounts of tert-butyl (trans)-2-(2,5-dimethoxybenzyl)-6-(2-methoxyphenyl)-4-oxopiperidine-1-carboxylate (compound 10) were synthesized with great effort; thus, we have tested the proposed reactions on an analog of compound 10. By optimizing these reactions first, we will make it more likely that the reactions on the actual compound 10 will succeed, allowing us to ultimately synthesize desired compound 3.

Abstract Name: From Servers to Pi: Evaluating Open-Source Speech-to-Text Across the Hardware Spectrum

The proliferation of open-source Speech-to-Text (STT) models has enabled a new wave of on-device voice applications. However, their performance across heterogeneous hardware remains underexplored. To address this gap, we conduct the first systematic benchmark of six leading STT engines on four environments. These range from GPU-accelerated servers to resource-constrained Raspberry Pi devices. We use a reproducible, programmatic pipeline and evaluate datasets of 1,500 and 10,000 samples. Our analysis covers transcription accuracy, latency, resource usage, and multilingual support. Results show that model viability is not absolute but depends on the target hardware. We identify critical trade-offs between accuracy and efficiency. This study provides a practical, data-driven guide to help practitioners navigate these trade-offs and select STT models best suited to their deployment constraints.

Abstract Name: Armor with Limits: Oil and Gas Field Workers' Perceived Value of Protective Clothing and Equipment

Fatality rates in the oil and gas extraction industry far exceed those of all U.S. workers, yet research on personal protective clothing (PPC) and personal protective equipment (PPE) in this context remains limited. Guided by the Customer Perceived Value (CPV) framework, this study examined how oil and gas field workers evaluate PPC and PPE and what drives their use. In-depth interviews were conducted with 10 experienced upstream production workers in Oklahoma (e.g., compressor foreman, roustabout, machinist; 13–20 years of experience). Findings indicate that workers' decisions are shaped by functional, psychological, and social value criteria. Participants typically wore long-sleeved flame-resistant (FR) shirts and pants, steel or composite toe boots, hard hats, safety glasses, and various gloves, often supplemented by hearing protection and personal gas monitors. Depending on the task, additional PPE included face shields, respirators, FR coveralls, Tyvek or sandblasting suits, and fall-protection harnesses for work at height. Despite physical discomfort and restricted mobility, participants consistently used PPE due to strong psychological benefits, particularly the desire to return home safely, protect their families, and maintain financial stability. Maintenance burden emerged as a critical pain point: laundering toxic, oil-soaked FR garments at home was labor intensive, raised concerns about residual contamination, and reduced functional value as perceived protection declined over time. Economic sacrifice further undermined perceived value, as gaps between employer allowances and market prices forced workers to overuse worn or damaged gear. Aesthetic and identity-related considerations also influenced compliance, with well-fitting, professional-looking gear viewed more favorably. Trust in PPE was conditional and fragile, especially regarding the chemical safety and durability of FR treatments. These findings suggest that design, procurement, and training strategies must jointly enhance protection, comfort, affordability, and credibility. Future research should quantify the relative influence of CPV dimensions on PPE compliance and test targeted interventions in larger samples.

Abstract Name: The Mentoring Promise: (Diversity+Equity+Inclusion) = Belonging

Purpose:For many men of color at Predominantly White Institutions (PWIs), college is not just an opportunity for academic achievement but a challenge in navigating environments that often overlook their identities. This research highlights the vital importance of belonging, where undergraduate students feel secure, valued, and empowered to be their authentic selves. Despite advancements in Diversity, Equity, Inclusion, and Belonging (DEIB), many still face racism, microaggressions, and stereotypes, leaving them feeling isolated on campus.**Methods:** This study employs an autoethnographic approach, analyzing personal narratives from Black male students to explore the significance of cultivating safe spaces. Qualitative data are gathered from the Barbershop Talk Experience, where students express themselves openly and engage in meaningful dialogue about their experiences. This method provides insight into candid conversations that foster a sense of community and belonging among participants. Literature emphasizes that sharing personal narratives in such environments facilitates healing and strengthens communal bonds, leading to collective empowerment. By situating findings from the Barbershop Talk Experience within this context, the study elucidates how affirming environments are vital for enhancing the educational experiences and well-being of men of color in PWIs.**Results:** Findings reveal compelling stories of Black male students who find support and solace in these environments. Participants reported transformative experiences that increased their confidence and sense of belonging, highlighting how cultural support significantly reduces barriers to academic engagement and retention.**Conclusions:** These findings underscore the need for fostering authentic belonging for academic success. Creating environments that honor students' identities enables men of color to thrive. Programs like Mentor Promise exemplify this commitment, empowering students to embrace their identities and enhance their college experiences.

Abstract Name: DNA Extraction from Teeth Using a Theralin-Based Approach

Background Extracting DNA from bones is crucial in cases involving unidentified human remains and mass disaster victims, where bone is often the only available source of DNA. Researchers at George Mason University have developed a method using Theralin™, a precipitating fixative that demineralizes bone. This process transforms the bone into a gum-like form, allowing it to be cut into smaller pieces and digested with lysis buffers. However, no research has yet determined the optimal DNA extraction method for Theralin-treated bone. This study aims to address that gap. **Methods** Human teeth, specifically third molars, will be used as the source for DNA extraction. Each tooth will be cleaned and demineralized into a workable, gum-like state. Two DNA extraction approaches will be applied. The control involves pulverizing the tooth and extracting DNA from the resulting powder using lysis buffer, a method adopted by FBI laboratories and other forensic institutions. The experimental method uses Theralin-based extraction. DNA will be quantified using a real-time PCR-based assay. Yields will be compared to assess the effectiveness of Theralin relative to the standard protocol. **Significance** This research evaluates the effectiveness of Theralin for DNA extraction from teeth. If successful, it could provide a reliable method for obtaining genetic material from dental samples, critical in forensic investigations. Because bones also contain DNA, results could suggest that Theralin is

effective on skeletal material as well. This has important implications for mass disaster scenarios, unidentified remains, historical or archaeological specimens, and cases involving exposure to harsh environmental conditions. Validating Theralin could advance forensic protocols and improve the ability to obtain high-quality DNA from human remains in complex investigative situations.

Abstract Name: The Medusa Effect: Evaluating the Influence of a Moon Jellyfish Aquarium on Student Experience in an Academic Library

The growing use of biophilic design in educational spaces has sparked interest in how natural, visually dynamic elements can enhance student well-being and engagement. The Medusa Effect investigates the impact of a moon jellyfish (*Aurelia aurita*) aquarium on perceptions of tranquility, creativity, and behavioral engagement within the Miami Dade College Padrón Campus Library. To assess these effects, we implemented an on-site (online) survey that students completed while physically present in the library environment. The instrument included Likert-scale items measuring perceived tranquility, creative stimulation, engagement, visit frequency, purpose of library use, and demographic characteristics. The aquarium was installed in a centrally visible location, ensuring that all participants were directly exposed to the display as they responded. Our findings indicate that the jellyfish aquarium contributed to noticeable improvements in the library atmosphere. Participants consistently reported heightened relaxation, increased creative inspiration, and a greater willingness to spend additional time in the space. Many participants described the aquarium as a calming and aesthetically enriching feature that enhanced their overall library experience. Notably, 60 percent of participants shared that the aquarium made them feel curious and inspired, motivating them to learn more about marine life and sparking new creative ideas. More than 50 percent of the respondents also stated that they would consider caring for jellyfish at home, even while acknowledging the substantial effort required to keep moon jellyfish alive and healthy. Many students highlighted the survey statement, noting that “maintaining a jellyfish aquarium requires daily care, stable water conditions, and specialized feeding.” These results suggest that integrating bio-inspired design elements, such as jellyfish aquariums, can meaningfully improve mood, comfort, and engagement within academic environments, highlighting their potential value for future campus design initiatives.

Abstract Name: The Impact of Spectral Gap on Greedy Coloring Performance in Small-World Networks

This study investigates how the spectral gap of small-world networks affects the performance of greedy coloring algorithms, specifically focusing on the number of colors required for solutions. The methodology employs spectral analysis techniques combined with systematic testing of greedy coloring algorithms on the Watts-Strogatz model. This work addresses the gap in understanding between global spectral properties and local coloring decisions, revealing relationships that could improve algorithm selection for graph coloring

problems. This study shows a negative correlation between spectral gap and number of colors used by the greedy algorithm in small-world networks. This expands our understanding by demonstrating a relationship between global and local properties. These results have the potential to improve coloring algorithms used for small-world networks.

Abstract Name: The role of HIV proteins in psychostimulant abuse

The amphetamine (AMPH) class of psychostimulants are highly addictive and their misuse is linked to behaviors associated with increased rates of human immunodeficiency virus (HIV) infection. In AMPH use disorder (AUD) patients, HIV infection increases the severity of AUD symptoms; however, there currently exists no mechanism that explains this phenomenon. AMPH functions by phosphorylating the human dopamine transporter (hDAT) N-terminus (NT) leading to the displacement of the hDAT-NT from phosphatidylinositol 4,5 bisphosphate (PIP2) and binding to the intracellular loop 4 domain of hDAT. This results in dopamine (DA) efflux rather than physiologically normal DA reuptake. Current psychostimulant use models depict blunted efflux as a cause for increased AMPH usage. In line with this, central nervous system viral replication persists in treated HIV patients and the resulting HIV proteins drive various neurological dysfunctions. The HIV protein Tat specifically is neurotoxic and has a high affinity for PIP2. We propose that Tat disrupts the hDAT/PIP2 interactions which are essential for AMPH-induced DA efflux leading to blunted DA efflux and increased AUD symptoms. We conducted molecular dynamic simulations to evaluate PIP2, hDAT, and Tat binding propensity; cellular and *Drosophila melanogaster* brain amperometry to evaluate the ability of Tat to regulate AMPH-induced DA efflux; and a behavioral assay in *Drosophila* to evaluate Tat's ability to alter AUD-related behaviors like escalation and preference. Our molecular dynamic simulations found that Tat has an ability to bind PIP2 and displace hDAT/PIP2 interactions. Further, Tat's ability to displace these interactions enabled a significant decrease in AMPH-induced DA efflux in vitro and ex vivo. In our behavioral assays, the addition of Tat led to significant increases in drug escalation and preference. Thus, through this proposed mechanism, we can better depict the double epidemic of HIV and AUD by partially explaining how HIV-Tat increases AUD symptoms in *Drosophila*.

Abstract Name: Comparison of Maximal Oxygen Uptake obtained via Seismofit and Cardiopulmonary Exercise Test

Introduction: Maximal oxygen uptake (VO2 Max) is a key health indicator, with sports performance and mortality implications. VO2 Max testing typically requires participants to complete a Cardiopulmonary Exercise Test (CPET), which can be time-intensive, physically demanding, and requires specialized equipment. A novel device (Seismofit) uses non-invasive technology in order to estimate VO2 Max; however, its effectiveness has not been studied. Methods: VO2 Max was measured in 24 healthy adults using the Seismofit device and a conventional cycle ergometer CPET. A paired t-test analysis was used to compare the average VO2 Max obtained via both testing methods. Results: There was no significant difference in VO2 Max between the Seismofit and CPET ($p > .05$). Conclusion: The Seismofit device provides equivalent VO2 Max measurement compared with the gold-standard CPET.

Abstract Name: Data, Discovery, and Development: A Mentor's Journey in Undergraduate Research

My journey at Tulsa Community College shows how intentional mentorship and collaborative practices can transform classroom learning into undergraduate research experiences (UREs). Beginning in 2017 with interdisciplinary projects, I introduced students to research and presentation skills through the integration of high-impact practices in my course. There were many limitations to developing a sustainable project at a community college that included length of student degree completion at the institution, IRB timelines, and funding limitations. Collaborative efforts overcame these barriers with innovative strategies for data-driven inquiry, including the use of publicly accessible datasets such as the CDC's Behavioral Risk Factor Surveillance System (BRFSS). This led to the development of a scaffolded lab and presentation framework to emphasize the interpretation of public health data, fostering both scientific literacy and critical thinking. Initially shared among faculty in 2018, these resources expanded during the pandemic to support online learning and have become integral to departmental teaching. Continuous assessment of student perceptions of the URE meeting institutional learning outcomes (critical thinking, personal responsibility, communication skills, and social responsibility) has informed improvements aligned with the overarching goal of linking the URE to career preparation. Since this project was launched, I have been able to support student presentations at local, state, and national conferences. My role in developing curriculum further embedded scaffolded research experiences into college resources emphasizing critical thinking via the significance and limitations of health data. Since 2022, as Co-Coordinator of Undergraduate Research, I have supported programs that empower students and faculty while contributing to national communities of practice. A recent milestone includes authoring an open educational resource (OER) textbook funded by an OSRHE grant, integrating CDC data tools to promote equitable access. Attendees will learn practical strategies for embedding research and data literacy into general education courses.

Abstract Name: Ethics in Translation: Ideology and Domestic Hierarchy in English and Japanese Translations of The Odyssey

This project examines how translators' cultural and ideological assumptions—what André Lefevere calls their “Universe of Discourse”—shape the way modern readers understand shame, hierarchy, and moral order in Homer's *Odyssey*. I focus on two scenes that raise difficult questions about gender and power: Helen's self-description in Book 4 and the execution of enslaved women in Book 22. By comparing four translators—Robert Fagles, Emily Wilson, Matsudaira Chiaki, and Nakatsukasa Tetsurō—I show how their choices reframe Homeric ideas about shame, domestic authority, and enslavement. Putting English and Japanese translations side by side allows patterns to emerge that would be impossible to see from within a single linguistic tradition. The project combines close reading of the Greek with a detailed comparison of each translator's word choices and tone. I pay particular attention to terms like κυνώπιδος (“dog-faced”) and ἀναιδείη (“shamelessness”), as well as vocabulary for enslaved women such as δμῳαί and ἀμφίπολοι. These words have very specific social and ethical meanings in Homer's world, and even small changes in translation can shift how modern readers interpret a character or judge an action. My analysis shows that translators inevitably reshape Homer's social world, whether by softening its harshness, emphasizing certain moral values, or trying to preserve its original structures as closely as possible. Ultimately, I argue that translation is always interpretive, and that our understanding of the *Odyssey*'s moral universe is inseparable from the cultural frameworks through which it is translated.

Abstract Name: Agrochemicals as infodisruptors on courtship and mating behavior of the wolf spider *Tigrosa helluo*

Agrochemicals are frequently applied multiple times per year within agricultural systems. These chemicals have the potential to disrupt sex pheromone communication systems of non-target beneficial generalist predators including spiders. We tested the infodisruptive effects of three frequently applied agrochemicals on the courtship and mating behavior of a common agricultural wolf spider species, *Tigrosa helluo*. We tested the insecticide imidacloprid, the fungicide propiconazole, and an organosilicone surfactant tank additive compared to a water control treatment. We allowed females to deposit pheromone-laden silk for one day on soil substrates, removed the female, then applied a field dose of an agrochemical or water to the substrate. The residues were allowed to dry for 30 minutes. Males were then placed on the substrate for ten minutes and we measured courtship responses to the residue. We then added the female that produced the pheromones and allowed the pairs to interact for 20 minutes and recorded courtship, mating, aggression (lunges) and cannibalism across pairs (N=177 pairs). We found no difference in the number of matings, cannibalism, or the number of males that courted across treatments, however males exposed to the surfactant showed significantly delayed courtship during exposure to only female silk compared to other treatments. During interactions with live females, males on surfactant treated soil resulted in further delays in male courtship, more female aggression, and shorter mating durations compared to all other treatments. Imidacloprid also delayed male courtship. Given that organosilicones are widely applied tank additives to most pesticides suggest that fields are frequently treated with chemicals that interfere with sexual communication among

lycosids. These surfactants may impair the chemosensory organs of spiders, chemically alter spider sex pheromones or both. Additional studies are needed to determine the mechanism of infodisruption.

Abstract Name: High-Precision Measurements of Half-Lives for ^{196}Au , ^{99}Mo , ^{122}Sb , ^{79}Kr , ^{77}Kr , ^{89}Zr , ^{85}Sr , and ^{77}Br Radionuclides via Photoactivation at the Madison Accelerator Laboratory.

The ground state half-lives of ^{196}Au , ^{99}Mo , ^{122}Sb , ^{79}Kr , ^{77}Kr , ^{89}Zr , ^{85}Sr , and ^{77}Br have been measured with high precision using the photoactivation analysis technique at an unconventional bremsstrahlung facility at the Madison Accelerator Laboratory that features a repurposed medical electron linear accelerator. The γ -ray activity was counted over about 5 half-lives with a high-purity germanium detector, enclosed into an ultra low-background lead shield. The preliminary measured half-lives are: $T_{1/2}(^{196}\text{Au})=6.143 \pm 0.009$ (stat) d; $T_{1/2}(^{99}\text{Mo})=65.874 \pm 0.025$ (stat) h; $T_{1/2}(^{122}\text{Sb})=2.690 \pm 0.012$ (stat) d; $T_{1/2}(^{79}\text{Kr})=32.787 \pm 0.072$ (stat) h; $T_{1/2}(^{77}\text{Kr})=71.506 \pm 1.591$ (stat) min; $T_{1/2}(^{89}\text{Zr})=86.187 \pm 2.235$ (stat) h; $T_{1/2}(^{85}\text{Sr})=66.274 \pm 0.509$ (stat) d; $T_{1/2}(^{77}\text{Br})=56.749 \pm 9.690$ (stat) h.

Abstract Name: Gender Data Collective: An Interdisciplinary, Collaborative Study on Regional-Based Sex Education and Gender Attitudes in the U.S.

Will be conducting a mixed-methods survey of college students in the U.S, studying K-12 sex education and gender attitudes. The survey will have five sections: demographics, childhood environments, K-12 sex education, current gender attitudes, and open-ended questions on personal awareness of the correlation between sex education and gender attitudes. Attitudes include: what do participants think “gender” means, their respect towards diversity of sexuality, their notions of feminine and masculine roles, and more. We will examine differences by regional variation in the Comprehensive Sexual Education curriculum, controlling for childhood environments and general demographics such as sex, race, and class. Our mixed-methods analysis

will include both quantitative and qualitative analyses. This study will be interdisciplinary and collaborative. It will be interdisciplinary in that the survey results will be analyzed through four different lenses: Women's Studies/Sociology, Public Health, and Political Science. It will be collaborative in that each lens will be operated by a team of two researchers, and all six partners will write a conversational paper reflecting on their results and evaluation, to create a comprehensive guide of evidence-based recommendations for effective sex education.

Abstract Name: Wild Andean Camelids Alter Post-glacial Soil Microbial Community

Tropical Andean glaciers are rapidly melting, and it is important to understand ecological community emergence following glacial retreat. Soil microbes are the earliest taxa to colonize land exposed by glacier loss. Vicuñas (*Vicugna vicugna*), wild South American camelids, create dung piles which concentrate nutrient deposits on otherwise nutrient-poor sediments and become colonized by plants decades before the surrounding landscape. We hypothesized that vicuñas alter soil microbes in glacier forefields. We compared microbial communities between animal-modified patches and adjacent unmodified glacial moraines. Sites (N=23) were located on two soil ages: older soils exposed by deglaciation for >135 years, and younger soils exposed by deglaciation in the last ~45–135 years. We extracted DNA from soil samples, sequenced 16S rRNA amplicon for prokaryote and 18S for eukaryote taxa, and compared alpha and beta diversity using the phyloseq and vegan packages in R. Animal-modified soils had higher prokaryote ASV richness than moraine reference soil, and lower-elevation soils had higher richness than higher-elevation soils (elevation: $X=27.61$, $p<0.0001$, treatment: $X=3.15$, $p=0.076$) and the interaction between elevation and treatment was significant ($X=7.20$, $p=0.0073$). Soil age was marginally significant ($X=3.55$, $p=0.060$). Eukaryotic ASV richness was lower on higher-elevation soils and the interaction of elevation and treatment was significant but treatment alone was not. Both prokaryote and eukaryote beta diversity of animal-modified soils was significantly different compared to moraine reference soils on recently-exposed soils ($p<0.05$). Following glacial retreat, vicuñas create patches that alter microbial diversity. Vicuñas and other native Andean wildlife species may facilitate the establishment of unique soil microbial communities and accelerate succession in recently-exposed high-elevation soils.

Abstract Name: Engaging “Bond” Angle with Nanomaterial Composites for Enhanced Halogen Bonding Toward Explosive Detection Interfaces

The expanding use of explosives globally, particularly by terrorists for improvised explosive devices (IEDs), calls for the development of fast, on-site sensing techniques that rely on fundamental intermolecular interactions at synthetic interfaces. One such interaction being explored for sensing schemes is halogen bonding (XB), a highly directional, noncovalent interaction formed between a region of positive electrostatic potential on a halogen atom (X) acting as a XB donor and electron rich portions of target molecules that act as a Lewis base, or XB acceptor. As leveraged by density functional theory (DFT) analysis, the strength of XB interactions relies on shorter XB bond distances and more linear R-X—B bond angles, which facilitate stronger, lower energy binding of the dimer molecule formed. While prior studies have sought to maximize interactions, few have explored or experimentally demonstrated how bond angles can enhance XB interactions. Herein, fundamental studies are conducted at self-assembled monolayers (SAMs) and gold nanoparticle (Au-NP) interfaces that are functionalized to engage in XB interactions. Alkanethiolate-stabilized Au-NPs, known as monolayer-protected gold clusters (MPCs), were enhanced with XB-donor capability by incorporating specialized XB donor thiol ligands including halogen terminated perfluorinated straight chain and rigid perfluoro-aromatic amide ligands – both of which were used within nanomaterial composite films of single-walled carbon nanotubes (SWCNTs) as a sensing interface in both solution and the gas phase. In particular, DFT and vapor studies targeting cyclohexanone (CH), a known by-product of hard-to-detect, non-volatile explosives (e.g., RDX), allowed for a sensing interface for CH that engaged XB bond angle to achieve detection limits of CH (< 10 ppm) that markedly outperform similar systems not considering this particular aspect of XB. The materials and methods presented in this study further demonstrate the potential of XB systems as a rapid and sensitive step toward developing field sensors for explosives.

Abstract Name: The Effect of Payroll on Team Success in Major League Baseball and Its Application to the Salary Cap Debate.

This project examines how payroll spending influences team success in Major League Baseball (MLB) and how these patterns relate to the ongoing debate over adopting a salary cap. As financial gaps between large- and small-market teams widen, concerns have increased about fairness, parity, and the league’s long-term stability. Existing research shows that success in MLB depends not only on total payroll but on how teams allocate their spending. Prioritizing key defensive positions, particularly pitchers and catchers, can enhance overall performance, whereas uneven or inefficient spending across positions may reduce cooperation and lead to diminishing returns. Studies also reveal limitations in MLB’s current revenue-sharing system. Although intended to help smaller-market teams, shared revenue is not always reinvested into talent, and some teams have instead lowered payroll. This suggests that revenue-sharing alone has not meaningfully narrowed the competitive gap. Additional research on salary structures in Minor League Baseball provides insight into how development systems, player pay, and organizational incentives shape competition and player movement. Salary negotiations and arbitration rules further complicate payroll decisions, as market

size and team incentives influence player earnings and contribute to league-wide inequality. Together, these findings indicate that competitive balance issues in MLB stem from both financial disparities and misaligned incentives built into the current economic system. This project seeks to determine whether MLB is experiencing a genuine competitive balance problem and to assess whether potential reforms—such as salary caps, adjustments to revenue-sharing, or redesigned incentive systems could address these challenges without intensifying labor tensions. Using publicly available databases such as Baseball-Reference.com, this research will analyze payroll trends, player movement, and negotiation mechanisms to evaluate where inefficiencies arise and how policy changes might improve competitive fairness. Ultimately, this project aims to contribute empirical insight to debates surrounding MLB's economic structure and the viability of its revenue-sharing system.

Abstract Name: Chernyshevsky's "What is to be Done?" and Anarcha-Feminism

This historical research paper examines the connection between Nikolai Chernyshevsky's 1863 novel *What is to be Done?* and the political ideology of anarcha-feminism, arguing that the novel is best categorized as an anarcha-feminist text. *What is to be Done?* is recognized by historians as the holy text of the Russian Revolution. The novel radicalized the Russian intelligentsia with radically simple demonstrations of utilitarian philosophy. Without this novel, the Russian Anarchist Terrorist movement and the Bolshevik Revolution would not have occurred. The exclusion of women's history from the metanarrative, however, has led previous historians to overlook the analysis of *What is to be Done?* as a fundamentally anarcha-feminist text. Anarcha-feminism is an adjustment to other leftist theories: it states that for hierarchy and class to be truly dissolved, patriarchy must be abolished first. This paper provides a comprehensive breakdown of the historiography of anarchism and previous analyses of *What is to be Done?*, identifying gaps that allowed for this ideological connection between the novel and anarcha-feminism to be missed. Next, the paper simultaneously analyzes the themes of the novel alongside the work of foundational anarcha-feminists like Emma Goldman, demonstrating their philosophical similarities. The mother of anarcha-feminism, Emma Goldman, was converted to the revolutionary cause as a teenager after reading *What is to be Done?* and modeled her life and moral compass after the protagonist of the novel, Vera Pavlovna. While it is commonly believed that *What is to be Done?* is a model for a socialist society akin to Leninism; it is more accurately a new model for gender roles. When it is broken down into its core components, *What is to be Done?* is about love that is uncontaminated by the policies of the patriarchal church and state—and this is the definition of anarcha-feminism.

Abstract Name: Combining oncolytic virotherapy and chemotherapy against fibrosarcoma

Oncolytic virotherapy is in clinical trials for common cancers, but its potential against rare cancers has only been minimally explored. Fibrosarcoma, the target cancer in this study, is a rare soft tissue malignancy with

high mortality and resistance rates. Our laboratory recently identified reovirus strain DB62 as highly effective at infecting and killing human fibrosarcoma cells. Here, we further characterized DB62 and evaluated its potential when in combination with chemotherapeutic agents, with the goal of enhancing cytotoxicity and reducing therapeutic resistance. We observed higher replication and induced cell death for DB62 compared to the commonly studied strain T3D, as shown by analysis of viral protein expression and quantification of cancer cell viability, respectively. To assess combination therapies, the optimal concentration for eight FDA-approved chemotherapeutic drugs was determined using viability assays. Among the combinations tested, DB62 in combination with methotrexate produced a synergistic effect, reducing cell viability beyond the expected values for individual treatments. These findings suggest that combining reovirus strain DB62 with methotrexate may provide a more effective therapeutic strategy for fibrosarcoma and warrant further preclinical investigation.

Abstract Name: Blackness and the Transness Between Us: Cultural Influence on Transgender Identity Across the Black Diaspora

This project examines how transgender people develop their transgender identities by analyzing the influences of cultural and legal environments across the Black diaspora. While transgender people are legally protected in most parts of the United States, identifying as a transgender person remains criminalized in Nigeria, where social stigma and legal sanctions restrict visibility and safety. To explore the effects of the difference in legal recognition, 28 Nigerian, African-American, and Nigerian-American transgender participants engaged in semi-structured interviews that examined identity questioning, stages of transition, sources of support, and barriers to affirmation. This paper focuses on findings across five dimensions: identity questioning, support groups, barriers to transition, stage in transition, and threats of violence. The data reveal that Nigerian participants often reported later identity questioning, received almost no support from community organizations, experienced the greatest threats of violence, and had the largest amount of non-transitioned transgender individuals. Conversely, African American and Nigerian American participants reported earlier identity questioning, broader access to community support, and were all actively medically transitioning or socially transitioned. Across all groups, queer and trans peers provided the most reliable and accessible form of affirmation, underscoring the central role of community in navigating systemic exclusion. By situating transgender identity within cultural, legal, and diasporic contexts, this research demonstrates how structural forces mediate the risks and opportunities of self-expression and underscores the importance of interdisciplinary frameworks for understanding identity across global contexts.

Abstract Name: Support or Silence? Empathy, Dignity, and Self-Censorship in Workplace Stress Communication

This study investigates how white- and blue-collar workers respond to coworker disclosures of workplace

stressors, focusing on the balance between supportive engagement and self-censorship. Prior research highlights self-censorship as the intentional withholding of information, motivated by fear of consequences, desire to avoid conflict, or strategic silence (Bar-Tal, 2017). Adamska (2017) further identifies acquiescence, defensive, prosocial, and opportunistic forms of self-censorship, each with distinct organizational implications. Occupational context may shape self-censorship behaviors such that blue-collar workers often face hierarchical structures and physical demands that can amplify defensive silence, while white-collar workers may experience greater autonomy but heightened reputational risks (Karasek, 1979; Hodson, 2001). Empathy and workplace dignity are proposed as key predictors of supportive communication. Empathy, conceptualized as monitoring, understanding, and responding to others' emotions (Abraham, 1999; King, 1995), has been linked to justice, moral reasoning, and compassionate communication (Miller, 2007). Workplace dignity, defined as feeling respected and valued, is associated with voice and prosocial action, whereas indignity correlates with silence and withdrawal (Lucas, 2017; Sayer, 2007). Together, these constructs may explain why some employees engage with coworkers' stress disclosures while others remain silent. To test these relationships, participants recruited through the Prolific platform will complete a 10-minute survey during winter 2026. Respondents will be randomly assigned scenarios depicting either white- or blue-collar coworkers discussing mental or physical stressors and will rate their likelihood of engaging in supportive or self-censoring behaviors. Measures of workplace dignity, self-censorship orientation, and emotional empathy will follow alongside occupational background and demographic questions. We anticipate finding differences in self-censorship and supportive behaviors between collar types, such that blue-collar workers display more defensive and white-collar workers elicit more opportunistic self-censorship, with empathy and dignity serving as significant predictors. Results will contribute to understanding how occupational context, emotional capacities, and perceptions of dignity shape communication around workplace stressors.

Abstract Name: Tracking Motivation in Students' First College Math Class: Does Prior Achievement Matter?

Required math courses are taken by many students in their first semester, yet little is understood about how students' math motivation changes across their first semester of college math. Guided by Situated Expectancy-Value Theory (SEVT; Eccles and Wigfield, 2020), we conducted a longitudinal study examining changes in 53 undergraduate students' math task value, math self-efficacy, and math anxiety at three different time points across one semester. We compared motivational trajectories across two math courses: one for mostly STEM majors with relatively higher placement test scores and a course for mostly humanities majors with relatively lower placement test scores. Past research suggests different learning practices and variable educational outcomes depending on prior achievement (Yip, 2009; DiFrancesca, 2016). To understand how teaching practices and classroom experiences may relate to motivation changes throughout the semester, we also conducted classroom observations and interviews with four participating instructors. Quantitative student data collection is ongoing, and we hypothesize that there will be differences in math motivation from the beginning to end of data collection as well as differing motivational trajectories between high- and low-math achieving students. Preliminary qualitative findings from classroom observations showed instructors most often utilized tactics that made student learning more enjoyable (situational interest), less costly and difficult (cost alleviation and encouragement) and more relevant to worldly contexts (relevance). Those educating the high-math achieving group utilized more situational interest than low-math achieving instructors. Instructor interviews, coded reliably ($\kappa = 0.83$), revealed similar practices across both courses, such as emphasizing growth mindset, high standards for students, engagement with course material, and students' use of campus and classroom resources. By understanding how math motivation shifts during the transition to college, we can highlight pathways to foster student resilience, reduce barriers to learning, and create environments where diverse students can thrive.

Abstract Name: A Writing Center How-To: A Guide For Tutoring Creative Writing Students

During my time as a creative writing student at the University of Findlay, a small, private university in NorthWest Ohio, I experienced a lack of resources from my college writing center to help with creative writing assignments. Writing center tutors were trained to help with academic writing rather than creative writing. My experience led me to the question, how can writing centers better help creative writing students with their assignments? To answer this question, I researched best practices for teaching creative writing and training writing center tutors. I also looked for different models at other college writing centers. The research shows that writing centers acknowledge that they have a lack of resources for creative writers (Birnbbaum and Kaufmann 1996, Denoto 2015, LaBlanc 1995, and Ozer 2020). The research also shows that most writing center tutors do not feel comfortable enough to help creative writing students (Cassorla 2004, Hutton 2023, and Ozer 2020). This project helps to solve this problem by creating a how-to guide for writing center tutors that addresses the basic genre of creative writing, how to approach a creative piece and the types of questions to ask creative writers so that they could get the most from their writing center appointment. This guide will be used in the tutoring training class required for all writing center tutors at the University of Findlay as well as in the University's DeLong Writing Center. Through its adoption of this guide, the University of Findlay's writing center could become a model for other schools looking to more effectively support their creative writing students.

Abstract Name: Effects of Fear of Cancer Reoccurrence among Adolescents and Young Adult Cancer Survivors

The fear of cancer recurrence, described as anxiety, weariness, or depression associated with the thought of reacquiring cancer after previously undergoing remission. FCR presentation can be significantly higher in adolescents and young adults (AYAS) compared to the general population. However, the underlying reasons associated with FCR among this group are not often discussed or investigated. Hence, the purpose of this study was to perform a narrative review that aims to synthesize current knowledge on the causes, predictors, and impact of FCR in AYAS, as well as identify any recurring patterns relating to fear of cancer recurrence, and examine interventions that are in place to mitigate the effects of FCR in adolescent and young adults. A comprehensive literature search using PRISMA methodology was conducted in scientific databases, combining terms such as "fear of cancer recurrence," "oncology," "teen," and "young adult." Eligible studies were published within the last 10–15 years, focusing on AYAs (ages 13–29). A thematic synthesis was performed to identify patterns and prevalence within existing data. Across studies, prior recurrence and a history of psychosocial distress or anxiety consistently emerged as strong predictors of FCR. Additional risk factors included pessimistic outlook, comorbidities, fewer follow-up visits, and limited cancer screening.

FCR was primarily manifested through depression, anxiety, and post-traumatic stress, underscoring its significant psychosocial impact on AYAs. Most studies emphasized the role of psychosocial interventions such as cognitive behavioral therapy, mindfulness, and acceptance/commitment therapy, although limitations were noted regarding durability and clarity of implementation. Conclusively, FCR is a factor particularly present in the AYA population, and its prevalence and severity can be predicted by the survivor's history of psychosocial disturbances. Moreover, there are current interventions in place, but further research is needed to maximize their effectiveness and improve the overall quality of adolescent and young adult cancer survivors.

Abstract Name: "Doing It All, All the Time": Black Women's Experiences of Urgency Culture and Self-Mattering

This poster will present a proposed qualitative study exploring how Black women describe and navigate urgency culture, and how these experiences shape their sense of self-mattering. The guiding research question is: What are Black women's stories of urgency culture, and how do these experiences affect their perceptions of self-mattering? The literature highlights that Black women disproportionately face expectations to over-perform, provide emotional labor, and prioritize others' needs before their own—a pattern deeply tied to race- and gender-based stereotypes and labor histories. Traditional definitions of mattering emphasize feeling valued and significant to others (Rosenberg & McCullough, 1981). Russell (2024) expands this concept by framing mattering as a mindset rooted in self-compassion, empathy, and awareness of the human labor sustaining institutions. Yet no research has examined how Black women's sense of mattering is influenced by urgency culture, defined as the expectation to at once respond to the needs of others while deprioritizing one's own well-being, often resulting in chronic overwhelm. The proposed study will employ a Black Feminist framework to understand how race, gender, and cultural expectations intersect to shape Black women lived experiences of urgency and self-worth. A qualitative design will guide data collection through semi-structured interviews, focus groups, and brief surveys with approximately 10–15 Black women across varied professional and academic contexts. Interviews will explore themes related to time pressure, emotional labor, internalized expectations, and perceptions of mattering. Data will be analyzed using thematic analysis to identify patterns and variations in how urgency culture shapes identity and emotional health. This research aims to fill a significant gap in psychological and sociocultural scholarship by centering Black women's voices and lived narratives. Findings will contribute insight into how urgency culture impacts well-being, with the goal of informing culturally responsive interventions that promote mattering, self-compassion, and sustainable work-life boundaries for Black women.

Abstract Name: Differential Expression of Splicing Factors during Human Induced Pluripotent Stem Cell-Derived Osteogenic Differentiation

Osteogenesis is the process of bone formation. Osteogenic differentiation refers to the process in which mesenchymal stem cells (MSCs) differentiate into pre-osteoblasts (preOBs), and then into osteoblasts (OBs), essential for bone development, metabolism, and repair. MSCs are multipotent stem cells that can differentiate into a variety of lineages, including osteoblasts, chondrocytes, and adipocytes. There are multiple mechanisms that regulate cellular differentiation and function. One of these mechanisms is alternative splicing, a process by which one gene can code for multiple proteins, known as isoforms. Different isoforms may be present in distinct types of cells or at different points in one cell's life, and abnormal isoforms may contribute to diseases. Alternative splicing is regulated by genes termed splicing factors. We previously identified differentially expressed genes in osteogenic differentiation by an integrated transcriptomic analysis. In this study, we evaluate the expression of splicing factors during osteogenic differentiation. MSCs derived from human induced pluripotent stem cells (hiPSCs) were cultured and differentiated into preOBs and OBs. Total RNA was isolated from MSCs, preOBs and OBs, and RT-qPCR was performed to analyze the expression of the selected splicing factors (NRIP2, SRSF1, SF3B4, and SNRNPB) which were identified to be differentially expressed among MSC, preOB and OB stages. Aberrations of these splicing factors are associated with skeletal developmental diseases, including Acrofacial Dysostosis I, Cerebrocostomandibular Syndrome, and other skeletal malformations. By examining the expression of these splicing factors during osteogenic differentiation, we aim to elucidate alternative splicing in normal osteogenesis. New knowledge from this investigation may facilitate future development of novel therapeutics and interventions for osteogenic diseases.

Abstract Name: Interactive Effects of SES and Parenting Stress with Maternal Depression in Predicting Child Internalizing and Externalizing Symptoms

Maternal depression is an established risk factor for internalizing and externalizing psychopathology in children. Although maternal depression, parenting stress, and Socioeconomic Status (SES) are known to be associated with child socioemotional adjustment, few studies have examined the interactive effects of SES and parenting stress with maternal depression in this association. This study examined the moderation of SES and parenting stress in the longitudinal associations between maternal depression and child internalizing/externalizing symptoms. Ninety-three mother-child dyads were recruited. Data was collected at two time points, one year apart (T1 and T2). Three variables were measured at T1 only. Maternal major depressive disorder was assessed using the Mood Episodes module of the Structural Clinical Interview for DSM-5 Disorders (SCID-5). SES was measured and coded using the Hollingshead Four-Factor Index of Socioeconomic Status, based on maternal and paternal education and occupation status. Parenting stress was self-reported by mothers using the Parenting Daily Hassles Scale (PDH). At both times, mothers rated child externalizing and internalizing symptoms using the Child Behavior Checklist (CBCL). Hierarchical multiple linear regressions were used. Baseline child externalizing and internalizing symptoms were included in the analysis as covariates. Results indicated that maternal depression, parenting stress, and SES did not predict child externalizing symptoms at T2 directly. However, SES and parenting stress each moderated the longitudinal association between maternal depression and child externalizing symptoms. In predicting child internalizing symptoms at T2, neither SES nor parenting stress moderated the longitudinal association between maternal depression and child internalizing symptoms; however, parenting stress positively predicted

child internalizing symptoms. In conclusion, parenting stress and SES affected the longitudinal influences of maternal depression on externalizing symptoms but not on internalizing symptoms in children. This suggests SES and parenting stress could identify children who are particularly vulnerable to externalizing symptoms resulting from maternal depression and inform targeted interventions.

Abstract Name: Anti-inflammatory and Antioxidant Effects of Sea Urchin Spine Extract

The therapeutic potency of natural products derived from aquatic life has been widely assessed in terms of wound treatment. This research investigates the anti-inflammatory and antioxidant activity of the Sea Urchin spine extract in an experimental setup using the L929 cell line in vitro. Cell migration and proliferation of L929 cell lines were tested using an MTT assay to assess cell metabolic activity, where the sea urchin spine extract was applied to the cells at two concentrations: 100 µg/ml (yielding around 136% viability) and 200 µg/ml (yielding around 95% viability). The active compounds of the sea urchin's spine were investigated via GC-MS; the antioxidant and antioxidant activities of the extract were evaluated by catalase test, GSH, and NO. GC-MS identified bioactive components, including bisabolol oxide, which has anti-inflammatory and anti-irritant properties, protects the skin from free radical damage, and improves the percutaneous absorbance of skin-care chemicals. Oleic acid was also identified, a compound known for its pro-inflammatory effect that accelerates tissue regeneration and the wound healing process. Moreover, the oxidative stress tests (GSH and NO) revealed significant anti-inflammatory and antioxidant actions of the sea urchin spine in both 100 µg/ml and 200 µg/ml, with roughly 0.098 and 0.103 mmol/L in the GSH test, and 20.46 and 20.6 mmol/L in the NO test, respectively. However, the CAT results were inconsistent with those of the GSH and NO; therefore, repetition of this test is recommended. Nevertheless, the identification of significant anti-inflammatory and antioxidant effects of the sea urchin spine qualifies it as a potential candidate in wound healing ointments. Keywords: sea urchin spine, anti-inflammatory, antioxidant, wound healing

Abstract Name: Why Doesn't Distress Lead to Help? Psychosocial Mechanisms Linking Mental-Health Symptoms to Treatment Engagement in College Students

Depression and anxiety are increasingly prevalent among college students, yet only a minority access professional mental-health services. Prior findings from the Healthy Minds Study show that psychological flourishing protects against distress, while loneliness and race-based traumatic stress are associated with greater symptom severity. However, these same factors show little association with treatment use, suggesting that many students recognize their distress but do not translate that awareness into help-seeking behavior. This raises a critical question: What determines whether psychological need results in actual engagement with

mental-health services?The present study will investigate psychosocial mechanisms that may shape this transition from distress to action. Using 2023–2024 Healthy Minds Study data from over 44,000 U.S. college students, we will examine whether sense of belonging, financial strain, perceived institutional prioritization of mental health, and mental-health stigma help explain why some students with significant symptoms pursue therapy while others do not. Logistic regression models will test whether these factors mediate or moderate the relationship between depression, anxiety, and past-year therapy use. By identifying the forces that either facilitate or block treatment engagement, this work aims to clarify why rising levels of student distress have not led to proportional increases in service utilization. Understanding how campus belonging, stigma, and resource perceptions shape help-seeking may inform institutional strategies capable of bridging the persistent gap between mental-health need and actual support.

Abstract Name: The Effect of Prolonged Conflict and Forced Migration on the Developing Minds of Syrian Refugee Youth

Syrian refugee youth face unique hardships with the interconnected biological, structural, and social effects of trauma and displacement that impact their mental health conditions. These challenges impede access to care and exacerbate depression, anxiety, and stress symptoms, with interventions that lack a holistic approach to addressing the needs of this population. This paper aims to explore the barriers to mental health care and review how integrated interventions that combine biological research, policy-level work, and a comprehensive understanding of real Syrian experiences are crucial to alleviate the mental health burden that the Syrian conflict has placed on numerous generations. This review synthesizes studies measuring the prevalence of biomarkers and inflammatory proteins; large-scale surveys assessing trauma exposure, executive function, and psychological symptom severity; and qualitative interviews with refugees and healthcare workers to capture lived experiences and propose an integrated intervention. This evidence shows that prolonged exposure to trauma and displacement activates neurobiological stress systems, specifically the corticotropin-releasing factor (CRF) and hypothalamic-pituitary-adrenal (HPA) axis pathways, contributing to the long-term persistence of emotional dysregulation in the child's brain. The continuous activation of hormones and increased symptomology interacts with Post Migration Living Difficulties (PMLDs) such as financial barriers, inadequate healthcare infrastructure, discrimination, and limited cultural interventions. Even when care is available, Syrian adolescents help-seeking behaviors are hindered by the normalization of trauma and intergenerational untreated mental health disorders. This stigma reinforces cycles of underdiagnosis and improper care and impacts the self-perception and identities of this youth population. Overall, it is apparent that Syrian refugee youth often face compounding disadvantages (biological sensitization, systemic neglect, social isolation) that perpetuate psychological distress and impede on successful integration into host countries. Improving the mental health of Syrian refugee youth requires multifaceted interventions that dismantle the stigma, rebuild trust, and center the lived realities of generations shaped by war.

Abstract Name: Resources in Mental Health and Education for Immigrant and Refugee Students: Charlotte, North Carolina

Charlotte, North Carolina is home to a robust immigrant and refugee student population, housing over 25,000 migrant students between Charlotte-Mecklenburg Schools (CMS) and the city's nine colleges and universities. Considering the magnitude of Charlotte's immigrant and refugee student population, the need for the city to provide academic, psychological, and social resources cannot be understated. As such, it is critical to examine how these resources are offered to this population, and how resources can be made more accessible for students. This project utilizes a combination of a literature review and surveys distributed to students as well as several leading resource organizations. Preliminary research for this project indicates that, in addition to initiatives executed by the Charlotte-Mecklenburg School system, there are a number of resource organizations across the city that provide ample support and services. This support targets a variety of fields including mental health, education, and community outreach. Organizations including ourBRIDGE for Kids, Charlotte for Ukraine, and International House provide support based on specific demographics. These characteristics include age, English language proficiency, income, and racial or ethnic background, which all play a decisive role in allocation of support. Review of literature and information also points to a lack of programming and resources for integrating immigrant and refugee students in Charlotte's private schools, with the exception of specialized organizations, such as The Nest Academy. This project aims to explore the services and resources offered by both the city and by independent organizations in Charlotte, and as a result, their impact on the growing child and adolescent immigrant and refugee population. Pursuing this project will aid in public awareness and understanding of the necessity for these services while investigating potential areas in which the resources can be improved upon, not just for this particular population, but for Charlotte as a community.

Abstract Name: Laboratory Comparison of Corona Emission from "Sharp" vs "Blunt" Lightning Rods

In the early 2000s, C.B. Moore et.al. of Langmuir Laboratory for Atmospheric Research published analyses of lightning-strike data taken from various lightning rods mounted on top of the Magdalena Mountains in New Mexico^{1,2}. Over a period of seven years, the blunt-tipped rods received several strikes from thunderstorms, while the sharper-tipped rods received no strikes at all. Those investigators hypothesized that, since sharp rods emit corona more readily than blunt ones, upward leaders (which make connection to downward leaders from the cloud, to complete the lightning channel) either did not form, or did not extend as high, from the sharp rods. Here we test their hypothesis, using Van de Graaf generators we have modified to accommodate standard-diameter blunt and sharp rods. We will measure the time and distance for which each type of rod neutralizes a distant test charge. This will be done with both negative- and positive-charging Van de Graafs (to simulate approaching positive and negative cloud-to-ground leaders, respectively), operating at the same charging rate. We expect that, regardless of whether the generator charge is negative or positive, the sharper rods should prove more effective than the blunt ones at neutralizing the distant test charge. If so, this will be consistent with the hypothesis of Moore et.al., that sharper rods are more effective than blunt ones at preventing upward leader formation because of their increased emission of corona.

Abstract Name: Shame as a Sociocultural Force in Contemporary Japanese Civil Litigation: Insights from the Okawa Elementary School Lawsuit

Despite overgeneralizations that reduce Japan to having a “shame culture”, shame continues to inform decision-making and social behavior in contemporary Japan. This is especially true in situations involving public exposure, criticism of social institutions, and social accountability. One such circumstance involved the Okawa Elementary School tragedy and aftereffects following the 2011 Great East Japan Earthquake. This research study aimed to investigate how cultural dynamics of shame influenced the civil lawsuit pursued by parents of children at the elementary school. Utilizing a multidisciplinary literature review and narrative accounts documented by Richard Lloyd Parry in *Ghosts of the Tsunami* (2017), this study examines how shame shaped decision-making for the involved parties. Books like Ruth Benedict’s *The Chrysanthemum and the Sword* (1946) form the foundation for the scholarly understanding of shame in Japan, and are built on by subsequent works in both English and Japanese. Pairing these works with *Ghosts of the Tsunami* creates a framework to understand how traditional notions of shame continue to impact contemporary events, like the Okawa Elementary School lawsuit. This case is particularly significant for this subject because it involves a school, an institution strongly associated with moral authority and responsibility in Japan. Findings indicate that families made their decision regarding participation in the lawsuit based on their personal grief, but also considering concerns about retaliation from the community or being perceived as troublesome. Conversely, the defendants responded to criticism through avoiding the subject. This reflects a cultural impulse to minimize exposure to oneself while also protecting institutional dignity. By viewing these individual behaviors with Japan’s complex cultural framework of shame, this study examines how social norms can affect the pursuit of civil lawsuits and influence public discourse following mass-death events. The findings contribute to research on how legal processes are affected by complex sociocultural factors.

Abstract Name: Acute Effects of Yohimbine HCl Supplementation on Resting Metabolic Rate and Energy Metabolism During Submaximal Aerobic Exercise

Yohimbine, an alpha-2 adrenergic receptor antagonist commonly included in fat-burning supplements, is marketed to increase lipolysis and enhance body composition and exercise performance. However, evidence for its acute metabolic effects in healthy adults remains limited. This study investigated whether a single oral dose of yohimbine hydrochloride (YH) influences resting metabolic rate (RMR), energy expenditure, or fuel utilization during aerobic exercise. Twelve physically active adults (8 males and 4 females; age = 21.7 ± 2.5 years; height = 178.9 ± 8.1 cm; mass = 78.3 ± 7.3 kg; % body fat = $19.2 \pm 7.3\%$) completed two randomized double-blind, placebo-controlled crossover trials consuming either 5 mg YH or a cornstarch placebo after an overnight fast. After 10 minutes of seated rest, participants underwent a 30-minute RMR assessment, followed by 30 minutes of cycling at the intensity corresponding to their first ventilatory threshold, previously determined using standard gas-exchange methods. Expired gases, heart rate, and ratings of

perceived exertion were measured every five minutes throughout exercise, and blood lactate concentration was assessed every ten minutes. RMR did not differ significantly between conditions (YH vs. PLA: 1688 ± 313 vs. 1661 ± 233 kcal/day, $p = 0.68$). During exercise, total oxygen consumption, estimated using VO₂ area under the curve, was also similar between trials (YH vs. PLA: 43.41 ± 8.33 vs. 43.84 ± 8.10 L, $p = 0.43$). No significant effects of YH were observed for heart rate, respiratory exchange ratio, perceived exertion, or blood lactate. These findings indicate that acute yohimbine supplementation does not alter resting metabolism, energy expenditure, or substrate utilization during moderate-intensity aerobic exercise in healthy young adults.

Abstract Name: Oh the (De)Humanity: Which Type of Dehumanization (Other, Self, Meta) Is Linked to Making Online Threats

We examined the link between dehumanizing language and making threats by expanding the Integrated Psycholinguistic Threat Assessment (IPTA) (Sinclair et al., 2025) framework and applying it to more than 15k subreddit posts of the extremist group known as involuntary celibates (self-titled “incels”). The original IPTA framework measured the casting of outgroups (not incel-identifying people), as lesser humans (other-dehumanization). The expanded IPTA framework added both whether the author dehumanized themselves (self-dehumanization) and if they perceived that outgroups dehumanized them (meta-dehumanization). These three overarching categories each included five dehumanization subtypes: Superhuman (lacking empathy, often due to being “too powerful”), In-Human (lacking morality, evil), Infrahuman (sharing characteristics with animals), Subhuman (more animal-like than human), Nonhuman (not human, things, objectification). The IPTA also assesses whether the post could represent a threat: i.e., tracks the presence of specific elements of an attack plan and subjective judgments of potential for action (posts viewed by coders as having a high potential for violent action were “red flagged”). Upon analysis, other-dehumanization and meta-dehumanization were significantly linked to both the presence of specific elements of a plan and red flagging. Self-dehumanization showed no link. Further regressions examined which subtypes of dehumanization were most strongly connected. Posts containing in-human and infrahuman forms of other-dehumanization were more likely to be red flagged. Whereas posts indicating that the author thought others viewed incels as completely unrecognizable as human (i.e., nonhuman) were red flagged. When it came to whether the post included specific elements of a plan, this nonhumanization was the only significant subtype for both other and meta-dehumanization.

Abstract Name: Serine Availability Modulates Yeast Sensitivity to the Cyanotoxin 2,4-Diaminobutyric Acid

Non-proteinogenic amino acids such as 2,4-diaminobutyric acid (2,4-DAB) are emerging cyanotoxins associated with cellular stress and growth defects in diverse organisms. Because serine supports multiple essential pathways, including protein synthesis, stress resistance, and sphingolipid metabolism, cells experiencing serine limitation may be especially vulnerable to toxin exposure. This project investigates how endogenous serine biosynthesis influences 2,4-DAB toxicity in *Saccharomyces cerevisiae*, a genetically tractable model for dissecting metabolic determinants of cell survival. Wild-type and SER2-manipulated yeast strains were cultured under serine-replete or serine-deficient conditions and exposed to defined concentrations of 2,4-DAB. Growth kinetics, viability assays, and early stress-response indicators were measured to evaluate how nutrient state alters susceptibility to toxin-induced damage. In serine-limited conditions, yeast displayed substantially reduced growth, heightened stress signaling, and significantly increased cell death following 2,4-DAB exposure. In contrast, serine-replete cultures or strains with intact SER2-dependent serine biosynthesis maintained higher viability and exhibited attenuated stress responses. These findings demonstrate that intracellular serine availability is a key modifier of 2,4-DAB toxicity and that metabolic state strongly shapes cellular resilience to cyanotoxin exposure. By defining how nutrient conditions modulate toxin sensitivity, this work highlights metabolic vulnerabilities that may influence organismal responses to environmental toxins. Ongoing experiments are examining whether 2,4-DAB can serve as a substrate for serine palmitoyltransferase (SPT), potentially generating atypical sphingolipids that contribute to stress and cell death.

Abstract Name: Evaluating how different sources of scientific evidence shaped the EPA's regulation of the herbicide Dacthal

The purpose of this project is to analyze the role of different sources of scientific evidence in the Environmental Protection Agency's regulation of the herbicide Dacthal. Per the 1946 Administrative Procedures Act, the 1970 Occupational Safety and Health Act, and the 1976 Toxic Substances Control Act, the EPA must be able to show that it makes its regulatory decisions based on the best available science. However, the lack of a standardized framework to guide the use of different sources of scientific evidence in EPA policymaking and ongoing concerns about biases associated with industry-generated data point to a continued need for more research on how the pesticide industry is able to influence the creation of evidence-based policy. Furthermore, because uncertainty remains regarding what specific sources of scientific evidence were prioritized during the EPA's decision to cancel Dacthal in 2024, the role of scientific evidence in this regulatory process warrants further investigation. To better understand the extent to which different sources of scientific evidence were prioritized during the EPA's regulation of Dacthal, a systematic review of the existing scientific literature regarding Dacthal's potential health hazards was conducted as well as document analysis of EPA Docket EPA-HQ-OPP-2011-0374 which contains the EPA documents relevant to the banning of Dacthal. These findings, along with interview responses shared by former EPA employees were triangulated and analyzed via process tracing which provided a case-oriented framework for systematically assessing specific events in which scientific data was used, who it was used by, and what outcomes resulted from its use. Based on preliminary findings, it appears that the EPA primarily used independently collected scientific evidence during early problem formulation stages of reviewing Dacthal to assess research gaps and then relied solely on industry-supplied data during later stages of the regulatory process.

Abstract Name: Students' Perception on Social Media

Social media has become a place where ordinary people can become overnight sensations. Their videos, personality, and ability to reach millions of screens attract people and their engagement just within a few seconds. Because of this, influencers work strategically to curate their videos to pertain to a certain audience that will guarantee the benefits of this engagement. Despite the work the influencer does, what truly brings engagement are the perceptions that viewers have of them. What do people, specifically college students, think when they engage with influencers? Are they trustworthy? Are they authentic? Are they someone they can see themselves in? This study will build upon previous research that explores trust and authenticity and will apply it to undergraduate and graduate students at Southern Methodist University (SMU) in Highland Park, Dallas, Texas, a private research institution in North Texas. This study will utilize a mixed methods approach where the data will provide a general outlook of the SMU student population through an anonymous, IRB approved Qualtrics survey. The survey will record a general demographic, students' perceived trust and authenticity, and possible future habits. In addition, interviews will occur with SMU students from diverse backgrounds to get deeper analysis into their perceptions. The separate survey and interview ensure full anonymity in survey responses and full confidentiality with interview responses. These results will be compared to see how students in a private institution in the North Texas area view social media and the impact influencers can have on college students.

Abstract Name: Gender Disparities in Mathematics GPA Among African-American High School Students

This study applies an intersectionality framework to examine gender-based disparities in mathematics achievement among African American high school students. Although prior research shows that African American girls often outperform boys in math, both groups continue to struggle with meeting grade-level expectations, signaling broader systemic inequities. Using data from the National Center for Education Statistics' High School Longitudinal Study (2009–2016), an independent t-test was conducted to determine whether a significant difference exists in 11th-grade mathematics GPA between African American males and females. Results indicate a statistically significant GPA gap of approximately -0.31 points ($p < .001$), suggesting consistent underperformance for one group with meaningful academic consequences. Even a difference of this magnitude can restrict access to advanced coursework, reduce competitiveness in college admissions, and contribute to long-term disparities in STEM pathways and future earnings. These findings underscore the necessity of equity-driven interventions, including culturally responsive teaching, expanded access to qualified math educators, and targeted supports such as small-group tutoring and mentoring. Addressing these intersecting race- and gender-based gaps is essential for promoting fair and sustainable academic outcomes for African American students.

Abstract Name: Reusing Waste: Prototype 3D Printer Filament Recycler

3D printers are known for their filament purge waste. This waste and prints failing to meet expectations are thrown out though the material has little imperfections. The objective is recycling waste into filament and to develop a method utilizing 3D printed parts to increase accessibility for 3D printer hobbyists. This recycling process focuses on PLA recycling as it is commonly used in Fused Deposition Modeling 3D printing. The filament must be ground down into granular pieces using a rotating tooth-crushing system. The ground filament will be poured into a funnel which has an auger screw to push the filament down. At the bottom of this system there will be a hot end extruding at 220°C. The filament will be cooled and stretched. At this point in the process, the filament is expected to have imperfections and will require further processing. Filament will go into a pelletizer. These pellets will go through another extruder at 190°C to a cooling and spooling system creating the finished product. All parts will be modeled in Fusion360 using the iterative design process; however, some parts cannot be printed due to the high temperatures and pressures. The expectation is 95% of waste filament recycled back into usable filament. The expected loss is from the grinding process in which particles can fall out of the grinder. The expected cost of the printed parts is less than 3kg of any given filament. While this can be done for any material the intended material is PLA due to its widespread use within the 3D printing community. By developing this method to allow the average user to recycle waste filament, it increases access as current filament recyclers are expensive. As 3D printing grows as a hobby, more waste is produced. This method decreases effects of waste filament on the environment.

Abstract Name: Role of Hypothalamic Oxytocin Receptor in Mediating Long-term Maternal Cardiovascular Benefits after Lactation

Epidemiological studies show that women who do not lactate have a higher risk of cardiovascular disease later in life. We hypothesized that lactation provides long-term cardiometabolic benefits through increased oxytocin production. Preliminary data from our lab showed that mice that did not lactate had lower circulating OXT and reduced hypothalamic expression of oxytocin (Oxt), oxytocin receptor (Oxtr), and CD38, a facilitator of central OXT release. This study aimed to investigate whether Oxtr signaling in the hypothalamus mediates the cardiovascular benefits of lactation. Experimental Design and Methods: Hypothalami (HT) from CD1 mice were collected at delivery and cultured for 24 hours. Tissue halves were exposed to media alone, plasma from dams one day after weaning, a CD38 antagonist, or both plasma and antagonist. Supernatants were collected at 4 and 24 hours. Tissue was collected 24 hours after the procedure, and gene expression of Oxt, Oxtr, and CD38 was measured using qRT-PCR. Cre-lox Oxtr hypothalamic knockout (KO) and control (CTR) mice were bred and assigned to lactated (KO-L, CTR-L) or non-lactated

(KO-NL, CTR-NL) groups. Blood pressure was measured at 6 months postpartum, and plasma OXT concentrations were assessed in lactated mice. One-way ANOVA with post hoc tests was used as appropriate. Results: HT explants treated with both CD38 antagonist and plasma showed a non-significant trend toward increased Oxtr and CD38 expression. CTR-L mice exhibited significantly lower systolic blood pressure than all other groups and lower diastolic and mean pressures compared to CTR-NL. Heart rate did not differ among groups. Plasma OXT tended to be lower in KO-L compared to CTR-L. Conclusion: Our tissue culture experiments demonstrate that lactation during pregnancy in mice increases Oxt levels by acting on Oxtr in the hypothalamus. Data from conditional knockout mice lacking Oxtr in the hypothalamus indicate that cardiovascular benefits of lactation are dependent on Oxtr.

Abstract Name: COVID-19 and Black Lives Matter Movement Oral History Project

The COVID-19 and Black Lives Matter Movement Oral History Project contributes to the documentation of milestone crises while those events remain vivid in collective memory, thereby preventing the loss of crucial personal narratives. Oral history, as a qualitative research method, involves the systematic recording and preservation of firsthand accounts of historical experiences. It captures the personal reflections, emotional responses, and societal impacts felt by individuals during and after pivotal events, thereby expanding traditional historical narratives to include the voices of everyday people. In doing so, oral history enhances the historical record by foregrounding the lived experiences of diverse communities. A specific subset of this field, crisis oral history, focuses on collecting testimonies during or immediately following moments of upheaval—such as war, pandemics, and natural disasters—when recollections are at their most vivid. This temporal proximity enables the capture of emotional intensity and nuanced memory, preserving the immediacy and authenticity of individual experiences. The project is further situated within the framework of public history and civic engagement, which extends historical scholarship beyond academia to engage wider audiences. Public history emphasizes accessibility, relevance, and community involvement, manifesting through museum exhibitions, archival collections, and other platforms that democratize historical knowledge. Public historians often adopt interdisciplinary, collaborative methodologies, including direct engagement with community members as co-creators of historical narratives. Through this lens, the project incorporates audio recordings, video interviews, and transcripts produced by students enrolled in Pace University's HIS196H course. Students investigate oral history methodologies and apply their training by conducting interviews with individuals whose perspectives on the COVID-19 pandemic and the Black Lives Matter movement offer critical insight into these contemporary crises. The collected materials are curated and disseminated via the COVID-19 and Black Lives Matter Oral History Project blog hosted on Pace University's website.

Abstract Name: Synthesis of Nitrogen Mustard–Modified HDAC Inhibitors for Enhanced Cancer Treatment

Histone deacetylase (HDAC) inhibitors are an established class of anticancer agents known for their ability to regulate gene expression and promote apoptosis in cancer cells. However, many existing HDAC inhibitors face limitations such as low selectivity and reduced therapeutic effectiveness. To overcome these challenges, this project focuses on developing novel compounds that combine the HDAC inhibitory function of existing ligands with the DNA-targeting properties of nitrogen mustard derivatives. Two precursors previously synthesized in our lab serve as the foundation for this design. One precursor was chemically modified to form a nitrogen mustard derivative, which exhibits independent anticancer potential and can also act as a reactive intermediate for further hybrid molecule formation. The combination of the nitrogen mustard derivative with the second precursor aims to produce a dual-function compound capable of simultaneously disrupting DNA replication and inhibiting HDAC activity, thereby enhancing overall anticancer efficacy. Structural design and synthesis are guided by rational drug design principles, with subsequent characterization and evaluation planned to assess stability and potential biological activity. While this research is ongoing, it highlights the promising role of hybrid molecule development in creating more potent and selective cancer treatments that integrate both epigenetic and DNA-targeting mechanisms.

Abstract Name: The Influence of the Gut Microbiome in Health and Disease

The microbiome is an intricate system comprising approximately 10-100 trillion microbes, which are understood to play a crucial role in maintaining overall health. Most microbiome activity occurs in the gastrointestinal tract, where dysbiosis (an imbalance in essential microbial populations) in the gut is linked to chronic pain and disease. This study utilizes a literature review methodology that includes targeted data extraction from existing research, evaluates the validity and reliability of the findings, and synthesizes conclusions based on the collected evidence. Therefore, the aim of this literature review is to comprehensively evaluate the existing knowledge about the association between gut microbiome and chronic pain. The gut microbiome interacts directly with various systems of the human body, including the endocrine, nervous, and cardiovascular systems. These connections provide collectable, important insights regarding disease states, progression, and treatment potential. Metabolite signaling enables communication between gut microbes and various organ systems. Individualized genetic data can be used to unlock key features of the microbiome and guide the development of personalized treatments. Molecules such as short-chain fatty acids, endotoxins, 16 rDNA, and branched-chain amino acids can serve as biomarkers to clarify disease. Approaches that analyze microbiome-based biomarkers have emerged as non-invasive and highly specific tools for detecting disease, enabling earlier identification of pathological states and more targeted treatment planning. Pharmacomicrobiomics is an emerging field that seeks to bridge the gap between the microbiome and drug metabolism, offering significant potential to advance personalized medicine and improve the treatment of various illnesses. In closing, a deeper understanding of the microbiome will, in turn, revolutionize care methods and lead to a decrease in disease incidence.

Abstract Name: Laboratory Performance Characteristics of Fine-Graded Asphalt Mixtures Containing Recycled Asphalt Materials

The economic and environmental advantages of reclaimed asphalt pavement (RAP), along with the conservation of non-renewable natural resources, have made its use in fine-graded asphalt mixtures an attractive alternative for pavement rehabilitation compared to traditional mixes. This study investigates the potential performance enhancement of fine-graded asphalt mixtures by incorporating RAP materials. Six different fine-graded asphalt mixtures were sampled from plant-produced materials placed on roads in Virginia. Laboratory testing assessed the durability, rutting resistance, and fatigue cracking susceptibility of the mixtures. Binder and mixture properties were analyzed to compare rutting performance and fatigue resistance. The results indicated that RAP increased the stiffness of the mixtures, improving their resistance to permanent deformation. However, it negatively affected fatigue performance, though this impact was mitigated by higher binder content. Additionally, dynamic modulus test results alone were insufficient to fully characterize mixture performance, and performance rankings varied across different laboratory tests. To validate these findings, field performance data are necessary.

Abstract Name: Wildfire Propagation Prediction from Multimodal Data using Deep Learning Models

Wildfires are increasingly devastating in the United States and across the world, threatening lives, infrastructure, and ecosystems. Accurate wildfire propagation prediction remains a major scientific challenge because it depends on interacting chemical, physical, and environmental processes influenced by climate, weather, topography, land cover, and human activity. This project addresses this gap by aiming to develop a robust, physics-informed deep learning framework for accurate, high-resolution wildfire propagation prediction. The unique contribution lies in integrating heterogeneous multimodal data with physical constraints derived from established fire behavior principles. First, we present a novel comprehensive multimodal dataset integrating geospatial attributes (coordinates, elevation, slope), meteorological variables (wind speed and direction, temperature, humidity), environmental indicators (fuel type, vegetation indices, moisture content), socio-economic factors (population density, urban development metrics), and historical fire progression maps from publicly available data sources. These heterogeneous data sources, spanning diverse spatial and temporal resolutions, are collected and organized into a unified framework, which provides a critical research resource. This resource facilitates not only immediate fire spread prediction, but also the investigation of long-range dependencies in wildfire behavior, enabling the analysis of wildfire evolution against dynamic changes in the climate and environment. Second, we are designing and evaluating deep learning models, including autoencoders, Convolutional Neural Networks (CNNs), and transformers, to capture spatial-temporal patterns governing fire spread using our curated historical fire dataset. To overcome the limitations of single-model architecture, we are also exploring hybrid approaches with physics-informed regularizations to improve the prediction accuracy. Ultimately, this project is expected to deliver both a novel benchmark multimodal dataset and a robust AI-driven modeling framework that improves wildfire propagation prediction accuracy, enhances emergency preparedness, and strengthens wildfire resilience.

Abstract Name: Beyond Access: How Social Mechanisms Shape WASH Infrastructure and Behavior in Rural Zambia

For over 50 years, non-governmental organizations have focused on increasing water, sanitation, and hygiene (WASH) practices in the developing world (Wit et al., 2024). While there have been great successes in the distribution of WASH resources, the sustainability of initiatives has been an ongoing issue (Taylor, 2013). This research examines how six behavioral mechanisms (accountability, diffusion, market, ownership, education, and shame) impact the sustainability of WASH initiatives in the Mbeza and Muchila communities in Zambia. During the summer of 2025, the researcher spent three months in Zambia assessing the impact of behavioral mechanisms on the sustainability of World Vision's WASH programs. World Vision is a global NGO that has a long history with WASH programs. A mixed-methods, person-centered approach was used to understand how people interact with WASH systems and how infrastructure outcomes are shaped by community behavior. Data was collected through semi-structured interviews (N=21) with community members, children, and a committee leader; school surveys across two schools and six classes; and direct observation of infrastructure outcomes. Findings show that strong systems of accountability (such as financial transparency and enforcement mechanisms), diffusion of practices through social networks, and market-based models (like solar-powered systems and community water fees) all contributed to sustainable outcomes. When community members were involved in decision-making and maintenance, a sense of ownership and responsibility increased. Education impacted the proper usage of WASH resources. Additionally, peer influence played a role in behavior change, especially among schoolchildren. Despite progress in World Vision area programs, issues such as locked ablution blocks, lack of soap and tissue, and poor reporting systems hinder long-term success. The findings underscore the need to embed sustainability into the design and delivery of WASH services to ensure continued impact.

Abstract Name: Rhythms of Resistance: The Role of Institutions and Cultural Expressions in Latinx College Students' Cultural Affirmation Processes

As of 2022, Latinx youth accounted for about one quarter of all U.S. children, from which the big majority were American born. These individuals not only navigate the complexities and challenges that come with coming of age and transitioning to college but face unique challenges in the process of self-identification. Latino kids who grow up in the United States often struggle to reconcile their vernacular culture and characteristics with the dominant American culture. They are constantly navigating the tension between their cultural identity at home and the persona they adopt in the broader American society, often opting to conceal their Latino identity due to negative stereotypes and reputation attached to it and fear of not fitting in. In this context, spaces such as college serve as transformative environments where Latinx students must negotiate their identity and experience not only the natural transformations and challenges that come with coming of age but also a deeper transformation in how they embrace or reject their vernacular culture. It is during this

phase of their lives that such transformations can be most clearly explored. Furthermore, examining how everyday tools like music accompany this process can serve as a magnifying glass into how students fight for recognition in a society that often marginalizes them, and how these tools help them reclaim their Latinx identity. The purpose of this study is to explore how Latinx students reconstruct cultural affirmation within the college environment, highlighting the institutional factors and cultural expressions that help students reconnect with their heritage, build a sense of belonging, and ultimately succeed in college. In this case, success not only being defined by academic achievement but also by the ability to integrate into the institutional and cultural fabric of their university, feeling empowered rather than constrained by their Latinx identity.

Abstract Name: Pathfinding using Machine Learning

In computer science, pathfinding refers to the use of algorithms to determine optimal routes from a starting point to a target goal while avoiding obstacles. Applications of pathfinding span across GPS navigation, robotics, autonomous vehicles, drone routing, and AI movement in video games. With dozens of pathfinding algorithms in existence for different applications, and each implementation resulting in unique trade-offs in accuracy and memory consumption, a systematic review is needed to produce a new standard multi-purpose approach, inspired by A*, favoring scalability and performance with contemporary processing demands in mind. Furthermore, the rise of GPU-based computing power, yielding advances in machine learning, presents an opportunity to question the role of AI in the optimization of pathfinding. Can machine learning improve performance, defined as computation time or memory usage, of an A*-based algorithm under certain conditions? If so, what is the relationship between performance gains and the density of the graph? To test this, a controlled simulated environment was created using C++ and the raylib 3D graphics engine, and a static connected graph of 3D nodes were generated and placed on the digital ground. Training was later done on a neural network designed to approximate the heuristic function, using data collected from the previously generated graph. Although the overhead introduced by machine learning is expected to lower performance in very low-density graphs, we hypothesize that incorporating a neural network, specifically into the heuristic function, will yield measurable gains in computation speed within medium-density graphs.

Abstract Name: Beyond Parenting: The Role of Executive Function in Child Emotion Regulation and Sleep

Childhood sleep problems are a significant public health concern. They extend beyond mere tiredness, significantly affecting children's emotion regulation, behavior, and long-term development. Child aggression and behavioral problems negatively impact parents, caregivers, and children, and parenting behaviors play a pivotal role in either mitigating or exacerbating these effects. Although research connects sleep problems to emotional-behavioral difficulties, the mediating roles of parental executive functioning (EF)—such as

working memory, impulse control, and task-switching—and parenting behaviors remain understudied. This study aims to address this gap by investigating how mothers' EF and parenting behaviors shape children's sleep patterns and emotional development. Using a sample of 25 mother-child dyads (with children aged 5), this research will employ a multi-method assessment approach. Maternal EF will be assessed through standardized laboratory tasks, including the color-word interference task (assessing impulse control and task-switching) and the letter-number sequencing task (assessing working memory). Concurrently, mothers will complete three validated questionnaires: the O'Leary Parenting Scale, the Early Childhood Behavior Questionnaire (ECBQ), and the Child Behavior Checklist (CBCL). The present study tests three primary hypotheses: (1) lower maternal EF will be associated with increased child sleep problems and emotion dysregulation; (2) lower maternal EF will predict more maladaptive parenting behaviors; and (3) parenting behaviors will mediate the relationship between maternal EF and child sleep outcomes. Data will be analyzed using correlation and multivariate regression analyses in the IBM SPSS software, controlling for potential covariates such as child sex and family socioeconomic status. The findings aim to elucidate a key pathway in family dynamics and sleep interventions, potentially informing targeted interventions that support parental self-regulation to improve child sleep and developmental trajectories. Ultimately, this study may help break cycles of dysfunctional family dynamics by promoting healthier sleep habits, thereby benefiting families and society.

Abstract Name: Affective Influences on The Neural and Subjective Timing of Error Awareness

The error-related negativity (ERN) and error positivity (Pe) are electrophysiological markers of performance monitoring. The ERN is elicited when an error occurs and appears to operate independently of whether the individual is consciously aware of the mistake. The Pe occurs after the ERN and is believed to reflect conscious awareness of the error. Prior research suggests that transient affective states exert limited influence on ERN and Pe amplitudes (Clayson, Clawson, & Larson, 2012), however the relationship between pre-task mood and the timing of conscious error awareness remains unexplored. The present study examined how a baseline affective state (i.e., mood) influences the neural and subjective dynamics of error awareness. Participants completed the Positive and Negative Affect Schedule (PANAS) to measure their present affect. They then completed a Stroop task embedded within a modified Libet clock paradigm, in which they reported both the presence and perceived timing of error awareness. EEG was recorded to extract ERN and Pe components time-locked to both response onset and subjective awareness reports. It was hypothesized that higher levels of negative affect would be associated with attenuated ERN and Pe amplitudes and delayed error awareness, reflecting reduced efficiency of performance monitoring during negative mood states. By integrating affective, neural, and phenomenological measures, this study has the potential to clarify the temporal and emotional determinants of conscious error detection and inform models of self-monitoring relevant to clinical populations.

Abstract Name: Communicating Hardship: Paralinguistic Clues in Children's Emotional Expression

Experiencing sustained adversity has a significant emotional impact on children's expression and overall well-being. Although children use vocal expression as a primary way to convey suffering, research in this area remains limited. Furthermore, assessment still relies heavily on subjective interpretation, and it frequently depends on technical acoustic analysis, which may miss subtle emotional cues that human listeners might detect. Guided by Scherer's model, trauma-informed framework, and paralinguistic features, we aim to explore how children express their feelings during hardship to enhance communication and better address their emotional and health needs. To capture these subtleties, our study integrates Klaus Scherer's Component Process Model, paralinguistic features, and trauma-informed care. Scherer's model conceptualizes emotions as a continuous appraisal process that sets off coordinated responses across multiple systems (cognitive, psychological, expressive, and subjective feelings). Children's paralinguistic features reflect the expressive component, which, in turn, the trauma-informed care model reveals how they appraise and internalize hardship. We listened to data recordings of 12 children migrating with their parents towards the United States (authorized by the primary data's PI). Our study used a qualitative phenomenological approach and thematic analysis. The ongoing analysis reveals that children often utilize monotone speech to distance themselves from difficult circumstances, and silence became a strong indication of extreme hardship. On the other hand, coherence emerged while talking about positive relationships. Adversity frequently affected children's vocal characteristics, even when syntax was unaltered. The UTEP IRB guidelines were closely adhered to, and all ethical measures were taken during the data collection process. Keywords: Children, Forced Displacement, Hardship, Vocal Expression, Syntax

Abstract Name: Increase in storm frequency impact on *Morella cerifera* growth and survival

Morella cerifera is an evergreen shrub native to the Atlantic and Gulf Coast regions. It is a moderately salt-tolerant species encroaching into grasslands dominated by the salt tolerant grass, *Spartina patens*, on Hog Island, Virginia. Hog Island receives storm surges and strong winds causing the landscape to be highly dynamic. Many of the factors that support the successful encroachment of *Morella cerifera* at early stages of development are largely unknown. It is important to study encroachment because it could impact the structural integrity of the island by adding stability to areas that need to erode regularly. *Morella cerifera* can grow from a seedling to an enclosed canopy thicket in 15 years; however, it is unknown how storms, which are predicted to increase in frequency, will impact its growth. To determine the impact of an increased frequency of storms on the growth of *Morella cerifera* an experiment was set up with twenty-four pots containing one *Morella cerifera* seedling and three plugs of *Spartina patens*. There were four groups: no disturbance, one storm disturbance, two storm disturbances, and three storm disturbances. Treatment groups were exposed to 30 ppt saline solution simulating saltwater inundation after a storm. Each of these simulated disturbances had a three week recovery period. As disturbance events increased, *Morella cerifera* experienced less growth, with a 50% decrease in growth after two disturbances relative to the control. In contrast, *Spartina*'s growth only decreased by 14% relative to the control after two disturbances. This is an indication

that an increase in storm frequency has a greater impact on the growth of *Morella cerifera* and may reduce its capacity to encroach into grasslands, while *Spartina* may continue to persist.

Abstract Name: Designing for Dignity: Biophilic and Biomimetic Approaches to Assisted Living Interiors

This project aims to explore how interior design can dismantle stigmas surrounding aging while affirming the beauty, identity, and lived experience of older adults, responding to the growing demand for supportive senior housing. As the senior population expands, many assisted living environments continue to rely on institutional design cues, visually confusing circulation, and acoustically harsh conditions that undermine well being and reinforce negative assumptions about aging. Research in biophilic design, environmental psychology, and aging in place highlights the value of natural materials, controlled daylight, tactile surfaces, intuitive spatial organization, and hygienic and easy to clean finishes that support occupant health and reduce environmental stress. Drawing from the sun as both metaphor and design framework, the interior uses circular motifs reminiscent of sunspots and soft organic squiggles symbolizing the lines formed over time, creating a visual language that celebrates the poetic process of being kissed by time. Methodological approaches include case studies of assisted living facilities, literature reviews on sensory responsive environments, interviews with staff and residents, and field observations documenting challenges related to glare, acoustics, and wayfinding. Anticipated outcomes include biophilic modern design strategies featuring warm materials, glare free lighting, gentle color contrast, and organic circulation routes that enhance clarity and comfort for residents, including those with visual impairments. Proposed solutions introduce restorative indoor outdoor connections, inclusive wayfinding systems grounded in the project's symbolic motifs, acoustically balanced communal spaces, and residential units designed for accessibility, personalization, healthy maintenance, and long term independence. By merging research driven design strategies with a narrative that honors the natural beauty of aging, this project reframes assisted living as a place of dignity, connection, and meaningful daily experience.

Abstract Name: Delving into the Logic behind Mancala

Mancala is a family of board games defined by the movement of sowing. Sowing is the distribution of the amount of pieces one has counter-clockwise around the board one-by-one. The generic layout of a typical Mancala board is six bins on each side and one big bin per player, otherwise known as the "store," where only the select player could interact with. The goal of the game is to collect the most pieces into the player's store. For this research project, the idea was to delve into the mathematics and logic behind the popular two-player version known as "Avalanche" in which a player could continue to move if their last piece landed in a non-empty bin. In this work, various research papers involving the simple solitaire mancala game, "Tchoukaillon," were utilized to analyze the importance of "sweeping" moves and the most optimal play. Through this, it was determined that discrete functions, matrices, and the Chinese Remainder Theorem were the best way to describe and detail the inner workings of the solitaire game. Along with this, a Python program

was built to incorporate the best possible move-sets involving various categories of moves and their effects. To connect it all together, trial and error of actually playing through the Avalanche gamemode led to a better understanding and analysis of the logic behind it. Furthermore, a new gamemode was created, named "Ambush," that could lead to further study.

Abstract Name: Rest vs. Risk: The Cost of Poor Sleep Habits for Student Well-Being

Sleep affects almost all aspects of life. Not getting enough sleep can cause physical, cognitive, and mental health issues. College students require adequate sleep to fulfill their academic tasks. This research study focused on identifying different factors that impact sleep and, examining the problem in context with depression. The main research questions were 'What factors impact college students' sleep quality?' and 'Does depression impact sleep?'. Additionally, the research explored different factors, like chronotype, bedtime procrastination, and cell phone use. Literature has suggested these factors may produce mental health problems and sleeping problems, and that college students often struggle with sleep. Moreover, high screen time can indicate worse sleep quality. The study employed a quantitative and descriptive research design. For the analysis, independent t-tests and Pearson product-moment correlation tests were conducted to analyze the different assessments used. Those assessments included the Pittsburgh Sleep Quality Index (PSQI), Morningness-Eveningness Questionnaire, Bedtime Procrastination Scale, questions regarding cell phone use, and the Patient Health Questionnaire (PHQ-9). An online survey that was distributed to seated students at a rural four-year university (N=101). Results showed significant correlations between sleep quality and depression. With rising depression, sleep quality decreased. Almost 50% of participants reported mild to severe depression levels. Additionally, evening people and individuals with higher bedtime procrastination reported higher levels of depression. Lastly, results showed that the usage of phones 30 minutes before sleep significantly increased sleep disturbance. These findings show the many different factors impacting college student sleep and mental health. With significant relationships between sleep quality and depression, and established literature connecting these factors to academic outcomes and retention, addressing sleep behaviors has the potential for multifaceted benefits for both students and universities. This study addresses these issues and proposes potential solutions at both the individual and institutional levels.

Abstract Name: Investigating the Effectiveness of Aromatherapy and its Supportive Combinations in Reducing Pain and Anxiety of Breast Cancer Patients

Introduction: Breast cancer surgery is often associated with pain and anxiety, which can hinder physical functioning and overall quality of life, even after treatment. Often, usual care and pharmacological treatments can neglect the management of these side effects or symptoms. Thus, complementary therapies, such as aromatherapy, can be utilized to alleviate pain and reduce anxiety in breast cancer patients. Aromatherapy-the

holistic practice of using essential and/or herbal oils- aims to improve a person's health by promoting effective healing beyond the standard biological treatment, addressing social and psychological well-being. While one systematic review reported "no effect" of aromatherapy on pain, the effectiveness of aromatherapy combined with other interventions has not been systematically reviewed in breast cancer populations. Therefore, this thesis serves to evaluate the effectiveness of aromatherapy, alone or integrated with other therapies such as music therapy in reducing pain and anxiety among breast cancer patients. Method: This systematic review will follow PRISMA 2020 guidelines. A comprehensive, systematic search will be conducted in PubMed, CINAHL, Cochrane Library, and SCOPUS for randomized controlled trials (RCTS) published from 2020 to 2025. Eligible studies will include adult women breast cancer surgery patients who received aromatherapy during various periods of breast cancer. Results: Based on preliminary literature screenings, evidence suggests that aromatherapy, particularly when paired with complementary interventions, yields to reduction in pain and anxiety of breast cancer patients. Conclusion: This review will contribute to the understanding of how non-pharmacological approaches, especially aromatherapy, can relieve the pain and anxiety endured by breast cancer surgery patients within the biopsychosocial framework. Findings can potentially clarify the extent of its effect, illuminate physiological and psychological mechanisms, and further aid in the development of optimized interventions for breast cancer patients that will mitigate the pain and anxiety experienced.

Abstract Name: Impacts of Von Restorff Effect on Memory Recall

The von Restorff effect was originally discovered in 1933 by Hedwig von Restorff, a German scientist. The von Restorff effect states that items and information that is perceptually distinct is more likely to be encoded and retrieved than information that blends into its surroundings (Manandhar, 2024). This project explores font color as a visual mechanism capable of producing such distinctness, focusing on how color can influence memory retention and recall. Prior studies show research that suggests that attention, color salience, and the encoding processes within the brain contribute to stronger memory traces for items that stand out visually, whereas homogenous stimuli are less likely to receive attention and prioritized cognitive processing (Elhalal, 2014). Building on this research, this empirical study is proposed to test whether red text, compared to standard black text color, can create an isolation effect in a word-recall task. The proposed experimental design consists of three conditions, red, black, and mixed-color, to determine whether or not red font color improves recall by drawing more attention more efficiently than a neutral format with homogenous stimuli. It is hypothesized that the mixed color condition will have greater impact on memory encoding, and retention of information. The model provides a foundation for testing how color-based distinctiveness supports memory performance. Understanding these mechanisms can help learn how visual distinctiveness can have practical implications. For example, intentional use of color can help educators guide students toward understanding key concepts in their learning plans as well as support cognitive organization. In marketing or media contexts, the von Restorff effect may impact the memorability of the media design.

Abstract Name: Influence of Cattle Grazing and Prescribed Fire on Longleaf Pine Avian Communities

Cattle (*Bos taurus*) grazing in longleaf pine (*Pinus palustris*) forests with a prescribed burning regime may sustain savannah-like conditions in the understory better than burning alone, increasing plant species richness and structural diversity, decreasing organic ground cover, and reducing potential needs for suppressing invasive plants with herbicides. Cattle grazing in longleaf pine mimics grazing patterns of American bison (*Bison bison*) populations that subsisted in the southeastern United States prior to European settlement, maintaining a grass- and forb-dominated understory desirable by many wildlife species. Specifically, our research objective is to evaluate how cattle grazing in combination with prescribed fire influences the longleaf pine avian community. Using autonomous recording units (ARUs) in 2 longleaf pine stands in central and southwest Louisiana, we are collecting data from 5 treatment plots: grazing + burning (mature stand), grazing + burning (young stand), burning only, pre-treatment grazing, and control (no disturbance). We began recording avian songs and calls in October 2022 and concluded in September 2025. ARUs record for 5 minutes every day at dawn. After downloading recordings, we review only those from every third day, documenting avian species heard, date, recording start time, ARU location, and treatment. Though data collection is currently ongoing, we intend to evaluate the difference in avian species richness among the 5 treatments to educate landowners—particularly those in southwestern and central Louisiana and southeastern Texas—on how the integration of cattle grazing into a fire-disturbed longleaf pine forest may create optimal habitat conditions for forest birds in these ecosystems.

Abstract Name: Modeling Isomeric Butanol Reactivity on TiO₂/Au(111) Inverse Model Catalysts

Biobutanol, or butanol sourced from biomass, can produce butene which serves as a viable chemical precursor for a fossil-fuel free route to plastic production. Developing a deeper understanding of the fundamental thermal catalytic processes of butanol over heterogeneous model catalysts aids in the design of more efficient catalysts. Temperature-programmed desorption (TPD) experiments demonstrate differences in both reactivity and selectivity for butanol isomers. 1-BuOH reveals little reactivity and high selectivity for butene (reduced) products, whereas 2-BuOH displays high reactivity and low selectivity, producing both 2-butanone (oxidized) and butene (reduced) products. To gain an atomically-detailed perspective on these processes, density functional theory (DFT) was used to investigate energetic trends and identify comparisons between 1- and 2-BuOH as they adsorb on Ti₃O_x nanoparticles supported on a Au(111) surface. Findings suggest Ti-OBuOH bonding, van der Waals interactions between the alkane chain and the Au surface, and electrostatic interactions between H and the nanoparticle all impact butanol's interactions on the catalyst material. Adsorption energies of both BuOH isomers place greater significance on Au surface interactions over Ti coordination number in determining favorability. The configuration of 2-BuOH enables it to interact more favorably with both the nanoparticle and Au surface compared to 1-BuOH, influencing reactivity and selectivity. Transition state energetics support experimentally observed trends for the thermodynamic favorability of 2-BuOH forming oxidized products compared to 1-BuOH.

Abstract Name: Between Rootwork and Revelation: African American Hoodoo and the Supernatural in Southern Black Literature

This project examines Hoodoo as both a lived religious practice in Florida and the Delta South and as a literary and cultural motif in African American folklore and fiction from the 1930s through the 1990s. It explores the intersections of oral tradition, ethnographic documentation, and literary expression to demonstrate how Hoodoo functions not only as a spiritual system but also as a framework for cultural memory and creative storytelling. Centering the works of Zora Neale Hurston and Toni Morrison, the project argues that Hoodoo has long served as a tool of resilience, identity formation, and community survival. It contributes to ongoing conversations in African American religion, folklore, literature, cultural history, and studies of race, memory, and the supernatural in the Black South. Research findings show that much existing scholarship reduces Hoodoo to superstition or remnants of an earlier cultural moment, overlooking its significance as a site of empowerment and creativity. However, oral accounts, folktales, and literary reinterpretations reveal a more layered understanding in which conjure practices operate as spiritual resources and narrative inspiration. This project, therefore, examines how Hurston's 1930s ethnographic work and her contributions to the Federal Writers' Project preserved and legitimized Hoodoo traditions, while later writers such as Morrison reshaped these traditions into literary strategies for representing history, trauma, and endurance within Black communities. The goals of this project are to: (1) recover the voices and practices present in African American communities in the Carolinas and Florida through oral traditions and ethnographic records, and (2) trace the literary evolution of Hoodoo—from Hurston's fieldwork to Morrison's fiction—to illustrate how Black Supernaturalism became central to cultural expression over the twentieth century. This study ultimately demonstrates that Hoodoo's spiritual and narrative power continues to shape African American cultural identity, providing pathways for understanding community memory, collective resilience, and Black creative expression.

Abstract Name: Improvement of Spatial Reasoning in LLMs via Automated Prompt Optimization

Despite their rapid evolution, large language models (LLMs) remain limited in their ability to spatially reason. LLMs lack comprehension of space, relationships between objects, environments, and physical constraints. LLMs rely on patterns in text to generate responses, which makes it difficult for them to interpret and manipulate information that relies on these concepts, limiting their utility for chemical and biochemical research. This project aims to explore solutions, including automated optimization of prompting, to improve LLMs' ability to use spatial reasoning and allow for more reliable use of LLMs in scientific research that involves complex physical interactions. Specifically, this project will evaluate how accurately base LLMs and optimized LLMs can predict the pKa values of titratable residues in proteins based on three-dimensional structure.

Abstract Name: Testing Dissimilar Metals and their Interface Strength: How do the Interface Characteristics of Collision-welded Metals Affect the Strength of their Weld?

Collision welding is an atypical method of welding first discovered during the Second World War, when soldiers noticed bomb fragments attached to sides of vehicles and other metal objects without any human interaction. Known as explosion welding, it is unique among welding methods, since it is able to bond metals that have differing characteristics such as melting points, heat capacities, etc., in addition to similar metals. It employs explosives to accelerate a flyer plate into an awaiting base plate. When they collide, the surfaces of the metal plates hit with so much force, the metals, briefly, act like liquids. This causes the formation of sinusoidal waves to propagate along the joined surfaces where the two plates meet, called the interface. The wave characteristics can be calculated using a first derivative test. The goal of my research is to compare which wave characteristic, wave length, frequency, or amplitude contributes most to the weld strength.

Abstract Name: Investigating the role of Protein Kinase C in axon guidance of spinal commissural neurons in zebrafish

Precise axon pathfinding is essential for establishing functional neural circuits during vertebrate spinal cord development. Axonal pathfinding is controlled by evolutionarily conserved molecular guidance cues that direct axons along the dorsal–ventral and anterior–posterior axes. Protein Kinase C (PKC) is known to regulate cytoskeletal dynamics and neural growth behavior in several systems, yet its specific contribution to axon navigation within the zebrafish spinal cord remains undefined. To determine the role of PKC in axon guidance, we have examined the pathfinding of commissural neurons in the spinal cord of zebrafish. Commissural primary ascending (CoPA) neurons are born dorsally and extend axons ventrally to the floorplate, cross to the contralateral side, and navigate dorsally and anteriorly to extend along the dorsal longitudinal fasciculus towards the hindbrain. These neurons, therefore, respond to multiple guidance cues to reach their destination, including Netrin/DCC (ventral extension), Slit/Robo signaling (midline crossing and dorsal growth), and non-canonical Wnt signaling (anterior turning). It remains unclear which guidance system requires PKC activity. Embryos preliminarily treated with the PKC inhibitor, GF109203X (10 μ M), exhibited axon pathfinding defects. Specifically, CoPA axons, in PKC inhibitor-treated embryos, extended within the floorplate for longer than normal distances, and often failed to extend dorsally once they crossed the midline. This phenotype is reminiscent of that seen in *robo2*^{-/-} mutants and suggests that PKC may be required for Slit/Robo signaling. Ongoing work using additional PKC inhibitors aims to dissect the molecular pathways regulating commissural axon pathfinding using this chemical genetic approach. By unraveling the influence of PKC on the development of zebrafish spinal circuits, this study seeks to reveal an underexplored signaling mechanism that shapes neuronal connectivity and provide broader insight into conserved molecular pathways governing vertebrate axon guidance.

Abstract Name: Cipe Pineles: Furthering Women's Role through Design

Cipe Pineles, born in 1908, faced the difficulties of the patriarchy head on as a working woman in design. Although she was turned down again and again, she still continued her journey of looking for a job, which eventually led to her working at Condé Nast. Her experience as an immigrant helped shape her perspective of design itself, viewing mistakes as not a discouragement, but as a path to something new and wonderful. As an art director of Seventeen and Charm, she helped the changing ideas of what women could do and their roles in society. Seventeen was geared toward younger teenage girls and women, treating them like intelligent individuals opposed to treating them as an addition of their mothers and future wives. Charm was directed toward the working women providing tips on the addition of work life and normalizing the idea of women in the workforce. These magazines showed women in workwear fashion and helped the process of normalization of the working women. She pushed the standard even more when she was the first women to join the Art Directors Club in 1948 after countless rejections of nominations and joined its hall of fame in 1975. This denied the idea that women should not be taken as serious as men and spread the idea that women could be and were just as skillful as men. This paper will explore how through Cipe Pineles' hard work, developed skills, actions, and tenacity, she broke through the many barriers that held herself and other women back from working in graphic design and helped the change in viewpoints of the general working women.

Abstract Name: Does productivity plateau after working 40+ hours a week

Research shows that in other parts of the world work life balance is better than in the United States contributing to Americans' lower mental well-being. To explore this further, I surveyed 411 Americans to understand how they feel about their productivity after working more than 40 hours a week and their control over their work schedules. Overall, 44% of respondents responded that they are very/slightly unproductive when working over 40 hours a week. Furthermore, I found that people with low and middle income feel very unproductive compared to those with high household income when working over 40 hours a week. In addition, those individuals with a high school degree or less feel more unproductive than those with more education when working over 40 hours a week. These patterns highlight how job income and education level affect productivity. Individuals in lower-income or lower-education groups often face limited autonomy, more rigid schedules, and greater job-related stress, all factors that contribute to decreased productivity when hours extend beyond the standard workweek. In contrast, those with higher income and education levels may have more control over their workload, better working conditions, and increased job security, which can help maintain productivity even when working longer hours. However, the findings also suggest that productivity is not determined by hours alone; instead, it is shaped by the combination of work environment, degree of control, and overall mental well-being.

Abstract Name: Bridging Disciplines: An Assessment of Interprofessional Education in Rehabilitation

Careers in rehabilitation are vital for addressing patients' physical needs, such as mobility, speech, and coordination. These fields encompass diverse occupations—each requiring specialized skills acquired through rigorous graduate and professional education. Advancements in addressing motor and sensory requirements have broadened the possibilities and applications within the field of rehabilitation. However, the complex interplay of patients' disorders and diseases necessitates interprofessional collaboration (IPC) for holistic and effective care. Interprofessional collaboration involves consistent networking and cooperation among various health professionals, pooling their expertise to craft optimal care strategies. By fostering communication, teamwork, and shared problem-solving, interprofessional education (IPE) offers a transformative framework for preparing future health professionals to engage in collaborative practice. Evidence suggests that IPE not only enhances students' readiness for interdisciplinary teamwork but also has sustained long-term effects, equipping professionals with collaborative skills that persist throughout their careers. Additionally, teams trained in IPE have demonstrated improved patient outcomes, such as higher recovery rates, reduced medical errors, and enhanced patient satisfaction. These outcomes stem from improved care coordination and holistic, patient-centered approaches that integrate physical, cognitive, and psychosocial elements of health. Using a scoping review, this study analyzes existing literature on IPE's role in rehabilitation practice. It explores key trends, barriers, and opportunities, laying the groundwork for future research on the long-term impact of IPE on healthcare education, collaborative practice, and patient outcomes.

Abstract Name: Verdant Echoes: An Emotional Plant Care Simulator

Verdant Echoes is a VR experience set in a cozy greenhouse where players nurture plants that grow in response to their emotions. Each session, a seedling evolves as the player speaks, and an LLM analyzes the speech transcript with help from a vocal timbre analysis model developed by VCU Engineering graduates. Those emotions control how the plant grows, turning the greenhouse into a visual diary across sessions. Verdant Echoes explores generative AI not as asset production but as a game mechanic for affective interaction, offering an immersive, calming space that develops with you and around you.

Abstract Name: The responsibilities of a student worker_Barara Fall

This autoethnography will explore how holding a job within college, especially within the first year of college, impacts and shapes the academic, social, and personal lives and experiences of students transferring into higher education for the first time. Drawing from my own personal experiences as a full-time student and part-time worker, I took the time to examine how this workload influenced me in terms of time management, stress management, social engagement in college, and an overall adjustment towards college life as a whole. Throughout this new school year and this research, I have traced back how my studies, emotional well-being, and daily habits were affected by the demands of a part-time job and the degree to which it was detrimental or beneficial to me as a student. The study highlights several themes, such as the constant struggle between academic priorities and financial responsibility, the strain of limited free time due to class and work schedules, and financial independence. While holding a job provides important benefits like income, time management, discipline, and practical work experience, it also contributes to fatigue, decreased participation in campus activities, and moments of academic strain. By relating personal experiences within the broader conversation of college workloads, economic pressure, and student success, this autoethnography attempts to shed light on the realities of what first-year college students with jobs face. Ultimately, this project argues that employment during the first year of college is a complex and often contradictory experience: it empowers students financially and emotionally while simultaneously amplifying stress and reducing opportunities for full campus participation. By sharing my story, I hope to provide a better understanding of how work shapes student identity, motivation, and resilience.

Abstract Name: Mini Skirts, Major Impact: Mary Quant

This research examines how Mary Quant transformed fashion design into a catalyst for cultural and social change during postwar Britain. Emerging amid the rise of youth culture in the 1950s and 60s, Quant challenged restrictive ideals of femininity by introducing bold, functional, and affordable designs that reflected the growing independence of women. Her signature creation—the miniskirt—became both a symbol of liberation and a visual marker of shifting gender norms, aligning with broader conversations surrounding autonomy, identity, and second-wave feminism. Through innovative silhouettes and experimentation with modern materials, Quant rejected the exclusivity of haute couture and reimagined clothing as a democratic form of self-expression. The impact of her boutique, Bazaar, further reshaped retail culture by fostering an environment rooted in accessibility. Quant's work illustrates how design can both reflect and influence social values, as media responses highlighted ongoing tensions surrounding women's visibility and bodily autonomy during her time. While her commercial success complicates purely feminist readings of her work, it also demonstrates how consumer culture and empowerment intersected during the 1960s. Mary Quant's designs revolutionized the fashion industry by merging functionality with sexual liberation; she transformed clothing into a medium of self-expression that challenged traditional gender norms for women and situated fashion as a form of activism and social change. Her legacy endures in contemporary fashion, feminist discourse, and ongoing conversations about the role of design in shaping cultural identity.

Abstract Name: The Striking History of Matchbox Design

This research examines how matchbooks and matchboxes became influential artifacts in design and visual culture. Beginning with early fire-starting tools in sixth-century China, the study traces the development of matches from simply functional to globally standardized packaging shaped by technological innovation. The Swedish safety match and the sliding-drawer box established the foundations of modern match design, while improvements in printing turned matchboxes into miniature canvases for illustration, typography, and branding. By the late nineteenth and early twentieth centuries, matchbooks evolved into pocket-sized billboards, showcasing advertisements for hotels, airlines, restaurants, and more. Their designs reflected broader movements like Art Deco and Modernism, capturing cultural identities across countries, from Soviet propaganda to Indian folk imagery and American corporate aesthetics. Exploring how matchbooks shifted to collectible ephemera, drawing on Arthur Danto's ideas about collecting, matchbooks gained meaning as personal and cultural artifacts, valued for the stories they hold about people, places, and design. Although their popularity declined in the mid-twentieth century with the rise of butane lighters and anti-smoking campaigns, matchbooks have re-emerged as nostalgic design objects. Today, boutique hotels, artists, and designers revive matchbooks as historic symbolism. This study shows that matchbooks reveal how design lives in ordinary objects. They demonstrate the power of small-scale design to communicate history and culture in ways that continue to resonate long after their original purpose has faded.

Abstract Name: Cardiovascular Risk Among Asian Americans: A Narrative Review

Cardiovascular disease (CVD) remains a major cause of morbidity and mortality in the United States, and key risk factors including hypertension, diabetes, and obesity continue to increase. Asian Americans represent one of the most diverse and rapidly growing racial groups, yet much of the existing research aggregates them into a single category, creating a significant literature gap that limits understanding of subgroup-specific CVD risk patterns. This narrative literature review explores current evidence on CVD prevalence, incidence, and major risk factors among Asian Americans while identifying how these patterns differ across subgroups. A systematic search was conducted using PubMed to locate peer-reviewed articles reporting trends, prevalence, incidence, or risk related to CVD among Asian Americans. Inclusion criteria required English-language studies presenting measurable CVD outcomes or risk-factor data for at least one Asian American subgroup; studies lacking relevant data or not focused on Asian Americans were excluded. A narrative synthesis approach was used to organize and interpret patterns across the literature. Three findings emerged from the reviewed studies. First, major CVD risk factors particularly hypertension, diabetes, and obesity remain prevalent within Asian American populations. Second, substantial subgroup variation exists: Filipino and South Asian Americans consistently show elevated levels of multiple CVD risk factors, whereas Chinese Americans demonstrate lower mortality but rising hypertension rates. Third, major gaps persist, including limited subgroup-specific reporting, underrepresentation of Southeast Asian and Pacific Islander Americans, and evidence that standard clinical risk-prediction tools may underestimate risk for certain Asian American subgroups. Overall, the literature indicates that CVD remains a significant concern among Asian Americans, with meaningful variation across subgroups. The continued lack of disaggregated data and subgroup-specific research limits accurate risk assessment and hinders the development of tailored prevention strategies, underscoring the need for more inclusive and culturally informed research.

Abstract Name: Flagellin-dependent signaling in non-motile bacteria

Bacteria assemble flagellin proteins into filaments, called flagella, for motility. These proteins activate mammalian innate immune receptors, like Toll-like receptor 5 (TLR5), which initiate host defenses against flagellated pathogens. As such, flagellins represent the trade-off between motility and immune evasion. However, several findings challenge this view. The motile pathogen *Helicobacter pylori* (Hp) produces flagellins that fail to bind TLR5, thus allowing Hp to evade host immunity. Yet, Hp still activates TLR5: Cag proteins function as non-flagellin TLR5 ligands. Moreover, in Tlr5 knockout mice, gut bacteria respond to the absence of Tlr5 by expressing genes associated with nutrient starvation. These observations suggest a homeostatic role for TLR5 apart from its function in host defense. To test if TLR5 activation benefits bacteria, we used *Citrobacter rodentium* (Cr), a bacterial pathogen that primarily colonizes the colon and cecum in mice. Although two intact flagellins (fliC and lafA) are present in the Cr genome, the genes required for flagellum biosynthesis are absent. Thus, Cr is predicted to lack flagella. Through both functional assays and TEM imaging, we confirmed that Cr is both non-flagellated and non-motile. Next, we tested whether Cr-encoded flagellins are Tlr5 ligands. Both FliC and LafA induced NF- κ B signaling in Tlr5 reporter cells, indicating that they activate Tlr5. Finally, we investigated the nutrient conditions that induce expression of Cr flagellins. To mimic the limited-nutrient environment of a mouse gut in vitro, we cultured Cr in low-nutrient conditions and measured fliC and lafA gene expression using quantitative PCR. These experiments lay the foundation for future studies to address the alternative ways non-motile bacteria use flagellin to control host signaling pathways, initiate immune responses, and shape their surrounding environment.

Abstract Name: Modeling Wildfire Smoke Exposure in the Mouse to Assess Dementia-Relevant Neurocognitive Outcomes

Wildfire smoke (WFS) is an emerging environmental pollutant. Recent epidemiology suggests that living in WFS prone areas increases the risk for dementia. Thus, research models are needed to assess neurological outcomes of WFS. In this research, the well-documented Teague smoke exposure system was adapted to simulate WFS exposures in mice. The Teague system, designed for combusting reference cigarettes, was adapted for use with wildfire-relevant wood media. Wood chips were ground to a course powder, mixed at different ratios, and packed into paper cartridges compatible with the Teague's robotics system. An ideal 45%:55% red oak to pine mixture was identified to efficiently ignite and exhibit a controlled static burn rate

consistent with that of a 3R4F reference cigarette. The exposure hood was fitted with a Thermo DataRam 4 particulate monitor, used to optimize particle dilution and burn duty cycle. An 8 min to 52 min minute on/off burn duty cycle was optimized. Serial dilution with particle aging was optimized to simulate a 100 µg/m³/day WFS particle exposure. Outbred mice were used to assess impacts on learning and memory. The novel object recognition, Barnes maze, and Morris water maze were employed. Latency values before and after simulated 89 ug/m³/day WFS exposure for 10-days at 4-h per day were compared. Preliminary findings show an impact on spatial learning in Barnes and Morris water maze tasks, with trials ongoing. Thus, the research here supports development of an effective research model to assess learning and memory impairment consequent simulated wildfire smoke exposure at particle levels equivalent to that experienced in urban centers such as New York City in the summer of 2023.

Abstract Name: The Correlation Between Hamstring Flexibility and Vertical Jump Height

The purpose of the research is to evaluate the correlation between hamstring flexibility and vertical height jump in recreationally active young adults. While the hamstring muscle group plays a crucial role in producing power during vertical jumping, limited flexibility may restrict range of motion, whereas excessive flexibility without adequate strength may be harmful. Existing research has largely focused on elite athletes, leaving a gap in understanding how these variables relate to average individuals. The research on elite athletes has generally shown that moderate to high hamstring flexibility, when paired with strong eccentric control is associated with improved jump mechanics. This cross-sectional study recruited approximately 20 recreational athletes aged 18-24, excluding those with recent lower-extremity musculoskeletal injuries. Hamstring flexibility was assessed using goniometric measurements of the hip flexion in both knee-bent and knee-extended positions. Vertical jump height was recorded using a plate analysis in the kinesiology lab. Additionally, participants were asked to perform warm-up stretches to control muscle stiffness. All data was collected in a controlled laboratory environment to reduce external influence. Findings from this study could contribute to clarifying the role of flexibility in power-based movements such vertical jump height and may inform training strategies geared toward optimizing performance and preventing injury. Results will be conducted by the end of the semester.

Abstract Name: Safeguarding Democracy: Lessons from U.S. Deterrence in West Berlin for Taiwan

Presently, the United States' most critical diplomatic relationship is with that of the People's Republic of China. America finds itself straining to maintain peace in Eastern Asia, as well as globally. As tensions rise between the U.S. and China, especially over American support for the democratic Republic of China, questions arise over the United States' ambiguous military obligations to Taiwan. At issue, is specifically how

the United States can continue effective deterrence of Beijing's advances on the island. The answers to such questions can be elucidated by developing an understanding of the United States' strategy in similar situations. This project seeks to understand the conditions that led to successful deterrence against the Soviet Union in the context of West Berlin by analyzing American national security policy to contain Soviet irredentism. The findings will then be compared to the current situation in Taiwan to garner a better conception of the potential strategies that the U.S. could utilize to deter further Chinese encroachment and protect Taiwanese sovereignty. By developing an understanding of the United States' position on West Berlin, this project will work to draw conclusions as to the extent of deterrence action that the U.S. can engage in without jeopardizing their critical relationship with the People's Republic of China.

Abstract Name: In Dignity and In Honor: The Leipzig 19 and the Black Body as a Script in the Medical Museum

In 2025, the skulls of 19 Black Americans were repatriated to New Orleans following more than a century in the custody of German medical institutions. These skulls, largely stripped of their names and identities, were taken from the corpses of 19 Black patients who died during the 1870's, and were exported to spend their afterlives benefitting European understandings of phrenology— a study which purported that intellect and morality could be determined based upon the shape and measurements of the human skull. Though their return reflects evolving standards in the field of repatriation, questions persist regarding the structure of these repatriations, delays in their return, and the deeper implications of deceased Black remains in scientific practice. This paper argues against a long-standing historical tradition of misappropriation, highlighting this occurrence as only a single incident in the ever-evolving and dynamic relationship between the global Black community and medical science, viewing this occurrence as neither insular nor discreet, but instead as an example of exploitation's role in the development of medical techniques. In deconstructing this event, therefore categorizing it by deconstructionist and symbolic terms, I seek to generate a more comprehensive picture of the exploitation of Black bodies in the scientific tradition through the use of the body as a 'script' in medical science, and emphasize the dual political and cultural importance of bodily repatriation as a method of remedying enduring legacies of trauma.

Abstract Name: Emotional Working Memory Across The Visual Mental Imagery Spectrum: Considerations for Aphantasia

In 2015, the term "aphantasia" was coined to describe a small group of individuals who lack the ability to voluntarily produce visual mental imagery. This caused a rising interest in aphantasia and its associated neural, behavioral, cognitive, and emotional features. Understanding the role of visual mental imagery in both emotional and cognitive processes, it is reasonable to question whether aphantasia may result in importantly unique experiences that may require improved therapeutic practices to account for these differences. Previous studies have found that aphantasics experience reduced emotional responses to recalled emotional events,

reduced affective processing, poor autobiographical memory, and other cognitive differences in a variety of domains. Notably, research shows that imagery play a central role in emotional generation and regulation as well as memory. As a result, almost all major therapeutic orientations include visual components, causing the aphantasic population to report reduced efficacy of psychotherapy and barriers to diagnosis and treatment due to unfamiliar symptomologies. This study aims to address a gap in the understanding of the connections between the emotional and cognitive realms of aphantasia by explaining the relationship between emotional working memory and visual mental imagery ability in adults. In a controlled lab environment, consenting adult participants in Greeley, Colorado completed two surveys and an emotional memory task that measured visual imagery ability and emotional working memory across multiple dimensions. This researcher hypothesized that those with lower visual mental imagery ability experience emotional working memory deficits. Research is ongoing at the present moment and is expected to be completed by March 2026.

Abstract Name: The Effects Of Perfectionism Along With Acculturation On The Anxiety And Depression Rates Of Asian Indian Immigrants

Asian Indian Immigrants often face expectations regarding perfectionism that are prominent in both their ethnic culture and American culture. The expectations of success in India are strongly correlated with ideas of perfectionism and specific standards that must be fulfilled to determine whether an individual has truly succeeded. Even while in the US, they face stereotypes regarding high intelligence and are pressured to meet these expectations, which impacts their mental health. This study uses comparative analysis to examine the effects of these expectations on the anxiety and depression rates in Asian Indian Immigrants, and also how factors of acculturation and stigma inhibit their willingness and ability to receive treatment for their mental disorders. The findings display that Asian Indian Immigrants portray an increased risk of developing anxiety and depression due to the pressure of living up to expectations created by both their ethnic culture and American culture. The expectations of being a model minority and representing their culture well add extra pressure on Indian Immigrants and immigrants in general. Being a model minority also acts as a barrier to immigrants' willingness to receive treatment due to the stigma around mental health in India. The added stress that comes with acculturation was shown to further increase the anxiety and depression rates in Asian Indian Immigrants due to the effects of stereotypes and discrimination. The factors of acculturation were also found to decrease an immigrant's willingness to receive treatment due to fear of judgment and fear of tarnishing family honor. These perfectionistic expectations and stereotypes were found to negatively impact the mental health of Asian Indian Immigrants and cause them to develop mental health disorders such as anxiety and depression.

Abstract Name: Human Associated Antimicrobial Resistance in Community Soils

Antimicrobial resistance occurs when bacteria develop the ability to survive drugs designed to kill them,

creating a growing public health challenge. The Centers for Disease Control and Prevention reports that resistant infections affect millions of people and cause numerous deaths in the United States each year. Because resistant bacteria can spread through humans, animals, and the environment, researchers are increasingly studying everyday locations to understand how resistance moves outside clinical settings. The PARE Project at Tufts University has shown that soil from parks, paths, and other community areas frequently contains antibiotic-resistant bacteria, providing evidence that human activity can introduce these organisms into the environment. Building on this research, soil was collected from four different locations, including the lawn near the TCC library, a hiking trail in the Cook County Forest Preserves, a site ten feet along the trail, and a site one hundred feet from the trail point, to examine the presence of human-associated antimicrobial resistance. When grown on MacConkey plates, the library lawn displayed the highest total bacterial growth and the greatest number of coliform colonies, which serve as indicators of human or animal contamination. The trail sites also supported diverse bacterial populations and contained resistant colonies, though in smaller proportions than the library lawn. These findings indicate that antibiotic-resistant bacteria are present in community soils and suggest that their abundance may correspond to patterns of human activity. This project demonstrates the importance of environmental monitoring in tracking the spread of antimicrobial resistance and reinforces the need for ongoing surveillance to protect public health.

Abstract Name: Uncovering a Tombstone: The Fate of Fascist Italians, 1943 - 1945

In the chaotic aftermath of Italy's September 1943 armistice, the German-backed Italian Social Republic drew thousands of volunteers who chose to continue fighting for Mussolini's failed regime. While most Italians welcomed the end of the war and rejected Fascism, these volunteers - ranging from seasoned soldiers to fervent youth - embraced a cause whose defeat had already become inevitable. Understanding why they continued the struggle sheds light on the final dramatic phase of Italy's fascist regime and reveals a psychological and ideological evolution that produced an increasingly brutal campaign of survival and revenge. The final two years of the war witnessed the rapid radicalization of these forces, particularly within volunteer formations such as Decima MAS and the infamous "Black Brigades". Contemporary songs, propaganda posters, and veteran testimony reveal how early motivations rooted in concepts of duty or honor soon gave way to a fatalistic worldview centered on sacrifice, retribution, and loyalty to fallen comrades. As partisan attacks expanded across northern Italy, these units became increasingly socially isolated and responded with harsh reprisals that further deepened local hostility. Their ideological hardening occurred alongside a constant dependency on German military support and resulted in a growing sense of paranoia. In the spring of 1945, German forces in northern Italy collapsed and Fascist loyalists faced overwhelming partisan strength. Many attempted to reach Allied forces to avoid torture and execution, while others fought to the death or were captured and often executed amid the chaotic dissolution of the Italian Social Republic. The fate of these volunteers illustrates how ideology, fear, and loyalty combined to help sustain a doomed regime long after its collapse had become apparent.

Abstract Name: Miami's Housing Crisis: Uncovering the Forces Behind Rising Costs and Charting a Path to Affordability

Miami has rapidly become one of the least affordable housing markets in the United States. What was once a vibrant, diverse city offering opportunity has turned into a place where many working families and young adults struggle just to keep a roof over their heads. This project seeks to answer a central question: What economic, social, and policy forces are driving the rise in Miami's housing costs, and what solutions could realistically improve long-term affordability? To address this question, the research draws on data from the U.S. Census Bureau, HUD, the Florida Housing Coalition, and other public sources. Using descriptive statistics and trend analysis, the study examines how factors such as rapid population growth, the influx of out-of-state buyers and investors, the expansion of short-term rentals, and limited development of affordable housing interact to widen the gap between income growth and housing prices. The findings highlight not only the economic pressures shaping Miami's housing market but also the human impact of these changes. The study discusses potential strategies, including inclusionary zoning, public-private housing partnerships, and incentives that support local homeownership, that could help promote greater stability and fairness. By understanding the root causes of Miami's affordability crisis, the city can take meaningful steps toward ensuring that its future growth benefits the entire community.

Abstract Name: Dreams and Reality: The Tragedy of Creation in *The Wind Rises*

Hayao Miyazaki's 2013 animated semi-fictional biopic, *The Wind Rises*, tells the tragic story of Jirō Horikoshi, the engineer who designed the Mitsubishi Zero fighter plane used by the Japanese Empire during World War II. The film sparked widespread controversy in both its domestic and international releases, with critics suggesting that it willfully ignores Japan's responsibility for thousands of deaths during the war in favor of whimsically romanticizing aeronautical engineering. Miyazaki has even been accused of the same fascist apologetics and revisionism that continue to plague Japan's cultural and historical discourses surrounding WWII. However, these same critics have failed to recognize not only the spirit of Miyazaki's film but also his nuanced, self-reflexive approach, which foregrounds the fraught implications of creation rather than fascism or militarization. In the film, although Jiro's dream does become inextricable from wartime destruction, Miyazaki avoids simplistic admonishment. Instead, he crafts a grounded and highly autobiographical reflection on the intractable confrontation between the nature of dreams and the circumstances of reality both from which they stem and ultimately seek to subvert—that is, the struggle between creators and creations. By engaging with the perspectives represented in Susan Napier's 2018 monolithic work in Miyazaki studies, *Miyazakiworld*, this paper examines the film's provocative thematic conundrum. Integrating textual analysis, historical context, and the intertextual influence of Paul Valéry's 1922 poem "The Graveyard by the Sea", I argue that Miyazaki conscientiously explores Jirō's poignant struggle with the relationship between creation and destruction through the lens of engineering. In a military-industrial world that inherently commodifies the works of dream-driven engineers, paralleling the worlds of filmmaking and animation, Miyazaki challenges the audience to question the pursuit of dreams intertwined with inescapable questions of nationhood, technology, and war.

Abstract Name: The Availability and Effectiveness of Nutritional Support Interventions on TB Outcomes Among Low-Income Populations

Tuberculosis (TB), a chronic infectious disease of the lungs, disproportionately affects low-income populations. TB outcomes are worsened by poverty, food insecurity, and unstable housing, which complicate the implementation of effective interventions. Nutritional status is a key determinant of TB treatment adherence, disease progression, and survival outcomes. Emerging evidence suggests that nutritional interventions, such as cash vouchers, dietary supplements, and feeding programs, may improve TB outcomes. However, the range, characteristics, and effectiveness of these interventions in low-income settings remain insufficiently explored. This scoping review aims to characterize the availability, nature, and effectiveness of nutritional interventions for TB outcomes in low-income populations globally. Using the Arksey and O'Malley framework with PRISMA-ScR methodology, we systematically searched PubMed, MEDLINE, EMBASE, and CINAHL, and found 50 eligible studies. Included studies evaluated nutritional interventions such as food vouchers, micronutrient supplementation, and conditional cash transfers in relation to outcomes, including treatment adherence and mortality. This review will underscore the importance of recognizing nutrition as both a preventative measure and a therapeutic support strategy in TB care, while drawing attention to critical gaps in literature and need for further research. Data extraction and synthesis are ongoing. Early findings report that meal vouchers and conditional cash transfer incentives are associated with lower TB-related mortality rates among lower to upper-middle-income populations. Future studies should advance evidence-based, effective nutritional interventions for TB outcomes in low-income populations and guide the development of targeted strategies to improve outcomes among nutritionally vulnerable groups, given the known adverse impact of malnutrition on infectious diseases.

Abstract Name: Immigration Perceptions and Well-Being in Brazil and the U.S.: A Cross-Country Study

This study investigates how perceptions of immigration relate to individual well-being, measured through self-reported happiness and life satisfaction. Using nationally representative data from the 2017–2021 World Values Survey (Wave 7), we employ probit regression models to examine how beliefs about immigration shape well-being outcomes. Specifically, we focus on whether respondents think immigration increases crime rates or contributes to higher unemployment among citizens in Brazil and the United States. By comparing these two distinct socio-political contexts, the study provides insight into whether and how attitudes toward immigration influence personal evaluations of life. Our preliminary results indicate that individual well-being is associated with a wide range of demographic and socioeconomic factors, including health conditions, education, gender, perceived social class, financial conditions, number of children, marital status, and sense of security. However, both the direction and magnitude of these effects vary between Brazil and the United States. Crucially, perceptions of immigration exhibit significant but divergent influences on well-being across the two countries. Respondents in the United States tend to evaluate immigration more negatively, and these negative perceptions correspond to stronger reductions in reported happiness and life satisfaction compared to

respondents in Brazil. The significance of this project lies in its contribution to understanding the psychological and social implications of immigration discourse. As debates over immigration continue to shape political climates worldwide, identifying how such perceptions affect individual well-being offers valuable insight for policymakers and social researchers. By highlighting cross-national differences, this study underscores the importance of cultural, economic, and institutional contexts in shaping both immigration attitudes and their consequences for individual well-being.

Abstract Name: Physical activity among toddlers in urban Bangladesh, a lower middle income country in South Asia

Background: Physical activity supports healthy growth and neurodevelopment and is linked to childhood obesity, key public health concerns in low- and middle-income countries. However, most evidence on children's activity patterns comes from high-income countries. Despite the importance of early movement behaviors and emerging evidence of cross-cultural variation, little is known about toddler physical activity in Bangladesh, a lower middle-income country in South Asia facing a dual burden of malnutrition, with high stunting and rising urban obesity. **Methods:** Data for this analysis came from 304 toddlers (mean age 20.52 months [Standard Deviation, SD 2.30]) enrolled in a cohort study in Dhaka, the capital of Bangladesh. Physical activity was assessed using the PRE-PAQ questionnaire. Parents reported how often their child played actively inside the house, how often they played with sit-and-ride or push toys, how often they played actively in the garden, yard, rooftop, or roadside, and how often they engaged in physical activity or play that made them sweat or breathe harder. **Results:** On average, toddlers in our study achieved 19 minutes of moderate to vigorous physical activity (MVPA) (SD = 35.66), and 278.34 minutes (SD = 179.81) of total physical activity per day. The MVPA average is under the recommended amount, while 67.96% of children met the total recommended daily amount of PA. Nearly all children had access to a place where they could be physically active. Additionally, 78.29% of parents reported that their child had access to a public park or a rooftop play area. **Conclusion:** Toddlers in urban Bangladesh get limited physical activity, and many lack access to appropriate places to be active. These findings highlight the need for future research to identify context-specific predictors of toddler physical activity to inform intervention development and targeting in low-resource, rapidly urbanizing settings.

Abstract Name: The Effects of Coping Motives on Alcohol Use Consequences

The purpose of this study was to examine the difference in alcohol use consequences between those who drink to cope with anxiety or depression symptoms and those who do not. Our research aimed to expand on earlier studies by placing emphasis on how coping with anxiety and depression influences alcohol consequences using constructs aligned with DSM-V symptom criteria. Research has consistently shown that those who drink to regulate distressing emotions experience more harmful consequences, making this an imperative area for prevention efforts. It was hypothesized that coping motivated drinking would be associated with an increased amount of alcohol related consequences. Participants were college students who participated in a Spit for Science study ($n = 457$). Spit for Science is a research initiative that aims to understand the biological and environmental underpinnings for substance use and mental health in college aged students. Those who participated completed a self-report measure evaluating drinking motives and alcohol consequences. We conducted an Independent Samples T-Test using our measures to evaluate drinking motives and alcohol consequences. Results show there is a significant difference in alcohol use consequences between those who drink to cope ($M=1.77$, $SD=2.25$) and those who did not drink to cope ($M=0.8294$, $SD=1.42$), $t(338) = -4.777$, $p < 0.001$. These results support the current research literature indicating that coping motivated drinking can result in more consequences. Other studies suggest that by developing positive coping strategies this not only decreases anxiety and depressive symptoms, but also decreases alcohol consequences. Therefore, highlighting the importance of teaching healthy coping skills and alternative coping mechanisms as an intervention strategy for risky alcohol consumption. Implementing new program approaches that teach students emotional regulating skills, stress management and positive coping strategies offer promising ways to reduce risky alcohol use.

Abstract Name: Can LLMs Recover Program Semantics? A Systematic Evaluation with Symbolic Execution

Obfuscation poses a persistent challenge for software engineering tasks such as program comprehension, maintenance, testing, and vulnerability detection. While compiler optimizations and third-party code often introduce transformations that obscure program intent, existing analysis tools and large language models (LLMs) struggle to recover the original semantics. In this work, we investigate whether LLMs, when fine-tuned with symbolic execution artifacts, can effectively deobfuscate programs and restore analyzability. We construct a benchmark by applying four widely studied transformations—control-flow flattening, opaque predicates, arithmetic encoding, and branch encoding—across diverse C programs from TUM Obfuscation Benchmarks, the LLVM test suite, and algorithmic repositories. We then compare three state-of-the-art LLMs under two training configurations: baseline fine-tuning on obfuscated/original code pairs, and enhanced fine-tuning with additional KLEE artifacts such as SMT constraints, path statistics, and test cases. Our evaluation examines syntactic correctness (compilation success), semantic fidelity (behavioral equivalence under symbolic execution), and code quality (readability and structure). Results show that GPT-4.1-mini achieves the strongest deobfuscation overall, and that incorporating KLEE artifacts consistently improves semantic preservation and compilation success across models. Across all four transformations, GPT-4.1-mini shows consistent gains with KLEE artifacts—compilation success increases from 75.8% to 87.9% and semantic scores improve by 6–7 points. These findings highlight deobfuscation as a broader software engineering

concern, demonstrating that combining LLMs with symbolic execution can strengthen automated testing, static analysis, and program comprehension in the presence of obfuscation.

Discipline: Sociology

Authors:

Abstract Name: Threshold Theory: Navigating Stake Escalation and Societal Pressure

This research project focuses on developing Threshold Theory, a new sociological framework synthesizing Liquid Modernity and Functionalism to explain how individuals and communities disengage from escalating societal pressures. My goal is to refine this theory using research on alternative lifestyles; minimalism, off-grid living, and decentralized education, as an adaptive response to modern changes. By conducting a literature review, studying case studies, and conducting survey research on students at UCO, I will provide a structured analysis of 'walking back from the threshold' as a functional response to contemporary instability.

Discipline: Music

Authors:

Abstract Name: Diary of a Child: A Pedagogical Exploration of Ernesto Lecuona's Children's Suite

In Western music education, the contributions of Cuban composers are often underrepresented despite their rich influence on global musical traditions. Among them, pianist and composer Ernesto Lecuona (1895–1963) stands out as a pivotal figure who brought Cuban and Afro-Cuban musical idioms into international recognition. Through his prolific output, including works ranging from pedagogical piano pieces to virtuosic concert repertoire, Lecuona bridged cultural and stylistic divides, expanding the reach of Latin and Afro-Cuban music. This poster presentation examines one of his lesser-known yet pedagogically significant works: *The Diary of a Child*, a piano suite composed for young learners. It highlights the suite's cultural and educational value by analyzing selected excerpts that incorporate Afro-Latin rhythms, syncopations, and melodic motifs within an accessible framework. To complement the analysis, attendees will also be able to listen to recorded excerpts from the suite, illustrating both its pedagogical potential and artistic richness. Special attention will be given to how these works introduce developing pianists to diverse musical languages while reinforcing essential technical and interpretive skills. By situating *The Diary of a Child* within the broader scope of piano pedagogy, this presentation seeks to advocate for a more inclusive repertoire that acknowledges and celebrates Latin American contributions. In doing so, it underscores both the artistic legacy of Ernesto Lecuona and the pedagogical opportunities his music offers for expanding cultural awareness in piano teaching.

Abstract Name: Snail Secret Slime: Uncovering the Antimicrobial and Antibiofilm Power of Mucin

Bacteria are constantly adapting to their environments, increasing their ability to resist antibiotics. This growing challenge highlights the need to identify new antimicrobial compounds naturally produced by microorganisms and other living organisms to improve the effectiveness of modern treatments. The Giant African Snail (*Achatina fulica*) secretes mucin that is commonly used in skin care for its rejuvenating properties, yet its antimicrobial potential remains underexplored. This study investigated the antimicrobial and antibiofilm properties of mucin extract from *A. fulica*, as well as an antimicrobial compound produced by an unknown soil microorganism. The snail mucin extract was tested against a panel of 20 bacterial strains and two fungal strains using a 96-well plate broth assay, 24-well plate spot assay, and biofilm assay to evaluate its effect on growth and biofilm formation. The unknown soil microorganism was also tested for antimicrobial activity against several pathogenic bacteria using a streak inhibition assay. Results showed that snail mucin significantly reduced the growth of Gram-negative bacteria, including *Escherichia coli*, *Pseudomonas aeruginosa*, and *Acinetobacter baumannii*. It also reduced biofilm formation in *Streptococcus oralis* and *Staphylococcus epidermidis*. The unknown microorganism displayed promising inhibition of growth in both Gram-negative and Gram-positive bacteria. These findings demonstrate that natural compounds from organisms such as snails and soil bacteria possess antimicrobial and antibiofilm properties that may contribute to addressing the global problem of antimicrobial resistance. Future studies will focus on identifying the unknown microorganism and isolating and characterizing the active compounds from *A. fulica*.

Abstract Name: Burden of Dementia Care Among Latina Women

Introduction Among Latine families, caregiving is disproportionately carried out by women, particularly when supporting relatives with progressive chronic illnesses such as dementia. Caring for a progressive illness such as dementia can be incredibly taxing for caregivers, placing Latina women at heightened risk for caregiver burnout. Family ideals and gendered expectations intersect to shape the caregiving experiences of Latina women, with profound effects on their physiological and psychological health. Yet, research overlooks the experiences of Latina women, resulting in a limited understanding of their unique needs and an inability to sufficiently support this group. This research aims to uncover both the origins and outcomes of caregiving disparities of Latina women by examining the sociocultural and systemic factors that intensify caregiving strain. Method Drawing on writings by Latin American philosophers such as Ofelia Schutte, Sor Juana Inés de la Cruz, and Octavio Paz, provide the sociocultural framework of the submissive and sacrificial role Latina women are placed into. Following includes a comprehensive literature review discussing the physiological and psychological effects of caregiving. Lastly, qualitative interviews with Latina caregivers, aged 18 to 65, will capture firsthand accounts of caregiving burden within this population. Preliminary findings from the literature and interviews indicate that dementia caregiving is associated with elevated cortisol levels, depressive symptoms, and other adverse health outcomes. Focusing specifically on Latina women reveals how traditional gender roles embedded within family structures and cultural expectations exacerbate these burdens. Predicted conclusion This study anticipates that Latina women caring for relatives with dementia face uniquely heightened caregiving strain, driven by intersecting cultural expectations and

systemic inequities. The goal of my research is to advocate for policy reforms and culturally grounded support systems that address the gendered roots of caregiving disparities and promote the well-being of Latina women.

Abstract Name: Mob Mentality: How the Media Shapes Societal Perspectives of the Mafia

This project examines how media depictions of the Mafia have shaped societal perceptions of organized crime. While Mafia films are central to United States popular culture, little research has analyzed how these narratives influenced crime reporting. This study addresses that gap through a case study of *The Godfather*. Through archival research, newspaper articles were coded as positive, neutral, or negative and divided into three periods: before the novel's publication, after the novel, and after the first film. This design enabled statistical comparisons using Pearson's chi-square tests and Kendall's tau-c correlations. Articles were identified using the search term "Mafia," chosen as the most widely recognized label for the Cosa Nostra. To produce a balanced dataset, one year of articles prior to the novel and three months following both the novel and the film were coded. From more than 5,000 identified articles, duplicates and unrelated pieces were removed, leaving over 700 articles from New York State publications for analysis. Findings reveal notable shifts in representation. Pearson's chi-square tests show both the novel and film corresponded with statistically significant differences in reporting compared to pre-novel coverage. Kendall's tau-c correlations revealed weak but positive relationships. Raw data indicated fewer negative portrayals and more neutral ones, with a modest rise in positive portrayals after the novel but a slight decline after the film. No significant difference was found between post-novel and post-film reporting, suggesting that the medium itself did not determine outcomes. Overall, the findings suggest entertainment media shifted Mafia coverage from predominantly negative portrayals to more neutral representations.

Abstract Name: Axon degeneration in hyperglycemia-induced zebrafish (*Danio rerio*)

Diabetic peripheral neuropathy (DPN) is the most common symptom of diabetes mellitus with patients often presenting with pain/tingling in the extremities and motor deficits. These symptoms arise because peripheral nerves degenerate due to elevated blood glucose levels, known as hyperglycemia. Although DPN is widespread and debilitating, treatment is limited to pain management because its molecular mechanisms remain unclear. The Clark lab has developed a model of hyperglycemia-induced DPN in larval zebrafish. Previous data from our lab has suggested that Lavendustin-A (LavA), an epidermal growth factor receptor (EGFR) inhibitor, facilitates remyelination in hyperglycemic zebrafish. Here, we tested if axons are also regenerating (as the myelin tube creates a structure that supports axonal regrowth and axons expressing

EGFR). To study this, Tg(olig2:DsRed) zebrafish (which tags motor nerve axons with red fluorescent protein) were incubated in egg water for five days, split into either control or glucose groups for five days, then divided into six groups: (control was split into egg water +1% DMSO (C12) or C12+65.5 uM LavA (C12Lav); glucose was split into four groups, glucose+1% DMSO (G12), G12+ 65.5 uM LavA (G12Lav), egg water+1% DMSO (R12) or R12+65.5uM LavA (R12Lav)). Preliminary data show that LavA treatment allows for axonal regeneration, although it is unclear if this is a direct effect of the EGFR inhibition or if it is due to the support of the myelin tube. I'm continuing this work to determine if the perineurium also regenerates and is capable of pulling regenerating axons back into functional fascicle, as perineurial cells are both affected by hyperglycemia and also express EGFR.

Abstract Name: Securing the Spark: Evaluating the Relationship Between Spatial Scale and Cost to Defend in Ukrainian Power Infrastructure

From the onset of the Russo-Ukrainian War in 2022, academics across the disciplines of economics and geography have concentrated on power generation sites as locations where spatiality, economics, and security demands intersect. This study utilizes thermal, hydroelectric, nuclear, and photovoltaic (PV) sites in Ukraine's Mykolaiv and Dnipropetrovsk Oblasts from 2022 to 2024 as a case study to conceptualize cost-to-defend (CDEF) as an energy production externality correlated to spatial scale. According to academic Hans Liwång, non-frontline distributed power generation infrastructure in the 21st century requires negligible inputs of defense material or manpower to maintain operability, in contrast to concentrated facilities with operability contingent on shielding from long-range munitions. Secondly, building on Liwång, this project incorporates Comprehensive Defense Theory, where defense is a whole-of-society problem where the cost to defend should be aggregated into the price for critical infrastructure by nations during war and peace. To evaluate the relationship between CDEF and spatiality, this study will incorporate the externality into the levelized cost of energy equation (LCOE) to create LCOE'. Ultimately, this project will evaluate whether spatially distributed methods of production, such as PV sites, are an economically efficient manner for states to achieve energy security. An evolved understanding of the correlation between kilowatt-hour costs and production spatiality will allow for public and private stakeholders to simultaneously increase energy security and decrease output costs through efficient resource allocation.

Abstract Name: The Development of Rectangular Rapid Flashing Beacon (RRFB) for Improving Pedestrian Safety

Among the various devices used at uncontrolled, marked pedestrian crossings, the Rectangular Rapid Flashing Beacon (RRFB) aims to enhance driver awareness and improve pedestrian safety. Prior research examined installation practices, applications, and both driver and pedestrian yielding behavior at the RRFB-

equipped crosswalks, as well as the importance of pedestrian safety in response to rising pedestrian fatalities and factors influencing crossing behavior. This study analyzes the effects of RRFB at an uncontrolled pedestrian crossing by studying pedestrian and vehicle behavior before and after the device was installed on Auburn University's campus on West Glenn Avenue through video observation and data extraction. The necessity of the device was analyzed for a multilane pedestrian crossing with the specific characteristics of a college campus environment. 400 events were collected before installation, and 400 events were collected after installation. Before installation, a high percentage of vehicles yielded to pedestrians, with the most common type being a soft yield. Only a small percentage of pedestrians were unobservant at the busy intersection during both observation periods. After the device was installed, the percentage of unyielding drivers decreased by 12%; however, the results were affected by a defect in the reflective flashing device. The total yield rate increased from 80% before installation to 92% after they were installed. These findings highlight the significant improvements in pedestrian safety that RRFB-equipped crosswalks provide through increased driver yielding rates.

Abstract Name: Strengthening the Referral Loop: Examining Follow-Up Practices in South Carolina School-Based Health Centers

School-based health centers (SBHCs) often mitigate common barriers to adolescent care by delivering services directly in school settings. Despite this accessibility, gaps remain in closing the referral loop when students require external speciality care. Data from a needs assessment of SBHCs in South Carolina in 2024 identified that about 50% of external referrals received follow-up, highlighting a significant area for strengthening continuity of care. Given SBHCs unique position to support coordinated care, examining current referral systems and follow-up practices can help identify opportunities for improvement. In November 2025, the Youth Access to Psychiatry Program administered a state-wide asset and needs assessment to all identified SBH program administrators ($n = 7$) within South Carolina. The assessment examined a range of organizational factors, including operational and service provision characteristics. Frequency counts were calculated for items related to referral outcomes to quantify the current landscape and identify service-level facilitators that may play a role in closing the referral loop. Preliminary results revealed that all programs (100%) communicated about referrals to parent/guardians while only 57% of SBH programs indicated additional follow up. Referrals were also communicated through student record documentation (29%) and providing referral directly to students (29%). External referrals were managed across various roles with similar proportions (43%) handled by school-based health providers, behavioral health providers or care coordinators. Among programs whose students' primary care providers (PCPs) were not affiliated with the SBHC, 71% shared updates with the PCP while 14% reported no communication or were unsure. In this poster session, additional findings will be discussed along with qualitative insights from the literature to contextualize these results. Findings from the needs assessment, particularly in comparison to 2024 data, will highlight key areas for SBHCs to improve referral outcomes.

Abstract Name: Chalcogen Polarization and Bonding between $X_2E \cdots Z$ Complexes: From Dative to Bridged

The sigma hole concept has found applications in many areas of chemistry including materials science and crystal engineering. The question of how to rationalize and model the influence of sigma holes (in tandem standard models of chemical bonding) for strong non-covalent and dative interactions remains an area of significant interest. In this contribution, we investigate the potential for and the nature of chemical bonding by Lewis bases in which the lone pair region(s) coincide with positive sigma hole regions due to strong polarization. That phenomenon occurs, we found, in certain group 16 bases. As the chalcogen atom, E, gets larger and softer going down the group in EX_2 complexes, the area on E outside the E-X overlap region may develop a positive potential if X is very strongly electron withdrawing. Consequently, that E site in the molecule, which normally acts as a conventional Lewis base due to the presence of lone pairs, exhibits an

anomalous bonding behavior. In this work, we consider specifically $X_2E\cdots Z$ type complexes in which $E = O, S, Se, Te, \text{ and } Po$, $X = H, F, CH_3, \text{ and } CF_3$, and $Z = BH_3, BF_3, BCl_3$, and their Al analogues. This range of model complexes enable us to demonstrate certain limits of sigma holes as predictors of bonding and also their significant influence as tools to tune base strength and the modes of bonding by bases. As well that as E gets larger and more polarized, for example, the complexes considered transition from a linear dative $X_2E\cdots Z$ type bond to a bridged structure.

Abstract Name: Going Home: Reminiscence Intervention for Asian Immigrants with Dementia Abstract

Older Asian adults account for more than 8% of dementia cases, despite being less than 6% of the nation's population. However, geographical, financial, and health challenges can make revisiting their home countries difficult. This program uses virtual reality to create a virtual home environment, helping to alleviate the sense of longing for home in this population. Going Home (GH) is a technology-based, culturally responsive reminiscence program designed for Asian immigrant persons with dementia (PwD). With our interdisciplinary team from social work, neurology, and electrical engineering, we aim to design, develop and test the feasibility, acceptability, and preliminary psychosocial outcomes of the GH Program. We will recruit 10 Asian PwD and their caregivers from Milwaukee, Madison, Chicago, and South Bend through in-person and virtual outreach by targeting specific community organizations. Examples of target populations includes Korean, Chinese, Hmong, Vietnamese, and Filipino families (etc.). This six-week program will incorporate the five senses (sight, hearing, taste, touch, smell) using prompts related to home, such as favorite cultural songs, traditional food, and family photos. We will then use survey data, observational summaries, and qualitative data from participants to create 10 systematic case studies. We expect that participating in GH will improve mood, cognition, quality of life, and behavioral and psychological symptoms among PwD's, enhance mood, positive aspects of caregiving, and caregiver self-efficacy while reducing caregiving burden among family caregivers; and improve the relationship quality between PwD and their caregivers. This study is innovative as it addresses the cultural needs of Asian families and actively engages PwD to share stories of home by recognizing cultural heritage and family traditions, thereby strengthening mutual understanding and relationships with caregivers. The long-term goal of the GH program is to improve the quality of life among underserved racial and ethnic groups by enhancing their access to culturally responsive dementia care.

Abstract Name: Carbon Dioxide Capture Project: Redefining Depollution

Capturing carbon dioxide gas from the environment is a current challenge for scientists seeking to mitigate the harm caused by manmade greenhouse gases. Recent work indicates organic compounds known as xylenediamines can be used as effective reversible traps for pulling carbon dioxide directly from the air. In

this work, we focused on the synthesis of 2-(nitrophenyl)methenamine which we aim to use as a gaseous carbon dioxide trapping system. Using readily available 2-nitrobenzaldehyde as a starting material, we reduced the aldehyde functional group to an alcohol group. 2-nitrobenzylalcohol was then converted to 2-nitrobenzyl chloride using thionyl chloride and pyridine. Two separate methods were used to convert the benzyl chloride into an amine: Delapine reaction and Gabriel synthesis. Future work seeks to determine the ability of 2-(nitrophenyl)methenamine to react with carbon dioxide and refine amine synthesis for ending product.

Abstract Name: Filling in the Gap: An Evidence-Based 9th Grade ELA Academic Writing Unit

A recent study of employers' most sought-out skills ranks written communication as the third most important skill for future employees (NACE 2024). Although an essential work and life skill for students, many English Language Arts (ELA) educators struggle to teach writing, leading students to lack critical knowledge in this area. While a fair amount of research exists surrounding educational writing theories (Herdi et al. 2025, Reed et al. 2023, Rosnanda et al. 2025), gaps remain in instruction as many teachers face difficulties transferring evidence-backed frameworks into their practices. With no one established method for teaching writing, professionals are left to adapt instructional methods on their own without an understanding of how well they will work for students. This project helps to resolve the lack of confidence teachers experience in this area of ELA by presenting a fully research-based and "ready-to-teach" unit plan. By compiling a list of effective writing instruction strategies from existing research and examining common patterns, the unit plan serves as a blueprint that 9th grade ELA educators can use to improve their teaching. Based solely on studied methods, this unit has the potential to equip teachers with the most effective strategies they need to strengthen students' writing skills. With the support of a strong unit plan, teachers can have the confidence to help every student reach their full potential as writers.

Abstract Name: An Analysis of Factors that Influence the Likelihood of Juvenile Transfer to Adult Criminal Court

Judicial transfer is a process by which judges are granted the deciding power over whether a child is tried in juvenile or adult criminal court. This decision can have significant impacts on a child's life and can be based on anything from the defendant's prior record to the judge's mood. While research exists on how judge partisanship and media attention affect sentencing in adult courts, study is lacking in the juvenile space. This project examines how judicial partisanship and media attention shape transfer decisions. By analyzing both historical shifts in juvenile justice laws and data from the National Juvenile Court Data Archive, the research examines the impact of factors like media attention around juvenile crime, national perceptions of the juvenile justice system, partisan judicial elections, electoral proximity, and defendant attributes on the likelihood of transfer. This project's findings will aid in the understanding of juvenile transfer decisions and in addressing inequities within the juvenile justice system. As data collection and access change under the

second Trump Administration, this project will also explore potential consequences of the elimination of specific oversight regarding race, ethnicity, gender, and other marginalized identities within the juvenile justice system. Understanding better which juveniles are more likely to be tried as adults and why will contribute to a significant gap in the research regarding the juvenile justice system.

Abstract Name: Prevent, Preserve, Protect: The New Age of Dental Treatment

Dental Hygienists focus on the prevention of disease within the oral cavity. Minimally invasive approaches for caries management emphasize preserving natural tooth structure, minimizing overtreatment, and improving the longevity of patient outcomes across their lifespan. This review analyzes evidence from quantitative and qualitative studies that evaluate the efficacy of both established and emerging non-invasive and micro-invasive agents. Advances in newer remineralization treatment modalities and bioactive materials have enhanced clinicians' ability to halt and control incipient carious lesions. These agents include silver diamine fluoride (SDF), self-assembling peptide P11-4 (SAP P11-4), povidone-iodine (PVP-1), fluoride varnish, glass ionomer sealants, and arginine-based technologies. Yearly application of SDF demonstrates promising results in arresting active lesions, particularly when focused on pediatric and special needs patients. Despite its aesthetic limitations of staining soft tissue and active lesions, a study showed a 77% average effectiveness of arresting active caries. Similarly, evidence shows that SDF has a higher fluoride release in a shorter amount of time when compared to varnish. Clinical findings from a study on SAP P11-4, a biomimetic peptide, demonstrate significant regression of proximal caries lesions across enamel and outer dentin stages, with 37-40% radiographic improvement reported. Another research study shows that Povidone-Iodine (PVP-1) has shown rapid antimicrobial activity, with a longitudinal study showing a 95% decrease of *Streptococcus mutans* after 12 months. Glass ionomer sealants should be a staple in pediatric and public health dentistry because they can be placed more effectively and adapt to moist environments. Additionally, research shows that the use of arginine-based technologies can shift biofilm ecology, creating an environment less favorable for cariogenic bacteria. The collective evidence demonstrates that minimally invasive dentistry, using established and emerging products, not only prevents and arrests caries but also aligns with a patient-centered, preventive model of care that clinicians should strive for.

Abstract Name: Relationship of Magnesium Supplementation with Calcium Levels in High Endurance Athletes

Endurance athletes are at an elevated risk of developing magnesium (Mg) deficiency due to its crucial role in regulating muscle contraction and breakdown by blocking calcium in muscle fibers. Calcium (Ca) triggers

muscle contractions by its release from the sarcoplasmic reticulum in striated muscle and triggers a conformational change, which eventually allows contraction via a cross-bridge. In the event of mitochondrial Ca overload, muscle breakdown can be triggered and subsequent release of reactive oxygen into the tissue. This study aims to determine the relationship between Mg and Ca levels in collegiate endurance runners undergoing Mg supplementation. This study is part of a larger investigation into the impact of magnesium on kidney function, performance, and stress in a total of 23 collegiate endurance runners (12 men, 11 women). Participants each ingested one 500mg supplement of Mg daily for 6 weeks. Blood draws were performed before and after supplementation to analyze their Mg and Ca levels. Two tubes were drawn from each participant and spun down to plasma. The samples were frozen at -80 degrees Fahrenheit to preserve them until clinical laboratory testing. The pre- and post-supplemental Mg and Ca values will be compared using a Pearson r correlation. A preliminary repeated measures ANOVA revealed statistically significant improvement levels of Mg: $F(1,21) = 54.03$, $p < .001$, $\eta^2 = .720$, from pre- (1.97mg/dL) to post-intervention (2.20). There was also a significant time $\times$ group interaction, $F(1,21) = 9.50$, $p = .006$, $\eta^2 = .312$, showing that the change over time differed between males (Group 1) and females (Group 2). Results of the correlation are pending the laboratory analysis of Ca levels.

Abstract Name: A Comparative Autoethnography - From My First-Hand Observations in Europe and the United States: How Do Everyday Business Practices Reveal Deeper Truths About National Economies and Personal Work Habits/Work-Life Balance?

This project explores how cultural norms surrounding work and leisure shape both economic outcomes and individual approaches to daily life. Drawing from my lived experiences studying and traveling across five European nations, I examine how differing business practices, government policies, and social attitudes toward labor reflect broader economic systems and collective mindsets. Using an autoethnographic and observational approach, I connect personal field notes, photographs, and secondary data with cross-cultural frameworks from psychology and economics to understand how cultural expectations become embedded in everyday economic behavior. This study investigates how variations in work ethic, business operations, and lifestyle - from Greece's relaxed post-crisis economy to France's legally limited 35-hour workweek - illuminate the complex interplay between culture, productivity, and psychological well-being. By situating these observations alongside American work culture, characterized by longer hours, limited vacation time, and a strong emphasis on output, the project highlights both parallels and striking contrasts in how nations construct meaning around labor, rest, and success. Beyond offering descriptive insights, this project demonstrates the value of autoethnography as a methodological tool for understanding economic psychology: lived experience becomes a form of data that reveals nuances often overlooked by traditional research. Ultimately, this work aims to contribute to a broader conversation about how cultural environments shape worker motivation, national economic rhythms, and the subjective experience of work. These insights have meaningful implications for future business leaders, policymakers, and organizations seeking to understand or redesign workplace norms in an increasingly globalized world.

Abstract Name: Retrospective Identification of Overlooked Suicide Risk Indicators in Jail Populations

The leading cause of death among incarcerated individuals is suicide. Suicide contributed to about 30% of all deaths in facilities between 2000 and 2019. The rate of suicides in local jails has increased by almost 15% from 2001 to 2019. Being incarcerated heightens many risk factors that are common with instances of suicide, isolation, and situational stress. Understanding risk factors involved with individuals who are incarcerated could help prevent the widespread problems of suicide that are seen in jails across the nation. The goal of this study was to determine patterns in individuals who have died by suicide and to examine possible risk factors that are not being pointed out currently in facilities. This study looked into the histories of five individuals at a local jail who died by suicide from 2017 to 2024 by using an in-depth review of medical, mental health, and security records, and cross-referencing profiles to detect patterns. All five individuals had a few common factors: all were white males over the age of 30, all had escalating criminal charges, all had chronic medical conditions, mental health diagnoses, and substance use, and all were in single cells while incarcerated. Studying the patterns of individuals who die from suicide in jails and facilities can inform prevention strategies by changing behavioral screenings, improving staff training, with the goal of decreasing the prevalence of suicide in jails.

Abstract Name: Examining the significance of human disturbance on nest selection in Great Gray Owls (*Strix nebulosa*) in southwest Montana

Great Gray Owls (*Strix nebulosa*) are one of the most understudied species in North America. In Montana, there is currently no peer-reviewed research about the species and many aspects of the species' ecology, including the influence of human disturbances on their populations, are not well understood. In this study, we aimed to quantify the effect of human landscape disturbances (roads, trails, recreation sites) on Great Gray Owl nest selection in southwest Montana. We used ten known nest sites with breeding attempts in the last five years that were identified by wildlife managers in southwest Montana. We then used a resource selection function to compare the human disturbance covariates between the used nest sites and randomly generated available points ($n = 10$ per nest site). We used a forward stepwise model selection approach to determine which combination of human disturbance variables best explained the observed data. Surprisingly, we found that Great Gray Owls selected for nest sites in areas with higher trail density ($p\text{-value} = 0.0476$). However, we found no support for an effect of roads or recreation sites on nest site selection. Latent habitat covariates such as trail construction creating gentler slopes with mixed open/forested areas, or the small sample size could have contributed to the observed results. The positive relationship with trail density could also be the result of a potential bias towards trails in our nest site data because nests are more likely to be found near trails than in less accessible areas. We were not able to measure intensity of use and seasonal availability of trails, therefore the influence of these factors could not be identified. Future research using a larger sample size and exploring the effects of intensity of trail use would be valuable to further evaluate the effects of human disturbance on nest selection.

Abstract Name: A Portrait of the Artist as a Statistician: A Reversal of the Probit Model to Suggest Sentence-Level Mechanical Patterns

In counterpoint to the prevailing research methodologies of deep and machine learning, this project aims to create a simpler, more transparent method, in the form of a python package, that reverses the use of the predictive probit model to suggest differentiating factors that may be key to conversations of authorial style and thus provide quantitative foundations for new lines of traditional, close-reading inquiry. The paper uses the Bloomsbury Group as an example case, but still intends, as an ancillary product, for the results of this demonstration to provide genuine insight into the authorial conventions of Virginia Woolf. Preliminary results of this analysis suggest a preference for non-proper nouns, optional reflexives, non-passive and non-perfect verb constructions, “adjunctive” adverbs, and intransitive prepositions, as well as a preference against interjections, definite articles, parenthetical asides, and the Oxford comma. Though the magnitudes and directions of these proclivities are subject to change as the method undergoes further refinement, these identified significant variables will likely persist and so offer a reasonable example of the method’s output. Average partial effect (APE) values denote the magnitude and direction of each variable’s influence, the significance of which is denoted by a p-value, each value being calculated by the script during probit analysis alongside all standard checks and corrections (psuedo-R2, LR-stat, Bonferroni, etc). All interpretations of these variables incorporate prevailing understandings of Woolf’s conventions and the effects that they engender within readers to contextualize qualitative judgements as to their reasonableness and effect on what readers experience as style. At conclusion, the script should provide users new to both authorial attribution (stylometric) studies and statistical analysis a means through which to test theories about standard authorial differentiation, development of style over time (intra-author differentiation over time), and authorial lineage (author series differentiation from representative analogues of each period).

Abstract Name: Zebrafish (Danio rerio) Exhibit Sex-Dependent Visual Responses To Shoals Exposed to Varying Doses of Hypoxanthine-3N-Oxide (C5H4N4O2)

Zebrafish (Danio rerio) are commonly used organisms for behavioral neuroscience as a result of their social behavior. Shoaling is a social behavior where members of a group of fish loosely aggregate together but do not move in a coordinated, synchronized fashion. The current project investigates whether zebrafish (Danio

erio) can behaviorally distinguish between shoals exposed to different concentrations of a synthetic alarm substance and whether these responses vary by sex. Previous research shows that zebrafish prefer stable social environments and can detect subtle movement changes within groups, making them a strong model for studying social and anxiety-like behaviors. However, little work has examined how alarm cue intensity interacts with subject sex to influence social preferences in the 3-Chamber Open-Tank Free-Swim Task (3C-OTFST), leaving an important gap in understanding predator-related social cues. Using the 3C-OTFST, individual subjects were placed in a center chamber and given simultaneous visual access to two flanking shoals: one exposed to a synthetic alarm substance (1.5 nM, 3.0 nM, or 5.0 nM H3NO) while the other shoal remained intact. Behavioral activity was digitally recorded with MediaRecorder and analyzed with EthoVision XT 16.0 to quantify movement patterns across experimental zones. The study found that responses to the lowest concentration (1.5 nM) were highly variable, with males showing significantly more immobility than females. At the highest concentration (5.0 nM), this pattern reversed in the unalarmed zone, with females showing increased immobility and males becoming more active. These results suggest that higher alarm cue concentrations produce stronger anti-predation responses, expressed in sex-specific ways. The findings will be discussed in the context of how zebrafish process social threat cues and how sex differences shape anti-predation behavioral strategies.
